Leroy Little Bear, a Blackfoot scholar in Canada, described the encounter between Indigenous knowledge and Western science as “jagged worldviews colliding.” Ethical codes to mediate this encounter, developed with the involvement of Indigenous representatives in several nations, generally refrain from setting out prescriptions on how to resolve differences in research approaches. In part, this is a response to the great diversity that exists from one local community to another and the increasing diversity within communities of self-identified Indigenous persons. In part, it is a statement of faith that peoples of different origins, and with different customs, carrying the burden of failed relationships in the past can meet on the high ground of respect for human dignity.

Ethical space for respectful dialogue has been opened up by developments within nation-states and

international forums during the past 30 years or so. The possibility for dialogue between peoples has been enlarged by new understandings of the multiple ways in which humans create trustworthy knowledge.

The challenges confronting the Indigenous research enterprise and, more generally, research involving Indigenous peoples and issues are also plentiful:

- How to balance group interests and individual interests to promote justice and inclusiveness
- How to respond to the needs of vulnerable groups at risk within Indigenous communities
- How to provide access to data for local benefit and also protect the privacy of members of small communities with dense networks of relationship
- How to enhance the skills and infrastructure in Indigenous communities so that they can engage in equitable research partnerships
- How to respect both the expectations of community accountability and the value of freedom of inquiry
- How to overcome reluctance among academic researchers and students to engage with Indigenous knowledge and Indigenous-led research

These will be challenges for research in Indigenous contexts during the next 30 years or so.

INDUCTION

In scientific research, induction is a form of reasoning used in pursuit of understanding and knowledge, establishing a relationship between observations and theory. Science applies inductive reasoning to establish theories, the purpose of which is to remove the need for continual observation so as to make statements about reality, using past experience to generalize with reasonable levels of certainty about the future. Research approaches that generalize from a particularity (typically a set of observations of some sort) to a broad statement, such as a theory or general proposition concerning a topic, apply inductive reasoning. Inductive reasoning in science is sometimes contrasted with deduction or, more properly, the hypothetico-deductive method, where sense is made of data by locating them within a general or theoretical context. However, induction and deduction may be better considered as complementary components of scientific reasoning.

It has been suggested that induction is of particular importance in qualitative research approaches. Induction lies behind any effort to generate general statements based on observations or efforts to develop theory from empirical data. For example, interview or ethnographic data (particularities) may be used to propose broad understanding or theories (generalities) that are intended to apply beyond the sample of participants interviewed or observed. Whenever such general statements are made, inductive reasoning is required. The validity of reasoning may be supported by probabilistic or statistical assessments; by recourse to claims concerning

representativeness, triangulation with other data sources, previous research, knowledge, or experience; or by analogy with similar generalizations. In qualitative research, inductive reasoning is used whenever it is argued that an explanation or theoretical framing of data from a small sample should be applied more generally. Such generalizations, however, face the problem of induction.

The Problem of Induction

Because induction involves inference, the outcome of inductive reasoning is never binding given that a contradictory case may always overturn the generalization. For instance, if it is argued inductively that all birds fly (based on a series of observations), this reasoning can be overturned when a single flightless bird is observed. Philosophers have identified this as the problem of induction, arguing that all theory must be regarded as tentative and prone to being overturned if a contradictory observation is made. This problem faces everyone using research (whether as a practitioner or as a researcher), especially if theory is contested, as it may often be within the social sciences. Inductively derived theory may provide reasonably dependable propositions that allow people to trust certain regularities in everyday life, be they in the home or in the laboratory. Within the natural sciences, induction has led to many theories that appear to operate in many settings (e.g., the laws of physics or of chemical reaction). However, in the social sciences, the numerous factors that may affect phenomena, the role of reflexive subjectivity in determining many processes, and the dependency on context all mean that theories might not survive translation into settings other than those where they were initially developed. When appraising research based on inductive reasoning, users (be they practitioners or social scientists) must always exercise caution, particularly if they seek to generalize the findings beyond the cases or settings described. They may also choose to postulate alternative explanations of data using rival inductive reasoning. This has also been described as the underdetermination of theory by data.

Philosophers of science have argued that the problem of induction can be overcome partly by incorporating inductive and deductive reasoning within the practice of science. Deductive reasoning contributes to scientific knowledge whenever a general theory, proposition, or axiom is used to explain observational

data, and much scientific activity involves “puzzle solving” using an established theoretical framework rather than development of new theory. Philosopher of science Karl Popper suggested further that scientists should intentionally seek out data that can falsify current theory. Growth in knowledge occurs as falsified theories are replaced by rival theories that explain a wider range of data. However, this does not replace induction within the research process because inductive reasoning is still required to develop new theory on the basis of cumulative observations.

Induction in Qualitative Research

Inductive reasoning is used to develop generalized propositions, hypotheses, and theory from empirical observations in all natural and social scientific disciplines. In social science research, inductive reasoning is of particular relevance in qualitative approaches that are used to extend existing theory into a new setting or to develop understanding and theory where none currently exists. Methodologies such as grounded theory use induction to systematically develop higher-level propositions that explain the structure of data. Theory here is grounded within the data that have been gathered, with the intention being to make claims about the factors that determine not only the activities of the sample but also those of the category of actors from which the sample has been drawn. For example, a study of old people living in residential homes may reason inductively from interview data with a sample of 20 that dependency, infirmity, and fears about the future are factors that more generally affect the population from which this sample has been drawn.

Such inductive inferences are highly contestable because of the underdetermination of theory by data permitting rival theoretical elaborations from the same data set as well as the relatively small sample size in most qualitative research designs. For this reason, qualitative researchers are generally cautious about generalization beyond the setting in which data have been collected. However, theory generated by this kind of research is rarely submitted to falsification using the kinds of hypothetico-deductive approaches outlined earlier. Analytic induction, developed originally by Florian Znaniecki, is one attempt to improve the generalizability of qualitative research by incorporating induction and deductive reasoning. In this approach, hypotheses developed by inductive reasoning from data are systematically tested against fresh data to progressively develop more universal rules or theory.

Case studies are used to stimulate theory building and to probe the plausibility of these theoretical formulations. Crucial case studies are used to attempt to falsify theory and must be selected based on a full understanding of the field of study. When no cases that falsify the theory developed can be found during the research program, this ensures higher generalizability.

Induction is a key element of scientific reasoning in qualitative research studies that seek to develop theory or models, but as an approach to knowledge growth it is limited by the problems of generalization beyond the specific research setting.

INFORMANT

The informant is a special category of research participant because of a particular expertise or knowledge that is brought to qualitative research. Informants know and understand the kind of information that is of interest to researchers. They offer an insider’s perspective and in-depth information that can represent the views of a group or even a community. It is the capacity to represent the knowledge of a larger group that distinguishes informants from other types of participants such as respondents to a questionnaire and people who are the subject of observation.

Qualitative researchers use informants in many research contexts, particularly ethnographies, needs assessments, focus groups, policy evaluations, and action research. An informant’s contribution to research may be a single interview or continual involvement. An informant will usually provide data through in-depth interviews, often face to face or by telephone. Sometimes an informant will assist during all stages of the research cycle, from identification of research questions to reviewing drafts of research findings.

There are advantages and disadvantages to using informants. Informants are advantageous because they can assist researchers in gaining trust and credibility

within a community, they allow the collection of in-depth information and continuing clarification of data, they may represent a diversity of people's views (including those of silent minorities), they may save researchers time and resources, and they are important gatekeepers for gaining access to additional participants. Disadvantages include the possibility that informants will pass on their own biases and political agendas, thereby influencing the reliability and validity of information obtained. The informant technique can easily be combined with other methods, and triangulation of informant data by using other techniques of data collection is recommended.

Good informants are more than just experts in the area of inquiry; they also reflect on it. This means that they can express a range of informed thoughts, feelings, insights, opinions, and facts about a topic. Researchers will often choose informants by asking members of a community to identify individuals who are both knowledgeable and respected for their expertise in the subject of inquiry. For example, to gain an understanding of popular culture in a high school, informants might include leaders from the student "in-groups" as well as teachers who are respected by students. These informants may suggest additional informants.

An informant is unique by virtue of particular status, experience, or knowledge. An informant is "in the know" for whatever a researcher is investigating. During the initial stages of research, an informant may give new information to a researcher. During the later stages, the information should serve to clarify and validate what the researcher has learned.

demand that, other than in exceptional circumstances, participants agree to research before it commences. That consent should be both informed and voluntary.

Ruth Faden and Tom Beauchamp argued that research participants need to understand that they are authorizing someone else to involve them in research and what they are authorizing. In most circumstances, researchers must provide potential participants with information about the purpose, methods, demands, risks, inconveniences, discomforts, and possible outcomes of the research, including whether and how the research results might be disseminated. What is going to happen to them and why? How long will the process take? What are the risks? What are the potential benefits? Who is funding the work?

In some cases, providing information to ensure informed consent may take considerable time and effort for both researchers and research participants. In other cases, it may be sufficient to provide potential participants with a list of their entitlements and a range of information they can request. Researchers are generally expected to record participants' agreement to take part.

In general, researchers must negotiate consent from all relevant people (as well as organizations, groups, and/or community elders), for all relevant matters, and (possibly) at all relevant times. Several researchers have argued that consent should be dynamic and continuous and not limited to the beginning of the research project. This point has been made particularly forcefully by anthropologists.

Faden and Beauchamp also depicted informed consent as an autonomous action committed intentionally with understanding and without controlling influences resulting either from coercion or manipulation by others or from psychiatric disorders. However, researchers may find it difficult to assess whether potential participants' circumstances allow them such freedom. In consequence, special procedures are often adopted when attempting to obtain consent or assent from vulnerable and dependent groups.

The complexities of informed consent have proved to be particularly problematic for qualitative researchers engaged in covert research or deception. Deception could compromise the informed and voluntary nature of consent, but some researchers have argued that consent need not be obtained where any harm caused by lack of consent might be outweighed by the public benefit obtained. In addition, it might be impossible to gain access to some participants if other people are not deceived. Qualitative researchers have also had difficulty with the ethics review process when

INFORMED CONSENT

Most professional and institutional, national, and international guidelines and ethical codes for research

institutionally standardized consent processes that mandate excessively formal information sheets or signed consent forms have been imposed. This might jeopardize the safety and autonomy of research participants, the quality of the research, and/or the integrity of the consent process itself.

IN-PERSON INTERVIEW

An in-person interview is a data collection method where the researcher is in the same location as the participant and asks questions to which the participant responds. An in-person interview is also referred to as a face-to-face interview because the researcher and participant are facing each other during the interview conversation. Interviews are a common source of qualitative data because they are an effective means to learn from participants about their perceptions of and experiences with a study's topic. Therefore, they are an appropriate type of data collection for most qualitative designs and can be implemented using different interview formats such as semi-structured and unstructured. When a researcher decides to conduct individual interviews, she or he must decide whether they will be conducted in person or by other means such as by telephone or web conferencing. In-person interviews have many strengths as a qualitative data source, but researchers must also consider the challenges associated with this method.

In-person interviews are generally the best choice when interviewing individuals who are geographically accessible. As with all types of interviews, researchers

using in-person interviews learn about participants' views in their own words. In addition, by conducting interviews in person, researchers are better able to develop rapport with participants, thereby increasing the likelihood of learning details about their views. Interviewers can also make observations during interviews when they are physically present. Observations may include important nonverbal cues used by interviewees, including hand motions and head nodding. If the in-person interviews take place in the participants' settings (e.g., their homes or places of work), then interviewers are able to observe individuals' context as well.

There are many considerations that must be addressed when collecting data with in-person interviews. Foremost, the researcher must evaluate whether the participant is located close enough to the researcher's location so that they may meet in person. The interview is usually scheduled in advance at a location that is accessible to both the researcher and the participant, preferably a location that is quiet and sufficiently private to protect the participant's confidentiality. To develop rapport, the interviewer should consider issues such as how she or he dresses and speaks to the participant to ensure the participant's comfort with the situation. As with all interviews, informed consent is essential for in-person interviews, and the researcher must decide how information will be recorded and locate suitable recording devices. Lapel microphones that can be clipped to the interviewer's and participant's clothing are particularly useful for audiorecording in-person interviews. Finally, the interviewer should know the questions to be asked and be able to take notes unobtrusively so that he or she is able to listen and maintain eye contact with the interviewee during the conversation.

INSIDER/OUTSIDER STATUS

The term *insider researcher* is used to describe a situation where the researcher is a part of the topic being investigated. For instance, an Aboriginal person who is examining the representation of local Aboriginal art may be defined as an insider researcher, whereas a researcher from overseas studying the same topic might be considered an outsider researcher.

Many academic disciplines encourage researchers to be reflective about their relationships with research participants, but emphasis on whether a researcher identifies as an insider or an outsider has been a particular focus of qualitative research in the areas of anthropology, feminism, and disability studies. The insider or outsider status of a researcher may have a considerable effect on the research process. For instance, being an insider or outsider may affect the way in which the researcher enters the field, the obligations that the researcher has to research participants, the ongoing nature of contact with research participants, and the level of trust demonstrated by research participants.

When a researcher already has established relationships with the research participants (as some insider researchers do), the nature of the investigation is quite different from that when the researcher must enter the field without previous connections. Some insiders report that when they conduct fieldwork, it is relatively easy to gain access to people and resources. Likewise, these insider researchers frequently report that research participants tend to indicate that they trust them far more than they might trust researchers who are perceived as outsiders. However, this shared identity may create tensions for a researcher because he or she can become aware of sensitive material that other community members do not want to disclose publicly. Such material requires careful attention to ethics, and a constant awareness of the need to establish clear boundaries, so as to avoid harm to the researcher and/or research participants.

Unlike outsiders, who tend to have exact dates when their research will begin and end, insiders are usually expected to have an ongoing connection with the research participants. Some research participants, therefore, may expect insiders to be more accountable for their research and responsive to community concerns than are outsiders. They also usually expect

insiders to be more aware of community sensibilities, and to use more appropriate language, compared with outsiders who might not be aware of established cultural practices.

Insider researchers need to be aware of both the similarities they share with research participants and the differences between them and research participants. For instance, a researcher who shares the same ethnicity as research participants may need to be reflective about the influence of differences such as gender, age, education, sexuality, and other factors that may affect the nature of the data collected. Even in the midst of such differences, however, insider researchers need to be reflective about the ways in which their insider status affected the rapport and trust they developed with research participants. By being reflective about the impact of being identified as an insider, and highlighting the effects that this identity had on the nature of the data collected, such connections with the field can be regarded as a strength of a particular form of immersed qualitative research.

INSTITUTIONAL ETHNOGRAPHY

Institutional ethnography works from and with people's everyday experience of their lives. It uses various qualitative research methods, including open-ended interactive interviewing, participant observation, and a distinctive approach to analyzing texts. In contrast to sociologies that are theoretically structured, institutional ethnography is a method of inquiry. It discovers the social rather than theorizing it, beginning with actual people, their doings, and how their doings are coordinated. It reaches beyond the scope of standard sociological ethnographies that are restricted to what can be found through observation and/or by drawing on people's experiential knowledge. It makes visible the translocal ruling relations

that are present in, organize, and are beyond people's everyday lives.

Institutional ethnographers have explored changes in managerial organization from the standpoint of nurses, the work of being patients in the context of medicine, how mothers' work contributes to their children's schools, how public discourses enter into and organize people's everyday lives, social work as work, and much more. Characteristically, institutional ethnographic studies such as those listed in Further Readings at the end of this entry explore institutional relations and organization from the standpoint of people's experience of and in them.

Encountering Actualities

Institutional ethnography inquires, investigates, examines, and observes; it does not impose sociologically authorized interpretations. The institutional ethnographer learns by encountering the actualities through observing or talking with those who are directly involved. But what does she or he encounter? There are two problems:

1. One problem is that there is a wild and woolly world out there that can never be tied down to any particular deployment of language (or other medium of representation). It is always more and other. So what should ethnography bring into focus?
2. A second problem is that of the ontology of the social. In other words, how does it exist out there so that we can learn from it rather than imposing our pregiven interpretations?

Institutional ethnography starts, as did Karl Marx and Friedrich Engels, with actual people, their work, and the conditions of their work. It adds something that is implicit but not stated—how their work is coordinated. That is the focus. That is how the *social* is identified. Actions or work are not just seen as done by individuals; rather, they are always seen under the aspect of how they are coordinated with the actions or work of others.

Language

Speech, writing, images, and so on are recognized as among people's activities—their doings or work. Sociology in general proceeds with what Dorothy

Smith calls a dual ontology that differentiates activities from what goes on in individuals' "heads"—mind, belief, ideology, theory, culture, and the like. The latter are treated as occupying a different realm from that of action. How they may affect or influence people's behavior then becomes an issue. That dual ontology is rejected by institutional ethnography. Language is action. Institutional ethnography takes up phenomena of language as central to the coordinating of people's subjectivities. This does not mean reducing mind and the like to language; rather, it is an ethnographic practice that attends to what is spoken, written, read, watched, and so on as doings, as embodied, as occurring, active in coordinating people's consciousnesses and, hence, as it is itself coordinated with other doings whether in language or not. Here is where *discourse* in Michel Foucault's sense becomes useful; discourse, as he used the term, is applied to standardized, generalized, and generalizing forms of making statements. Institutional ethnography activates his concept, introducing the presence of people and how discourse coordinates their doings (whether in language or not). For institutional ethnography, there are always people whose work orients through texts to futures, pasts, and elsewhere and to others we may never encounter other than through their written words or their imaging.

Ethnography

Originating during the women's movement of the 1970s, institutional ethnography learned to work with and from people's embodied experience situated in our everyday lives. Explorations do not discard local actualities of time and place, but insofar as inquiry moves into regions beyond anyone's everyday experience, it must do so in the same mode. The social relations that coordinate across particular local settings, and hence cannot be located in any one, must be pieced together by discovering how multiple settings are coordinated.

Sociological ethnography in general has a commitment to the careful and faithful description of people's everyday lives. Institutional ethnography, however, goes further in seeking to discover and explicate the extra- or translocal ruling relations and organization in which people participate, often without realizing. Research aims to explicate just how things come about for us as they do, particularly as the translocal, text-mediated forms of coordinating our work enter

into and organize our everyday lives. Whereas the term *ethnography* preserves the commitment to careful descriptive research, the term *institutional* adds a commitment to discovering how extra- or translocal relations (sometimes called the ruling relations) enter into and coordinate what is going on locally and to discovering how those relations are put together in people's work.

Institutional ethnographies do not just produce case studies. As institutional ethnographies reach into the translocal ruling relations, they engage with and explicate relations that are generalized and that generalize, create commensurabilities, and standardize. Generalization appears in what is described and analyzed. It is there in the ethnographer's data. Each study creates a window from a different angle into the generalizing social relations that rule our societies. Even though each may address a different institutional function, it contributes to our knowledge of how the ruling relations work.

Texts

In the ontology of the social that Smith wrote specifically for institutional ethnography, texts (or documents) appear as key media of coordinating—and controlling—people's activities across local settings. Texts that replicate words or images independent of the presence of speakers or the activity of representation (e.g., acting, dancing) are the objectified coordinators of people at work in different places and at different times. The term *text* here refers to any set of words, numbers, or images appearing in replicable material forms—film, print, television, radio, computer, DVD, and so on—such that the same words and numbers of images can be read, heard, and seen by people who are not directly connected with one another.

In institutional ethnography, texts are not treated independent of people's courses of action. They are recognized and analyzed as they enter into and organize the sequences that form relations coordinating people's doings, our work, through time and across space.

Recognizing texts as in action is tricky. They must never be treated as if they were independent of the work settings in which they are produced and/or read, heard, and seen. Analyzing them as they enter into the organization of people's work is a key move in institutional ethnographic practice. Texts do not need to be a major focus, but in our world of the 21st century there is almost no situation of people's work that is

not somehow or another hooked into translocal relations mediated by a text or texts.

Work

Institutional ethnographers have found the concept of work to be useful in focusing observation and interview talk. As used in institutional ethnography, the concept of work does not mean just what is done at the place of employment; rather, it means anything that people are doing that involves effort, competence, resources, and definite conditions and that is intended. For example, the institutional ethnographic concept of work would include standing in line at the bank while waiting for a teller, waiting for breakfast to arrive in a seniors' residence, reading a newspaper or watching the television news, taking out the garbage, putting on makeup, filling in a form applying for maternal leave, and so on. People have an expert knowledge of work in this generous sense, and institutional ethnographic interviews rely on it. The translocal relations in which our everyday lives are embedded can be explored, as Susan Turner did as sequences of work organized and standardized by texts. Ellen Pence described the processing interchanges organizing judicial processes in domestic abuse cases; texts come in to be worked on (e.g., forms to fill in, reports to write) and are passed on to the next position in the sequence.

Problematic

Starting in the actualities of people's experience locates a study's problematic—how inquiry will orient to the institutional regime or other aspects of the ruling relations. Rather than adopting a concept or theory to frame a study, it starts with people's experience of and in institutional relations or organization and takes direction from there. For example, Alison Griffith and Dorothy Smith started exploring the work that mothers do in relation to their children's schools out of their own experience as "single parents." Beginning where people are and with a concern about what is going on in their lives, inquiry opens up the institutional complex, aiming to explicate just how translocal institutional relations and organization are shaping their lives and activities. Because we are exploring the real world, there are no natural boundaries; the problematic organizes the relevances of inquiry. Thus, Janet Rankin and Marie Campbell explored the restructuring of hospital services in the

province of British Columbia, Canada, examining the new managerial practices from the standpoint of the changing work experience of nurses.

INSTITUTIONAL RESEARCH

Institutional research (IR) is any qualitative, quantitative, or mixed methodology research activity undertaken in a college, university, hospital, or other

institutional setting that produces data, information, or knowledge in support of the institution's efforts to measure the effectiveness of its mission, goals, and objectives. IR was conceived during the 1950s as a mechanism for centralizing and facilitating the compilation, analysis, and reporting of data regarding an individual college or university, and since that time IR has also been adopted by companies and organizations outside the world of education. The accountability, quality assurance, and institutional effectiveness movements that drove much of higher education and other industry sectors over the subsequent decades, along with new developments in technology and significant increases in reporting demands of federal agencies, served to accelerate and expand the growth of the IR function. Today IR provides a complex and diverse set of activities designed to enhance administrative decision making, respond to the external demands placed on institutions, inform institutional policy development, and provide empirical data to underpin institutional planning and budgeting.

IR is conducted in a collaborative manner similar to action research where the members of the IR office will work with their colleagues from across the organization in planning research and assessment activities and in the actual collection, analysis, and interpretation of data. As practiced within the context of institutional effectiveness, IR personnel help their peers (a) to identify mission-critical policies, programs, personnel, and performances to assess; (b) to collect, analyze, and interpret relevant data; and (c) to use the results of the analysis to improve or enhance the institution.

Functions of an Institutional Research Office

The IR function assumes diverse roles within an organization. While it serves to gather, organize, and make sense of data and information regarding the institution, IR also assists the institution in stepping back, with a measure of objectivity, to reflect analytically on the meaning and import of those findings as they affect institutional growth, stability, and quality.

The IR functions can vary based on the size and nature of the institution. For example, at larger doctoral degree-granting, research-focused, or comprehensive institutions, IR offices may be more likely to

focus on academic research studies, whereas those IR offices found in 2- and 4-year institutions may be more dedicated to conducting environmental analysis studies and outcome assessments. Despite these differences in emphasis based on institutional setting and context, offices of IR typically perform planning support, decision-making support, policy formation support, assessment support, research studies, data management, data analysis, external reporting functions, and internal reporting functions.

Planning Support. To support strategic planning activities, the IR office will typically assist administrative leaders in the coordination, facilitation, and generation of information and analyses to produce integrated planning for growth in the company, facilities, budget, and staffing. In this role, IR personnel will help their colleagues to develop measurable goals and objectives in alignment with the institution's mission and vision, develop data collection strategies and mechanisms, assist with the data analysis and interpretation, and ensure quality and integrity throughout the process.

Decision-Making Support. In a data-driven management environment, IR provides administrators with the critical information they need for decision making. To this end, IR staff members may conduct environmental scans, internal data mining, and longitudinal studies to help administrators discover trends and tendencies and plan for the future accordingly.

Policy Formation Support. As institutions develop policies in new and emerging areas, the administration calls on IR to conduct policy and data analysis, collect information, and conduct research to learn more about the particularities of these areas. A typical project in policy formation support is to collect and analyze exemplary policies from other institutions, professional societies, or governmental agencies that can become the foundation for the creation of the institution's new policy.

Assessment Support. A major function for IR is to provide assessment guidance and support for all offices within the organization. This work includes coordination for planning, assessment, accountability, and provision of data analysis and interpretation and external research to learn more about processes. Projects in

this area include quality improvement or enhancement plans in which units measure their performance in meeting productivity or service goals and objectives.

Conducting Research Studies. IR staff members regularly conduct research and analytic studies such as student or customer opinion research, survey research, evaluation studies for assessing institutional effectiveness, enrollment or product management research, facility use, staffing patterns, productivity (e.g., worker performance), benchmarking, environmental scanning, and emerging industry sector issues. In education, these studies can include measuring the success of a new degree program, measuring differences in learning outcomes by instructional methodology (e.g., online vs. face-to-face instruction), trends in student persistence/attrition and graduation rates, and satisfaction with new facilities.

Data Management. The IR office works with other areas in the organization (e.g., information technology, budget, human resources) to improve the institution's database management systems and its overall collection, organization, maintenance, and/or verification of data. This work can involve developing better data fields, database queries, and reporting formats.

Data Analysis. IR staff members provide their colleagues with a wide variety of quantitative and qualitative data analysis and interpretation assistance. These services include coding and categorization guidance, manual and computer-aided analysis, peer review, and overall quality control.

External Reporting. An IR office often serves as the official source for an institution's external reports, especially those produced in compliance with federal or state requirements. In U.S. higher education, reports filed by the Integrated Postsecondary Education Data System (IPEDS), a system of surveys designed to collect data from all primary providers of postsecondary education, are the most important external reports filed each year. In addition to state and federal reports, the IR office may also provide institutional data for guides to colleges or other external organizations such as accreditation bodies.

Internal Reporting. To meet an organization's internal knowledge needs, an IR office will produce data presentations, publish reports, and disseminate data and information to stakeholders within the institution. A major effort in this area usually includes the publication of a factbook or an institutional report card in which important outcomes, events, and accomplishments are reported on an annual basis.

Institutional Review and Qualitative Research

Qualitative research methodologies and methods are used in IR to provide useful insights regarding perspectives of board members, personnel, customers, and other stakeholders critical to institutions and to give context to the numbers. Qualitative research is useful when measuring complex phenomena such as leadership and brand and when gaining insights into diverse academic cultures. Qualitative methodologies can also help to bring both the researchers and the decision makers closer to the research participants, and through this greater proximity can come thicker and richer descriptions, interpretations, explanations, and understandings of stakeholder expectations and needs. For example, naturalistic qualitative inquiry can help researchers and colleagues to follow their customers through stages of pre- and post-sales not only to bring a depth and richness to the outcomes collected but also to learn how customers develop lived experiences of the institution and its products. Finally, qualitative research has special value in IR because generalization of findings outside of the institution may be of lesser importance given that the focus of the particular study may be the individual program, department, factory, or unique corporate culture.

Institutional researchers use a number of qualitative research methods in their work. The most common of these include ethnographic techniques such as interviews, field observations, and participant observation. Focus groups are also popular data collection approaches found in IR work. Because of the institution-specific focus of many IR projects, case studies are broadly used as well. Finally, many IR studies involve document analysis as researchers collect and study catalogs, handbooks, policy manuals, mission statements, and a variety of internal work products.

The circularity of the institutional effectiveness model encourages many IR investigators to employ action research, participatory action research, appreciative

inquiry, and other collaborative research approaches. All of these methodologies have been shown to be effective in IR projects that focus on producing change within institutions of higher education or measuring improvements generated from data collection, analysis, and interpretation.

Institutional Review Subject Areas Amenable to Qualitative Approaches

Across the wide array of subject areas on which studies may be conducted by IR staff members, many of the topics are quite amenable to qualitative research approaches. The following examples are just a few of the processes and outcomes that lend themselves to the use of qualitative inquiry.

Learning Outcomes. The major challenge in measuring learning outcomes is to create more direct measures of students' or trainees' acquired knowledge and skills. Whereas indirect measures such as grade point averages and program completion rates can tell the researchers some aspects of participants' learning, organizations are continually seeking measures that will enable them to collect better evidence of student or trainee success. Field observations in classroom, clinical, or corporate settings can allow the researchers to gather firsthand knowledge of how trainees and students are mastering certain competencies. Content analysis of training and educational program participants' work products to determine patterns of quality is another effective qualitative means to produce more direct evidence of learning.

Quality of Life. The question of what makes for a quality work experience for its employees is of critical importance to a company. Workforce stabilization rates can give an institution some general ideas of staff stabilization, but these numeric figures might not tell a company's leadership what difference makes a difference between those workers who stay with a company and those who leave. Case studies focusing on those employees who persist in their departments or those parts of a company that seem to retain higher percentages of their workers can shed new light on what aspects of their corporate lives make the biggest differences in employees' persistence. Such studies can also help an institution to identify best practices and emerging trends, particularly with peer-to-peer relationships.

Engagement. The assessment of engagement, or the degree to which administrators, staff members, and customers perceive their connectedness to an institution, lends itself to a variety of qualitative research approaches due to the subjective nature of the phenomenon. In qualitative engagement studies, IR staff members could conduct group or individual interviews with managers to discover what particular events of their corporate lives make them feel especially connected to their fellow workers and high-ranking leadership in the company. Such interviews would be especially effective when used in connection with some of the standardized questionnaires of engagement for those organizations with diverse workforces or unique corporate structures.

Institutional Culture. Organizations are quite interested in understanding their unique cultures and learning what employee characteristics predict success in their companies. Institutions are also curious to learn more about their corporate identities and how insiders and outsiders come to accept or challenge these self-perceptions. Ethnographic and participant observation approaches can prove to be effective for IR investigators to immerse themselves in their organization's culture and learn firsthand from their current and former stakeholders the customs, rituals, and practices that make the institution culturally distinctive.

Future Trends in Institutional Review

IR investigators, like many of their research colleagues, are increasingly using mixed methodology designs to take advantage of the complementary nature that qualitative and quantitative approaches bring to the study of institutions. By bringing meaning and context to the numbers, and by bringing central tendencies and ranges to individuals' perceptions and experiences, these researchers present institutional decision makers with not only a richer and more varied picture of their institutions but also better information from which to measure the effectiveness of the institutional mission, goals, and objectives.

INSTITUTIONAL REVIEW BOARDS

Institutional review boards (IRBs) are official university bodies in the United States that are authorized to evaluate research proposals to ensure ethical research practices. Comparable bodies exist under different names in different countries. For example, in the United Kingdom they are called research ethics committees, whereas in Canada they are referred to as research ethics boards. The justification for such boards is derived from some of the past century's most notoriously unethical research endeavors. The most egregious of these abuses occurred in the natural sciences, but high-profile instances of ethically questionable research led to IRBs also having jurisdiction over social science research. Qualitative researchers have been critical of this development. They have pointed out that the IRB process is based on alien assumptions about the nature of research and knowledge production, resulting in rules for ethical research conduct that at times do not mesh with the pragmatics of qualitative research.

Today IRBs have jurisdiction over all university-affiliated research in most Western countries. Faculty members and students cannot conduct research without ethics approval from an IRB. Those who do not secure such approval can be sanctioned by their universities, and universities are also accountable to

federal authorities if unapproved research is conducted under their auspices.

The emergence of these boards is usually justified with reference to “research” that Nazis conducted on unwilling research “participants.” In trying to prevent such practices, IRBs are guided by three dominant assumptions and a series of practical policies that follow from these assumptions. The first assumption is *respect for human dignity*. This manifests most prominently in the notion that individuals should formally consent to participate in research in full awareness of the harms and benefits that might be associated with such research. The second assumption is *balancing of harms and benefits*. This entails having researchers adopt the least risky research designs while trying to maximize benefits to participants and society. The third assumption is *justice*. This suggests that the risks or benefits of research should not fall disproportionately on any particular group and also that the ethics review process should itself be procedurally fair.

Qualitative researchers have been among the most vocal critics of such boards, accentuating that IRBs often conceptualize “research” with reference to a classic laboratory setting that does not cohere with the real-world practicalities of much social scientific research. Rules about securing informed consent, for example, are often impractical or unworkable in participant observation settings. Requirements that researchers set out their research questions in advance so that they can be evaluated by IRBs can also clash with the emergent nature of much qualitative inquiry. Such problems are compounded by the fact that IRBs across the United States have occasionally interpreted the official rules in quite different ways.

INTEGRITY IN QUALITATIVE RESEARCH

Integrity is honesty and probity within the conduct of qualitative research, and it underpins ethical practice in all of the activities that comprise data collection and analysis. It is characterized by openness and wholeness on the part of the researcher and can be understood as a type of “straightforwardness” or “moral uprightness” that rejects intentional duplicity and deceit. Integrity is central to ethical research principles that focus on the responsibility of the researcher to do no harm, to gain informed consent from participants, and to represent respondents’ views as accurately as possible as part of the epistemological process. Integrity within empirical research is not an abstract concern; it directly informs the choice of methods as part of legitimizing knowledge production within an “appropriate” theoretical framework. These methods may include in-depth interviews, focus groups, participant observation, and nonparticipant observation, and all entail different forms of ethical rigor in their execution that is centered on taking participants’ accounts seriously.

The collection of qualitative data that describe meaning and experience is rooted in a subjective paradigm that is not value free and is inextricably linked to the goals of the researcher who might not be emotionally detached from the topic of inquiry. In this sense, qualitative research is not neutral or objective, and acknowledgment of the values and assumptions that frame research is an important feature of integrity. Openness, however, is not always fully achievable during the process of connecting experience to understanding, and the sharing of information between the researcher and participants can be problematic and a negotiated process. Thus, integrity can be complicated and compromised, and it is always political.

Politics of Integrity

Balancing rights and responsibilities in the qualitative research process entails equalizing the search for knowledge with concerns about vulnerability, confidentiality, and intrusion in the lives of participants.

These concerns are connected to the power dynamics that are likely to be present in research, and they relate not only to the power relationship between researchers and participants but also to that between researchers and funding bodies/host institutions. There is much in the literature about the personal empowerment of research participants through their contribution to heightening awareness about a particular social issue, but there is less about the empowerment of researchers that can be constrained and sometimes disenfranchised by the requirements imposed by research funders. These requirements can intrude into and color both research conduct and output, with researchers feeling obliged to take account of the political positioning of funding bodies. This suggests that acting with integrity is not a linear construct but rather points to the reality of ethical research practice that is complex and often multifaceted.

Working with participants who are unsympathetic or resistant to the aims of a research project can challenge both the integrity and resilience of researchers and can be stressful for both parties. This raises the question of whether integrity can be seen as conditional and, if so, what are the caveats or constraints that inhibit full openness. Examples from the feminist literature illustrate that the “ideological distance” between researchers and their participants can be bridged by revelation strategies on the part of the researchers that are partial, staged, and characterized by reference to the more general rather than the highly detailed and specific. In some circumstances, full openness must be sacrificed to the needs of completing research effectively, and this may involve some measure of unexplication of researchers’ agendas. This does not signify the collapse of ethical rigor; rather, it points to relative and contextual understandings of “truth telling” that inscribe empirical work within the human and social sciences. Integrity is itself a social construct that cannot be self-serving if it is to be an effective safeguard for researchers and participants alike within sociological research. Ethical research processes, to be meaningful, must be pragmatic and responsive to the circumstances of the research, and the adoption of a narrow purist model may leave areas of human experience hidden and neglected.

The Role of Intention

Integrity within qualitative research is not just an issue at the design stage but also a continuing practical concern

throughout the entire research process, including the analysis and reporting phases where issues of interpretation are key and now seen as part of postmodern intellectual license. Although it is incumbent on researchers to be cognizant of the implications of research both for participants and for policy, it is often intent rather than the consequences that determine whether or not research behavior can be seen as moral. This is because qualitative research is often messy and unpredictable, and researchers cannot be held to account for outcomes that could not have been expected even with the best-formulated plans. The synthesis and analysis of personal experience for public consumption that characterizes much qualitative research carries with it a particular obligation for researchers to adopt an ethics of care approach to ensure that respondents are not subject to exploitation and positioned only in terms of their utilitarian value. This can be challenging for researchers, and not only because any harm that may accrue to respondents from participating in research might not be immediately evident. Being clear and transparent about the extent of the commitment expected from participants together with adherence to confidentiality practices can minimize adverse effects but cannot be a guarantee of “pain-free” outcomes.

The preceding has discussed the main constitutive features of integrity within qualitative research that contributes to ethically sound research practice. Although research must be rigorous, if it is to be regarded as intellectually compelling and politically persuasive, it must also be open to scrutiny in terms of method and process. Probity forms part of an ethical continuum that entails an uncertain slippery path of forward and backward across all of the stages of knowledge production, but it must be remembered that integrity is contingent on context and situation rather than on abstract principles.

Excerpt From *The Menopause Club: Five Hot Middle-Aged Women Talk About Their Bodies*

We are all white, heterosexual, professional women in academia, some of us graduate students and others professors, ranging in age from 45 to 61. Our academic areas are communication studies, sociology, and women's studies.

We decided we would engage in interactive focus groups to explore our experiences with being "plus or minus 50." In this project, we seek to understand how our experiences in this time of our lives contribute to our identities, and how—through communication—we construct (interpersonally and socially) our identities as "new middle-aged" women. Through multiple conversations in five interactive focus groups over 18 months, we all acted in alternating roles as facilitators, researchers, and participants. The conversations were audiotaped, transcribed, analyzed, reacted to by each of us, reanalyzed, and written as narrative.

...

"I used to think I was pretty sexy," Catherine says.

Nancy agrees. "That used to be a pretty big part of my identity, too."

"I thought I could have sex at whim, and I did," Catherine confesses. "It wasn't that I was a party animal per se, but I considered myself a sexual revolutionary. I don't anymore, obviously."

"Why do you say 'obviously'?" Barbara asks the question all of us are wondering.

"I really don't have the sex drive I had," Catherine says with a grimace.

...

Nancy picks up a book from a stack next to her. "Herrick (2004) says sex is better after 50, after menopause. I want to say to her, 'what hormones are you on, I want some of them.'" We laugh.

Barbara says, "I think sex is just different when you're older. I still really like sex."

...

"Yet I have to admit that I have hang-ups with my aging body." Leslie looks down, and her voice moves to a whisper. "I try to keep myself covered during sex so Mark can't see my body."

...

"I constantly fight putting my body down," says Catherine.

"I do too," Nancy says. The others are surprised as they think Nancy has a fantastic body.

...

Leslie interjects. "I think I'm in denial. I remember three years ago looking in the mirror and going, 'wow, my eyes are really baggy and they're wrinkled, and my pores are large,' and I thought, 'oh, it must just be whatever temporary ailment I thought it was at the time.' And then, about six months ago, I thought, 'this temporary situation has now lasted 2½ years.'" Jan suppresses a chuckle as Leslie continues. "Now what's so funny is, I keep thinking, 'I'm not really a heavy person, but I just keep gaining weight, and I haven't been thin

for a long time. This is just temporary.' I don't know when I'm going to come out of that."

...

"I don't wear any makeup at all," Nancy says. "Not a drop. To me it's too much trouble." Jan thinks about the amount of makeup she has on today and smiles to herself at how we all are in some ways similar and in other ways different.

"I wear eye shadow when I go to work," Barbara adds.

"You have beautiful skin," Catherine says to Nancy. "I never go without makeup."

Nancy nods. "I have nice skin, but now there are changes occurring that bother me. Like with my neck."

"My neck is horrible," says Catherine.

...

Jan doesn't see anything on Catherine's neck, but she's afraid she'll be rude if she looks too closely, so she turns to examining herself instead. "Yeah, and now look at what my newest aging change is! I read this in a magazine last week!" Jan says, holding out the top of her hand to show the group. She pulls up the skin on the back of her hand. "See how it stays up? It's supposed to go back down if you have young looking skin!" she says accusingly to her skin.

Nancy tries it on her hand. "Oh, great, now there's something else I have to be concerned about!"

...

"I wonder how much of our aging issues have to do with our bodily changes and how much they have to do with society's unrealistic expectations for women's bodies at any age," Jan thinks out loud. "I guess as we age and our bodies cooperate less with being pushed, pulled, and dieted into strange and unnatural shapes, we feel the conflict more strongly between culture's ideal and our realistic possibilities."

Nancy echoes the thought. "We all seem to not want to be so involved in our body image, to accept our aging bodies. But do we? Are we any different in that respect than our mothers were?"

...

"What strikes me," Nancy continues, "is our desire to not care so much about our bodies, how we look, yet we keep going back to our appearance over and over and it's clear that it does matter. Actually, I think both things are true. On the one hand, we don't care like we used to. Hey, we can't because we don't have the same options and we know we don't look like young models anymore. We're reasonable and intelligent women, so we don't let ourselves want what we can't have. We also see that other things are much more important. On the other hand, we do care that the aging process changes us so much. The changes are a lot to get used to, and it's nice that we have time to get used to them. So while we don't want to look like 20-year-old models, we do want to look as good as we can and stay in shape. We aren't sure we won't have plastic surgery or make changes, but at the same time we don't want to want to make changes."

INTERACTIVE FOCUS GROUPS

Interactive focus groups, a variation on traditional focus groups, are characterized by a resistance to one facilitator or leader, collaboration in forming research questions, multiple voices, flexibility of conversation and direction, and collaborative writing and analysis. Interactive focus groups let researchers analyze, reflect, and share *in vivo*, using their group discourse itself as a method of inquiry as well as data to be analyzed. Interactive focus groups allow researchers to equalize the hegemonic power relationship between traditional research participants and researchers through a dialogic process that views all of those involved in the research process as co-participants. The focus of the interactive focus group is threefold: to discuss the topic at hand, to jointly reflect on the discussion in the group, and to analyze the discourse used in the discussion as a way of understanding how meaning is constructed in the group.

Unlike traditional focus groups, which are highly constrained and organized, in interactive focus groups the discussion is as unstructured as possible, allowing for multiple perspectives. Although interactive focus groups have “ringleaders,” all participants are co-researchers, yielding a group process somewhere between that of a leaderless group and a group with all leaders. At different times, different participants may take the lead.

Unlike traditional focus groups in which participants are strangers to each other, and thus their interactions have few consequences past the group session, interactive focus groups typically consist of participants already in an existing “*bona fide*” group or relationship, and the purpose is to observe how their prior group culture plays itself out in the focus group environment and to watch a system in action and interaction. This process entails multiple focus group sessions to build on previous sessions and encourage reflection, empathy, and trust between sessions. In analysis of interactive focus group sessions, the conversation itself can be investigated as a speech event to understand the joint construction of meaning taking place during the sessions through conversation and interaction.

Interactive focus groups are a moral and ethical methodological choice that let participants have a say in how the research is conducted given that they are able to exert control over the conversation. This approach provides an opportunity to tilt the balance of

power in the research relationship from one single researcher to the group as co-participants.

Specific ethical concerns must be taken into consideration when using an interactive focus group approach. The first is the confidentiality of the information discussed. Although group members can be asked to maintain both confidentiality and anonymity, participants cannot control for this or guarantee it. Participants in interactive focus groups are especially vulnerable to group coercion or pressure to disclose information that they might not have intended to disclose. Creating a safe environment in which participants can share painful and emotional experiences is a challenge that must be met in any focus group, but this is especially true in interactive focus groups because of the tendency for deeper emotional and personal disclosure during these sessions.

INTERACTIVE INTERVIEW

Interactive interviewing is an interpretive practice for getting an in-depth and intimate understanding of people’s experiences with emotionally charged and sensitive topics such as childbirth, illness, loss, and eating disorders. Emphasizing the communicative and joint sensemaking that occurs in interviewing, this approach involves the sharing of personal and social experiences of both respondents and researchers, who tell (and sometimes write) their stories in the context of a developing relationship. This entry discusses the goals, concerns, and practices associated with this type of interviewing.

Interactive interviewing is a collaborative communication process occurring between researchers and respondents in small group settings. The goal of an interactive interview is for all of those participating, usually two to four people (including the primary

researcher), to act both as researchers and as research participants. Each person has the opportunity to share his or her story in the context of the developing relationships among all participants. Interactive interviewing works especially well when all participants also are trained as researchers. If that is not the case, however, participants can be given an important role in determining the research process and its contents as well as in interpreting the meaning of the interviews.

Likewise, the feelings, insights, and stories that the primary researcher brings to the interactive session are as important as those brought by other participants; the understandings that emerge among all parties during interaction—what they learn together—are as compelling as the stories each person brings to the session. Ideally, all participants should have some history together or be willing to work to develop a strong affiliation. It is helpful for the researcher as well as the co-participants to have personal experience with the topic under investigation; if that is not the case, the researcher should be willing to take on the roles and lived experiences of other participants in this regard. This strategy is particularly useful when the researcher is examining personal topics that require reciprocity and the building of trust.

Interactive interviewing requires considerable time, multiple interview sessions, and attention to communication and emotions. It also may involve participating in shared activities outside the formal interview situation. This approach does not have rigid rules for proceeding; rather, it is flexible and continually guided by the ongoing interaction within the interview context. Participants engaged in this kind of research must be open to vulnerability and emotional investment while working through the intricacies of sensitive issues. In some cases, research roles may overlap with friendship, caretaking, and therapeutic roles, and the primary researcher must have plans in place for coping with that possibility.

Interactive interviewing reflects the way in which relationships develop in real life as conversations where one person's disclosures and self-probing invite another's disclosures and self-probing, where an increasingly intimate and trusting context makes it possible for a person to reveal more of himself or herself and to probe deeper into another's feelings and thoughts, where listening to and asking questions about another person's plight lead to greater understanding of one's own plight, and where the examination and comparison of experiences offer new insight into both lives.

This intersubjective process provides a contextual basis for a level of understanding and interpretation that is not present in traditional hierarchical interview situations where interviewers reveal little about themselves, aloofly ask questions in one or two brief sessions, and encourage little or no relationship development with respondents. When interviewers do reveal something about themselves in traditional interviews, it often is viewed as a "tactic" to get respondents to "open up."

Interactive interviewing differs from life history research in its emphasis on the researcher as well as the respondent and in the attention paid to the dynamics of the interview situation. In addition, an interactive interview differs from a therapeutic interview in that intervention and change are not primary goals (although they may be achieved). Furthermore, the relationship between the interviewer and the respondent is not as distinctly hierarchical or as guided by a set of rules as is the relationship between the therapist and the client. Instead, all participants are expected to probe both "self" and "other."

Many practical and ethical questions arise in doing interpretive interactive interviewing, including the following. Who can do this kind of research? What are some of the considerations that should be taken into account? What procedures should be followed? How do participants provide a supportive context that encourages talk about intimate experiences? What precautions should researchers take to avoid doing harm to themselves and to respondents? How might participants handle the silences—what is not talked about—in the interview? How might participants respond if the interview becomes emotional? Is it feasible/desirable to merge the goals of therapy and research?

Many of these questions have been addressed during the past two decades by interpretive social scientists, especially feminist scholars, who have challenged traditional interviewing practices. Many ethical questions and concerns about the ethics of merging therapeutic and research goals continue to be debated heavily. Carolyn Ellis and her colleagues, for example, have suggested that research that does not offer potential healing for self, participants, audience members, and/or positive social change for communities and nations is suspect. They believe that researchers should care about and for participants rather than treating them like subjects. Other scholars have argued that researchers are not therapists and are not equipped to do therapy and that therapeutic goals are not ethical or suitable in

social science research projects. Whatever their position on these matters, those practicing interactive interviews should be aware of the complex issues that arise in this research and should consider them fully in the context of their particular projects.

INTER- AND INTRACODER RELIABILITY

Inter- and intracoder reliability refers to two processes related to the analysis of written materials. Intercoder reliability involves at least two researchers' independently coding the materials, whereas intracoder reliability refers to the consistent manner by which the researcher codes. Inter- and intracoder reliability is a major point of interest to researchers who believe that qualitative research lacks sufficient analytic rigor.

Both quantitative and qualitative researchers use inter- and intracoder reliability. The former find a strong use in conducting content analysis resorting to calculations and measurements sometimes based on

“agreement indexes” using percentages or statistical techniques, whereas the latter find it particularly useful to analyze interview and focus group transcripts. This entry discusses the use of inter- and intracoder reliability only by qualitative researchers. It should be noted, however, that the existence of computer programs has enabled qualitative researchers to bend their approach toward that of quantitative researchers. Some see this development as a welcome bridge between the two paradigms of research.

Although the formal objective of inter- and intracoder reliability in qualitative research is to produce codes that lend themselves to development of concepts and theory, the latent aim is to train students to analyze transcripts. In this latter purpose, the researcher mentors students (i.e., the other coders) in how to analyze materials. Still, the formal analysis of materials/transcripts remains the primary goal.

The Process of Coding

Becoming wholly familiar with the transcribed text is an urgent requirement for all coders. The coder notes the overt statements as referents to the empirical world, and he or she carefully notes these in the materials. It does not matter substantially whether these notes are placed within the text (e.g., with the use of a word processing program) or are penciled in on the side of the text. Some engage in “line-by-line coding” as suggested by Anselm Strauss, whereas others find it more worthwhile to take somewhat larger chunks of text of, say, two or three “sentences” or even a whole “paragraph.” During this first stage of coding, the coder will also probably pay particular attention to covert meanings that reside within the text.

To achieve intercoder reliability, the two (or more) coders get together after the first round of independent coding to discuss their results. At this stage, they also will discuss the more suitable codes that will lend themselves to analysis. In many instances, however, the coders will maintain virtually all codes until a higher stage of coding is reached. Each coder also takes these opportunities to check for intracoder reliability.

As the coding process thickens, the coders might agree that some codes to statements about the empirical referents should be abandoned, refined, combined, or merged with other codes. Coders might want to abandon codes if they refer to sporadic statements in the text or if they seem to fall outside the parameters of the study. Sometimes coders may seek a refinement,

especially if the code captures a category that is too broad (e.g., “education” might need to be refined as “education for girls”). On further inspection, coders might decide to combine two or more codes into an entirely new code (e.g., “uneasiness” and “flustering” might be combined into “embarrassment”). Finally, when a code occurs too infrequently, it might be more easily subsumed under a more commonly occurring code.

After such reworkings, the coders now engage in a further rereading of the text and pay particular attention to any themes that might emerge from the codes themselves. Again, each coder engages in this process initially independent of the other coder(s), although a time constraint might forcefully parlay itself into this stage of the process and make it impossible to continue on this parallel coding track.

There is one dimension of intracoder reliability that is often overlooked in research and that affects both inter- and intracoder reliability; namely, the pattern of the sequence of codes. As was the case in the focus group research by Deborah and Will van den Hoonaard, described in *The Equality of Women and Men: The Experience of the Bahá'í Community of Canada*, the researchers noted a peculiar sequential pattern when coding the empirical referents. When the researchers laid out all of the codes, they noticed that the codes occurred in a distinctive sequential chronological pattern. In each of the 12 focus group transcripts, there was a decisive moment in the transcript when the group started to reflect on, and revise, statements that the group had made earlier in the discussion about group members' experience with equality. This sequential pattern of codes was so consistent that the researchers began to see it as an identifying moment for the focus group. If the researchers had simply summed all of the codes without regard to their relational placement in the whole transcript, they would not have noted this important transition in the consultations of the focus groups. Thus, the researchers were able to identify the “career” of the focus group discussion.

Challenges

To achieve inter- and intracoder reliability, coders should be apprised of several important challenges that lie ahead of this analytic process. First, it might be difficult for the software program to take into account the subtleties of changing the codes along the way. Second, it is not always easy to find the proper balance between having too many codes and having

too few codes; the former will overwhelm the analysis in a meaningless way, whereas the latter will underwhelm the analysis. Third, the time required to develop all of the codes can outstretch resources and the time periods. Fourth, it is difficult to decide when checks on coder reliability are no longer required (only during the initial phase of the coding process or well into the stage of creating concepts?). Fifth, it can be difficult to distinguish overt statements from covert statements. Sixth, the way in which coders come to agree on the relevant codes might not be clear (such agreement cannot always be predicated on the experience of veteran researchers or on the fresh insights of novice researchers). Despite these challenges, many researchers will always be drawn to coder reliability.

INTERDISCIPLINARY QUALITATIVE STUDIES CONFERENCE

The Interdisciplinary Qualitative Studies (IQS) Conference has been held annually in January at the Georgia Center for Continuing Education on the campus of the University of Georgia since 1988 and is one of a handful of such conferences held around the globe. Its purpose is to provide a venue for presentation of scholarship on qualitative research methods, design, epistemology, and related theoretical concerns as well as examples of innovative qualitative work across the human and professional sciences. Although

annual themes and keynote speakers reflect ongoing issues and concerns in the practice and study of qualitative research, presentations represent the range of qualitative study.

The conference typically runs for 2½ days in early January. On days immediately preceding and following the conference, workshops on various skills and topics are offered. In addition to three or four invited keynote speeches or presentations, the conference program is organized around individual papers, papers grouped into symposia, panel discussions, poster sessions, additional workshops, roundtable discussions, and alternative formats proposed by presenters. These presentations are organized in the program by their substantive or methodological subject. All sessions except invited ones are refereed given that the program is intended to support innovation and to provide a safe environment for experimentation and transformative endeavors. Individual research consultations are offered to attendees by senior methodologists throughout the conference.

The IQS Conference originated as an outreach effort of the Qualitative Interest Group (QUIG) at the University of Georgia. QUIG is an association of faculty and staff members from across the university who were brought together in 1985 through a development grant provided by the College of Education. The IQS Conference itself remains a project supported principally by the College of Education but also aided by departments and units around the university that contribute to its interdisciplinary orientation. Still known locally as the QUIG conference, it is coordinated by a rotation of QUIG members, and the yearly theme and keynote speakers are selected by that year's coordinator. Conference themes have emphasized the range of qualitative methods and practices as well as topics such as ethics, fostering diversity and social justice through qualitative research, alternative representation, teaching qualitative traditions, integrating the arts with research, and a variety of epistemological issues.

INTERDISCIPLINARY RESEARCH

Interdisciplinary research integrates perspectives and methods from two or more disciplines to investigate a topic or an issue. It has been distinguished from multidisciplinary research in which individuals and teams trained in different academic traditions focus on a common problem but are not charged with integrating concepts and methods to address that problem. It has also been distinguished from, or regarded as a subtype of, transdisciplinary research where diverse researchers attempt to transcend disciplinary boundaries to create novel ways of thinking about the topic of interest and to advance methods of investigation. Although interdisciplinary research has a long history, it has gained prominence recently due to the “big science” revolution that encourages and funds large, interdisciplinary, and multimethod research and to technological advances that enhance conceptual and methodological integration. Increasingly, researchers, funders, and policymakers have come to recognize that multiple perspectives and methods are needed to better understand and solve complicated issues. The added value of interdisciplinary approaches has been demonstrated in research on a range of complex questions such as the effects of poverty on child and family well-being; the ethical, legal, and social implications of genetic research; health and health behaviors; and the multiple interlinked influences on child development (e.g., biological, environmental, familial, community, cultural). These are complicated phenomena that require a matching complexity and integration of methods at multiple levels for their study.

Although much has been written about the value of interdisciplinary research and its correlate mixed methods, there is little available about the actual practice and use of qualitative methods in interdisciplinary projects—the ways in which large and diverse research teams have integrated qualitative approaches, the transformations that qualitative methods can bring about, and the real challenges that exist for qualitative methodologists working on interdisciplinary teams or for researchers on the team who are not trained in the methods. Research findings are reported with varying degrees of success at integrating qualitative perspectives and methods, but the activities that lay behind successful or unsuccessful integration are not transparent. This entry provides a brief synopsis of the potential of qualitative methods in collaborative interdisciplinary research and the factors that enhance or impede integration.

The Potential of Qualitative Methods

Increasingly, different disciplines are adopting qualitative methods as one means to investigate pertinent research questions. Until very recently, researchers in fields such as sociology, psychology, education, nursing, and public health were suspect or marginalized if they wanted to employ ethnographic or interview methods in their studies. Although these views have not dissipated entirely, there is more appreciation for the depth of understanding that qualitative methods can bring to interdisciplinary research. If employed at all phases of the research project, from research design through sampling, data collection, analysis, and report writing, qualitative methods can suggest new lines of inquiry, new foci of investigation, alternative statistical models, and novel interpretations of complex phenomena. Methods such as participant observation, semi-structured interviews, document analysis, life histories, and case studies bring other disciplinary perspectives to a research team by their mere introduction. For example, an explanatory or cultural models type of interview can elicit individuals' ideas about disease causation, symptoms, prognosis, and treatment and can be used in clinic and research settings. There have also been a number of interdisciplinary studies of poverty and child and family well-being that use qualitative approaches. Sociological questionnaires and psychological assessments have provided important information on correlations among societal, familial, and individual variables, but ethnographic research and case studies add holistic accounts of how low-income families raise their children and make ends meet in contexts of limited resources and poverty programs. In addition, they bring theoretical perspectives from their anthropological or sociological origins, such as theories of inequality and social justice, that can be used in interpreting or contextualizing findings from other methods.

The addition of qualitative methods to interdisciplinary research can also uncover expected findings that suggest new foci of investigation or different variables for analyses. For example, the ethnographic component of *Welfare, Families, and Children: A Three-City Study* (a project examining the effects of the 1996 welfare reforms in the United States on low-income families) found that children within the same family had differential access to health insurance and other resources. This finding was unanticipated and led to new survey questions and statistical analyses. Ethnographic investigations into the complexity of families led to new ways of

thinking about "single mothers" and to different categorizations, or variables, for use in further analysis.

Collaborations between qualitative methodologists and researchers trained in other methods can lead to novel approaches and models. For example, ethnographers' collaborations with a geographer on the Three-City Study led to a new method called *geoethnography*, where ethnographic data from participant observations and interviews are combined with geographic information systems (GIS) technology to map and depict important spatial dimensions of individuals' lives as affected by social structures and processes, in this case, the spatial and temporal aspects of how caregivers of children with disabilities navigated and linked services. Combining ethnographic data and GIS methods helped researchers to see both "context" and "content" in a spatial dimension, and the alternative way of representing data identified issues that would not have been apparent otherwise.

Factors That Enhance or Impede the Use of Qualitative Methods

There are a number of factors that affect the degree to which research is truly interdisciplinary. These include the expertise of members of the team in how to integrate concepts and methods from different academic arenas and how committed they are to adopting unfamiliar methods. Teams of interdisciplinary researchers focused on social science kinds of questions may represent the full range of academic departments. For example, a team investigating the ethical, legal, and social implications of large-scale genomic research is likely to be composed of researchers in medical and human genetics, sociology, anthropology, law, philosophy, and public health. Methods of investigation in each of these fields are different and usually unknown to individuals outside the particular disciplinary tradition. The degree to which an interdisciplinary project will succeed in incorporating theoretical insights and methodological approaches of its diverse members depends in large part on communication and translation. If disciplines are separate cultures, each with its own tradition of thought and practice, then interdisciplinary work, at least in the beginning, is much about coming to an understanding of cultures that are different from one's own.

Linking qualitative and quantitative approaches ideally should begin at project conception. An integrated study can use qualitative research to indicate constructs or hypotheses that need to be addressed

with quantitative data collection. In the next wave, quantitative data can be used to test hypotheses generated from (for example) ethnographic work, ensuring that conclusions drawn from the ethnographic work are not biased due to small or selected samples. Conversely, quantitative data can raise important issues that can be studied in more depth in the next wave of qualitative data collection. That is, the ideal feedback loop entails ensuring that results obtained from one approach are examined during the next wave of data collection using the other method. This process requires commitment from the research team as well as prompt processing and analysis of data from each wave of data collection.

The extent to which the study includes feedback loops between methods will strongly influence the ability to use both sets of data to triangulate results. Three elements of mixed methods research design influence the ability to capitalize on intended integration: (1) what constructs are measured, (2) when assessments take place, and (3) who is assessed. Large longitudinal studies designed to employ both qualitative and quantitative methods vary along all three of these dimensions. Qualitative methods may be used to assess the same constructs as those to be measured using questionnaires or standardized instruments, or the two assessments may be intended to address separate research questions and the constructs of interest might not overlap at all. Failure to collect data on the same domains or constructs eliminates the ability to influence later data collection across methods and makes integration of results difficult or irrelevant. The schedule of assessments may be concurrent or staggered (with one type always preceding the other). Concurrent data collection reduces the sources of discrepancy between findings from the two methods. However, staggering assessments can strengthen feedback between methods. For example, if qualitative assessments are intended to provide insight into the quantitative measures selected, conducting qualitative assessments well in advance of quantitative data collection is advised. Finally, both qualitative and quantitative data may be collected on none, some, or all of the same study participants. Most often, qualitative data are collected on a small subset of participants who are also participating in the quantitative assessments or on a smaller and completely separate sample selected to “match” the larger sample on key variables. Rarely are both methods used to assess the same sample.

The most comprehensive integration can occur when qualitative and quantitative data are collected on all participants. In this case, qualitative data can be analyzed and used to create typologies or variables for use in further quantitative analysis and to provide interpretation and context for quantitative results. Quantitative data can be used to provide statistical support for qualitative interpretations. Combined analyses can extend the validity and generalizability of findings by combining information from in-depth interviews or observations with scores from standard assessments in the same analysis. For example, my colleagues and I have conducted semi-structured interviews with 150 families (250 mothers and fathers) of Mexican and Puerto Rico origin that had a child age 5 years or younger with mental retardation or developmental delay. Interview data were used to rate each parent on a 5-point scale in terms of his or her level of use, awareness, and satisfaction with services, and these outcomes were related to family and child characteristics. In another case, quantitative methods were central to ascertaining the degree to which these Latino families viewed religion as a source of support and what child and family characteristics correlated with this variable, but qualitative data were essential in revealing the ways in which people actually thought about and used religion as a support system. In another example of parents of children with fragile X syndrome, responses from open-ended questions were used to check the consistency and validity of the responses to standard survey questions and to provide a meaningful context for the statistical results.

The biggest challenge in any multidisciplinary team approach is determining the relative weight assigned to each approach. This weight is often reflected both in the amount of resources devoted to collection of both types of data and in who is included in the decisions. It is often difficult to include methods different from those in which most investigators were trained. A longitudinal project is expensive, and there may be debates about the amount of money to allocate to qualitative research. Decisions about the research design are often among the most contentious issues facing a longitudinal research team, and both qualitative and quantitative methodologists must be involved in that process if the team hopes to use both types of data to address research questions. Given these issues, successful integration is influenced by the extent to which the principal investigator and the entire

research team are committed to, and experienced in, integrating data.

Finally, the level of investment of the research team in a specific research question may affect the ability to integrate data. High levels of investment in a given topic can facilitate integration when the research team focuses on that topic, and interest in the topic ensures that adequate resources will be devoted to measurement. In contrast, integration may fail if qualitative researchers are interested in topics that do not interest quantitative researchers and vice versa. Low levels of interest in a given topic make it unlikely that resources will be allocated to measurement of the constructs and changing protocols if discrepant results from the two approaches are obtained. Integrating qualitative and quantitative methods should provide more depth and breadth in understanding complex developmental phenomena. Each approach offers sophisticated techniques that promise more precision and validity in measurement, including addressing issues of cultural sensitivity and describing and understanding patterns of change. Although advanced methods in each tradition are available, they are seldom used in tandem and useful models and examples for combining them are lacking.

INTERNATIONAL ASSOCIATION OF QUALITATIVE INQUIRY

On May 7, 2005, the International Association of Qualitative Inquiry (IAQI) was established during the First International Congress of Qualitative Inquiry at the University of Illinois at Urbana-Champaign. The founding members were President Norman Denzin, University of Illinois at Urbana-Champaign; Vice President Judith Robinson, University of Liverpool; and Treasurer Grant Kien, University of Illinois at Urbana-Champaign. The foundation of the IAQI was a response to the desire of many members of the international qualitative inquiry community for an organization that would facilitate the global development of qualitative inquiry and could actively speak on behalf of the interests and concerns of qualitative researchers. In keeping with these ends, the IAQI seeks to foster shared learning and to advocate and lobby on behalf of qualitative research methods and findings that have a broader social justice agenda.

To discuss the governance and direction of the organization, the IAQI convenes annually during the International Congress of Qualitative Inquiry. Throughout the year, a volunteer-based international advisory committee works to address issues raised at the annual meeting and to provide representation in specific regional and interest-based dialogues.

As of January 2007, less than 2 years after its launch, the IAQI's membership consisted of more than 1,000 members from more than 55 nations. In addition to a membership listserv, the IAQI produces the *IAQI Newsletter*, a quarterly publication that keeps members informed about upcoming conferences, publications, calls for papers, and professional opportunities regarding qualitative inquiry. The IAQI has also partnered with scholarly presses to advance the dissemination of qualitative methodologies. At the time of this writing, negotiations are under way to establish a journal for the

IAQI. Furthermore, the IAQI maintains an archive of white papers making policy recommendations based on the findings and principles guiding qualitative inquiry.

The IAQI takes an interdisciplinary standpoint spanning the fields of educational policy research, the humanities, communications, health care, social science, social welfare, business, and law. It continues to promote discussions that foreground performative, feminist, Indigenous, queer, democratic, and participatory modes of critical ethical inquiry that question the notions of research, science, and ethics as put forth by traditional methodologies.

INTERNATIONAL CONGRESS OF QUALITATIVE INQUIRY

The International Congress of Qualitative Inquiry is a conference and associated workshop series hosted by the International Center for Qualitative Inquiry at the University of Illinois at Urbana-Champaign. The center and congress director is Norman Denzin. The congress is one implementation of the center vision that includes the goal “to facilitate the development of qualitative research methods across a wide variety of academic disciplines.”

The first congress was held May 5–7, 2005, on the theme “Qualitative Inquiry in a Time of Global Uncertainty” and included the launch of the International Association of Qualitative Inquiry. More than 650 papers were presented by delegates from more than 45 nations. The keynote speakers were Janice Morse (University of Utah) on “The Politics of Evidence” and Linda Tuhiwai Smith (University of Auckland, New Zealand) on “On Tricky Ground: Researching the Native in the Age of Uncertainty.” Eleven preconference workshops were held, including “Feminist Qualitative Research in the New Century,” “Autoethnography,” and “Interpreting, Writing Up, and Evaluating Qualitative Materials.”

The second congress was held May 4–6, 2006, on the theme “Ethics, Politics, and Human Subject Research in the New Millennium.” This congress attracted even more papers than the first—more than 900—from an even wider constituency of more than 55 nations. The keynote speakers were Marie Battiste (University of Saskatchewan, Canada) on “The Global Challenge: Research Ethics for Protecting Indigenous Knowledge and Heritage” and Michelle Fine (National Academies of Science) on “Do You Believe in Geneva? Participatory Action Research, Critical Methods, and Indigenous Knowledges.” Sixteen preconference workshops were held, including “Case Study With Distant Inhabitants,” “Heartbeats: Writing Performance Texts,” and “New Experimental Writing Forms.”

The third congress was held May 2–5, 2007, on the theme “Qualitative Inquiry and the Politics of Evidence.” The keynote speakers were D. Soyini (University of North Carolina) on “Dangerous Ethnography and Utopian Performative” and Julianne Cheek (University of South Australia) on “A Fine Line: Positioning Qualitative Inquiry in the Wake of the Politics of Evidence.” Sixteen preconference workshops were held, including “Doing Situational Maps,” “Evidence-Based Social Work,” and “Writing Lives and Writing Deaths.”

The International Congress of Qualitative Inquiry website includes a call for papers, details of past conferences, a conference paper archive, a facility to join an announcement listserv and view its archive, and a qualitative inquiry community blog.

INTERNATIONAL HUMAN SCIENCE RESEARCH CONFERENCE

The International Human Science Research Conference (IHSRC) has been held annually since 1982. It provides a collegial gathering place for presentations and dialogue for faculty members, graduate students, and others who are interested in the practice, theories, and

principles that are related to qualitative research. According to the 1988 program, “The conference draws people who are interested in studying experiences as they occur for the individual, taking into account the larger social and historical context of human life. From this perspective, all of us who participate in this conference are researchers. That is, we are searching to discover that which is fundamentally human.”

Within the context of this organization, *human science* is defined broadly, although the phenomenological and hermeneutical traditions have been especially influential. The origin of the conference illustrates this point. The first meeting, in 1982, took place at the University of Michigan, Ann Arbor, and grew out of a phenomenology seminar organized by graduate students and faculty members, mainly from education. The invited speakers for the first conference included Thomas Luckmann, Amedeo Giorgi, Max van Manen, and Ton Beekman. The second conference was hosted by Amedeo Giorgi, who chaired the program in phenomenological psychology at Duquesne University and who continues to play a central role in the IHSRC. Over the years, the conference has included qualitative researchers from other orientations such as grounded theory and social constructionism.

Until 1989, the conference was held in either Canada or the United States. Subsequently, the participants decided that it should alternate between North America and Europe. In 1995 it was held in South Africa, and in 2001 it was held in Japan. Most years the conference organizers have selected a broad theme (e.g., “Integration of the Human Sciences,” “Ethical Foundations and Implications,” “Caring for the Next Generation”) as a focus. Although the nature of the conference has remained relatively constant over time, the conference comes to life in a distinct way each year as it is hosted by a new university in a new location.

The IHSRC is unique in that it has existed for a quarter century with minimal organizational structure: it has no officers, board of directors, dues, bylaws, or the other paraphernalia associated with professional organizations. There is just an annual newsletter that is funded out of the conference fees. The organization is kept going by the dedication and enthusiasm of its members.

INTERNATIONAL INSTITUTE FOR QUALITATIVE METHODOLOGY

The International Institute for Qualitative Methodology (IIQM) was established at the University of Alberta, Edmonton, Canada, in 1998 for the purpose of facilitating the development and use of qualitative methods globally. The objectives were as follows:

- Provide leadership to address issues in qualitative inquiry and facilitate the development of qualitative methods
- Promote excellence in qualitative research through education and research
- Provide a forum for collaboration among international experts in the field of qualitative inquiry

To achieve the IIQM’s global mission, the founding director, Janice Morse, initiated an administrative structure consisting of international sites in each major continent, and these sites in turn were linked to universities and research centers within their geographic regions or linguistic groups (called *cooperating sites*). Initially, international sites were established on six continents as follows: North America, University of Alberta; Australia, University of Newcastle; South America, Universidad de São Paulo; Europe and Great Britain/Europe, Universiteit Utrecht; Africa, Rand African University; and Asia, Ewha Womans University. In 2000, two other sites were added: Ibero-America, University of Guadalajara; and the Middle East, Ben-Gurion University of the Negev. Further expansion in 2006 resulted in the addition of two new sites and some reorganization. Sites for the United Kingdom and Scandinavia were established at the University of Bournemouth and the University of Aarhus, Denmark, respectively. The Australian site moved to the University of South Australia, and the European site was relocated to the University of Berlin, Germany. As of November 2006, these 10 international sites were linked to 115 cooperating sites under the guidance of an international advisory board.

The cooperating sites are responsible for establishing and maintaining their own programs directed toward making qualitative inquiry visible and accessible. Each site is also expected to maintain a website. Support or assistance may be requested from the international site or from the institute at the University

of Alberta. Hence, the IIQM is a huge network of institutions linked with the common goal of developing qualitative inquiry.

Programs

The programs developed by the IIQM and its affiliate sites make for a large movement promoting qualitative research. Space limitations here allow only a general description of these efforts.

Conferences and workshops: Two international conferences, Advances in Qualitative Methods and Qualitative Health Research, are sponsored annually, with conferences often alternating between the Alberta and international sites. Individual language and regional groups also hold annual conferences, including the Ibero-American Conference and conferences held by the Israeli Center for Qualitative Inquiry and the University of Bournemouth. In addition, a weeklong series of workshops, "Thinking Qualitatively," takes place each summer at the IIQM in Edmonton, Alberta.

International dissertation award: A prize is awarded annually for the best qualitative dissertation in any discipline.

Qual Press: The Qual Press publishes a series of excellent qualitative studies, including the winners of the dissertation award, published as monographs.

International Journal of Qualitative Methods (IJQM): This is a quarterly, open-access, web-based journal in which authors may publish innovative work in the development of qualitative methods.

Summer program and internships: This is a 10-week summer program held at the IIQM and typically consisting of two courses: Principles of Qualitative Inquiry and Inside Analysis. The "Thinking Qualitatively" workshops are also offered during the summer.

International collaborative research: The networking available through the IIQM fosters international collaboration and comparative research.

Internal support: The IIQM encourages the development of qualitative research laboratories, networking, journal and writing clubs, and seminars according to the needs at each site.

INTERNATIONAL JOURNAL OF QUALITATIVE METHODS

The *International Journal of Qualitative Methods (IJQM)* is an open-access, internet-based, refereed journal. Established in 2002, it is published quarterly. The *IJQM* is sponsored by the International Institute for Qualitative Methodology (IIQM) at the University of Alberta, Edmonton, Canada.

The publishing mandate of the *IJQM* focuses on articles that describe, develop, and disseminate qualitative methods. As a multidisciplinary international journal, the *IJQM* has a readership consisting of academics, students, and professionals who undertake qualitative research worldwide. The regional editors manage article submissions and reviews in languages other than English, as well as posting translations of published articles as they become available.

The current Editor and Associate Editor (Cindy Jardine and Lisa Given, respectively) work out of the IIQM in Edmonton, Alberta, Canada, and oversee the work of the *IJQM*'s regional editors. As of 2008, these were Margareth Angelo, Escola de Efermagem da USP, Brazil; Dan Bar-On, International Center for Qualitative Methodology, Ben-Gurion University of the Negev, Israel; Bas Levering, University of Utrecht, The Netherlands; Lea Kacen, International Center for Qualitative Methodology, Ben-Gurion University of the Negev, Israel; Irena Madjar, University of Newcastle, Australia; Francisco J. Mercado Martinez, PROGICS, University of Guadalajara, Mexico; Neila van der Linde, University of Johannesburg, South Africa; and Kyung Rim Shin, Ewha Womans University, Korea. Moira Calder serves as technical editor.

The journal is divided into sections: full-length articles, keynote addresses, insider insights (short "how-to" methodological briefs edited by Lisa Given, University of Alberta, Canada), and abstracts from the

two IIQM international conferences (Advances in Qualitative Methods and Qualitative Health Research).

Examples of recent articles include the following:

- Agar, M. (2006). Culture: Can you take it anywhere? [keynote address]. *International Journal of Qualitative Methods*, 5(2), Article 11. Retrieved from http://www.ualberta.ca/~iiqm/backissues/5_2/html/agar.htm
- Epstein, I., Stevens, B., McKeever, P., & Baruchel, S. (2006). Photo elicitation interview (PEI): Using photos to elicit children's perspectives. *International Journal of Qualitative Methods*, 5(3), Article 1. Retrieved from http://www.ualberta.ca/~iiqm/backissues/5_3/html/epstein.htm
- Jensen, D. F. N. (2006). Metaphors as a bridge to understanding educational and social contexts. *International Journal of Qualitative Methods*, 5(1), Article 4. Retrieved from http://www.ualberta.ca/~iiqm/backissues/5_1/html/jensen.htm

The *IJQM* is indexed in Academic Abstracts FullTEXT, Academic Search, BioMedical FullTEXT, Business Source, Canadian Reference Centre, Canadian MAS FullTEXT, Health Source, Humanities Source, MasterFILE, Public Library FullTEXT, Primary Search, Social Science Center, Sociological Abstracts, and Topic Search.

INTERNET IN QUALITATIVE RESEARCH

The internet is a social phenomenon, a tool, and also a field-site for qualitative research. The relationship of the internet to the research project depends largely on how the internet is defined.

The term *internet* originally described a network of computers that made possible the decentralized transmission of information. In popular use, however, *the internet* is an ambiguous term referencing or encompassing innumerable technologies, uses, and social spaces. Because these technologies, the capacities for communication, and the types of social interaction made possible by the internet vary so widely,

qualitative researchers find it necessary to define the concept more narrowly within individual studies. This is complicated by the fact that the study of the internet cuts across all academic disciplines. There are no central methodological or theoretical guidelines, and research findings are widely distributed and decentralized. As a consequence, qualitative researchers may find it challenging to locate previous studies that might prove to be useful in the design and enactment of their own studies.

Depending on the role the internet plays in the qualitative research project or how it is conceptualized by researchers, different epistemological, logistical, and ethical considerations will come into play. The internet tends to be used or studied in one or more of the following ways:

- *The study of any social phenomenon using the internet as a tool for collecting, sorting, storing, and/or analyzing information gathered:* This refers to inquiry related to any topic that uses various capacities and interfaces available on the internet to augment or replace traditional qualitative methods of collecting, storing, sorting, and analyzing information. The internet is also associated with the use of data analysis software, albeit inaccurately given that the internet is not strictly necessary to enable the functioning of such analytical tools.

- *The study of social phenomena that are mediated by, rely on, or are interwoven with the internet for their composition or function:* This refers to inquiry focused on the way in which people use or experience various aspects of the internet or on the cultural formations emerging from or made possible through the internet. Methods drawn from a wide range of disciplines can be adapted to studying internet use or computer-mediated environments.

- *The study of the internet or aspects of it as phenomena in themselves:* This refers to inquiry focused on the network, technologies, or capacities of the internet. This research scenario is distinguished from the preceding ones because of a greater focus on various features and implications of this globe-spanning network of connectivity rather than on those social phenomena resulting from internet use.

These categorizations of inquiry are not necessarily mutually exclusive. Researchers studying an

online community may conceptualize the internet as a tool for collecting information, the field-site, and also as an object of analysis. A researcher exploring the way in which information flows through the network may use the internet as a tool and also consider the social impact of this mapping.

It is important to distinguish between the research scenario, as already categorized, and the characteristics of the internet that will become salient as the purpose of research is identified or unfolds. Depending on the focal point in each scenario, the internet can acquire or display particular characteristics that, in turn, influence the design and enactment of the research project.

As a hypothetical example, consider the following. Researcher 1, studying how breast cancer survivors frame their experiences, defines the internet as a tool, using various internet media to contact participants, schedule interviews, distribute open-ended question lists, collect research diaries, organize and sort data, and so forth. Researcher 2, studying how women feel about being members of a virtual breast cancer group, conceptualizes the internet as a field-site, observing interaction practices and group norms among participants. Researcher 3, studying personal websites created by breast cancer survivors, focuses on hyperlinks among websites, mapping the network of connections created by these common elements. In the first case, the information processing and transmitting features of the internet are salient, but only inasmuch as these tools function effectively. In the second case, the virtual or internet-mediated characteristics of the group are salient, but they are tertiary to the primary focus on the group itself. In the third case, the internet itself is the phenomenon; links among users are the primary focus. Each researcher asks distinct questions that highlight or hide various aspects of the internet.

Salient Characteristics of the Internet

Certain uses and capacities are noted as important considerations in the development of qualitative studies of the internet or in its use. This list is not exhaustive but rather general and intended heuristically.

Internet as a Medium of Communication

Inductive naturalistic principles and processes guide qualitative inquiry. In the examination of the construction, negotiation, and maintenance of human

social practices and structures, qualitative researchers engage in the process of studying communicative practices in context. As a medium for communication, the internet provides multiple means of interaction and performance of identity and community.

Although composed of vast networks of connections between computers, the internet is more associated with the tangible capacities afforded by these instantaneous connections. Users focus less on the networks of connections than on the texts, still and moving images, and sounds facilitated by these networks. People use the internet in ways that parallel, but depart from or extend, earlier media for communication such as letter writing, telephone, sticky notes, and bulletin boards. People can use multiple media simultaneously. These uses can be asynchronous or synchronous; one-to-one, one-to-many, or many-to-many; anonymous or not anonymous. The presentation of self may be represented in writing, sound, moving and still images, video (live or prerecorded), avatars, various displayed artifacts, and so forth.

Use of a particular form of internet medium may appear to be homogeneous at the surface level of activity. For example, the seemingly simple practice of sending text messages could be conceptualized as variously as a conversation continuer, a marker of presence, a sign of status, an opportunity to represent oneself authentically, a move of parental resistance, an opportunity to wear a mask, a location device, or a signal for unified action.

If used as a tool for research, the capabilities of the internet should be matched to the goals, topics, and participants of the project. Because internet technologies are defined and adapted in distinctive ways by different users and groups, this is often an inductive process. Collecting life histories via email may be satisfactory, but allowing participants to create ongoing life history accounts on websites that they can design with color and images may yield richly textured results. Yet although this shift would be quite suitable for certain users, it would be completely foreign to others. For an interview study, real-time chat rooms may provide anonymous participation and spontaneous conversation, but that might not be adequate for certain participants or research questions. Interviewing via video may be preferred by some participants, but others might provide more information if they also had an instant messaging window open; sometimes people cannot say something vocally or face to face but can and will express it in text. Email

interviews may be better suited to participants who have busy schedules and desire time to consider their responses, but they may be unsuitable for users who are more familiar with shorter, more immediate forms of interaction. The key is to make a conscious and measured effort to match the mode to the context, the users' preferences, and the research question.

Internet as Geographically Dispersed

This capacity of the internet is generally taken for granted in everyday communication with others. Internet interfaces disregard location and distance, enabling the instantaneous and inexpensive transmission of information between people and databases. Logistically, the distance-collapsing capacity of the internet allows researchers to connect to participants around the globe. This increases and/or alters the available pool of participants and can enable questions and comparisons that were previously less available.

Research can be designed around questions of interaction and social behavior unbound from the restrictions of proximity or geography. Participants can be selected on the basis of their appropriate fit within the research questions rather than on the basis of their physical location or convenience to researchers. This requires a shift from physical to discursive boundaries for the ethnographic project.

Internet as Anonymous

Certain interaction environments facilitate a sense of anonymity. This has obvious advantages for certain topics or methods of qualitative inquiry. Part of this perception is facilitated by the internet's disconnection from geographic markers, meaning that one's participation in interaction with other people is not necessarily linked to one's physical proximity to others as would be the case in all face-to-face contexts.

In addition to the natural—but not necessary—separation between people interacting via internet-mediated communication, certain interfaces are designed to promote and protect anonymity. These anonymous interaction environments may allow participants to speak more freely without restraints brought about by social norms, mores, and conventions. This feature is useful in studies of risky or deviant behaviors or of socially unacceptable attitudes.

Anonymity and geographic distance both complicate and ease ethical considerations. In meeting the

ethical requirements for conducting research involving human subjects in most countries, researchers are required to, among other things, gain informed consent. In an anonymous environment, it is difficult, if not impossible, to ascertain whether the user is capable of granting informed consent. The physical and legal markers traditionally available to qualitative researchers in the field are obviously absent if the participant wishes to remain bodiless, nameless, and faceless in an online context. This has raised the question of whether regulations associated with informed consent are appropriately designed to protect human subjects. Using the internet as a method of interacting with participants may actually facilitate protection of human subjects; the participants have many outlets to withdraw from the study, and certain interaction environments can improve the likelihood of maintaining confidentiality. These ethical issues require close attention by qualitative researchers.

As an interpretive issue rather than a legalistic one, anonymity can be discomfiting for researchers who might not know who the participants are, at least not in any embodied tangible way. This raises concerns about authenticity. On the one hand, interacting with participants in anonymous environments results in the loss of many of the interactional qualities taken for granted in face-to-face interviews and observations. This may constitute a meaningful gap of information for researchers who rely on these qualities as a way of knowing. On the other hand, similar gaps occur in more traditional research and interaction environments but are generally considered to be more a problem of interpretive clarity than a natural condition of doing research with unfamiliar participants.

Internet as Chrono-Malleable

In addition to collapsing distance, internet technologies can disrupt the traditional use of time in interaction. Because internet technologies accommodate both asynchronous and synchronous communication between individuals and groups, the use of time can be determined more individually. In real-time conversations, users can see their messages before they are sent. Backspacing and editing are made possible by stopping time in this way. In text-based environments, pauses and gaps are expected. Users may be participating in multiple conversations or tasks at once. Users may experience different speeds of connection or interruptions in service. In asynchronous media such as email and threaded

discussions, these pauses can be quite long, perhaps even weeks or months. In synchronous audiovisual contexts as well, users expect and work around disjunctive and fragmented interactions.

The chrono-malleable features of internet-mediated communication can assist researchers, for example, in conducting interviews. Complications regarding venue, commuting, and scheduling conflicts are less restrictive when interactions occur on the internet.

The elasticity of time can be associated with greater perceived control over the communication process. Because of the time-stop nature of most online media, as well as the knowledge that connections sometimes fail, users have the opportunity to reflect on and revise their utterances and actions. In the midst of a conversation (synchronous or asynchronous), users can reflect on comments or messages before responding and can review their own messages before sending. Designing research to take advantage of these capabilities can significantly enhance both the scope of a study and the collection of information from participants.

Internet as Multimodal

Communication via the internet occurs in multiple modes (alternately or simultaneously). Whether sponsored by software and hardware, a person's individual use, or the emergence of dyadic or group norms over time, these multiple modes operate on the sensemaking practices of users. Consequently, the issue of the internet as multimodal becomes meaningful when designing interactions in the research context.

Users tend to employ more than one communication technology at once. For example, a child might be writing an email, downloading music, updating his or her personal web space, and watching streaming video. When instant messages pop up on the screen, the child is prompted to type a reply within a new or continued conversation.

Qualitative researchers study these complex interplays of time, spatiality, technology, and information flow. They also use these as tools to augment the ways in which they communicate with participants. Researchers can use one channel with a group and use different "back channels" with individuals to interact privately while the larger group activity is occurring. These nondisruptive "whispers" can add valuable data that might not otherwise be captured in the moment.

Certain environments are set up to facilitate multiple simultaneous modes of interaction, such as interactive gaming. Even in straightforward information transmission environments, which were not designed to facilitate a sense of presence, programs can evolve into shared spaces as the meanings, relationships, and communities created by the interactions transcend the limitations of the programs in which people are interacting.

Researchers might study how these multimodal interactions occur or are made sense of in the cultural context, or they might simply use this capacity as a means of augmenting data gathering. Whether the technology provides the multiple modes or the users adapt technologies to a multimodal way of thinking is less important than the fact that these characteristics can influence the way in which users perceive contexts and interact with one another. For researchers, this has great potential for augmenting traditional approaches and creating previously impossible methods of interacting with participants.

Internet as a Context of Social Construction

The internet involves discursive forms of presentation and interaction that can be witnessed immediately or archived in various iterations and moments. These facilitate researchers' abilities to witness and analyze the structure of talk, the negotiation of meaning and identity, the development of relationships and communities, and the construction of social structures as these occur discursively. Linguistic and social structures emerging through social interaction via the internet provide the opportunity for researchers to track and analyze how language builds and sustains social reality.

The internet is not novel in that individual use, habitual practice across groups, and technical capacities constitute patterns of temporal interactions, building social structures that may become concrete realities. These processes describe any language system. The internet is unique, however, in that it leaves visible traces of these processes. Internet technologies allow researchers to see the visible artifacts of this negotiation process in forms divorced from both the source and the intended or actual audience. Websites and website archives, for example, can give researchers a means of studying the ways in which social realities are displayed or how these might be negotiated over time.

Ethical Considerations

When geography no longer determines the boundaries of the study's parameters, researchers can be less constrained by the structure, space, and time within which interactions occur. Social behaviors and texts are easily captured for analysis. Observing internet use as it constructs social reality can be accomplished easily; obtaining access to online groups is a straightforward process, as is downloading and archiving the interactions of these groups.

This deceptively simple process of access must be balanced with ethical considerations. Not all qualitative researchers conduct studies that involve human subjects, but even this distinction comes into play in debates about ethics in internet research. In general, although this list certainly is not all-inclusive, ethical challenges and controversy arise in the following circumstances:

- Some users perceive publicly accessible discourse sites as private. For example, although many online discussion groups appear to be public, members may perceive their interactions to be private and may be surprised or angered by intruding researchers. Other groups know that their communications are public but nonetheless do not want to be studied.
- Anonymity (where necessary) is difficult to guarantee. For example, some users have writing styles that are readily identifiable in their online communities, so that researchers' use of pseudonyms does not guarantee anonymity. Also, search engines are often capable of finding statements used in published qualitative research reports.
- Online discussion sites can be highly transient. For example, researchers who gain access permission in June might not be studying the same population in July.
- Vulnerable persons are difficult to identify in certain online environments. For example, age is difficult, if not impossible, to verify in certain online environments.
- Confidentiality of participants' talk in these groups is nearly impossible to preserve with the sophistication of search engines. Ongoing discussions and statements about ethical problems and guidelines can provide researchers with useful background information on how others have approached and dealt with these complex and evolving concerns.

Ethical guidelines and stances vary by person, institution, and country. Given the variations in ethical

stances, as well as the diversity of methodological choices, each researcher must explore and define research within his or her own integral framework. Comprehending and critically evaluating the broader discussions about ethics is essential—not only discussions within internet studies or disciplines but also discussions within communities of qualitative researchers.

INTERPRETATION

Data do not necessarily speak for themselves. Rather, findings can be viewed from multiple perspectives. The process by which a researcher construes meaning from research findings is referred to as interpretation. It involves helping the readers to make sense of the findings produced in a research study. A qualitative researcher may use theoretical orientations to provide interpretations of findings or may generate interpretations a priori.

Interpreting qualitative findings begins with a researcher's own assumptions regarding the world, life, and people. In this manner, worldviews tend to influence how one comes to make meaning or sense of data acquired from a research study. Nobody lives in a philosophical or worldview vacuum; the paradigms that a researcher comes to accept as true tend to color the results of his or her research findings.

Considerable debate exists among contemporary qualitative researchers regarding the role of interpretation, particularly with respect to grounded theory. Traditional models posed that researchers must work vigilantly to hold their own life paradigms at bay when viewing qualitative research results. In this model, qualitative researchers exercise disciplined restraint, so that they essentially avoid interpretation. That step should be left to the readers to make.

More recent approaches, in contrast, view interpretation as an apt part of the qualitative process. In this model, researchers are free to explore a variety of perspectives on the study's findings. Theories or paradigms are fair game for helping the readers to best understand a context for the study's results or to place the findings into larger frameworks.

Some researchers argue that interpretation is a necessary component of the qualitative method. For example, most feminist qualitative researchers rely on a predetermined set of assumptions to make meaning from their data collections. If they were studying, say, a group of Amish women who told the researchers that they were happy living in subordination to their husbands, the feminist qualitative researchers likely would interpret those findings from a preset grid of understanding. Simply giving voice to these women typically would not complete the research project. Rather, such researchers would integrate these findings through a feminist paradigm. That step is interpretation.

Qualitative researchers sometimes argue that everyone possesses assumptions about life and to deny these is simply to deny one's humanity. Consequently, rather than attempting to stay their interpretive bent, a qualitative researcher's role is to explicitly state the perspective used to make interpretations. In this thinking, qualitative researchers' role is to interact with findings based on their theoretical orientation while clearly informing the readers how that orientation was used to generate conclusions.

Finally, postmodern thought has contributed significantly to the role of interpretation in qualitative research. Essentially, this is the notion that absolute truth does not exist and the context of a situation determines its meaning. Postmodern researchers tend to argue, therefore, that all research findings are relative to the perspective of the readers. As such, interpretation becomes a valuable component to assist the readers with context and meaning for best understanding the research results.

INTERPRETIVE INQUIRY

Interpretive inquiry, as is the case with all other forms of qualitative inquiry, focuses on understanding (interpreting) the meanings, purposes, and intentions (interpretations) people give to their own actions and interactions with others. What distinguishes interpretive inquiry from the other approaches to qualitative research is the desire to step aside from various issues that have long been central to discussions about the nature and purposes of social and educational research. Drawing on the work of philosophers such as Richard Rorty, interpretivists believe that researchers should drop their concerns about theories of knowledge; abandon the philosophical doctrine of realism/neorealism; recast major concepts such as objectivity, subjectivity, and relativism; and rethink the role of methods in the research process.

This major conceptual shift means that interpretive inquirers do not see social and educational research as "scientific" in the conventional sense of that term. To the contrary, they emphasize the idea that research is a moral and practical activity that shares much in common with other forms of inquiry such as those practiced by novelists, journalists, and ordinary people in their day-to-day lives. These ideas, especially the idea that there are no special research methods that automatically and inevitably lead to the truth, mean that the knowledge claims made by researchers cannot be seen as automatically and inevitably superior to the knowledge claims made by nonresearchers.

Philosophical Issues

For interpretivists, the most crucial philosophical realization of the recent past is that there can be no theory-free observation or knowledge. Although nearly all researchers agree that observation/knowledge is influenced strongly by the interests and values of the observer, interpretivists are the most aggressive in pursuing the implications of this realization. When this idea is taken to its logical conclusion, they conclude that it undermines various key elements of both quantitative research and the methodically driven

forms of qualitative research. In particular, this realization undermines the philosophical doctrine of realism/neorealism.

Most approaches to social and educational research are based on a realist/neorealist position holding that there is a reality “out there” that can be known or depicted as it really is, at least in principle, independent of the interests and purposes of researchers. Interpretivists find this claim to be unintelligible. Although they have no problem with the idea that there is a reality “out there,” they argue that the idea of no theory-free observation/knowledge means that as finite humans we can never access that reality as it really is. There is no way to factor out or eliminate the influence of the particular interests and purposes of particular researchers.

This does not mean that interpretivists are antirealists in the sense that they believe that nothing exists outside of our minds. They are nonrealists, meaning they believe that there may be a reality “out there,” but our descriptions/interpretations of that reality are not “out there.” Social and educational reality is always something we make or construct, not something we find or discover.

This nonrealist position leads to a number of crucial issues that differentiate interpretive inquiry from other forms of research. First, interpretivists are antifoundationalists in the sense that they do not accept that there is a foundation (Archimedean point) on which to base knowledge claims because there is no privileged position from which to interpret the world. There is no theory-free knowledge and, accordingly, no foundation on which to adjudicate different claims to knowledge. This means that no interpretation or construction of reality can be judged as uniquely right or wrong. Various constructions of what is happening in a social setting at any particular time can be given, but none is free of further interpretation and reinterpretation based on different interests and purposes.

Nonrealism also results in a redefinition of the important concepts of objectivity, subjectivity, and relativism. Objectivity usually refers to researcher detachment and accurate depiction, whereas subjectivity conventionally means that someone has let particular interests and purposes influence the research process and, thereby, distort reality. This is unintelligible to interpretivists. If reality cannot be observed independent of particular interests and purposes, then it is impossible to distinguish between who has been objective and presented an accurate representation of

reality and who has been subjective and presented an inaccurate representation of reality. For interpretivists, objectivity is best seen as a compliment one pays to another who happens to agree with one’s interpretation or construction of reality. Subjectivity, in contrast, refers to disagreement or the idea that another has introduced an interpretation that one considers beside the point.

Relativism has long been defined in terms of “anything goes,” a situation in which every claim to knowledge is considered to be as good as every other claim to knowledge. Interpretivists do not accept this sweeping definition; rather, they argue that relativism is an expression of our human finitude in the sense that all we can say about knowledge is to describe the particular forms of justification for knowledge that are contingent on time and place. There are no permanent or time- and place-free criteria (extralinguistic criteria) available for sorting out claims to knowledge. However, interpretivists add that this contingency does not mean that researchers are exempt from presenting the best cases possible for their interpretations or constructions of reality. Some claims to knowledge are better than others, but they are better for moral and practical reasons, not for epistemological reasons.

Conceptual/Practical Issues

The actual inquiry procedures employed by interpretivists are the same as those used by other qualitative researchers. The major difference is that most qualitative researchers (and all quantitative researchers) hold that certain methods must be employed to obtain a valid study. Interpretivists do not accept that certain techniques are necessary minima and argue that exactly what an inquirer does when in the field or how fieldnotes are analyzed can vary from situation to situation. For example, in some instances an inquirer might decide that something like member checks are needed, whereas in other situations member checks might be judged as unproductive and, hence, unnecessary. However, just because interpretive inquirers do not see any particular procedures as mandatory does not mean that they see them as arbitrary. Inquirers always are obligated to make a case for the procedures they employed and did not employ.

The goal of interpretive inquiry is the interpretation of the interpretations people give to their own actions and the actions of others (double hermeneutic). This is a process that is very much like ordinary conversation.

The major difference between researchers and lay-people is that the former undertake the process more self-consciously and more intensely. The regulative ideal for this conversational interest in understanding is what Rorty referred to as human solidarity rather than objectivity, meaning that interpretive inquiry has an ethical/moral basis, not an epistemological one. Thus, inquiry and the search for knowledge can be understood only in practical and moral terms. Inquiry is a moral activity in that it focuses on the understandings we construct about ourselves in relation to others and is a practical matter in the sense that it has implications for the task of building the kind of society in which we would like to live.

How, then, do interpretive inquirers distinguish good research/interpretations from bad ones? For the process of interpretation and understanding, there are no fixed criteria, as presumably is the case for other research approaches, for making such decisions. Interpretivists hold that such judgments are practical accomplishments, taken through dialogue and persuasion, that are worked out as we go along. There are three points of interest here. First, interpretive criteria are not rules that determine judgments but rather characterizing traits, expressed as values, that influence judgments. This allows that any particular criterion one poses can be variously interpreted at different times and under different conditions.

Second, the traits that are expected from inquiry are gathered into lists that are open-ended in that they are constantly subject to change and modification. A list can be added to, subtracted from, and generally recast. The limits or possibilities for such recasting are the result of the actual use to which the list is put. The limits are a practical matter; they are established in practice and cannot be distilled into abstract formulas. Finally, judgments about the quality of inquiry are not only a practical activity but also a moral endeavor because they always must respond to questions of the following kind. What kind of person do I become if I choose to honor one interpretation over another? What kind of society will we have if we decide that this interpretation is better than another interpretation?

Interpretivists have bypassed many issues central to the more conventional understandings that dominate quantitative research and many versions of qualitative research. The focus is on the interpretation of the interpretations people give to their own actions and activities. The regulative ideal for interpretation is not objectivity but rather human solidarity. For this reason,

interpretivism is thought of not as a scientific activity but rather as a practical and moral undertaking.

INTERPRETIVE PHENOMENOLOGY

Interpretive phenomenology, also called hermeneutical phenomenology, is based on the assumption that humans are interpretation through and through. Humans dwell in the world with no capacity to be completely free of the world. Interpretive phenomenology holds that there is no access to brute data (i.e., data containing no presuppositions or preunderstandings). Human science mirrors humans in that humans are the kind of beings who allow other beings to be revealed and known. Interpretive phenomenology can be contrasted with transcendental phenomenology that seeks to reduce things down to their essence—their least interpreted essence of a thought or mental process. Transcendental phenomenology seeks to bracket presuppositions and try to approach something as though one had no prior experiences, ideas, suppositions, or expectations.

Background

Interpretive phenomenology is at once philosophical and methodological. It seeks to overcome Cartesian epistemology that holds to a representational view of the mind and a mind–body dualism. An interpretive phenomenological understanding of the human is distinct from the Cartesian private subject standing over against or apart from an objective separate world. The

human is embodied, situated, finite, and thrown into a particular culture, time, and place. This situated, social, and sentient person dwells in a world of common meanings, habits, practices, meanings, and skills that are socially prior to the individual and are socially disclosed or encountered. These socially situated meanings, habits, practices, and skills are the foci of interpretive phenomenology. Interpretive phenomenology relies on disclosive practices that allow social practices, embodied intentionality, common taken-for-granted background meanings, habits, rituals, practices, and everyday life to show up (i.e., become visible and intelligible). The mind–body–world problem will not be solved so long as we have only the two grids: theories of the disembodied mind and theories about the physiological mechanistic body. Maurice Merleau-Ponty's insight was to dissolve the mind–body problem by studying the situated, sentient, and social body. The distance between the Cartesian theoretical grids of mind with explicit beliefs and thoughts and the bottom-level physiological theories of cells, tissues, and organ systems is too great. Intermediate middle terms such as those experienced by the situated, sentient, embodied, and socially constituted person are needed to understand the connections within the embodied mind and world. Such middle terms include habits, practices, skills, rituals, and so on. But more important than dissolving the mind–body dualism handed down from René Descartes is the human's commonsense self-understandings in everyday life, when the body in the world is working well, and when it breaks down as in illness.

Merleau-Ponty, drawing on both Edmund Husserl and Martin Heidegger, understood the centrality of the body for any access to the world. Charles Taylor, in his book *The Explanation of Behavior*, used Merleau-Ponty's nonmechanistic, holistic understanding of the body to dismantle the grip of behaviorism on psychology. Likewise, in his philosophical papers, Taylor worked on constitutive and expressive theories of meaning using Alexander von Humboldt and Johann Gottfried von Herder, German Romantic thinkers, to demonstrate how we dwell in language. These thinkers expand the theory of meaning beyond correspondence and truth condition theories of meaning to theories of the constitutive and expressive functions of meaning.

New words can constitute new self-understandings and perceptual experiences. Likewise, bringing an expression into public can change the mood, climate, and focus of a group. Once an aspect of our experience

is articulated, given language, and given public expression, we have a different access to it. To dwell in a world is also to dwell in a language, or even multiple languages, and in multiple worlds of discourse and culture. And as noted by Ludwig Wittgenstein, one cannot adequately understand or imagine language without understanding the form of life that gave birth to the language.

Once the epistemological assumptions of the atomistic, monological individual are discarded, it becomes easier to understand how language and expressive constitutive meaning are possible. The old vision of an instrumental self-making self, the one who observes rather than participates in language, is replaced by a situated, social sentient participant. This socially constituted person dwells in a world of common meanings, habits, practices, meanings, and skills. These meanings and practices are socially disclosed rather than hermetically sealed in private minds, cut loose from a knowing body. Embodied intentionality is accessible. One can study the breakdown situation of illness and what illness disrupts in everyday life can be. The "other" becomes a means of discovery of self as well as other. The interpretive researcher seeks to identify and articulate particularities, situated actions, and thinking in action. Commonalities and distinctions are sought rather than sameness described as decontextualized properties and formal attributes.

The Method

To take up the method of interpretive phenomenology, the goal is to enter the hermeneutic circle in the most propitious way to study the phenomena at hand. This requires a lot of thought about developing lines of inquiry in ways that will allow for extending, disconfirming, and/or expanding the researcher's understanding. The researcher also reflects on his or her own assumptions coming into the research with the aim of making them as clear as possible. The researcher still holds open the expectation that, in doing the research, new unnoticed assumptions will be uncovered and the previously described assumptions will be challenged. The researcher may read the text in a stance of idealization, rejection, or some other systematic misinterpretation of the text. Here it is useful to have an interpretive team to reach consensual validation of interpretations of the text. The interpreter does well to keep in mind the maxim that "the person's world is livable." Total rejection or idealization means that the

interpreter does not yet have the best grasp of the participant's lived experiences. The possibility of understanding the speech, text, activities, meanings, habits, and practices of the other is based on the phenomenological assumption that these meanings, practices, and the like are shared and public rather than private and idiosyncratic. Consequently, they are intelligible and accessible by persons sharing common humanity, language, and some degree of access to the culture or subculture.

The interpreter's project is to understand the world of the participants or events. A dialogue is created between practical concerns and lived experiences of the group or practices being studied and the researcher's engaged participation, observation, and dwelling in the immediacy of the participants' world. The interpreter moves between situations and practical worlds of the participants, examining the foreground and probing the background meanings and practices that make the foreground possible.

The aim of interpretive phenomenology is dialogue and understanding, and this requires an ethos of respect for the voice, actions, and texts of those studied. Reducing the interpretive account to power terms, or theoretical constructs and causal explanations based on hidden meanings or mechanisms, is not the goal. Being true to the text, or articulating the phenomenon in its own terms, is the aim. This is not as simple or straightforward as it sounds given that the interpreter is working off of taken-for-granted background meanings and practices that might not have ever been clearly articulated or given good public language. The researcher follows his or her paths of understanding and interpretation and keeps track of transitions in understanding as well as transitions in the situation. An insightful and successful articulation gathers up the most meanings and gives the best grasp of the situation, accounting for more in the text than do rival interpretations. Natives reading the account might comment that the research has put into words what they had always known but had not been able to say or describe.

The interpreter moves between parts of the text and the whole of the text, examining congruities and incongruities. The interpreter seeks to discover commonalities, incongruities, puzzles, and repeated unified concerns. Three discovery and presentational strategies are typically used: paradigm cases, thematic analysis, and exemplars. Each is described briefly in what follows.

Paradigm Cases

Paradigm cases are strong instances of a phenomenon. The paradigm case may just stand out to readers as being a strong example of "something" before the interpreter understands what the paradigm case illustrates. This gives the interpreter an open-ended inductive approach to the text. Contrast and similar paradigm cases, such as "coping with stigma," may help the interpreter to identify and articulate prevailing meanings in the paradigm case. The paradigm case is used as both a discovery method and, later in writing up the findings, as a presentational strategy.

Thematic Analysis

Themes within and across participants or events may be identified. Themes express meaningful patterns, stances of the participants, or concerns. Themes may be qualitatively distinct from one another. A theme is kept close to the text, and textual examples of the theme are required to identify another portion of text exemplifying the same theme.

Exemplars

Paradigm cases and thematic analyses may be augmented by exemplars. Exemplars illustrate common patterns of meaning, common situations, and embodied skilled know-how. They are useful in presenting the interpretation so that the readers understand the practical world(s) being articulated.

Summary

Interpretive phenomenology focuses on understanding practical worlds, skilled know-how, situated understanding, and embodied lived experiences. The embodied knower is irrevocably connected to the world and is socially constituted. Rigor involves staying true to the text, engaging in consensual validation, and allowing the readers to participate in the validation process by presenting texts associated with the interpretations made by the researcher. Phenomena to be interpreted may be found in practical worlds, cultural encounters, experiences of coping, skilled know-how, habits, practices, and common meanings. The interpreter uses participant observation, observation, first-person experience/near accounts of real events, videotapes, interviews, and all sources of text

relevant to the lines of inquiry being pursued. Films, novels, biographies, and memoirs may also be used.

INTERPRETIVE RESEARCH

Interpretive research is a framework and practice within social science research that is invested in philosophical and methodological ways of understanding social reality. It is widely viewed as a practice (and a set of paradigms) embedded in different theoretical frameworks ranging from ethnomethodology to critical feminist theory. As an epistemological framework, it has been used widely across the social and human sciences, especially anthropology, sociology, communication, cultural studies, social work, and education.

Central to the interpretive framework is the notion of *Verstehen* or understanding (first discussed by Max Weber). Since Weber, several philosophers and social scientists have emphasized the inseparability of

understanding from interpretation. At some level, then, all social research is interpretive because all such research is guided by the researcher's desire to understand (and therefore interpret) social reality. Whether the focus is on *quanta* or *qualia*, at bottom it is still understanding that is being sought by researchers across the board. In a Nietzschean sense, then, there are "no facts, only interpretations." However, the kind of understanding being sought is usually determined by researchers based on the varying ontological, epistemological, and methodological beliefs to which they subscribe.

Having said that all social research is interpretive, it becomes important to somewhat disentangle what interpretive research means within the larger complex web of qualitative research. Within qualitative research, interpretive paradigms, practices, and methods have become central and have been constantly shaping and reshaping specific research methods. This antinaturalistic framework (from postpositivist naturalism to interpretivism and postmodern hermeneutics) focuses on understanding and meaning-making, as opposed to explanation, as the main purpose of research.

Schools of Thought in Interpretive Research

Over several decades, social science researchers have emphasized that qualitative understanding of any phenomenon is based in making meaning of specific experiences and, therefore, is inherently an interpretive practice.

Hermeneutics

According to Hans-Georg Gadamer, hermeneutics (literally the study of interpretation with its historical roots in biblical interpretations) recognizes that our being and doing are intimately connected. This is the way we are fundamentally, and philosophical hermeneutics focuses in different ways on the relationship between the predisposed self-understanding of the interpreter and the "active character" of everything that addresses this understanding.

Ethnography and Interpretation

Clifford Geertz criticized what he called the "casual references" to the *Verstehen* approach or emic analysis and emphasized the need to acknowledge that

it is interpretation, rather than an exact understanding, that qualitative researchers can hope for. At bottom, according to Geertz, anthropological research and representation is only interpretive—and second- or thirdhand at that—given that the firsthand “understanding” or “interpretation” really lies with the “subject” such as the individual, group, or community being studied.

Qualitative Methods and the Interpretive Turn

Norman Denzin and Yvonna Lincoln discussed the tension in qualitative research between the interpretive and postpositivist sensibilities. In interpretive research, meaning is disclosed, discovered, and experienced. The emphasis is on sensemaking, description, and detail. For the antinaturalistic interpretive researcher, human action constitutes subjective interpretations of meanings. Therefore, meaning-making is underscored as the primary goal of interpretive research in the understanding of social phenomena.

Traditional Ethnography, the Chicago School, and Decolonizing Research

Over time, interpretive theories have shifted from colonizing postpositivist theories toward emancipatory theories such as feminism. Traditional interpretive research saw colonizers (missionaries included) and White male anthropologists interpreting the “native” through the study of “other” cultures. By the end of the 19th century, the Chicago School emphasized the development of an interpretive methodology that focused on narrative life histories allowing the researcher to tell the subject’s story. Although this was a huge shift from earlier paradigms methodologically (for the first time, life stories were told as spoken by ordinary people and were accepted as scholarship), this project was still implicated in a racist one. The underlying suggestion was that first colonizers and then White male scholars provided the natives and people of color across the world with history and research. A large part of scholarship in the social sciences and the humanities was geared in aiding this process. Feminist writer bell hooks, in her reading of the cover of Stephen Tyler’s book *Writing Culture*, illustrated the intersection of race and gender in these othering Orientalist studies of culture and meanings.

According to Ngugi Wa Thongo, both the legality and the life advancement power of the Western, privileged written word established a postcolonial situation where even natives worldwide tended to abide by the implications of the written text. From then to the next moment into the modernist phase was a huge leap. At the same time, certain colonial notions continued in these postcolonial musings and struggles with research. The “underprivileged” and the “socially cheated” became the focus. New interpretive theories of ethnomethodology, phenomenology, critical theory, and feminism evolved, and the recognition of the native as a colonial notion that needed to be decolonized and no longer deferred began to gain more and more prominence. The focus shifted to provide the space for voices that were earlier unheard. The need for emancipatory facilitatory research was recognized.

The Blurred Genres

This phase saw interpretive researchers with set practices and methods moving to “local” meanings. The scientific article was gradually being replaced by the essay as a form of representation. Sensemaking and the role of the researcher in the project started to become central to the different interpretive paradigms. The crisis of representation analyzed the various aspects of the written word. The difference between writing and fieldwork began to be addressed, and the three sets of representation (the researched’s interpretation of the phenomena in question, the researcher’s interpretation of the researched’s interpretation, and the readers’ interpretation of the researcher’s representation of his or her interpretation) gained significance.

The postmodern experimental struggle arose out of these crises. The idea of the detached observer had been abandoned, and the continuous, complex ontological and methodological struggle with meaning, subjectivity, and researcher reflexivity began to gain more and more grounding.

Interpretive Theories/Paradigms and Communities

There are several interpretive theories/paradigms and research communities today. Denzin and Lincoln discussed important interpretive theories and paradigms, including ethnomethodology, phenomenology, positivist and postpositivist models,

constructivist–interpretive models, critical and feminist–poststructural models. These various theories and paradigms are embedded in and complicated by each other and, therefore, are grouped together here. They are also further complicated by various interpretive communities. Among these theories and paradigms in which qualitative research lies embedded, there are various research communities and fields that have evolved and enriched interpretive research practices. Some of these are cultural studies, queer studies, Indigenous research studies, ethnic studies, and Marxist studies. Although all of these theories, paradigms, and communities lie entangled in each other and speak to each other in interconnected and varying ways, here they are divided into two sections to provide a quick, at-a-glance map of this complex web called interpretive research.

Interpretive Theories and Paradigms

Positivist and Postpositivist

This type of research has included both quantitative and qualitative work. The focus has been on modeling the method of inquiry on that of the natural sciences, and the usual method of representation is the scientific report. The focus is on criteria such as internal and external validity, reliability, and objectivity.

Ethnomethodology

This is a theoretical framework as well as a method. It has features in common with naturalism (e.g., a reluctance to impose meanings), focuses on details and being embedded in the subject of study, and locates this detailed process in “how” questions of social phenomena. David Silverman discussed ethnomethodology’s location in the study of talk-in-interaction.

Phenomenology

Literally speaking, phenomenology is a philosophical theoretical system of ideas that discusses the ways in which humans experience phenomena in the world. Put simply, a phenomenological approach, then, is invested in the meanings of these various phenomena. This complex concept was made famous by the works of Edmund Husserl, Martin Heidegger, Jean-Paul Sartre, Maurice Merleau-Ponty, and Alfred Schultz.

Constructivist–Interpretivist

Here the focus is more on conducting interpretive case studies based on ethnomethodological

perspectives. Criteria and questions of validity still remain central; however, the postpositivist ideas of criteria are replaced by terms such as *credibility*, *transferability*, *dependability*, and *confirmability*. The idea that all reality and interpretations are socially constructed is core in this paradigm.

Feminist Theory

Over time, feminist theory has reformulated interpretive theory in building theoretical constructs that deal with “difference,” privileged a materialist–realist ontology, and argued that difference is constructed through gender. The deconstruction of the category “woman,” and destabilization of the notion of the privileged woman ethnographer studying women in feminist anthropology, extends to interpretive research as it highlights the centrality of feminism and the performance of gender in every discourse.

Poststructural feminist discourse highlights the problem of traditional texts and their inability to describe and capture lived experiences, especially of those who have been historically marginalized and oppressed.

Interpretive Communities

Critical Cultural Studies

This is a field of research that brings together a hybrid body of theories across disciplines ranging from postmodern to feminist to queer theory and is invested in the significance of cultural representations, texts, practices, and subjectivities in understanding language, culture, and identity. A major emphasis on praxis marks this paradigm, and tensions between a cultural studies project committed to lived experience (meaning) and a more structural project embedded in the effects of experience, seen through lenses of race, class, and gender (among several other structurally dominant oppressive realities), are key debates in this field.

Queer Studies

This is a minor subdiscipline committed to challenging and interpreting social reality outside of the dominant, normative, heterosexist social order. New ways of understanding the body, and nonnormative sexualities that include lesbian, gay, transgender, transsexual, and bisexual, are constantly evolving and questioning the everyday performance of gender in this field.

Indigenous and Resistance-Based Studies

This is an emerging field that complicates the long ongoing debate of who studies whom and why. These projects are about people of color in the United States and across the world conducted by people of color themselves. Questions of privilege still exist across this very broad category of people of color based on gender, class, caste, disability, and sexuality. Decolonizing research methods and trying to weave research reflexively through the various privileges and discriminatory histories across the world remain the central foci of this field.

Marxist Studies

This is a body of research that privileges emancipatory research, focuses on dialogue, and has evolved into a field that now underscores class, race, and gender in various economic, historical, and sociocultural analyses.

These interpretive theories, paradigms, and communities continue to inform and complicate each other through a variety of methods and practices. The intersectionality of race, gender, class, caste, disability, and sexuality underscores and informs these constantly evolving theories, paradigms, and fields of study/communities.

Common Methods Used in Interpretive Research

Various methods across disciplines are used in conducting interpretive research, including a variety of ethnographic methods, classic traditional interviews, case studies, focus groups, observational studies apart from ethnographies, and analyses of cultural records, archival documents, artifacts, visual materials, multimedia texts, or personal experiences.

Future of Interpretive Research

The call now within this set of interpretive practices is that the social sciences and humanities turn into sites for critical social change through discussions about race, gender, class, caste, sexuality, disability, nation, democracy, globalization, and war. The rigid binary between what gets called social science and how it is distinct from the humanities needs to be questioned further, focusing on making scholarship more accessible and productive toward the goal of progressive social change.

INTERSUBJECTIVITY

Intersubjectivity refers to shared understanding. Drawing on the philosophical notion of subjectivity (i.e., that meaning is necessarily colored by one's experiences and biases), intersubjectivity recognizes that meaning is based on one's position of reference and is socially mediated through interaction. In other words, knowing is not simply the product of individual minds in isolation. In qualitative research, intersubjectivity not only points to the ways in which we share understanding with others but also indicates that meaning and understanding lie along a continuum of mutual intelligibility. This notion is of particular interest to researchers who study verbal social interactions in general. In various modes of research on discursive processes, shared ways of knowing are of particular interest in trying to reveal analytic positions on the

way in which complex social systems come to create meaning for their participants.

Methodologically, intersubjectivity has influenced many social science disciplines' approaches to language, meaning, learning, and identity. It posits that the social and cultural contexts in which communicative events take shape affect individuals' sense of self and ways of knowing via their interactions with other selves as well as with the larger social structures into which these interactions coalesce. Intersubjectivity implies that knowing or understanding is not an individual endeavor but rather is socially situated; knowing cannot exist in a vacuum or a cognitive abstract system.

Although ways of knowing rely on shared understanding, we cannot share understanding completely with others. When two parties communicate, each party may have a sense of understanding the other. In addition, someone analyzing this interaction may have a different sense of how those parties understand each other. For example, someone may notice that her friend's chair is about to break. She may elicit a straightforward warning ("the chair you are sitting on is about to break") or a more indirect one ("you might soon land where you least expect"). In both of these cases, the intended message is disputable from the perspective of the speaker, hearer, or observer. In the former, the speaker may mean that the chair sitter is overweight; in the latter, this may be a routine joke they share indicating that someone is about to fall. In either case, and with all communication, there is a possible range of intersubjectivity, both intended and realized.

Due to the range of intersubjective overlap, analyzing qualitative data or facets of social life requires an appreciation for gaps in understanding, ways in which to minimize these gaps, and an understanding of what existent gaps signify. At an analytic level, intersubjectivity is a construct that allows one to conceive of how others can be understood when analyzing interactions, texts, or artifacts. At a disciplinary level, intersubjectivity within modes of research perspectives allows researchers and audiences to understand the underlying assumptions, ideologies, and beliefs grounding their research projects.

INTERTEXTUALITY

Intertextuality is a basic principle of interpretation. As a mode of literary interpretation, intertextuality holds that the interpretation of a text is often based on possessing critical knowledge of other key texts. At first, this dealt with the identification and interpretation of various allusions, or references, from key texts in the canon of Western knowledge. Up until the end of the 20th century, it was assumed that most readers in Western countries had a working knowledge of the Bible, Greek literature, philosophy and mythology, and Shakespeare, among others. Intertextuality often consisted of identifying allusions from these canonical works in other literary works.

With the advent of the postmodern era, as delineated by Jean-François Lyotard, these grand narratives were no longer assumed to hold. Instead, the emphasis was shifted toward looking at how literary texts were defined in relation to other texts. This work, first pursued by Julia Kristeva, was itself based on the relational insights of the structuralists. Structuralism held that most, if not all, important concepts did not possess absolute definitions but instead were defined by how they were related to other concepts. This work had its own beginnings in phonology but soon was extended to linguistic and other code patterns. Kristeva drew her primary insights from Mikhail Bakhtin.

Qualitative research sometimes looks for patterns of intertextuality in narrative texts and in particular field narratives. The main role of intertextuality in our field, however, centers on intertextual relations among various systems of codes. Early proponents of this view included Claude Lévi-Strauss in anthropology and Roland Barthes in cultural analysis.

As a structuralist, Lévi-Strauss was interested in discovering relational codes within various cultures. In his research, he also sought universal codes across cultures in areas such as kinship relations and taboo.

In both cases, he found that seemingly absolute notions such as “who is related to whom” and “what is edible and inedible” are defined by relations of codes to other codes within a culture. Barthes, another structuralist, explored similar issues when looking at matters within popular culture in France during the 1950s and 1960s. Barthes’s work is the basis of much current work in diverse contemporary areas such as marketing analysis and mass media studies.

With the turn to poststructuralism, there was also a turn away from looking for cultural universals. The lesson from intertextuality in literature was the fact that there are no independent texts given that no text can stand on its own but is determined by other texts. In our contemporary milieu, researchers have taken this same stance toward codes. Qualitative researchers, therefore, are more interested in discovering reflections of code systems in relation to other code systems. These systems may be quite similar on the surface, such as codes dealing with consumerism and power, or quite dissimilar, such as codes dealing with family issues and market exchange. Current thinkers, including Umberto Eco and Jean Baudrillard, continue this lively sort of intertextual code critique and interpretation.

INTERVIEW GUIDE

Interview guides summarize the content that researchers cover during interviews. At one extreme, they may provide very minimal directions, leading to “less structured” interviews that are designed primarily to explore the participant’s own perspective on the research topic. At the other extreme, interview guides may contain elaborate specifications to ensure that the researcher’s topics of interest are thoroughly covered.

At the least structured end of the continuum are approaches such as James Spradley’s ethnographic interviewing, which avoids substantively oriented topics in favor of general questions that draw out the participant’s own accounts. For example, Spradley’s approach often begins with “grand tour” questions such as “Tell me about a typical instance of. . . .” These grand tour questions help to locate the basic elements that the participant associates with the research topic, and the interviewer follows them with “mini-tour” questions such as “You mentioned [topic]; can you tell me more about. . . .?”

In contrast to unstructured interviews, the most highly structured format is undoubtedly the survey questionnaire, which amounts to an interview guide that prespecifies both the content and the possible responses for each question. Most qualitative interviewers prefer to position themselves between these two extremes by using a semi-structured interview. In that case, the interview guide typically contains a general framework for the interview, but the researcher also has the freedom to pursue the questions in a different order and to allocate more time to some questions than to others depending on what is most appropriate for discussing the research topic with each individual participant.

Another common distinction is between question-based guides and topic-based guides. Questions are the more common format for interview guides, so that the expected content of the interview is outlined in terms of a series of questions the interviewer intends to ask. In contrast, a topic-based guide consists of a list of areas and issues the interviewer wants to hear about, and these also are often organized in an outline format to make it easier to monitor which topics have already been covered.

One likely reason for the popularity of question-based interview guides is their ability to suggest probes and follow-up questions that can elaborate on the basic set of questions. Because the list of basic questions suggests a sequence for the overall content of the interview, it points to places where a further probe or follow-up question can either extend the discussion of the current question or move the conversation toward the next question. More formal versions of interviews will contain specific probes and follow-up questions that the interviewer can use in conjunction with the basic questions. (Note, however, that general probes such as “Can you give me an example?” and

“What else can you tell me about that?” are rarely written out in interview guides.)

INTERVIEWING

Interviewing is a conversational practice where knowledge is produced through the interaction between an interviewer and an interviewee or a group of interviewees. Unlike everyday conversations, the research interview is most often carried out to serve the researcher's ends, which are external to the conversation itself (e.g., to obtain knowledge about a given topic or some area of human experience). In most cases, research interviewing involves a “one-way dialogue” with the researcher asking questions and the interviewee being cast in the role of respondent.

The qualitative research interview has become one of the most widespread knowledge-producing practices across the social scientific disciplines. Although interviewing was a marginalized practice in many social science disciplines for years, it is part of the mainstream today.

Many different forms of interviewing exist. Interviews can be formally conducted in surveys, through the internet, over the telephone, or in face-to-face interaction, and they can be informally conducted; for example, as part of ethnographic fieldwork. Research interviews can be more or less structured. In survey research interviewing, standardized questions are posed and the answers are given in forms that are amenable to quantitative procedures. Most qualitative research interviews are semi-structured as a consequence of the agenda being set by the researcher's interests yet with room for the respondent's

more spontaneous descriptions and narratives. Some interviews approach a more unstructured form, including the life history interview, which sometimes operates with just a single opening question, inviting the interviewee to recount the story of his or her life.

The Process of Interviewing

The concrete interaction between the interviewer and the interviewee is just one stage in the process of doing interview research. The interview itself is carried out to enable the researcher to answer one or more of his or her research questions. These are formulated in advance when the researcher thematizes and designs the study. Before deciding to carry out the interview, the researcher should always consider whether interviewing is in fact the most adequate way in which to answer the questions that interest the researcher. One should not do an interview just because one (mistakenly) thinks that it is the easiest way of doing research.

The Actual Interview

The interview conversation is introduced by a briefing in which the interviewer defines the situation for the participant and informs him or her about the purpose of the interview. Usually, the interviewer has prepared an interview guide in which the research questions are given a form that renders them suitable to be posed directly as interview questions. Good questions are typically brief, simple, and open, and often the researcher will be interested in concrete descriptions of the respondent's experiences rather than more abstract reflections. Concrete descriptions are obtained by posing “what” and “how” questions (e.g., “what happened when . . . ?,” “how did you react when . . . ?”) rather than “why” questions. Small differences between questions can elicit different kinds of responses (e.g., the difference between asking “what did you think about it?” and “what did you feel about it?”). The interview is normally rounded off with a debriefing, which may include giving the participant a chance to add some comments or pose questions about the study.

Transcriptions

Most research interviews are audiorecorded and then transcribed. Unless the researcher works directly with the audiorecording of the interview, it is the transcription

rather than the original oral interview conversation that serves as the researcher's primary data source when he or she interprets and analyzes the interview. Transcribing interviews is an interpretive process that demands prolonged practice and sensitivity to the many differences between oral speech and written texts, and the disembodied and decontextualized nature of texts should be kept in mind during the later processes of analysis. Some researchers videorecord their interviews; this provides the possibility of taking nonverbal aspects of the communication into account, but the downside is the huge amount of information that can be difficult and time-consuming to categorize and analyze.

Different kinds of computer software can be helpful in the process of structuring and (especially) coding the interview material, most commonly in the form of texts but also as audio- and videorecordings. There are, however, a wide variety of modes of interview analyses in addition to coding where assistance from computer programs is less helpful (e.g., narrative analysis, discursive analysis, deconstruction).

Analyzing and Reporting Interviews

The way in which the researcher proceeds with analyzing the material should depend on the purpose of the interview study. Is the study carried out as action research with the goal of enabling the participant to improve his or her practice, is it conducted to obtain knowledge for its own sake, or is the purpose something entirely different? The purpose of the interview study should also be borne in mind during the final stage of the research process, which is the reporting of the results obtained. Writing a good and readable research report is an art that, in the case of interview research, involves the dilemma between pages filled with (too many) interview quotes, on the one hand, leaving the readers with the sometimes bewildering task of understanding and analyzing the material, and pages filled with the researcher's interpretations without corroborating and contextualized evidence from the actual interviews, on the other hand.

Ethics

Ethical issues should be considered at all stages of the interview process. Qualitative interviewing is a practice that has the potential to probe deeply into the private lives of the respondents with the intention of

placing their accounts in the public arena. Consequently, confidentiality, informed consent, and a consideration of the consequences of participating in the study should be taken as ethical rules of thumb. Concerning the consequences, it is an ethical challenge to the interviewer that the openness and intimacy of the interview situation can lead the respondents to disclose information they may later regret, and there is a risk that the interaction may become a quasi-therapeutic relationship for which most researchers have not been trained.

History and Epistemologies of Interviewing

We can presuppose that humans have interviewed each other in some form or other for as long as they have mastered the use of language. Many different kinds of professional uses of interviews have been developed in the course of human history. Religious confessions, oral examinations, and legal interrogations are interview practices that are older than journalistic, therapeutic, and research interviewing. The term *interview* came into use during the 17th century, and the first journalistic interview (with Mormon leader Brigham Young) was published as late as 1859.

An early systematic use of interviewing as a means of obtaining validated knowledge is found in Plato's dialogues. Here Socrates seeks knowledge through dialectical questioning. When the modern social sciences emerged during the 19th century, interviews became a preferred method of inquiry, albeit often in the form of quantifiable survey interviewing. Members of the Chicago School of Sociology practiced qualitative interviewing from the 1920s onward, and other early interview researchers (not often acknowledged as such) include Sigmund Freud, who developed psychoanalysis through his interviews with patients, and Jean Piaget, who interviewed children in natural settings.

Qualitative interviews also became part of industrial research to maximize workers' effectiveness (e.g., at Western Electric's Hawthorne plant in Illinois during the 1920s with more than 21,000 interviews conducted), and since the 1950s commercial and market interviews, especially in the form of focus groups, have been a growth industry. Today, interviews are pervasive in what some have called the "interview society," where everyone's opinions seem worthy of being brought forth and where interviews function as

a confessional social technique in the construction of people's identities. And with the rise of postpositivist social science since the 1960s, interviewing has become a significant research practice in phenomenological, interpretive, discursive, poststructuralist, and related approaches.

Important epistemological discussions concerning the objectivity, validity, reliability, and generalizability of the knowledge produced through interviewing continue in current debates. One aspect of this discussion that is integral to the practitioners of interviewing concerns the issue of whether interviews can provide a more or less direct pipeline to the participants' lifeworlds provided that the interviewer engages in nondirectional unbiased questioning. Some researchers question this idea and argue that interviews are active meaning-making practices that produce, rather than uncover, antecedent meaning elements. If an interview does not give direct access to the respondent's psyche, more attention should perhaps be directed to the interview situation itself as a discursive practice to understand the potential of interviewing as a research method.

IN VIVO CODING

In vivo coding is the practice of assigning a label to a section of data, such as an interview transcript, using

a word or short phrase taken from that section of the data. This entry describes this practice and some applications and problems associated with it.

The aim of creating an in vivo code is to ensure that concepts stay as close as possible to research participants' own words or use their own terms because they capture a key element of what is being described. Some common examples are vernacular or memorable terms used by participants to describe a feature or type of person relevant to their social world (e.g., "hot-rodger," "old-fashioned guy").

In vivo coding is associated chiefly with grounded theory methodology. Here it is differentiated from other types of coding that assign conceptual or theoretical terms to sections of data that are drawn from the wider literature or the researcher's own interpretations. As such, in vivo coding is associated with the earlier stages of coding one's data when concepts or categories are being identified or developed. However, in vivo coding is also relevant to other methodologies that are concerned with the specific words or phrases used in the material being studied, including discourse analysis, membership categorization analysis, and thematic analysis.

Whatever methodology is used, in vivo coding may create problems of reliability and validity at later stages of the research process because generalizing across cases can be difficult. Some researchers, therefore, would caution against overusing in vivo codes to segment data or at least would suggest choosing them carefully and only if the same words or terms occur with relative frequency throughout the whole data set.

In vivo coding has also been both incorporated into and encouraged by the development of computer-assisted qualitative data analysis (CAQDAS) packages. Many of these packages have a simple in vivo coding option built into the software. However, depending on the software package, it might not be easy to differentiate in vivo codes from those created by an alternative method such as conceptual or theoretical coding. Therefore, researchers using CAQDAS have used a variety of methods for indicating whether a code has been created in vivo, including enclosing the word or phrase in quotation marks. Despite this limitation, software packages provide researchers with the ability to easily retrieve, explore, and modify different instances where in vivo codes have been used across their data sets.

In summary, in vivo coding enables qualitative researchers to maintain a connection to the terms used

within their data while undertaking more formal methods of analysis such as concept and theory building.

JOURNAL OF CONTEMPORARY ETHNOGRAPHY

The *Journal of Contemporary Ethnography* is a peer-reviewed, international, and interdisciplinary forum for research using ethnographic methods such as participant observation, unobtrusive observation, intensive interviewing, contextualized discourse analysis, and field sampling to analyze social life as it occurs in natural settings. The journal publishes in-depth investigations that examine a wide range of social interactions and practices from a variety of academic disciplines, including anthropology, communications, cultural studies, criminal justice, education, health studies, management, and sociology.

The *Journal of Contemporary Ethnography* was first published in 1972 as *Urban Life*. Later it changed its name to *Urban Life and Culture*. The journal is currently published six times a year. Most issues have three to five lengthy academic articles. Examples of articles in recent issues include “Color-Blind Ideology and the Cultural Appropriation of Hip-Hop,” “The Balikbayan Researcher: Negotiating Vulnerability in Fieldwork With Filipino Labor Brokers,” and “Telling the Code of the Street: An Ethnomethodological Ethnography.” Other pieces explore identity and inner-city gangs, the impact of social class on parents’ attitudes toward their children’s education, and ambivalence in the K-9 officer–patrol dog relationship. The journal also publishes book reviews, mostly in the

form of review essays. From time to time it offers single-themed special issues dedicated to such topics as indicated by the following titles: “Ethnography Under the Gun: Fieldwork in Zones of Conflict, War, and Peace,” “Gender Crime and (In)Justice,” and “Analytic Autoethnography.”

In 2005, in his inaugural issue as the editor of the *Journal of Contemporary Ethnography*, Scott Hunt explained that the *Journal of Contemporary Ethnography* publishes ethnographies that are “close-up” and “analytic” descriptions of social life. In other words, close-up ethnographies are those where the researcher has been physically close to the persons and settings of the study and has also spent a significant period of time in the field. This type of work allows ethnographers not only to “tell” about modes of life, but to portray points of view and perspectives of the people under study. Another important characteristic of the ethnographic pieces published in the *Journal of Contemporary Ethnography* is that they are analytic, that is, the articles identify patterns and regularities of social life. Although most articles published in this journal are characterized by being close-up and analytic, there is ample room for variation.

JOURNAL OF MIXED METHODS RESEARCH

The *Journal of Mixed Methods Research (JMMR)* debuted in 2007 as an international and multidisciplinary publication venue that focuses on methodological, theoretical, and empirical articles about mixed methods research across the social, behavioral, health, and human sciences. *JMMR* is published in English on a quarterly basis and is available both in print and via online access through Sage Publications' Journals Online. This journal publishes two types of articles: methodological-theoretical discussions and original mixed methods research, which are peer reviewed by expert reviewers, including members of *JMMR*'s distinguished editorial board. Each issue also includes an editorial from the founding editors, John W. Creswell and Abbas Tashakkori, as well as book and/or software reviews.

JMMR defines mixed methods research as research in which the investigator collects and analyzes data, integrates the findings, and draws inferences using both qualitative and quantitative approaches or methods in a single study or program of inquiry. Therefore, this journal is appropriate for research that combines qualitative research with quantitative research, but not for research that combines multiple types of qualitative (or quantitative) research (i.e., multimethod research). Methodological-theoretical articles address topics such as paradigm stance, designs, and analytic techniques which advance understanding of mixed methods research.

Original research articles in *JMMR* must report and explicitly integrate both a qualitative and a quantitative strand. Since the overall goal of this journal is to advance mixed methods research, the original research articles also discuss their contributions to and implications for mixed methods research.

Since the 1970s and 1980s, mixed methods research has emerged as a viable and increasingly popular approach to research as well as a field of inquiry of its own. Despite this interest in mixed methods, most journals tend to publish either quantitative or qualitative research and scholars using mixed methods research often have difficulty getting their studies successfully reviewed and published. Additionally, scholars writing about the methodological aspects of mixed methods research often published their work in diverse disciplinary-based journals, making key writings in the field of mixed methods difficult to locate. Therefore, *JMMR* was founded to provide a dedicated forum for the growing community of international and multidisciplinary scholars of mixed methods research and aims to be the premiere outlet for scholarly discussions about and applications of mixed methods research.

K

KEY INFORMANT

Key informants, or key actors, are individuals who are articulate and knowledgeable about their community. They are often cultural brokers straddling two cultures. This role gives them a special vantage point in describing their culture. Key actors play a pivotal role in the theater of qualitative research, providing an understanding of cultural norms and responsibilities. Key informants represent an efficient source of invaluable cultural information. It is impossible to interview everyone and observe everything in a community and, logistically, it is easier to work with one or two reliable key informants than it is to assemble a series of focus groups.

Key informants help to establish a link between the researcher and the community. They may provide detailed historical data, photographs, manuscripts, knowledge about interpersonal relationships, a contextual framework in which to observe and interpret behavior, and a wealth of information about the nuances of everyday life. Key informants typically provide information through interviews and informal conversation. In research on communities and large organizational studies where there is a paucity of relevant archival documentation, particularly concerning vested interests and power dynamics, key informants are especially valuable.

Key informants generally answer questions about the group in a comprehensive, albeit meandering, fashion. Key informants provide not only personal feelings or opinions, but reflect on larger social patterns as

well. They are considered “teachers” by some ethnographic researchers because they impart information, insight, and understanding. However, their insights are rarely accepted blindly. Their views are compared and combined with interviews, observations, and survey data in order to make a complete study. More to the point, key informant and qualitative researchers are collaborators, using questions, answers, and probes to better understand how and why things work.

The competency of key informants is often measured by length of time they have been in the community, knowledge of community and neighboring communities or organizations, knowledge about a specific topic, and type and degree of interaction with community members. Key informants are often assessed in terms of *inter-coder reliability*, or the degree to which they interpret the same event in the same manner. In some cases, they are measured by the ability to offer completely different perspectives about the same situation, based on their different roles in the community. There are several drawbacks to using key informants, including bias (particularly as a result of selection, role, and/or proximity to phenomena under study), memory failure, distortion, and guilt by association. Qualitative researchers and evaluators traditionally rely most heavily on a few key informants throughout a study or research project to triangulate findings and enhance rigor.

KNOWLEDGE

As a first take, one might argue that *human knowledge* (called *knowledge* hereafter) is the holding of accurate information or warranted understandings and beliefs about the universe and any thing or idea or concept that resides within it. This includes understanding of material and nonmaterial phenomena, characteristics of these phenomena, and relationships among these phenomena. Still, there is no universally accepted definition of knowledge. Therefore, in this entry, I focus less on a Platonic or essentialist approach to definition and rely more on what Ludwig Wittgenstein called the family resemblance approach to definition. My goal is for readers to experience some important meanings and issues surrounding the concept of knowledge. I consider the ontology of knowledge, the “problem of knowledge,” and the 20th-century “received view” of knowledge, and offer a critique of the received view. Last, I provide an inclusive conception or theory of knowledge that respects qualitative and quantitative notions of knowledge. Throughout this essay, I make reference to important philosophers and social theorists that I recommend beginning readers examine in more depth; links to websites that can be used for this purpose are listed at the end of the entry.

The Knowledge Family

There are many members of the knowledge “family.” One can contrast scientific knowledge (knowledge about scientific “objects” that come into conceptual existence as researchers define and describe their objects of study); commonsense knowledge (knowledge based on traditions and day-to-day experiences, enabling people to make sense of their worlds, providing

order and predictability); and religious knowledge (metaphysical knowledge such as knowledge of God(s), an afterlife, spirituality, religious ethics, and morality). It is not uncommon for polemicists from these knowledge communities to attempt to colonize others—for example, someone working in the scientific community may claim to have the “best” or superior knowledge of human development or the origins of the universe vis-à-vis religious knowledge, or vice versa. Intellectual expansionism of this sort is perhaps the key reason for paradigm and cultural “wars” periodically seen in academia and popular culture. The debates typically are, at their core, about knowledge (what is it and who has it) and power.

One knowledge typology in cognitive psychology juxtaposes declarative knowledge (knowledge of factual information represented in declarative sentences and propositions) with procedural knowledge (knowledge of how to do something or reach a goal, sometimes characterized by production rules). Psychology also discusses situated knowledge (knowledge that appears to be context dependent). Another contrast is explicit knowledge (which is expressed in words and numbers) and what Michael Polanyi calls tacit knowledge (which is intuitive and difficult to articulate and share with others).

Another typology contrasts subjective knowledge (knowledge based on experience and thought but often understood in individual or personal or nuanced ways); intersubjective knowledge (knowledge created, shared, and understood in a language or cultural community); and objective knowledge. Objective knowledge is sometimes defined as timeless or universal knowledge, sometimes as the stuff of our empirical experiences, the “reality” that we sense through interaction with our environments; this sort of knowledge often is claimed to be available to everyone. The concept of objective knowledge is often defined differently and is controversial; it is not uncommon for objective knowledge to be defined simply as what people agree to be true, which is what I call *intersubjective knowledge*. Many additional types of knowledge can be added to this list.

Ontology of Knowledge

Knowledge is conceptual, and it is discovered and constructed by humans. It is nonmaterial (but real); it is “stored” in our brains (in ways we do not fully understand); and it is processed through physical relationships operating in our brains. Without humans,

this knowledge would no longer exist. However, some philosophers contend that many true statements would be true even in the absence of human life (e.g., Kant's synthetic a priori truths, such as the mathematical statement $2 + 2 = 4$). Many philosophers (e.g., Plato) and scientists have claimed that many truths are universal, necessary, and unchanging. I show below that many philosophers consider knowledge literally to be *justified, true belief*.

One might argue that knowledge exists in the sense of storage in many physical ways—for example, in brains, books, libraries, cultures, and computer chips. Although knowledge is physically housed in individuals and their artifacts, knowledge also exists (as an emergent property) at the intersubjective and group levels of social reality. This reality is the focus of disciplines such as sociology, political science, anthropology, and economics.

Social and cultural knowledge emerge from brains (that are socialized, enculturated, educated) but it exists as a higher (i.e., social) level of reality. Émile Durkheim expressed this point in his *Rules of Sociological Method* when he argued that *social facts* (e.g., status, roles, culture, language, shared beliefs, social practices, and patterns of behavior) are “things” that cannot be reduced to psychology and they are “*sui generis*” (which is a Latin expression meaning of its own kind, unique, or independent). Again, knowledge exists at an individual level, but it also exists, according to most social scientists, as an emergent social reality. I argue that this emergent reality is an intersubjective reality or, using Peter Berger and Thomas Luckman's language, an objectified reality. Durkheim and most social theorists contend that social reality is shown in “choices” and impacts of choices that individuals make in their environments. This view of social reality is formally called *structuralism* (see Émile Durkheim, Claude Lévi-Strauss, Ferdinand de Saussure, and poststructuralists Michel Foucault and Jacques Derrida).

The Knowledge Problem

Debates about knowledge have continued unabated since at least the time of Socrates. For example: (a) Is truth universal or relative? (b) What is the foundation of knowledge? (c) Is truth obtainable or is inductive probability the best we can obtain in the human sciences? The famous Greek dialogues concerning truth and knowledge are still highly relevant today (e.g., *Meno*, *Protagoras*, the *Republic*, *Theaetetus*), especially

the debates between Socrates/Plato and the Sophists (such as Protagoras, who famously said “man is the measure of all things,” and Gorgias). As constructed here, the Platonic position sees knowledge as necessary, absolute, and unchanging, and this includes knowledge of axiological concepts such as justice and virtue. For Platonists, knowledge is desired and distinct from “mere belief.” Statements are true or false. The lack of a third possibility is called the “law of the excluded middle.” Fuzzy logic and other projects in philosophy, including some versions of skepticism, deny the concept of necessary truth and the law of the excluded middle (e.g., Gorgias). The Platonic position regarding knowledge stands in contrast to the Sophist position, famously detested (“sophistry”) by Socrates and Plato and most other Western philosophers over the ensuing 2,400 years. The Sophists were quite satisfied with knowledge as belief that is well received and widely held by educated people, and they viewed truth and knowledge pluralistically and relative to social, cultural, and individual agents, and saw it as changing over time (historicism). The Sophists' view of knowledge equates with relativism. Much Anglo-American (in contrast to Continental) philosophy still defends the “Platonic” notion of knowledge as absolute, universal, and unchanging.

This long-standing knowledge debate between absolutism and relativism is at the core of the quantitative versus qualitative paradigm wars, with advocates of quantitative research taking the Platonic position (assuming that researchers produce true knowledge about a lawful world), and advocates of qualitative research taking the Sophist or relativist position (assuming that researchers write about local or contextually specific knowledge). Regarding many social and psychological phenomena, some version of relativism appears warranted. It would be helpful if *varieties* of relativism (ontological, epistemological, ethical, methodological) were better articulated in the literature. Mixed methods research (i.e., the third methodological paradigm along with qualitative and quantitative) draws on the “truth- or use-value” obtained through the use of qualitative *and* quantitative viewpoints; this is done under the banner of philosophical/methodological pragmatism (claiming that the most one can hope for in research is warranted assertability about claims); pluralism (there are many truths and realities); and perspectivalism (i.e., many true statements can be said about the same phenomenon, all of which might be informative). It is unlikely that the

“knowledge problem” of absolute versus relative truth will ever be fully resolved because there are too many conflicting and countervailing values, issues, perspectives, and forces operating simultaneously.

The Received View

In Anglo-American philosophy, the standard view of knowledge has long been that knowledge is *justified, true belief*. This idea is commonly called the JTB theory of knowledge (or simply JTB). According to JTB, the three ingredients (justification, truth, and belief) are necessary and jointly sufficient for knowledge; therefore, they provide an essentialist definition of knowledge. One component of knowledge is *belief*; it is necessary that one believe something. One might believe that income *tends* to increase with education; one might believe that opposite poles (+, –) on *all* pairs of magnets produce attractive forces. Second, it is necessary that one’s belief is *true*. Using the same examples, it would have to be the case that income increases with college education (in all cases, for universal or necessary knowledge, and in many or most cases, for inductive or probabilistic knowledge); in the second example, it would have to be the case that opposite poles always result in a pulling force because it was a universal claim. Third, one’s true belief must be warranted or *justified* in order to constitute knowledge. Unlike, truth, however, justification comes in degrees; to meet this third criterion, justification must be considered strong or adequate (presumably as decided by an expert). Again, if you have a justified true belief, then you have knowledge according to JTB.

JTB is a useful starting point for much philosophical research and debate. Some widely discussed theories of truth include correspondence theory (a statement is true if it corresponds to the facts in the world); coherence theory (a belief is true if it is logically consistent with the other beliefs in one’s knowledge system); and pragmatism (a statement is instrumentally true or meaningful or warranted if it allows one to successfully adapt to one’s environment and if it works in practice). Some popular theories of justification include Cartesian foundationalism, modest foundationalism, coherentism, evidentialism, reliabilism, and truth tracking. Throughout history, various forms of skepticism have questioned the possibility of the necessary or universal truth that JTB assumes. Much of Anglo-American epistemology focuses on challenges and technical revisions to JTB.

Some Problems with JTB from a Human Sciences Perspective

In addition to technical problems identified with JTB in the literature, several commonsense problems arise when we try to define what counts as truth from the perspective of human or social science. First, JTB focuses on what we “know,” but can we *know* that we *should* or *ought* to use JTB? It seems that one should make explicit the epistemic values presupposed by JTB; that is, JTB highly values or prizes truth and what one might call logical-rationality. There are, however, other potential, additional, or alternative epistemic values that one might desire in one’s theory of knowledge such as taking an instrumental approach and valuing explanation, prediction, and control, or taking a humanistic approach and valuing assertions that provide personal and social meaning and contentment, personal growth, personal freedom to differ, and social or political claims.

Second, JTB works well for propositions that result in true or false conclusions, but many natural language statements (especially value statements) do not fit this form. Statements such as “John Dewey was a good person” or “Apples taste better than pears” are excluded from JTB analysis because they do not result in true or false statements. Regarding values and rationality, perhaps a reasonable person would agree with some value-laden statements (e.g., slavery is wrong, Hitler was evil, murder is wrong), but there is no universal agreement on the truth or falsity of many other value judgments (e.g., abortion is always wrong, Søren Kierkegaard was the first existentialist, the democratic party is correct on the issue of class equality, Jacques Derrida was a better writer than Michel Foucault). Many statements about concepts, values, and social issues are better viewed along truth continua than as true–false binaries.

Third, JTB assumes the existence of a universal rationality (an assumption that became commonplace during the Enlightenment). In direct contrast, many human scientists (e.g., anthropologists, sociologists) have shown that what is reasonable to people varies by time, place, culture, person, and along many additional dimensions. Psychologists Daryl and Sandra Bem (in a social psychology book written in the 1970s) labeled individuals’ reasoning process *psycho-logic* because it varies by person. Qualitative research also shows that rationality is just one of many characteristics of humans. To focus only on the dimension

of rationality is to misunderstand the complexity of humans.

Fourth, I would argue that David Hume's *problem of induction* is closely related to this issue of proof in human scientific research; according to this problem, all we can ever obtain is knowledge of what we experience, but all we experience are particulars. Relatedly, the future might not resemble the past (perhaps the sun will not appear tomorrow), and what we have not observed might be different from what we have observed, eliminating the possibility of certainty in theoretical generalizations and statements about unobservables. Many theories, generalizations, and laws in science, however, make claims to universal knowledge (e.g., the law of universal gravitation in physics, the law of effect in behavioral psychology). The law of universal gravitation in physics might be true, but we cannot ever know if it is, and the law of effect in the psychology of learning clearly is not true in a strict sense.

The last problem is that JTB theory appears to assume that propositions exist and can be tested in isolation. JTB excels in examining single, particularistic statements; it falters when examining webs of statements. As Willard van Orman Quine has shown, scientific statements are best viewed *holistically* (i.e., as embedded in webs of interrelated statements) rather than existing separately. This is why hypotheses cannot be tested in isolation and why theories survive when particular predictions and claims are not empirically supported; a researcher can modify the web or theory, adjusting it to fit the particular finding that the researcher does not want to reject by modifying a different part of the theory. In relation to the paradigm wars, internal contradictions and intra-paradigmatic differences oftentimes are glossed over because of the desire to emphasize inter-paradigmatic differences.

As argued here, strict adherence to classical JTB theory can lead to problematic conclusions, especially for the human or social sciences. An irony is that social researchers claiming to adhere to JTB, strictly speaking, *do not have knowledge* about the vast majority of phenomena about which they claim to have knowledge. In one sense, qualitative research would appear to fare better than quantitative research because it focuses more on the here and now, on the particulars, the local, which do not appear to seriously violate the problem of induction. At the same time, qualitative research views the world as relational, complex, and constantly changing, which would suggest

that knowledge is at best fleeting or ephemeral. Quantitative research would appear to be in serious trouble if universal knowledge or laws are claimed (which is a long-standing goal and practice of traditional science). Perhaps JTB can only be a true theory of knowledge if it is defined as such, which would make it a tautology (although one could still consider it a useful tautology). My view of JTB is that it provides an important and useful starting point (and comparison point) for thinking about knowledge, but for the human sciences, it is problematic because of the questionable assumptions of universal rationality and deductive and foundational truth. This is likely why inductive reasoning and standpoint epistemologies have become common in the philosophy of social science and qualitative research.

A Current View of Knowledge?

Since the late 19th century, many developments have occurred that provide insight on the nature of knowledge and the problem of knowledge. I will briefly mention a few. At the end of the 19th century, Friedrich Nietzsche introduced the concept of *perspectivism* (or perspectivalism), which rejects the idea of objective or absolute truth and argues that there are multiple ways to view the same phenomenon or object. What is called truth or knowledge often is simply a name for a point of view. Other writers (such as Richard Rorty) have echoed this idea. A related concept is hermeneutics, which refers to the interpretation of texts. Applied to knowledge, the idea becomes that knowledge and meaning is a type of narrative that always is open to new interpretations (e.g., Derrida, Foucault). Derrida famously said "there is nothing outside the text." We change over time and it seems natural that new and sometimes better "textual" interpretations will occur. Derrida also argued that binary oppositions (deep structures assumed by the structuralist Lévi-Strauss) are neither pure nor independent (e.g., qualitative and quantitative, male and female, day and night), and that each opposing category is present to some degree in the other (e.g., in what Derrida called a *supplement*). The world cannot be analyzed in the sense of cutting it into pure (objective) categories. Foucault argued that knowledge is not separate from power; the categories of knowledge and power overlap and cannot be untangled. Where one finds the operation of knowledge, one also will find the power. Many "free" choices are made by individuals because they

have internalized the knowledge structures of their communities.

Thomas Kuhn made many important points about knowledge in his book *The Structure of Scientific Revolutions*, where he suggested that scientific knowledge has a large social component and that observation always is theory-laden. Researchers operate within paradigms that use exemplars, languages, conceptual systems, and value systems that inform members how to do good science and provide the theories and ideas to presuppose. In Kuhn's system, most researchers work day to day trying to "solve puzzles" during normal science, rather than trying to overthrow the paradigm or its assumptions. Kuhn believes that knowledge is the result of psychological and social factors *and* objective (i.e., empirical, measurable) factors operating in experience and the world.

Perhaps the best position on knowledge for the social sciences came from a monograph by Peter Berger (a sociological theorist) and Thomas Luckman (a phenomenologist), written in 1966 and titled *The Social Construction of Reality*. They provided a reciprocal model of knowledge based on the processes of externalization, objectification, and internalization. People act on their world, creating culture and practices (externalization). Through these actions and beliefs, social knowledge is objectified and it, therefore, is real; social constructs and knowledge exist beyond any single individual but it is housed within the consciousness of community members. This social reality, in turn, causes people not only to believe certain things, act in certain ways, and to be certain kinds of people through the process of internalization (operating through socialization, but also operating through other forms of social control such as formal and informal laws, and interpersonal reinforcement and punishment). Because people internalize the ideas of their cultures and subcultures, the beliefs are "taken for granted" and seem natural (almost like "instincts") and justified and right. A cyclical process of externalization, objectification, internalization, and subjectification continues over time and varies by community or place. Social constructivists are right that we construct social thought, but the "scientific" structuralists also are right that we are born into structures that help make us what we are. There also is human freedom within structures, and individual perspectives help determine our personal identities, experiences, and schema systems (e.g., Jerome Bruner calls individual constructivism the "personalization of knowledge").

Here are several tentative conclusions about knowledge: (a) knowledge is based on empirical reality, but it also is socially and individually constructed, and, therefore, arguments that only one of these statements is true rely on a false choice; (b) the truth component of JTB is too strict and needs to be reconceptualized for the social and human sciences; intersubjective agreement among thoughtful community members (e.g., experts) is, perhaps, a better criterion; (c) a more commonsense definition of knowledge (than JTB) works fine in most language communities or "language games," and those definitions typically are "true enough"; (d) much human and social knowledge is perspectival and in most cases this is not a logical problem of contraction because many true statements can simultaneously be made about the same social or scientific object; (e) much of what is considered to be knowledge needs to be indexed to time, place, and culture (i.e., what we consider to be knowledge changes); and (f) it is important to carefully analyze the various meanings of the term *knowledge*, especially when one operates in different language communities.

LEAVING THE FIELD

Gaining access to a field of research in qualitative designs raises issues concerning self-presentation, negotiation of roles, research bargains and interactions, and personal relationships with informants and other participants. However, these issues are also important when completing a piece of fieldwork and leaving the field for the last time. Relations between researcher and those researched built up during the period of fieldwork may have ramifications for participants after the researcher has left the field. It is therefore an issue of research ethics how field relations are terminated, and working in the field has interpersonal dimensions for a researcher: There may be psychological and emotional sequelae for a researcher seeking to leave a field setting.

Ethical Dimensions of Leaving the Field

Power relations between field researcher and those researched may become evident in the expectations of these parties when fieldwork ends. Researchers may have greater access to resources (physical, intellectual, cultural) than those they research. Also, during fieldwork, a number of formal or informal research bargains may have been struck between researcher and participants, such as an agreement not to undermine hierarchies or other commitments concerning behavior or confidentiality. Such research bargains with informants may meet psychosocial needs; for example, to have an interested, unengaged, or neutral

ear to listen. Participants may be willing to talk or be observed, so long as their anonymity is respected. Sometimes there will be a more tangible bargain; for instance, to assist in some project or struggle or to provide feedback to support participants' objectives. When leaving the field, the researcher's commitment to these bargains needs to be confirmed explicitly so that participants are reassured that their trust and participation in the research are respected and rewarded.

Informal relations may also have developed during fieldwork, including emotional or psychosocial engagements with researchers. These affective relations must be addressed before a researcher leaves a field, and culturally appropriate forms of valediction must be undertaken. Researchers may need to use informants to check what kinds of expectations are held by participants concerning departure.

Consequences for the Researcher

Fieldworkers may experience loss when leaving a field setting where they have built up working and living relationships with informants and participants. This loss must be managed and acknowledged. There are accounts of relations being sustained subsequent to leaving the field, and this is acceptable, subject to cultural constraints.

Other Issues in Leaving the Field

Field relations do not fit within a standardized pattern and, on occasion, unusual research bargains may have been struck. There may be financial issues to be settled, if money or goods have been promised to research

informants or participants. Other research bargains may involve providing education or training, facilitating connections to influential persons, or sustaining personal contacts where friendships or relationships have emerged between researcher and participants. More frequently, there may have been an agreement to present findings from the study to participants in one form or another.

LIFE STORIES

Producing life stories is an increasingly popular form of narrative-based inquiry in fields as diverse as anthropology, education, gerontology, history, law, medicine, psychology, sociology, and women's studies. Methods of inquiry into lived experience appear under such labels as autobiography, biography, autoethnography, life history, and oral history. Despite their differences, the common purpose of these methods is to inquire into lived experience and to re-present that experience in a narrative form that provides rich detail and context about the life (or lives) in question. Life storytelling can be understood as an intellectual site where the narrative turn in the social sciences meets the desire to exercise the descriptive and analytic processes that C. Wright Mills famously called the *sociological imagination*.

Although distinctions between life stories, oral histories, autobiographies, and life histories are contested and problematic, they typically seek to provide accounts and analyses of how people make sense of their lived experience in the construction of both individual and social identity. Some life historians claim that the analysis of the social, historical, political, and economic contexts of such experiences is what transforms a life story into a life history. That is, life histories situate stories of individual lives within a bigger picture. This contextual location of a life story (or lives) allows us to explore the generative interplay

between individuals and culture that characterizes a life history.

By positioning descriptions of everyday life within the contexts in which they occur, life history narratives can convey a sense of how individual lives are not free-floating, but are socially constructed. For example, from many studies of teachers' careers and lives, Ivor Goodson concludes that the significance of various limits and possibilities for individual lives are both contained and enabled by their location in the social world; otherwise, individuals are inevitably constructed as victims, powerless in the evolution of their lives.

Foci for continuing debate among life historians includes the relationship between researcher and researched and how this affects the construction of life histories. The postmodern turn in social research has also brought under scrutiny questions about the nature of identity, truth, structure, and agency and the warrantability and defensibility of claims about the veracity of individual and collective voices in the representation of lives and experience. For example, William Tierney argues that a goal of life history work in a postmodern age should be to break the stranglehold of meta-narratives that establish rules for truth, legitimacy, and identity.

LIMINAL PERSPECTIVE

A liminal perspective toward analysis studies the in-between space in relationships, social roles, and contexts in times or at places of transition and change. Victor Turner furthered the idea of liminality as manifested through ritual as social actors move through

ambiguity and transition. To Turner, the liminal phase was the stage of a transitional ritual in which a person is between social states (which Turner referred to in the title of one of his key articles, “Betwixt and Between”). Turner found that people sharing liminal spaces were in an antistructure state of communities in which they were relatively equal to and bonded with each other, while othered and marginalized by the rest of society. Turner specifically studied the role of rituals in these liminal spaces.

As a type of cultural analysis, studies of liminality look at social spaces in which change takes place, the boundaries between and around these spaces, and the borderlands surrounding these spaces. Researchers studying liminality would look at the way communication, ritual, and processes mark social spaces and move people between and through them.

The liminal perspective has been used in research concerning chronic illness and disability, ethnicity and immigration, group oppression, and bisexuality, among others. For example, Jean Jackson’s 1991 research studied the liminal space of chronic pain as a borderland between the mind and the body, while Joanne Warner and colleague Jonathan Gabe’s 2004 study examined the gap between mental health service providers and the otherness of the people with whom they work. Donna Goodwin and colleagues looked at the language (metaphors) used to indicate and describe the position of social liminality occupied by persons with a disability. Anette Forss and colleagues’ 2004 study examined the liminal space of uncertainty among women who had received abnormal Pap smear test results.

Ben Rampton’s 1999 study of multiracial youth, Samuel Marc Davidson’s 2006 study of bisexual Latino men, and Paul Tabar’s 2005 study of a Lebanese folkloric dance performed by immigrants from Lebanon living in Australia all used the lens of liminality to explore the discourse involved in forming, transforming, and articulating new identities.

The study of liminal spaces is important because it is at places and moments of change and transformation that one can see most clearly the processes of domination and resistance, of inclusion and exclusion, and of marginalization and socialization. It is in society’s borderlands that one is challenged to recognize the other and the self and to see oneself in another.

LITERATURE IN QUALITATIVE RESEARCH

Literature is an art form that requires readers to attend to its details and imaginatively engage with characters and situations for emotional and intellectual impact. Unlike texts where individuals pay particular attention to information, literature invites readers into a literary space of human experience, which is of particular interest to qualitative researchers. Numerous genres constitute the field of literature in qualitative research including novels, short stories, poetry, drama, e-literature, and forms of nonfiction such as autobiography and personal journalism. In some instances, the qualities of the oral storytelling tradition are important, especially in genres such as ballads, myths, folktales, and legends. Qualitative researchers may use literature as a focus for participant response either through discussion or creation; they may use literary genres to represent the data or the larger study; or they may refer to the literary text as a data source. Specific advantages for researchers using literature are noted at the end of this entry.

Types of Literature

Any literary form may be used depending on the purposes of the researcher. Below are four common types of literature with some examples of genres that are used regularly by the qualitative researcher.

Poetry

Poetry has the advantage of conveying specific sensory details, rhythmic structures, and evocative images in a compact and carefully crafted structure. From very few words, the reader can experience the impact of the experience being related. Researchers have used poetic forms to represent the cadences of participant voices, the details of a research context,

and representations of research literature and their emotional interpretations of research events. Poetry also has been paired with other art forms such as painting, particularly in arts-based research. Poetry has a distinct advantage because its rhythms and figurative devices enable an embodied sense of the research, which is more difficult to achieve in prose.

Fiction

This type of literature commonly includes genres such as novels, short stories, and dramas. Other examples used in qualitative research are novellas, letters, and diary entries. Researchers rely on fictional texts to focus or elicit participant response and for reporting research findings. The advantages of using fiction include the possibility of representing participants as characters, engaging readers in a narrative of the research site and events, highlighting participant voices and dialogue, and more accurately representing situations where the need for confidentiality is great. Researchers have been debating the ethical implications of portraying participants through the personae of characters, especially when including thoughts as well as dialogue. Some researchers restrict representation of participants to actual responses and observable actions, while others include inner dialogue when it can be supported by the data. Still other researchers argue that they create fictional characters to represent an amalgamation of several participants, details of which can be supported by the data.

Nonfiction

Nonfiction, when categorized as literature, includes such genres as biography and autoethnography. This type of literature represents a shift in the field of journalism from an emphasis on objective reporting to the recognition that fictional and poetic techniques can add to the veracity of the portrayal. Autoethnography, which is particular to qualitative research, is a genre that challenges the notion of the objective observer and the silent author through using literary techniques. Researchers write from their own experiences, relating them to historical, social, and cultural contexts. This reflexive process enables a deep look at self-other interactions. An advantage to using nonfiction (or what is sometimes called *creative nonfiction*) is its similarity to more traditional forms of reporting research.

E-Literature

This emerging form of literature is taking on greater prominence as researchers investigate digital literacy and online activities. E-literature relies on the characteristics of digital technology such as hyperlinks and multimedia representations as well as readers' comfort with ambiguity and willingness for interaction with the text. Although it is not yet common to see research results represented online beyond basic hypertexts, the number of researchers who are asking participants to use and report on their interpretation of e-literature is growing. This area will gain more prominence in the years to come.

Research Possibilities With Literature

The versatility of literature enables writers to portray the breadth of human experience. In a similar vein, it offers researchers a variety of approaches for exploring what and how participants understand and for representing those insights. There are three main areas where literature is used in qualitative research: participant response, representation of data, and as data itself.

Participant Response

Literature has long been used, particularly in education, as a focus for participant response. These studies take several forms including having an individual or group read the literature and then respond to the literary experience with their insights about the text, its connection to their experience, and their recognition of literary processes. Researchers also use literature to raise issues that they wish to discuss with participants. For example, a number of educational researchers have invited teenagers to read young adult novels to prompt discussions of adolescent experience. In other instances, researchers invite participants to read literature and then represent their interpretations through other art forms such as multimedia productions or artistic creations.

Researchers also rely on the participants' creation of literary forms. For example, they may invite participants to write in various literary forms to explore issues of identity, literacy, writing processes, or the development of insight. Some researchers use a combination of reading and writing literature as a way to research experience such as exploring the construction of female identity through story and poetry.

Representation of Data

Over the past 10 years, qualitative researchers have increased their use of literary forms to represent their data. Some researchers report on their study through a short story or a drama. Others have used a series of poems. Many researchers use a combination of more traditional academic forms interspersed with narratives, poems or other literary genres. Using literature as a form of representation sometimes enables a researcher to respect confidentiality through the veil of fiction. For example, some studies have been represented as a novella or as a collection of poetry to protect participants' identities.

Researchers need to be cautioned that literary forms, particularly poetry, demand skillful writing. A badly executed poem, such as one that does not attend to word choice or rhythm, can diminish the quality of the research report. Many researchers who are interested in writing literary forms join writing groups, read books about writing a particular genre, or carefully study published forms of the literature. As the use of literary forms gains greater acceptance in the academic community, researchers are expanding the variety and possibilities of literature in research.

Literature as Data

The literature that participants create can be used as a data source and analyzed according to themes, metaphors, or other literary aspects. Researchers also use literature as data in discursive research. A published novel, poem or other literary genre can become a source for analysis. For instance, a researcher might use a novel by Virginia Woolf to investigate the complex phenomenon of human consciousness. Literature, because of its detailed representations of human experience, is often used in hermeneutic phenomenology as another perspective about the topic in question. For example, in a study that investigates the experience of beginning teachers, researchers can refer to a novel that represents such an experience as an instance of the phenomenon.

The Advantages of Using Literature in Qualitative Research

The very reasons individuals appreciate literature as a cultural art form are the reasons that make it a powerful choice for research—either to elicit or represent data. Literature is a source of sensory details, figurative

language, and experiences with human consciousness. These qualities can offer verisimilitude to research. Furthermore, through writing research reports in literary forms, researchers can demonstrate their theoretical framework such as illustrating poststructuralist writing.

Literature also offers alternatives to ethical issues in qualitative research. Readers can explore various perspectives and voices through reading literary forms that better represent the complexity of human relations. Furthermore, by representing data in a literary form, researchers can create more confidential reporting about participants. Finally, literary writing often makes research texts more readable and can broaden the audience for qualitative research.

LITERATURE REVIEW

The concept of a literature review is very much a plural rather than a singular one as there are many literatures a researcher must examine to produce a coherent literature review. For example, by doing qualitative research, the researcher is joining an ongoing debate in some shape or form. The originality of an idea, an approach, or a theoretical reinterpretation

adds to existing literature. The objective of this entry is to describe the plurality of literature, to underline the difference between general and specific literatures, to highlight how to use theoretical literature as a tool to increase understanding of a subject area and test a research question or hypothesis, and to examine the methodology and data literatures that form important parts of the research process.

One of the most important considerations for the qualitative researcher is the plurality inherent in the idea of a literature review: A number of reviews of different aspects of literature have to take place before a coherent research project can begin. In a subject like education, there are so many categories and therefore literatures that a review can look almost frightening. For example, in a review on the topic of education policy, one is seeking to examine the concept of education policy, looking for policy examples to apply to that concept and looking for relevant education research that uses a policy framework. Within this notion, one could be looking for a context or a history of an education policy document. One might also seek a wider understanding by looking at the philosophy or sociology underlying the policy document. One will need to decide whether to use traditional sources; that is, books and journals, or edited sources from the World Wide Web—for example, records of governmental committees and commissions. That really is the tip of the iceberg. Les Bell and Howard Stevenson begin their book on education policy with what they do not seek to explore surrounding the concept. The lesson for the researcher is to define literature boundaries; that is, to acknowledge the complexity of a concept and then underline what aspects of the concept a literature review can address.

An understanding of the general and specific literatures is crucial for all researchers considering the construction of a research proposal. Knowledge of where to find the relevant sources is therefore crucial. With both undergraduate and postgraduate students, a balance is necessary between the traditional print sources (i.e., books and journal articles) and up-to-date and free electronic resources available on the World Wide Web. The internet has changed the way people view knowledge and has made information more accessible to those who know where to find it. A good application of social theory here is Pierre Bourdieu's notion of cultural capital. So, one does not just need to know where to find literature sources; one needs the resources and technology to access the

information. For the researcher, finding literature can be a frustrating experience, but it is the tutor or the supervisor's role to guide the student to the literature. It is up to the student to decide what is and what is not relevant literature to use within research designs.

The use of theory and theoretical literature is also an important consideration. Once a research design has been created, ideas and theoretical frameworks can be used and tested to both question and increase understanding of the qualitative research being carried out. For example, the views of a modern social theorist such as Max Weber can be put into context and applied to a contemporary research problem. There are again literatures in relation when using somebody like Weber. There are the famous texts such as *Economy and Society*. There is Weber's published PhD dissertation: *The Agrarian Sociology of Ancient Civilizations*. There are the recent published works within the academic community that keeps the Weberian discourse fresh and up to date in both book and journal form. One can even divide the Weberian journal literature up with *Max Weber Studies* and the publications applying a Weberian perspective to wider ranging subject literature. Weber was German, so if one considers his original works have been translated into English, that adds even more potential references and literature sources to a potential literature review. However, are these sources available to the researcher—for example, what happens if literature is not translated from German into English?

What is often neglected by researchers is the method, methodology, and data literature that encompasses different, but important parts of the qualitative research processes. Method literature relates to how to use different techniques; that is, interviews or participant observation are used in the field. Methodology refers to how a researcher uses methods and sets out how methods are used and data are collected. There are interestingly two distinct literature reviews for both method and methodology that can be confusing for the researcher. The position of the data collection, presentation, and analysis chapter within a research proposal or project often means that the literature revolving around data is often neglected by researchers. David Silverman has written extensively on data analysis. How data are presented is also worth literature review as this is one of the more enjoyable parts of the research project as empirical data can be used to begin to test the research question.

It is important to apply the different literature elements to a particular source; for example, using

Colin Robson's book to see whether different literatures are covered or not. There is no intended criticism of the text, so a question could be, which aspects of the research project are covered and which are not? For a researcher, one of the best places to look for literature sources is the reference list or bibliography. Robson has a reference list and author index of over 30 pages. The reference list is user-friendly, as each entry has a number in bold that indicates where the publication is referred to in the book. Looking at the contents page, there is a list of references in a further reading compilation. This list allows the researcher to focus on relevant key texts that relate to particular literature sources that correspond to different parts of the research process. Unfortunately, there is no actual literature review chapter in the book. The idea of flexibility applies to all aspects of research design, including the literature review. It is good to see, in Robson, two parts of the book dedicated to the methods of data collection and dealing with the data, including further reading lists at the end of eight chapters. This alleviates some of the fear expressed in the previous paragraph. Most research books have chapters on data. The issue to raise here is that many researchers neglect data literature and need to plan more time to explore this part of the research project rather than focusing on data presentation and analysis.

Reviewing literature is a complex but enjoyable part of qualitative research. There are many different aspects of literature from general subjects to the specific, through theoretical approaches, into method and methodological literature, and finally into data collection, presentation and analysis. It is worth working through what Chris Hart titles a chapter "Bibliographical Framework," in his text *Doing a Literature Search* (2001), but I think it is worth finding a balance between traditional sources of books and journals with a coherent use of information communication technology knowledge and techniques. Another way for researchers to extend their knowledge and increase understanding is to read reviews of the academic literature within journals. Access to literary sources is the perennial issue for researchers and electronic access to global literature is a research skill that researchers are having to engage with and develop as more sources become available in this format.

LIVED EXPERIENCE

Lived experience, as it is explored and understood in qualitative research, is a representation and understanding of a researcher or research subject's human experiences, choices, and options and how those factors influence one's perception of knowledge. Lived experience speaks to the personal and unique perspective of researchers and how their experiences are shaped by subjective factors of their identity including race, class, gender, sexuality, religion, political associations, and other roles and characteristics that determine how people live their daily lives. Lived experience, then, leads to a self-awareness that acknowledges the integrity of an individual life and how separate life experiences can resemble and respond to larger public and social themes, creating a space for storytelling, interpretation, and meaning-making. Lived experience allows a researcher to use a single life to learn about society and about how individual experiences are communicated.

Carolyn Ellis and colleagues have done extensive work on the usefulness of lived experience as a research technique, investigating emotions, gendered experiences, loss, and the inevitable transitions of life. Pioneers in the field have demonstrated writing and research

techniques that best utilize this method of privileging the voice and experience of the author-researcher, including autoethnography, memoir, narrative writing, and performance.

Lived experience responds not only to people's experiences, but also to how people live through and respond to those experiences. The body of work on lived experience focuses on everyday life occurrences and self-awareness. As a life history or life story, lived experience concentrates on ordinary, everyday events (language, rituals, routines) while privileging experience as a way of knowing and interpreting the world. Lived experience also offers a perspective through which to make comparisons for research and serves as a testimonial to survival.

The lived experience method does not critique individual lives, but rather it presents them for comparison with others. The method is evaluated based on its verisimilitude and ability to evoke an emotional response from readers and scholars. The work represents common experiences that are life changing and life affirming. Lived experience seeks to understand the distinctions between lives and experiences and tries to understand why some experiences are privileged

over others. The method concentrates on what people do and how they do it.

Research questions for this method are generally centered on the lived experiences of the participants, but they also focus on the topic of research. Lived experience acknowledges every aspect of a person's life and identity, even those areas that are not directly connected to the research topic or question.

MARGINALIZATION

Marginalization is the process through which members of some segments of society find themselves out of the mainstream based on their membership in socially meaningful groups. Groups may become marginalized based on a variety of characteristics such as religion, social class, ethnicity, visible racial characteristics, gender, age, and sexual orientation. People's social status related to these characteristics is based on an interpretation of their meaningfulness rather than on any innate qualities they might have.

This entry looks at the promise of qualitative research methods to bring to light the life experiences of members of marginalized populations. It outlines how researchers have used qualitative research methods to explore the experiences of members of marginalized groups and to understand the social world of disenfranchised groups. The entry also demonstrates how the strategies that members of marginalized groups use to negotiate their role as research participants can be used as data to enrich an understanding of the shape of their marginalization.

Researchers have traditionally used qualitative research to access the points of view and, more recently, the voices of members of groups who find themselves ignored by those who have the power to establish the generally accepted definition of the situation. One way to think about this process is through the concept of the hierarchy of credibility. In any group, people take for granted that those with the highest social status have the greatest understanding of any situation or setting and, therefore, the right to

explain or define the way things are. For example, if one wants to understand the state of affairs in a prison, one is more likely to ask the warden for his or her explanation than the prisoners'. People tend to believe that not only does the warden know the "truth" about how things happen in a prison, but also that his or her point of view is likely to be more accurate and unbiased than those of the prisoners who are incarcerated there. If one was to seek the point of view of the inmates, one would likely discover a perspective that is markedly different from that of prison officials.

Similarly, in political processes or in the media, those who are at the top of the hierarchy of credibility appear as experts whose point of view reflects societal consensus. Members of groups who are marginal are often referred to as special-interest groups whose point of view and understanding of reality reflect a biased and self-centered position. It is unheard of, for example, to see corporate executives referred to as special interest groups even though their points of view are just as likely to reflect their self-interest as anyone else's.

Just as individuals may experience marginalization because of their membership in particular groups, some areas of research are marginalized and therefore accorded less value because of the topic being studied and/or the method being used to conduct the study. For example, studies about family life may be accorded lower status than those about issues related to the work-force because of their association with women. Similarly, studies related to aging, and therefore the researchers who carry out such studies, are marginalized within their disciplines. As well, as society has become more urbanized, the vast majority of research has involved urban populations. Rural populations

often are not considered in research, and the issues that affect rural social contexts are noticeably absent.

Early Uses of Qualitative Research

The Chicago School of Sociology, which originated in the early 20th century, used qualitative methods, specifically ethnographic field methods, to study groups that existed on the social margins of society. Classic studies include Harvey W. Zorbaugh's 1929 study, *The Gold Coast and the Slum* and Nels Anderson's 1923 book, *The Hobo*. In 1943, William Foote Whyte published *Street Corner Society*, an ethnography of the subculture of poor Italian youth. All of these books were groundbreaking in that the authors spent time hanging around with and participating in the social lives of the poor men whose lives they were seeking to understand. These groundbreaking studies presented the points of view and the everyday lives of the people whose situations they were studying rather than the professional interpretations of, for example, social workers whose mandate was to improve the lives of those less fortunate by finding ways to assimilate them into the mainstream.

Later scholars of the Chicago School also studied marginal groups. In 1963, Howard S. Becker published *Outsiders*, which explored the so-called deviant worlds of marijuana users and dance musicians. This book argued that deviance, rather than being an innate characteristic of some people, was a result of their being labeled and that so-called deviant acts were social constructions created by moral entrepreneurs. In 1967, Elliot Liebow authored *Tally's Corner*, which explored the social world of young, African American men in a large city.

Later Uses of Qualitative Research

These early studies explored the impact of marginalization that was based on social class, ethnicity, and race. In the latter part of the 20th century, qualitative research began to explore the lived experience of groups whose marginalization was premised on gender, age, and sexual orientation. As well, researchers began to look at how the social place of people affected the way they understood their role and participated in qualitative research.

Early feminist scholars, for example, argued that when women interviewed other women, the power differential between the researcher and the researched

was not as present as in traditional, survey research. Ann Oakley, for example, described women's interviewing other women as a contradiction in terms. Marjorie L. DeVault suggested that when women interviewed other women, they needed to acknowledge that women, a marginalized group, had a standpoint that could not be encompassed by categories developed, in advance, by male researchers. These and other feminist scholars argued that qualitative research methods could allow scholars to understand the lived experience of those who inhabited the social margins of society. Their philosophy privileged the points of view of the members of marginalized groups rather than those of higher status—in this case, men.

The Marginalization of Qualitative Research

Qualitative research occupies a marginal position in many disciplines. Those who carry out qualitative research may find it very difficult to publish in core journals in their fields or to acquire research funding. Qualitative researchers have responded to this situation by creating journals dedicated to qualitative research—for example, *Qualitative Sociology* and *Qualitative Inquiry*—and by founding organizations such as the International Society for Critical Health Psychology. In Canada, there is an annual conference, The Qualitatives, which provides a venue where qualitative researchers do not have to apologize for or justify their use of qualitative methods.

Howard S. Becker in "The Epistemology of Qualitative Research" has outlined some of the social processes that demonstrate the lower status of qualitative research. One indication is quantitative researchers' practice of asking qualitative researchers to explain their research using the language of quantitative research; for example, reliability, validity, and hypothesis testing. They do not address the questions related to the way qualitative researchers judge good work; for example, accuracy and breadth. This phenomenon is reminiscent of the situation of colonized groups who find that colonizers think that everything should be translated into their own language. Also, quantitative workers in the social sciences often require that qualitative work answer to their criteria—that is, reliability, representativeness of samples, and the using of comparison groups—rather than to the criteria that make sense within the epistemology of qualitative research.

Qualitative researchers might well use their own experience of marginalization when they consider work they are doing with marginalized populations. DeVault argues that qualitative researchers should avoid using routine research procedures that lead them to conventional understandings that are tied to the interests of the powerful. She also cautions qualitative researchers to include racial-ethnic positioning when they develop their analyses in qualitative studies. In *Liberating Method*, DeVault provides an example of her narrative analysis of an African American dietician that takes into account the situation of a woman of color who is being interviewed by a European American woman. DeVault notes that members of marginalized cultural groups learn skills that allow them to adapt their speech to different cultural contexts. Members of dominant groups have no need to develop this skill, for, like the quantitative researchers, they are confident that their speech is the standard, taken-for-granted way of speaking.

Participant observation provides a powerful qualitative method for understanding the social world of marginalized groups. Timothy Diamond, for example, studied the social world of workers and residents in nursing homes in *Making Gray Gold: Narratives of Nursing Home Care*. Diamond went to nursing assistant school and worked as a nursing-home assistant in several nursing homes over a period of years and gained precious insight into the social worlds of nursing assistants, most of whom were immigrant women, and nursing-home residents. Similarly, Elliot Liebow provides an incisive understanding of the situation of homeless women in *Tell Them Who I Am: The Lives of Homeless Women*. Liebow volunteered in homeless shelters for women over a period of time. He went to great lengths to provide homeless women with a voice in his research. He gave copies of his manuscript to both a homeless woman and a shelter administrator and included their comments about his analysis in the book.

The desire to study marginalized populations in an ethical fashion raises issues that may not be envisioned in codes of research ethics. For example, in studying captive populations, it may be more challenging while at the same time more important to preserve research participants' privacy and confidentiality. Such research may require the collaboration of officials and staff members, which may lead to the "pet" factor (i.e., where the researcher may be viewed as on side with officials) and once again, compromise confidentiality.

There are also particular ethical issues in the study of Aboriginal populations. Historically, researchers often collected information and stories from Aboriginal groups that they then took away with them. This practice has led to a concern of cultural appropriation as well as loss of voice and history. Researchers must be particularly cognizant of possible cultural differences (e.g., a focus on collectivities rather than on individuals) that may go unrecognized. Some writers have argued that anonymity in the reporting of research takes the voice and identity away from participants in research.

The Experience of Marginalization

One facet of marginalization is the experience of interaction with members of dominant groups. In fact, one might argue that one learns that he or she is marginal through how others treat or react to him or her. For example, as a woman becomes older, she will find that people begin to treat her differently than they did when she was younger. They may make comments about how young she looks for her age, feign surprise that she is old enough to have grandchildren, or joke with her on her birthday that she is decades younger than she really is. Remarks of this kind communicate to a woman that people now perceive her as old enough to be an appropriate target of these kinds of statements. At the same time, a woman in this situation will begin to feel invisible and may discover that her opinion is not taken as seriously as it used to be. In a sense, this individual is learning to be old through the way others treat her; that is, as a member of the marginalized group of older women. Nonetheless, some women report this experience as being liberating because they no longer have to worry about what others think about them.

When an older woman becomes a widow, she becomes doubly marginalized through being a member of two marginalized categories—old women and widows. Some scholars refer to this type of situation as double jeopardy, and an older widow who is a member of visible minority may experience multiple jeopardy. She may come into a research situation feeling a considerable level of uncertainty. The next few paragraphs illustrate how a widow's feelings of subordination affected the interaction in a primarily interview study of older women's widowhood experiences.

The Widows' Journeys

In the 2001 study, *The Widowed Self: The Older Woman's Journey Through Widowhood*, Canadian women over 50 who had become widows within the previous 10 years were asked to share their experiences in in-depth interviews. Scattered throughout the interviews are terms or phrases that characterized the women's speech and stories as intrinsically trivial. Consequently, several women used terms like "gabbing," "yakking," and "rambling" to describe their way of participating in the interview. Here are some examples of these self-deprecating remarks:

- Emily: I think I've said a lot of rambling and likely you've . . . already heard all of this.
- Betty: I'm spending a lot of time yakkin' to you for nothing. It won't do any good; it's just history.
- Eleanor: I haven't given you much chance to ask a question. I've been doing an awful lot of gabbing.
- Sarah: I've yakked on for quite a while here.

Interaction Strategies as Data

Deborah K. van den Hoonaard's 2001 *The Widowed Self: The Older Woman's Journey Through Widowhood* presents the results of an in-depth interview study in which the participants were Canadian women over 50 who had become widows within the previous 10 years. The questions were broad in order to encourage the women to explain what they thought was most important about their experience with becoming widows. Nonetheless, many participants asked for reassurance throughout the interview that they were being competent research participants. Questions about whether they were answering the questions correctly were interspersed throughout the interviews. In addition, some women were concerned that there might be a correct answer to a question or whether their answers made sense or were coherent.

It is possible to gain a better understanding of the shape of a group's marginalization by how they attempt to compensate for or guard against falling into stereotypic behavior. Using the example of older widows, the stereotype of older women's being overly

garrulous became visible through comments that they made during interviews suggesting they have internalized this stereotype. The women worried that they might be "gabbing on" or "yakking" too much. The women also indicated a concern that they might be straying away from the topic at hand.

Older women have a spoiled identity. Being an old widow means having an identity that is doubly spoiled. Widows recognize that most people do not want to hear about their experiences. Their approach to the interview situation and their desire not to talk too much or too negatively communicated aspects of the women's experiences as widows. They told of the precarious nature of the women's identity: at any moment they might have been discredited as competent research participants.

Older widowers, however, present a contrasting approach to becoming marginalized as older men and as widowers. One can gain an understanding of their situation by looking at the way they negotiate their role as interview participants. Van den Hoonaard studied the experiences of widowers over 60, most of whom were Canadian. Older men, especially widowers, in the interview situation worked very hard to present themselves as real, masculine men. They were reacting to a precariousness in their identities as men by using impression management to reinforce their masculinity.

The widowers' task was a difficult one, for there is no available, familiar image of being an old man and a widower that men can adopt in their presentation of self and still portray themselves as masculine. They used the symbols and practices borrowed from a repertoire of dominant masculinity they had learned in their youth. Analyzing the interactional strategies the widowers used as data makes visible the marginal, untenable position of old men who are subject to ageism and have no model of old masculinity on which to depend. The situation elicited a particularly forceful effort on the part of the participants to establish themselves as real men through taking charge of the interview by interrupting the female interviewer, using diminutive language to refer to women, lecturing the researcher about a variety of topics including the essential differences between women and men and older women's unattractiveness, and emphasizing their heterosexuality by referring to themselves as bachelors.

Some widowers used strong, masculine language and profanity that is not usually used by women of their generation or in the presence of women by men of their generation. They expressed their marginalization through an amplified demonstration of hegemonic masculinity.

Another example of an interview strategy that reflects marginal status comes from Deborah K. and

Will C. van den Hoonaard's ongoing interview study of non-European immigrants to the Maritime provinces of Canada. A very homogeneous population originating primarily from the United Kingdom and France characterizes this region. In the previous two examples, the marginalized groups included people who had previously been members of more dominant groups; that is, younger married women and men. In this case, the participants were members of a persecuted religious minority (i.e., Baha'is) who had come to Canada as refugees.

Unlike the participants in the first two studies, members of this group had occupied a marginal position all of their lives. Thus, they had not experienced the social process of becoming marginalized. Although the members of this group were socially marginal in their communities because they were both a religious and visible minority, they were in a more secure position than they had been in the past. Participants in this study were appreciative of the host community and reluctant to appear to be ungrateful for the improvements in their lives and aspirations. They expressed their marginality through describing examples of their overcoming prejudice rather than through complaining of their marginal status. For example, one woman spoke with pride about her solution to her neighbors' fears that she might be a terrorist by inviting that neighbor for a tour of her home.

These three examples viewed together demonstrate that members of marginal groups communicate levels of discomfort with their role in research that reflect their marginal social status. The ways the participants communicate and manage their discomfort can reveal a lot about being members of those groups and the social meaning of their status as members of marginalized groups.

The social process of interaction during interviews, when used as data, can contribute to an understanding of the way people, particularly those in marginalized positions, experience their everyday lives. Researchers can learn much by problematizing the interaction that takes place during interviews rather than taking it for granted or seeing it merely as a problem of methodology.

MARGINALIZED POPULATIONS

Marginalized populations are those excluded from mainstream social, economic, cultural, or political life. Examples of marginalized populations include, but are by no means limited to, groups excluded due to race, religion, political or cultural group, age, gender, or financial status. To what extent such populations are marginalized, however, is context specific and reliant on the cultural organization of the social site in question.

Acknowledging marginalized populations in research necessarily involves acknowledging unequal power relationships between groups within society. These power imbalances occur either within the research process or within society more broadly to shape the way research is conducted, interpreted, and acted upon. It is argued that, given the dominant voices that underpin quantitative research, research that aims to emancipate marginalized populations must be qualitative in nature. This belief is suggested, as qualitative research aims to "give voice" to participants and allow them to tell their stories. However, participants in qualitative research often remain as participants and are sought out by the researcher (rather than seeking out the researcher) to participate in the researcher's (rather than their own) agenda. As such, the research process remains deeply political, as researchers and participants may not share a common power base and may instead come at the issue from different perspectives. New approaches, however, challenge traditional demarcations between researcher and participants and provide new ways to both engage marginalized populations in research and use research to challenge marginalization in society.

Participatory research methods provide ways for both researchers and participants to identify research topics, gather evidence to illustrate these, and disseminate findings. As such, participatory research provides a framework for reflexivity during the research process to identify issues such as voice, representation,

vulnerability, and control. Often participatory projects also contain an action component where participants take an active role in deciding how the results are used to their own, and the researcher's, advantage.

Critical research methods provide another avenue through which unequal power relationships can be documented and challenged. Although some critical approaches are also participatory, often they assume more traditional researcher and participant roles and instead focus on exposing the underlying differentiations between groups and the social functions they perform. The advantages and disadvantages of these differentiations and the power hierarchies used to enforce them are scrutinized with the purpose of highlighting inequities and championing the cause of marginalized groups.

In conclusion, marginalized populations have come to be a focus of qualitative research, particularly for those examining oppressive social structures, such as critical researchers. Researchers working with marginalized populations should be acutely aware of the political nature of their research and seek to minimize the power differentials. Action and participatory research methods have been identified as offering the most promise to dissolve traditional research hierarchies.

brands, or services within that market—to help organizations make better business decisions. Finding out what the customer (current, past, or potential) wants lies at the heart of market research. Often organizations think, or assume, that they know what their customers need and want and how their products and services are perceived. Market research can deepen this understanding and can also raise questions about the assumptions that organizations make about their customers. It provides a dispassionate and structured perspective that enables organizations to better understand their customers and, as a result, to develop products and services that more closely match their needs. Data obtained from market research is fed into a broad pool of information, such as sales and economic data, trends, and predictions, which are gathered from a variety of sources. This information pool is used by marketers or strategists within the organization to help develop corporate strategy and consumer communications.

However, over recent decades, the role of market research has broadened, and it has moved away from a purely data-gathering function. Currently, market research is often used to help identify potential opportunities for the future. Instead of data, market researchers are increasingly expected to help develop ideas and concepts that are an extension of the data and that help clients to develop their markets. Many market researchers and clients view research as a creative process, which is useful when developing new products, services, brands, or advertising. It can also be used to help define organizational strategy. Although the core qualitative skills of moderating, analysis, conceptual thinking, and presentation are just as relevant from this creative perspective, they are applied to different methodologies, such as brainstorming, creative thinking sessions, idea generation, and evaluation. Sometimes this approach is called *marketing research* to differentiate it from *market research*.

Adopting this broader definition, marketing research is seen as a process of helping clients (whether commercial or noncommercial organizations) to better understand their target audiences; to help create, develop, and fine-tune their products or services; and to more precisely tailor their communications for this target audience. Consumers are involved as active participants in this process rather than as sources of information. They work with the researcher to develop ideas or help shape the ideas developed by the client. At the same time, research has broadened its scope—for example, it may involve

MARKET RESEARCH

Traditionally, market research has been understood as the process of gathering, analyzing, and interpreting data about a particular market—and the products,

input to organizational restructuring, employee communications, and external communications as well as specific products, brands, and services. There is a strong consultancy component that is implicit in this way of understanding market research.

However, there are researchers who would regard these areas as outside the remit of market research. These researchers feel that the role of market research should predominantly remain within the area of data gathering to preserve its authority by providing objective and scientifically based input. This is a time of change for the market research industry, and it is therefore difficult to clearly define the borders of market research.

To a large extent, these two different perspectives reflect philosophical directions in society as a whole. Traditional market research has grown out of a scientific model. Marketing research, which is more concerned with usefulness than scientific rigor, has grown out of social constructionism and postmodernism, with their emphases on context, interpretation, and the speed of change and innovation. Qualitative market research in particular often adopts a social constructionist perspective and has its theoretical basis in phenomenology and ethnomethodology. These perspectives explore how the social world is constructed by people rather than by assuming that social relations are given.

Market Research Within the Broader Field of Research

Market research needs to be differentiated from the broader area of research. There are large areas of research, mostly in the academic field, that bear little relationship to market research. Market research implies research that is conducted as a commercial activity by specialist market research practitioners. However, this definition does not necessarily mean that the research is carried out solely for commercial organizations. Although market research techniques were developed largely to cater to commercial-sector needs, they have spread into almost all areas of contemporary life. Commercial research now includes research conducted by professional researchers for noncommercial or not-for-profit organizations; for example, central government, charities, broadcasters, educational, and health services. It is also conducted within organizations, helping to shape corporate change and employee communications, and it is carried out to examine the interaction between staff and customers, with a view to improving staff–customer

relations. It has been carried out among almost all occupations, among children, and among different ethnic groups, nationally and internationally.

It is also important to note that the focus in market research is quite different than that of academic research. The value of commercial market research rests largely on the usefulness of the findings themselves—rather than the methodological approach. By contrast, in academic research, the methodological and theoretical knowledge gained through the study is regarded as at least as important as the findings. One consequence of this difference in emphasis, which is discussed above, is that commercial researchers have developed approaches that go beyond research into the area of idea generation, creativity, and consultancy to better meet the needs of their clients. Commercial research also differs from academic research in terms of project size and time scale. A commercial project may be quite small-scale and completed in a month or two—and researchers may be involved in 10 or more diverse projects over the course of a year. An academic study is more likely to be extensive in scope and to take much longer than an equivalent commercial study.

What Do Market Researchers Do?

Essentially, a market research project, in very simplified form, involves the following elements:

- An organization (the client) identifies a need for information about an external group, such as its current and potential customers or users of a particular product or service. The client believes that this information can be gained by interviewing and/or observational, ethnographic, or other participant data-gathering methods.
- A researcher or team of researchers, usually specialists from an outside research agency, is invited in to discuss the issues or problems with the client team at a briefing meeting. The project will be discussed and the research objectives will be refined. A project design will then be decided. This design includes details of the basis on which research participants are selected (the research sample).
- In interview-based research (the dominant methodology in commercial research), the research agency will arrange for the appropriate research participants to be recruited. In observational or other field methods, the researcher will engage in detailed observation of people or situations or ask research

participants to carry out specified data-gathering tasks, as agreed on with the client. These tasks may include unstructured interviews. These activities are known as fieldwork.

- Often, in interview-based work, researchers will use a topic guide, which outlines the key areas that need to be covered in the research. However, this guide is an aide-memoire, not a questionnaire. The researcher will amend and refine their inquiry as the research process develops. The aim is to elicit useful and relevant information, not to produce answers to pre-prepared questions.
- The material that is produced from the research—audiorecordings, videos, notes, drawings, and so on—is then analyzed and interpreted. This process involves intensive immersion in the data to draw out overall meaning and highlight its relevance to the concerns of the client.
- The researcher then presents the findings, conclusions, and recommendations to the client in a presentation or debrief and sometimes followed by a written report.
- The project may be followed up with workshops within the organization. The purpose of the workshops is to disseminate the findings and encourage different interest groups to draw out the implications of the research for their own work.

Market Research Methodologies

There is a host of different market research methodologies, although all of these are rooted in either a quantitative or qualitative approach, as in academic research. Quantitative research is concerned with numbers: the proportion of people who do, say, think, and behave in a particular way—the classic survey research. Qualitative research is concerned to know not only what people do, but also why they do it; not what they want, but why they want it. In this sense, it is the “softer” side of research. Although research projects may be complex, with mixed or hybrid methodologies, they are usually able to classify the various elements of a market research study as either qualitative or quantitative in focus. As qualitative and quantitative methodologies are discussed in detail elsewhere, this section will outline the ways in which market research methodologies differ from academic approaches.

In the past, qualitative and quantitative market research were treated as more or less separate entities. Qualitative research could either be employed as an initial research stage, followed up by quantification, or

the two approaches were used separately, depending on the nature of the research problem. Increasingly, qualitative and quantitative approaches have come together, with the realization that they offer different perspectives rather than being opposing approaches. As a result, mixed methodologies are now common.

This mix is part of a general broadening of approaches, which has been particularly marked in qualitative methodologies. Until the past few years, qualitative market research was largely synonymous with focus groups and in-depth interviews and did not have the breadth and methodological focus of academic research. This tendency was driven largely by time pressures—groups are fairly quick to set up, analysis can be carried out fairly quickly by the researchers involved, and groups are easy and convenient for clients to view. However, this emphasis on group work is changing for a number of reasons; for one, it is a result of more marketing-literate consumers due to client demands to experience the consumer firsthand and because of concerns about the artificiality of the interview situation.

Within market research, and particularly within quantitative research, new technologies are having a growing impact. For a start, a whole new field of research topics has been created around internet usage. However, technology has also had a wide impact on methodologies. Online interviewing and focus groups, blogs, self-completion questionnaires online, and so on are changing the relationship between the customer, organization, and, often, the research agency. It is too early to gauge the effects of these changes on the market research industry.

Market research is a fast-moving industry and has become fragmented, with different sectors catering to different client needs. This fragmentation is likely to continue in the future as the market research sector continues to grow and diversify. As Philly Desai points out, we live in a time of rapid social change and declining trust in authority. This cultural change has created challenges for research, which has traditionally relied on relatively fixed categories of identity that are assumed to remain stable over time. From a postmodern perspective, this can no longer be assumed. Market research is going through a process of reassessment in order to deal with these changes.

MAXQDA (SOFTWARE)

MAXqda is a computer-assisted data analysis software program, which originates from a program called MAX that was developed in the mid-1980s. This entry relates to MAXqda2, released in 2004. MAXqda is user-friendly with many quick-access buttons that facilitate the

MAXqda Windows Screen View

Source: Copyright MAXqda; used by permission.

coding and analysis process. The program only handles text files in rich text format, but these may contain graphics. Text cut from documents or websites can be pasted to create new documents. MAXqda supports and facilitates the development of a hierarchical code system, which may be useful for grounded theory analysis. Alternatively, all codes can be entered as first-level codes to avoid a code hierarchy.

The coding process in MAXqda is quick and flexible. Once a segment is selected, coding can be done by selecting and clicking a code or by dragging the segment to the code. Once a code is selected, it can be attached to successive segments with a single click. In vivo coding can be used to create codes from words in the text. There is also an undo function for removing assigned codes. In MAXqda, the user-interface default setting integrates four viewers: documents, codes, text, and retrieved segments in a single screen; this ability keeps the researcher close to the data. Codes are displayed in the margin of the Text Browser in different colors that can be chosen by the researcher. The coded transcript can be printed.

MAXqda enables relatively sophisticated manipulation and analysis of codes. Complex code combinations, using Boolean logic and user-defined proximity relationships, can be identified and retrieved. Analysis of code co-occurrence is facilitated by the Code Relation Browser, which graphically depicts the code coincidence, while the Code Matrix Browser shows the occurrence of codes or selected codes by source. These tools are quickly accessible as buttons on the user interface. Autocoding is possible, although the size of the autocoded segment is somewhat less flexible than in some packages.

An unusual feature is the inclusion of a code-weighting facility. Weights from 1–100 are user-defined and can be used to indicate the degree to which a code is relevant. The weighting factor can be used as a filter when retrieving segments and adds a degree of flexibility compared to a more conventional categorical coding system. There are two supplementary programs available: MAXdictio, which provides word-frequency counts for quantitative content analysis, and MAXmaps, a mapping tool. MAXqda 2007 has many new features, increasing flexibility and visualization of codes and code relationships.

MEANING

The word *meaning* denotes an association between at least two semiotic elements: (1) something that expresses or represents something else, and (2) something that is expressed or represented. Following Ferdinand de Saussure, structuralist semioticians call (1) above a *signifier*, and (2) a *signified*, and their unity a *sign*. Within structuralist perspectives, meaning is often seen as arbitrary. For example, although it is known that the word *dog* refers to quadrupeds of the canine family whereas the word *cat* refers to their feline counterparts, any other words or combinations of sounds—such as *chien* and *chat* in the French language—can function equally well as long as their use becomes commonly shared. Although most signifiers stand in arbitrary relationships with their signifieds, structuralist theories posit that meanings are generated by complex systems of signification based on formal and abstract rules. These rules give birth to meaning by creating structures of opposition. Thus, for example, one understands the meaning of the word *white* in association with, and in opposition to, the meaning of the word *black*. Theoretical perspectives derived from structuralist semiotics, such as the structural anthropology of Claude Lévi-Strauss, the social theory of Louis Althusser, and the psychology of Jacques Lacan, tend to view meaning as relatively stable across time, relatively fixed in the deep structures of language and culture, and relatively independent of individual instances of situated speech.

Even though structuralist theories of meaning have been dominant in the social and cultural sciences, over the past 3 decades their hegemony has been considerably weakened by the advent of post-structuralism (which emphasizes polysemy—or the multiplicity of meaning—and the power of interpretation) and the renewed interest in pragmatism. Together with pragmatism and some versions of post-structuralism (like social semiotics and the cultural theory of Michel Foucault and Mikhail Bakhtin), phenomenological, hermeneutic, pragmatist, and

constructionist perspectives tend to differ from structural theories of meaning in important ways. From within these perspectives, following the work of semioticians like Charles Sanders Peirce, one can understand meaning to be emerging from a triadic relation between an object, a sign vehicle that expresses that object, and the sense that someone makes of this association. Because interpretation is always situated in contexts defined by historical, ideological, economic, spatial, and technological boundaries as well as embodied in social beings, the concept of meaning here takes on more dynamic features. For example, within pragmatism and symbolic interactionism, meaning lies in the response to an act; within phenomenology, meaning originates in the lived experience of being in the world; and within hermeneutic perspectives, meaning arises from awareness of contexts and the dialectical relationships between contexts and texts. Supporters of these perspectives—despite their subtle differences in emphasis—tend to agree that meaning is actively constructed and renegotiated by social agents interacting with one another. Meaning is thus relative, open to interpretive freedom, and transformation; meaning varies across contexts, groups, and instances of speech.

MEMBER CHECK

The member check (also referred to as member or respondent validation) is a strategy most often used to optimize the validity of qualitative research findings. Research participants are asked to evaluate one or more of the following: whether (a) researchers accurately rendered their experiences that were the target of study, in the service of what Joseph Maxwell described as *descriptive validity*; (b) researchers fully

captured the meaning those experiences had for them, in the service of what Maxwell called *interpretive validity*; or whether (c) researchers' final interpretive (e.g., ethnographic, phenomenological) accounts of those experiences do justice to them, in the service of what Maxwell called *theoretical validity*. Here the member check constitutes what Jeasik Cho and Allen Trent described as a transaction between researchers and participants whereby data are played back to participants to ensure that researchers get it right: that their understandings correspond with those of the participants from whom those data were derived. Members' evaluations are the gold standard against which researchers' analytic and interpretive efforts are judged.

When conceived as an instrument of validation, member checking may be embedded in primary data collection procedures as, for example, when researchers ask participants to elaborate on or clarify what they have said in interviews or done in observed scenes or when researchers sum up what they have heard at the end of an interview or seen following an observation session and then ask participants to comment on the accuracy of these summaries. Member checking here is an ongoing process that is integral to data collection, as opposed to a separate procedure. Member checking can also be a separate event occurring some time after primary data collection has been completed with each individual participant, as soon as some analysis has been completed of that participant's data, or after all data have been collected and partly or fully analyzed in a study. Member checking may be conducted with all of the participants in a study or with a purposefully selected sample of them.

The Debate Over Member Checking

Member checking is a controversial practice as it embodies what is commonly referred to as "the crisis of representation," or the problem of how faithfully to render the lives of others. Member checking raises a host of epistemological and ethical questions, most notably: What data or interpretations are research participants in a position to validate? What is the right course of action should participants decide researchers got it wrong? Does a member's refusal to validate a researcher's interpretation invalidate it? Is member checking appropriately conceived as a validation enterprise at all?

Although participants are certainly experts regarding their own lives, they may not be able to authorize summaries and interpretations of data that encompass other people's lives. If these interpretations are in the form of theories, phenomenological descriptions, or other renderings intended for audiences of qualitative researchers, they may be totally inaccessible to participants. Whether participants can certify the "truth" of a text depends on what text they are shown. Participants may not necessarily be in a position even to verify data-near texts, such as transcripts or descriptive fieldnotes, derived from their own lives. Participants may have forgotten what they once said or did, regret having said or done it, and therefore see the member checking process as a way to erase the past. Seeing transcripts of what they said in the past may engender discomfort in participants. Yet, participants may also validate researchers' interpretations out of a desire not to offend researchers or be completely uninterested in such an exercise. Moreover, narrative accounts are themselves inherently revisionist as every telling of an experience leads to a retelling of it. Accordingly, participants' accounts of an event offered at different times, and even within the same interview session, may be inconsistent as they are constantly being revised in the very act of telling. These are only some of the reasons scholars have increasingly proposed that member checking is less about optimizing validity and more about an opportunity for further reflecting on members' own experiences and for self-transformation.

The member check is located in the highly contested terrain between voice and discourse, or between interpretive and theoretical validity. A prime directive in qualitative research is to "give voice to the voiceless," yet participants' voices are muted when researchers represent their lives in ways they had not anticipated or that they find offensive. Whenever members feel that researchers have misunderstood them, researchers are faced with the serious issue of narrative ownership as they must decide, for example, whether members' refusal to authorize an interpretation means that researchers must abandon it and whether this abandonment serves the interests of either knowledge development or social advocacy.

The member check requires researchers to clarify its purpose and how it will be accomplished. Researchers must decide exactly what will be checked by whom, and what influence the outcome of this

process will have on the findings of the study. The inherently narrative nature of human beings and social nature of the research enterprise make the member check a practice to be used with caution, discernment, and regard for both getting it right and doing the right thing.

MEMBERSHIP CATEGORIZATION DEVICE ANALYSIS (MCDA)

Membership categorization device analysis (MCDA) is a qualitative methodology that aims to describe the processes involved in the way members of society invoke and use categories to organize and understand the social world. MCDA was developed by Harvey Sacks alongside his work on conversation analysis. MCDA is part of the ethnomethodological tradition where the data are treated as the topic of analysis. Attention is paid to describing the underlying structures and procedures employed to accomplish the activities under study.

Membership categorization is a fundamental part of social activity and as such is also a moral activity. It is used to attribute social identities and attain social order. Investigating members' use of categories and devices in any setting (e.g., news story, everyday conversation, interview account) is a means of showing how identities, social relationships, and institutional phenomena are produced.

If one wants to describe members' activities and the way one produces and organizes them, one needs to establish how he or she chooses among the available category sets for grasping some event. MCDA does this by constructing the machinery that would produce the actual occurrences that are part of social life. Take as an example a simple sentence, "The baby cried. The mommy picked it up." This sentence is the focus of a seminal paper by Sacks in which he describes the basis of MCDA. One can begin to examine what it means and, importantly, the rules that underpin this understanding. The mother picking up the baby is heard to be the mother of the child. The mother and child are recognized as a pair of related categories. This meaning is evident as it is a standard type of pairing. The fact that the mother picks up the crying baby also infers that this activity is bound to her role as a mother. It is the responsibility of a mother of a child to attend to the child if he or she is crying. This inference exemplifies the way in which one attends in daily life to members' methods for producing a world that one recognizes as orderly and moral or as rule-governed.

When people do description, they use categories from a collection; for example, family (mother, father, children). This process is called a membership categorization device (MCD). A collection will contain at least one category that may be applied to a population containing at least one member. Using rules of application, the collection of membership categories provides for the pairing of at least one population member and one categorization device member. An MCD is then a collection plus rules of application. Sets of categories are inference rich in that they store a great deal of the knowledge that members have about their society. Members generate and use categories in their descriptions, such as in interview accounts or newspaper stories. Description is done through the selection of particular categories and the setting up of particular rules (social norms) regarding their use.

Categories can be related to each other; for example, as pairs that may be contained in a collection

containing laypeople. This collection will contain a set of rights and responsibilities concerning the activity of giving help (between laypersons). Another collection of categories may be set up composed of laypeople and professionals. These will be set up as two separate classes. The professional class is constructed by reference to special distributions of knowledge existing about how to deal with some trouble. An example of a professional class would be medical doctors. Accordingly, they have special rights for dealing with some trouble; for example, illness. In such a context, all those who are not professionals are laypeople. So, for example, analysis of patient interview accounts about the experience of health care may reveal how laypeople construct the respective roles and responsibilities of patients and doctors.

The Research Process

MCDA can be carried out on most types of discourse. The starting point for analysis is to treat the data as the topic of investigation. The next step is to become familiar with the data through reading and rereading and to identify central categories such as people and places. This step will enable the location of standard relational pairs such as doctors and patients or contrast pairs such as patients happy with their care and those who are not. These categories are sometimes explicit, or they may be implied through the activities happening in the discourse. The following stage is to describe the activities associated with each of the categories. What is inferred is important as well as what appears to be explicit. Reference to Sacks's work on the different types of rules used in membership categorization may be useful at this stage. At this point, one can look closely at the categories together with the work associated with them to describe the social actions that are implied. For example, in studying an interaction between a doctor and a patient, the responsibilities associated with the respective roles may become evident through the way patients describe their experience of consultations with doctors in qualitative interviews.

Value and Limitations of MCDA

MCDA research may be aimed at academic and applied audiences. Studies may focus on the specifics

of social interaction revealed in the analysis that will add to a particular body of academic knowledge; for example, studies of everyday conversation. Research may also be conducted to develop understandings of institutional phenomena, such as health care.

It is important to emphasize that MCDA is a methodology that entails a method, rather than a technique that can be applied atheoretically. It is therefore most appropriate to in-depth data analysis.

MEMOIRS

Memoirs, or life stories, are collections of significant or memorable events in one's life that are captured in narrative form. The researcher or author is the main character of a chronological or fragmented story that highlights significant or memorable events during the research or author's personal experience in the field. Memoirs are based on a compilation of information gathered during the process of discovery and the process of writing. These stories can be written from fieldnotes, journals, taped interviews, transcripts, and memory.

Memoirs hold collaborative potential as a research tool because they represent the researcher's knowledge and understanding of a particular subject matter; they can also be used as research material. Some researchers have relied on memoirs to serve as data for projects and opportunities to get an insider view of the field they are studying.

Writers make themselves vulnerable by reflecting on their experiences in the field, reflections that include uncomfortable situations and potential biases they may have had prior to the study, exposing themselves as a participant in their own research endeavor. The negotiation of the writer's positionality becomes a part of the story being told and details that would not be included in the final research report are detailed in the memoir of the research experience. Memoirs require authors to name their experiences, identify commonalities, and make personal judgments, giving the reader the insight of the researcher's point of view and the benefit of his or her experience. Memoirs reflect research scenarios, techniques, and potential outcomes that prepare researchers for the field experience and the postfield experience.

Memoirs require writers to have the capacity to write evocatively with amazing detail and description, merging the immediacy of their experience with the intellectual jargon of their field. As a research method and approach, memoir writing can be beneficial and therapeutic for the writer, but some of the limitations of the method include the focus on a single experience and interpretation of an experience that might lead to overgeneralization or dismissal of other experiences.

"I Offered My Heart": Excerpt From a Memoir

If and when I fall in love, she never promised it would last, only laughed at the possibility, pretending to know how pitiful and desperate I would become, how sprung and wide open I would be. My mother envisioned an attractive man with a ridiculous name. She warned me to guard my heart and not wear it on my sleeve. Importantly, I must learn how to dress for church, how to wear a slip, how to put on stockings. Defiantly, at eighteen I stopped wearing slips, and was undoubtedly labeled a hussy when a staring eye could detect my pantyline. My heart, because it didn't understand the logic of caution, was unguarded, unprotected from the honey smooth lines of a pretty man. Needy for the love and affection I could only get from a man, I offered my heart as a token of my affection, and usually had it returned, broken.

Another concern for memoir writers is that the story has the capacity to implicate identifiable characters in the life of the author. In order to protect the integrity and anonymity of characters, these stories occasionally include some fictional elements and pseudonyms.

Though the story focuses on a specific event or a turning point, it also tells the overall story of a life over time, including predictable everyday life occurrences. Memoirs are somewhat one-sided because even though they may consider and mention alternative perspectives, the voice, truth, and ideology of the author is privileged. Memoir-style writing is used in qualitative approaches such as autoethnography, reflexive ethnography, and narrative inquiry.

MEMOS AND MEMOING

Memoing is the act of recording reflective notes about what the researcher (fieldworker, data coder, and/or analyst) is learning from the data. Memos accumulate as written ideas or records about concepts and their relationships. They are notes by the researcher to herself or himself about some hypothesis regarding a category or property and especially relationships between categories. These memos add to the credibility and trustworthiness of qualitative research and provide a record of the meanings derived from the data. There are no rules pertaining to memoing; however, each memo should contain one idea and should be dated and referenced. Memos

evolve as the research proceeds and may differ substantially in style and manner.

Unfortunately, the human mind tends to forget much that has been experienced or observed at quite a rapid rate. When doing research, some method is needed to overcome this tendency, as recalling details is an extremely important contributor to the qualitative research process and its credibility. Credibility can be defined as the confidence that can be placed in both the data and the analysis. Credibility is synonymous with validity in quantitative research. One of the means to enhance credibility is to jot notes. As the researcher cannot rely on memorization, jotting notes adds to the defensibility of the results. However, the research setting does not always allow for jotting notes, and memoing can even compromise the credibility in certain situations, in which case mental notes must be made. Unfortunately, these electrical traces in the brain have an even higher rate of decay. By jotting down cursory phrases, quotes, key words, and the like, during inconspicuous moments, the researcher can jog her or his memory when comprehensive fieldnotes are later compiled.

Another important use of memoing is for qualitative data analysis purposes, such as in ethnography and grounded theory. Ethnography is a form of qualitative research that focuses on the discovery and/or comprehensive description of the culture of a group of people. Grounded theory is another form of qualitative research that aims at generating and developing a theory from data that are systematically gathered and analyzed. In both ethnography and grounded theory, data analysis happens at two levels: textual and conceptual. The first entails reading the complete corpus of field data and memoing throughout. Barney Glaser has emphasized that memoing is prioritized, or stated differently, when an idea occurs and the researcher pauses and records it. This process is often referred to as *open-ended coding*. It is as if the researcher must build a puzzle without a picture and starts sorting through the pieces of data. As the researcher forms ideas, they are written down as memos. Theoretical memoing is about attempts to derive meaning from the data. Methodological or operational memoing comprises reminders, instructions, or critiques that the researcher writes to herself or himself as the analysis unfolds. The conceptual level entails theorizing about concepts, categories, properties, and themes and the relationships between these. This theorizing is often referred to as *axial coding*, and integrative memos are used. The researcher begins to fit the

pieces of the puzzle together. Sometimes a piece that initially appeared to fit is discovered not to fit. As the researcher becomes more theoretically sensitive, the fit between conceptual pointers and categories becomes easier. It is quite feasible that initial memos later appear rather naive and erroneous as the researcher gains a better understanding and interpretation. However, the two levels mentioned are never clearly demarcated. The analysis is mostly simultaneous or parallel and often entails recurring phases of data collection, coding, memoing, and sorting. Memos help the researcher to achieve an analytical distance from the raw data and force the researcher to conceptualize.

Memoing involves total creative freedom. There are no rules regarding writing, grammar, or style. A memo is purely an instrument to capture the outflow of ideas, insights, and observations. When the researcher writes the thoughts down, they become concrete, and they are recorded. There are no wrong or poorly written memos. Each researcher develops her or his own style. Memos evolve and increase in complexity, density, clarity, and accuracy as the data analysis progresses. Memos written later may negate, amend, extend, and/or clarify earlier written ones. Memos keep the researcher embedded in the empirical reality and contribute to the trustworthiness of qualitative research. Trustworthiness is synonymous with reliability in quantitative research. For this reason, regardless of time constraints, memoing should never be regarded as superfluous. It is a very important element of qualitative data analysis.

There are a few hints or technical features for good memoing. It is not advisable to write in the margins of transcripts or fieldnotes because initial notes might call for review and might result in confusion. Memos should always be dated and referenced with regard to what they refer to. Memos should contain a heading and should be cross-referenced. A list of emerging codes should be kept handy to avoid duplications. Memos are never about people, but rather about conceptual ideas derived from incidents. Researchers should never be hesitant to modify existing memos. Restrict each memo to one idea. If two ideas are together on one card, this complicates the sorting later.

Diagrams are graphic memos and play a very important conceptual role. Diagrams are visual devices that depict something. They illustrate the density and complexity of the qualitative analysis. A diagram helps the researcher discover gaps and flaws in the relationships of categories and of the logic. Often diagrams are preceded

by listings, especially early in the analysis process. These listings provide a foundation for diagrams.

There are several versions of personal computer software packages available for qualitative data analysis that lend themselves to memoing. There are also blogs on the internet that the inexperienced user may access for tips and ideas regarding the use of such software. Some programs further enable the researcher to graphically display and examine both hierarchical and relational connections among codes.

META-ANALYSIS

Meta-analysis is generally defined as the analysis of analyses. The term generally is associated with quantitative methodologies, but it does have qualitative analogs. This technique is distinctly different from secondary analyses where the original data from a study are reanalyzed.

Meta-analyses can be separated into two categories: integrative and interpretive studies. Integrative studies focus on summarizing the data and are usually

quantitative in nature. Interpretive studies focuses on developing concepts and operationalizing concepts a priori. Interpretive analysis can be carried out using quantitative and qualitative approaches, does not have a priori concepts to test, and leads to the development of new interpretations from the analysis of multiple field studies. The goal is not to aggregate the data (e.g., determining and overall effect size) but to reinterpret.

Quantitative meta-analysis reviews statistically a collection of analyses from related individual studies in order to provide a summarization or integration of the results. The core of this review is the calculation of an effect size. The effect size can be based on the difference between two groups divided by their pooled standard deviation or a correlation between two variables. Gene Glass's work is the point where quantitative meta-analysis, in its current form, became a popular integrative methodology, but he was not the first to use quantitative techniques to integrate research observations.

Qualitative meta-analysis also involves the synthesis of evidence from primary studies, but there are numerous forms of synthesis with different goals, though most are interpretive techniques. Meta-ethnography, meta-study, realist synthesis narrative summary, thematic analysis, and cross-case analysis are some examples.

Meta-ethnography is comprised of three techniques for synthesizing qualitative studies: reciprocal translation analysis, which is the identification of key metaphors or themes in studies; refutational synthesis, where key metaphors or themes are identified and contradictions between studies examined; and lines of argument synthesis, where a general interpretation is developed based on the observations in the separate studies.

Meta-theory, part of the meta-study group of techniques, along with meta-method and meta-data, is a critical analysis of specific theoretical frameworks. Meta-method is an analysis of the methodologies utilized and how the methodologies affect specific research areas. Meta-data is a synthesis of data presented in articles and reports.

Realist synthesis is a theory-driven technique for synthesizing evidence. The technique uses a wide variety and types of data in a support or refutation model of a specific theory. Narrative summary allows for the selection and description of primary studies along with interpretation. Mathew Miles and A. M. Huberman provide systematic multiple strategies for

intercase synthesis such as meta-matrices for clustering and separating data.

META-ETHNOGRAPHY

When several studies deal with the same topic, the researcher may want to analyze the relationship between them by carrying out a research synthesis. Meta-ethnography is an approach to research synthesis that is especially appropriate for qualitative studies. It is important to understand its history as a genre of research synthesis, how meta-ethnography maintains the fundamental assumptions of qualitative research, the types of syntheses possible, and what other qualitative approaches have been developed from meta-ethnography.

The growth of research in education and social and behavioral sciences in the 1960s and 1970s made research synthesis a key topic in the late 1970s and early 1980s. This interest was sparked by a range of developments including the reemergence of qualitative research methods, expansion of research funding, and a shift in universities to emphasize scholarship. As the volume of studies expanded, methodologies for synthesizing this research also developed. On the quantitative side, meta-analysis was developed. On the qualitative side, meta-ethnography was developed to avoid what was seen as the tendency of quantitative studies to simply add or aggregate results. In anthropology, there has been an ethnology tradition, but it

was linked to a theoretical school that was in decline because of its inability to explain conflict. As the number of qualitative studies increased, the pressure was to say what this burgeoning scholarship was yielding.

George Noblit and Dwight Hare in their 1988 book, *Meta-Ethnography: Synthesizing Qualitative Studies*, argued for an approach that focused on engaging the theoretical or interpretative schemes each study employed. To avoid simple aggregation, they used a translation theory of explanation in which the metaphors or themes of each study would be translated into the terms of the other studies. The process then involved translating the set of metaphors or themes from each study into each other. Three types of synthesis were identified. A reciprocal translation is used when the studies seem to be addressing similar ideas. The synthesis task then is to either decide which set of metaphors can subsume other sets or develop a new set of metaphors that can account for all the studies involved. A refutational synthesis is appropriate when studies disagree on key points, and the synthesis task becomes specifying the nature of the refutation and its salience. A line of argument synthesis is when studies are not fully commensurate but speak to different aspects of a larger phenomenon. The synthesis task is to specify the larger phenomenon and how the various studies can be taken as a line of argument about the nature of the larger phenomena.

Meta-ethnography has led to a family of similar techniques including meta-study and meta-synthesis as well as grounded theory approaches. Each of these approaches has developed in response to a particular set of interests and all remain important. Meta-ethnography is being used in fields such as medicine, medical sociology, nursing, and education. This has been in part spawned by interests in evidence-based practice. However, this usage is controversial because it requires a theory of the relation of research to practice that is unspecified. Meta-ethnography has also been used to advance theory. Yet theory is used in different ways in different qualitative approaches, and the ramifications of this usage needs to be explored. Finally, history needs to be conceptualized as meta-ethnography is used to speak about studies over time.

META-NARRATIVE

Meta-narrative can be understood in two ways: (1) as a narrative *about* narrative or (2) as a narrative *above* narrative. Both understandings are discussed in this entry.

A narrative is a story that describes a particular sequence of events in the context of particular characters. The content and structure of narratives are deliberately (although sometimes unconsciously) selected to support a particular point of view and to encourage a particular interpretation or understanding. The analysis of narrative—that is, the narratives constructed in the course of thinking about narrative—creates meta-narratives. Thus, for example, when Robert McNamara reconsidered the Vietnam War in his book *Argument Without End: In Search of Answers to the Vietnam Tragedy*, he created a meta-narrative about the Vietnam War. When Errol Morse made the film *Fog of War* about McNamara's book, he created a further meta-narrative on both the war and McNamara's views of it. Similarly, researchers who use narrative analysis to study family caregiving or teaching may construct meta-narratives in the course of their analyses.

Postmodern thinkers have identified meta-narratives that function not only as explanations but also as mechanisms of social control. These meta-narratives, which may include classic texts (e.g., the Bible or *The Little Red Book of Mao Zedong*), archetypal accounts (e.g., stories of scientific discovery or “rags to riches” biographies), or grand, cultural epics (e.g., *The Ring of the Niebelungen* or *Gilgamesh*) form the basis for the totality of a society's beliefs. Meta-narratives, according to postmodern thought, function in society as universal and absolute truth. Jean-François Lyotard, who developed the concept of grand or master narratives, asserted that the most pervasive of all stories was the emancipation narrative, which asserted that the whole of history makes sense and furthermore is a history of progress toward some greater good. Postmodernists reject meta-narratives and, in particular, the notion of any universal, overriding, decontextualized truth, positing that such

beliefs should be replaced by more local, contextual, and limited accounts of society and the world.

Lyotard's concept of the emancipation narrative can be seen in the view of normal science described by Thomas Kuhn as a paradigm, and some scholars equate meta-narratives with paradigms. As such, meta-narratives provide an organizing framework for knowledge and, through this mechanism, distinguish between knowledge that is legitimate and knowledge that is unjustified. People may also organize their experiences according to a meta-narrative. For example, the meta-narrative of psychoanalysis structures an individual's childhood memories differently from the meta-narrative of symbolic interactionism.

METAPHOR

In its most basic form, metaphor is a rhetorical trope, or figure of speech. As a trope, it is keenly related to two other tropes—simile and synecdoche. In the case of synecdoche, an entity is equated with one of its most important parts. For instance, a *car* might be described as one's *wheels*. With simile, one object is described as being like another (usually unrelated) object. For example, one could say that a *rose* is like a *lover's tears*.

Metaphor is a very powerful trope. In the case of metaphor, one goes beyond the mere comparisons of simile and actually equates two objects that are on the surface not related. By doing so, one often forces the reader to consider some aspect of the main object that might not come to awareness without this powerful

equating process. Here is an example—my *dog* is my *lighthouse*. In literal terms, this sentence is simply false and most likely meaningless. In metaphorical terms, it highlights the role of the author's dog as a beacon of stability, safety, and protection.

Over the years, awareness of metaphor has extended well beyond its basic role as a figure of speech. In particular, there has been a long and complex conversation on the role of metaphor in meaning. For analytic philosophy, metaphor was a difficult puzzle to solve; the insistence of the role of denotation and other literal modes in meaning made such figurative approaches as metaphor problematic.

Figurative approaches to meaning in general, and metaphors in particular, have played an important role in qualitative research, both in terms of writing up results and in conceptualizing findings. First, qualitative researchers need to be sensitive to the metaphors their informants use in their field studies. These metaphors are often important clues into the interior lives and meaning patterns of these informants. Second, metaphors are often encoded in the ordinary ways of looking at things. These are called *dead metaphors*. Common dead metaphors include *table legs* and *eyes of needles*. Reflecting on dead metaphors, especially those from different cultures, often reveals deep-seated differences among cultures. Finally, metaphors are powerful writing tools in that they allow one to foreground important findings in a vivid and economical fashion. The most extensive theoretical treatment on metaphor, and one that has extensive practical application to qualitative research, was conducted by George Lakoff and Mark Johnson. Lakoff and Johnson powerfully assert that all thought is metaphorical. These metaphorical dimensions can be orientational (good is up), structural (arguments are war), or ontological (mind is a machine). Identifying these sorts of hidden metaphors in ordinary discourse and conceptualization has extensive practical potential for qualitative theorists and researchers.

Finally, there is also a potentially fruitful interplay between qualitative research and semiotics in the area of metaphor. In particular, metaphors are clear examples of abductive reasoning and can therefore be systematically linked with other abductive endeavors dealing with the search for clues, patterns, omens, and hunches.

META-SYNTHESIS

Meta-synthesis refers to research approaches that integrate the collective products of extant bodies of qualitative research findings using systematic, formal processes for the purpose of generating overarching inductively derived claims about phenomena of interest. Where sizeable bodies of published qualitative work exist within a field of study, meta-synthesis serves as an inquiry approach with the potential of generating comprehensive and substantial claims beyond those that can be warranted on the basis of individual qualitative studies. Meta-synthesis has become particularly popular in academic fields in which public policy is driven by reliance upon evidence because it offers the appeal of rendering the kinds of insights that qualitative research typically yields into more conclusive forms of knowledge within that evidentiary context.

The Essence of Meta-Synthesis

Qualitative meta-synthesis differs from the conventional or critical integrative literature review in that the new conceptualizations it produces result from a systematic, structured, and auditable analysis and synthesis of the entire body of qualitatively derived knowledge within a field. The original studies constitute the data and, upon them, coherent procedures for generating the research question, selecting the sample selection, collecting and analyzing data, and coming to conclusions are applied. Unlike quantitative meta-analysis, which seeks simplification through aggregation, or qualitative secondary analysis, which seeks expansion and clarification, qualitative meta-synthesis demands exploitation of variations and complexities within the data set toward an integrative conclusion that extends beyond the scope of what would have been achievable within the temporal, spatial, or epistemological confines of individual studies or programs of research.

Although various approaches exist for summing up a collection of similar studies or contrasting findings derived from similar methodological approaches, meta-synthesis is distinct in explicitly acknowledging the objective of synthesizing new knowledge on the basis of products that are interpretive accounts of cases, events, or phenomena. Because the extant research may draw upon such diverse inductive approaches as phenomenology, grounded theory, ethnography, and interpretive description, meta-synthesis methods must account for both process and product before credible substantive claims can be made about what is known as an outcome of the systematic synthetic process.

Styles of Meta-Synthesis

Meta-Ethnography and Meta-Theorizing

Meta-ethnography, an early approach to meta-synthesis, reflects an attempt to push at the edges of conventional anthropological research so as to enlarge upon existing scholarly discourse without falling into the trap of mere aggregation of findings. It advances a series of theoretical steps by which findings of one study can be reinterpreted using the analytic schema of another such that some of the more pervasive puzzles of human phenomena might be more fully explored. Similar approaches have also been applied within sociology in which meta-theorizing has emerged as an effort to align divergent theoretical approaches toward increasingly coherent social theory.

Meta-Study

Drawing inspiration from the approaches devised for the purpose of meta-theorizing, meta-study involves three distinct analytic operations prior to synthesis of new knowledge. It requires a distinct critical analysis of (1) the theoretical biases and disciplinary assumptions upon which existing research products within a field have been developed, (2) the implications of the methodological approaches that have been taken toward understanding a particular phenomenon, and (3) an aggregative analysis of the nature and characteristics of the data sets upon which the extant findings have been generated. Deconstructing the existing knowledge by exposing and critically examining the foundations upon which it has been built, meta-study invites a synthetic integration within the context of self-conscious recognition of the limits of that understanding.

Formal Grounded Theory

Formal grounded theory builds upon the logic of grounded theory methodology and applies it to strategies by which researchers can integrate preconceived understandings of the field with the theories that emerge among and between scholars exploring basic social processes. It has been envisioned as a means by which original studies become the bricks within which larger and more coherent theoretical structures might eventually be built. In keeping with the traditions from which grounded theory methodology emerged, this approach relies upon constant comparative analysis among and between emerging theories about phenomena such that the variations permit an increasing strength to the theoretical logic that can be produced. Using formal grounded theory, scholars attempt to generate explanations that work “for now,” recognizing that, in the context of complex phenomena, new and increasingly elegant theories inevitably emerge. In this way, formal grounded theory holds the potential of representing a state of the science within a field of social theory.

Qualitative Meta-Synthesis

In addition to these specific methodological approaches, there has emerged a diverse body of literature within the applied health sciences on approaches to synthesizing bodies of qualitative research. Although initial attempts referenced aggregating qualitative findings or conducting qualitative meta-analysis, the fundamental problems associated with reliance upon cumulative approaches has yielded a common understanding that contextual considerations related to the production of original research must be accounted for if the synthetic product is to have any utilitarian value within the practice or policy-making world.

Qualitative meta-synthesis has, therefore, come to represent a research approach that forcefully addresses the conditions and approaches that went into the making of primary research findings. It increasingly relies upon communicable and systematic interpretive techniques that peel back the layers in how current knowledge has been constructed and attempt to rebuild increasingly credible understandings of the patterns and themes that can be detected within those aspects of human experience for which qualitative research holds particular promise. Where it meets its objective, it advances a synthesis that thoughtfully accounts for all

of the ingredient parts that went into the production of the new coherent whole.

Procedural Basics of Meta-Synthesis

Most scholars writing about qualitative meta-synthesis caution that it is not an appropriate method for the neophyte researcher. Perhaps because the collection and construction of data in many qualitative studies is highly time-intensive, inexperienced or impatient researchers may be initially attracted to the idea of engaging in qualitative analysis without having to deal with the complexities of exhaustive primary field research. However, where such attempts have been made, they tend to appropriate the label of qualitative meta-synthesis for what is essentially a critical literature review, and often on the basis of a highly circumscribed set of original papers.

Because the potential to re-create original biases is accentuated if one does not detect and understand them, qualitative meta-synthesis requires large-scale and highly systematized approaches to each phase of the research process. First, an initial review of the literature is required to determine that there is a sufficiently mature body of published qualitative work within the field to warrant a meta-synthesis and, if so, to frame the research question that will orient the entire project. From that foundation, the methodological strategy requires a predetermined set of rules with regard to finding and selecting studies. Beyond having access to excellent search capacities across a range of databases and information sources, the meta-synthesist must establish and refine inclusion–exclusion criteria and generate a defensible and auditable set of rules with regard to such complex matters as what constitutes a qualitative study in the first place, what boundaries will be set for the search (i.e., the manner in which unpublished research, graduate theses and dissertations, and “gray” literature will be handled), and what variations on the substantive question will and will not be considered relevant in answering the new research question at hand. This process requires as careful of an accounting for the studies not selected and the basis for exclusion as for those that become part of the eventual sample.

Once the data set, including all research fitting the inclusion rules, has been retrieved and agreed upon, a systematic coding and data management system must be applied so that the attributes and the findings of each study can be examined and interpreted against

those of all others. Because it is difficult to determine the intricacies of all such challenges before a full appreciation for the nature of the data set is possible, the rules for extracting and documenting study attributes and summarizing findings must be worked out and explicitly recorded to ensure that the approach is both systematic and auditable. Once a viable data management system has been achieved, there are still inevitable problems with such issues as resolving contradictory findings within and among studies, deciding how to handle multiple reports of single studies and secondary analyses of groups of studies, and working with research products at highly disparate levels of conceptualization. Although studies whose reports reflect some form of thematic analysis of the study phenomenon may be relatively straightforward to consider against one another, those whose results are underanalyzed or paradoxically, those whose reports are already configured as highly conceptualized overarching or metaphoric representations are particularly challenging in this regard.

Once these matters of data management are resolved, the meta-synthesist is confronted with the challenge of attempting to work out how the various study findings might play out if reinterpreted according to analytic frameworks that have been presented in relation to the other studies. Formal analysis is conducted in relation to the characteristics and products of the primary studies across a set of common scales, which permit estimates of what might be termed *effect magnitude* of the major elements. Typically, within the range of schema that have arisen from the data set there will be several that can be set in competition for their relative utility in accounting for the variation within the phenomenon and at the same time resolving the problems that led to the disparate conceptualizations that have been suggested by the original researchers. Ultimately, the meta-synthesist's task is not simply to determine a best fit, but rather to transform the data set that exists, with all of its inherent strengths and limitations, into a new conceptualization with the capacity of integrating the entire body of qualitatively derived knowledge about the phenomenon.

Challenges for Meta-Synthesis

Qualitative meta-synthesis properly conducted is a major research initiative well beyond the scope of individual scholars working alone. Because what is known through qualitative findings about a particular

phenomenon typically includes studies using different disciplinary assumptions, methodological approaches, spatial locations, and temporal moments, interdisciplinary teams of experienced researchers are most likely to possess the knowledge and resources to do justice to the enterprise. However, because qualitative meta-synthesis is not yet widely accepted as a coherent methodological strategy for producing evidence, funding such major team projects remains a challenge.

Within the qualitative meta-synthesis scholarly literature, there are tensions between appreciation of the essentially deconstructive aspect of the enterprise (scratching below the surface to expose the bases upon which one thinks one knows) and between that which strives to be constructive (transforming the existing knowledge into a product that is better and more usable). These in part arise from the epistemological variations within the genre, with many bodies of qualitative research reflecting a full range of knowledge representations from social construction to objective truth. Thus, even for the most seasoned of scholars, these matters of what it means to come to a conclusion remain highly contested.

A surprisingly difficult aspect of qualitative meta-synthesis is the matter of evaluating the quality of original research products. Because they typically reflect such disparate study forms, theoretical scaffolding, sample sizes, inductive approaches, and levels of conceptual integration, the quality measures of various historical and disciplinary periods feature prominently in what has been recorded. Many reports of qualitative studies have also been dramatically shaped by the page limits and format requirements of various scholarly journals, which have been variously friendly to the products of qualitative scholarship. Thus, in many fields, there is much that is published in a form with which one might take issue. If excellent insights contained in less methodologically tight vehicles are eliminated from consideration, qualitative meta-synthesists run the risk of reproducing methodological fetishism and, perhaps, technically accurate, but sadly "bloodless" findings.

Perhaps the foremost challenge relates to ascertaining the role that qualitative meta-synthesis is to play in the larger goal of research integration. If the underlying motivation is to put qualitative findings to use, working out approaches to synthesizing the accumulated knowledge obtained through qualitative approaches is an essential step toward learning how best to integrate that species of knowledge with the

current state of the science deriving from quantitative forms of inquiry. When knowledge within a field can be effectively informed by the products deriving from quite disparate scientific approaches, proponents of meta-synthesis will have achieved their objective.

METHODOLOGICAL HOLISM VERSUS INDIVIDUALISM

This entry speaks to the nature of the individual element. Individualism says that the individual element is an independent entity that has self-contained properties, although of course it draws on resources around it. An example is the popular idea that the individual is responsible for his or her own fate. One's success and failure depend ultimately on how hard one works.

Holism says that the individual element is inextricably tied to other individuals. Individuals are interdependent, and they are internally related in the sense

that each is imbued with and constituted by the qualities of others. An example is a child in a family. The child's psychology depends utterly on the way he or she is treated. Any intrinsic tendencies are modulated and mediated by experience. From this perspective, the child is not entirely responsible for his or her behavior.

Holism regards individuals or elements as reciprocally influencing each other. The child affects the family while being affected by it. This dialectical relation of individuals and elements comprises a system, or a whole. The whole is composed of individuals and affected by them. It is not independent of individuals. However, the whole is not simply a sum of independent individuals sequentially summed together, one after the other. The whole is more than the sum of the parts.

Solomon Asch explains the holistic nature of social interactions in the case of two boys carrying a log. The boys adjust their actions to each other and to the object. The two do not apply force separately. There is a unity of action that embraces the participants and the common object. This performance is a new product, unlike what each participant would do singly and also unlike the sum of their separate exertions. What each contributes is a function of his relation to the other and how the other acts. The other's actions lead to changes in the self's behavior. Self is permeated by other. Larger social units, such as teams and institutions, manifest other kinds of emergent properties.

Emergence is central to holism. It denotes that the whole is different from the sum of the individual constituents. This whole then affects the qualities of the constituents. They are not self-sufficient, independent qualities.

These examples illustrate how the two approaches construe the nature, or existence, of the individual. These ontological perspectives of individualism and holism entail corresponding epistemologies, or ways of acquiring knowledge.

An ontology that construes individual elements as self-contained and self-determining and as combining arithmetically to form groups necessarily insists that knowledge of things consists of reducing complexity to simple, separate individual elements—for example, a group is simply a collection of individuals coexisting. An ontology that construes elements as part of a system of relations that constitute them insists that knowledge of things requires understanding elements as complex, multifaceted entities that are dialectically related to other things and embody their features.

Individualistic and holistic ontologies and epistemologies also entail distinctive methodologies.

Methodological Individualism

Positivism

Methodological individualism is the hallmark of positivism. Positivism construes phenomena as simple, homogeneous, and separate variables. A variable is defined as qualitatively invariant and only quantitatively variable. The reason it is qualitatively invariant is because it is separate from other variables. This separation prevents others from imbuing it with their qualities, altering its quality and complicating it. Intelligence, depression, aggression, and all other psychological phenomena are construed as separate variables with simple, fixed qualities; only their degree varies in different conditions. This ontology leads positivists to concentrate on measuring quantities of variables. They eschew investigating or theorizing about their qualities that are taken for granted as obvious, simple, and fixed.

Methodological individualism is also evident in positivistic instruments such as questionnaires. Each item on a questionnaire is a separate (discrete) element that supposedly taps a discrete psychological attribute. Items are randomly presented in order to prevent any association among them that would bias the subject away from responding to each one independently. In addition, each response is treated as a separate element that is accorded equal weight and can be summed with the others. Sums are indifferent to the order of the elements: $5 + 3 + 1$ is the same sum as $1 + 3 + 5$. Sums presume that items are independent of each other and that a 5 at the beginning is the same as a 5 at the end of a sequence. Of course, responses are statistically correlated together (e.g., in factor analysis). However, it is a correlation of separate, independent items.

Qualitative Methodology

One might suppose that methodological individualism, or atomism, is the basis of positivistic, quantitative methodology, while holism is the basis of qualitative methodology. However, this division would be a simplification. In fact, individualism is pervasive in qualitative research along with holism.

Individualism in qualitative methodology takes the form of treating individual subjects as self-contained individuals who create their own meanings and behaviors. Researchers focus on recording and reporting individuals' subjective accounts. They do not attempt to understand an individual's subjectivity as influenced by other people and conditions. This treatment is characteristic of a good deal of discourse analysis. Although some analysts relate discourse to cultural values and practices, many emphasize discourse as an invention of the individual speaker. Margaret Wetherell and Jonathan Potter (1987) advocate this position.

This perspective appears, for example, in Wetherell's analysis of a 17-year-old boy's sexuality. She analyzes the discourse Aaron, the 17-year-old boy, had with his friends about a weekend during which he slept with four girls. At one point, his friend Paul wondered whether Aaron had deliberately set out to have lots of sex ("out on the pull") that weekend. Wetherell analyzes the conversation as follows:

What I wish to note is Paul's new description of Aaron's activities as "out on the pull." This account seems to be heard [by Aaron] as an uncalled for accusation in relation to the events of Friday night and Aaron and Phil issue denials . . . in attempting to reformulate and minimize the actions so described—"just out as a group of friends." (Wetherell, 1998, p. 399)

Wetherell construes dialogue as a way that individuals represent themselves to each other and themselves. She focuses on the mechanics of how individuals accomplish this representation: Paul describes Aaron; Aaron hears the description; he responds. This methodology does not go beyond identifying sequential conversational acts. It does not utilize long patterns of dialogue to interpret statements, code them, organize them, or make inferences or deductions from them concerning psychological or cultural issues. This restriction conforms to discourse theory that speech is an invention that expresses the individual—it is not a reflection of cultural or psychological processes. Wetherell is not interested in the nature of Aaron's sexual desire—that is, whether it is impersonal, egocentric, loving, considerate, domineering, instrumental, and so on—and how these sexual qualities might reflect macro cultural factors. She is concerned with how individuals voluntarily present sex in discourse.

Methodological Holism

Holistic methodology is only found in qualitative methodology. It does not appear in positivistic approaches to research. One of the most important applications of holism in qualitative methodology is Wilhelm Dilthey's hermeneutics. The central idea is that the psychological significance of any behavioral expression can be discerned only by relating that response to other responses. The significance of a response is not transparent in a single behavior. For example, to know whether a remark is a joke or an insult, one must situate it in a context of other comments, the speaker's countenance, and other behaviors. By itself, the comment is ambiguous. The context disambiguates the element.

This relating of behaviors in order to disclose psychological phenomena is known as the hermeneutic circle. If one wants to hermeneutically interpret the psychology of a mother who spanks her child, for example, one must know how the child acted before he or she was spanked, how the mother behaves toward him or her in other situations, what she says to him or her during and after the spanking, how she behaves toward him or her after the spanking, her facial expression during the spanking, how she explains the spanking to her husband and friends, and so on. Only this complex configuration of related behaviors reveals whether her spanking was motivated by concern for the child's well-being, hatred for the child, revenge against the child, or by frustration that was provoked by an event unrelated to the child.

Similarly, the cognitive processes that enable students to perform well on math tests are only known by observing their extended solution to several math problems in different situations. Test performance may express a number of psychological phenomena. It may reflect the student's ability to memorize material, or it may reflect test-taking ability, anxiety, or mathematical reasoning. Which of these possibilities is operative is only disclosed by observing the pattern of steps that pupils take to solve problems in different situations.

Kurt Goldstein used a hermeneutic analysis to diagnose neurological deficits. He observed the pattern of responses by which patients match a colored stimulus with objects of similar color. Normal and impaired subjects often find the same number of objects that match the hue of the stimulus; however, their pattern of responses is quite different. The patient proceeds sequentially by first matching the stimulus to an object that most closely resembles it (O_1), then matching

another object (O_2) to (O_1), then matching (O_3) to (O_2), and so on. In contrast, normal subjects compare each color directly with the stimulus color. The qualitative difference in the behavioral patterns reveals the patient's deficit.

This process is a hermeneutical, holistic analysis because it examines patterns of interrelated responses that indicate the quality and significance of each. The fact that O_3 is matched to O_2 rather than to the stimulus hue makes it a different (impaired) kind of response and indicates it to be a different kind of response. Hermeneutic methodology that elucidates patterns is holistic. In contrast, counting the number of correct matches and comparing the sums for normals' and patients' obscure patterns and the qualitative differences of responses within them. As mentioned, sums of responses are indifferent to their order and their interrelationship. A sum treats each response as separate and independent. Sums are individualistic forms of methodology, while patterns are holistic.

Cultural Hermeneutics

The highest form of methodological holism not only elucidates patterns of behaviors among individuals, but also recognizes the internal relationship between psychological phenomena and cultural phenomena. This cultural-hermeneutical interpretation of psychology was actually the crux of 19th-century German hermeneutics. It has been largely overlooked as hermeneuticists focus on the behaviors of individuals apart from culture. However, Dilthey maintained that the interpretation of meaning belongs to the larger science of history. To understand means to understand historically. It means to understand that psychological phenomena such as self-concept, sexuality, motivation, reasoning, memory, emotions, perception, mental illness, and developmental processes are integral components of macro cultural factors such as institutions, artifacts, and cultural concepts, and embody their features. Cultural hermeneutics elucidates this cultural quality of psychological phenomena, as Carl Ratner explains in his writings.

A Synthesis

In their current forms, holism and individualism approach psychological phenomena very differently and are antithetical. However, a synthesis is possible. This synthesis cannot be an eclectic, unprincipled,

combining together, for this type of synthesis would combine weaknesses as well as strengths. Nor can the synthesis take the form of a golden mean that is in between the extremes, for that negates the strengths of the positions by watering them down with their opposites.

A workable synthesis requires a reformulation that makes holism and individualism logically consistent through a set of common principles. Lev Vygotsky explained what this synthesis involves. He said that an analysis of complex patterns into units is necessary and workable. It requires construing the part as embodying qualities of related parts, patterns, and wholes. This process reformulates the individualistic concept of an element as an independent entity with a self-contained quality. It makes the unit logically consistent with its holistic existence, internally related to other units.

Vygotsky (1987) explained this process as follows:

A psychology concerned with the study of the complex whole must replace the method of decomposing the whole into its elements with that of partitioning the whole into its units . . . in which the characteristics of the whole are present. . . . In contrast to the term “element,” the term “unit” designates a product of analysis that possesses all the basic characteristics of the whole. . . . The living cell is the real unit of biological analysis because it preserves the basic characteristics of life that are inherent in the living organism. (pp. 46–47)

These units can be studied, counted, and added. The benefits of analysis can thus be integrated into methodological holism. This ability enables holism to become a precise, rigorous, scientific approach. It loses its pejorative connotation as a mystical, ineffable, and impractical methodology.

METHODOLOGY

Research methodology consists of the assumptions, postulates, rules, and methods—the blueprint or roadmap—that researchers employ to render their work open to analysis, critique, replication, repetition, and/or adaptation and to choose research methods. This term is often used interchangeably with research methods, but in this entry it will refer to research methods as the tools or techniques with which researchers collect their data. These tools or techniques are wisely chosen only when they are derived from and related to the larger set of assumptions and procedures that constitute the overall research methodology the study utilizes. All empirical research, regardless of whether it is considered to be qualitative, quantitative, or both includes a discussion of research methodology. Most qualitative research methodology books and texts refer to the constituent components of research methodology as defined in this entry—guiding paradigms, aspects of research design (study community, population, sampling and analysis units), methods of data collection, and analysis and dissemination. This entry includes all of these under the same rubric.

What Research Methodology Is Not

Theory is not included in this entry as part of research methodology. Theory is extremely important in providing the initial arguments for the study, framing its formative conceptual model, and guiding directions in data collection and analysis. Methodology consists of the actions to be taken in the study and the reasons for

these actions in testing or generating theory. Ethical considerations are also very important in any research involving human or animal subjects, participants, or partners. Research ethics, however, will not be considered in this entry, even though when one considers questions such as what is the importance of this research or with whom should one conduct the research and in what kinds of partnerships, or whether particular approaches to data collection might be harmful to study participants, one is raising ethical considerations that affect one's methodological decision making.

Methodological Decisions.

Decisions about qualitative research methodology include (a) selection of guiding paradigm; (b) identification of research questions; (c) development of a formative conceptual model; (d) site selection, study population, and study sample; (e) topics, procedures, and tools for data collection; and (f) and procedures for data analysis and interpretation.

Guiding Paradigms

Qualitative research typically includes positivist, interpretist, constructionist, critical, and participatory paradigms. The positivist perspective stems from the long history of naturalistic observation in real-world situations. Views of positivism range from conservative to progressive-activist, but all involve the belief that reality is external to self and can be observed using tools that produce information that can be understood and interpreted by others. Positivism is linked historically to social activism through the idea that social situations can be studied, critiqued, and subsequently changed. Positivists may collect data through observations or various forms of instruments and often derive explanations for their results from preexisting theory without concern for whether the study population understands or agrees with their views.

Interpretivist approaches focus on the meanings attributed to events, places, behaviors and interactions, people, and artifacts. These meanings have historical depth and are widely shared, negotiated, and co-constructed. Approaches that fall under the interpretivist rubric are phenomenological, interactionist, constructivist, and hermeneutic. They assume that social phenomena are constructed or co-constructed by self and can be discovered by collecting and analyzing

conversations and texts. Interpretivist approaches are heavily dependent upon the researcher's involvement with the study community since meaning emerges both through interaction among participants and between the researcher and the participants. Verification of the research results occurs through interaction with study participants.

Critical approaches view individual and group behavior and meaning as shaped by structures and processes of dominance. Critical researchers study and reveal different patterns of locally, nationally, and internationally situated dominance and control; the ways in which they are sustained and reproduced; and the responses of individuals and groups to these structures and power differentials, which may involve agency, resistance, voice, and various forms of advocacy. Critical approaches often, but not always, involve participants as partners in uncovering and addressing power imbalances, inequities, and injustices.

Social ecologists situate human behavior in the context of interactive spheres of social and other forms of influence with varying degrees of proximity to or influence on the individual. These spheres (e.g., family, peers and friends, community social institutions, and macrosocietal influences [media, political parties, etc.]) are interactive, changes in one sphere influence changes in other spheres and individual actions can also bring about change in any sphere. Thus, ecological research is also potentially activist and participatory, though not necessarily with reference to changing structures of power and dominance.

These frames of reference or paradigms are not mutually exclusive. Researchers can choose positivist interpretivist or critical and ecological approaches simultaneously, depending on the study topic, research question, and personal preferences.

Defining the Research Question

Most people begin asking questions about the world around them as soon as they begin to speak. The questions that social science researchers ask about the work around them come from a number of different sources. These sources include queries stemming from the observation of discrepancies in what people do, between what they do and what they say, differential historical or developmental trajectories, perceived inequalities, observed differences between one's own and others' beliefs and experience, and questions about what accounts for differential outcomes in educational,

health, or other experiences. Qualitative research questions are usually framed as explorations of behaviors, factors accounting for behaviors, the meanings associated with behaviors, and contexts in which meanings, behaviors, and other factors occur. Questions may also address changes over time—for example, has parental involvement in children’s education at Humbolt Community School changed over time; has it changed because of an intervention or because of the program for parental training; or has it changed because organized times and places have been arranged for observed parent and child interaction (see Table 1).

Framing paradigms will shape the ways in which questions are framed. For example, interpretivists will focus more intensively on the meanings parents give for their actions; critical theorists will focus on contexts and factors associated with the power differentials shaping and explaining differential parental behavior. Ecologists will combine factors and contexts to consider the immediate social, environmental, organizational, political, and other aspects that influence parental involvement.

Formulating a Conceptual Model

Qualitative researchers are best advised to generate a formative or exploratory conceptual model prior to

beginning a study. This model is sometimes referred to as concept mapping, a process that identifies domains and the relationships among them. More linear conceptual models (as shown in Figure 1) identify a primary dependent or focal domain (e.g., educational inequality or mental health treatment access) and the primary independent domains that are believed to be correlated with it and, possibly, to predict it (e.g., the effect of allocation of educational resources, teacher training, or union policies or language gaps on student performance, or stigma attributed to mental illness or limited knowledge of depression symptoms on help-seeking behavior). These domains can be further disaggregated or deconstructed prior to entering the field, resulting in taxonomies that constitute initial coding schemes and an initial guide to field research. The model and coding schemes are modifiable, with modifications beginning with field work.

Defining the Study Site, Study Population, Study Sample

Study Site

The study site is the location where the research takes place. Study sites may include institutions (clinics, hospitals, schools and university campuses, voluntary

Table 1 Sample Questions

Explorations or descriptions of behavior	What are the ways in which parents in Humbolt Community School are involved in their children’s education?
Factors accounting for behaviors	What are the factors that account for differences in the involvement of Humbolt Community School parents in their children’s education?
Meanings associated with behavior	What are the meanings and values that Humbolt parents attribute to different types of involvement in their children’s education?
Contexts related to meanings, behaviors, and other factors	What are the school, community, historical, or other conditions that facilitate or impede parental involvement in children’s education in Humbolt Community School?
Changes over time	Has parental involvement in children’s education at Humbolt Community School changed over time?
Changes because of an intervention	Has parental involvement in children’s education at Humbolt Community School changed because of our program of parental training?

Figure 1 Example of a Simple Conceptual Model

organizations, social groups, recreational areas, community organizations, businesses of different sizes, and cyberlocations or networks). All forms of qualitative research take place in a community defined by place and time in which interactions occur among members either directly through face-to-face interaction or via electronic forms of communication (telephone, videoconferencing, internet). Communities also may be defined by ethnic and/or racial membership along with other social and cultural characteristics such as ability level and links to a specific institution. The study site is chosen as a place where the study questions can be answered through the use of interactive research methods that require face-to-face engagement or its equivalent (in the case of distant or internet research).

Study Populations

An important methodological consideration is the selection of the study population. Any qualitative study must provide good reason for the identification and selection of the study population. The study population may be defined as the group or groups of interest to the researcher in relation to the study question. In collaborative research designs, it would focus on those members or groups within the study population that are willing to partner with the researchers. The rationale for selection of the study population may include one or all of the following factors: the study question, population need, research design considerations, personal values, and funder requirements. Study population may refer to a variety of units of investigation and analysis at multiple levels—census districts, towns, families, and individuals. Thus, for example, if one wanted to study variations in women's participation in milking cooperatives and prior experience suggested that characteristics of the village made a difference in fostering participation, one could say that the first-level study population would consist of

all villages that include women-run milk cooperatives and that the second-level study population would include all women in each of these villages. Similarly, in a comparative study of elementary school students' participation in exercise, all elementary schools in the study area or community would constitute the first-level study population, and all students in those schools, the second-level study population. The study design would consider using sampling from each of these levels to obtain representative data on the study topic. Making these strategic decisions is part of the methodology of a study.

Study Sample

The study populations constitute the universe or basis from which to choose the study sample. Making decisions about the study sample or samples, like making decisions about the study population, are central to a study's methodological considerations. Sampling units may include individuals, events (e.g., occasions when the topic of interest occurs, such as classroom events when students are asked to problem solve or students clash with instructors, or community events when people gather for civic ceremonies, such as the U.S. Fourth of July Independence Day celebration), or cultural rituals (e.g., jazz or fiddle festivals or Veterans Day in the United States, honoring those who have died in national wars). Even if the research design calls for the study of a single community, school or clinic, or student, researchers must still make decisions about which units to choose for sampling purposes and why. Further, in mixed methods designs, study methodology must differentiate and coordinate sample selection at different levels (e.g., school, classroom, student) and for qualitative and quantitative study purposes.

Rubrics for Sampling

Qualitative methodology usually follows sampling rubrics that are based on principles that differ somewhat from those used by survey researchers. Rubrics for qualitative sampling include various types of criterion sampling, used when representation is desired and randomization is not required, and probability sampling when representation and randomization are required. Since science calls for rigorous explanation and definition of research decisions, sampling choices must always be explained. Criterion sampling refers to the criteria that delineate characteristics desired in

the study units to be selected. Researchers may decide to choose sampling units for convenience or coincidence, an approach that may be useful in the initial stages of a study or in conducting a pilot study. Better and more systematic approaches to criterion sampling include respondent characteristics, ideal case, ends or midpoint of a continuum, uniqueness or geographic representation (as in targeted sampling), or respondent driven sampling, a network or snowball approach to sampling that promises accurate representation of a population. Larger studies calling for representative sampling to obtain the full array of variation in the designated study topic utilize systematic selection (identification of cases based on intervals; e.g., every fifth patient) where the universe cannot be bounded or defined, and random sampling, using a table of random numbers to select individuals, each of whom has an equal chance of being selected where the universe is known and can be delineated. Qualitative research methodology requires delineating of sampling decisions made on the basis of these rubrics.

Methods of Data Collection

In qualitative research, methods of data collection almost always involve face-to-face interaction with the study community and the study participants. The researcher is the most important instrument of data collection. This collection calls for considerable introspection, reflection on possible biases, and maintenance of personal notes that help the researcher sort out how his or her personality, personal values, and implicit prejudices may interact with the research situation or influence the setting, and therefore change the data that can be collected or to narrow or otherwise bend or influence what the researcher observes or notes. Collection of face-to-face data occurs in two ways: through observation (what the researcher sees) and through interviewing (what respondents tell researchers). Observation and interviewing can be conducted along a continuum from less to more involvement in the study site, depending on which paradigm the researcher prefers, as well as what the object of the study is. The more structured or predefined the observation or interview process, the more it imposes on the participants' lived situation and the less it engages the researcher in interaction with the participant.

Qualitative data collection techniques (research methods) focus on data collection at the sociocultural (collective) and individual levels. Methods involve

obtaining information on observations and reported perceptions regarding rituals, ceremonies, patterned activity, formal and informal social and organizational relationships, history and historical events, norms, beliefs and shared attitudes, and stories illustrating main themes or concerns in the research setting, and so on. At the group or cultural level, basic data collection methods include various forms of setting and group observations, interviewing, elicitation techniques, networks, GIS mapping, and some forms of photography.

At the individual level (personal views and experience of the respondent), data collection methods include open-ended, timed open-ended, and timed and precoded observations of individuals or groups in a naturalistic setting (classroom, park, playground, etc.) and unstructured and semi-structured open-ended interviews with individuals or groups. Unstructured open-ended interviews are used to discover the characteristics of a domain in the research model from the perspective of the individual. Semi-structured interviews, which ask all individuals in a selected sample the same open-ended interview questions, obtain patterns of similarity and variations that can characterize the study sample of individuals and, at the same time, provide the items important for constructing surveys to be used with a larger group. Networks, photography, and elicitation data including individually drawn maps can also focus on individuals' personal experience and perceptions.

There are many special data collection techniques that can be utilized at both levels, including various forms of elicitation (where interviewees respond to photographs, drawings, or other material designed to elicit variations in response), GIS mapping, family or extended kinship networks, and narrative-based performances that generate audience response and dialogue. In framing study methodology, the job of the researcher is to determine which of these approaches to data collection are useful to obtain relevant cultural and individual level data for a study and how they should be applied in the study setting.

Recording Qualitative Data

Qualitative data consists of recorded observations and interviews in the form of fieldnotes. The strength of a qualitative study depends on the quality of these recordings. Some forms of qualitative research rely heavily on observations in the field; that is, in the community or other setting in which the research

takes place. Other forms of qualitative research may focus on reports of experience and interviews of various types and less on observed context. Fieldnotes can be recorded either by hand using pencil and paper and later entered into a computer, or they may be recorded utilizing audiovisual equipment such as tape or digital voice recorders or digital photography or video cameras. The least intrusive form of recording consists of a small notebook in which the researcher records jottings. Jottings are words, abbreviations, diagrams, quotes, and other brief notes that follow the subject matter and sequencing of the observation or interview and can be transformed into full-scale descriptions with quotations as quickly as possible following return from the field. Some researchers prefer to dictate their jottings in the form of more elaborate fieldnotes on a digital recorder and download them into computers from which they can be easily transcribed. Others use handheld PDAs or small computers. Reliance on forms of recording other than pencil and paper invariably introduces complexities in the field ranging from technology failure (before or after recording) to loss of tapes or digital recordings and reactions from participants. Transfer time required to make these recordings useful in the form of text also is greater.

Data Analysis

Decisions about which protocols for analysis of qualitative data to use are based on the interaction of research questions, study model, and text and archival and audiovisual data. All qualitative data can be manipulated and coded. Coding categories can range conceptually from more concrete to more abstract and reflect themes and patterns found within and across domains in the study model. Continuous comparisons, as analytic codes emerge, should produce a final set of codes that can be applied to the entire data set and a set of comments, memos, and analytic summaries that can be utilized for overall analysis and interpretation.

Analysis generally proceeds by conducting comparisons and contrasts to extract themes and patterns first within and then across domains, extracting new domains and finally refining and testing the revised theoretical model against the data. These analysis steps can include triangulation of all forms of qualitative and quantitative or survey data. A variety of software packages are available for coding, extracting comments quotes and summaries, and constructing text-based

and visual relationships among coding categories and analytic domains.

Final methodological decisions center on uses of research results. Qualitative research results can be used to improve services, formulate and test interventions, contribute to survey research development, change or critique policies, and support advocates for various forms of social change. Dissemination and use decisions include the selection of research or dissemination partners, and a consideration of specific audiences, appropriate formats, and the roles and responsibilities of members of the research team in the dissemination process.

METHODS

The term *methods* refers to the ways in which qualitative researchers collect data to build their argument. Regardless of paradigmatic preference, all qualitative research methods have common characteristics. They are conducted in an exchange between real people. They focus on meanings as conveyed by participants in the research setting in addition to behavior. And they take into consideration the social, cultural, and physical contexts within which individuals live, work, and interact. All forms of qualitative research including ethnography are most noted for their commitment to learning about and understanding the perspectives of others rather than imposing the researcher's own

views, biases, and theories in explaining differences across populations or communities in beliefs and behaviors. Most qualitative researchers believe that people's beliefs and behaviors, no matter how different from their own, are understandable and make sense in the context in which they live. Sensemaking through the eyes and lived experience of the people is at the heart of good qualitative research.

The roots of qualitative research methods lie in the experiences of early travelers in Europe and the Middle East who wrote down their observations in the form of representations of the people whom they met in their travels and in the German folklorists and interpretivists of the late 19th century who focused on folk knowledge and folklore. Administrators in the British Colonial Service formalized ethnography as a tool for improving indirect rule, and early American anthropologists, influenced by researchers such as Franz Boas, sought to use observations, interviews, measurements, and interpretations of cultural works to understand the perspectives of American Indians and immigrants and to debunk notions regarding racial differences in intellect and capacity.

Certain methods, such as participant observation (PO), are central to qualitative research. PO calls for engaging with people residing in communities such as neighborhoods, towns, schools, clinics, self-help groups, or other gatherings who share a common history, goals, and directions; entering into relationships with them; learning from them; and recording their behavior. Other methods, such as interviewing, are favored by qualitative researchers who do not necessarily go into the field (where people live and work), but instead rely heavily on respondents' oral and otherwise recorded reports of their lives and experiences.

There are many approaches to methods (or data collection techniques) that can be subsumed under general headings. These may include: observations and other forms of visual documentation (i.e., what researchers see), interviews (i.e., what researchers learn through verbal or, occasionally, written reports from respondents or participants), elicitation techniques (i.e., what researchers learn from providing visual or oral stimulate with which respondents are asked to engage), and various forms of mapping. Each of these approaches can be further subdivided—for example, interviews may be conducted with key informants or local experts about community or organizations wide issues or dynamics, and in-depth interviews or narratives may be conducted with individuals about

their own personal beliefs, behaviors, and experiences. Network interviews focus on the breadth, composition, and behaviors of social networks. Group interviews may be formal (e.g., organized by the researcher) or informal (e.g., carried out in the context of daily observations in research settings) and may focus on individuals' beliefs and experiences, life histories, and social networks. Finally, surveys, while not qualitative, are ethnographic to the extent that they derive from local needs, issues, meanings, and measures and are administered on a face-to-face basis.

Researchers make choices about research methods depending on a number of factors, such as: level (e.g., social or community or personal), time availability (e.g., length of time needed to complete data collection), financial resource availability (e.g., cost of data collection including interviews or observations and transcription, translation, and coding), and cultural or situational appropriateness (e.g., type of interaction, privacy requirements, and literacy). This entry discusses the major approaches to methods of data collection in field or qualitative research, reasons for choice, and strengths and limitations.

Observation

Observation is considered as fundamental to good qualitative research. Observation can be used to collect various sorts of behavioral or interactional data. The collection of observational data ranges from open-ended (a search for pattern) to closed and coded (a search for pattern confirmation). Observations also vary along a continuum from participatory, where the researcher is accepted as someone who is regularly present and a member of the study community, to non-participatory, where the researcher is an outsider who conducts systematic observations without interacting with anyone.

Participant Observation

Researchers involved in PO enter the community setting; establish positive relationships with key gatekeepers, stakeholders, and local experts; and, over time, are invited to participate in the life of the community and are given access to many or most settings and activities. Often the researcher affiliates with a family or a mentor that is ideally a neutral force who can provide introductions to many sectors of the community, support when things are not clear or go

wrong, and language instruction if the researcher needs to learn the local language. Active participation in the life of the community, which may mean taking on certain responsibilities, teaches the researcher how to behave and to think and understand how decisions are made in that cultural setting.

PO is a form of apprenticeship in which the researcher does not lose or hide his or her identity on entry, but adds to it by learning new roles and responsibilities; for example, teaching in an elementary school in northeastern Australia, producing maple sugar in Connecticut, or hunting reindeer in Lapland. Participant observers record what they observe in the form of fieldnotes based on their own voice recordings, paper and pencil jottings, and computers. As they observe and record, they note what terms, material products, and rituals mean and how activities are carried out, and they observe patterns such as gender differences in roles and responsibilities and decision making, power differentials, and resource distribution in families and communities, or influences on the acquisition of basic medications. After an initial period of entry, PO is not intrusive (it generally does not bring about changes in behavior patterns and beliefs), and for most researchers with social skills, it increases the social and content validity of the data collected. PO is stressful for researchers because it constantly tests their ability to adapt to new and unfamiliar situations in the field and challenges their ability to remain engaged enough to gain understanding, but disengaged enough to observe and record their observations and conversations that constitute the record of data accumulation in the setting.

Systematic and Structured Forms of Observation

As observers narrow and focus their interests, they may wish to observe more systematically by using a process of comparison and contrast, which seeks to describe variation in events, processes, or behaviors identified in PO and to discover what might account for these variations. Once the range of variation is identified and described in general, researchers may further sample specify the nature of their observations, using coding or observation schemes, indices and other qualitative or even quantitative measures, and collecting data in specific locations and at specified time intervals. For example, researchers interested in site-based factors promoting drug use in

dance places and bars might list and observe in different types of locations varying by size and configuration of space, type of music, type of client, and items sold on the premises. Having classified sites, they may wish to observe, using an observational checklist or coding scheme in a sample of each type of site, and to schedule their observations hourly over a 5-hour basis to monitor changes over time. Focused observation can be carried out with preexisting observation schemes imposed on a setting. Good qualitative researchers, however, will use PO approaches first to evaluate whether and how an externally derived observation scheme can be made more relevant to the setting and study problem.

Interviews

Like observations, qualitative interviews can range from unstructured to highly structured, but all interviews are open-ended in that respondents can answer in whatever way and to whatever extent they wish and in that there is some interaction with the interviewer who may probe, extend questions, or raise new topics. Interviews are usually carried out in a place that offers privacy to protect confidentiality, often at a distance from the field site. The relationship between a researcher and a key informant is generally personal and intimate and endures over time. Thus, key informants are not usually paid for most of their interviews. However, in-depth interviews carried out and recorded with individuals about their personal experiences may be compensated with material goods, gift certificates, or actual cash. There are many different types of in-depth interviews, which call for different interviewing techniques in the field. But all of them require face-to-face interviews (although some interviews may be conducted by telephone or online), the jotting down of responses (or audiorecording), and the transcribing of what respondents have said in as much detail as possible. Interviewers must have ways of transcribing and translating interviews as quickly as possible after the interview so as not to lose information.

Key Informant and Local Expert Interviews

Ethnographers seek out key informants or local experts who can provide information about the community or the particular topic in which they are interested and who can link them with other knowledgeable

people. Key informants often become close friends and confidants and can become partners in the research. They are helpful in validating the hunches of the researcher and can protect the researcher and the community from misrepresentation. They may also provide personal insights and experience, but their main contribution lies in their knowledge and understanding of events, relationships, and meanings at the community level. Examples of types of people who have local expertise are block club leaders, school hall monitors, administrative assistants, and small shopkeepers. Key informant or local expert interviews are open-ended and usually initiated with a handful of questions that cover very general topics. A good local expert provides lengthy responses to questions and enjoys reflecting on and sharing information about the subject matter.

In-Depth Interview on Individual Experience

Qualitative researchers carry out in-depth interviews on individual experience, beliefs, behaviors, and meanings in order to discover and explore the range of variation among individuals and to find patterns of similarity and difference. These interviews can be open-ended initially and can move toward semi-structured interview schedules in which a sample of respondents are asked the same open-ended questions and responses are compared to identify variation as well as common patterns. In-depth interviews are utilized to look for themes and higher-order patterns (i.e., relationships among themes) and to explain and theorize them. In addition to general open-ended interviews about respondents' personal opinions and experiences, in-depth interviews can include qualitative network interviews in which interviewers ask about people with different types of relationships to the respondent and narrative interviews that query in detail respondents' histories in relation to historical and current events, life careers, and other such themes. Various types of formal and informal group interviews also call for open-ended interviewing protocols structured in accordance with the needs and the requirements of the research.

The most important consideration in in-depth interviews is that respondents must be allowed to answer in their own words and at length in order for researchers to understand the interviewee's meanings, perceptions, beliefs, attitudes, and descriptions of their own behavior. At the same time, the interviewer must have some

questions ready to ask if there is a lull in the conversation requiring the researcher to attempt to structure a direction in the interview. Interviewers must be able to redirect respondents' responses and to recognize when they wish to avoid or divert the question.

Multimedia Documentation

Many ethnographers use various forms of audiovisual and multimedia documentation to record their work. The simplest and least intrusive form of documentation is the audiorecorder. Most audiorecording uses digital recorders, downloading the results of interviews to computer files for transcription. Considerations in purchasing a recorder include recording capacity and clarity of microphone. Using an external microphone placed midway between the interviewer and the interviewee is recommended. Audiorecording group interviews is not recommended since most equipment does not record accurately voices at different distances from the equipment or the interplay of conversation as speakers interrupt one another. Audiovisual records of events and conversations allow for capturing interpersonal interaction in natural or contrived settings. Video cameras are relatively inexpensive and produce records in digital format that can be downloaded, entered into a text-management program, and coded for visual, contextual, and interactional voice cues and conversational topics. Some types of analysis (such as discourse analysis) require careful recording of conversations and cannot be carried out without the use of video cameras. Digital cameras are used for a variety of purposes in the field. The simplest use of digital cameras involves obtaining a visual record of people, activities, rituals, daily routines, and a general description of the field setting. They must be accompanied by text data describing the persons or activities in the photograph and providing other detailed information in order to act as valuable records.

Photographs can be used to reveal details of settings or situations that are not readily accessible. For example, photographs of low-income urban housing might illustrate the idea that an external view is insufficient to determine the degree of deterioration of housing conditions by collecting distance views that do not show deterioration, external close-up views that show external deterioration, and interior views that show extreme interior deterioration. Photographs of bridges might be used to display vulnerability to invasion or natural disasters. Satellite photographs

might be used to illustrate the distribution of greenery or erosion in an environment. As with other forms of qualitative data, photographs are as important as the theories behind them, so qualitative researchers should think carefully about the reasons for taking photographs. Although photography may be well received in some settings, it may be rejected in others. Researchers must take care to discover the etiquette surrounding photographs in their field settings and should not assume that all people are willing to have their photographs taken. Improper attention to these details may result in unpleasant conflicts and confrontation. Qualitative researchers should always ask permission, especially when photographing individuals who might be recognized.

Audiovisual data collection may require consent, which can be problematic when researchers are interested in a group process. Photographs may also require release forms if they are to be used in scientific publications or for commercial or promotional purposes.

Cultural Elicitation

Many qualitative researchers are interested in the way groups of people organize their understandings of the world. Some refer to this process as *cognitive mapping*. Although individuals may map their world cognitively, cohesive groups of individuals do so collectively. Cultural elicitation is an approach that involves obtaining simple listings or comparisons from a small number of people on the components of a known cultural domain and submitting them to computer programs that analyze them, using forms of proximity analysis to produce cultural portrayals of the way group members organize the components. The most commonly used approach to cultural elicitation is pile sorting. Pile sorting uses a procedure of free-listing items within a cultural domain and subjecting them to sorting in a small sample of representatives (15–30). Other approaches involve triad sorting, Guttman scaling, consensus analysis, and decision-making models. When using these approaches, it is important to remember that where there is previously known variation, elicitation protocols should be utilized with groups that are known to differ (e.g., parents and children, teachers and students, youth and older adults, young women and young men). There may be differences across age, ethnicity, language grouping, organizational affiliation, and so on. Thus, cultural elicitation research and results are best interpreted

when more rather than less is known about the study community beforehand.

Social and Other Forms of Site Mapping

Mapping settings is an important, ongoing activity for qualitative researchers working in any kind of field setting, even if their primary focus is the collection of in-depth or focus group data and consists of a set of techniques that is widely recommended for use by all qualitative researchers. For those researchers involved in PO, mapping settings geographically involves drawing a diagram of the setting that includes specific landmarks, groups, and the locations of activities. Since settings change over time, researchers should map their sites continuously to demonstrate continuities and changes over time. Qualitative researchers can also invite respondents to map their activity spaces or their communities. Maps can then be compiled across respondents, and respondents can be compared across different age or other social categories to see if there are cross-group differences in the construction of activity spaces. GIS (geographic information system) mapping now allows for more rigorous and complex overlays of databases on geographic space. With GIS, one can more easily observe disparities of various kinds. GIS also allows for digitized mapping of local spaces not found on existing digital maps. For example, students can map their school and locate places where students play, learn, and harass each other. These spatial differences can contribute to interventions designed to improve the quality of play and reduce various forms of harassment.

Ethnographic Surveys

The term *ethnographic survey* is not commonly used. In this entry, it is used to refer to the construction of survey variables and scales that are obtained through other forms of qualitative inquiry in the field site rather than from generic theory applied to the research problem. Scales may emerge from qualitative data collected during the formative stages of a project, from dimensions that appear to be important in the field that have counterparts in existing scales, or from some combination of both. Survey items, scales, and variables are pilot tested in the study site and utilized to demonstrate a range of variation and correlates and predictors of the main dependent variables. Most surveys are constructed

based on previously identified domains and scales. Some research shows, however, that scales constructed based on formative research measure important dimensions more accurately than generic scales and are better predictors of variance in the dependent variable. For this reason, it is recommended that ethnographic researchers construct their own surveys to make sure that the surveys reflect cultural realities in the field. It is possible to construct cross-culturally valid and acceptable surveys in which the meanings of variables and scales are clearly understood across different settings, age groups, and other differences. This process takes time and cross-translation. There is no guarantee that scales developed in one location and in one place and time will be relevant to other locations, places, and times. All questionnaire components including those derived from other locations and studies must be piloted in the local setting to ensure that the items have meaning and social validity (i.e., that they measure what they are intended to measure).

In summary, there are many methods available for the collection of qualitative data, and each has its strengths and disadvantages. Many if not most of these approaches can be used in a single study, and all of them can be used in empirical nonparticipatory or participatory research models.

MIXED METHODS RESEARCH

As a new approach to conducting social and health inquiry research, mixed methods research has attracted substantial interest and followers during the past 20 years. With the current acceptance and legitimacy of qualitative research and the long-term use of quantitative research, mixed methods provides a means for combining the strengths of both approaches to best understand research problems. Researchers need to be aware of the possibility of combining qualitative and quantitative methods when appropriate for addressing their research questions.

A Definition

Mixed methods is defined as research in which the inquirer or investigator collects and analyzes data, integrates the findings, and draws inferences using both qualitative and quantitative approaches or methods in a single study or a program of study. This definition is the current one being used in the call for manuscripts for the *Journal of Mixed Methods Research*. This definition permits viewing *mixed methods* as a broad umbrella term encompassing perspectives that see it as a research method of data collection and analysis, a methodology that spans the process of research from philosophical assumptions to interpretations, a philosophy of research, and a set of procedures used within existing research designs such as case studies, experiments, and narrative projects. Overall, this definition has general agreement among leading mixed methods writers today.

When researchers apply this definition, they employ an approach that has several characteristics. They are collecting and analyzing both quantitative and qualitative data. This suggests that two "strands" are implemented in a mixed methods study, and that the researchers have the skills needed in both quantitative

and qualitative research to engage in these procedures. It also suggests that the collection of multiple forms of qualitative data (or multiple forms of quantitative data) would not constitute a mixed methods study. This form of research might be considered multimethod research. Also in applying the definition, researchers will mix, combine, or link the data in certain ways. Three ways are apparent in the mixed methods literature for mixing the quantitative and qualitative data: by combining or integrating them, by connecting them from the data analysis step of the first source of data to the data collection step of the second source of data so that one source builds on the other or helps to explain the other, or by embedding one secondary or supporting source of data into a larger source of data to provide additional information in a study. In the process of research, these three forms of mixing—merging, connecting, or embedding—will occur during various stages of the research, such as during data collection, data analysis, or interpretation.

Reasons for Mixing in Different Research Designs

Regardless of the form of mixing, the reasons for mixing the methods in a study need to be clearly identified by researchers. One reason for using mixed methods research is that the use of both qualitative and quantitative approaches will provide a more complete understanding of the research problem than either approach alone. In this case, the researcher might collect both quantitative and qualitative data at the same time (concurrently) and merge the data to form one interpretation of the data. This interpretation would provide both quantitative information about magnitude and frequency as well as qualitative information from individual perspectives from participants and the context in which they were commenting on the research problem. This design is called the triangulation or concurrent mixed methods design. A triangulation design in mixed methods is not the same as the use of the term *triangulation* in qualitative research in which inquirers draw evidence from different sources or different participants to develop a code or a theme. In mixed methods, it means that the quantitative data and the qualitative data are merged by the researcher in the analysis. Another reason for mixing is to follow up on initial exploratory findings. This reason applies when the researcher seeks to explore first qualitatively and then to test this exploration with a large quantitative

sample of a population. For example, the inquirer might collect and analyze qualitative data in the first phase of the study. The results of this analysis might then be used to identify items for a questionnaire or to build a typology of categories to be further tested quantitatively in the second phase. This design is called an *exploratory sequential mixed methods design*. Another reason for using mixed methods is that the researcher may want to better explain initial quantitative results. This situation occurs when the researcher begins with quantitative data collection and analysis in a first phase and then follows up with a second phase of qualitative data collection and analysis to help explain in more detail the results of the first quantitative phase. This type of design is called an *explanatory sequential mixed methods design*. A final reason for using mixed methods research is to enhance a larger data set with a smaller, more focused data set. For example, an investigator might conduct an experiment and within that experiment collect qualitative data that provides information as to how the participants experienced the intervention. This design would be called an *embedded mixed methods design*.

Mixed Methods as a Field of Study

The clarification of these types of mixed methods designs and the reasons for using them has evolved since the 1980s. Although researchers have collected both quantitative and qualitative data throughout the 20th century, the development of mixed methods as a systematic approach to research is a relatively recent phenomenon dating back to the late 1970s. The writings on triangulation in 1979, for example, illustrate the idea of integrating both quantitative and qualitative data in a single study. These were followed by authors who felt that research problems might be best studied using both qualitative and quantitative data. By 1989, several evaluators had documented the varied purposes of conducting mixed methods studies and had mapped the various evaluation studies that incorporated this form of inquiry. Sociologists also began writing in the late 1980s about the processes involved in conducting mixed methods research. By the late 1990s and early 21st century, writers such as Abbas Tashakkori, Charles Teddlie, John Creswell, and Vicki Plano Clark had extensively mapped the landscape of mixed methods research and its designs and procedures. Today, numerous

disciplines and fields have published empirical studies and methodological discussions about mixed methods, including areas such as sociology, evaluation, education, counseling psychology, family science, nursing, and family medicine.

Advances in Mixed Methods Research

From this short history, it is possible to sketch several advances in mixed methods that characterize the field of mixed methods research as it is known today. Much work has been done to specify and to classify the types of mixed methods designs used by researchers. A parsimonious set of four designs can now be specified as general models for conducting this form of inquiry. Also known are the types of decisions needed to select one design over the others. Researchers decide on their type of design by asking themselves if the qualitative and quantitative approaches are used in tandem, or concurrently, or with one following or building on the other sequentially. Further, the researchers decide on the weight or priority to be given to the quantitative and qualitative approaches in the study and on how the two approaches will be mixed in a merged, connected, or embedded fashion. Researchers also decide whether they will use a theory or philosophical perspective as an overall lens for their project. Such a lens might be drawn from feminist perspectives, racial or ethnic perspectives, disability perspectives, or social or health science theories.

Advances have also been made in considering the philosophical foundation for conducting mixed methods research. From an either-or adversarial position between quantitative and qualitative research in the late 1970s and early 1980s, the field has evolved into exploring and debating the philosophical basis for mixed methods, the identification of one “best” philosophical paradigm to use, and the use of multiple paradigms in a mixed methods study. The paradigm debate about whether one can mix different realities of quantitative and qualitative research (and thus conduct mixed methods research) were heatedly debated during the middle 1990s, especially in the field of evaluation. This debate is still present, but writers such as those in the *Handbook of Mixed Methods in Social and Behavioral Research* edited by Abbas Tashakkori and Charles Teddlie have recently advocated for pragmatism with roots in John Dewey,

George Herbert Mead, and William James as the best paradigm. Pragmatism has been interpreted to mean that researchers employ multiple approaches, focus on what works, and acknowledge the importance of the research question rather than the specific methods used. Other writers, such as Donna Mertens have advocated for a transformative-emancipatory perspective as the best approach, a perspective that recognizes the principles of social justice and the study of underrepresented groups. Amid these calls for a best paradigm are those writers such as Jennifer Greene, Creswell, and Plano Clark, who suggest that multiple paradigms may be used in mixed methods research and that they need to be honored, acknowledged, and related to the types of designs chosen by the inquirer.

Another development has been the move toward standardizing the language and terms employed in mixed methods research. For example, terms mentioned earlier for describing the types of designs (e.g., triangulation design) are becoming more frequently used. New terms that have a bimethods orientation are reported in the mixed methods literature. For example, Tony Onwuegbuzie talks about legitimacy as a substitute for validity, Udo Kelle refers to inferences rather than to conclusions, and an entire glossary of terms for mixed methods research is found in Tashakkori and Teddlie's *Handbook of Mixed Methods*. A language of notation for creating diagrams of designs has also developed using arrows to indicate sequence and pluses to show the combination of procedures. Even the shorthand labels of mixed methods (QUAL, QUAN) provide equity in the number of letters and an abbreviated form used in describing mixed methods studies.

The name for this form of inquiry—mixed methods—is also open to debate. It has been called multi-method research (especially in the health sciences), integrated research (suggesting that there is a combination or mixing of information), hybrid research (indicating that it is neither qualitative or quantitative alone), triangulation (showing that the strengths of one method are offset by the weaknesses of the other method), combined research (emphasizing the combination of quantitative and qualitative approaches), and mixed research (illustrating that more than methods are being mixed). Since 2003, with the publication of Tashakkori and Teddlie's *Handbook of Mixed Methods*, the term *mixed methods* has, for the most part, been the standard term used to label this form of inquiry.

Challenges

As mixed methods research attracts interest and reaches an increasingly wider audience in fields of study and around the world, some individuals are voicing challenges to this form of inquiry. Writers are concerned about whether qualitative research has been relegated to secondary status in mixed methods experiments that include a small, embedded qualitative component. They are also concerned about integrating incompatible views of reality when researchers combine postpositivist views of a single reality with constructionist views of multiple realities. Some individuals are concerned about the dominance of certain voices in the discussion about mixed methods and whether the discourse is open and accessible to all writers. Others focus on issues of confidentiality in using the same participants in both phases of a sequential two-phase project.

Unquestionably, more discussion is needed about the adaptation and acceptance of mixed methods in various social and health science fields. Continued work needs to be done to better understand the procedures of sampling, the ways of merging quantitative and qualitative data, the suitability of current software programs to aid the mixed methods researcher, how individuals on research teams can effectively coordinate their individual expertise in quantitative and qualitative research, how to bridge the emerging division between philosophical approaches and method approaches, and the challenge to beginning researchers to understanding three approaches to inquiry—quantitative, qualitative, and mixed. Despite these challenges, the movement of mixed methods continues to advance and its growth is seen in an enhanced understanding of it as described in journals, in books, and at national and international conferences.

MULTICULTURAL RESEARCH

The term *multicultural* was coined in Canada in the 1960s and initially used in reference to the ethnic and cultural diversity in the population. Over the years, it has been adopted in most Northern and Western countries and is increasingly used in countries of the South. In many places, the term has been expanded to include other aspects of social diversity including gender, (dis)ability, sexual identity, and social class. In all of its iterations, the term is used in three distinct yet interrelated ways:

- to describe a demographic reality,
- to refer to state and institutional policies designed to manage or respond to demographic diversity, and
- to designate an ideal that brings together commitments to include all members of a society or community in the affairs of that entity, to recognize the importance of group identities, and to work for social justice in all spheres of activity.

Multicultural research, then, investigates the range of phenomena associated with the three definitions of multicultural. Of particular note in the realm of qualitative research have been discussions about ensuring research includes voices and perspectives reflecting the range of diversity within the community, examining existing research paradigms and epistemologies to uncover the ways in which these are inherently exclusionary, and considering how research ethics need to be modified to accommodate a multicultural reality.

Research About Diverse Groups

The recognition of demographic diversity caused some researchers to think about ways to include members of minoritized groups among the participants in various

research studies. In the field of marketing, for example, considerable effort continues to be given to conducting focus groups that reflect the demographic diversity of a community. This desire to be more inclusive in terms of participants has been met with mixed results as researchers across a variety of fields have discovered that members of minoritized groups are not always pleased to be asked to participate in research that is designed by “outsiders” for purposes that may have little or no importance for the minoritized group or groups in question. Some attribute this distrust to the legacy of research that was done to (rather than for or with) members of minoritized groups. This past experience has included horrendous examples, such as the medical experiments done on African American men in Tuskegee, Alabama, in which the subjects were allowed to suffer through syphilis with little or no treatment in order that the scientists could study the progress of the disease within this segment of the population. In the social sciences, there have been numerous examples, especially in anthropology, of studies of particular ethnocultural groups that have presented static and distorted pictures of groups. Although not as deadly as the Tuskegee experiments, this type of research has had an insidious effect on how members of dominant groups have perceived members of minoritized groups.

In part, establishing trust is being addressed in some disciplines by attention to creating a more diverse population within the research community. The American Anthropological Association, for example, established a committee on minority participation as early as 1970 for the express purpose of encouraging more researchers of minority backgrounds to enter and stay in the discipline. To this end, the committee has sponsored research on the reasons that people of minoritized backgrounds feel marginalized within the field and has developed mechanisms to support the work of researchers from minoritized groups. Similarly, the American Sociology Association has recently (2005) conducted a study to examine the reasons members of racialized groups are underrepresented in that field. Based on the findings, it seems that members of minoritized groups are being pushed out of the discipline, especially in doctoral studies and in the professoriate. Further research has been recommended to understand the issue more clearly and to develop solutions to the problem.

Additionally, some research bodies have attempted to facilitate collaborative relationships with minoritized

communities such that those being researched become partners in the research process instead of objects of study. In Canada, for example, the Social Sciences and Humanities Research Council entered into a dialogue with Indigenous researchers to establish new approaches to conducting Aboriginal research. The new paradigm rests on a number of premises including respect for Indigenous knowledge traditions, ensuring Indigenous communities benefit from the research, and placing the research primarily in the control of Indigenous peoples.

Examining Conventional Research Paradigms

As early as 1985, educational researcher John Stanfield noted that true inclusion was more than just a matter of doing research about or with minoritized groups. He pointed to the ethnocentrism that was inherent in the epistemologies underlying existing approaches to social science research. Feminist scholars, such as Patti Lather, raised similar concerns about the sexism that had become an integral part of the traditions of quantitative and qualitative research. This awareness has led researchers from minoritized groups to develop ways of “talking back” to accepted research paradigms and approaches. A number of methods that center decolonization, gender, and race and question taken-for-granted paradigms such as ability and heteronormativity have been and are being developed and refined. Although many of these new paradigms have their roots in concerns about one issue (e.g., sexism or racism), they are increasingly developing in ways that account for the range of diversity.

Critical race theory (CRT), for example, which originated in legal scholarship in the United States specifically for the purpose of drawing attention to the ways in which legal processes and scholarship systematically discount race and support existing regimes of racism, in its more recent iterations examines issues of gender and class as indivisible from issues of race. Closely related to CRT is queer legal theory (QLT), which in turn has been adopted and adapted by researchers in other disciplines. CRT and QLT begin by assuming the permanence of racism and heterosexism, respectively. They draw attention to the ways in which arguments are constructed so that White privilege and heteronormativity continue to be supported even when programs and policies are developed that are ostensibly for the benefit of minoritized groups.

Perhaps most important, they both use the technique of counter-storytelling as a way of challenging the status quo. Because conventional approaches to social science research tend to reinforce notions of minoritized groups as deficient, CRT and QLT ask researchers to ground their analysis in the lived experience of members of minoritized groups and to construct counter-stories that highlight the micro-aggressions, or the everyday injustices, that members of minoritized groups encounter, the systemic barriers and systematic campaigns that are used to claw back policies or programs that might promote the interests of minoritized group members, and the ways in which the lived experience of minoritized group members makes unique contributions to social science knowledge.

The concerns about the ways in which mainstream epistemologies are in themselves oppressive and discriminatory has also led a small number of researchers from dominant groups, working individually or with colleagues from minoritized groups, to think more deeply about their own practice. In the field of communications, for example, Fred Jandt and Delores Tanno have examined the ways in which imperialism, domination, and ethnocentrism are built into research processes. Their work has highlighted the process of othering that has taken place through conventional research traditions and the multiple ways in which the identities of the other have been defined in negative terms. Their argument for paying attention to the ways minoritized groups define themselves echoes across the social sciences. Additionally, they point to the need to think and talk more about the phenomenon of who is allowed to study whom. In particular they note that for a variety of reasons, it has been acceptable within the disciplines for members of dominant groups to study minoritized groups, but that research by minoritized groups about dominant groups has been far more contentious. This tendency is an issue that deserves more attention and discussion among qualitative researchers across the disciplines.

Research Ethics

Conversations about the ethics of research have been taking place across many disciplines as researchers become more familiar with the implications of doing multicultural research. In particular, concerns have surfaced about whether the conventional approach to ethics in research involving human subjects is sufficient to address the issues that arise in working across

a multiplicity of cultures. An issue that is receiving considerable attention in areas such as health care is that of the appropriateness of an ethical model based on an assumption of the primacy of the individual and a model of a contractual relationship. This attention has raised a number of questions that researchers across the disciplines ought to engage. For example, in traditions where major decisions are made collaboratively, is it sufficient or even appropriate to approach people as individuals to become involved in a research project? Might it be necessary to think of ways that informed consent becomes an issue of a collective rather than an individual? Where the basis for relationship is more personal than it typically is in the mainstream of Northern and Western societies, are there ways of thinking about informed consent that can move beyond signing forms that appear to be contracts and can thus interfere with the relationship between researchers and participants? In the quest to find new ethical standards for multicultural research, do we need to abandon the moral fundamentalism on which the current ethics practices are based? Ethical standards have been introduced to protect people from the types of heinous acts that have been committed in the past in the name of research, and they are designed to ensure that issues of integrity, justice, and non-maleficence remain forefront in the interactions between researchers and research participants. Thus, it is imperative that qualitative researchers engage with others involved in research practice to rethink existing approaches to ethics.

Doing multicultural research requires thinking with colleagues about the range of issues that arise in learning about and representing the diversity that exists in our societies. Above all, it is a matter of working for social justice through all aspects of research.

MULTIMEDIA IN QUALITATIVE RESEARCH

Over the years, scholars have employed various media and multimedia approaches in the practices of qualitative research. Whereas people often associate the term *multimedia* with electronic or digital media, the practices of recording and representing cultural processes and artifacts through multiple forms of photography, film, or audiorecording go back to the earliest days of cultural anthropology. What is interesting is that as the theoretical assumptions of research and representation in qualitative research have changed, so too have the ways in which researchers have employed media and multimedia approaches in their research designs.

The History of Multimedia in Qualitative Research

In a certain sense, multimedia has been a part of qualitative research since its beginnings. When 19th-century anthropologists attempted to salvage cultures they believed were doomed for extinction due to the spread of modernity, industrialization, and commercial culture, they documented these cultures through photography, early methods of audiorecording, and film.

Among the best known of early salvage ethnographers was Edward Sheriff Curtis, a North American who photographed the Native American Indians in the late 1880s. In 1900, commissioned by J. P. Morgan to produce a series of volumes on Native Americans, Curtis took over 40,000 images and made over 10,000 wax cylinder recordings of Native American language, songs, and rituals. Although these documents are a product of 19th-century romanticism that reflect many racist assumptions concerning Native American

culture, they remain an important collection of one of the few glimpses into earlier Native American life available for contemporary Native Americans, and constitute perhaps the earliest example of multimedia use in qualitative research. Robert Flaherty's film *Nanook of the North* (1922), on the lives of Arctic people in a hostile environment, is another key example of these early days of media use in qualitative research. Flaherty, convinced that he was documenting a fading culture, famously edited out all evidence of modern adaptation on the part of the natives he was filming. In the work of Curtis, Flaherty, and many others, media were viewed as unproblematic methods for relaying a realistic portrayal of the cultures under examination. This view of media and the knowledge constructed through qualitative research more generally would not be challenged for several decades.

Film and methods of audiorecording were expensive and cumbersome in the early years of the 20th century. Thus, sociologists as well as anthropologists of this era experimented with the more affordable and more portable medium of photography. One example is Lewis Hine, who had studied sociology under qualitative researchers W. I. Thomas and Florian Znaniecki at the University of Chicago. Drawing upon the urban focus of the Chicago school, Hine became known as a chronicler of the urban conditions of New York City. He photographed thousands of the immigrants arriving at Ellis Island in the United States between 1904 and 1909 and served as photographer for the National Child Labor Committee in the 1920s and 1930s. Hine's work set the standard for urban sociologists and photojournalists who wished to employ visual methods to produce a sympathetic vision of society's disadvantaged.

Although audiorecording was introduced in the United States after U.S. soldiers brought back its techniques from Germany, initial machines were too cumbersome to use in fieldwork settings. The introduction of the audiocassette recorder in the early 1970s forever changed the method of the audio interview in qualitative research. One of the important appeals of the audiocassette recorder was that it bore the promise of an enhanced rigor within qualitative research methods. With cassette recordings, researchers could move from selective, summarized notes to verbatim transcripts and could produce and analyze data using increasingly sophisticated technologies.

The introduction of the audiocassette recorder and later the relatively portable video recorder coincided with the moment of blurred genres within qualitative

methodologies. During this era from roughly 1970 to 1985, researchers embraced a range of theoretical foundations for their work, some of which—such as semiotics, feminism, and cross-cultural and ethnic perspectives—challenged the realist assumptions of media use that had been central to qualitative research in the decades before. Films, photography, audiorecordings, and other multimedia products came to be seen as objects and artifacts in their own right, and qualitative researchers thus grappled with the crisis of representation through multimedia in differing ways. Feminist sociologists experimented with the collection of oral histories and the multimedia presentations of individuals and groups, often forging presentations that broke conventions of academia to bring attention to the ways in which knowledge was co-constructed dialogically. Filmmakers such as Les McLaren and Annie Stiven eschewed the paternalistic voiceover of earlier films in favor of experimental efforts to reflect the complexity of the thought, language, and culture of Papua New Guineans. Others made the processes of filmmaking and writing part of the final research product. Tim and Patsy Asch's *The Ax Fight* is a key reflexive film in this regard as it shocks, then explains, and finally instructs the audience on the power of filmic editing in the construction of cultural knowledge. Rather than attempting to capture and relay what was observed, media in the context of qualitative inquiry thus became an alternative way of contributing to the perception of culture and cultural activities.

Reflexivity about the process of documenting also raised the issue of who was behind the camera, recorder, or pen. Throughout the 1970s, 1980s, and 1990s, colonial rule was coming to an end in places such as Bangladesh, Algeria, Mali, Sierra Leone, and Belize, and many Western qualitative researchers shifted knowledge production processes into the hands of those who had traditionally been represented by those of the West. A growing desire to construct their own images and narratives led many Indigenous communities to produce their own films, oral histories, and videos, and, later, CD-ROMs, web pages, and exhibits.

Multimedia in Contemporary Qualitative Inquiry

Today, the use of various media in qualitative inquiry extends through the disciplines of sociology, anthropology, education, and other humanities and social

sciences and is informed by various approaches, including grounded theory, discourse analysis, textual analysis, cultural analysis, visual theory, social learning, and material culture studies.

Currently, several anthropologists are experimenting with documentary filmmaking and the recording of everyday life, constructing documents that aim to engage with contemporary social problems. Elinor Ochs, director of the Sloan Center on the Everyday Lives of Families, is working with colleagues to create a digital video archive of middle-class families engaging in such practices as dinnertime and the return home after work and school. Building on traditions of film and visual anthropology, Lucien Taylor and Lisa Barbash have produced *Made in USA* (1990) on child labor in the Los Angeles garment industry and *In and Out of Africa* (1992) on taste and race relations in the African art market.

With the crisis in representation, scholars from various disciplines increasingly engaged with media cultural studies, as that field problematized the practices of both the construction and the interpretation of mediated materials. In the 1980s, scholars engaged in qualitative interviews organized around television watching, music and radio listening, and the viewing of visual culture. Research by David Morley and Charlotte Brundsen, David Buckingham, Angela McRobbie, and others in the United Kingdom, the United States, and Australia theorized that cultural practices of media interpretation were creative within the constraints of a hegemony articulated by and reinforced within mainstream media productions. Elihu Katz, Klaus Bruhn Jensen, Ien Ang, and others articulated the situatedness of media constructions and interpretations within various cultures as globalization introduced mediated cultures across national borders and boundaries. Theories of the active audience, while relatively short-lived within media studies itself, continued to have resonance among disciplines that had heretofore approached media unproblematically as propaganda or mechanisms for the unproblematic transmission of meanings.

Several branches of scholarship have broken ground in multimedia qualitative inquiry in recent years. Some researchers have immersed themselves in mediated environments for observation and documentation, such as Sunaina Maira's study of second-generation South Asian immigrants and the "ethno chic" scene of bhangra parties, and Rob Drew's observations of karaoke culture in the United States.

Other scholars have immersed their research participants in the process of media creation for the purpose of observing and analyzing the construction of knowledge and of communicating identities to others. Elizabeth Bird has observed as research participants have engaged in the creation of fictional television programs, Jane Brown has invited adolescent girls to use fashion magazines as the raw materials from which to construct collages, and David Gauntlett has encouraged participants to play with and envision new video games. Equally of interest has been the proliferation of studies of game creators and creative personnel and processes within the media industries.

The digital media environment has created a host of new applications for multimedia within qualitative inquiry, including not only new methods of gathering, archiving, and presenting data, but also new ways in which researchers might interact both with each other and with research participants. During the 1980s and 1990s, researchers began to participate in listservs on qualitative inquiry and constructed web pages through which to share detailed information about ongoing studies. As a larger percentage of the population engaged in online ventures throughout the 1990s, qualitative researchers experimented with studies of online communities and online gaming. In the first decade of the new millennium, qualitative researchers extended earlier listserv and web-based conversations to specialized blogs such as *Savage Minds*, the site for anthropological inquiry. Digital media studies scholars experimented with the creation of digital art that comments on emergent social situations through social theory, art, sound, and animation. In recent years, scholars have posted video essays on YouTube and in various online collaboratives. The internet and email have made online interviewing more accessible, and virtual ethnographies provide opportunities for participant observation in online spaces. Software for the rigorous analysis of qualitative inquiry has further provided legitimacy to methodologies, and online archives provide opportunities for comparative and historical research in ways not dreamed possible in earlier times.

For scholars interested in multimedia methods within qualitative inquiry, the development of new theories to address the emergent digital realm has become a significant challenge. As multimedia qualitative inquiry continues to develop in relation to the assumptions of the field, its new form will no doubt be

reflexive, transdisciplinary, richly sensory—and both inherently problematic and deeply intriguing.

MUSIC IN QUALITATIVE RESEARCH

Music in qualitative research can refer to both qualitative studies focusing on musical contents and issues and to research shaped by musical concepts and approaches.

Research on Musical Contents and Issues

This section provides a brief overview of qualitative research in social sciences disciplines that focus on musical issues, specifically ethnomusicology, sociology of music, and music education.

Ethnomusicology

Ethnomusicology emerged in the late 19th century and early 20th century in Germany and central Europe, practiced by composers such as Béla Bartók and Zoltán Kodály and musicologists such as Curt Sachs, shortly after taking roots in the United States. The discipline of ethnomusicology draws its intellectual roots, theories, and methods primarily from musicology and cultural anthropology. Ethnomusicologists are typically concerned with broad questions on the use and function of music, the role and status of musicians, the concepts that lie behind music behavior, and other similar

questions, aiming to understand music in the context of human behavior and meaning-making. As leading scholars Alan Merriam and Bruno Nettl have noted, the emphasis is upon music in its total context: the investigator aims to gain a broad knowledge of the way music fits into and is used within the wider culture. Given these goals and the early recognition (decades before other social sciences disciplines) of cultural context and situated meaning as shaping knowledge and understanding, ethnomusicology has drawn on qualitative methods from the beginning.

Initially ethnomusicology focused on non-European music of oral traditions, but in more recent years the field has expanded to embrace various musical styles from all parts of the world, including Western vernacular settings. In the postmodern turn of the past 30 years and the eroding distinctions between mainstream versus exotic cultures, as well as the juxtaposition of research genres and methods, ethnomusicology has provided an important research model for other music disciplines, including the sociology of music and music education.

Sociology of Music

Sociology of music is commonly defined as the application and development of sociological theories and methodologies to examine the role of music in society and to study music behavior and attitudes as part of social action. Sociology of music originated in the early 20th century in Europe and the United States, mostly using philosophical and quantitative approaches. In the past 30 years, as a result of the postmodern turn that affected all the social sciences and the expansion of research issues and contents in sociology, its methodologies encompassed qualitative methods. The paradigm shift from an objective reality (as exemplified, for example, by Immanuel Kant's notion of universal taste) to multiple, constructed realities that are grounded in specific social contexts and are worthy of attention required exploratory research methods that examine what people do and the meanings they attributed to it. Sociology of music is closely related to the sociology of culture; in particular, the sociology of popular culture. The view of music as a sociological and cultural entity heightened attention to the issues of identity formation through music. Other important areas of research are the ongoing construction of musical fields including the systems and logics of production and consumption, meanings,

and attitudes; patterns of evolving musical taste; and the role of music in everyday life.

The interest in diverse social classes and cultures and their respective values, recognizing the need to understand different social perspectives, motivated researchers to reach beyond their traditional disciplinary boundaries to disciplines such as ethnomusicology and folklore in conceptualizing and designing research studies and analyzing and interpreting behaviors and events. Thus, the expansion of the field is manifested in the number of publications, the softening of boundaries between disciplines with increased dialogue and interchange, and in the range of theoretical perspectives and diversity of methodologies.

Music Education

Research in music education, dating to the 1930s, initially was modeled after psychology, drawing mostly on quantitative methods with the occasional philosophical and historical research. The 1980s witnessed the cautious but steady emergence of qualitative studies, opening up new directions for research, including the study of school music, with a focus on the operational, perceived, and experienced curricula; musical cultures of children; and creativity, composition, and musical thought processes of listeners, composers, and conductors. The recognition that music teaching and learning are embedded in social contexts and meanings acknowledged the diversity of students' cultural and musical values and made for a more pluralistic worldview.

The use of qualitative methodologies increased significantly in the mid-'90s and after. An increasing international exchange of ideas and scholars brought in phenomenological, sociological, and anthropological perspectives. This culture of openness and expansion generated new venues for research, including the two qualitative conferences at the University of Illinois, at Urbana-Champaign (1994, 1996); the biannual *Research in Music Education* in Exeter, England (2001, 2003, 2005, 2007); and *Narrative in Music Education* (2006, 2008) in Arizona and established new research journals such as *Research Studies in Music Education* and *Music Education Research*. Cumulatively, these events and journals are evidence of the growing prominence of qualitative scholarship.

Research in music education encompasses diverse qualitative genres, from the applied genres of evaluation, formative and action research, to the more basic

genres of ethnography and phenomenology. The examination of the educational aspects of musical cultures informed by ethnomusicology and studies of people's lived experience of music informed by phenomenology co-exist with and inform the school-based, practice-oriented teacher and action research and formative research with its emphasis on the development of materials and use of technology.

Research Shaped by Musical Concepts and Sensitivities

The first section centered on qualitative research that examines musical contents and issues. This section discusses how musicianship can contribute to the processes and products of qualitative research. This discussion is part of the broader domain of aesthetic and arts-based inquiry. In the conversation surrounding arts-based inquiry, starting in the 1990s, it was the disciplines of visual art, literature, and drama that have taken a leading role; the voice of music was mute. Ironically, researchers in music education, like colleagues in other scholarly disciplines, have privileged the visual, the numerical, and the textual over the auditory, the embodied, and the textural.

However, there is an increasing recognition of the important contributions of music to research in the social sciences. At the heart of music-based inquiry is the assumption that the personal and cultural dimensions of lived experience can be better understood by drawing on what are essentially auditory and musical experiences, addressing areas of qualitative inquiry that have not been explored. Involvement in music as creators, performers, and listeners requires engagement with the evanescent aspects of world, aspects essential for research in the human sciences.

The contributions of musicianship to social science research can be applied to three aspects of the research endeavor: design and data collection, drawing on embodiment, improvisation, and dialogue; data analysis and representation, drawing on musical elements and concepts; and the communication of research, including music presentation as research that draws on performance.

Conceptualizing and Cultivating Sensitivities

Viennese conductor and philosopher of music Victor Zuckerkandl observed that in seeing, touching, and tasting, one reaches through the sensation to an object, to a thing. Tone is the only sensation not that of

a thing. Highlighting the evanescent, processual qualities of music, musicologist David Burrows has suggested that we see the world as a noun and hear it as a verb. The theme of stability versus fluidity is developed by philosopher of music and music education Wayne Bowman, who has pointed out that there is no sonic counterpart to the constancy and objectivity characteristic of vision: sonorous experience is invariably the experience of process and change—change of direction, of quality, of intensity. Cultural historian Walter Ong comments that all sensation takes place in time, but no other sensory field totally resists a holding action, stabilization, in quite this way. Vision not only can register motion, but it can also register immobility. Indeed, it favors immobility, for to examine something closely by vision, one prefers to have it quiet.

Given that fluidity is basic to all lived experience, cultural and personal, working within the fluid auditory mode heightens attention to qualities of experience that are hard to capture by traditional methods. Drawing on these qualities, researcher of music and arts education Liora Bresler highlights the fluidity of observations and interviews, the attunement they involve, and their embodied and improvisatory nature that attends to the temporal evanescent nature of lived experience. Learning to hear cultivates sensitivities that are essential to the conduct of educational research, fieldwork as well as analysis, involving a tuning that is essential in establishing connections and achieving empathic understanding. It is this tuning that allows improvisation, an interaction with participants and with data that is responsive.

Conceptualizing and Structuring Qualitative Research

Musical processes are parallel to (and some would say, inherent to) qualitative research processes, shaping data collection, data analysis, and data representation. Traditional scientific research has focused on rigorous and replicable methods and representation that adheres to a formal scientific style. However, as Karl Popper has observed half a century ago, scientific methods emphasize the prespecified aspects of refutation, rather than the messier, complex processes of generating conjectures and theories. Music-based inquiry attends to these processes of meaning-making and the construction of knowledge and understanding.

The notion that musical concepts can provide structures for conceptualizing and communicating qualitative research was raised in Bresler and Robert Stake's chapter in Richard Colwell's *Handbook on Research in Music*

Teaching and Learning (and exemplified in Bresler's writing) and by Fred Erickson in his important work on musicality in speech. Gertina van Schalkwyk uses the metaphor of a concerto and the polyrhythmic patterns of an African ceremonial rituals for organizing and structuring research. Peter Gouzouasis and Alexandra LaMonde chose the musical form of a sonata to examine tetrads, cognitive models of a simple fourfold structure, to refine or discover entities in cultures and technologies that are hidden from view in the psyche.

A third category of music-based inquiry is what Melissa Cahnmann refers to as stand-alone art, where musical performances are presented as products of research. Following the tradition of A/r/tography, music educator Gouzouasis integrates the roles of the artist-researcher-teacher in his music performances.

Challenges

For the past 40 years, the scholarly qualitative research community has discussed and debated the appropriateness of various criteria, generating alternative trustworthy criteria for both processes and products. Music-based inquiry, hoping to expand research not only beyond the quantitative but also beyond the verbal, faces the challenges of creating new sets of criteria compatible with the new goals and understanding of its research. Still at its infancy, the next decades will tell what is good music-based inquiry and what music-based inquiry is good for!

N

NARRATIVE ANALYSIS

Narrative analysis refers to a family of analytic methods for interpreting texts that have in common a storied form. As in all families, there is conflict and disagreement among those holding different perspectives. Analysis of data is only one component of the broader field of narrative inquiry. Methods are case centered, and the cases that form the basis for analysis can be individuals, identity groups, communities, organizations, or even nations. Methods can be used to interpret different kinds of texts—oral, written, and visual.

The term *narrative* is illusive, carrying many meanings and used in a variety of ways by different scholars, often used synonymously with story. In the familiar everyday form, a speaker connects events to a sequence that is consequential for later action and for the meanings listeners are supposed to take away from the story. Events are perceived as important, selected, organized, connected, and evaluated as meaningful for a particular listener. The definition emphasizes the contextual nature of oral stories; they are told (indeed performed) with the active participation of an audience and are designed to accomplish particular aims. Oral stories are strategic, functional, and purposeful. Other forms of oral communication include chronicles, reports, arguments, and question and answer exchanges.

Among scholars working in the human sciences with personal (first-person) accounts for research purposes, the narrative unit can differ, and its form is often linked to a discipline. In anthropology and social history, narrative can refer to a life story that the

researcher weaves from threads of interviews, observations, and documents. At the other end of the continuum lies the very restrictive definition of social linguistics. Here, narrative refers to a discrete unit of discourse, an extended answer by a research participant to a single question, topically centered and temporally organized. Resting in the middle on a continuum of working definitions is research in psychology and sociology. Here, personal narrative encompasses long sections of talk—extended accounts of lives in context that develop over the course of single or multiple interviews or therapeutic conversations. The diversity of working definitions underscores the absence of a single meaning or unit of analysis. The term is employed in the social sciences to refer to texts at several levels that overlap: stories told by research participants (stories, which are themselves interpretive), the interpretive account an investigator develops based on interviews and fieldwork observation (i.e., a story about stories), and even the interpretive narrative a reader constructs after engaging with the participant's and investigator's narratives. Analytic work with visual materials pushes the elusive boundaries of narrative definition further.

In my thinking over time about the burgeoning field of narrative research, I have grouped the various forms of analysis into a simple typology: thematic, structural, dialogic-performative, and visual narrative analysis. The thematic form interrogates what a story or group of stories is about, while the structural form attends to how a story is composed to communicate particular communicative aims. These two broad approaches are the building blocks of all narrative analysis; others draw on components of them and add

other dimensions. The dialogic or performative analysis interrogates how talk among speakers is interactively (i.e., dialogically) produced and performed as narrative; the investigator is actively present in the text. Finally, the visual narrative approach links words and images in a visual narrative analysis in which investigators interpret found images (in archives and other collections) and craft a narrative where the researcher is part of the image-making process. In all four analytic approaches, study is grounded in the particular: how a speaker or writer assembles and sequences events and uses language and/or visual images to communicate meaning, that is, to make particular points to an audience.

Attention to sequences of action distinguishes narrative methods from other qualitative approaches. Narrative analysts interrogate intention and language—how and why events are storied, not simply the content to which language refers. Narrative analysts ask the following questions: For whom was the story constructed and for what purpose? How is it composed? What cultural resources does it draw on or take for granted? What storehouse of cultural plots does it call up? What does the story accomplish? Are there gaps and inconsistencies that might suggest preferred, alternative, or counternarratives? There are many ways to narrate an experience: How a speaker, writer, or visual artist chooses to do it is significant, suggesting lines of inquiry that would be missed without focused attention or close reading. Some investigators in the social sciences attend to language, form, and social context (including audience) more than others do.

Elliot Mishler contrasts category-centered approaches in social research, which strip individuals of agency and consciousness, with case-based approaches that can restore agency in research and theory; individuals are respected as subjects with histories and intentions. The study of cases can generate categories or, to put it differently, theoretical generalization; the histories of the physical and social sciences are full of examples where theoretical propositions were derived from close study of individual instances. Narrative analysis joins this long tradition of case-centered inquiry, interrogating stories developed in interviews and fieldwork and in archival documents and visual media.

NARRATIVE GENRE ANALYSIS

Narrative has been studied extensively in the social sciences as a privileged communication mode by means of which social actors make sense of their self and the world around them. This focus has implicated a longstanding inquiry into personal experience (i.e., autobiographical) narratives of nonshared past events (i.e., either in the form of life stories or of key-events stories) that are normally elicited in research interviews. In the light of this history, the questions and methods of narrative genre analyses have been shaped by the use of such a type of narrative as a point of entry into tellers' identities. For instance, the emphasis has been on what a well-formed structure or a rupture of structure in a telling may mean with regard to the teller's sense of self.

Overall, the dominant view of the narrative genre's main characteristics can be summed up as follows: a coherent and well-structured telling with a beginning, middle, and an end that grants the teller strong telling rights. This telling is about a series of temporally ordered events that build up to a complicating action that is normally resolved. The teller employs a variety of linguistic and other semiotic means to show the significance (i.e., tellability) of the events and the emotional impact they have had on him or her.

Underlying the above view is a tradition of essentializing and homogenizing narrative as one archetypal genre. The move to the exploration of narrative variability has thus been slower than in other genre analyses. The scrutiny of the different types of stories people tell in a variety of ordinary and institutional contexts can mostly be found within socially minded linguistic studies. These studies have demonstrated that the kinds of stories told and the ways they are told depend both on the local context (e.g., who tells a story to whom and why) and on the larger social and cultural contexts. This context-specificity involves the types and degrees of co-construction between teller and audience, the kinds of events narrated, how (much) a story is embedded into its surrounding discursive context, the emphasis placed on presenting the events as factual and authentic, and so on. Genre analysis has also shown that variations from the narrative prototype of personal past events are frequent outside the narrative interview. For instance, stories of shared (or known) events and of future or hypothetical events abound in conversational contexts. Thus, the importance of including these and other types of stories in narrative genre analysis not just as atypical but as stories in their own right that serve specific purposes in specific contexts is becoming increasingly recognized.

On a final note, narrative genre analysis has moved away from an earlier emphasis on prototypical text features to an exploration of narrative genres as social practices: as routine and socioculturally ways of acting in ways that link with and produce social life.

NARRATIVE INQUIRY

Narrative inquiry is first and foremost a way of understanding experience. It is also a research methodology. It is, then, both a view of the phenomena of people's experiences and a methodology for narratively inquiring into experience and thus allows for the intimate study of individuals' experiences over time and in context. Beginning with a narrative view of experience, researchers attend to place, temporality, and sociality, from within a methodological three-dimensional narrative inquiry space that allows for inquiry into both researchers' and participants' storied life experiences. Within this space, each story told and lived is situated and understood within larger cultural, social, and institutional narratives. Narrative inquiry is marked by its emphasis on relational engagement between researcher and research participants. Narrative inquiry, across various disciplines and multiple professional fields, aims at understanding and making meaning of experience through conversations, dialogue, and participation in the ongoing lives of research participants. Each discipline and field of study brings slightly different ways of understanding and different contexts to the narrative study of experience that deepen the methodology of narrative inquiry.

The introduction of narrative inquiry as a research methodology has reshaped the field of qualitative research, especially with its close attention to experience as a narrative phenomenon and its emphasis on relational engagement that places relational ethics at the heart of inquiry. This entry reviews the process of narrative inquiry and its philosophical foundations, describes the creation of field and research texts, and explores ethical issues that are raised with this methodology.

Narrative in Qualitative Research

Over the past 2 decades, researchers have taken a narrative turn to understanding experience. Although there is a history of narrative work within the traditions of narratology, in the 1990s researchers began to specifically develop a research methodology called narrative inquiry. Narrative inquiry and narrative research, terms used almost interchangeably in the current research literature, signify a research methodology. However, within the broad field of qualitative research, there are many analytic methods or forms of

narrative analysis. Some forms of narrative analysis are used as methods within other qualitative research methodologies.

In studying and understanding experience narratively, researchers recognize the centrality of relationships, the relationships among participants and researchers, and the relationships of experiences studied through and over time and in unique places and multilayered contexts. Amidst these relationships, participants relate and live through stories that speak of and to their experiences of living. The process of narrative inquiry is composed of engaging with participants in the field, creating field texts, and writing both interim and final research texts. Throughout this process, ethical considerations require that researchers remain attentive to ethical tensions, obligations, and responsibilities in their relationships with participants.

Philosophical Underpinnings

John Dewey's theory of experience is most often cited as the philosophical underpinning of narrative inquiry. Dewey's two criteria of experience, interaction and continuity enacted in situations, provide the grounding for attending to experience through the three-dimensional narrative inquiry space with dimensions of temporality, place, and sociality. Jerome Bruner's ideas about paradigmatic and narrative knowing in psychology, David Carr's ideas about the narrative structure and coherence of lives in philosophy, Mary Catherine Bateson's ideas about continuity and improvisation as a response to the uncertainties in life contexts in anthropology, and Robert Coles's ideas about narrative in life and teaching practice in medicine also provide a philosophical base for narrative inquiry. As narrative inquirers seek to inquire into experience, they must begin their inquiries with narrative self-studies into their own experiences. Narrative inquiries, thus, have both autobiographical narrative groundings as well as more theoretical groundings. The autobiographical narrative inquiries are the starting points for initially shaping and deepening the research puzzle.

Process of Narrative Inquiry

Narrative inquiries begin with inquiring into researchers' own stories of experience. Because narrative inquiry is an ongoing reflexive and reflective methodology, narrative inquirers need to inquire continually into their experiences before, during, and after each inquiry.

Within the methodology of narrative inquiry, there are particular methods that are employed. There are two starting points for narrative inquiry: listening to individuals tell their stories and living alongside participants as they live their stories. The most frequently used starting point is with telling of stories, and the methods most commonly used are interviews and conversations or interviews as conversations. Some narrative inquirers also use artifacts to trigger the telling of stories. In the second starting point, narrative inquirers begin with living alongside participants using visual media and/or participant observation. For narrative inquirers who begin with living stories, telling stories using methods such as conversations, oral histories, and interviews also plays a part. Whether the beginning point is living or telling stories, inquirers need to attend to the ways individual narratives of experience are embedded in social, cultural, and institutional narratives. Each inquiry reflects the ambiguities, complexities, difficulties, and uncertainties encountered by the inquirer as she or he lives in the field and writes field texts and interim and final research texts.

In the Field

Prior to engaging with research participants, narrative inquirers need to undertake a reflective inquiry process into their narrative understandings in relation to the particular research phenomenon with its attendant research puzzle. These narrative reflections are central to the research process and become part of the research texts. Entering the field begins with negotiation of relationships and the research puzzles to be explored. Negotiations of purpose, transitions, intentions, and texts are an ongoing process throughout the inquiry. Narrative inquirers also negotiate ways they can be helpful to the participant(s) both during and after the research.

As the negotiations begin, narrative inquirers are attentive to the three-dimensional narrative inquiry space and attend to experience temporally, socially, and spatially. Once in the field, researchers recognize that narrative inquiry is a way of living in the field and as such, the research becomes part of life. Given the complexity and depth of the research, researchers' lives become entwined with participants' lives.

Field Texts

Depending on the starting point of the inquiry (living or telling), different methods are used to compose field

texts. Field texts, commonly called data, are composed from conversations, interviews, and participant observations, as well as from artifacts. Artifacts that may become part of the field texts include artwork, photographs, memory box items, documents, plans, policies, annals, and chronologies. Field texts are co-compositions, reflective of researchers and participants, and need to be understood as telling and showing those aspects of experience that the relationship allows. Field texts are composed with attention to the three-dimensional narrative inquiry space. Temporality comes into play in two ways: the first is that field texts are composed over multiple interactions with participants; the second, through participants' reflections on and of earlier life experiences. Sociality directs attention inward toward the participants' thoughts, emotions, and moral responses and outward to events and actions. Place directs attention to places where lives were lived as well as to the places where inquiry events occur.

Field texts are embedded within research relationships and reflect multiple nested stories. Field texts are shaped into interim research texts, which are shared and negotiated with participants prior to being composed into final research texts. Research texts are composed from field texts and interim research texts.

Narrative inquirers are well served by participating within a response community. Within a response community, works in progress (interim research texts) can be shared and discussed. Response communities are critical elements within the inquiry, as they help inquirers recognize how they shape both the experiences of their participants and their research puzzles. These communities consist of people the researcher values and trusts to provide responsive and responsible dialogue about the unfolding inquiry. Response communities, marked by diversity, can enrich the research, particularly if they are composed of interdisciplinary, intergenerational, cross-cultural, and academic and nonacademic members. Given the iterative nature of narrative inquiries, there is continuous interplay among field texts, interim research texts, and final research texts.

Research Texts

During the composition of research texts, narrative inquirers are attentive to both participants and possible public audiences. Research texts are shared with participants, who remain the most influential voice in the move to final research texts. Research texts need to reflect the narrative quality of the experiences of

both participants and researcher and the ways these stories of experiences are embedded within social, cultural, and institutional narratives.

Research texts are negotiated between researcher and participants. Researchers, however, also owe responsibility to the scholarly community and must compose research texts that answer the questions of "so what?" or "who cares?" These questions speak to the social significance of each narrative inquiry. Research texts can take multiple forms, including textual, visual, and audible forms.

In narrative inquiry it is imperative to address the question of how larger social, institutional, and cultural narratives inform our understanding and shape the researchers' and participants' stories by which they live. Paying attention to these contextual narratives enables researchers to further deepen the complexity of the living and telling of stories.

Ultimately, research texts develop out of the repeated asking of questions concerning the significance of the research. Research texts also attend to the personal and practical significance of the research, paying attention to the growth for researchers and participants that can occur in the (re)living and (re)telling of the experience.

Ethics

Because narrative inquiry is a relational research methodology, ethical issues are central throughout the inquiry. Ethical requirements move beyond institutional requirements of privacy, confidentiality, and informed consent. Attending to the way participation in a narrative inquiry shapes each participant's life, the negotiations of entry, exit, and representations of experience are central ethical concerns. Issues of informed consent bring forth questions of who has the right to give consent, how one maintains informed consent throughout the inquiry, and how participants consent to final research texts that reveal personal experiences and place those experiences within a larger context. Researchers require thoughtful sensitivity and wide-awakeness as they compose research texts, particularly when they work with marginalized and/or vulnerable populations, such as with children and in cross-cultural settings.

Narrative inquirers have to balance issues of voice, signature, and audience. Within each inquiry, researchers attempt to represent the multiplicity of voices and signatures, which are reflected in the

importance of diverse textual structures and accounts. Narrative inquiries are always filled with rich temporally unfolding narrative accounts, as they represent the lived and told experiences of participants and researchers. Yet, as narrative inquirers come to know in relational ways, the inquiries also become an intervention, which requires the researcher to remain attentive to ethical issues long after leaving the field and composing final research texts.

History (JNLH). The working definition of narratives is that they usually concern real or pretend memories, often largely in the past tense, though there are narratives given in the future or historical present tense. Narratives often contain a chronological sequence of events, but not always. Narratives are often spoken, but there are musical, pictorial, dramatic, and other performed narratives. At present, some focus on the analysis of narrative; others, on its use. All studies of narrative require interpretation—hermeneutic scholarship, necessitating the use of qualitative methods.

As of mid-2006, *NI* published 394 contributions, including 247 reports of original research, 120 responses to original research, 22 book reviews, and 5 editorials. Of the reports of original research, 76% used exclusively qualitative methods and 24% used a mixture of qualitative and quantitative methods. No articles were exclusively quantitative. Of the articles that used a mixture of qualitative and quantitative methods, over 80% dealt with developmental psychology and education, especially language acquisition involving children exclusively or children speaking with adults (e.g., parents, teachers, or policemen). Although there is no reason that qualitative methods cannot be used in conjunction with quantitative methods, the nature of narrative inquiry about individuals past adolescence does not seem to lend itself to the grouping variables essential for quantitative analysis.

The qualitative methods used in *NI* articles come from diverse academic traditions, including psychology, linguistics, education, English, language studies, sociology, anthropology, medicine, nursing, health studies, history, communication studies and disorders, journalism, geriatrics, and political science. The *JNLH* was conceived of as an interdisciplinary publishing venue. What is astonishing is that after over 15 years practitioners of such diverse disciplines still find common ground in the study of narrative.

Narratives from individuals of many cultures and walks of life are published in *NI*. Though most are from North Americans and/or from Europeans, South Americans, Asians, Africans, mid-Easterners, and others are also common. All socioeconomic groups are represented, though special attention is given to marginalized individuals—including Holocaust survivors, prostitutes, beggars, illegal immigrants, and mental patients. Qualitative methods are especially adept at facilitating one's understanding of individuals very different from oneself.

From the outset, *NI* published responses to others' scholarship, and such responses constitute 30% of

NARRATIVE INQUIRY (JOURNAL)

Narrative Inquiry (NI) began publication in 1991 and was originally known as *Journal of Narrative and Life*

what is published. In this way, too, the scholarship of *NI* recruits qualitative methods for close listening and careful reading of others.

NARRATIVE INTERVIEW

A narrative interview is an interview that is organized to facilitate the development of a text that can be interpreted through narrative analysis. Narrative analysis is guided by a theory of narrative, and these theories of narrative vary in the influence of the reader, the text, and the intent of the author on interpretation. For this reason, the content and structure of a narrative interview will depend both on the theory of narrative being used in the analysis and on the research question. That being said, there are some commonalities among all narratives that will facilitate interviews for use in narrative analysis.

Informants often relate experiences in narrative format; that is, they select and order events in ways that both reflect their own meanings and convey those meanings to others. The content and structure of the narrative contains implied meanings that are as important to understanding the narrative as the overt meanings—and perhaps more important. Narrative interviews provide informants with many opportunities to select and order events themselves rather than to put events into a preordained structure. For this reason, narrative interviews are often organized temporally, in the manner of a life story or as in life history research. Questions such as, “When did you first notice . . .” or “How did you begin . . .” allow respondents to set the perimeters of the temporal context they find relevant. Decisions about relevant and irrelevant content are made during the course of the interview, both by the informant and in collaboration with the researcher, but no information is a priori ruled out, for any event or interpretation can contribute to the meaning of a story.

Narrative interviews can use semi-structured or unstructured formats depending upon the research

question and the goal of the analysis. Questions should be sufficiently open-ended to encourage participants to explain themselves fully, but it is not necessary that every question elicit a story. Often narratives are constructed by the researcher from component parts offered by the informant across the interview or interviews. Questions that are closed (i.e., require a yes or no answer) or that offer a set of fixed choices (e.g., always, sometimes, never) do not facilitate the development of narratives. However, questions that begin, for example, “Tell me a story about . . .” may intimidate informants who do not normally think in those terms. Narrative interviews, thus, require artful design, with questions carefully ordered to build on previous questions. Narrative interviews are also facilitated by the use of neutral probes that elicit information about actions and explanations. Questions such as, “How did it happen that . . .” or “What did you do then?” elicit the thinking that underlies the connection of the events or experiences selected for the informant’s story. Revealing those connections is the primary goal of the narrative interview.

NARRATIVE TEXTS

Narrative texts are a form of discourse that has been fixed by writing. Some postmodern scholars have defined text to include anything that can be interpreted, from a photograph to a film score. For this entry, Paul Ricoeur’s definition of a text as a discourse fixed by writing is used; however, it is important to recognize that some scholars recognize forms other than the written word as having textuality.

Scholars of rhetoric divide texts into different types depending on the author’s intent. Narratives are characterized by temporal organization: beginning to

middle to end. Events unfolding over time constitute the plot. Other central features of narratives include characters, a setting for the plot, and a theme or message that is conveyed both by the words of the story and by the selection and ordering of events that are included within it. Narratives, as compared to expository texts, use voice to convey a particular point of view—all narratives take a point of view, although the point of view may be that of an omniscient observer. Point of view is used to support the narrative's theme by supporting the credibility or worthiness of the narrator. The purpose of a narrative text is to tell a story, usually the story of a resolution to a problem.

In contrast, the purpose of expository texts is to explain, inform, or teach. The voice of expository texts is therefore neutral and objective. Recipes, laundry lists, and textbooks are examples of expository texts. Research reports are often structured as expository texts, using language that minimizes the author's voice and obscures the role of selection and exclusion of events or information in the development of a theme or message. Many qualitative researchers have decried this approach and developed alternative forms of research representation, some of which include narrative elements such as the story of the research or the researcher.

Both narrative and expository texts can be used as qualitative data. For example, historians often rely on expository texts such as lists of supplies ordered by a military unit during a particular period of World War I or by cataloguing the equipment advertised for use by nurses in the 1940s. Similarly, interviewers may request expositions from informants, perhaps as journal entries or logs, or may elicit expositions in interviews and then fix those expositions as texts via transcription. Interviewers may also elicit narratives from informants, either in writing or as discourse.

The boundary between expository and narrative texts is itself controversial. Some scholars contend that all texts are narrative because of the meanings they convey and because of the deliberate selection or omission of events or information. This liminality is nowhere more apparent than in qualitative research reports in which the exposition of findings, the voice of the author, the context of the study, and the narratives of informants come together.

NATURALISTIC DATA

Naturalistic data can be defined as data that make up records of human activities that are neither elicited by nor affected by the actions of social researchers. The test for whether data are naturalistic is if the social researcher is ill, interviews and ethnographic observations would have to be cancelled, but therapy sessions, parliamentary debates, and everyday phone calls would still take place.

From the start, social science has worked largely with self-reported materials (e.g., surveys or interviews) or researcher-manipulated materials (e.g., experiments). Occasional critics argued for unobtrusive measures, yet in practice this attempt took the form of indirect measures of behavior (e.g., garbage as a cue to consumption habits) or the use of materials such as diaries with little discussion of their analysis. Although ethnographers often collect material through observation, this collection is typically in the form of fieldnotes or interviews that embed researcher categories into the material, making it particularly hard to recover the original patterning of the interaction.

The analysis of records of people interacting was stimulated most fundamentally by Harvey Sacks and the tradition of conversation analysis that he and his colleagues developed. This work started to exploit developments in audio and now videorecording technology.

Advantages commonly offered for working with naturalistic data include the following:

1. It does not flood the research setting with the researcher's own categories, which are embedded in the questions.
2. It avoids encouraging participants to provide normatively appropriate descriptions, as interviews often do.
3. It does not leave the researcher to make a range of potentially problematic inferences from the data

collection arena to the topic of study. Claims about health helplines, for example, are not dependent on what callers or nurses say about health helplines.

4. It can open the researcher to novel issues and concerns that were not predicted at the start of the research.
5. It is a rich record of people living their lives, pursuing goals, managing institutional tasks, and so on.

Naturalistic data can allow readers and referees of research reports to access transcripts of the material and, increasingly, web-based audio and videorecords.

In practice, a variety of sources of reactivity may arise, for participants will be aware of the recording and may have some idea of the research questions. Moreover, the processes of transcription themselves involve theoretical and analytic judgments that prioritize some phenomena (e.g., overlap between speakers) and downplay others (e.g., regional accent). Although naturalistic data may not be orchestrated by the researcher as in an interview or experiment, it is not entirely independent of researcher's categories and judgments. For this reason, the term *naturalistic data* is preferable to natural data.

It is likely that social researchers will increasingly work with naturalistic data as new digital technologies make it simpler to capture and work with high quality audio and videorecords of people living their lives.

in life experiences. This type of inquiry stems from the naturalistic paradigm that situates itself opposite the positivist paradigm. The naturalistic paradigm, or naturalism, makes specific claims about epistemology (i.e., how one comes to know), ontology (i.e., the nature of human existence), and axiology (i.e., one's values) that influence naturalistic inquiry.

Characteristics of Naturalistic Inquiry

There are several characteristics fundamental to naturalistic inquiry. One value central to naturalistic inquiry is that reality is multiple and socially constructed. The concept of multiple realities resists the notion that the truth of human experience is out there waiting for researchers to discover it. Reality is subjective rather than objective. Subjective and multiple realities are possible because all knowledge is socially constructed. The concept of social construction places emphasis on human interaction, and the context in which those interactions occur, as the basis for how one comes to know or understand phenomena. Researchers cannot understand human behavior outside of its context or natural environment such as village life, organizations, night clubs, and classrooms. In addition, the researcher, the people under investigation, and the setting influence each other; thus, no explicit distinction exists between the researcher and the researched. The lack of a distinct boundary between the investigator and informants acknowledges the implicit and explicit influence researchers have on the setting. The relationship between the researcher and the object of inquiry (which includes the people and the context) are interdependent, thus influencing observations and findings.

The relationships between the researcher, research participants, and context inhibit value-free, neutral, or unbiased inquiry. In addition, other preexisting factors contribute to the value-laden nature of research, such as personal experience and interest in a particular topic, because they will shape researchers' understanding of phenomenon. Naturalistic inquiry is value bound because paradigmatic and theoretical choices guiding inquiry dictate the methods used for data collection, analysis, and interpretation of findings.

NATURALISTIC INQUIRY

Naturalistic inquiry focuses research endeavors on how people behave in natural settings while engaging

Conducting Naturalistic Inquiry

Naturalistic inquiry is based on the notion that context is essential for understanding human behavior, and

acquiring knowledge of human experience outside of its natural context is not possible. Conducting research in participants' natural environments is essential. Researchers must meet participants where they are, in the field, so that data collection occurs while people are engaging in their everyday practices. Research conducted in the field allows investigators to observe participants in action in an effort to obtain a more complete understanding of the phenomenon under investigation. During the process of engaging in naturalistic inquiry, the researcher becomes the instrument for collecting data. Human beings as data collecting instruments are necessary because only humans can gather and evaluate the meaning of complex interactions. Attending to these processes in the field is necessary because the complexity of human interaction is available only in the settings of everyday life, not in a controlled laboratory setting or through created instruments.

Conducting naturalistic inquiry is an inductive and emergent process where researchers build upon and ground their findings in the data collected. The process of conducting naturalistic research, including study design, emerges from experiences in the field while an investigator is actively engaged in inquiry because human phenomena and action cannot be predicted. Thus, observations in the field will influence and promote changes to a study's design. Researchers entering the field intent on studying a specific behavior may find another type of interaction worthy of investigation. Although study design is inductive and changes as research progresses, strategic planning is necessary for successful inquiry.

Selecting a Site

Selecting a site or multiple sites for investigation should involve purposive or deliberate sampling to ensure that participants have direct experience with the issues or topics under examination. This type of sampling increases the breadth and depth of data collected. There are several techniques for identifying sites for studying human behavior within its natural context. Researchers can study locations to which they already have access and familiarity or seek out unknown settings where gaining access or entry requires permission from the party or parties with the authority to grant access. Once access is granted to an unfamiliar scene or a researcher decides to enter a context in which she or he is a member, the researcher

must then engage the various methods she or he will use to collect data systematically.

Data Collection

Naturalistic inquiry employs several qualitative methods for data collection because these approaches capture the complex nuances of human experience. Naturalistic researchers can use ethnography, ethnomethodology, critical ethnography, or autoethnography to conduct naturalistic inquiries. Each of these methodologies includes some type of observation. Researchers complete this observation in the roles of participant-observer, complete participant, observer-participant, or complete observer. The site of field research, including any restraints against how data are recorded, dictates the type of role a researcher uses and will determine a researcher's level of immersion in the scene. Researchers record observations from the field in the form of fieldnotes. Not all scenes allow investigators to take notes while simultaneously engaging in observation. In these instances, researchers record observations as soon as possible after leaving the field. Experiences are recorded in fieldnotes chronologically. Fieldnotes should describe observations in significant detail, incorporating interactions between and with participants. Fieldnotes include researchers' impressions, thoughts, and feelings about exchanges. To supplement fieldnotes, researchers may conduct in-depth interviews with participants. Individuals who can provide the observer with additional insight or historical knowledge about the scene are ideal for in-depth interviews in naturalistic inquiries. Researchers complete the research and leave the scene when observations yield no new information or when observations become redundant (this state is also known as theoretical saturation).

Analysis

Explaining one or more aspects of human behavior is the goal of analysis in naturalistic research. Researchers conduct inductive analysis during the data collection process and after leaving the scene use grounded theory and the constant comparative method. This approach allows researchers to situate their findings in the data. Context-specific hypotheses emerge from these findings, and although not generalizable to large populations, propositions are applicable

to specific settings and often offer some insight into different but similar settings.

Reporting

Naturalistic researchers select methods of reporting that allow detailed description of the constructed multiple realities gleaned from the setting. There are three common methods for writing up the case: realist, confessional, and impressionist tales. Written in a distant third-person voice, realist tales place emphasis on the participants' experiences. Alternatively, confessional tales are first-person accounts of a researcher's experience in the field. Impressionist tales take greater artistic license than either realist or confessional tales to bring the reader into an unfolding narrative of the field experience. Other methods for reporting findings, such as performance and photography, are also available for presenting findings.

Issues of generalizability, validity, and reliability are raised during the reporting stage of the naturalistic research process, although researchers may receive inquiries from participants and interested others about these issues during all phases of the study. Objectivity, prediction, and control are three of the goals of scientific research; however, they are not the focus of naturalistic inquiry because of the epistemological orientation of naturalism. Claims about cause and effect as they relate to human experience are not an aim of naturalistic inquiry. Thickly describing observed phenomena and illustrating the multiple realities of a scene take precedence. When qualitative researchers, including those who conduct naturalistic inquiry, use the term *generalizability*, they are referring to the ability to identify common patterns in human interactions rather than to making broad assertions about large populations; some researchers refer to this concept as *transferability*. How research is conducted and reported answers questions about the validity and reliability (otherwise known as dependability or credibility) of a study. The writing up of research should resonate with participants, reflecting their experiences. Successful reporting of findings from naturalistic inquiry will resonate with participants. Researchers also reveal their positionality for participants and audiences, giving readers insight into the investigator's personal experiences and biases, increasing the ethos of interpretations.

Ethical Issues

The ethical issues of conducting naturalistic inquiry are vast and are in constant need of negotiation throughout the research process. In addition to gaining access and receiving the proper approval from a researcher's ethics review board, investigators should seek approval to conduct research from participants. However, researchers should view their ethical responsibilities as only partially complete when they receive informed consent in writing from participants. As the research study design emerges and as changes are made to accommodate these developments, researchers should inform participants. Revisiting the issue of consent throughout a project is important as a researcher gains the trust of participants and personal relationships develop. In addition to protecting the privacy and confidentiality of participants and informants, researchers negotiate the ethics of conducting naturalistic research by returning to the field to share findings and interpretations with participants.

Summary

The goal of naturalistic inquiry is to describe and understand human behavior as it occurs in its natural contexts. The naturalistic paradigm that influences inquiry makes several claims about how researchers make sense of human interactions. Naturalistic researchers understand reality as multiple and socially constructed and therefore subjective. Context interacts with human experience to create and shape human reality. Separating knowledge from its natural context is impossible. In order to understand human phenomena, researchers must enter the environments of the people or phenomena they seek to understand. Working in the scene or field links the researcher with the researched; they are inseparable and influence researchers' understanding of what they observe and how those observations are interpreted. Value-free inquiry is not possible because the researchers cannot separate their experiences from what they observe in the field. No researcher is neutral. These tenets of naturalistic inquiry influence how research is conducted and dictate the types of claims a researcher may make about human phenomena.

Several qualitative methodologies fall under the naturalistic umbrella. These methodologies rely primarily on some form of participant observation, making the human researcher the instrument of data

collection. Researchers need to purposively select the participants and scene necessary to respond to their interest in a topic or issue. Once in the field, researchers take fieldnotes documenting their observations. In addition to collecting data in the field, researchers may also conduct in-depth interviews with informants to substantiate or supplement observations. Research is collected until theoretical saturation is reached.

Although situated in observations, study designs in naturalistic inquiry are emergent because human phenomena are unpredictable. In addition, this approach allows researchers the flexibility necessary to make adjustments to the focus of observations. Analysis of data uses grounded theory, allowing researchers to situate findings and interpretation of those findings in the data. Findings are reported in a format that is conducive for describing human behavior in rich terms. Interpretations of findings should represent the experience of participants. Therefore, reports of a study's findings should resonate with participants. Resonance should not, however, compromise ethics in a naturalistic study. The spirit of naturalistic inquiry requires researchers to pay special attention to their human subjects to gain understanding of human interactions and behavior while maintaining ethical mandates like confidentiality and privacy, be they institutional or relational.

NATURALISTIC OBSERVATION

The central defining features of naturalistic observation are that it takes place in the natural setting for the phenomenon of interest, the researcher does not attempt to manipulate that setting in any way, and no constraints (e.g., predetermined categories) are placed on the outcome of the investigation. Naturalistic observation seeks to provide authentic, rich descriptions of the behavior of interest as it naturally exists and unfolds in its real context. It emphasizes understanding and describing social activities from the point of view of the participants themselves. Naturalistic observation asserts that such understanding is possible only through firsthand accounts.

Data collection typically involves unstructured observation and informal interviewing, with note taking, audiorecording, and occasionally videorecording used to record data. Particular attention is paid to what participants say as a way to understand the meanings they attach to events and activities. Naturalistic observation is also characterized by emergent research design, purposeful sampling, and inductive data analysis. Believing that data must come from real life, researchers work to get as close to their data as possible. At the same time, investigators strive to be as unobtrusive as possible so as not to disrupt the natural setting being studied.

A major strength of naturalistic observation is that the data collected closely reflect the real, naturally occurring context and the actual actions of the participants in that context. The trustworthiness of the data arises from this emphasis on the natural setting. With its flexible, unstructured approach, naturalistic observation often captures behavior that may not have been anticipated while also allowing for focusing on specific areas of interest. Naturalistic observation affords opportunities to explore complex phenomena (e.g., interactions between individuals in everyday life settings such as work places) not easily investigated by other more structured methods such as surveys or field experiments.

The major weakness of naturalistic observation is its potential for generating reactivity or observer effect. This weakness may be addressed through the use of

multiple observers and tests of intercoder reliability, although this strategy could result in even more reactivity in some settings, such as those involving only a few participants in a relatively small space. Member checking, while intrusive, is also helpful. Some researchers employ covert observation to reduce reactivity, although this approach is not always seen as acceptable in that it violates the principle of informed consent. Closely related to the problem of observer effect is the problem of observer bias, the idea that data will be limited by the characteristics of the individual collecting those data. Naturalistic observation typically yields large amounts of textual data that require a lot of time to manage and analyze. Finally, naturalistic observation is not effective for studying infrequently occurring or unpredictable behaviors, as this would require inordinate amounts of time in the field.

NATURAL SETTING

Qualitative research is conducted in natural settings. This means qualitative researchers study things as they are. They do not manipulate the environment. For instance, there are no experimental and control groups. Although multiple approaches to research are used (i.e., case study, ethnography, phenomenology, arts-based, feminist, critical theory, etc.), data are collected in the field, not in a lab. Ordinary events and behaviors are studied in their everyday context. This process generally involves interacting with people by interviewing them and observing the setting. Rather than removing people from their settings, qualitative researchers go to the people, allowing for the gathering of sensory data: what is seen, felt, heard, and even tasted or smelled.

Research conducted in the field (fieldwork) requires the researcher to have the basic skills of interviewing

and observing as well as the ability to analyze artifacts. The data that are gathered are transformed into thick, rich description, a hallmark of qualitative studies. Fieldwork can be conducted in a variety of settings. Common settings include organizations such as banks, nonprofit organizations, school classrooms, the military, hospitals, clinics, and sports teams, among others. For her research, Carol Rambo Ronai spent time at an exotic dancing club. When the research is focused on individuals, common settings for interviews include the person's home, restaurants or coffee shops, or other settings of their choice. Mark Neumann conducted his research at the Grand Canyon, interviewing the people who live, work, and travel there.

Ethical issues need to be considered when entering natural settings for research purposes. Access to settings needs to be gained and sometimes negotiated. In addition, provisions for exiting the site need to be considered so that participants do not feel abandoned or exploited. Reciprocity is important: Although it is clear the researcher will gain something from being in the setting, what the participants will gain deserves contemplation. It is important to realize that the researcher's presence in the setting may unintentionally change it; recognition of this potential is essential. Researchers need to be conscious of the roles they may be asked to or tempted to take on in the setting. For example, as trust is gained, researchers may be asked to intervene in difficult situations; they may feel compelled to right what they consider to be a wrong; they may form close friendships with participants. Ethical issues are innately embedded in natural settings.

Rather than measure and predict, qualitative researchers describe, interpret, and analyze. Natural settings are recognized as complex, interactive systems, and the focus is not on discrete variables. This focus makes natural settings (as opposed to labs) appropriate sites for conducting qualitative research.

NEGATIVE CASE ANALYSIS

Negative case analysis is a central data analytic approach in qualitative methods and is essential to the rigor of most data analytic plans. It is seen in what grounded theorists call constant comparison procedure and what Michael Agar refers to as “breakdown” and “resolution.” Negative case analysis is necessitated by purposely sought or spontaneously appearing pieces of data that differ from the researcher’s expectations, assumptions, or working theories. Although there is always some dread attached to the appearance of cases that appear to call into question one’s carefully constructed analytic framework, negative cases are integral to strengthening findings. As Matthew Miles and Michael Huberman suggest in their seminal text on qualitative data analysis, the outcome of negative case analyses can run the gamut from refuting to refining findings.

Whether actively sought (“occasioned breakdown” in Agar’s terms) or spontaneously occurring (what Agar calls “mandated breakdown”), negative cases are not a rare occurrence, but rather are a natural part of any study. It would be highly unlikely in real life for everything to fall exactly in line and act the same, and particularly unlikely in the early stages of analysis and hypothesis creation. Finding and understanding negative cases not only strengthens a good study, but these cases protect against researcher biases in what and how data are seen and reported. These negative cases can be, among other things, people, places, or events that differ in meaningful ways from other data points. Miles and Huberman describe how well-organized data displays can simplify the process of locating outliers by a simple scan of the data array.

The proper response to these negative cases is to seek to understand where and how these new data diverge from the rest and from the standing theory, to make the necessary revisions to the theory to include these unique findings, and then to test these revisions

in the iterative manner that is synonymous with qualitative analysis. It is important to note that, unlike in traditional quantitative methods, in qualitative methods, outliers are neither ignored nor is the working theory necessarily rejected when countering evidence is found. In fact, Miles and Huberman caution not to discard the working hypothesis too quickly, pending analysis of the proportion of positive and negative evidence.

Even on the rare chance that no spontaneous negative cases appear naturally, most qualitative methods advocate that researchers actively search for disconfirming evidence. This search includes seeking outlying data that could disprove the working hypothesis or confirm an alternative one, intervening variables that might refute assumed causal relationships, as well as collecting new data from additional sources. Miles and Huberman also suggest seeking out a friendly skeptic to review your working hypotheses and data. It is only through actively seeking to test and refute one’s findings and to explain not only the consistent, but also the inconsistent data that one can truly come to a final, rigorously defensible understanding of one’s research findings.

NEGOTIATING EXIT

Negotiating exit from a research site resembles gaining initial access: handling relationships; deciding how, when, and if to return to the field; balancing requests for reciprocity; identifying and responding to information needs of various stakeholders; arranging disposition of data; and ensuring program continuation once researcher support disappears. Negotiating exit is a key step in preparing to leave the site of a research project,

particularly where researcher–participant relationships have been forged.

Relationships, Friendships, and Dependencies

Qualitative researchers create friendships, dependencies, and sometimes hostilities with field participants. Because researchers cannot simply pack up and slip away at midnight, negotiating how to say good-bye, maintain desired relationships, and end those that cannot be maintained are crucial parts of the exit process. Of first concern are key informants and good friends. Strategies for the difficult process of maintaining long-distance relationships must be negotiated. Friends must know if the researcher will return to the field and for what reasons and how often they will write, email, or call—all are problematic once researchers return home to their normal lives.

Other contact may be needed beyond that of maintaining friendships. Researchers or their students and colleagues may want to return to the field site because they need further data collection or need to begin new projects, they discover that they have neglected to collect some critical data, they need to check on the validity of their interpretations of data, or they require additional data to answer questions raised during data analysis that were unanticipated in the field. Preexisting field contacts can facilitate return. If researchers cannot return, clear lines of communication, goodwill, and firm relationships in the field make possible asking key informants to collect information or answer questions that arise during data analysis, checking initial and subsequent formulation of results with participants, or validating interpretations.

Leaving the field can be more problematic with casual field acquaintances researchers develop, given the expectations such individuals develop of researchers. Researchers are linked to a more cosmopolitan and often wealthier community than that of participants, and therefore are sources of information, intellectual stimulation, outside contacts, and resources. Participants whose slight marginalization from the community makes them perfect insider–outsider informants also may have expectations of the researcher as a source of companionship, status, and even financing. Although important to the researcher for data, casual acquaintances may highly value their contact with the researcher for other reasons. The nature and depth of such expectations may be difficult for researchers to

identify. Some participants simply mourn the loss of emotional ties and status.

Others will miss the economic resources researchers provide when they, for example, obtain scarce foreign pharmaceuticals for participants, link local craftspeople to buyers in the United States, buy school supplies for students and teachers in a local school, rent from local property owners, or pay for language classes. Researchers represent career development for local professionals who obtain from them new ideas or techniques that enhance performance and reputations in ways that locals without such access cannot. Since attenuating or ending these benefits can cause loss or hardship, researchers must explain what resources they are able to continue providing or help participants develop alternative sources of supply. Once they have left the field, researchers also must decide how to handle ongoing requests from, or the reality of help needed by, field participants, including for such things as obtaining further education for themselves and their children.

In summary, it is unethical and unwise to burn bridges to field-based colleagues and participants. Although ignoring formalities of farewell for uncooperative or hostile participants is tempting, as is avoiding development of strategies for managing expectations by casual acquaintances, these individuals may be exactly those who, if alienated or insulted, could bar access to needed data or prevent researchers from returning.

Reciprocity, Feedback, and Dissemination

Too often, researchers fail to pay participants back for allowing them to investigate their worksites and lives. Most researchers simply disappear once their research project is finished, leaving participants totally unaware of what has been learned or written about them. Both disappearance and lack of reciprocity are poor research etiquette and are unethical. Since qualitative researchers usually do not provide financial incentives for participation in studies, reciprocity involves exchanges of intangibles—friendship, information, services, and contacts. Much research has procedures for reciprocity built in; participatory or collaborative action research, for example, is designed to provide benefits directly to the community or group under study. However, too often, only the researcher derives benefits from the study in the form of publications and fame. III

will be generated when participants believe researchers have become famous at their expense. Often, simple acknowledgment of their contribution in publications is sufficient. Some researchers give participants visibility like that of researchers by inviting participants to co-author articles and papers and join them as conference presenters. Others donate publication royalties to communities they studied. In projects involving successful interventions, researchers should give control or comparison groups the same training and information that the intervention group received after the project is complete so that all participants benefit equally. Applied or action researchers can make themselves available to answer questions, provide ongoing inservice, or give workshops.

Feedback and dissemination procedures are needed both in the field and after the project is completed. Researchers must decide what to tell participants, when, and how often during the course of data collection when they are asked for information during a project or when participants simply want to know what the researcher is finding out. Participants always are entitled to know the results of studies done about them; failure to provide such information at minimum causes hurt feelings and often “poisons the well” for future researchers, inhibiting useful continuing investigations in the same community. However, providing feedback is problematic. Participants may not want to hear what researchers actually found if it contradicts their views, researchers might be reluctant to disclose negative information provided by one group of participants about another, and researchers never present participants or their programs as favorably as participants wish.

Researchers can consult with participant groups to find out exactly what kinds of information they need and give them only that information. However, it usually is both impossible to anticipate future information needs and to withhold negative data. Researchers should make it quite clear from the outset that feedback may be neither positive or in line with participant expectations. Researchers also can embed negative information in context so that participants understand all the factors leading to specific outcomes. For example, although an educational innovation may have produced negative results, data showing that teachers received insufficient training, that the students enrolled differed from the desired target population, or that materials were delivered late, tells the whole story in ways that remove the onus of failure from practitioners.

Once researchers leave the field, dissemination begins. Different participant groups need different kinds of information; researchers should identify the multiple audiences in the field site first, and then negotiate in advance how and what kinds of information will be provided. Researchers can prepare several kinds of reports and use multiple dissemination modalities—oral presentations, written reports of varying lengths and complexity, workshops and inservices, and publications in media ranging from websites, flyers, and the popular press and scholarly publications. For example, teachers in schools will need different kinds of information from those needed by parents, school administrators, and funding agencies. Since much of the world now has access to websites, internet technology may provide more useful, faster, and more reliable means of communication than paper, telephone, and postal services. However, researchers never should rely on online communication alone, even in countries with high levels of access to technology.

Disposition of Data

Participants and other stakeholders have a right to know what will be done with information collected about them once a study is complete. This knowledge ensures that the data will not be used for purposes participants have not approved or by other researchers for purposes not originally intended—unless the data are completely anonymized so that participants cannot be identified.

Researchers protect the privacy of research participants by disposing of data in special ways; this need for privacy is why ethics review boards typically require researchers to describe how data will be disposed of once a study is completed. Disposition procedures (if applicable) should be decided upon and negotiated with stakeholders as part of the informed consent process before the study begins.

Ensuring Program Continuation

Applied, participatory, or action research helps participants develop and set up programs or innovations aimed at solving human problems, usually with the help of funds obtained to establish both the program and the research itself. As the most visible connection to the source of funding, and often as the writers who developed the funded proposal, researchers should help participants figure out how to perpetuate the program, if desired, once the funding ends and the researcher leaves. Researchers can teach participants

how to write proposals and access new sources of funding and help participants institutionalize or naturalize a program so that it is adopted by the organization or community and paid for as regular practice.

NEUTRALITY IN QUALITATIVE RESEARCH

In research, the term *neutrality* implies that an inquiry is free of bias or is separated from the researcher's perspectives, background, position, or conditioning circumstances. When a researcher or the research is said to be neutral, the inquiry is also implied to be trustworthy and legitimate. Although legitimacy and trustworthiness are important values in qualitative research, neutrality is often seen as an impossible goal. This entry explains why neutrality is less useful as a term to judge qualitative inquiry and suggests ways to achieve legitimacy and trustworthiness while acknowledging researcher bias.

Neutrality is a term that is often attached to research to demonstrate that it provides an objective and unbiased view of the object under study. Procedures are developed to ensure data are valid and reliable and imply that the results are trustworthy and important. The objective worldview assumes that reality can be understood, that it never changes, and that the researcher can observe the reality without affecting it. In this way, any other neutral researcher will obtain identical results if replicating the research. This view places the researcher at a distance from the research and assumes there is no investment in or influence on a given outcome.

Worldviews have shifted, especially in the social sciences. In social science research, knowledge is viewed as constructed rather than seen as some unchanging reality. The approach to research has also shifted. Researchers using qualitative approaches in social science inquiries recognize that the objects of their study cannot be fully understood in an objective and unbiased way; they are too complex and changing. Even the term *object* is less useful in qualitative inquiry. No longer is the researcher separated from the research. The relationship between the observers and the observed is a critical part of the research. The relationship affects what is observed, how observations are interpreted, and eventually how interpretations are reported.

The nature of these relationships means that the researcher is part of the inquiry rather than separated from it. The various methods of data collection in qualitative research provide a sense of how close or distant the researcher is from whom or what is being observed. Qualitative data arise from interviews, observations, reflection, dialogue, and interpretation and provide perspective on a research problem in rich, real-world, descriptive terms. Interpretation and understanding of the data will necessarily depend on the patterns of interactions, the kinds of questions asked, and the experiences and perspectives the researcher holds. The researcher approaches the research problem with a background and a set of experiences that cannot be turned off. However, the relationships between researcher and the observed may vary greatly.

Inside the social sciences, there is a range of qualitative research methodologies that stretch from post-positivist inquiry to autoethnography. Postpositivist qualitative approaches might use a consistent set of survey-like questions in interviews; the process varies little with the expectation that the findings will be minimally affected by the researcher's relationship with the informant. However, even postpositivist approaches recognize that contexts affect findings and that complete neutrality is impossible. On the other hand, in autoethnography, the researchers tell their own personal stories and reflections to provide insights on the meaning of an experience so that the reader might understand it in a new way. The storytelling is intended to explain reality from a distinct point of view, as in a woman's view of a workplace promotional experience. Some qualitative approaches, such as action research, are intentionally biased. The researcher is attempting to change the situation under study—hardly a neutral position.

Some outside the social sciences may view the absence of neutrality as a signal that the research is not trustworthy or useful. However, legitimacy and credibility can be strengthened through transparent procedures and clear descriptions of the relationships and perspectives of the researcher both during data collection and in its reporting. Researchers who are honest about the data, clear about how data are obtained, and use the data to some larger ends are more likely to be viewed as trustworthy and legitimate within and outside the social sciences.

Changes in how research is funded have also affected impressions of neutrality or trustworthiness. As businesses and corporations have begun to fund inquiry, the ability of the researcher to appear neutral is diminishing. Findings from the research that are considered important can be construed as beholden to commercial interests. These interests determine what is funded and what is studied and have the potential to determine what is reported. Some claim to achieve neutrality in these circumstances, but achieving neutrality is difficult, if not impossible. Trustworthiness and legitimacy are best achieved through clear descriptions of relationships and underlying assumptions and thoroughly revealing connections to funders.

Although terms like neutrality are less useful to qualitative researchers, some researchers find the term important. Qualitative procedures used during the research process can aim toward neutrality by seeking a balance of perspectives and a fair reflection of the circumstances of the research. For example, the researcher might empathize with informants but avoid taking their side in reporting and take care to gather and report diverse views. Recognizing the potential to be drawn into the world of the observed and maintaining a focus on the research plan may help the researcher maintain a greater degree of neutrality when needed.

Although the methodology has evolved and changed and the academic and financial circumstances of researchers have posed challenges to issues such as neutrality, qualitative inquiry offers significant, legitimate, and trustworthy contributions to social science knowledge. The avenue to legitimacy in qualitative research—as in any research endeavor—is authentic and transparent work that stays true to its original purpose.

NEUTRAL QUESTION

A neutral question is a question posed to a participant during data collection and stated by the investigator in a way that does not direct or bias the answer provided by the participant. Writing neutral questions can be challenging, but it is also an important aspect of collecting qualitative data. The general purpose of qualitative research is to learn about the views and experiences of participants from their own perspectives. Well-designed neutral questions allow participants to decide how they will answer a question, helping to ensure that the investigator is learning what the participant thinks instead of learning what the participant thinks the investigator wants to learn. Due to their importance, neutral questions are used in different types of qualitative data collection techniques including focus groups, in-person interviews, and telephone interviews.

Qualitative researchers pose open-ended questions that encourage participants to create and share their own options for how to respond. To encourage participants to express their perspectives freely, these questions should be stated in a neutral way in addition to being stated as open-ended. Nonneutral questions may lead participants to feel that they should answer a certain way regardless of how they really think; therefore, these questions can introduce bias into the study's findings. Questions can be perceived as leading if they indicate preferred responses or limit the range of possible responses.

Consider a qualitative study where researchers want to learn how adolescents describe their experiences with smoking. They might ask, “As you know, smoking is bad for your health. What do you think about trying to quit smoking now?” This question is not neutral because the participant may feel pressured to respond a certain way because the interviewer favors positive responses related to quitting. A more neutral question could be, “Tell me about your current smoking status.” Then, if the participant states that she or he is thinking about quitting, the interviewer could follow up and ask for more information.

Although important, neutral questions are not always easy to develop when planning questions to ask during data collection. Researchers should avoid using words that may be perceived as leading within the study’s context. When possible, questions should be stated using the language of participants and not the technical terms derived from the literature on the topic. Researchers should evaluate whether there are certain responses that they might value more than others and check that this preference is not evident in the question wordings. Even with these aspects in mind, it can still be difficult to design questions that are completely neutral. Researchers should consider writing their main questions to be as broad and as neutral as possible and then follow up the responses to these open-ended questions with probes if there are specific dimensions, viewpoints, or language that need to be explored further. Finally, researchers should pilot their questions with individuals similar to the participants to see if they are perceived as neutral.

NONESSENTIALISM

Nonessentialism is a philosophical doctrine that stands in opposition to the philosophy of essentialism. Briefly, essentialists argue that an object or concept can be defined in terms of certain core or essential

properties that it must possess and that make it what it is. When applied to people, essentialism argues that human thoughts, feelings, and behavior can be understood in terms of a common human nature (a view sometimes referred to as humanism), or in the case of religious essentialism, that people are created with or for a predetermined purpose. Taken at its literal meaning, nonessentialism argues that there is no essence or set of common, predetermined qualities belonging to entities in the world. The philosophy of nonessentialism has been in existence for as long as essentialism, which it attempts to deny (in its weak sense) or refute (in its stronger sense of antiessentialism).

As a modern philosophical movement, however, nonessentialist philosophy is usually applied only to people, and in this form, its roots can be traced back to the existentialists of the first half of the 20th century. Most prominent of these was Jean-Paul Sartre, whose starting point for his nonessentialist philosophy was Fyodor Dostoyevsky’s observation that if God did not exist, everything would be permitted. Since, for Sartre, God does not exist, or at the very least, His existence can no longer be accepted a priori, everything is indeed permitted. Sartre’s project was therefore to outline new criteria for how people should conduct themselves that did not rely on essentialist concepts such as the will of God or human nature. Seen in this way, existentialism is a theory and practice of ethics.

Existentialism and Phenomenology

Simply put, this atheist existentialism can be reduced to the claim that existence precedes essence. Sartre made a distinction between beings-in-themselves (*en-soi*), which encompassed inanimate objects and most animals whose essence precedes or is coincidental with their existence, and beings-for-themselves (*pour-soi*), predominantly people who exist first and only later define themselves, largely through their actions. In the absence of a God to impose a specific purpose or a particular destiny for humankind, people’s existence can be said to precede their essence. For Sartre and the atheist existentialists, people come into the world alone and without purpose, and it is up to each individual to create her or his own unique and individual essential nature.

This nonessentialism is, according to the usual definition, also antihumanist, since it argues against a common or predetermined human nature that can be

invoked to justify the decisions and actions of individuals or groups of people. Sartre refers to such an essentialist recourse to human nature as *mauvaise foi* or bad faith (sometimes translated as self-deception), which is to be avoided if people wish to live authentic lives and be true to their individually chosen paths. However, nonessentialism is not the only ethical response to the nonexistence of God, and Sartre points out that some strands of philosophic atheism, such as those found in the writing of Voltaire and Immanuel Kant, simply replace God with a universal but nonreligious human nature in which each person is a particular example of a universal conception. Confusion arises, however, when Sartre attempts to align this nonessentialist existentialism with the humanist movement, as he does in his published lecture "Existentialism and Humanism." The difficulty lies in the fact that Sartre is using the term *humanism* largely to oppose the religious view, in the sense that human actions and human destiny are determined by individual human beings rather than by a transcendental God. This definition is counter to the more usual definition of the term humanism as referring to the existence of a common (and usually positive or good) human nature shared by all. In this latter and more commonly accepted sense, Sartre's nonessentialism is very much antihumanist.

This antihumanist, nonessentialist view has some important consequences, not only for philosophers, but also for researchers. If, as the existentialists maintain, there is no common human nature, then social research has little or nothing to say about people in general. Each person is genuinely and completely unique and cannot be summed up or defined as part of a greater whole. For this reason, Sartre advocates the novel as the most authentic form of research report, since it provides a deeply subjective account of a particular and unique human experience. Many of his own novels and plays, such as *Nausea* and *Roads to Freedom*, can be regarded as forms of narrative research, albeit with fictional subjects. Arguably, however, in the absence of any universal human tropes and with an almost unlimited number of ways in which to choose to live, the distinction between fictional and real lives becomes blurred.

The epistemological and ontological basis of Sartre's existentialism is founded in the German phenomenological tradition, which argues that the world can be known only through our subjective experiences of it, which arrive through our senses. In its purest form, phenomenology, therefore, entails a suspension

or bracketing of all preconceptions in order to focus on the pure sense-data or phenomena that are present to people's inner, subjective consciousness. Unlike the scientific empiricists, most phenomenologists make no attempt to extrapolate from these internal experiences to a description of what the real outside world might be like, although Edmund Husserl argued that the method of bracketing (*epoché*) might ultimately lead to an understanding of the essential nature of things.

Although Husserl could therefore be described as an essentialist, Sartre was drawn toward the nonessentialist hermeneutic phenomenology of Martin Heidegger and Hans-Georg Gadamer. Hermeneutic phenomenology originated in the attempt to understand ancient texts and argued that they could not be interpreted with reference to universal tropes such as human nature or the prevailing *Zeitgeist*, but only by researchers immersing themselves in the text and attempting to imagine themselves in the position of the original author. This practice is a deeply subjective approach that defies any attempt at generalization in favor of a unique perspective on a unique text written at a specific time by a specific author. Although more traditional researchers might criticize such an approach as biased or prejudiced, Gadamer argues for the idea of prejudice as a positive influence in research, as the valuable pre-understanding that the researcher inevitably brings to the data and that constitutes the personal or subjective aspect of the hermeneutic circle. This, of course, is in contrast to Husserl's transcendental phenomenology of bracketing out or suspending one's preconceptions about the outside world. The focus of nonessentialist research is, therefore, a doubly subjective amalgam of the unique individual case and the individual presuppositions that the unique individual researcher brings to her or his interpretation of the case.

Poststructuralism and Deconstruction

The French literary critic Roland Barthes advocated an alternative nonessentialist position that emphasized (but also challenged) the interpretive aspect of Gadamerian hermeneutics by proclaiming the impossibility of ever being able to decipher the intentions of the original author of a text. For Barthes, the author is dead as the final authority on her or his own writing. Although Barthes was concerned with literary criticism, his views have been extended by poststructuralists such as Jacques Derrida to refer to all written texts and indeed,

to all attempts at representation. In fact, Derrida's position is far stronger than that of Barthes and might be more accurately described as antiessentialist. Derrida argues that it is impossible to produce a text (he uses the word text in a very broad sense to encompass all forms of expression) that communicates a pure, unambiguous, essential meaning of a concept. He claims that all texts, however, strongly advocate for a single, essential truth, but contain other, often contradictory points of view. All texts contain the seeds of their own undoing, and if read in a close and attentive way, they will begin to unravel. Derrida refers to this close reading for internal contradictions as deconstruction.

Deconstruction is at work on various levels of the research process. On the one hand, the interview transcripts of individual research subjects can be deconstructed for hidden contradictory meanings by the researcher in order to draw out the inevitable multiplicities of the narrative account. On the other hand, the research report is itself open to deconstruction by its readers. Unlike Barthes, who suggests that the readers bring their own point of view to the research report, Derrida argues that multiple points of view are already written into the text and merely require bringing to the surface.

This poststructuralist account of hermeneutic phenomenology challenges Gadamer's emphasis on the researcher's ability to, as it were, stand in the shoes of the original writer. Barthes not only questions the authority of the researcher's interpretation of the essence of the text, but more radically, takes the view that the original author has no more authority in asserting the meaning or essence of her or his own text than any of her or his readers. Derrida goes even farther by suggesting that, in any case, there can be no single essential meaning and that all texts contain multiple and often contradictory truths.

For poststructuralist researchers, then, the tenets of nonessentialism apply not only to the subject of the research, but also to the researcher's own interpretation of what the subject has to say. First, nonessentialist researchers will be cautious about making generalizations from their findings. Unlike transcendental phenomenologists, they make no attempt to derive common themes and categories from their data since they do not believe in any essential core that is common to all people. Unlike grounded theorists, they are not concerned with generalizable theories since they are reluctant to theorize about the common features of groups of people. Conscious that they have no

greater authority than the subjects of their research, they prefer to give a voice to individual participants—to allow the narrative accounts of the research subjects to stand alone, sometimes without the imposition of analysis or theorizing by the researcher.

We might summarize the nonessentialist researcher's attitude toward the subjects of their research as regarding them as a collection of unique individual persons rather than collectively as people. However, the poststructuralists would wish to go farther, arguing not only against a common human nature, but also against the enduring stability of the individual personality. As well as there being no common core, there is also no individual core that persists over time. The individual self is in constant flux and cannot be appealed to as a driver or justification for an individual's decisions or actions. This position is most succinctly summed up in Michel Foucault's plea: "Do not ask me who I am and do not ask me to remain the same" (*The Archaeology of Knowledge*, p. 17).

The narrative accounts provided by individual subjects will therefore vary depending on the time, place, and circumstances in which they were produced, and the nonessentialist researcher, therefore, exercises caution in taking these accounts as definitive statements or indeed, even as *accurate* statements about the subjects' lived experience.

In addition, nonessentialist researchers operating within the poststructuralist tradition are aware that their own interpretations of the data are but single, unique accounts that should not be privileged over and above any others. After Barthes, then, the nonessentialist accepts not only the death of the research subject as the author of a definitive (or even accurate) account of their own reality, but also the death of the researcher's privileged position of analyzing, interpreting, and authoring the subject's account in the form of a research paper. The authority for analysis, theorizing, and general meaning-making, therefore, falls to the many readers of the research report rather than the putative author. As Barthes points out, the death of the writer implies the birth of the reader; the reader of the text becomes an author (either literally or figuratively) in her or his own right.

A Nonessentialist Paradigm of Qualitative Research

Although a coherent nonessentialist research paradigm is possible, it will oppose many of the taken-for-granted

tenets of qualitative research and has some profound implications for the validity, reliability, and generalizability of research findings. We have already touched upon the issue of generalizability, which is in many ways a meaningless concept for the nonessentialist researcher. In a world without universal essences, research subjects will be chosen on the basis of their individual characteristics or situations, and the findings from one or more subjects will not be generalized to a wider population or to a universal theoretical statement. The focus of meaning-making for nonessentialists is therefore on transferability rather than generalizability, and this is largely the responsibility of the reader rather than the writer. The task of the writer of a research report is simply to present individual stories, narratives or cases, and the reader of the report must decide on the extent to which the findings apply to other specific individual cases. That is not to say that people might not share similarities; nonessentialism does not argue that there cannot be any commonality between individuals, but only that there is no necessary or predetermined human nature shared by all, nor even necessarily a constant self experienced by individuals over time.

This idea immediately calls into question the usually held concept of researcher reliability. If reliability is understood to refer to the accuracy or consistency of the findings, then nonessentialist researchers would not expect the outcome of any research encounter with a particular subject to resemble any other encounter, even with the same subject. Clearly, in the absence of a reliable (i.e., constant) core personality or self, people should not expect any reliable or predictable findings, either between different researchers or with the same researcher over time.

Turning to the question of validity, people are faced with the thorny issue of the meaning and identification of truth in a nonessentialist world. Clearly, it would make little or no sense to search for universal social or psychological truths since this implies the existence of an essence or human nature common to all people. As argued above, nonessentialist researchers must resist the impulse to think in terms of people in the collective sense at all and focus instead on individual persons. There are at least two ways of approaching this somewhat problematic notion of truth for nonessentialist researchers.

First, there is the view that the truth of the account given by the individual subject should be heard in as pure and unadulterated a form as possible, a view held, for example, by some feminist narrative researchers

and also by many in the mental health user movement. This approach is often driven by a political agenda that points to the historical suppression of the voices of oppressed underclasses such as women and mental health service users and argues for their right to be heard in a way that is uncontaminated and undistorted by the power politics of the usual researcher–researched relationship. This approach discourages analysis or theorizing by the researcher in favor of a straightforward, subjective narrative account or story by the research subject. The truth, in this case, is more or less whatever the subject says that it is; since it derives directly from his or her subjective experience, it is not open to dispute.

This is a simple and straightforward nonessentialist response to the challenge of validity, which embraces the issue of multiple truths. However, because this approach is often driven by a political agenda, problems sometimes arise when researchers attempt to apply their findings to a wider social arena, such as when mental health policy or practice is based substantially on the subjective views of individual service users, or when feminist writers attempt to derive general principles of gender politics from the experiences of a small number of individual women. In fact, the issue of essentialism has polarized debate in feminist theory and research between those “radical feminists” who argue that women are essentially different from (and perhaps superior to) men and the nonessentialist “new feminists” who argue for equality based on similarity rather than difference.

Second, there is the view of truth as a social construction between the researcher and the research subject. This view is informed in some cases by the constructionist idea that social reality is co-created from moment to moment by the participants in the research project and in other cases, by the dialogic theories that self is constructed through dialogue. In either case, we might expect different research encounters to produce different and perhaps contradictory truths, even if they involve the same participants.

The issues of power and politics are equally relevant here since most qualitative researchers recognize a power differential between researcher and research subject. At one end of the power spectrum, the Foucauldian discourse analyst or the symbolic interactionist might impose her or his own analytic structure on the data. At the other end of the spectrum, the collaborative inquirer might be aiming for a completely democratic or egalitarian relationship that dissolves

the boundaries between researcher and research subject and their roles in the process of data collection and analysis. The logical culmination of this position might be the methodology of autoethnography, which fully and completely merges the roles of researcher and researched in a single person. If the concept of validity is in some way related to the search for truth, then the nonessentialist researcher will regard it as a spurious notion since truth is at best elusive and at worst, illusory.

NONPARTICIPANT OBSERVATION

Nonparticipation observation is a relatively unobtrusive qualitative research strategy for gathering primary data about some aspect of the social world without interacting directly with its participants. Nonparticipant observers sometimes are physically copresent with research participants in a naturalistic setting, but other times may not be present in the setting.

Researchers may engage in nonparticipant observation for a number of reasons. First, the researcher may have limited or no access to a particular group and therefore may not have the opportunity to engage in participant observation. For example, a researcher might be interested in studying the social behaviors of

professional athletes on the field or how parents control their children in public settings, yet is neither an athlete nor a parent. In both cases, nonparticipant observers could take a position within the setting and record what they observe without interacting directly with participants.

Second, the research setting might be one in which participant observation would be dangerous or difficult. Doing research on riots or mobs, for example, is difficult because of their spontaneous nature. Researching collective action (e.g., demonstrations, protests) directly may be undesirable. In these settings, researchers may rely on video recorded by news agencies or insiders to observe social behavior. Film and video use also allows for the observation of historical social phenomena.

Third, the researcher may be interested less in the subjectively experienced dimensions of social action and more in reified patterns that emerge from such action. For example, one may derive insight from observing how people utilize public space, such as a national park, an internet café, a mall, or a classroom, without interacting with users. The question of researcher reactivity arises here, that is, questioning the extent to which nonparticipant observation potentially affects the setting.

Nonparticipant observation may be overt or covert, occurring in public or private settings. Unique ethical issues will arise with each combination: the covert observer in a public setting must deal with a different set of ethical considerations than an overt observer in a public setting, and so on. Each combination will also affect how the observer might collect data. Typical strategies include writing fieldnotes or audio- or videorecording social action. Recording behavior overtly might be interpreted by participants as exceptional or intrusive, thus potentially affecting their behavior, while covert observation may break ethics norms.

Digital media such as the internet provide opportunities for new forms of nonparticipant observation. Researchers may have an interest in the interactions among members of an internet community to which they do not belong. Given the open access and anonymity associated with many digital spaces, nonparticipant observers could register with a digital community and “lurk,” reading all the messages posted by community members without ever posting themselves. Researchers may browse web pages, create avatars in digital worlds, or subscribe to email lists—each providing an opportunity for observation with minimal

impact on the setting. Data from digital media are often more easily recorded because the researcher can use screenshots, copy-and-paste functions, and save messages and logs.

NONPROBABILITY SAMPLING

Nonprobability sampling is a common technique in qualitative research where researchers use their judgment to select a sample. Unlike probability sampling, where each participant has the same chance of being selected, participants selected using the nonprobability sampling technique are chosen because they meet preestablished criteria.

Some of the more common types of nonprobability sampling techniques are convenience sampling, snowball sampling, and purposive sampling. In convenience sampling, participants are selected because they are accessible and therefore relatively easy for the researcher to recruit. With snowball sampling, new participants to the study are recruited when current participants refer other, potential participants to the researcher (e.g., as they are members of the same group or share similar interests that are relevant to the project at hand). Purposive sampling refers to a process where participants are selected because they meet criteria that have been predetermined by the researcher as relevant to addressing the research question (e.g., people of a particular age or other demographic category). These three techniques each highlight that nonprobability sampling requires the researcher to make the final decision in terms of who does and does not participate in the study. Often, these

techniques are used together to recruit individuals to participate in the study.

This sampling approach, which provides researchers with the capacity to construct their own sample, is considered quite useful in certain circumstances. For instance, there may be certain situations in which nonprobability sampling is the only way to access individuals from certain subcultures. That is, if one were trying to study members of a closed-membership organization (such as organized crime), one might realistically need to recruit participants using a snowball sampling technique, starting with one key informant. Furthermore, nonprobability sampling can also be quite appropriate when researchers are interested in studying the traits of a specific group and are not necessarily concerned with extending the results to the broader population. This need is quite applicable to qualitative research, where the researcher wants to study a particular group in some depth and as a result, may try to select people individually who represent typical traits from within that group. Nonprobability sampling might also be considered quite appropriate for pilot studies, where the researcher is trying to determine whether a problem is viable on a larger scale. In this instance, the researcher may choose to use a convenience sample because the data are less expensive and less time-intensive to collect.

Despite its utility, nonprobability sampling does raise some concerns. First, it may limit the researcher's capacity to point to the transferability of data. That is, for researchers who do wish to extend the interpretation of their findings to other groups, it may be particularly difficult to do so. For example, if one studies the attitudes of only single mothers toward daycare facilities, it would be difficult to transfer these findings to mothers with partners, as their situations and needs are likely quite different. Another common concern relates to bias and the possibility that the researcher may have shown bias in selecting study participants by using these techniques. Issues of bias and transferability must be considered and addressed at the data collection, analysis, and writing stages of the research process. In spite of these concerns, nonprobability sampling provides an appropriate means by which qualitative researchers can study specific groups, recruit elusive populations, and conduct exploratory research.

NONVERBAL COMMUNICATION

Nonverbal communication (NVC), or body language, is communication without words. It includes any bodily expression, such as eye or facial movements, posture, and actions to which an observer attributes meaning. The term also includes vocal cues or signals, such as crying, shouting, or silences, although these cues are, strictly speaking, verbal. Although spoken language is very important, NVC and the interpretation of it are also critical in creating meaning between individuals and within groups. For this reason, it is an essential part of all qualitative research and analysis.

NVC often acts at an unconscious level; one may “leak” signals. Body signals can also be learned and consciously used by the sender, for example, maintaining eye contact or smiling to encourage rapport. NVC is regarded as more primitive and powerful than verbal communication, and it acts in different ways. Some messages, for example those containing emotional content, may be better communicated nonverbally; these messages can be more ambiguous and subtle.

NVC has a role in replacing or reinforcing verbal messages. Topics that are rarely discussed tend to have underdeveloped vocabularies, and NVC can fill the gaps. It can also contradict speech so that one receives a mixed message. Most important, NVC enables conversation to flow by offering a common code that all of those involved in a dialogue will understand, for example taking turns to speak or knowing the appropriate level of intimacy.

NVC is relevant in a number of research areas: It is key when establishing rapport with research participants, for example, making eye contact, when researchers introduce themselves. The way the room is laid out, for example, a board room or as a circle, also conveys messages about what is expected of participants.

NVC helps moderators to steer the research situation, for instance, by avoiding eye contact to close off one conversation, looking encouragingly and smiling at nontalkers, turning the body away, using closed or

open-ended questions, leaning forward, and silence. The energy level in a group can also provide important signals about response to material being researched. Researchers are not reading nonverbal behavior just in a simple body-language sense; they are also looking for consonance or dissonance between verbal and nonverbal clues and are attempting to understand why this is happening.

Nonverbal research approaches, such as drawing or role-play, are used to access and interpret different types of data. They shift the researcher–participant interaction away from a question-and-answer session and can offer a broader understanding of the issues. This approach is particularly useful with participants who are less verbal, and it can also enable access to emotional content. There are many enabling and projective techniques available to facilitate nonverbal research approaches.

Nonverbal approaches also present the researcher with a wide range of materials for analysis and interpretation, in addition to verbal content. These can be used to help convey the findings to the client team.

NUD*IST/N6 (SOFTWARE)

See NVIVO (SOFTWARE)

NVIVO (SOFTWARE)

The trustworthiness of qualitative research depends upon the integrity of data gathering and analysis, the robustness of processes, and the demonstration of thoroughness. One tool that assists a researcher to manage these tasks well is the NVivo data management and searching program, which enables a researcher to demonstrate the integrity, robustness, and therefore, trustworthiness of an investigation.

NVivo Screen View

Source: Used by permission of QSR International.

The benefits of NVivo lie in its user-intuitive interface and its extensive data storage, search, and retrieval capacity. The program uses a coding system that underpins generation of relationships between elements in the data. It is an effective relational database that provides the researcher with the flexibility to

- test tentative theorizing about relationships within the data;
- discover and explore new relationships as data analysis unfolds;
- map relationships;
- track data analysis; and
- log and save search results.

Another essential feature is the ability of NVivo's memos to record the researcher's thoughts and processes alongside, but not within, the data analysis. Creating memos for this purpose provides a rich source of information about research processes, theorizing and

searching implications that are particularly useful when a project is protracted, and involves multiple researchers or is multinational. Because memos are separate from the actual data, the independence and integrity of data are maintained by ensuring against contamination from the researcher's perspective. In this way, trustworthiness are in-built into the data management process, provided the researcher is mindful about using the potential of the software with integrity.

These features make NVivo a sophisticated addition to a qualitative researcher's toolkit, but it remains the researcher's responsibility to ensure the authenticity of the research project and output by aligning methodology, epistemology, and ontology. Because NVivo makes it easier for researchers to demonstrate robustness in their practice by assisting the management of data and by establishing trustworthiness, the research process becomes more transparent and therefore is open to closer scrutiny. As a result, the researcher needs to think carefully through the methodological approach

as well as the process of analysis. The aim is to ensure that the research questions are answered from the relationships emerging out of the data being searched.

NVivo does not analyze data for the researcher. It is a management tool enabling greater depth in analysis and facilitating the searching of large quantities of transcript data so that the researcher can make considered judgments. Although NVivo is able to assist the researcher to manage data efficiently in rapid time frames, it takes time to learn to how utilize NVivo's power so that

the researcher's first judgment will be to ascertain the efficacy of this tool in each research project.

OBJECTIVISM

This entry describes the central claims of objectivism as it relates to ontology and epistemology and explains how the existence of multiple perspectives is compatible with objectivism.

Definitions

Objectivism is the notion that an objective reality exists and can be increasingly known through the accumulation of more complete information. Objectivism is thus an ontology (the world exists, is real), and an epistemology (knowledge can increasingly approximate the real nature, or quality, of its object—i.e., knowledge can become increasingly objective). Objectivist epistemology presupposes an objectivist ontology—to objectively know the world, there must be a real objective, definite world. (The inverse relation is not necessary—it is theoretically possible that a real world exists but cannot be known objectively because human perception is biased, for example.)

The relation between objectivist ontology and epistemology is best articulated by the philosophy of science known as critical realism. Mario Bunge explained that this perspective keeps the 17th-century distinction between the thing in itself and the thing for us (as known by us). But critical realism removes Immanuel Kant's thesis that the former is unknowable and that the thing for us is identical with the phenomenal object, that is, with appearance. Critical realism maintains that the thing in itself can be known (in a

gradual fashion). Things are too grand and complex to be known through the senses; they can and must be known by conceptual thinking objectified in scientific theories.

The Claims of Objectivism

Objectivism is a perspective adopted by certain practitioners in all the social sciences. In the field of psychology (which is used to illustrate the principles discussed throughout this entry), objectivist ontology means that psychological phenomena—such as emotions, perceptions, reasoning, intelligence, memory, motivation, personality, developmental processes, and mental illness—are real and have definite properties and causes. At a given moment, I have a real anger at my brother because I interpret his action to have been willfully selfish, and I recall that this is a typical behavior of his that I have decided I cannot tolerate any longer. My memory, reasoning, interpretation, decision, and anger are real, and they have definite qualities. A psychologist, a policeman, a judge, or layperson such as my brother who wants to understand my psychology must objectively comprehend the real, objective qualities of my psychological phenomena.

Objectivist ontology and epistemology are reflected in objective descriptions of phenomena. This perspective is known as semantic realism. Whatever the organization of a people's psychology may be (which may be complex and contradictory), this definite, real form must be denoted in a truthful description.

Ontological, epistemological, semantic, and methodological realism require each other. Denying any one of them undermines all the others. For

instance, denying semantic realism—by severing discourse from knowledge about reality and claiming that contradictory statements about psychology are equally true and useful—implies that there is no ontological psychological reality that needs to be reflected in discourse. If ontological reality exists and affects us, then it would be foolhardy and dangerous to ignore it in our discourse.

Ontological, epistemological, and semantic realism-objectivism yield universal theories, thinking, methods, explanations, and descriptions.

Since a psychological phenomenon has a definite reality—which may be complex and contradictory—all descriptions must strive to apprehend it. My anger at my brother incorporates cognition, memory, interpretation, and contradictory feelings of kinship; however, this entire package is one package that must be described and explained in one true and complete account. It cannot be described equally completely and accurately by different accounts. An account that said I truly loved my brother, but was afraid to admit it would be inaccurate. Of course, accounts may describe different aspects of the complex whole, but they must all be consistent with each other to represent the real unity of my psychological package.

A given psychological reality unifies and universalizes the theory, epistemology, mentality, and methodology of all those who would comprehend it.

Pluralism

A plurality of contradictory theories, methodologies, and epistemologies cannot exist for an extended time because they cannot all explain and describe the single reality of the organization of psychology equally well. Freudian notions of the Oedipus complex cannot coexist with behaviorism to explain my anger toward my brother. As Albert Einstein said, at any given time, among competing theories, methodologies, epistemologies, and conclusions that constitute the stock of accumulated knowledge about a particular phenomenon, one is the best (most comprehensive, logical, predictive) way to comprehend its single reality.

Diverse viewpoints are important for generating novel ideas that eventually are sifted out to yield the most comprehensive, logical, coherent, and empirically verifiable one at a particular time. The best one commands general agreement because all observers are striving to comprehend the same, definite object. Diversity and pluralism are stepping stones to general

validity and agreement. They are not goals in themselves, nor do they constitute a state of scientific achievement.

One is not objective simply because one entertains a diversity of perspectives. On the contrary, maintaining a diversity of perspectives precludes discovering the best representation/approximation of the single reality that confronts us. It is objectively the case that automobile manufacturers contribute to global warming by resisting ecologically-friendly improvements in cars (e.g., mileage standards). If someone tries to balance this fact by insisting on a different perspective (say, that automobile manufacturers bear no responsibility for global warming), his or her pluralism and balance have destroyed objectivity.

Of course, diverse viewpoints reappear whenever established theories, methodologies, and conclusions are questioned. But no sooner do they reappear than they are again sifted to yield more valid, agreed-upon constructs.

Objectivism-Realism, Psychological Science, and Communication

Ontological, epistemological, and semantic objectivism-realism are fundamental to all science. There can be a psychological science, for example, only if psychological phenomena are real and can be objectively known (to an increasing degree). To deny objectivist ontology or epistemology is to renounce the possibility of psychological science. If psychological phenomena are not real and have no definite properties, or if humans cannot objectively know these properties, then there can be no scientific study of psychology.

Denying objectivism not only precludes psychological science but also precludes informal understanding and communication about psychology. My brother could not understand the complex phenomenon made up of my anger, reasoning, memory, and interpretation either because it would not be real and definite, or because his epistemology (like that of all humans) would be incapable of knowing my psychology. I might say I felt angry, but if my anger was not real, this statement would just be idle discourse on my part. Or I might really feel angry, but my brother would be under no obligation to understand this anger because epistemology simply cannot comprehend psychological phenomena, even if they are real. Denying objectivist ontology and/or epistemology means that nothing meaningful can be said about

social psychological issues. Comments about them would be nothing more than idle utterances that express nothing real. Also, not everyone agrees that the choice is objectivism or unintelligibility.

Challenges to Objectivism: Realism and Psychological Science

Social constructionists and postmodernists advocate this kind of antirealist, anti-objectivist position. They reject the view that psychology is a science leading to objective truth and claim there are no substantive psychological phenomena. Instead, people construct their psychologies as they discourse with one another. Psychology is nothing more than momentarily created discourse about psychological themes (such as desire, emotion, thinking, motivation, recall). Conversely, discourse about psychological phenomena is nothing more than discourse. It does not refer to real phenomena that can be objectively known.

Social constructionists and postmodernists raise three challenges to objectivism and psychological science.

1. Psychological phenomena are socially constructed and culturally specific; they are not universal. Consequently, different epistemologies are necessary for apprehending different phenomena. To study “saving face” in Taiwan requires a special epistemology that is different from studying romantic love in California. In other words, ontological relativism leads to epistemological relativism. This perspective repudiates universal epistemology on the grounds that it would overlook culturally unique features of psychology. A unique phenomenon is intelligible only to an epistemology and methodology that are specifically honed to its qualities.

Epistemological relativism here means that different epistemologies are necessary in different cultures. Such relativism may be perceived to be not an inclusive welcoming of diverse epistemologies into a culture (to gain varied insights from each), but an exclusionary, divisive relativism that accepts only one epistemology—the Indigenous one—as appropriate in a given culture. Other viewpoints are banished to other cultures.

2. The observer is inextricably formed by his or her distinctive cultural outlook to understand only the culturally relative phenomenon of his or her niche. A person’s formation precludes him or her from understanding the

subtle, complex psychology of people outside his or her niche. Thus, men may be prevented from commenting on “women’s issues” or Whites cannot comment on Blacks because they lack the appropriate cultural epistemology.

The distinctive cultural formation of researchers also precludes them from endorsing a single general theory and methodology that transcend their Indigenous cultures.

3. The ontological relativity of psychological phenomena (emotions, perceptions, mental illness, self-concept, intelligence) means they are unreal, indefinite, ineffable, inexplicable, random, spontaneous, idiosyncratic (i.e., beyond the pale of general cultural psychological principles), and open to numerous, impressionistic, interpretations, descriptions, and explanations from diverse methodologies. This is the argument that ontological (cultural) relativism entails ontological and epistemological nihilism. This argument denies cultural–psychological reality and denies it can be (really) known. Girishwar Misra, an Indian Indigenous psychologist, echoes extreme constructionists such as Kenneth Gergen in claiming there is no objective reality that psychologists have to map and examine the accuracy of that mapping with the objective reality.

Nihilists say that all epistemologies and methodologies are equally acceptable in all situations because there is no objective reality that would make any more useful than any other. Theories and methodologies are purely a matter of personal preference—in other words, “whatever works best for me.”

Objectivist Rebuttals to Constructionism

Objectivists have used these challenges to refine objectivism, not deny it, in the following ways.

1. Ontological relativism does not imply ontological, epistemological, semantic, or methodological nihilism.

With psychology, for example, objectivists argue that the fact that a people’s psychology is culturally constructed and specific does not mean it is unreal, indefinite, ineffable, inexplicable, random, spontaneous, idiosyncratic (i.e., beyond the pale of general psychological principles), and open to numerous,

impressionistic interpretations, descriptions, and explanations. Culturally organized psychology is real and has definite features that are independent of the researcher who studies it—just as the powers accorded to a president, a judge, a policeman, a CEO, or a landlord are real, definite, objective, and powerful although they are humanly constructed and accepted. Ontological relativism (the culturally relative organization of psychology) is compatible with ontological, epistemological, and semantic realism. John Searle aptly said that the denial of external realism, typically in the form of idealism, is the ultimate bad faith of philosophy because it arrogantly arrogates to each individual the power to fashion the world as he or she wishes.

Actually, most relativists are realists, not nihilists. They believe that culturally relative psychology is real and can be objectively known with culturally Indigenous epistemology.

2. Ontological relativism is consistent with epistemological, semantic, and methodological universalism.

Objectivism holds that a culturally specific psychological phenomenon does not require a distinctive epistemology or methodology that is available only inside the culture. The researcher must certainly acquire knowledge about the phenomenon's particular content through understanding the culture. But this is far different from claiming that a culture-bound epistemology and methodology are necessary for comprehending the phenomenon.

This point may be illustrated by a comparative example from biology. An ornithologist who visits a new ecology has to learn about different anatomies of birds that are specific to particular ecologies. But his or her way of comprehending them does not change. The ornithologist uses a general theory about the factors that form bird anatomy, and he or she uses established research procedures and cognitive processes (logic, analysis) to understand the anatomy of these particular birds. In other words, the ornithologist applies general theories and procedures to elucidate the distinctive properties of specific species. The specific content of this species' anatomy does not require a distinctive epistemology and methodology for comprehending it. In fact, any local epistemology and methodology that did not utilize generally accepted principles would fail to explain the local birds' anatomy.

The same is true for psychological phenomena. Their content is culturally specific and variable, but general theoretical, epistemological, and methodological principles are necessary to identify culturally specific content. Without them, Indigenous understandings will be deficient.

Outsiders can understand the subtle, complex cultural-psychological meanings of a foreign people. As Searle observed, one can understand the beliefs people have without sharing them. Anthropologists routinely understand the emotions, thoughts, perceptions, reasoning processes, self-concept, mental illness, and motivation of people very different from themselves. Moreover, they convey their understanding to readers of their works who are even farther removed from the Indigenous culture.

These second- and third-order understandings (removed from the first order of the Indigenous people themselves) are made possible by the human capacity to represent particular events and experiences in general (cultural) symbols that are understandable by other people who have not participated in the event or experience. Symbolic language developed to enable people in different positions to communicate information that was not directly experienced. A hunter in one location could communicate in general symbols (words) to a hunter in another location what he or she had seen (e.g., a band of deer heading toward the second hill) so that the second hunter could gear his action toward this event he did not experience. Robert Merton explained that denying that one person can understand the experience of another is to deny social existence and communication.

3. Culturally embedded scientists can produce and agree to universal science.

Psychologists can objectively comprehend the psychology of diverse people by undergoing scientific training that teaches them general principles and methodologies that are applicable in any setting. Natural scientists undergo similar scientific training. Regardless of their cultural backgrounds and Indigenous beliefs about physical phenomena, they all learn the scientific vocabulary of their discipline (atoms, molecules, genes, germs, cells, gravity, thermodynamics, sound waves) that have proven to more accurately describe and explain their subject matter than their Indigenous beliefs did. Since science is more objective and accurate than Indigenous beliefs, scientists renounce the

latter and adopt the universal conceptual system that best explains their subject matter.

Exactly the same is true for social scientists. All cultural psychologists, for example, can come to agree on scientific cultural psychological concepts that explain the culturally organized psychology of people. Scientific cultural psychology transcends the culture (cultural psychology and relative epistemologies) of its practitioners just as natural science does.

The Indigenous psychology contention that all thought processes are restricted to the conditions of their birth is wrong. As Searle says, the mistake is to suppose that because all facts are stated from within a culture and a point of view that therefore the facts exist only relative to a culture, a point of view, an interpretive community.

Objectivism and Qualitative Methodology

Positivists and many qualitative methodologists alike misconstrue objectivism as antithetical to qualitative methodology. Positivists take this opposition as repudiating any value to qualitative methodology. Many qualitative methodologists applaud the opposition between qualitative methodology and objectivism because they regard objectivism as an impersonal, reified, distorting concept that discounts the subjectivity of subjects and researchers. In this view, validating people's subjectivity requires eschewing objectivism.

These two positions both err in accepting positivistic objectivism as the only true objectivism. In fact, it is possible to investigate social psychological phenomena objectively in a manner that is sensitive to complex, social psychological issues. An objective qualitative methodology dissolves the positivistic objection to qualitative methodology, and it dissolves the postmodern objection to objectivism.

There is a strong objectivist, realist tradition in qualitative methodology. Wilhelm Dilthey, for example, believed that psychological phenomena such as meanings could, and should, be objectively ascertained through a rigorous, scientific procedure of *Verstehen*. *Verstehen* is not an expression of the researcher's spontaneous, personal subjectivity; it is a systematic analysis of other people's meaning. Dilthey emphasized that hermeneutic interpretation of meaning could/should have *Allgemeingultigkeit*, or general validity, because it was objectively apprehended and could be demonstrated to, and accepted by, all interested parties.

Dilthey explained that hermeneutics had this objective from its beginning. It arose in the Greek enlightenment as a method for interpreting and critiquing Homer. Hermeneutics became more sophisticated during the second and third centuries B.C. The literary heritage of Greece was gathered in libraries, and the Alexandrian philologists sought to identify and discard inauthentic texts. They developed strict rules for identifying style, content, inner coherence, and meanings. These rules had to facilitate objective interpretation of the texts to determine which were authentic and which were not. This strict application of hermeneutics led to excising the last books of the *Iliad* and the *Odyssey* because they could not have been authored by Homer. Dilthey observes that hermeneutical methods were necessitated by a struggle over different interpretations. The struggle made it imperative to develop rigorous rules to justify one's interpretation as more valid than the opposition's.

Hermeneutics took another leap during the 16th and 17th centuries in order to provide an accurate or correct interpretation of classical religious texts and the Bible. Protestant theologians sought to invalidate the Catholic interpretation. To do so, they elaborated essential rules for interpretation. The rules had to culminate in convincing arguments that would validate the Protestant viewpoint and undermine the credibility of Catholicism.

Objectivism in qualitative methodology underlies the development of specific analytical, interpretive procedures such as grounded theory and phenomenology.

Objectivism and Human Fulfillment

Proponents of objectivism hold that it is indispensable for human fulfillment because it reveals the reality and necessity that people have to deal with to fulfill themselves. Objectivism is imperative because the way one understands and deals with the world has life-and-death consequences. Life-and-death consequences follow from whether there really is global warming, whether cholesterol heightens the risk of heart attacks, whether poverty leads to impaired cognitive functioning, whether Saddam Hussein had weapons of mass destruction in 2003, whether psychosis is due to social stress, whether an elderly person is incompetent to make medical and financial decisions about and/or by him- or herself, and whether one is loved by one's spouse. Humanizing life requires being objective about these things. Denying objectivism—which is

fashionable among some who call themselves humanists (e.g., social constructionists, postmodernists, philosophical idealists)—obscures real conditions, factors, principles, processes, and problems that debilitate people and that need to be transformed in specific new directions. Objectivism is humanism, and antiobjectivism and antirealism is antihumanism.

biases of researchers. The validity, reliability, and generalizability of most (classically defined) empirical research projects—those that are rooted in the traditional principles of the scientific method—are described as being dependent upon their objectivity (among other factors). Consequently, quantitative researchers actively seek to ensure objectivity through a variety of means, including the standardization of testing procedures and the minimization of flexible data analysis and interpretation. Research projects from this perspective should be untainted by researcher characteristics and therefore repeatable. It is argued that only with such measures can the findings of studies be accurate and dependable. This view of objectivity as a necessary characteristic of research projects is usually associated with work that is rooted in the positivist or postpositivist tradition. This paradigm suggests that there is a single, identifiable truth that can be learned (or at least approached) through rigorous scientific research. To this end, biases and personal viewpoints should be controlled for and as a result, irrelevant to the findings.

From most qualitative researchers' perspectives (which occupy a vast array of paradigmatic affiliations and methodological preferences), objectivity is viewed much differently. Rather than aspiring to conduct research that is objective or neutral, notions of subjectivity are largely acknowledged and embraced. Qualitative researchers are commonly depicted as co-authors and/or co-constructors of reality with their research project participants. Rather than presenting themselves as detached scientific investigators, they are more apt to identify as integral research instruments and/or even passionate advocates for a specific cause. Qualitative work in this regard celebrates the reflexive nature of research. That is, the highly interpretive, diversely conducted nature of qualitative data collection and analysis naturally—indeed, necessarily—are affected by the biases of researchers. Therefore, unlike quantitative researchers, most qualitative researchers do not aspire to conduct studies that are objective.

However, it is necessary to point out that qualitative research in most cases ascribes to a notion of subjectivity that is much different from an unsupported haphazard subjectivity (absolute relativism) that could be situated on the opposite end of the spectrum from scientific objectivity. Subjective qualitative research, marked by researchers' honesty, transparency, and contextualization throughout the research process, is valid in that it offers meaning, lends insight, and in some cases, leads to socially responsible action.

OBJECTIVITY

Objectivity, a term that is commonly associated with quantitative research, can be broadly described as the extent to which research projects are undistorted by the

Researchers are often positioned as advocates who are indeed presenting a credible, trustworthy depiction of a people, condition, or phenomenon, but doing it from a real, contextualized, involved position. Data are not, then, presented as subjectively emanating from the researchers' whimsies; rather, they authentically, purposefully, and contextually emerge from the dynamic intersection of researchers' and research participants' unique identities, beliefs, ideas, passions, and actions.

OBSERVATIONAL RESEARCH

Observation is one of the oldest and most fundamental research method approaches. It involves collecting impressions of the world using all of one's senses, especially looking and listening, in a systematic and purposeful way to learn about a phenomenon of interest. Although frequently employed on its own, observational research is often used with other methods such as interviewing and document analysis. Both quantitative and qualitative researchers, and those working somewhere along the continuum between these two approaches, use observation. More quantitative observation is often referred to as systematic or structured observation and more qualitative approaches include naturalistic observation, nonstructured observation, and participant observation. This entry focuses on qualitative observational research. It begins by relating some of the characteristics of qualitative observation, goes on to describe the method or doing of observation, explores the issues of the role of the observer and ethical concerns, and closes with overviews of the strengths and weaknesses of this methodological approach.

Characteristics of Qualitative Observational Research

Qualitative observational research attempts to capture life as experienced by the research participants rather

than through categories that have been predetermined by the researcher. Observational research assumes behavior is purposeful, reflecting deeper values and beliefs. Although it may be conducted in a laboratory or another setting chosen by the researcher, it more typically takes place in natural settings to capture behavior as it occurs in the real world. It usually involves direct contact between the researcher and participants though indirect data collection methods such as audio- or video-recording may also be used. Qualitative observational research is exploratory. It seeks to uncover unanticipated phenomena. It uses inductive reasoning with the conceptual constructs used to account for observations being developed during and after data collection from the observed behavior itself. Qualitative observational research uses idiographic rather than nomothetic causal explanation. It is constructivist in approach, emphasizing meanings that the participants attach to activities and events. Qualitative observational research recognizes the subjective role of the researcher. It acknowledges reactivity to be inevitable on the part of both the observed and the observer and seeks to address and understand this through researcher reflexivity.

Qualitative observational research is associated with a number of theoretical traditions and broad research methodologies including ethnomethodology, grounded theory, dramaturgy, institutional ethnography, and participatory action research.

Methods: Doing Observational Research

The Research Process

Observational research, like any research, begins with the selection of a research problem. This problem is often presented as an area of research interest, with more specific research questions being articulated after more is learned through observation in the field. Although some researchers prefer to enter the field and begin observation immediately without the potential blinders of preconceived notions, many conduct a literature search to identify relevant indicators and explanatory concepts that may inform the project. Researchers gather both descriptive and relational data through observing behavior in the setting of interest. Findings are articulated, often with an explanatory model or one or more explanatory theoretical constructs, in reports of the research.

Qualitative observation is characterized by an emergent research design. This design involves a

cyclical process, moving back and forth between inductive and deductive reasoning: Themes are identified through the analysis of observed behavior; these themes suggest areas for focusing subsequent observation; subsequent observations suggest new themes that then initiate more observations. Data collection continues until saturation, the point at which the observer learns nothing new from continued observation.

What Is Observed

Observation is holistic in its approach, with researchers collecting data about many aspects of the research setting and its participants. Researchers pay attention to the actors or participants in a setting, collecting sociodemographic (e.g., age, gender, education, class) and descriptive (e.g., dress and stature) information, trying to determine who the people are. Acts, activities, and events are observed and recorded to discover what people do and with whom, what is happening, and if there are any trends and patterns discernible in these activities. Observers attend to what people say, the words they use, accounts and explanations they give of their behavior, and the personal and social meanings and the attitudes and beliefs that are revealed through their talk. Relationships between people, both individually and within groups and between people and groups of people and organizations, are explored. Characteristics of the physical setting, including the objects found in it, are noted. Where possible and often through the collection and examination of documents, information is gathered about the history of the phenomenon of interest and the research setting. Observers attend to mundane, everyday details, believing that what is actually happening is often evident in what might be seen to be trivial and taken for granted. Through observation practices such as these, researchers strive to identify broad trends and patterns of behavior.

Fieldnotes

Data are most frequently recorded in the form of fieldnotes. From initial jottings made during observation, researchers develop full fieldnotes usually within 24 hours of data collection while memory is still strong. Fieldnotes always include written descriptions of what was observed and may also contain maps, diagrams, and documents or other objects gathered while

observing. While writing up fieldnotes, observers often have insights about what has been observed, and these are recorded as theoretical or analytical fieldnotes. Researchers also keep track of conditions in the setting, their own state of mind, attention span, and other variables that might affect the process of observation. These records are referred to as either method fieldnotes or a reflexive journal. Fieldnotes are the core data log for analysis in observational research.

Researcher Roles in Observation

The role adopted by the researcher is important in that it constrains what can be observed. Several schemes have been developed to describe these roles. Raymond L. Gold's typology, dating from the late 1950s and commonly used, is based on the degree that the researcher participates in the setting, ranging from complete observer (no interaction between the observer and the observed) through observer as participant, participant as observer, and complete participant. More recently, some researchers have asserted that all observers participate in a setting in some way and prefer to use the term *membership*, varying from peripheral through active to full membership to describe researcher roles. The purpose of an observation study, the characteristics of the observer, and the nature of the setting all contribute to the choice of an appropriate research role. For example, in a study of the work of a nursery school teacher conducted on site in an actual nursery school by an adult male researcher, it may be best for the observer to adopt the research role of complete observer or peripheral membership to remain relatively nonobtrusive and to not disrupt the normal flow of activities. In presenting the findings of observation research, it is important that the researcher role and its entailments in the particular research setting be described.

Ethical Issues in Observational Research

A number of ethical issues are associated with observational research. Of major concern is the use of deception by the researcher. Practicing covert observation, assuming a false role, or misleading participants about the research in other ways may (depending on the circumstances) violate the principle of informed consent; due care and attention must be paid to ethical issues in these cases. Researchers must maintain confidentiality, both protecting the identity of participants and

refusing to reveal sensitive information gathered during the research process that could harm the individuals involved. Researchers must be inclusive, realistically representing the voices of all participants in a research setting. Key informants and gatekeepers may block access to the less powerful, and ways to bypass them must be found. Member checking helps to ensure that participant's accounts and meanings are authentic. Observational methods are often used for exploring deviant behavior. Researchers may observe or participate in illegal or deviant behavior as part of the data gathering process. This behavior can result in what is called *guilty knowledge* and presents the ethical dilemma of whether or not this behavior should be reported to police or health or other authorities to protect and help participants and the community.

Strengths of Observational Research

Qualitative observation, with its flexible and emergent research design, is effective for exploring topics about which little is known. It is well suited to the study of social processes over time. The rich descriptions it generates can result in deeper, fuller understanding of phenomena. It is particularly powerful when combined with other methods such as interviewing. Most forms of qualitative observational research are relatively unobtrusive and therefore nonreactive and able to generate highly trustworthy data. Finally, observational research is well suited to both the discovery of new information (theory generation) and the validation of existing knowledge (theory confirmation).

Weaknesses of Observational Research

Observation is not suited to all research inquiries. Not all phenomena, such as cognitive processes, can be directly observed. Infrequently occurring acts are difficult to capture even with prolonged time spent in the field. Observation requires a substantial amount of time and other resources and is usually tied to one specific place, raising issues related to the transferability of findings to other settings. Repeated observations in a number of settings and thick descriptions of what was observed that help readers determine how transferable findings are to other settings help to address this problem.

As observation is very dependent on the ability of the observer (reflected in the idea of researcher-as-instrument), it is subject to observer bias that occurs

when researchers channel both their observation and interpretation of data through what they know. Strategies to reduce observer bias include maintaining reflective journals that actively examine this issue; prolonged engagement in the field that allows for discovery of unanticipated phenomena; triangulation of data sources, researchers and methods; negative case analysis; member checking; peer debriefing; and providing thick descriptions of what was observed. Novice researchers may not have the experience and skill to be effective observers. They need training and especially apprenticeship, as the best way to learn is by actually doing observation.

Recently, researchers working from a postmodernist perspective have questioned the desirability and feasibility of objectivity in observational research and point to a number of factors that inevitably threaten objectivity. They maintain the researcher's situation (e.g., gender, class, and ethnicity) must be fully understood as it acts as a lens through which observation is conducted. They assert there will always be multiple accounts of what is happening depending on who is describing an event and that no single account may be privileged over another. Postmodernist researchers argue for thinking of observation as a context for interaction among those involved in the research, as collaboration between the researcher and the participants.

OBSERVATION SCHEDULE

An observation schedule is a form prepared prior to data collection that delineates the behavior and situational features to be observed and recorded during observation. Observation schedules vary on a quantitative–qualitative continuum. More quantitative observation schedules, sometimes referred to as observation checklists, use carefully and explicitly predefined categories of variables that can be counted and analyzed statistically. More qualitative observation schedules act as flexible guidelines for data collection, listing topics of interest and providing space to record notes about new themes that emerge during observation. Heavily structured observation schedules are best suited to contexts where more is known about the topic of interest; more flexible, less structured observation schedules are more effective in situations where less is known about the research questions.

Usually taking the form of a single sheet of paper, observation schedules are most frequently used with structured observation. Categories included on the data collection form are derived from the purposes of the research project and from what is known about the variables or themes of interest. Observation schedules are typically pretested and modified before implementation.

Observation schedules allow factual information to be recorded immediately. Factual data collected typically include some or all of relevant demographic information (e.g., age, gender), the role of participants in the research setting (e.g., job title), counts of the number of individuals present, and elements of the physical setting. Investigators also document what participants do (acts and activities) either by checking

predetermined categories or by making notes about what is observed. What people say (words and the meanings ascribed to them) and relationships among participants are usually also of interest. In developing observation schedules, researchers attend to ease of use. More quantitative observation schedules will include explicitly defined categories that are exhaustive and mutually exclusive and that, wherever possible, avoid subjective measures requiring judgment or inference. More qualitative observation schedules seek to list as many emerging themes of interest to the project as is possible. Observation schedules are well suited to tracking time and if designed to do so, can capture the frequency, sequence, and duration of events observed. Most researchers recommend leaving space on observation schedules, including the most explicitly quantitative forms, for recording data that do not fit into preselected categories and impressions and other more subjective data that may inform the study.

Observation schedules provide clear guides for focusing observation and recording data. In studies involving more than one observer, they allow for tests of intercoder reliability and serve to enhance consistency among observers. Heavily structured observation schedules are less flexible, restricting attention and limiting the ability of observers to see new things. The use of observation schedules can be intrusive and result in reactivity in research settings. However, it has been found that this is usually ameliorated through habituation.

OBSERVER BIAS

Errors and biases can occur in all types of social science research, whether it is qualitatively driven or quantitatively led. One type of bias that may occur

during observational methods is *observer bias*. This term refers to the ways in which errors may unconsciously occur when gathering and analyzing observational data. The observer's age, gender, social class, values, schemas, and expectations may lead certain observations to be recorded as significant and others to be ignored if the observer regards them as unimportant. Further, observers may associate meanings to the observed behavior that are different from the meanings associated by the person(s) displaying the behavior.

Psychological studies have shown that bias in human perception and expectation can encourage findings that correspond with those perceptions and expectations. In one study, Miriam Goldstein, J. Roy Hopkins, and Michael J. Strube found that students who were led to believe that an individual's performance would decrease as a result of consuming alcohol reported corresponding observations. The decrease in performance was not evident in the observed behavior as the individual observed—a trained confederate who drank a nonalcoholic drink—maintained consistent performance throughout the observation.

Although the researcher cannot alter some influencing characteristics, such as age, observer bias can be reduced if the researcher adopts specific strategies during the observation, for example, using standardized forms. Standardized forms, as used in structured observations, can help to reduce the impact of selective perception, as the forms direct the observer's attention to those behaviors or activities that are closely related to the central research project. The use of multiple observers can also highlight deviations from the main research topic, misinterpretations, omissions, and overemphasis. Further, triangulation—the use of multiple methods or data sources to study the observational individual(s)—enables findings to be cross-checked and any biases or errors to be highlighted.

Observer bias can also manifest itself in more subtle ways, which are more difficult to eliminate. Those being observed may modify their behavior, disguise their actions, and alter their opinions because they do not wish to share them with the researcher. Behavior may be changed according to how those being observed think they are expected to behave. Such responses are often referred to as the Hawthorne effect, taken from the name of a factory where the effect was first identified—the Western Electric Company's Hawthorne Works in Chicago. As completely neutral observations may be difficult to

achieve, when reporting observational findings researchers should acknowledge and discuss the factors that may have contributed to observer bias and how these factors may have altered the interpretation of the findings. This discussion will enable readers to make an informed judgment when assessing the value of the observational findings.

ONTOLOGY

Ontology derives from the Greek words for *thing* and *rational account*. In classical and speculative philosophy, ontology was the philosophical science of being. Its general aim was to provide reasoned, deductive accounts of the fundamental sorts of things that existed. Ontology was not concerned with the specific nature of empirical entities, but rather with more basic questions of the universal forms of existence. Examples of classical ontological questions are as follows: Are bodies the only things that exist, or are immaterial forms real? Is there a supreme intelligence in the universe, or is all activity reducible to mechanical motion? Are individuals alone real, or are collectivities independently real? Are there real objects of universal terms, or are universals simply names that humans give to mental abstractions? The very generality of these questions means that they will always have some connection to the investigation of natural and social phenomena. In the contemporary era, however, it would be wrong to continue to think of ontology as a fundamental science given that hypothetical-empirical methods of research (at least in the natural sciences) have permanently displaced the deductive-rationalist methods of classical philosophy.

The last systematic attempt at fundamental ontology in the work of Martin Heidegger hoped to displace

the domination of empirical science by demonstrating that its conclusions were relative to unexamined frames of meaning. The answer to the question, "What is being?" differs depending on the frames of meaning within which the question is asked. The scientific answer to this question refuses to admit all nonquantifiable data into an acceptable account of reality. The consequence of this method is that the world is reduced to the sum total of individual things. Since these things are assumed to be meaningless in themselves and anything that might exist beyond individual things but is not quantifiable is ruled irrelevant, the entire world is reduced to mere raw materials for scientific and technological manipulation. The importance of this aspect of Heidegger's work has not impeded the further extension of the hegemony of quantitative methods in both the natural and social sciences. His alternative, to let beings be, has not proven a globally convincing alternative.

Nevertheless, ontological questioning remains an essential moment of any adequate social scientific research. The importance of ontological questioning, however, does not mean that it is reasonable any longer to expect deductive expositions of the essential nature of social reality. It would be anachronistic to pose these questions with the goal of arriving at a totalized system of universal principles in mind. In the contemporary period, ontology, or more particularly, social ontology, remains essential as a critical propaedeutic to empirical research.

Social Ontology

The term *social ontology* derives from the work of Carol C. Gould. In this more restricted sense, ontology aims at providing general accounts of the nature of social reality. Its practice is linked explicitly to the goal of avoiding a naive (unreflective, uncritical) empiricism that would reduce the nature of social reality to that which is disclosed by statistical and empirical methods of research. From an ontological perspective, the problem of statistical-empirical methods is not that they cannot uncover important data about social dynamics or patterns of behavior, but rather that they rest upon an untheorized and undisclosed ontological assumption: Social reality is identical to the conclusions of statistical-empirical research. In other words, the empirical researcher who does not explicitly pose ontological questions fails to ask the most important question of social research:

How did the given social reality come to be constituted as it appears? The social ontologist recognizes that unlike the objects of natural science, which are not produced by human action and thus constitute a reality that truly is given to the mind to investigate, social reality is the result of complex forms of human action and interaction. That fact means that social reality is dynamic in a way that natural reality is not. The fundamental forms of social reality can change precisely because they are determined by forms of action and interaction that create a field of possibilities, but that simultaneously exclude the realization of most of them. Posing critical ontological questions thus opens up the field of social possibilities, whereas proceeding on the assumption that that which is real in society is identical to the conclusions of statistical-empirical research keeps the field of possibilities hidden. An example will clarify this claim.

The newspapers are regularly full of stories about crime. Quite detailed demographic and statistical analyses of the causes and trends of crime are easy to find in the popular press. These analyses are generally accompanied by definite psychological and sociological assumptions that can differ within a narrow range of alternatives (some accounts give relatively more weight to sociological factors such as class and race; others tend toward a more psychologistic approach, linking criminal activity to a specific mindset that increases the propensity for antisocial behavior). What one rarely finds in these accounts, however, is an inquiry into the meaning of crime. That is, these accounts generally assume without argument that crime is some independently real entity and the criminal, thus, an objective variable that can be studied as one would study the behavior of a neutrino or a magnetic field. In other words, empirical research proceeds on the basis of assumptions that the investigator may not even be aware of, but these assumptions predetermined the sorts of questions asked and the range of answers that will prove acceptable. This predetermination of questions and answers at the same time limits the range of policy options that will be defended by the conclusions of the research. If sociological factors are paramount, then various projects of social development (poverty reduction programs, education, etc.) will be favored. If psychologistic assumptions rule, then strategies of deterrence (designed to make a life of crime less appealing) will be favored. The aim of social ontological investigation is not to support one policy option over the other, but rather, to

work beneath the givens of empirical research to disclose the wider field of possibilities for social action and organization closed off to empirical methods because of their unreflective approach. As opposed to the positive nature of empirical research (positive in the sense of being governed by the goal of accumulating data that can support policy), social ontological research is primarily negative. Negative here means aimed at the breaking up of fixed and untested assumptions that illegitimately limit the field of questions and answers that guide empirical inquiry.

Social Ontology and Social Criticism

The negative form of inquiry proceeds by taking the givens of empirical research and making them the target of ontological questioning. That is, it asks whether or not, or under what conditions, the fixed object of empirical research actually exists. Consider the example of crime and the criminal once again. Positive methods assume the objective reality of crime and criminals and seek to draw inductive generalizations about causes, behaviors, and practical remedies. Ontological investigation asks deeper questions: What constitutes criminal behavior? Is being a criminal being something fundamentally distinct from being a not-criminal? What general social conditions must obtain for their being the categories of crime and criminal? Are these conditions universal (transhistorical and cross-cultural), or are they historically specific terms, apart from specific policy options in any given society? Is it possible to conceive on the basis of real social potentialities a different form of social organization in which crime and criminals would no longer exist?

These sorts of focused questions are only the beginning of negative inquiry. As the questioning proceeds, it will lead the questioner into more fundamental questions, questions that establish contact between social ontology and the deeper questions of classical ontology. If the first set of questions reveals that specific factors must be in place for a given social reality to appear in the form that it does (to use the example of crime once again, a civil legal institution separate from religious authority that permits the distinction between crime and sin), then the general conclusion follows that social reality is more fluid than natural reality. From this general conclusion follow more general questions: In what sense can institutions be said to exist independently of the individuals whose behaviors they govern? Does institutional reality depend

upon the beliefs of people, or is it a reified whole that determines people's beliefs and actions? In what sense is society an object of research? Is social reality distinct from the individuals who make it up? The general methodological implication of this form of questioning is to open up a difference between the given appearances of social belief and the action and general underlying processes that produce changes in the institutional configurations in which beliefs and actions develop. In short, social ontology undermines the plausibility of uncritical empiricism that identifies social reality as such with given forms of organization, belief, and action.

Empirical approaches to understanding society that simply assume that what the researcher sees is the truth about society run the risk of not only ignoring the historical development of different social forms (and thus, the possibility of deeper social transformations in the future) but also misunderstanding the nature of individuals whose belief and action purportedly constitute the foundation of social life. Methodological individualism—the claim that only individuals are real and that collective entities such as classes and movements are understandable only if their behavior is reduced to the behavior of the individuals who make them up—is the necessary counterpart to empiricist social research. Since the empiricist necessarily refuses the distinction between apparent forms of reality and essential underlying, constitutive structures and relations, the possibility of collective subjects, is ruled out from the beginning. It does not follow from this argument that there are in fact collective agents; that is a question that can be decided only by fundamental inquiry into the nature of social reality. The point of ontological questioning is to test presupposed assumptions by working beneath the manifest forms of action in given social formations. This deep questioning extends all the way down into those elements of human subjects that appear most natural: sex, skin color as an objective determinant of race, the biological needs that structure the human organism, and so on. There can be no certainty that what appears to be natural (i.e., fixed independently of institutional structure) is in truth natural without ontological investigation.

Contemporary Relevance of Ontology in Social Research

The need for this form of ontological questioning of given social reality follows from the basic structure of

human thought. Although he did not use the term *social ontology*, Theodor Adorno's inquiry into the basic relationship between thinking consciousness (subject) and the object of thought reveals clearly its necessity. Adorno demonstrates in *Negative Dialectics* that human thinking is essentially contradictory. Because thought depends upon universal concepts to organize the raw material of sense data, but the objects of that sense data are material particulars, the very processes by which human beings cognize the world distances the human mind from it. That is, there is always a cognitive deficit between the conceptual forms through which the world is known and the intrinsic (particular) structure of the things of the world itself. The same point holds whether one is referring to natural or social reality. To simply assume that a categorical system corresponds to a nonconceptual reality (as positivism must) is to ignore the essential difference between universal concepts and particular things and the relations between them. Since concepts are necessary for there to be objects of thought at all, there can be no question of abstracting from conceptual structures to get at the things themselves as Edmund Husserl argued. Instead, genuine thinking for Adorno must engage in an ongoing dialectical process of conceptualization and criticism of achieved conceptualization, constantly reopening the conceptual closure the mind must impose upon the world. The point of this constant reopening is not to end up with some definite ontology (general or social), but rather it is to remind subjects that no particular conceptual system is ever fully adequate to the complexity of reality.

In this sense, ontology today is best practiced as a critical discipline rather than a positive philosophical science. Positive knowledge of social, like natural, reality cannot do without empirical and statistical methods. These methods, however, must be located in a more fundamental matrix of critical (ontological) thought. Critical thinking here does not mean what it has come to mean in the social sciences today—problem solving—but rather, it refers to the essentially negative nature of thinking. That is, thinking negates the givenness or independence of the object. Any object of thought must become an object of consciousness before it can be named and classified. All systems of naming and classification follow from the structure of human consciousness itself, which, as noted above, converts material particulars into universal concepts. Critical thinking remains mindful of this

dialectical conversion process and thus, refuses just what the empiricist demands—total closure of the field of thinking by the given forms of reality that constitute the object of its claims. The general ontological conclusion of this approach to the problem is simply that reality is not a fixed object that can be known once for all. What is real is determined by the dynamic processes implicit in both nature and society and the structures of mind upon which active cognition of those processes depends. Without this, awareness of the dynamic and changeable nature of the real empirical knowledge continually compromises its truth value by falsely universalizing conclusions drawn from particular sets of data.

It would appear, then, that the sort of ontological investigation that remains vital today entails both relativistic and idealist conclusions. Such a conclusion, however, is too hasty. Ontology is essentially a form of questioning. Questions open up the field of research; they do not determine answers. Hence, whether relativism or idealism is true cannot be decided simply from a process of critical questioning of apparent natural and social forms. In fact, to assume that some definite systematic conclusion follows from a process of questioning is the result of a demand that questioning cease, whereas the whole point of ontological investigation is to make clear the reasons why questioning cannot terminate in any absolutely final conclusions. Since the real is a dynamic process (or processes) of change and development, there can be no final, one-sided conclusions as to its essential nature. To argue that everything is relative or that the implication of consciousness in the cognitive determination of material reality leads to idealism is to miss the real point of ontological criticism. The real point, once again, is to undermine the positivist drive to reduce reality as such to its apparent forms in any given moment of time. To grasp natural and social reality as processes of change and development is thus to grasp that the opposites that structure classical ontology (ideal–material, relative–absolute) are always both present in the object. One does not exclude the other; each implies the other. That social and natural reality change means that there is always going to be an element of relativity in empirical knowledge; it does not mean that truth is relative. The first formulation is not a general theory of truth; the second is. The second contradicts itself (by absolutizing relativity); the first asserts a particular conclusion of critical investigation.

It is, therefore, as the necessary foundation of critical understanding that ontology remains relevant to social research. Unless fundamental questions are posed, social research runs the risk of being determined by immediate appearances, to the detriment of both understanding and making efficacious contributions to public policy. Policy recommendations that follow from unreflective assumptions about the nature of social institutions and agents necessarily remain hostage to given modes of social action. If those modes of social action are problematic, however, then policies that assume their necessity will serve to exacerbate rather than ameliorate their effects. The various social wars of the last 3 decades, on poverty, on crime, and so on, are cases in point of manifest policy failure owing to the naive assumptions about the nature of the social problem (and thus, about the basic nature of social institutions and agents) that guided them. Thus, although ontology as a fundamental philosophical science may no longer have an important role, the deep questions that motivated it remain an essential element of illuminating social research.

OPEN CODING

Open coding refers to the initial phase of the coding process in the grounded theory approach to qualitative research (generating theory from data) espoused by Anselm Strauss and Juliet Corbin. They call this initial stage of data analysis open coding because they view the process as the “opening up” of the text in order to uncover ideas and meanings it holds.

The process of open coding begins with the collection of raw data (e.g., interviews, fieldnotes, art, reports, diaries). The intent of open coding is to break down the data into segments in order to interpret them. Detailed word-by-word and line-by-line analysis is conducted by researchers asking what is going on. The researcher discovers, names, defines, and develops as many ideas and concepts as possible without concern for how they will ultimately be used. How the issues and themes within the data relate must be systematically assessed, but such relationships can be discovered only once the multitude of ideas and concepts it holds have been uncovered.

Turning data into concepts is the process of taking words or objects and attaching a label to them that represents an interpretation of them. When data collection is ongoing, the concepts identified guide what further data are collected. Such theoretical sampling, sampling based on the concepts uncovered in the data, is contingent upon the open coding process. The topic of study and issues of concern to the researcher play a key role in the ideas and concepts identified; however, the researcher is advised to be vigilant in keeping an open mind when analyzing the data.

Any phenomenon (e.g., event, incident, action, object, process) may be multiply classified. For instance, a statement by the spouse of an incarcerated offender, “I’m worried that my daughter keeps getting into fist fights,” may be coded as *fighting*, as *parental concern* for his or her child, and as actions signifying the need for *assistance or therapy*. The development of such concepts provides the opportunity for researchers to classify similar phenomena together, ordering and reducing the data. Data segments are, therefore, compared so that they may be grouped together as examples of the same concept or differentiated to form new ones. For instance, the concepts of cheating, stealing, and fighting share the property of being deviant and may be grouped together under the more abstract category labeled deviant acts. In the process of open coding, researchers also search for the dimensions of categories, such as frequency (how often) and intensity (how severe).

In the coding process advocated by Strauss and Corbin, open coding precedes axial coding, the refinement and development of specific categories, and selective coding, where categories are related around a core or central theme in an attempt to explain a phenomenon.

Some critics have expressed concern that the advantages of this style of microanalysis may be

outweighed by the drawbacks of stripping away context and thereby obscuring larger storylines.

Open coding may be recorded in a variety of ways, for example, through marginal notes, the use of word processing programs, or specialized software programs designed for qualitative research where code labels are attached to data segments for easy retrieval.

OPEN-ENDED QUESTION

An open-ended question is a type of question that researchers pose to research participants that allows them to select how they orient to the research topic. Also referred to as nondirective questions, open-ended questions provide participants of research interviews or written surveys with the opportunity to choose the terms with which to construct their descriptions and highlight the topics that are meaningful to them. The freedom on the part of research participants to elaborate on self-selected aspects related to the researcher's topic of examination in response to open-ended questions contrasts with the kind of responses called for by closed questions, which provide possible answers in the question and structure the format in which interviewees should respond. Open-ended questions make no presumptions about the kinds of answers participants might provide and are sometimes used as a way to develop the response options used in standardized survey formats.

The "grand tour" and "mini tour" questions outlined by the ethnographer James Spradley are good examples of open-ended questions, for example:

- Describe a typical day at work.
- Describe what you usually do when you encounter *x* at work.

One guideline for using open-ended interview questions is to begin with general questions and to request more detail from participants with probes. For example, a general question such as, "Tell me how you came to be doing *y*," might be followed up with the probe, "You mentioned *z*; give me an example of that." Participants' descriptions of their subjective states may also be elicited via probes: "You mentioned *y*; tell me what that was like for you." A useful closing question in any qualitative interview is the open-ended question, "Is there anything we have not talked about that you would like to add?"

Although Spradley's use of open-ended questions is in the context of ethnographic interviews that examine questions about culture, open-ended questions may be used in a range of qualitative interview formats, including open-ended or in-depth individual interviews, group conversations and focus groups, and in (quantitative) questionnaires to elicit written data.

Interviewers must take care to pose open-ended questions purposefully, for if questions are too broad and the researcher has provided insufficient context for the research purpose, participants may not know how to respond, and lengthy clarification sequences may ensue. Another challenge faced by qualitative researchers lies in the analysis of data generated from open-ended questions. Since participants are free to respond to open-ended questions in whatever way they choose, data generated are likely to be wide-ranging in topic, complexity, and length.

ORAL HISTORY

Oral history is one of the oldest, best known, and most often used methods in qualitative research. Oral historians ask people to talk about their overall life experiences or to discuss specific experiences and events in a narrative form, recording this information with either audio or video equipment. The aim of oral history is to gain first-hand knowledge from people who have lived through different social–historical–political periods and events. This methodology allows the researcher to document what the person has lived through and to analyze this information for underlying meanings and significance that such an event or a time period has for the informant. Oral history provides information that cannot be gleaned from any other sources, and it gives voice to ordinary and often marginalized peoples whose stories might never have been documented otherwise.

Oral history is of importance for qualitative research since it forms the basis for many studies. As one of the foremost open-ended techniques for gathering information about people, it has had a major impact on other types of qualitative interviews. That is, interviewing modes such as open-ended interviews, life story interviews, and semi-structured interviews often draw upon the oral history tradition. Oral history has not only influenced interviewing techniques, but also opened up ways of thinking about data collection in general and about the value of combining oral history with different modes of learning about others—such as the analysis of written formal documents and observations. Finally, oral history cuts across disciplines in the humanities and the social sciences, making it a research method that is used by scholars, students, educators, writers, and folklorists working from diverse backgrounds and interests.

This entry presents an overview of oral history, its scope and major contributors, and then briefly describes its basic techniques. It ends with examples of major oral history projects that have been undertaken around the world in recent years and information on resources of interest for beginning and experienced oral historians.

An Overview of Oral History

Oral history has been used as a way of passing down memories of the past for centuries and of sharing memories across cultures, predating written history.

There has not always been consensus among social science researchers concerning the reliability of oral history as a data collection method or concerning its ability to serve as a rigorous research method. However, in spite of these periodic reservations, oral histories have been systematically collected and analyzed for the last 2 centuries. This informal method of preserving information about past events emerged as an important methodological tool of social science and historical research during the decade of the 1940s with the advent of the tape recorder. For over 60 years, therefore, oral history has enjoyed a renaissance.

Paul Thompson, a British scholar and one of the world's foremost oral historians working within sociology and social history, has carried out hundreds of oral histories and historical studies of its uses by looking at over hundreds of years of work. As Thompson notes, oral history gained in popularity in the United States and Europe during the 19th century. For example, collections of oral histories of influential Americans began as early as the 1860s, and the interest in the field led to the establishment of the American Folklore Society in 1890. The Chicago School of Sociology, based in the University of Chicago, which became one of the premier social science departments in the country and in the world, adopted oral histories as their major method of documentation and analysis of urban social life in the 1920s. Perhaps this work is best epitomized by William I. Thomas and Florian Znaniecki's monumental sociological research on Polish immigration to other countries in Europe and to the United States.

Oral histories have been used extensively throughout Western Europe and Scandinavia, in Latin and South America, in Africa, and in Asia. A nonexhaustive list of the diverse topics studied include urban issues, especially long-term poverty, slum and inner-city life, and the social consequences of this poverty, such as delinquency and homelessness; immigration, focusing on issues of socialization, education, and assimilation; labor issues, such as experiences in industries such as fisheries, education, and cotton mills and labor union development; the arts, looking at the life stories of musicians and artists; military and war issues that center on battle experiences of former soldiers, conscientious objectors, and antifascist wartime partisans; health issues and wellness, including research on former psychiatric patients, caregivers, and people suffering from terminal diseases; and research on diverse populations and cultures such as Native Americans,

Indigenous Aborigines in Australia, former Black slaves in the United States, migrant workers, home-steaders, lesbians and gays, and survivors of the Holocaust and of state terror and torture, to mention just a few. A short list of scholars and folklorists who are well known for their innovative work in oral history include Studs Terkel, who collected hundreds of narratives from working people throughout the United States; anthropologist Oscar Lewis, who documented stories of Mexican families; Neil Rafeek of Scotland, who focused on issues of social justice; Wilma Klug Baum, who directed the Bancroft Library's Oral History Project at the University of California at Berkeley for over 40 years; Luisa Passerini, an Italian professor of history who has studied fascism, student radicals, and the feminist movement; and Alessandro Portelli, a professor of American literature in Italy, who has recorded stories from people living in Rome's slums, Kentucky coal miners, veterans of World War II and the Vietnam War, and student activists from around the world. Portelli's contributions also extend to the theory and practice of oral history by drawing connections between personal memories and history and by looking at how dialogue, representation, narrative, and genre link historical analysis together with literary theory, linguistic theory, and anthropology.

As can be seen, oral history is not monopolized by any one discipline; research using this methodology can be found in the fields of history, art, literature, sociology, anthropology, cultural studies, feminist studies, social work, education, and psychology. Furthermore, oral historians working in these different disciplines often borrow from one another, thus adding an interdisciplinary aspect to their studies.

The Method: Eliciting Oral Histories

The techniques used in eliciting oral histories share the following commonalities: questions are open-ended and person and experience centered, and the questions aim to elicit rich detail on the topic being studied and involve active listening. Opening questions can be extremely general and open-ended, leaving it to the interviewee to direct the interview. For example, one might say, "Please tell me your life story, talking about whatever you wish." Alternatively, the question can be much more focused, centering on a particular event or historical period. Here, the researcher might ask, "Please tell me what happened on the day the Nazis marched into your town." Oftentimes, oral historians

begin with a broad question and then move on to more specific questions where they ask the participants to recount specific details connected to the topic of the study. As a rule, as the interviewee proceeds with the story, the interviewer attempts to elicit more and more detail about personal memories and experiences without disrupting the narrative flow. Therefore, a successful oral historian must develop excellent listening and nonverbal behavioral skills that encourage the biographer to continue with the testimony. In addition, to collect rich material, oral historians must demonstrate interpersonal and cultural sensitivity and refrain from asking judgmental questions that can make the interviewee feel uncomfortable. Oral histories range in time; they can take from one hour to several hours. Some interviews last only one session while others take place over days and perhaps even weeks or months. In addition to the interview, oral historians often also ask their participants to provide artifacts or documents, such as letters and diaries from different historical periods that add another dimension to their stories.

Oral History Projects and Resources

Over the last 20 years, oral histories have been used in many different frameworks and institutions. Two examples of projects that have made important contributions to social science and history include the Survivors of the Shoah Visual History Foundation that was established in 1994 by director Steven Spielberg. The foundation videorecorded testimonies of Holocaust survivors and witnesses, recently making these interviews available for educational and research purposes. There are nearly 52,000 testimonies in the database that were collected in 32 languages and 56 countries. To date, this massive global undertaking has produced two CD-ROMs and eight documentary films. A second important oral history project is the Veterans History Project that was established by the U.S. Congress in 2000. This project aims to gather first-hand accounts of American veterans from all of the wars from the 20th century onward through audio and visual recordings or through written memoirs. The endeavor also interviews individuals who, as civilians, actively supported war efforts, such as war industry workers, USO (i.e., United Service Organizations) workers, and medical staff.

People interested in oral history can find a number of resources on the internet. The Oral History

Association, which was established in the United States in 1966, has an international membership from many fields. This organization has established guidelines and evaluation standards for oral history interviews. Furthermore, the association gives awards for excellent achievements in the categories of publications, media productions, teaching, and oral history projects. A second internet resource is the Oral History Society (OHS), which was founded in Great Britain. The OHS offers conferences, practical training, national and international networking, funding and employment opportunities, and a journal on oral history. These resources, along with many others, have moved oral history research from the periphery into mainstream research.

ORAL HISTORY REVIEW (JOURNAL)

The *Oral History Review* is the official publication of the Oral History Association. The Oral History Association (OHA) commenced activities in 1966, but it did not establish its journal until 1973. Prior to establishing the *Oral History Review*, the association published proceedings of its first seven meetings.

With the growing determination for scholars to work from the ground up perpetuated by the Annales

School of inquiry and accordingly eschewing traditional documentary history, the OHA widened its scope. In the process, it welcomed not only academics to the fold, but also archivists, librarians, students, journalists, teachers, and personal historians not only to the OHA, but also to the *Oral History Review*, a benefit of membership. Academic subscribers are by no means exclusively historians; anthropologists, folklorists, communication specialists, political scientists, sociologists, and many other fields benefit from membership and find publishing opportunities.

The *Oral History Review* explores a multiplicity of issues. Although many articles discuss scholars' ongoing projects interviewing eyewitnesses to or participants in past events, other articles have dealt with theories of oral history, memory, and methodologies. Still other articles have discussed the recording process, transcription, authorization, and authority as related to the human memory.

In addition to articles, not only by professional academics, but also by students and personal historians, the *Oral History Review* includes book reviews and media reviews. The intent is to provide the widest forum possible for exploring issues, providing guidance, and sharing experiences. The *Oral History Review* intends to be the journal of record not only for the OHA, but also for the discipline of oral history within the United States and, accordingly, seeks to present the finest work being done in the field. Its issues help to shape and to direct the scholarship and lead the discussion of the oral history community not only in the United States, but also throughout the English-speaking world.

Initially self-published, the journal has in recent years been professionally produced by university presses. Its biannual issues (March and September) generally include three or four peer-reviewed, double-blinded articles, as well as a selection of book and media reviews. Its subscription list is an international one as are its articles and reviews. Currently, approximately half of its subscribers are institutional.

ORIENTATIONAL PERSPECTIVE

One commonly asserted strength of qualitative inquiry is the inductive, naturalistic strategy of approaching a setting without predetermined hypotheses. Understanding and theory emerge from fieldwork experiences and are grounded in the data. An orientational perspective, in contrast, eschews any pretense of open-mindedness in the search for grounded or emergent theory. Orientational qualitative inquiry begins with an explicit theoretical or ideological perspective that determines what conceptual framework will direct fieldwork and the interpretation of findings. For example, one can undertake a study from a feminist perspective, a Marxist perspective, a capitalist perspective, or a Freudian perspective, among others. In these instances, the ideological orientation or perspective of the researcher determines the focus of inquiry. This entry describes several examples of an orientational perspective and how such frameworks operate in qualitative research.

Examples of Orientational Perspectives

The concepts and conceptual frameworks one uses, whether unconsciously as a matter of tradition and training or intentionally as a matter of choice, carry embedded messages about what and who is important. A feminist perspective, for example, presumes the importance of gender in human relationships and societal processes and orients the study in that direction. The orientation of feminist inquiry can include working toward a sense of connectedness and equality between researcher and researched—explicitly acknowledging and valuing women’s ways of knowing so as to integrate reason, emotion, intuition, experience, and analytic thought—and using qualitative inquiry to support change, especially generating findings about women that will contribute to their liberation and empowerment. In essence, a feminist orientation uses the lens of gender inequality to shape the inquiry.

Feminist inquiry challenges the phenomenological notion that one can cleanse oneself of such fundamental language-based conceptions when doing fieldwork and data analysis. Moreover, feminist inquiry provides not only conceptual and analytical direction, but also methodological orientation in emphasizing participatory, collaborative, change-oriented, and empowering forms of inquiry.

A quite different theoretical framing for inquiry would be a Freudian orientation, which assumes that

individual behavior must be understood as a manifestation of the struggle between id, ego, and superego as influenced by very early childhood relationships and sexual experiences that have left their mark on the unconscious.

Racism can be another defining lens—or orientation—for qualitative inquiry in research and evaluation; from this perspective, racial issues are a defining characteristic of societal interactions and an essential framework for making sense of human interactions and patterns that differentiate important aspects of the lives of people with different racial or ethnic backgrounds. Queer theory, an orientational perspective focused on sexual orientation, combines social constructionist insights with a critique of cultural inhibitions about lesbian, gay, bisexual, and transgender experiences. Empowerment evaluation uses the inquiry to build the capacity of those studied to tell and to conduct their own stories; the inquiry is oriented toward empowerment of those involved.

In each of these distinct and different orientational examples—feminism, racism, queer theory, and empowerment evaluation—the qualitative researcher begins with presumptions about what the important factors are in the setting to be studied. The question is not whether gender, race, sexual orientation, or disempowerment is an issue or factor; that is presumed. The question is how issues of gender, race, sexual orientation, or disempowerment are manifest in the setting under study—and the implications of those manifestations for the lives of those who are the focus of the inquiry. Orientations can be combined, as in a feminist psychoanalytical framework.

One of the most influential orientational frameworks is critical theory, with its attention to how injustice and oppression shape people’s perceptions and experiences. Critical theory is oriented to issues of power and social justice, including economic, racial, gender, and social inequalities. In a qualitative inquiry oriented by critical theory concerns, whether the focus of the study be on culture, education, religion, politics, family, or whatever, the inquiry will address injustice at some level and in some way. Thus, what gives critical theory its name—what makes it critical—is that it seeks not just to study and understand society, but rather to critique and change society. Influenced by Marxism, informed by the presumption of the centrality of class conflict in understanding community and societal structures, and updated in the radical struggles of the 1960s, critical theory provides a framework—both philosophy and methods—for approaching research and evaluation as

fundamentally and explicitly political and as change-oriented forms of engagement.

Definition and Purpose of Orientational Qualitative Inquiry

Qualitative research can be conducted within any of these theoretical or ideological orientations, but the focus of inquiry is determined by the framework the researcher chooses to use. Research findings are interpreted and given meaning from the perspective of that theory. Such qualitative inquiry, therefore, aims to describe and explain specific manifestations of general patterns that are assumed. Thus, the goal is confirmation and elucidation of factors (such as race, gender, inequality, power) that have already been identified as central, rather than discovery of new key factors. The term *orientational* is used to describe such studies because they are oriented in a particular direction or framed from a specific perspective. Orientational is a more neutral and descriptive term than *ideologically based* inquiry.

The extent to which any particular study is orientational is a matter of degree. Ethnographic studies can be viewed as orientational to the extent that they presume the centrality of culture in explaining human experience. Critical ethnography combines a focus on culture with commitment to use findings for change. Symbolic interactionism is orientational in that it focuses on the importance of the meanings that emerge as people define situations through interpersonal interactions. Orientational qualitative inquiry is a legitimate and an important approach to theoretical or ideological elaboration, confirmation, and elucidation. In doing such work, researchers must be very clear about the theoretical framework being used and the implications of that perspective on study focus, data collection, fieldwork, and analysis.

OTHERNESS

Otherness is the condition or quality of being different or “other,” particularly if the differences in question are strange, bizarre, or exotic. Otherness has emerged as a widely discussed mental construct of pragmatic significance in the humanities and social sciences over the last 3 decades. Dialogues on rethinking sociality, for example, have seriously considered otherness and related concepts such as intersubjectivity and recognition in the contexts of social relations, social problems, and social organizations. Definitions of otherness and its functions, utility, and sociopolitical impact have been explored rather widely; robust and quickly growing bodies of literature on otherness are situated in philosophy, psychoanalysis, Jewish and African American studies, and psychology, as well as in sociology and anthropology where the concept is more established.

Functionalist, phenomenological, conflict, and interactionist theoretical orientations have been employed in symmetry with an equally diverse range of quantitative and qualitative research strategies in the study of the topic. Otherness-oriented research foci include the cultural context of identity, social stratification, and moral order development and maintenance. Specific examples include ethnic reflexivity in cultural definition (i.e., the role of other as a reference and contrast point relative to sameness), cultural system artifacts (e.g., beliefs, art, morals, law, behaviors, and customs), race and ethnic relations, and a plethora of social justice issues (e.g., racial profiling, same-sex marriage, homelessness, polygamy, and especially immigration policy).

Whereas the bulk of the extant literature on otherness originates from European philosophy that focuses on abstract topics such as the dimensions of otherness and the search for a phenomenology of othering, the concept has been particularly consequential to the development of (a) cultural studies in both anthropology and sociology; (b) the evolution of subjective philosophies of science and qualitative inquiry, generally, and ethnography, specifically; and (c) deviance and social control (i.e., criminology and criminal justice).

Key works in cultural and social anthropology, such as *Argonauts of the Western Pacific* (1922/2002) by Bronislaw Malinowski and *Coming of Age in Samoa: Study of Primitive Youth for Western Civilisation* (1928/2001) by Margaret Mead, shaped and solidified the scientific utility of other in contextualizing group awareness and sense of belonging.

These confessional and reflexive ethnographies translated cultural differences by contrasting the cultural indicators of otherness (e.g., language, gender, familial and social relations, religious beliefs, and designations of taboo and deviance) with ideations of sameness—a benchmark set by the researchers' own cultural backgrounds and realities.

Urban sociology and the Chicago School also embraced an ethnographic fieldwork orientation to otherness. From constructivist and relativist paradigms, the highly stratified nature of American society and its innate disenfranchised segment served as a ready venue for descriptive portrayals of the other in famous works such as Gary Alan Fine's *Shared Fantasy: Role Playing Games as Social Worlds*.

Although early ethnographies explored and detailed the historical and regionally specific context of cultural identity, otherness has been instrumental in contemporary works on ethnic communities as transforming cultural products, as opposed to the natural and primordial characterizations described in early anthropological portrayals of, often tribal, underdeveloped, and remote, societies. The age of political correctness has ushered in a collective consciousness, a part of which involves placing a premium on respect for diversity. Accordingly, many works have appeared that center on affirmation of group identity in advocacy of maintaining otherness. The processes of shaping, masking, and unmasking stigmatized identity, via a constructionist or deconstructionist approach and using case study or participant observation symmetries, have resulted in various topics being explored; topics range from Japan-residing Koreans to the devaluation of farmers in the United States.

Although otherness has certainly affected multiple academic disciplines, it is perhaps in the once sociological subfield of criminology (emergent recently as an independent field of study) that the concept is most central to mainstream theory and related social policy and practitioner outcomes. Rational choice and deterrence theories, for example, are directly traceable to the social thought of Émile Durkheim on social order that was predicated on the seemingly illogical notion that crime is not only beneficial to society, but necessary. Through identification of deviance (and crime as extreme deviance) as a reference point for socially detrimental and undesirable behavior, Durkheim used such otherness to illustrate how the majority was dependent on labeling negative others so as to establish moral order and stave off chaos. Today, the criminal law utilizes the other toward affirmation of moral boundaries and the

criminal justice system serves the function of moral boundary maintenance.

Whereas rational choice theories of crime (i.e., classical criminology) have relied on an otherness–sameness continuum to invoke normative consensus as a theoretical reference point of departure, otherness has been most pronounced in conflict criminology. The conflict perspective (also known as critical or Marxist criminology) is traceable to the works of Frank Tannenbaum (1938), Edwin Lemert (1951), and Howard Becker (1963) who first proposed that criminal behavior was attributable to the process of labeling. Labeling contends that the very act of criminalization is itself an arbitrary label given to certain types of behavior (e.g., vagrancy, lewdness). The upheaval during the civil rights and Vietnam War era in the United States and disenchantment with society's traditions and customs revolved around challenges to formal authority and sameness. Social justice-oriented works of the day took issue with formal mechanisms rooted in the other. William Chambliss's famous "The Saints and the Roughnecks" illustrated the dissimilar treatment of affluent and working-class youth groups by police and school officials.

Otherness has been equally consequential to social learning and cultural transmission theories of crime. Subcultures, countercultures, and contracultures are defined in terms of variance from sameness, and numerous theories contending their criminogenic nature have been concerned with depicting elements and properties of the collective other. In *Delinquent Boys: The Culture of the Gang* (1955), Albert K. Cohen popularized the term *middle-class measuring rod*—a reference point of acceptable academic and social performance by which others in lower social classes might be compared and discussed. More pointedly, Walter B. Miller (1958) introduced *focal concerns*—a simplistic and primal set of values held by the lower class (e.g., trouble, toughness, excitement, and fate) that lead to crime and other social problems as compared to middle- and upperclass values leading to conventional behavior and upward mobility.

Beyond criminology, it remains unseen how otherness and its ramifications will be affected by modern technology and the quickly changing nature of contemporary society. Conventional views generally express a breakdown of the other attributable to virtual and electronic communication that serves to break down stereotypes based on regional, religious, and ethnic differences previously upheld by distance, isolation and homogeneity. Alternatively, social

forces, while certain to modify social relations toward more holistic and broader networks, may act to maintain otherness through a reaffirming solidification of the core (i.e., a reinvestment of sameness).

OVER-RAPPORT

Over-rapport refers to the potential of the researcher to become over-engaged and too familiar with research participants. This situation can lead to a loss of distance and perspective that may impact detrimentally on the process of research. The term *over-rapport* is particularly associated with ethnography in which participant observation is usually employed as a research method in order to study groups and cultures. Over-rapport frequently involves the enculturation of the researcher within a social group that is the object of her or his study and thus loss of her or his capacity to see and note the social processes and interactions with the fresh eyes of an outsider.

Over-rapport is a particular problem within ethnography, where researchers may spend long periods in close contact with the groups that are the focus of fieldwork, perhaps living and working within the group. The

prolonged immersion within the social context being studied in order to explore behaviors and meanings, may lead to a loss of objectivity, sometimes referred to as “going native,” involving the adoption of the values, customs, and practices of the group. An example of the way in which over-rapport might be demonstrated includes identification with participants and the introduction of value judgments about their behavior, perhaps uncritically praising their achievements in the report of the research. Another example might be the over-representation of one subgroup to the detriment or absence of another, where the researcher has become over-familiar with just a few of the participants within the field. More extreme examples include the conduct of a romantic or sexual relationship with one or more research participants, or even marriage between the primary investigator and a research participant.

More recently, with a postmodern take on ethnography, the notions of objectivity and distance from what one is studying have been challenged, with the consequence that a concept such as over-rapport becomes problematic, suggesting as it does that there is an ideal relationship or distance that as an investigator one should maintain with one's research participants. The introduction of postmodern perspectives results in interest in the cultural practices through which the product of the research process is rendered as an ethnographic text. Thus, the form as well as the content of ethnographic writing is open to interrogation and scrutiny. One way in which this challenge has been addressed is to reflexively write oneself into the research, acknowledging one's subjectivity, and the relationships and power dynamics existing between the researcher and those being researched.

P

PARADIGM

A paradigm is a set of assumptions and perceptual orientations shared by members of a research community. Paradigms determine how members of research communities view both the phenomena their particular community studies and the research methods that should be employed to study those phenomena.

The paradigm construct was initially developed to make sense of phenomena in the physical sciences. During the last quarter of the 20th century, however, social scientists appropriated the construct to account for the growing interest in and acceptance of qualitative research methods in a number of social science fields that previously had defined research in quantitative (and often in experimental-design) terms. More recently the meaning of the term has expanded, and the term has become part of popular culture. This entry reviews the history and evolution of the paradigm construct and concludes with a look at the concept of research purposes as an alternative.

Paradigms in the Physical Sciences

The paradigm construct was initially developed and popularized by physical science historian Thomas Kuhn in his book, *The Structure of Scientific Revolutions*. Kuhn employed the construct to make sense of a phenomenon that he and other historians had noticed when they studied the process of conceptual change within the physical sciences: Fundamental changes in thinking within a scientific discipline—the shift from Newton's to Einstein's version of

physics, for instance—did not occur incrementally and were not merely modifications that resulted from what Kuhn called *normal science*, that is, day-to-day scientific experimentation and other procedures associated with what traditionally has been called *the scientific method*. Rather, they reflected radical shifts in perspective—or, in Kuhn's words, *paradigm revolutions*—that were triggered by problems that could not be resolved either by the field's standard operating research procedures or by its established ways of thinking.

Kuhn compared paradigm revolutions to the holistic shifts in perspective demonstrated by gestalt psychologists when they used pictures that people could see in two quite different ways, for example, as a bird and an antelope. Kuhn quickly added a caveat to this comparison, however: Although most people can learn to shift their points of view and see the gestalt psychologists' picture in one way at one moment and in the next moment, as something quite different (they can learn to see both a bird and an antelope in the picture alluded to above, for example, though of course not simultaneously), scientists who have been socialized to accept a particular paradigmatic perspective assume that what they see is reality rather than merely a perspective of reality. Consequently, according to Kuhn, when a new paradigm becomes accepted by members of a scientific community, that community will have rejected older ways of thinking and doing research and embraced new research methods, fundamentally different perceptions of the physical phenomena that members of the field studied, and radically different views of the field itself.

Kuhn's Construct in the Social Sciences

In the 1970s, qualitative research methods began gaining a foothold in certain social science fields that previously had defined research almost exclusively in quantitative terms. For some 20th-century qualitative researchers such as Matthew Miles and Michael Huberman, the growing acceptance of qualitative methods represented nothing more than the addition of new and somewhat unique research techniques to social scientists' methodological arsenal. For others such as Egon Guba and Yvonna Lincoln, however, the growing acceptance of qualitative procedures signaled a revolution that was more-or-less equivalent to the paradigm revolutions Kuhn had discussed in a physical science context.

Indeed, for Lincoln and Guba—and others who followed their intellectual lead including, but certainly not limited to, Guba's students Patti Lather and Thomas Schwandt and Lincoln's later collaborator Norman Denzin—the growing acceptance of qualitative methods in some social science fields signaled that at least some people within the social sciences were embracing a radically different view of knowledge and knowing (i.e., a different epistemology), as well as a new and different view of reality (i.e., a new ontology). (Lincoln and Guba also talked about a new view of ethics—i.e., a new axiology—but the axiology notion was never as extensively developed or as widely embraced as the epistemological and ontological notions.)

According to the new perspective touted by Lincoln and Guba and others (including qualitative research methods textbook authors such as Michael Quinn Patton), knowledge is constructed, not discovered. Furthermore, because people live and work in different places and consequently construct reality in very different ways, the world consists of multiple realities rather than a single, unitary reality.

It follows, then, that social scientists' task is not to discover what is true—for from this new perspective, there is no single, absolute truth to discover—but to describe, as accurately as possible, how different people in different contexts have constructed reality and what these people take to be true. This means that case study design and qualitative methods are the procedures of choice if one wants to do research that is consistent with the new view of knowledge and reality Lincoln and Guba articulated.

Initially, Lincoln and Guba called their new view of knowledge, reality, and research the *naturalistic*

paradigm; later, they renamed it the *constructivist paradigm*. The older, more traditional view was dubbed the *positivist paradigm*.

In time, Lincoln and Guba also added a third paradigm to the list of perspectives that they saw as operative within social science fields. They labeled this third perspective the *critical theory paradigm*. The critical theory paradigm, as Lincoln and Guba portrayed it, at least, actually was a kind of metaparadigm because it encompassed a number of other paradigms including (but not limited to) the neo-Marxist, feminist, participatory, poststructuralist, and postmodern paradigms.

Incommensurability and the Paradigm Wars

Like Kuhn, Lincoln and Guba assumed that paradigms were incommensurable. One cannot embrace both the positivist and the naturalistic-constructivist paradigm, Lincoln and Guba argued; rather, one must choose sides and embrace only one paradigmatic perspective.

Not surprisingly, the emphasis on choosing sides had a significant impact on the nature of discourse within a number of social science fields, including the field of educational research where Lincoln and Guba's paradigm talk was especially influential. One prominent member of the educational research field, N. L. Gage, coined the term *paradigm wars* to characterize the adversarial character of the methodological debates that were occurring within the field during the final quarter of the 20th century.

In time, open warfare gave way to what Robert Donmoyer has referred to as an era of *big-tent politics*. During this era, a place was made at the research community's table for people with a variety of paradigmatic proclivities and methodological preferences. This acceptance was shown in a number of ways. New journals were established, for instance, and new formats that were compatible with a constructivist view of knowledge were added to the list of possible session formats at research conferences.

The big-tent strategy minimized conflict within the field, but it also promoted balkanization: Like-minded people tended to read each other's work, but they almost never read or conversed with those who saw research—and the world in general—differently than they did.

One unfortunate consequence of this balkanization became evident within the educational research field in recent years when traditionalists finally began to

challenge much of the more radical thinking and research procedures associated with the qualitative revolution that had occurred during the final quarter of the 20th century. A committee of traditional researchers set up by the National Research Council (the research arm of the National Academies of Science in the United States) to define what constituted *scientific* (and by implication, fundable) research in education, for instance, either dismissed, misinterpreted, or—as was mostly the case—simply ignored the thinking of all but the most traditional qualitative researchers. Indeed, arguably the most noteworthy part of the bibliography of the committee's report, *Scientific Research in Education*, was what was not included in it. The lack of representation of key bodies of seemingly relevant literature is a testament to the impact of big-tent politics and the balkanization this strategy produced.

Ironically, Kuhn, himself, signaled unequivocally in the second edition of *The Structure of Scientific Revolutions* that he never meant to imply that incommensurability was synonymous with logical incompatibility. It is impossible to view the world from incommensurable perspectives at any given moment, of course, just as it is impossible to see an antelope while one is seeing a bird in one of the gestalt psychologists' purposely ambiguous pictures. But one can shift one's point of view and view the world—and the process of research—from a variety of paradigmatic points of view.

To be sure, Kuhn did indicate that physical scientists who have been socialized to accept a particular paradigm are not inclined to employ different paradigmatic perspectives to view either the physical world or their work. In the second edition of his book, however, Kuhn clarified that this description of what normally happens (and what may be highly functional) in physical science disciplines is not inevitable. It certainly is not a prescription for what ought to happen in all fields.

The Paradigm Concept Redefined

A number of scholars, in fact, have argued that certain social science fields actually require that multiple paradigms be operative in the field at any given time (though not, necessarily, in a single study). Their argument is that the problems and phenomena focused on in certain fields are so complex that they can be addressed adequately only if they are viewed and researched from a variety of paradigmatic perspectives.

Gage (who developed the paradigm-wars notion mentioned above) and Lee Shulman, for instance, both have articulated variations of the above argument in discussing what is required to study and ultimately understand the phenomenon of teaching. Of course, both scholars also redefined the paradigm concept in the process of articulating their positions. Gage, for instance, suggested that the term *paradigm* is nothing more than a synonym for models, patterns, and schemata, while Shulman viewed different paradigms simply as the different programs of research in which different researchers are engaged. Shulman, in fact, explicitly acknowledged that he was using a “weaker” meaning of paradigm than Kuhn (and, of course, also Lincoln and Guba) employed.

There is at least one other significant difference between Shulman and Gage's weaker definition of *paradigm*, on the one hand, and Kuhn's definition, on the other: Although Kuhn seems to suggest that different paradigms are likely to conflict, Shulman and Gage's weaker conception assumes that different paradigms will be complementary. Shulman, for instance, compared the findings emerging from studies generated from different research paradigms to different pieces of a puzzle; the assumption is that the pieces provided by different paradigms will easily fit together and that, once this is done, a coherent picture of the phenomenon will emerge.

Assuming a priori that different paradigms will produce complementary findings ultimately is rooted in a naïve faith in the power of empirical data. This faith in empiricism ignores the facts (a) that the meaning of empirical data is shaped by the a priori language that researchers employ to frame their research questions and studies, (b) that different researchers often frame their work in radically different ways, and (c) that these different frames can reflect quite different and even at times contradictory purposes.

One consequence of assuming that researchers' findings will always be complementary is that researchers who make this assumption can easily overlook honest to goodness incommensurability. Gage, for instance, argued that there is no conflict between the quantitative, experimental paradigm he embraced and the paradigm that qualitative researchers adhere to because qualitative research can be employed to identify intervening variables in the cause-and-effect generalizations that he and his colleagues were attempting to generate. Although it is certainly the case that qualitative procedures can play this role, Gage's belief in

the complementary nature of paradigms led him to overlook—or at least cavalierly discount—the fact that many qualitative researchers disavowed the search for cause–effect generalizations and in some cases the entire notion of causation in the social world.

Thus, those who employ the weaker definition of paradigm exhibit a problem that is, in essence, the opposite of the problem exhibited by those who assume that incommensurability is a synonym for logical incompatibility. Although the latter group of scholars tends to overestimate the significance and implications of paradigm differences (and as a consequence encourages balkanization within research communities), those who assume a priori that the knowledge generated from different paradigms will be complementary ignore—or at least obscure—the fact that there may, indeed, be fundamental differences within research communities.

Paradigm Proliferation

In recent years, at least two noteworthy movements have occurred with respect to the paradigm construct. The first movement involved the proliferation of paradigms within the social sciences. As noted, Lincoln and Guba initially identified two paradigms and later added a third. The third paradigm, however, was actually a metaparadigm that supposedly encompassed a variety of different paradigms.

This proliferation of paradigms expanded even further when a number of scholars began equating the paradigm notion with ethnicity and the life experiences of different social groups. Certain African American scholars such as John Stanfield and Cynthia Dillard, for example, began to write about a unique Afro-centric epistemology that was a product of the unique African–American experience.

Of course, not all members of a particular ethnic group have the same sets of experiences. Gender, for example, undoubtedly influences life experience at least as much as ethnicity, so consequently, once researchers equate the notion of paradigm with the notion of life experience, it would seem as if researchers cannot merely talk about, say, a Latino paradigm; they must also talk about a Latina paradigm. But all Latinas are not the same. There are rich Latinas, middle-class Latinas, and poor Latinas. And of course, there are gay Latinos, lesbian Latinas, and undoubtedly, even transgender Latinos. All of these factors contribute to a person's life experiences and consequently

all have been associated with unique ways of knowing and, by implication, distinct paradigms.

Indeed, since all individuals' life experiences are at least to some degree idiosyncratic, the logical end point of equating the paradigm notion with life experience would seem to be that people will all, sooner or later, be seen as operating out of their own unique paradigms. And to the extent that assumptions about incommensurability and logical incompatibility are still operative when this happens, people will, in effect, have embraced a radical form of solipsism and have created a much more extreme version of balkanization than was ever operative in the past.

The Paradigm Construct in Popular Culture

Although the proliferation of paradigms was occurring in the academy, a somewhat related movement was playing itself out beyond the academy's doors: Popular culture began appropriating the paradigm notion.

The business world, for instance, discovered the construct. In an April 1999 article by Hal Espen in *The New York Times*, for example, a Levi Strauss executive is quoted as saying that the public's growing preference for loose rather than tight-fitting blue jeans was not a fad; rather it was, in his words, a paradigm shift. In an October 2007 article in the same newspaper, Mark Bittman talked about the old paradigm of macaroni and spaghetti being replaced by a new pasta paradigm.

Politicians, too, have begun to talk about the need for a new paradigm. One U.S. Senator, for example, talked in a public television documentary about the need for a paradigm shift in the way the country thought of workforce development. The senator suggested that, in the past, workforce development was seen as the responsibility of one level of government; with the new perspective—or, to use the senator's language, the new paradigm—workforce development would be a shared responsibility of a federal, state, and local partnership.

In the process of employing the paradigm notion, popular culture has put its own spin on Kuhn's construct. When used in politics and business, for instance, the term tends to serve a marketing or public relations function: The term can add heft and gravity to the most mundane matters, for a new paradigm does, indeed, seem to have far more significance than a new perspective. Furthermore, in a modernist culture that uncritically assumes that progress is good, talk of a new paradigm can suggest—in lieu of thoughtful

arguments and convincing evidence—that new ideas and/or new ways of doing business are not only radically different from older ideas and procedures, but also that they are significantly better.

Given the term's public relations cachet, it is hardly surprising that popular culture has embraced the paradigm notion. It seems likely that this cachet also is behind at least some of the paradigm proliferation that has occurred within the academy in recent years.

An Emerging Alternative to Paradigm Talk

In part because of the proliferation of paradigms, both within the academy and in popular culture, some scholars have suggested that the paradigm construct has lost its meaning and is no longer useful for making sense of social scientists' different research orientations. One alternative that has been proposed was inspired by Jurgen Habermas's writings about the role of interest and purpose in human understanding.

The author of a classification scheme of qualitative research approaches that is based on researchers' differing, overarching purposes argues that purpose-talk has a number of advantages over the paradigm-talk that has been employed in the past. He argues, for example, that talk of differing purposes does not assume a priori that different research orientations are so incommensurable that researchers guided by one purpose cannot understand and learn from the work of those guided by a radically different purpose. He also notes that purpose talk opens the door for mixing orientations when appropriate. After all, in some situations, a person can legitimately attempt to accomplish a number of quite different purposes. Policymaking (and, consequently, policy research) for example, often requires finding ways to accommodate and balance even antithetical points of view.

It is not clear, at this point, whether purpose-talk will replace talk of different, incommensurable paradigms. What is clear, however, is that a number of quite different meanings have become associated with the paradigm construct, so those who read or hear the term need to attend to the particular way a particular author or speaker is using Kuhn's construct.

PARA-ETHNOGRAPHY

The concept of *para-ethnography* was formulated to address the challenges of pursuing anthropological ethnography within new contexts of fieldwork, notably, though not exclusively, in settings dominated by scientific knowledge and/or a technocratic ethos. The concept refers to wide-ranging experiments in ethnographic method currently underway in the early 21st century in the domains of science, engineering, finance, law, medicine, politics, government, design, art, and architecture. These experiments speak to a particular problem: How do we pursue our inquiry when our subjects are themselves engaged in intellectual labors that resemble approximately or are entirely indistinguishable from our own methodological practices? Para-ethnography answers this question by proposing an analytical relationship in which we and our subjects—keenly reflexive subjects—can experiment collaboratively with the conventions of ethnographic inquiry. This methodological stance demands that we treat our subjects as epistemic partners who are not merely informing our research but who participate in shaping its theoretical agendas and its methodological exigencies. By treating our subjects as collaborators, as epistemic partners, our analytical interests and theirs can be pursued simultaneously, and we can share insights and thus develop a common analytical exchange. Crucially, we can pursue

this kind of collaboration even if the ultimate aims of our analyses are different, if not radically opposed.

Para-ethnography is, on the one hand, premised on the central intellectual imperative of classical anthropological ethnography, notably as espoused by Bronislaw Malinowski, to evoke and to reproduce the native point of view. On the other hand, it is predicated on relationships of complicity with our subjects—a state of ambiguity and improper seeming alliance—that now pervade ethnographic encounters establishing new possibilities for creating anthropological knowledge.

Para-ethnography is a concept that is very much in the making, yet it has already yielded a series of important insights on the changing nature and shifting contingencies of anthropological fieldwork. Five of these orienting insights are noted very briefly below.

1. The para-ethnographic is a self-conscious critical faculty operating in diverse domains as a way of dealing with contradictions, exceptions, and facts that are fugitive, suggesting a social realm and social processes not in alignment with conventional representations and reigning modes of knowledge and analysis. The para-ethnographic operates as a kind of social thought—expressed in genres such as the anecdotal, hype, and intuition—within institutions dominated by a technocratic ethos, an ethos that, under changed contemporary circumstances, simply does not discipline thought and action as efficiently as it once did. Making ethnography from these found para-ethnographic narratives redefines the status of the subject or informant and asks what different accounts one wants from such key figures in the fieldwork process.

2. If the opening gambit of the ethnography is an orienting foray into a strategically selected culture of expertise, then that milieu of fieldwork cannot be treated conventionally or traditionally. Experts are to be treated not as colleagues helping to inform fieldwork to occur elsewhere but instead as subjects fully within our own analytical ambit whose cognitive purview and social action range potentially over multiple, if not countless, sites and locales. Nor can they be treated as conventional natives or tokens of their cultures to be systematically understood; instead, they must be treated as agents who actively participate in shaping emergent social realms. These subjects must be treated like partners in research, a fiction to be sustained more or less strongly around the key concept of para-ethnography. This concept is distinctly not about an ethnography of elite cultures; rather, it is about

access to an imaginary for fieldwork that can be shaped only by alliances with makers of visionary knowledge who are already in the scene of fieldwork. The imaginaries of these knowledge makers who have preceded the ethnographer are what the dreams of contemporary fieldwork are made of.

3. The para-ethnographer is typically an expert subject, for example, a scientist, who is perplexed by the significance of his or her own professional practices and who, in the shadow of his or her formal knowledge work, creates intricate cultural narratives that might never be fully voiced but nonetheless mimic the form and the content of an ethnographic engagement with the world. Various fragmentary discourses are continuously spun off from this kind of knowledge work that connects formal scientific inquiry to the existential condition of the scientist cum para-ethnographer. Ethical and moral apprehensions as well as political and commercial preoccupations, although typically not fully articulated, nonetheless circulate in complex relationship to formal scientific practices, thereby constituting the ecologies of discourse that create the field or ground in which strategies and designs of anthropological research take form. In effect, every project of ethnography enters sites of fieldwork through a zone of collateral counterpart knowledge that it cannot ignore in finding its way to the preferred scenes of ordinary everyday life with which it is traditionally comfortable. The fundamental problem here is in confronting the politics of knowledge that any project of fieldwork involves and the ethnographer's efforts to make this politics of knowledge itself part of the design of investigation.

4. The questions, motives, and purposes that project anthropologists into fieldwork are thus not simply those raised within the discipline of anthropology or posed by the contextualizing social theories or historical narratives of contiguous academic specializations; rather, they arise from orienting engagements with counterparts and actors already defined within the field of ethnographic inquiry.

5. Under the conditions we are stipulating, where meaning is fugitive and social facts are elusive, distinct dilemmas are created for the individual. Cultural innovations continually destabilize social consensus, posing acute struggles for the perplexed subject—struggles that gain expression through various manifestations of the para-ethnographic. We are interested in how these narratives become linked together—through networks

of interlocutors—conferring a distinctive social character on, for the most part, technical knowledge allowing expertise to be juxtaposed in ways that render them acutely relevant to a broad range of anthropological questions.

For example, biotech startup companies are infused with shifting stories in which science is relentlessly narrated in relationship to the requirements of finance and a future in which scientists and financial backers have a stake. The optimism of science is continually mediated by the anxieties associated with commercial risk. For the scientists, who themselves are also typically investors in these startups, these risks often have a deeply personal character. Their stories—their para-ethnographic narratives—are not merely about professional reputation, career possibilities, or shareholder equity, but also about the fate of their children's education, their retirement savings, their mortgages, and their marriages. And of course, these stories premised on yet unpatented or fully tested drugs or other devices to relieve human afflictions and prolong life are addressed to a particular community of sufferers—the market—and to the public at large. Again, these discourses continually move among personal, professional, commercial, financial, scientific, ethical, and political domains of meaning and significance framing consciousness and sub-consciousness of our time.

Para-ethnography is thus not merely a matter of identifying a new ethnographic subject—an accomplished autodidact; rather, it opens far deeper questions of how culture is manifest in the contemporary. What is at stake in the para-ethnography are analytical engagements with formations of culture that are not fully contingent on convention, tradition, and the past, but rather, constitute future-oriented cognitive practices that can generate novel configurations of meaning and action. Indeed, this ability gives rise to a radical assertion—spontaneously generated para-ethnographies are built into the structure of the contemporary; they mediate intellectually the shifting form and content of a continuously unfolding skein of experience.

Para-ethnography allows anthropologists, sociologists and others who employ various ethnographic and qualitative approaches to examine the shifting conditions of their intellectual practices. Like ethnography in general, para-ethnography provides little in the way of practical knowledge of how, for example, to deal

with ethics review committees, funding agencies, or journal editors. Rather it provides a framework for experiment at a time when social and cultural phenomena are unstable and conventional analytical tools are of limited, if any, value. It speaks to the novice ethnographer who discovers that the conditions of fieldwork are rich with new possibilities, but finds little in the way of guidance from either classical or critical ethnographic traditions.

PARTICIPANT

Advancing the understanding of human behavior depends heavily on the contributions of research participants. Participants are also referred to as subjects,

respondents, interviewees, focus group members, informants, and so on. Participants contribute data to research in a number of ways, such as through questionnaires, interviews, experiments, personal health records, narratives, focus groups, and direct observation.

Participants are usually considered to be individuals or groups who agree to take part in a research process. The agreement to participate in research bestows obligations on researchers to ensure that participants are treated in a manner that conforms to accepted ethical standards. In other words, participants should receive sufficient information to give free and informed consent prior to taking part in research. This includes information that describes the individual or group invited to participate, who is doing the research (e.g., researcher's name and affiliation), the nature and duration of participation required (e.g., interview, task performance), confidentiality safeguards, and any expected harms (e.g., distress or pain) or benefits (e.g., payment, new knowledge). Additionally, informed consent generally includes a statement that research participants may decline their participation or withdraw participation at any time, without penalty.

Some research participants (e.g., some children and mentally incompetent persons) lack the legal or mental capacity to give informed consent. In such circumstances, an authorized third party such as a parent or guardian should be involved in the informed consent process.

Creating opportunities for informed consent is not always possible or desirable, and this desire is often the case in naturalistic observation. When people know they are being observed, they may alter their behavior as a consequence of awareness that they are being observed, a concept known as reactivity. To avoid reactivity, participants in naturalistic research settings are usually unaware that they are being observed and therefore do not engage in an informed consent process. In these situations, it is incumbent on the researcher to be respectful of their privacy and dignity. For example, a researcher may decide to observe the interactions of consenting adults in a sex club, but it would violate participants' dignity if these adults were to be identified as a result.

Some research methodologies fundamentally transform the traditional relationship of researcher-as-observer and participant-as-observed. For example, in action research the researcher often becomes a resource to the participants who are being studied. It is

the participants (often disadvantaged groups) who will assume significant control over the research process, including the defining of research questions and research designs, in order to achieve their goals. Given the reduced inequality in power relationships between research and participants in action research, the ethical obligations and requirements of informed consent for participants are also much more negotiable and often less clearly defined than in other types of research.

PARTICIPANT OBSERVATION

Participant observation is a method of data collection in which the researcher takes part in everyday activities related to an area of social life in order to study an aspect of that life through the observation of events in their natural contexts. The purpose of participant observation is to gain a deep understanding of a particular topic or situation through the meanings ascribed to it by the individuals who live and experience it. The term was first used by social anthropologist Bronislaw Malinowski in the 1920s, and the approach was further developed by the Chicago School under the leadership of Robert Park and Howard Becker. Participant observation is regarded as being especially appropriate for studying social phenomena about which little is known and where the behavior of interest is not readily available to public view. Through its emphasis on firsthand access to the real world and its meanings it is effective in allowing understanding of the way of life of others.

Participant observation is characterized by emergent design involving a variety of methods including direct observation of human behavior and the physical features of settings, informal interviewing, and document analysis. Researchers adopt roles that have been described by Raymond Gold as varying along a continuum of participation ranging from complete observer

(no participation), through participant-as-observer (more observer than participant) and observer-as-participant (more participant than observer) to complete participant. Data are typically recorded in the form of fieldnotes that, in order for the investigator to remain as unobtrusive as possible, are written up from memory either in secluded areas such as washrooms or at the end of the day. Participant observation usually entails prolonged engagement in the field that allows for gathering more detailed and accurate information. For example, a researcher who observes a setting for several months can identify discrepancies between what people say and what they actually do.

Several methodological problems are associated with participant observation. It is not well suited to the study of large groups or populations. Gaining access to social contexts of interest—in other words, obtaining permission to collect data, establishing credibility, and earning the trust of those being observed—can be very challenging. Personal characteristics such as gender, age, and ethnicity of the investigator can interfere with access. A variety of strategies are used by researchers to overcome access problems, such as choosing a setting to which one already has some relationship through work or personal life, taking on a small task that benefits the group to be observed, and staying in the field long enough for habituation to occur. Finally, it is well known that the presence of an observer will change to at least some extent the context being studied that may threaten the trustworthiness of the data collected.

PARTICIPANTS AS CO-RESEARCHERS

Participants as co-researchers refers to a participatory method of research that situates participants as joint

contributors and investigators to the findings of a research project. This qualitative research approach validates and privileges the experiences of participants, making them experts and therefore co-researchers and collaborators in the process of gathering and interpreting data. In traditional research, the researcher is assumed to be the authority figure who will collect, interpret, and situate the findings while the participant (or “researched”) merely represents the community being investigated. In these situations, the researcher and participant (or organization) have a time-limited relationship that expires when the research project is complete.

This method is an interdisciplinary approach often used in the social sciences, including but not limited to feminist or women’s studies, health communication, sociology, and anthropology. Participant involvement in the research process varies and can be seen as beneficial or problematic.

Benefits of Utilizing Participants as Co-Researchers

Participants as co-researchers is an approach that promotes participant involvement in the research process. Participants have the opportunity to tell their own stories and give an insider perspective to the process of being the object or subject of research. Participants are also able to offer their own interpretation of the researcher’s findings, voicing their opinion in response to the researcher, thereby giving voice to the community or group that is being researched. Together, the researcher and participant work to come to conclusions, engaging in dialogue and offering each other feedback.

Additionally, utilizing participants as co-researchers gives researchers the opportunity to use the experiences and knowledge of participants to learn about and discuss the research. Co-researchers contribute to the research by offering credibility to the findings and credibility to the researcher (within the community or organization). The involvement of an active participant encourages other participants to join the conversation and respond with their own interpretations. This encouragement allows the researcher to take on the role of student, allowing the research process to be a learning event.

The insider status of participants in research projects contributes to the benefit of “insider” status and, more generally, to the information gathered in the study. When

Black Southern Women: Their Lived Realities

In the author's dissertation work, tentatively titled *Black Southern Women: Their Lived Realities*, the participants were invited to share the stories and experiences of their lives growing up and raising families in the rural South. As a former member of the community, the author collaborated with approximately 10 participants, allowing them to be equally invested and equally involved in the process of collecting, writing, interpreting, and editing the stories they wrote. Their involvement began during the early stages of recommending other participants and retelling stories in individual and group settings to ensure adequate information was available. As co-investigators their stories were instrumental in establishing and representing a corporate set of themes and experiences. The author shared her experiences with the participants, and together, they were able to compare and contrast their ideas about the topics of research. Though the co-researchers in this project were not involved in the writing stages, they did have the opportunity to respond to the stories the author wrote, offering their unique perspectives and feedback as participants in the research and characters in the stories.

The resulting research project is a collaboration between the researcher and the researched, including participants as co-researchers.

participants are co-researchers, they share knowledge, access, and responsibility, which offers a perspective that would usually be unavailable to an outside researcher. Additionally, when participants take on a valid role in the research, they are further motivated to cooperate; that prompts others to become active participants as well. When participants are invited to be co-researchers in the process, they become equally invested in the success of the project. Participants become involved in the process of research from the initial inquiries of the investigation to findings and conclusions. Their feedback offers an opportunity to consider the perspective of the people being represented in the research. This method merges the experience of the participants with the research skills of the researcher. Participants as co-researchers transition from a role of being asked questions and being observed, to asking questions and observing. Co-researchers, however, are not necessarily credited as co-authors but rather as collaborators in the writing process.

The original researcher remains individually responsible and accountable for the technical responsibilities

of the research because participants turned co-researchers often are not familiar or comfortable with the concept of fieldnotes, formal interviewing, transcribing, or writing, but they can offer their opinions, observations, and expertise, being involved in varying degrees over the course of the project. The theory development remains the responsibility of the first researcher, who is more familiar with the process of research; co-researchers contribute alternatives to the theory and responses and interpretations of events in their own words.

Challenges of Utilizing Participants as Co-Researchers

In addition to the benefits of utilizing participants as co-researchers, there are also some disadvantages. Although inviting participants as co-researchers allows the researcher the benefit of access and credibility, there is still a risk of misrepresentation. Researchers are likely able to invite only one person or a small group of participants to be co-researchers, a restriction that means that only a limited perspective is being represented or considered in the research while many others remain marginalized. A wider range of co-researchers would offer a wider perspective; however, a large group of co-researchers would make the research itself particularly problematic in that the researcher would then be responsible for equipping a large group of representatives for a research project, a responsibility that would require time and resources that are usually lacking.

Co-researchers as participants as a method of participatory research offers the opportunity for otherwise unidentifiable or unavailable themes and conclusions to be drawn; however, there is also the chance that more observable conclusions will be overlooked. The view of participants as co-researchers is limited to their perspective as insiders, a limitation that means that they may ignore important data that they have grown accustomed to as participants. There are benefits to entering a new environment for the first time, so the researcher must negotiate his or her role as a new participant, a teacher, a learner, and a co-researcher simultaneously.

PARTICIPATORY ACTION RESEARCH (PAR)

Participatory action research (PAR) has its origins in the second half of the 20th century. Traditionally, its genesis has been traced back to work conducted by the social psychologist Kurt Lewin in the 1940s and 1950s, particularly in his development of action research. However, although Lewin's work has been influential, contemporary approaches to PAR have increasingly been shaped by several other intellectual traditions, including Marxism, feminism, post-positivism, and Paulo Freire's approach to principles of adult education. Thus, while action research introduced the notion that academic and professional researchers could legitimately collaborate with individuals and groups while maintaining their integrity as experts, PAR has continuously sought to critique and challenge the researcher–researched relation through its emphasis on the politics of participation in the research process. It is perhaps this single issue that has made PAR one of the most contentious methodologies in social research today and therefore of significant relevance to this encyclopedia. This entry on PAR is organized into three sections: history, themes, and issues in PAR; methodological considerations; and contemporary trajectories and critique.

As discussed above, it is important to note that PAR and other forms of participatory research have been and remain contested terrain. One effect of this

contention is that PAR is used interchangeably, and often loosely, by researchers to denote any one of a range of research methodologies that have participation of subjects as their focus. This practice is reflected in the literature where, for example, there is a significant degree of conceptual slippage over terminology. Thus, it is not unusual to read accounts of action research that are actually discussing PAR; likewise, it is also possible to come across accounts of PAR where participation of individuals or groups in a study is questionable. As such, therefore, there is no definitive or pure model of PAR. Rather, there are versions of PAR across a broad spectrum that emphasize participation in the research process. In this sense, PAR can be thought of as lying at one end of a continuum of participation where individuals or groups have maximum control over all aspects of the research, from conception, design, implementation, data collection, analysis, and reporting of findings to a situation where the subjects of a study are systematically excluded from any involvement or control over the research process.

History, Themes, and Issues

The origins and development of PAR are both complex and difficult to map with any precision. As already noted, this difficulty is not only because the term is used loosely and often interchangeably with concepts such as action research, but also because PAR is itself a blend of a broad range of research approaches and epistemologies that includes participatory research, action research, feminist praxis, critical ethnography, Aboriginal research methodologies, transformative education, critical and eco-pedagogies, and popular education. Despite this blend of traditions, it is possible to outline some general contours and key features that have marked PAR's historical development over the last 50 years.

First, it is clear that the impetus for exploring forms of participatory research—though they were not necessarily named as such—came from the third world in the early 1960s. Inspired by political events such as anticolonial struggles, scholars such as Freire and Orlando Fals-Borda began to focus their attention on how social science research could be used to relocate the everyday experiences and struggles of the poor, oppressed, and marginalized from the periphery to the center of social inquiry. Within this scenario, social research was to be transformed from an

abstract, detached, disinterested, and objective science conducted by outside experts into an emancipatory process centered on what Freire called *conscientization*, where the poor were to become agents of social and political transformation aimed at creating just, peaceful, and democratic societies.

Second, independence from colonial powers invariably led to the emergence of forms of popular education through national literacy campaigns, such as those led by Fidel Castro in Cuba and the Sandinistas in Nicaragua. The aim of these literacy campaigns was not merely to inculcate functional literacy in the populations of the global south, but to foster forms of popular consciousness that were critical, emancipatory, and democratic. The general thrust of these movements, it should be emphasized, was not only radical but revolutionary (i.e., these movements had as their focus societal transformation). These developments have had their counterpart in the countries of the global north. Although not driven by the anticolonial and revolutionary contexts of the south, forms of adult and community education, labor and union programs, transformative education, green and ecology movements, and more recently the emergence of an international network of Indigenous and antiglobalization groups have informed the politics of PAR through their commitment to a communitarian ethics of organization and practice.

A third strand in the development of PAR relates to its action component. As discussed, while the history of action research is connected with the development of PAR, it nevertheless can be distinguished from it in three important ways. First, action research has primarily European and North American origins. Second, it has been principally developed by academic researchers working from universities within the advanced capitalist world of the global north. Third, its ideological orientation has tended to be liberal, focusing on the improvement of professional practices—this is why it has proven to be so popular among researchers working with teachers and other professional groups. However, in recent years, action researchers have also become concerned with issues of social justice that have shaped PAR. Although much action research continues to express its traditionally liberal–professional focus, there are a significant number of action researchers who have attempted to incorporate the radical lessons of both participatory research and popular education within their practice.

Methodological Considerations

Over its relatively short history, PAR has drawn on a wide array of theoretical traditions within the social sciences including sociology, social psychology, neo-Marxism, critical theory, feminist theory, and more recently, postmodernism. Although these theoretical traditions have been important, the emergence and development of PAR has also continued to be informed and shaped by practice in the field. As noted above, such practice has been generated by anticolonial movements, popular and community struggles, transformative adult education initiatives, and more recently, new social movements (e.g., environmentalism, gay and lesbian groups, antiglobalization). One of the defining characteristics of PAR from its beginnings, therefore, has been the centrality of the dialogical relationship between theory and practice. Indeed, the history of PAR is marked by a reliance on forms of knowledge, experience, and understanding generated within the everyday world that have all too often been dismissed as common sense by mainstream social sciences. Three key themes have emerged from this nexus that have defined PAR methodology.

First, PAR has tended to align itself with a nonpositivist approach to social inquiry. This methodological stance has its origins in a critique and rejection of conventional social science research as a form of cultural imperialism. The essence of this critique is that traditional forms of social science research, particularly quantitative methodologies, systematically reproduce power relations that contribute to the domination of subordinate groups within capitalism. In particular, the hierarchical organization of the social sciences, their procedures for data collection and analysis, and rigid adherence to the separation of researcher and subjects in the pursuit of objectivity are seen to produce forms of knowledge that are imbued with relations of exploitation, power, and control. The effect of this critique within PAR has been a tendency to adopt methodologies that favor qualitative or interpretive forms of inquiry that are accessible, comprehensible, and immediately responsive to the needs of groups that use them. Qualitative approaches are also favored on both technical and ideological grounds for the following reasons:

- They provide a more rounded and holistic perspective that produces thick description of complex social processes.
- They are better suited to small-scale, local studies (in this respect they are less susceptible to colonization by outside experts).

- They hold the potential for marginalized groups to have greater access to—and thereby have more of a say over—the research process than do quantitative methodologies.
- Last, used as part of a participatory process, qualitative methodologies also encourage engagement in nascent forms of reflexivity that stimulate local discursive practices and group activities that constitute PAR.

A second theme that has defined PAR is its embracing of the broad spectrum of theoretical frameworks that now go under the label of critical theory. Some of these theoretical frameworks have been alluded to above; they include versions of Marxism and neo-Marxism, feminism, Freirian pedagogy, postcolonial critiques, postmodernism, cultural studies, and critical ethnography. Critical theory has yielded some of PAR's key conceptual practices. For example, Freire's concept of conscientization, Gramsci's notion of hegemony, or the feminist analysis of patriarchy have shaped the character and organization of the PAR process itself.

Third, PAR is committed to a politics of equity and social transformation that many other research traditions would dismiss as ideological. This commitment is evident in several ways. PAR is political in the sense that its core values and practices have emerged from a critique of Western social science methodologies that it views as deeply implicated in the maintenance of social and political order within capitalism. Alternatively, this theme is expressed through its commitment to work with (as opposed to on) subordinate, marginalized, and oppressed groups to improve and empower their position within society. This commitment stems from the recognition that the social is constituted by asymmetrical power relations in the workplace, the family, education, and more broadly, within politics and civil society that systematically generate inequalities between individuals and groups. The recognition that these inequalities are endemic to capitalist societies—particularly in the contemporary neoliberal era—has produced a strong ethical stance that research should focus on issues of social justice. Arising from this ethical stance, PAR has also been equally committed to democratic engagement, transparency and openness, a strong cooperative and communitarian ethos, inclusion, and a steadfast conviction to issues concerned with equity, social justice, and sustainability. These core values have made PAR a particularly flexible methodology, adaptable across a broad range of issues and contexts.

Contemporary Trajectories and Critique

Despite its history of marginalization within the Western social sciences, PAR and other forms of participatory research (e.g., community action research), have in recent years become the focus of increased attention from a wide range of government bodies, international development agencies, NGOs (non-governmental organizations), and private management consultants. However, it is important to understand that the adoption of the concept and practice of participation has been radically recontextualized within the discourses employed by these organizations. For example, one needs only to consult the World Bank's website (www.worldbank.org) to understand how the discursive practices of participation are now being used to exert forms of neoliberal governmentality through quasimethodologies that resemble PAR. It is in this respect that PAR, and other forms of research that employ a participatory process (e.g., management techniques involving a team concept), has been co-opted and reconstituted so that they are distinctly at odds with the emancipatory, indeed revolutionary, principles on which PAR was originally founded. In this context, it is also important to remember the critique that both institutional and critical ethnographers have made of PAR—that power relations between professional researchers and participants are not necessarily equalized or erased through the mere act of participation. Thus, qualitative researchers need to approach studies that claim a participatory methodology cautiously. As noted above, although the fact of participation in a research project may be compatible with Western values of empowerment, liberation, and democracy, it may also be equally bound to technologies of normalization, focused on subjugation, control, and exploitation.

PEER DEBRIEFING

Peer debriefing, also called analytic triangulation, is the process whereby a researcher calls upon a disinterested peer—a peer who is not involved in the research project—to aid in probing the researcher's thinking around all or parts of the research process. This probing includes, but is not limited to, methodology, interpretation, and analysis of data. As such, it is regarded as one of a complement of techniques used to enhance the credibility and trustworthiness of qualitative research through the use of external peers. It is often compared to or paralleled with internal validity in quantitative research. Although there is no prescribed set of procedures in peer debriefing, a primary aim is a more complete exploration and explication by the researcher of his or her values and interests and how these might come to bear on the conduct, interpretation, and analysis of the research project.

Of primary importance to peer debriefing is the selection of a peer debriefer(s) who is able to meaningfully interrogate the research both substantively and methodologically. For example, it is imperative that a qualitative researcher skillfully negotiate political and ethical concerns that may arise as he or she conducts research. This skill is especially critical to studies that are dependent upon rapport and relationships established with participants in the field. A peer debriefer may help the researcher in considering and weighing alternative responses to sensitive situations and thus potentially refiguring subsequent steps in the emergent methodological design. Alternatively, researchers may find themselves confronted with issues of substance—in defining and considering what is of importance to the study, for example. In such cases, peer debriefers familiar with the area of study may probe the researcher's thought around what is relevant to the study, why it is relevant, and suggest alternatives that might precipitate new insights.

Accordingly, it is important that a peer debriefer has knowledge of the phenomenon under study as well as knowledge of qualitative methodology.

Other important considerations in the selection of a peer debriefer are the degree of trust between researcher and peer debriefer, relations of authority, and concerns related to confidentiality and responsibility regarding protection of research participants. Each consideration influences how much a researcher may be willing or able to reveal and how deeply a peer debriefer is willing to probe.

Peer debriefing may also serve as a process whereby researchers and peer debriefers critically interrogate emerging theories. As researchers begin to make sense of data, peer debriefers may help to clarify interpretations and challenge researcher assumptions contributing to the credibility of the findings, analyses, and conclusions drawn. Further, peer debriefing may serve a therapeutic function. The conduct of research, especially prolonged research, often becomes challenging psychologically and emotionally. Peer debriefers who are able to listen sympathetically may provide an additional measure of soundness to the research.

PEER REVIEW

Peer review, also known as expert review, independent scientific review, or auditing, is a method used by administrators, funding officials, journal editors, and researchers to inform decision making and to improve the research process and outcomes by engaging independent and qualified experts to provide critical and consultative evaluation of the merits of a research project or product, proposal. Depending on its environment, peer reviewing can differ as to its purposes, participants, process, and product. In qualitative

research, peer review may also be used to improve a research proposal or project's trustworthiness.

Higher Education Institutions and Research Organizations

In colleges, universities, and independent research institutions, peer review is often a required internal gatekeeping process through which research proposals must successfully pass before investigators submit proposed research projects to ethics review boards or external funding sources. Points of focus in this internal review include the project's significance and methodological integrity (i.e., does the project have the potential to contribute to the identified body of knowledge or applied or clinical area, is the research question clearly articulated, is the research design appropriate to the question being investigated, are the participants clearly identified, are the methods adequately described and logically cohere, and are ethical concerns identified and addressed?). These internal peer reviews are conducted by faculty members, researchers, and others with the expertise and knowledge to render decisions of quality and to offer improvements. Outcomes include approval for external submission, guidance for a revision and resubmission, or the project's dismissal.

Grant and Trust Funding

Peer review is often the preferred method for judging a proposal's merits and rigor for research funding and for deciding how best to allocate scarce public or private resources. Whether conducted by an individual or by groups sometimes called panel reviews or review committees, peer review for governmental and private foundation and trust funding focuses on the proposed project's significance and methodological integrity. In addition, a peer reviewer is required to give special attention to assessing a researcher's potential to complete the proposed project (e.g., past performance with funded projects, availability of critical resources, and institutional support) and whether or not funds should be allocated to underwrite the proposed activities. Individuals conducting these peer reviews may be selected based upon their published body of work, including a record of successfully securing their own research funding or some other set of criteria demonstrating their expertise in judging the quality of and potential for investigators' success in completing their proposed research projects. Outcomes include the

awarding of funding, a revise and resubmit scenario, or rejection.

Scholarly Publications

Peer review is considered the highest and most rigorous form of editorial review in determining the publication merits of papers, chapters, and books. With scholarly or academic journals, editors and their boards of reviewers (referees) serve as the major gatekeepers for judging what texts are deemed to be of the highest quality and significance and therefore worthy of publication. To ensure the greater independence of the peer reviewing process, some editors also combine peer review with what is called blind review, in which the referees do not know the identities of the authors and the other reviewers and the authors do not know the identities of the reviewers. Journal referees are selected based upon their scholarly record and their content and/or methodological knowledge of the paper or work to be reviewed. Another important function of editorial peer review is the mentoring process through which editors help authors learn how to improve their papers. Outcomes include acceptance of the submission, revisions and resubmissions, or declination of the paper.

Qualitative Research Projects

In qualitative projects, researchers may call upon peers with relevant methodological and content area expertise and experience to scrutinize and critique a study's procedures and outcomes. This type of peer review, sometimes called investigator triangulation, provides researchers with an objective source familiar with the research or the phenomenon being explored to review the study's methodology, to analyze portions of data, and to critique findings. This peer reviewer can provide support and guidance, challenge researchers' assumptions and findings, and help improve the study's rigor or trustworthiness. Some experts advise that this peer reviewing process be used throughout a study's duration. This support can be provided via formal, written reports or through informal conversations and emails.

Qualitative researchers can also use peer reviewers to improve data analysis and interpretation credibility by seeking the assistance of peer debriefers and using the feedback to reach consensus on the findings' coherence and agreement as to the findings' credibility or to generate additional reflections. Peer debriefing in

qualitative research can also help prevent researchers from becoming overly intrusive in their research participants' lives, from going "native," or becoming overly connected with the research site and its inhabitants. The goal is to help researchers become more aware of their work's impact on themselves and other study participants.

Concerns About Peer Review

Although peer review is commonly practiced, it is not without controversy. Concerns include questions about what constitutes high quality and what individuals or organizations gain authority to set peer review quality standards. The definition of peer and what constitutes independent are additional concerns. In defining peer, disagreements arise over what constitutes relevant methodological and content area expertise and experience for a particular project. There can also be concerns regarding a peer review panel or editorial board's diversity (i.e., backgrounds, expertise, cultural, racial, ethnic, and gender) and the reviewed projects. The issue of a conflict of interest between the independent peer reviewer and a research proposal or paper's author can raise serious credibility issues as to the integrity of peer review system to identify and support high quality scientific research and to promote the professional development of the field in question.

In qualitative research, additional concerns include if quality standards not seen as being sensitive to the particularities of qualitative research are arbitrarily applied to determine a qualitative work product's merits. A related concern is the use of standardized checklists and templates for determining research projects' quality that have potential for restricting novel, creative, artistic, or critical approaches to research.

PERCEPTION

Perception is a mode of apprehending reality and experience through the senses, thus enabling discernment of figure, form, language, behavior, and action. Individual perception influences opinion, judgment, understanding of a situation or person, meaning of an experience, and how one responds to a situation. A common way of defining perception is "how we see things." However, perception is a process involving not only the senses but also complex underlying mechanisms.

Perception, which is mediated through the interconnectedness of mind and body, is an individual's access to experience and interpretation in the world. Perception of varying objects depends on the context in which they are experienced for interpretation and meaning. Perception is like a set of lenses through which an individual views reality. These lenses evolve from perspectives of location, subjectivity, particularity, history, embodiment, contradiction, and the web of teachings imparted to the individual.

Qualitative researchers are most interested in individual perception to gain access to understanding the meaning of experience for an individual, a culture, and or social groups.

Individuals give voice to their perceptions through narratives, storytelling, behavior, and reactions to individuals or groups. Researchers are able to understand multiple realities that are socially constructed based on these perceptions. Perceptions are interpretations, and for most individuals, interpretations become their truth. Thus perceptions are extremely powerful and influential in human thought and behavior.

Characteristic of a multistoried world are innumerable perceptions of the same experience, culture, or entity. Perceptions are influenced by the embeddedness of the context in which they reside. Contingency, including the temporal, history, customs, traditions, belief systems, and language, all contribute to a multifaceted layer for interpretation of the origin of perceptions, of how individuals "see" and interpret their immediate reality and experience.

Perceptions are subjective, and when in interaction, individuals or groups engage in an intersubjective

dialogue or dialect where the potential for different interpretations exist. Individuals and groups often “see” entities quite differently based on different life contexts and contingencies. This “perceptual disparity,” where two different subjective perceptions of the same event or experience are contradictory, occurs in the intersubjective space between two people or groups and can be the source of misunderstanding, injustice, and human conflict.

Qualitative researchers understand the importance of individual and/or group perceptions to the interpretation of human experience. Perception also includes the researcher. It is imperative that qualitative researchers have thoroughly examined and come to an understanding of their own original perceptions of what is at hand in a research study, so as to suspend these perceptions to the extent possible, to prevent “contamination” and to enable accurate study and understanding of another way of viewing experience, sometimes completely contradictory to one’s own.

If the goal of the qualitative researcher is understanding, the perceptions of others are critical in interpreting data in a study. The potential for perceptions to be detrimental to an individual or a cultural group makes such study even more critical. Biases, prejudice, unsubstantiated judgments, or false assumptions are powerful perceptions with the potential of misunderstanding, punishment, banishment or oppression.

together ethnographic methods and theoretical concepts from performance studies. As a field of inquiry that bridges communications studies and drama and theater, performance studies considers *performance* broadly. Performance includes cultural activities deemed theatrical or self-consciously constructed performative works of art such as play productions, performance art, or educational drama inclusive of any performative or dramatic form—storytelling, dance, music, street theater, video, and so on. Performance studies provides insights into the nature of social relations by examining performances in real life, such as public gatherings, rituals, games, or sporting events that are seen as performative. Performance ethnography also investigates social dramas or dramatic moments in everyday life, such as moments of conflict, and inquires into everyday interactions, which include culturally conditioned behavior of the performance of social roles—roles as father, daughter, employee, and so on, as well as roles associated with gender as discussed by Judith Butler or roles with race, status, age, and so on—and communicative or speech acts that are performative—as J. L. Austin suggested, words that do something or have an impact in the world. The notion of performativity, associated with performance studies, is a way of conceiving of an activity or action as similar to a theatrical event in form and/or effect and to describe the potential of language to be performative. Performance studies is a broad area of inquiry that draws on theory from various fields including anthropology, sociology, psychology (psychoanalysis, psychodrama), literary theory, linguistics, postcritical and poststructuralist philosophy, and theater studies.

As a research approach, performance ethnography grew out of the so-called crisis of representation. Critiques of meta-narratives, truth claims, and the production of knowledge legitimized other ways of knowing, alternative approaches to doing research, and new forms of representing research. New paradigm researchers acknowledged the fallacy of objectivity, the oppressive dominance of the written word, and the colonizing effect this had for the “other” as the object of investigation. In the fields of anthropology and communication studies, performance became regarded as a legitimate and an ethical way of representing ethnographic understanding. For Dwight Conquergood, performance was an ethical act; it addressed the crisis of representation by offering an embodied, empathic way of knowing and of deeply sensing the other. As such, performance ethnography developed alongside other

PERFORMANCE ETHNOGRAPHY

Performance ethnography describes a set of interrelated and still emerging qualitative approaches that bring

Popular Theatre With Young Offenders

Popular theatre is a process of theatre that involves participants in creating theatre to identify issues of concern to them, to analyze the conditions and causes of situations, and to search for possibilities for change. The following excerpt is from an ethnographic performance text detailing a popular theatre project with a group of incarcerated males at a Canadian young offender center. The study asked how popular theatre could help us to better understand the experiences of the youth toward finding appropriate approaches to meeting their needs and explored how facilitating a popular theatre project, in a context such as this, could help bring about individual and social change.

In performing the piece, two researchers, Diane Conrad and Gail Campbell, took on various roles and acted out situations depicting the popular theatre work with the youth. The performance focused on the researchers' experiences of facilitating the project and on the themes and issues raised by the youth. The text examines the perceptions of the young offenders in relation to the institutional context and the perspectives of the researchers, raising questions about the popular theatre process.

Titles and images were projected throughout the performance.

ON THE INSIDE

Images of a young offender bullying another young offender on screen.

A series of mini scenes follow with performers playing various young offenders . . .

In the gym

George is shooting baskets.
Stanley walks past George.

Stanley: I'm going to get you.

George: Fuck you.

Stanley: Don't turn your back in the shower, bitch.

RECTI"FU"CK"ATION

Various images of graffiti text and drawings on screen. Both Researchers move into research space.

Researcher 1: Have you noticed all these . . . are they homo-erotic images and stories that keep coming up?

Researcher 2: Yes. They're hard to miss . . . the gay characters, the pick-up lines, male prostitutes, bum fucking jokes all mixed up together with talk of hiding things up there—"hooping it," strip search and references to rape.

Researcher 1: I wonder if this kind of stuff actually goes on in here. Janice?

Researcher 2 takes on the role of Janice.

Janice: I'm surprised at all the sexual references too. They keep coming back to it. But you know, there's never been a case of sexual abuse or rape reported in here . . .

Although of course they are subject to a strip search at any given moment. If there's even a suspicion of anything gone missing, like a nail from the shop or something, the whole unit is strip-searched. Or if they've had a visitor that is suspicious . . .

Recti"fuck"ation. *This image was created by the boys as part of a graffiti writing and drawing activity.*

SEX & POWER

Image of a graffiti drawing showing stick figures in postures on screen. and dialogue representing anal sex/rape/strip search.

Researcher 1: We read that rape is a real threat in adult prisons. With all the jokes and rumours that the boys hear, we wondered if it was the boys' fears that something like this could happen to them made them bring up all these images.

Researcher 2: We imagined how we would feel if we knew we could be strip searched at any moment, even if we hadn't done anything wrong.

Researcher 1: In adult prison it's not even so much about sex, as it is about power.

Performers move into prison space representing a holding cell. Researcher 1 becomes Neil, a new young offender, pacing. Fred is in the cell with him.

Fred: So has anyone hit on you yet?

Neil: What do you mean?

Fred: You're lucky, man. After my first week, I had to get twelve stitches in my ring.

(Makes a gesture to indicate his behind.)

Neil: Really? (Looking frightened.)

Fred winks at audience with a knowing smile.

Fred: *(Putting his arm around Neil.)* That's okay, stick with me. I'll look out for you.

alternative qualitative or new paradigm methods, such as Jean Clandinin and Michael Connelly's narrative inquiry, Carolyn Ellis and Art Bochner's autoethnography, and Elliot Eisner, Tom Barone, and others' arts-based ways of knowing and representing research.

An exploration of performance in qualitative research indicates that performance ethnography has emerged as a collection of interrelated methods that can be employed at any or all stages of the research process—for generating or gathering research material, for interpreting or analyzing material, and for representing research.

Performance ethnography as a method for generating research material—for gathering participant responses—may take various forms. The primary methods in ethnography are observation or participant observation, along with interviews, focus groups, fieldnotes, and the like. Correspondingly, performance ethnography employs ethnographic methods in the observation of and/or participation in performance as understood from a performance studies perspective. Performance ethnographers find or create opportunities to observe and/or participate in performances in the broadest sense. As such, performance ethnography involves inquiry into performance in any or all of its

cultural or social contexts—in theatrical performances and/or in everyday life performances.

Performance ethnography may include the investigation of the processes and/or products of intentionally created theatrical type performances with participants and/or responses to such performances by audiences of play productions, of popular theater approaches or playbuilding methods as described by Joe Norris. Theatrical creation with participants as a research method offers an alternative way of drawing out participants' understandings. It offers an alternative performative way of knowing—a unique and powerful way of accessing knowledge, drawing out responses that are spontaneous, intuitive, tacit, experiential, embodied and affective, rather than simply cognitive. In my research experience, reenacting moments like those from real life is a particularly appropriate way of collectively studying lived experience. It engages participants in a process of knowledge production—of expressing, interpreting, and re-presenting their ideas.

Performative ethnographic inquiry in the context of dramatic or theatrical creation may also include investigation of real-life performances that occur in the process of creation, but outside of the theatrical

performances themselves, in conversations arising from the performance or in preparation for performance—in other words, in participant observation of those conversations and preparations.

In the analysis or interpretation of research, performance ethnography also has applications. In fact, as implied above, analysis and interpretation are inherent in the process of dramatic or theatrical creation. “Acting out” involves a process that is critical and analytic. As performance theorists such as Richard Schechner and Richard Courtney describe, by taking on a role, the “player” exists simultaneously in two worlds: as a character in the experience of the “as if” world and as an actor evaluating the situation from the outside, within the real world. The player is both involved in and detached from both realities, alternating from one to the other, observing the self in action, comparing the two worlds to arrive at some new understanding or meaning. Schechner claims that fundamental to all performance is this characteristic of restored behavior or twice-behaved behavior, which is symbolic, reflexive, and loaded with significance. The play frame opens a liminal space where the “not me” can encounter the “not not me.” As such, performance is a process both for generating and for interpretation or analysis of research material.

Furthermore, I describe the interpretive process in which I engage when thinking and writing about performative moments in my work with participants as a kind of performance analysis—an approach similar to Norman Fairclough’s critical discourse analysis, drawing on theoretical concepts from performance studies to analyze or interpret instances of performance. In doing so, I have scripted performative moments from both inside and out of the theatrical performances of participants. These are ethnodramatic vignettes of performative moments recreated in order to discuss them. The scripting process, itself an interpretive one, is followed by analyses of the moments in question drawing on relevant theoretical perspectives with the aim of making meaning of and from the performative interactions.

As a method for representing research, performed ethnography or ethnodrama is perhaps the most widely employed application of performance ethnography. Performed ethnography or ethnodrama has gained acceptance as a powerful medium for disseminating research results with the potential to engage diverse audiences with the research in ways that are empathic, emotional, and embodied as well as intellectual.

To this end, researchers in anthropology, communications or performance studies, various health care fields, education, arts and drama education, and drama and theater have written ethnodramas and/or performed their research. Norman K. Denzin calls ethnodrama a powerful way for ethnography to recover and interrogate the meanings of lived experience. Johnny Saldaña makes a distinction between ethnotheater as a live research performance event and ethnodrama as the written script.

As well as the specific methods mentioned above, the notion of performance has been embraced in qualitative research for its productive possibilities in the broadest sense. Performance or performativity have been taken up as critical pedagogy and in critical arts education. Charles Garoian suggests that performance opens a liminal pedagogical space that allows for a reflexive learning process that recognizes the experiences, memories, and multiple perspectives of participants and encourages discussion of complex and contradictory issues. The notion of performance has also been taken up in doing arts-based inquiry and writing various kinds of performative texts. According to Denzin, texts that are performative are creative, passionate, visceral, and kinetic; focus on process over product; are critically reflexive on the part of the researcher; and experiment with form including popular arts forms—they are open texts with multiple meanings and multiple ways of relating to the work, allowing dialogue with research participants, appealing to diverse audiences, and raising questions rather than formulating conclusions. For Denzin, performance ethnography as praxis is a way of acting on the world in order to change it. Performance creates an open, dialogic space for inquiry and expression through an interpretation of events and their contexts. Performance creates opportunities for communion among participants, researchers, and research audiences.

In performance ethnography, participants’ performances, both staged and in real life, provide insight into their lived experiences and their cultural worlds. Moreover, as anthropologist Johannes Fabian claims, some types of cultural knowledge cannot simply be called up and expressed in discursive statements by informants but can be represented only through enactment or performance. He claims that knowledge about culture or social life is performative rather than informative. In this way, Fabian pushes insight about

performance toward its methodological imperative, as a method as well as the subject of ethnographic research.

PHENOMENOGRAPHY

Phenomenography is a research approach aimed at the study of variation of human experiences of phenomena in the world. Etymologically, the word *phenomenography* is derived from the Greek words *phainomenon* (phenomenon, appearance) and *graphein* (write, describe). Phenomenography is thus about the description of things as they appear to us. Emerging as a methodology in the 1970s, phenomenography has gradually developed in different strands—as an empirical research approach and in a

theoretical direction as variation theory. Focusing mainly on the empirical, methodological approach, this entry describes the goals of phenomenography, the processes used to collect and analyze data, and the strengths and limitations of such research.

Phenomenographic Research Approach

The object of phenomenography is the variation of human experience of the world. It is grounded in empirical research in education on variation in undergraduate students' learning outcomes and was initially developed during the 1970s by a group of researchers led by Ference Marton at Göteborg University in Sweden. The initial studies tried to answer the question, "Why do students learn different things from reading the same text?" The findings from these studies identified and described a limited number of different ways of understanding the text. They also found a clear relationship between students' ways of understanding the text and their approach to the task of reading the text. The qualitatively different ways of understanding the text were closely linked to the variation in approach to learning (deep vs. surface approach) adopted by the learners. This relationship between understanding and approach implies a principle of intentionality in approaching learning tasks, or broader, as ways of experiencing a particular problem or situation. Since these first studies hundreds of empirical studies have been conducted, mainly in research on learning, but phenomenography has also been used in other areas such as business administration, information literacy, and information behavior research. Geographically, phenomenography has spread from Sweden to Australia and to South East Asia. Currently, a network of phenomenographic researchers have clusters in Göteborg, Sweden; Hong Kong; and Australia.

Variation and Experience

The study of variation implies an interest in capturing various dimensions or facets of a phenomenon as it appears to a number of people. *A way of experiencing something* constitutes the research unit in phenomenography, which means that the research takes its point of departure in human individuals. A way of

experiencing is a particular way of being aware of something and is seen as a relation between a person and the specific phenomenon under study. The concept of a way of experiencing has gradually replaced earlier terms like *conception*, *way of understanding*, and *way of seeing*. In many texts, these terms are used interchangeably to denote this central phenomenographic concept. The study of experience is not exclusive to phenomenography. Phenomenology likewise has human experience as its research object, but although phenomenography is directed at studying and mapping variation in experiences of a phenomenon, phenomenology is concerned with capturing the essence of a phenomenon.

During the last decades, phenomenographers have addressed the question, “What is a way of experiencing a phenomenon?” explored within a framework of the anatomy of awareness. This question implies a shift from empirical toward more theoretical research interests. (This strand of phenomenography has developed into variation theory.) The theoretical and empirical research strands are closely interrelated. One empirically grounded, basic assumption that has an important theoretical implication is that a particular way of experiencing a problem or a situation and a way of acting in relation to that same problem or situation reflect each other. One does not cause the other because experiencing and acting are inseparably intertwined. This intertwining implies that phenomenography does not take a dualistic stance related to differences between word and deed, meaning that ways of experiencing are considered as integrating thought, action, and feeling. Another theoretical feature is the relationship between the ways of experiencing a phenomenon and the categories created to describe them. The former constitutes the research unit, while the categories of description form the outcome of phenomenographic research. Although ways of experiencing derive from individuals, categories of description refer to the collective level—the qualitatively different ways in which a phenomenon may appear to people.

Collecting Data

In most phenomenographic research, data have been collected through interviews, although there are examples of videorecording as well as document analysis. The selection of interviewees is guided by the interest to collect rich material about the phenomenon

of study and with the object of identifying and describing variation in experiences of this particular phenomenon. Generally, the number of participants has been 15 to 30 people, but there are examples of both smaller and larger numbers.

The focus on experience implies that it is not the world as such that is being explored but the world as experienced by human beings, or expressed somewhat differently, the phenomenon as it appears to a number of people. In much phenomenographic writing this characteristic is labeled a *second-order perspective*. This second-order perspective is usually manifest in research questions, which are formulated in terms such as, “What are higher educators’ views of information literacy” or “How do high school students experience information seeking related to a learning assignment?”

Interviews are guided by the research question and are semi-structured. Before preparing interview questions, the researcher should thoroughly delineate and penetrate the phenomenon under study in order to discern its outer and inner structure, the various possible meanings of the phenomenon, and various characteristics that may be linked to the phenomenon in different contexts or situations. One way to do this is to study and consider previous research on the phenomenon within different research traditions. The intention behind this understanding is not to impose a particular view on the research participants—on the contrary, the idea is for the researcher to be as open as possible to the varying experiences that may be encountered during interviews.

Interview questions are formulated in ways that allow interviewees to express their own views on the phenomenon under study. For instance, as in a study on educators’ views of information literacy education, researchers used such questions as, “What does teaching information literacy mean to you?” “What does students’ learning about information literacy mean to you?” or “Tell a story of a time when you experienced that teaching and learning information literacy worked really well.” These major questions are followed by probing questions to facilitate the development of rich material on as concrete a level as possible, for example, “What do you mean when you say . . . ?” or “Please give me an example of what you said in order to help me understand better.” An alternative to such open-ended questions might be to give participants a concrete assignment of an information seeking character and then to observe and interview them about their ways of managing and thinking about the

task. This approach implies that the researcher should assume the role of an attentive listener, attempting to see the internal logic manifest and latent in what is expressed in the interview.

Phenomenographic interviews are not intended to bring out attitudes or ready answers held by interviewees. Instead, the interview is seen as a means for the interviewee to think about, reflect on, and formulate ways of experiencing a particular phenomenon. In this way, the various experiences sought in the study are being shaped through the interview for further analysis by the researcher. Interviews are audiorecorded and transcribed verbatim.

Data Analysis

The objective of phenomenographic analysis is to identify and describe variation in ways of experiencing the phenomenon, a goal that is the object of research. The outcome of analysis, that is, the research findings, is presented in a limited number of categories of description that illustrate the variation of experiences of the phenomenon.

Analysis is conducted in several steps through reading and rereading interview protocols, with somewhat differing foci linked to the various phases of analysis. Preliminary analysis is accomplished already during data collection and continues during the transcription of the recorded interviews as the researcher becomes familiarized with the material and identifies themes emerging from the material. These themes may form various aspects or facets of the phenomenon under study, some of which may be foreseen by the researcher's previous understanding of the phenomenon and others appearing in the interview material. This process implies an abductive type of analysis, moving between empirical data and theoretical concepts to let one illuminate and contribute to the other. The purpose of analysis is to identify new facets and nuances with regard to meaning and structure in the various ways of experiencing the phenomenon. These aspects are further analyzed through comparative analysis with the aim of identifying differences and similarities linked to each aspect. Such comparisons are conducted in two contexts: one in the context of other extracts drawn from all interviews that touch upon the same theme; the other in the context of the individual interview.

Categories of description are the result of the researcher's work on identifying, formulating, and

describing the critical features of the meaning and structure of the ways of experiencing as well as of the relationship between the categories, which together form an outcome space. Validity is achieved in relation to the data available and the transparency in the researcher's path through data analysis. Quotations from interviews are used in two ways: (1) to illustrate a critical feature of a category and (2) to clarify the difference between one category and another. Often, not least in learning research, there is a hierarchical structure between the categories, defined through an increasing complexity of ways of experiencing the phenomenon. More complex ways of experiencing means that the categories comprise more dimensions and a simultaneous awareness of these dimensions.

Strengths and Limitations

With its origins in empirical research, phenomenography continues to prove fruitful for empirical research in various fields inside and outside pedagogy. A large amount of phenomenographic studies have been related to varying ways of experiencing concepts like photosynthesis, matter, or information literacy. The concept of learning has been the object of several studies. In Library and Information Science, the study of concepts such as relevance, enough, and the use of information for managers' decision making have followed in this tradition. Phenomenographic findings have allowed new features of phenomena to appear, carrying new facets and nuances compared to more general models of, for instance, information seeking or information literacy. At the same time, the more elaborate insights into phenomena offered through the description of variation implies a holistic view of the studied phenomena.

Phenomenography has been criticized for not taking context into account, voicing the risk that interviewer and interviewees may not refer to the same phenomenon in interviews about concepts separated from a particular situation or context. This concern is an observation worth serious consideration and concerns the validity of research findings. One way of dealing with this problem is found in examples of phenomenographic studies conducted in relation to actual processes or situations in which interviewees have been involved during the study. Another way of dealing with this issue is to ensure that interviews are carried out in ways that inscribe the phenomenon

under study in situations or contexts that are familiar to interviewees and where there is a basis for mutual understanding in the researcher–participant relationship. When ways of experiencing are separated from the individuals through the categories of description, the variation described may be compared with findings from other contexts, for instance, across contexts of learning in formal education and work–life learning.

Phenomenographic research findings hold strong potential relevance for various professional practices. Knowledge about differences between various ways of experiencing particular phenomena and of the potential for change from less to more complex understandings are important in a number of fields such as teaching and learning, as well as for developing services and tools within different institutional practices.

PHENOMENOLOGY

Phenomenology is the reflective study of prereflective or lived experience. To say it somewhat differently, a main characteristic of the phenomenological tradition is that it is the study of the lifeworld as we immediately experience it, prereflectively, rather than as we conceptualize, theorize, categorize, or reflect on it. Phenomenology is now commonly considered to be one of the alternative qualitative research methodologies to which researchers can turn. But phenomenology is also a term that can carry quite different meanings depending on theoretical and practical contexts.

Originally, phenomenology was the name for the major movement in philosophy and the humanities in continental Europe in the 20th century. More recently, the term has acquired a broader meaning as phenomenology has been developed as a human science that is employed in professional disciplines such as education, health science, clinical psychology, and law. Phenomenological research is the study of lived or experiential meaning and attempts to describe and interpret these meanings in the ways that they emerge and are shaped by consciousness, language, our cognitive and noncognitive sensibilities, and by our pre-understandings and presuppositions. Phenomenology may explore the unique meanings of any human experience or phenomenon. For example, it may study what it is like to have a conversation, how students experience difficulty in learning something, how pain is experienced in childbirth, what it is like to experience obsessive compulsions, how young people begin to experience secrecy and inwardness, and so forth.

This entry describes the emergence of traditions and contexts, some key concepts of phenomenology, and methods of phenomenology as a human science.

The Emergence of Traditions and Their Contexts

Within the large sweep of phenomenological philosophy, a variety of phenomenological schools and traditions may be distinguished, such as transcendental, existential, hermeneutic, linguistic, and ethical phenomenology. Often these traditions are strongly associated with renowned phenomenological scholars.

Transcendental phenomenology may be identified with the pathbreaking work of Edmund Husserl and his interpreters. Some basic terms of transcendental phenomenology are *intentionality*, *eidetic reduction*, and *constitution of meaning*. For Husserl, phenomenology is the rigorous, human science of all conceivable transcendental phenomena. It describes the way that knowledge comes into being in consciousness and clarifies the assumptions upon which all human understandings are grounded.

Existential phenomenology is often associated with Martin Heidegger, Jean-Paul Sartre, and Simone de Beauvoir. Some basic terms of existential phenomenology are *modes of being*, *ontology*, and *lifeworld*. In his last work, *The Crisis of the European Sciences*, Husserl had already turned phenomenological analysis from the transcendental ego and consciousness to the prereflective lifeworld of everyday experience. Martin Heidegger and Maurice Merleau-Ponty radicalized this turn toward the existential world as we live and experience it. With Heidegger, this turn became an ontological rather than an epistemological project. Instead of asking how the being of things are constituted as intentional objects in consciousness, Heidegger asked how the being of beings shows itself as a revealing of being itself.

Hermeneutic phenomenology is linked especially with Hans-Georg Gadamer and with Paul Ricoeur. Some basic terms of hermeneutic phenomenology are *interpretation*, *textual meaning*, *dialogue*, *preunderstanding*, and *tradition*. Phenomenology becomes hermeneutical when its method is taken to be interpretive (rather than purely descriptive as in transcendental phenomenology). But the contrast between descriptive and interpretive phenomenology is sometimes oversimplified by researchers in the professional disciplines. Heidegger argued that all description is always already interpretation. Every form of human understanding is interpretive.

Linguistic phenomenology includes the French poststructuralist work of Maurice Blanchot, Jacques Derrida, and Michel Foucault, even though the latter denied that he was a phenomenologist. Basic terms of linguistic phenomenology are *textual autonomy*, *signification*, *intertextuality*, *deconstruction*, *the outside*, *discourse*, and *space of the text*. The work of Foucault on the nature of language and discourse contributes to certain explorations of the relation between understanding, culture, historicity, identity, and human life. But it is especially in the work of Derrida and

colleagues such as H el ene Cixous, where we can speak of a radical linguistic phenomenology.

Ethical phenomenology is exemplified in the work of Max Scheler, but later with the thinking of Emmanuel Levinas and his translator Alphonso Lingis. Basic terms of ethical phenomenology are *otherness*, *responsibility*, *I-Thou*, *the face*, and *(non)relationality*. Ethical phenomenology received its first impetus especially by Max Scheler in his study *The Nature of Sympathy*. For Levinas, the Husserlian focus on the essence of things and Heidegger's preoccupation with the modalities of being in the world all are manifestations of the primacy of being, self, or mineness in traditional philosophical phenomenology. For a truly profound understanding of human reality one must not only ask for the meaning of being or presence, but also for the meaning of what is otherwise than being: alterity or the infinite. Levinas finds the phenomenological power of this question in the encounter with the face of the other.

Phenomenology of Practice

Since the mid-1990s, phenomenology has been widely imported into the practical, applied, or professional disciplines such as the health sciences, education, clinical psychology, and pedagogical disciplines. Within these professional fields, phenomenology has a somewhat different history than most other qualitative research approaches. For example, action research developed from within the field of sociology and had a distinct and critical-political social agenda; ethnography emerged as a distinct anthropological field research method. In North America, phenomenology seeped into the professional fields in part via ethnomethodology, ethnography, interpretive sociology, and other such social science streams and in part through pockets of interest such as humanistic psychology, the work of existential psychology, and educational studies and pedagogy. Phenomenological inquiries have become attractive because they offer an alternative to managerial, instrumental, and technological ways of understanding knowledge, and they lead to more ethically and experientially sensitive epistemologies and ontologies of practice.

Before there was any significant interest in phenomenology in North America, a unique experiment had taken place in the Netherlands, Belgium, Germany, Switzerland, and France. For example, the University of Utrecht School can be considered a

genuinely original contribution to the international discussion about phenomenology in the professions. It consisted of an assortment of phenomenologically oriented psychologists, educators, pedagogues, pediatricians, sociologists, criminologists, jurists, psychiatrists, and other medical doctors who formed a more or less close association of like-minded academic and professional practitioners. Scholars such as the psychiatrist J. H van den Berg wrote among other things about the changing nature of childhood; the pedagogue-philosopher O. F. F. Bollnow wrote on the pedagogical atmosphere; M. J. Langeveld established the field of phenomenological pedagogy; the medical doctor F. J. J. Buytendijk produced numerous studies on topics such as pain, human movement, touch, and obsessive compulsiveness.

The practical phenomenological psychology of Amadeo Georgi and Clark E. Moustakas was inspired by the Dutch school. In education, phenomenology was introduced through the writings of Maxine Greene and Max van Manen and in the health sciences through the works of Patricia Benner and Kay Toombs, and so on.

In recent years, further developments in phenomenological methodology, as originally inspired by continental scholars, are found in all the major professional disciplines. These phenomenological methods share a concern with the concrete particulars of everyday life, but they are now more sensitive to subjective and intersubjective roots of meaning, to the complexity of relations between language and experience, to the cultural and gendered contexts of interpretive meaning, and to the textual dimensions of phenomenological writing and reflection. The growing interest in the relevance of such phenomenological methodologies for research and the knowledge base of professional practices attests to the vitality of concerns with reflective interpretation and experiencing sensitive understanding.

Concepts of Phenomenology

It has been said that a proper understanding of phenomenology can be gained only through doing it. Phenomenological understanding needs to be practiced as method, and identified as a style of thinking—a manner of orienting to experience as we live through it.

Within the discipline of philosophy, phenomenology is practiced through the methods of the reduction.

And as a human science, phenomenology has imported an additional variety of empirical data gathering techniques and reflective methods. It explores ways of doing research that remain focused on and sensitive to the concrete, subjective, and prereflective dimensions of the lifeworld.

Different phenomenologists such as Husserl, Heidegger, Merleau-Ponty, and Derrida agree that phenomenological understanding is achieved through language. A good phenomenological text can make us suddenly “see” something in a manner that enriches our understanding of everyday life experience and may transform our practices. But phenomenological reflection also runs up against the limits of language. The production of insight must proceed through the creation of a research text that speaks to our cognitive and noncognitive sensibilities. Thus, phenomenological understanding is distinctly existential, emotive, enactive, embodied, situational, and nontheoretic. A powerful phenomenological text thrives on a certain irrevocable tension between what is unique and what is shared, between particular and transcendent meaning, between what can be thought and what remains unthought, and between the reflective and the prereflective spheres of the lifeworld.

Lived Experience

The term *lived experience* derives from the German *erlebnis*—experience as we live through it and recognize it as a particular type of experience. It could be argued that human experience is the main epistemological basis for many other qualitative research traditions, but the concept of lived experience possesses special methodological significance for phenomenology. The notion of lived experience, as used in the works of Husserl, Merleau-Ponty, and like-minded phenomenologists, announces the intent to explore directly the original or prereflective dimensions of human existence.

Our language can be seen as an immense linguistic map that names the possibilities of human lived experiences. The value of phenomenology is that it prioritizes and investigates how the human being experiences the world: how the patient experiences illness, how the teacher experiences the pedagogical encounter, how the student experiences a moment of success or failure, and how we experience novel ways of interacting with others and the world through computer mediated devices, social network technologies,

new media, and so forth. Every lived experience (phenomenon) can become a topic for phenomenological inquiry. The phenomenological attitude keeps us reflectively attentive to the ways human beings live through experiences in the immediacy of the present that is only recoverable as an elusive past.

Phenomenology is interested in recovering the living moment of the now—even before we put language to it or describe it in words. Or to say this differently, phenomenology tries to show how our words, concepts, and theories always shape (distort) and give structure to our experiences as we live them. But the living moment of the present is always already absent in our effort to return to it. For example, it is one thing to get lost in a novel, but it is another to retrospectively capture what happened to us, just now, as we slipped into this textual space and began to dwell in the story. Similarly, we may identify and rate with empirical descriptors the nature and intensity of various forms of pain, but the actual moment of being struck by pain or the lingering discomfort of suffering pain somehow seem to be beyond words as we try to retrospectively appropriate the experience. These experiences can be described, but ultimately the meaning of the primal experience is beyond propositional discourse.

Lifeworld

The lifeworld is the pregiven world, the existent world as we find ourselves in it. Husserl described the lifeworld as the “world of immediate experience,” the world as “already there,” the world as experienced in the “natural, primordial attitude.” He distinguished between our theoretical attitude to life, as borrowed from the Greeks, and our natural pretheoretical attitude to life on which all science and theorizing is based and from which all theorizing is ultimately derived. Husserl employs the term *natural* for what is original and naive, prior to critical or theoretical reflection.

Each lifeworld shows certain pervading structures or styles that can be explored phenomenologically. Alfred Schutz and Thomas Luckmann elaborated this notion in a sociological direction in their book *Structures of the Life-world*. We could examine how the lifeworld of the child has different experiential qualities from the lifeworld of the adult. Each of us may be seen to inhabit different lifeworlds at different times of the day, such as the lived world of work and

the lived world of home. Moreover, lifeworlds intersect and are partly nested within each other. Heidegger gave to the idea of lifeworld an even more worldly, existential thrust by speaking of phenomenology as the study of being, the study of our modes-of-being or ways-of-being-in-the-world. Ludwig Wittgenstein’s notion of “form of life” and “language games” can be understood as a more linguistic approach to the idea of lifeworld.

The Reduction

It is impossible to understand transcendental phenomenological method without understanding the meaning and significance of the reduction. *Reduction* is the technical term that describes the phenomenological device of bracketing (*epoché*) that permits us to discover the experiential surge of the lifeworld. The aim of the reduction is to reach a direct and primal contact with the world as we experience it rather than as we conceptualize it. But the discovery of the prereflective lifeworld through the technique of the reduction always transcends the lifeworld—when we bracket lived experience, we experience meaning. The reduction is meant to bring the aspects of meaning that belong to the phenomena of our lifeworld into nearness. In particular it aims to bring into focus the uniqueness of the phenomenon to which we are oriented.

The method of human science is never simply a matter of procedure, whether simple procedures or advanced procedures. Rather the reduction refers to a certain thoughtfulness. To come to an understanding of the unique meaning and significance of something we need to reflect on it by practicing a careful attentiveness. The term *reduction* is somewhat misleading since reduction—the ambition to make reflection emulate the unreflective life of consciousness—is ironically a protest against reductionism. So how then is reflection supposed to emulate lived experience? Of course, the emulator is language, and the process of emulating is performed through writing, and the intent of writing is to produce textual portrayals that resonate the kinds of meanings that we seem to recognize in prereflective experience.

There exist many philosophical investigations and explications of the reduction that can make this topic complex and confusing. That is not surprising in view of the fact that the project of phenomenology can be understood in a variety of ways. Here several levels of

reduction may be distinguished for their methodological usefulness: wonder or heuristic reduction, openness or hermeneutic reduction, concreteness or phenomenological reduction, universality in contingency or eidetic reduction, and flexible rationality or methodological reduction. Each of these dimensions of the reduction needs to be practiced as if in concert.

Human Science Methods

The reduction is the method central to the phenomenological study of the lifeworld; however, in the work of more ontologically oriented phenomenologists, the reduction does not bracket the phenomenon away from the world, but rather it restores the contextual and always already existing meaningfulness of the world.

As phenomenology was adopted by various disciplines associated with professional practices, empirical and reflective methods were imported that are derived from the humanities and the social sciences. Empirical methods such as interviewing, observation, eliciting written descriptions, and borrowing from literary and artistic sources are now used to gather experiential material. These data are best collected in the form of descriptions of lived-through moments, experiential anecdotal accounts, remembered stories of particular experiences, narrative fragments, and fictional experiences. Thus, phenomenological experiential accounts should not be confused with opinions, interpretations, views, or explanations of certain phenomena.

Phenomenological inquiry cannot be formalized into a series of technical procedures. However, a variety of data gathering activities may be identified that can help in doing phenomenological inquiry. These activities fall into two types: empirical and reflective methods.

Empirical Methods

Our personal life experiences are immediately accessible to us in a way that no one else's are. However, the phenomenologist does not want to trouble the reader with purely private, autobiographical facticities of his or her life. In drawing up personal descriptions of lived experiences, the phenomenologist knows that the patterns of meaning of one's own experiences are also the possible experiences of others and therefore may be recognizable by others. By

conducting a personal description of a lived experience, the researcher aims to describe a phenomenon as much as possible in concrete and lived-through terms. In other words, the focus is on the direct description of a particular situation or event as it is lived through without offering causal explanations or interpretive generalizations.

In the various strands and disciplines in the social and human sciences, the interview serves differing purposes. For example, ethnographic interviews study cultural practices and meanings. Survey or opinion interviews study the ways people perceive or feel about certain issues, their beliefs, views, and so forth. In the context of phenomenological research there are, broadly speaking, two types of interview: The phenomenological interview is used as a means for exploring and gathering experiential material. The hermeneutic interview is used to explore interpretive meaning aspects of lived experience material.

Sometimes, the best way to enter a person's lifeworld is to participate in it. For example, to gain access to the experience of young children, it may be important to play with them and follow them into their play spaces. Participatory and close observation generates different forms of experiential material than is obtained through written or interview approaches. Observational method may require that one be a participant and an observer at the same time, maintaining an orientation of reflectivity while guarding against the more manipulative and artificial attitude that a reflective attitude tends to insert in a social situation and relation.

Fictional literature, such as novels and short stories, is sometimes an excellent source for experiential material. The phenomenological value of a novel, for example, is determined by what may be called the perceptiveness and the intuitive sensitivity of the author. Phenomena such as love, grief, illness, faith, success, fear, death, hope, struggle, or loss are the stuff of which novels are made. Through an experientially powerful novel, then, one is given the chance of living through an experience that provides the opportunity of gaining insight into certain aspects of the human condition.

Reflective Methods

Whereas empirical methods aim to explore the range and varieties of prereflective experiential material that is appropriate for the phenomenon under

study, reflective methods aim to interpret the aspects of meaning or meaningfulness that are associated with this phenomenon and that assist with the reduction.

Phenomenological reflection aims to perceive the meanings of human experiences; and in a sense, it is something everyone does constantly in everyday life. For example, when we meet a friend, we do not just perceive a man or a woman. We see a person who differs from other men and women precisely in that respect that makes us relate and talk to this person as a friend.

But what is much more difficult is to come to a reflective determination and explication of what a friend is. This determination and explication of meaning then is the more difficult task of phenomenological reflection. A perhaps more notorious illustration of this difficulty concerns the experience of time. What could be more easily grasped than time? We regulate our lives by time. We carry the time around on our wrist. We divide the day into morning, afternoon, evening, and nighttime. We reflect on past time and anticipate the time to come. We even talk about the time going by, sometimes quickly and at other times more slowly. And yet when someone asks us, "What is time anyway?" we are quickly at our wit's end to describe it. What is it that goes by fast or slowly when we say that the time is elapsing? How does our sense of time change as we become more continuously and immediately accessible to each other through mobile devices and the internet? So there is a difference between our prereflective lived understanding of the meaning of time and a self-reflective grasp of the phenomenological structure of the lived meaning of time. To get at the latter is a reflective and often laborious task, involving a process of reflectively appropriating, of clarifying, and of making explicit thematic aspects of meaning of the lived experience.

Our lived experiences and the structures of meanings (themes) in terms of which these lived experiences can be described and interpreted constitute the immense complexity of the lifeworld. Existential themes that may prove especially helpful as guides for reflection in the research process include lived space (spatiality), lived body (corporeality), lived time (temporality), and lived human relation (relationality or communality). We can always ask about any experience the fundamental questions that correspond to such lifeworld existentials. Therefore, spatiality, corporeality, temporality, relationality, and alterity are

productive categories for the process of phenomenological questioning, reflecting, and writing.

PHOTOGRAPHS IN QUALITATIVE RESEARCH

Photographs, along with other visual representations such as drawings, cartoons, videos, and even color swatches, play a variety of roles in qualitative research because they offer a visual medium in addition to the more common verbal medium. They complement the spoken word and often enable a richer, more holistic understanding of research participants' worlds as well as often act as stimuli, for example, in the development of advertising, packaging, brand development, and corporate imagery.

Broadly, photographs can have a role in two aspects of research. They can be a form of data gathered from research participants and initiated either by the researcher or by the research participants. Alternatively, they can be used as a stimulus that is provided by the researcher to act as a prompt or as a focus of discussion. However, these two aspects are not discrete and often overlap. For example, material provided by the researcher can be elaborated and

modified by research participants as part of a task carried out in group sessions.

Photographs as Research Data

Research Participants as Photographers

Photographs have an important role in broadening the researcher's understanding of research participants' lives outside the research context. Many research situations, for example, focus groups and in-depth interviews, while invaluable forums for gathering research data are necessarily artificial because researchers are taking people out of their normal context. It is therefore, useful to develop means of capturing data in a real-life situation and to supplement data gathered from structured research. Asking participants to carry out a specified task before the research session, for instance, serves two purposes. It sensitizes them to the topic to be discussed and it enables them to capture some aspects of their worlds that they can bring into the research situation to be examined and that the researcher can retain and incorporate into the analysis and research findings.

Photographs are often ideal as a preinterview (or postinterview) task. Participants can be given disposable or digital cameras and instructed to take photographs that are relevant to the project. Instructions can be as broad as, "Please take photographs of anything that is important in your life" or they can be quite specific, for example, "Please take photographs of all the pairs of shoes that you own, photographing each pair separately" or "Take pictures of store fascias that you find particularly attractive or unattractive." Participants are asked—and paid—to have the photographs developed or to download or print them so that they are available in the follow-up research session. Participants then talk through the photos—this talk may trigger conversation involving other participants—explaining why they are relevant, what their importance is, and how they link to the topic that is being researched.

This discussion with the researcher or with the whole group is an essential part of the research process because it enables the participant to explain the context of the photos and to give his or her personal interpretation of their importance. There is a danger with photographs, as with all visual data, that

they can be seen as self-explanatory, especially as they are often visually very powerful. However, photographs are a primary source of data that offers the potential to gain insights that are not accessible through interview methods, and they need analysis and interpretation as researchers would do with verbal data. This is not to say that photographs cannot have a secondary role of "bringing the consumer to life" in a subsequent client presentation, but treating this function as their primary role undersells the potential of these data.

Researcher as Photographer

The researcher can also act as photographer, using the photographs as a complementary form of data to the interviewing itself. This task may involve taking photographs of participants (with their permission and having explained exactly how the photos will be used), photographing their home or work environments, their possessions, their family, and so on, depending on the nature of the project. These photos may be shown to the research participant in a research situation and the meaning of the content explored, and/or they may be used by the researcher to examine differences between participants so that generalized themes may be drawn out. In addition, they can be very useful in helping clients understand the lives and priorities of their target audiences.

Increasingly, videos are used in these situations instead of still photographs, although physically holding a photograph, which represents a frozen moment in time, can be very effective in allowing participants or the researcher to reflect on the meaning of the action or setting without the pressure to move on to the next scene.

Photographs as Stimuli

The familiar phrase, "A picture speaks a thousand words" is very apt when applied to certain areas that need to be explored qualitatively, such as imagery, emotional meaning, and brand identity that, to a large extent, depend on visual understanding. Photographs and other pictorial stimuli operate at a visual level—a level that is very important for emotional content—and the form in which, consciously or unconsciously, such content is often stored. Photographs work because they are in some ways closer than words to the language of emotions.

Using Photographs to Explore an Organization's Purpose

In a study by Campbell Keegan Ltd., we (Sheila Keegan and Rosie Campbell) were commissioned by a government funding body for arts within the United Kingdom. The organization was undergoing a review of its role and its responsibilities to the general public, particular arts groups, and to art in general. Our role was to explore, with employees at all levels within the organization, their views on the role of the arts in society and, specifically, what they felt the arts body should be doing to promote arts within the wider community.

We conducted a number of 3-hour discussion groups with a mix of employees who worked in different job functions. One of the tasks we asked research participants to carry out, as part of this discussion, was to tear out photographs from magazines that reflected their feelings about the organization they worked for. The purpose of this exercise was to move people away from verbal descriptions. Participants were very familiar with discussing the organization in words and in conceptual terms, and it was clear that verbal descriptions had become rather repetitive and stale. We wanted to create a shift in their thinking by forcing them to express themselves visually, which we hoped would bring out different perceptions of the organization. We encouraged them to choose a photo quickly, without too much consideration, and then asked them to tear it out of the magazine. We then went around the group and asked participants to explain why they had chosen that particular picture. Often they were unclear initially why they had chosen it—it was

Collage Representing the Image of an Organization Produced by a Group.

Source: Photo by Sheila Keegan; used by permission.

often a partially unconscious choice. However, as they linked the visual with their experiences, perceptions, emotions, and expectations related to the organization, many unexpressed thoughts and feelings emerged. These were shared and then discussed by the whole group, who added their own input. This process provided a much fuller and more holistic understanding of the organization than words alone could have provided.

Just as photographs acting as data can be produced by either the researcher or the research participants, so photographs acting as stimuli can be preprepared and introduced by the researcher into the research situation; in addition, photographs can be used by participants to express emotions and to develop concepts or directions related to the specific project.

Researcher-Introduced Photographic Material

Often, it is too costly, time consuming, impractical, or inappropriate to introduce finished products, concepts, or even embryonic ideas into qualitative research. In fact, much creative qualitative research is carried out to actually generate these ideas and to develop them in the research process. Nonetheless, it is important to be able to introduce stimuli that will

help participants discuss an area and that will facilitate the development of embryonic ideas. Photographic material can be very helpful in this role, and it can be used in a variety of ways.

Sometimes it can be as simple as introducing photographs as visual prompts, for example, a range of shampoo brands, visuals of a store layout, or pictures of a hospital reception area in order to explore patient experiences. The photographs focus participants on the topic and aid recall of detail.

Photographs can also be used to help set the mood or explore preferences and experiences. For example, when trying to evaluate a proposed out-of-town shopping center, photographs of existing shopping centers might be shown to enable discussion of what works and what does not work.

Mood boards are commonly used as a way of exploring feeling or imagery. These are a set of

boards displaying a range and variety of visual images, with each board attempting to capture a different theme or mood, for example, happiness, success, or energy. The boards are preprepared and can be used in a variety of ways to explore participants' thoughts and feelings about brands, companies, service experiences, and in particular, participants' relationships with them.

Another use of photos as preprepared material is in the form of *photomatics*—series of photographed scenes depicting a storyline related to an advertisement, a proposed development, or some other future event. This method allows participants to engage more easily with the concept and helps them visualize the effect.

Photographs as Participant Representations

Photographs are extremely versatile tools that research participants can use in a variety of ways to express their feelings, images, or hopes to help develop concepts or future scenarios. Some examples of how they may be used are the following:

Picture sorts. Participants are given a preselected set of visual images, approximately 50–150, and asked to use them to explore perceptions and imagery of a brand or institution. For example, “Does this reflect how you feel about *x* or not? Why/why not? What does it say about *x*? How could you change this?” And so on.

Collage. Participants work either individually or in groups. They are given scissors, glue, and sheets of paper and asked to cut and paste pictures to create a collage representing their thoughts, imagery, and feelings about a product or brand, an organization, or an experience. As there is a visual focus, nonrationalized responses are encouraged. The potential applications of this technique are broad, ranging from depicting current brand identities, moods, feelings, and participants' desires in a marketplace to exploring possible futures.

Storyboards. These can be produced by participants in order to depict a sequential process, using photographs as above, but portraying change over time.

All of these approaches require discussion and interpretation by research participants before analysis and integration into the overall research findings.

PHOTONOVELLA AND PHOTOVOICE

Photonovella and photovoice are related approaches to participant-driven, photo-based research. Advocates of each form of research are clear about the rich ambiguities and constructedness of the interpretations that their methods evoke. Photonovella is historically most closely connected with popular literature, the arts, and those health and educational researchers interested in working with research participants linked with institutions such as schools or clinics in the development of representational or informational narratives built around sequential images. Photovoice is more closely linked to photo-documentary, engaged journalism, and in some cases, a feminist revisioning of participatory and action research approaches used in visual sociology or visual anthropology. Photovoice has often been used by research participants in community self-study or in needs and asset assessment and can lead to the creation and discussion of photo essays or exhibits that serve as a vehicle for engaging institutions about policy around community concerns. Both approaches highlight the importance of the camera as a tool for supporting the independent inquiry of research participants less constrained by intended or unintended researcher controls, access, and literacy.

Photonovella

Photonovella as a research method is linked to photo-based forms of popular literature called *fotonovela* in

Mexico, *photoroman* in France and Quebec, and *fotoromanzi* in Italy. Aimed at an adult audience, these magazines featured original tableau photographs or still images from films combined with text balloon dialogue. Like romance novels, radio soap operas, or film melodramas, photonovella typically featured archetypal male and female characters caught in intense relationship crises. As with many popular media, some more recent photonovella have moved to more graphic stories and images. Though photonovella have been commonly available since the 1950s, they were largely ignored or criticized as a low art form in academic circles until fairly recently. In the 1990s, activist Hispanic artists found in the form that was largely unknown to English-speaking cultures a vehicle for exploration and representation. Institutionally, there is evidence back to the 1970s of organizations such as the Peace Corps. in the United States and more recently, health and education agencies such as UNICEF using the photonovella as a means of getting information to communities globally.

The method typically involves participants and researchers in identifying both a story important to the group and an audience for whom the creation and distribution of that story is deemed important. This opening inquiry can take many forms, but ideally should involve visual and performative elements, in anticipation of the tableau process to follow. When the group focuses on creating a story, a collective–creative process of performance tableau and photography results in iconic images that are then assembled in a comic book–style sequence. Just as the details of pose and point of view are part of the visual negotiation, the sequencing of the images and the addition of dialogue each represents significant data analysis and manipulation.

As visual-literary forms, *fotonovela*, *photoroman*, or *fotoromanzi* (now commonly, and perhaps problematically, anglicized as photonovella in the academic literature) have a number of unique advantages that have proven very useful for researchers interested in gathering, analyzing, and dispersing complex narrative data in collaboration with diverse communities of participants. Participant-driven, image-based research has demonstrated the power of the camera as a tool for gathering and representing the complexity of research participants' visual culture.

Arts-based research involving both individual and collective visual and performance-oriented creation are demonstrating the power of expressive media in

Excerpt from Mahamad's First Day in a Canadian School. This frame is selected from a 3-frame story created by immigrant and refugee children in which they combined performance, tableaux photography, digital manipulations and narrative text in cartoon balloons, to represent their memories of their first day in a North American school.

supporting research participants in getting at and sharing important stories in a research context. The burgeoning access to more localized publication and distribution of findings is revolutionizing research both in terms of the input that research participants can have in that important final stage of the process, and also in terms of complex reconceptualizations of what counts as the significance and impact of an academic's work. Particularly when all of the digital technologies for gathering, creatively manipulating, and publishing and distributing of data are involved, the photonovella and photovoice forms represent a significant converging of contemporary methodological research opportunities.

Photovoice

The term *photovoice* was coined in the mid 1990s and institutionalized more or less simultaneously by several individuals who have each developed support

organizations in the past 10 years. It has links to a tradition of engaged journalism and social action that can be traced back to the beginnings of photography. Documentary and poster work on child labor from the 1880s are early examples of this sort of documentary with social purpose. Technological advances that simplified both photography and the mass publication of images have led to expanded use of photographs in both journalism and social science research since the 1920s and 1930s. By the 1960s, these approaches had evolved and converged to the point that visual anthropology and visual sociology were each recognized (if somewhat marginalized) members of the academic community.

PhotoVoice (PV) as an organization based in England is specifically a blending of ethnographic method and journalism aimed at supporting the active pursuit of social justice through the support of individuals and institutional projects incorporating participant-generated photographs. These projects can result in richly visual documentation and journalism. The approach can result in exhibitions with socially engaged themes. It also provides visual resources to the participants for use in their own protest or policy-making. Additionally, this approach generates funds that support the individual photographers as well as the PV organization by combining a structure that is part photographer's cooperative image-marketing agency and part social justice NGO (nongovernmental organization).

PV as an organization based in the United States is strongly identified with public health research and community-level inquiry. In this context, photovoice is presented explicitly as a research method with strong ties to action research informed by feminist concerns about representation and process. Although the U.S. organization also emphasizes the active involvement of the participants because its secondary attention is to institutions and an academic audience, there is much more focus on human subjects research methodology. The method articulates approaches to research question development, refinement, and data analysis that is based in participant developed visual data and research process. Both organizations are actively involved in exhibition as a significant form of dissemination, but the U.S. approach to photovoice directs its resources toward scholarly publication and the not-for-profit academic press while the British organization is linked to news agencies, mass media,

and more of an ethical commerce or fair trade model of exchange.

PILOT STUDY

A pilot study is a small-scale implementation of a larger study or of part of a larger study. Pilot studies last for shorter amounts of time and usually involve a smaller number of participants, sites, or organizations. Though traditionally associated with quantitative experimental design, pilot studies can be used in any methodological setting, especially when attempting to collect data in a new format or location or to simply examine potential roadblocks before full implementation.

A pilot study may also be viewed as a feasibility study. A feasibility study is completed to determine if the full study can be accomplished. Feasibility studies are practical when there is concern that a full-scale study may not be possible due to concerns about cost, procedures, personnel, and other issues.

Pilot studies are not simply exploratory in nature. They are designed with a clear purpose of developing some conclusions and pushing an area of research or foreshadowed problem where reformulation or the generation of other researchable questions can occur. Therefore, pilot studies should have a sound methodology before initiation.

Certain quantitative and qualitative studies have similar concerns related to sample, data collection procedures, instruments and artifacts, and data storage. The pilot study may assist in determining which type of site or sites to investigate. It answers the basic question, "Which sites are available, appropriate, and useful?" A researcher can examine and test a given type of site for inclusion in the larger study. In educational research, an example is determining which elementary school classrooms appear appropriate for examining interactive video conferencing.

The sample of interviewees or participants of interest can also be examined. The pilot study allows the researcher to practice mapping the field to locate types of individuals of interest for the later study. It helps to answer the question, "Who should I talk to or observe to get the information I desire?" In reference to the videoconference example, as the pilot study occurs, the researcher decides to interview children based on their level of engagement in the conference and employ a maximum variation sample.

Sample studies also have the added benefit of allowing the researcher to practice face-to-face interactions with the participants in order to develop interview skills and determine potential problems, such as a high mobility rate among the participants, which would decrease the possibility of a prolonged interview window. Sample studies allow the researcher to develop clear procedures for determining which individuals should be included in the study and which should not. This ability is important because the cost and time involved in determining and collecting a sample of participants can be prohibitive.

Data collection involves the actual procedures for data collection, instrument use, or equipment use, to name a few. Procedurally, a pilot study can help answer questions such as (1) how many times will interaction or contact with the participants be needed; (2) how long will these interactions take if it runs smoothly or if it does not; (3) how many interviews or observations appear to be realistic; (4) what are issues regarding ethics, anonymity, and so on of these interactions; and (5) are multiple data collectors needed and will they all need to be trained and then examined to see if they can collect the data properly? As the amount of data desired, length of the study, and type of sample increase, the need to examine and test data collection procedures becomes paramount. For example, after running a pilot study in two video conferencing

classrooms and collecting fieldnotes on interactions and behaviors, the researcher realizes that a yearlong data collection model is too enormous, the data are overwhelming, and a second researcher is required.

The instruments or artifacts for the study may be surveys, interview protocols, interview notes, fieldnotes, audio- and videorecordings, historical or other documents, and so on. Each type of instrument, document, or artifact has unique characteristics related to data collection; therefore the need to refine the data collection with reference to the types of data is important.

Pilot studies provide the opportunity to examine adjustments or alternatives. For example, some open-ended questions in a survey may be reformatted to a yes or no response. A pilot study can also help determine the types of wording or questioning techniques that will provide rich responses and those that do not. It can also help determine easier techniques for collecting field observation notes. The number of documents needed from an organization could be reduced because the problem area or research question was refined during the pilot study.

The data collected can be extensive and difficult to incorporate and store into useable formats for later description, analysis, and interpretation. If the collected data is to be input into a database system such as Excel, NVivo, or Altria, it will have to be coded by hand or electronically and then checked for accuracy. Data completed on bubble sheets are notoriously read into databases incorrectly. A pilot study will allow the examination of the types of problems, costs, and time needed to properly manage and organize, describe, analyze, and interpret the collected data. In addition, the examination of the data from the pilot study can help determine if other interviews, documents, or artifacts must be collected in the full study.

Design-based research or design experiment studies may be a bridge between pilot studies and full-scale studies and are more closely aligned with qualitative research than the name appears. The focus is the understanding of complexity in educational settings, that is, messy environments, yet allowing flexible design revisions during the study. In essence, this type of design allows for the examination of many of the key components for which a pilot study has traditionally been used.

PLACE/SPACE IN QUALITATIVE RESEARCH

Although philosophers and scientists have long offered explanations and theories as to the nature of space and place, it is in the social sciences where particular ways of understanding and interpreting space and place have been centrally and practically implicated in empirical research, and hence, used to understand the multiple ways of viewing and explaining the social world. All social science disciplines engage to some extent with space and place, even if not always explicitly. Indeed, most empirical research into human life is based somewhere and at some scale, and these spatial contexts have varying degrees of importance and are accorded varying degrees of priority. Frequently, in sociological, anthropological, economic, or psychological studies, for example, a country, region, city, town, neighborhood, or settings for working and living in will be an important part of the overall inquiry and questions asked. Studies might refer to space and place as broad-brush macroscale classifications such as developing world, coastal, rural or urban, South East, Deep South, or forested, or studies might use microscale classifications such as clinical environments, schools, factories, or homes that equally imply some sort of spatial parameters. Studies might simply describe these physical borders of the research, or they might go farther and develop and convey a feel for a location and its layout, for example, in describing a town or workplace, and analyze the human activity therein.

Certain academic disciplines have strong connections to and traditional uses of space and place, including environmental psychology, architecture, and urban planning. It is, however, in the discipline of human geography where space and place have perhaps been brought most significantly to the forefront, the discipline by definition being concerned with the spatial organization and character of human life. In this sense, space and place have been elevated to a central position in geographical analysis and explanation, and the theoretical wing of human geography has debated very directly and identified over time what space and place are. Beginning in the late 1950s, the quantitative revolution in human geography focused geographical analysis at the macroscale, often at the regional or national level. The era of spatial science reduced space to little more than a featureless, characterless void on which the geometry of aggregate human activity was mathematically mapped, modeled, and predicted. The aim was ultimately to look for order in the social world—locational models of industry and concentric ring models of urban land use being popular recognizable examples. In these research endeavors, places were represented as little more than locations or points between which distances (spaces) were calculated. Fueled by emerging computer technology, this remained the dominant mode of inquiry in human geography until the 1970s, when humanistic and Marxist geographers began to present a wide-ranging critique that include the following observations: (a) In looking collectively at populations for sameness, spatial science was blind to human diversity and character. (b) People do not conform to rational predictive models that disguise human individuality and unpredictability. (c) Spatial science had become an exercise in mapping for mapping's sake. In other words, a spatial fetishism had led to space being privileged above all other relational features of social and economic life and being given a distinct reality in its own right. (d) Little or no attention was given in spatial science to explaining social processes, such as those relating to gender and class, beyond their abstract spatial patterning.

Emerging from these critiques, deeper understandings of societal behavior and processes were sought by humanists and Marxists. The investigation of space, hence, changed from its mathematical properties (and how they might be influential or overcome) to how different human practices create space and place. Developing these ideas, the rapid emergence of qualitative methods in human geography introduced

new ways of understanding and investigating space and place, ways that recognize them as having social and cultural character far beyond any physical attributes. These understandings have been adopted by qualitative researchers from other social science disciplines. Although space and place are inextricably linked, below they are considered individually.

Place

In contemporary qualitative research, place is thought of as a bounded phenomenon—ranging from the scale of regions to buildings—but within which and with which social and psychological relations are formed. Leading the debate in the 1970s, leading humanists Ted Relph and Yi Fu Tuan drew from phenomenology and introduced the idea of sense of place, referring to attachments to and the symbolic qualities of places. Indeed, a sense of place is thought to be an outcome of psychological, social processes that create individual and collective relations with physical locales. These processes may involve interaction through physical copresence or occupation (either short or long term), or indirectly through access to various forms of representation (such as in popular media).

The result of these processes is that places can have many qualities for humans and evoke a range of emotions from the personally very positive (happiness, healing, therapeutic, nostalgic) to the personally very negative (fear, anxiety, sadness, grief). Places can be sites of struggle or unity as people regard or use places similarly or differently or use them to support and play out their agenda. Such battle lines, hence, could be ideological (left wing vs. right wing political orientation), social and cultural (gay vs. homophobic, male vs. female) demographic (old vs. young), economic (corporate vs. public), or professional (nurses vs. doctors), and dominant groups might exclude or disadvantage other groups (insiders vs. outsiders). In the latter case, knowing one's place becomes an important issue as minority transgressors of prosocial norms (e.g., homeless, travelers, protesters) hold alternative ideas about and alternative uses of places. Conversely, placelessness is an important concept for describing particular social phenomenon. Referring to a lack of traditional attachments and identities to one or any place, it particularly helps explain human relations with and within the growing number of transient and in-between places in society, such as highway or motorway service stations, hotels, and airports.

Since the late 1980s, the cultural turn in social science—and in particular human geography—has impacted significantly on understandings of place. Research has become increasingly concerned with how places are constructed by culture (how dominant cultural activities and identities lead to different place experiences and identity) and how cultures are constructed by places (how places are venues for cultural expression, effectively representing culture). Developing humanistic ideas, three theoretical and philosophical traditions have been drawn on to articulate how this construction occurs. First, as the cultural geographer Mike Crang has outlined, Edmund Husserl's ideas on intentionality emphasize an object's intended use as being part of its overall meaning (objects are thus about things). By extension, places are thought to similarly involve human intention and to be about things. Second, philosophical debates suggest that essences are the many characteristics that define objects and by extension, places. Finally, Martin Heidegger's idea of imbedded knowledge suggested that consciousness is always being consciousness of something else in the world and all knowledge then is necessarily place related. Based on these ideas, the list of cultures and places currently considered by geographers and others is considerable, including art, music and film, history and landscape, consumer trends, workplaces, ethnicity, and empire. Indeed, inquiry spans almost the full range of social life.

Space

Contemporary ideas on space draw equally from the same disciplinary, theoretical, and philosophical ideas as those on place. Practically, in qualitative research, space is not regarded as absolute and a void or distance to be measured or crossed, but is understood as relative, coming into existence because of social processes and phenomena. Hence, in qualitative research, questions on space are becoming centered around how space is produced and navigated differently by different people (men, women, older people). Although spaces exist at multiple scales, when talking about spaces, social scientists are typically referring to the social spaces within and that make up places, for example, spaces within a city, town, or building. These kinds of propositions have often drawn on social theory to inform them, Michel Foucault and Henri Lefebvre being major sources of inspiration for geographers and sociologists alike. Foucault's work in particular has helped shed light on the institutional production of space—how

space, through its surveillance and other regulation, is an essential ingredient in both the institutional exercising of power and how it is navigated by various forms of resistance. Although the negotiation of space, and spaces in conflict, has long been a priority for qualitative researchers (e.g., in researching experiences of ageing, disability), most recently spaces in everyday life have become a focus of attention. These are not just special, problematic, or rare negotiations, but are typical. Here then lies an attention in qualitative research to the rhythm of everyday life and spatial and cultural practices such as shopping and socializing that are important in people's lives.

A Changing World to Study

Radical developments and changes in society have forced serious reconsideration of both space and place in research, both in terms of what they are and what significance they have for research. Cyberspace, for example, is considered by some to be structured by its own spaces and places, which impact on traditional physical spaces and places. Scholars observe that people increasingly immerse themselves in cyberspace as they surf and navigate the web, visit websites, and spend time communicating and interacting. Another contemporary challenge has been globalization. The world is increasingly linked and seemingly place uniqueness disappears; for example, McDonald's is found everywhere, shopping malls all look the same, people do the same types of things the world over. Moreover, society is increasingly interdependent—socially, culturally, and economically—and interresponsible. These are, of course, sociological and economic questions, though they are highly spatial. Commentators realize that globalization and the internet do not mean the death of distance or the end of geography, but opportunities to explore new places and spatial relationships. More generally, the postmodern condition has changed the nature of social and economic life—its space and places—and the way in which researchers have sought to understand it. Here then lies an attention in spatial research to the local, specific, unique, while researchers have been less willing to look for grand theories and seek universal meta-narratives and explanations for life.

Disciplines

In terms of disciplines, the cultural turn in human geography has infused a cultural sensitivity across many of its subdisciplines, whether they be empirically

based around human activity (health geography, transport geography), geographically distinct (urban geography, rural geography), or based around societal relations (feminist geography, economic geography). However, beyond human geography, a spatial turn and a cultural turn in other social sciences have been closely linked. The emerging sociology of place, for example, emphasizes the role of space and place in key sociological debates on inequality, difference, power, policy, community, organizations, movements, identity, and memory. Sociology's many subdisciplines have also been affected. As one possible example among many, the spatial turn in sports sociology can be traced back to the early 1990s. In this specialist field of research, greater attention is being paid to the social production of sports spaces and places and the social relations within sports places and places in terms of struggle and identity. Indeed, rather than defining the body through sports spaces, attention is being paid to how different bodies create or produce sports spaces. Meanwhile, in the health sciences, a spatial turn in qualitative nursing research can be traced back almost 10 years and helps these professional researchers understand the persistent structural and financial reform of traditional institutional sites and settings such as hospitals (changes in places); the increasing diversity in the distribution and type of service provision, including community-based settings (changes between places); and emerging physical and narrative remoteness between nurses and patients (changes within places). New geographies of nursing have provided a clear understanding of how the job category of nurse and the numerous activities involved in nursing relate dynamically to places, including how the social dynamics of places impact working experiences and activities, how places characterize particular professional specialties, and how places provide attachments, symbolism, and identity that are embedded in their everyday clinical activities. Obviously, sports sociology and nursing research are two very specialized examples, and many other spatial turns have affected many other fields of inquiry.

Methods

In terms of methods used in unpacking space and place, the range used does not vary significantly from that used throughout the social sciences. Observational methods of various types, interviews, focus groups, and document analysis are all viable approaches to unpacking space and place, used independently or in

combination. The difference, however, from nonspatial research is subtle in the things that these methods seek to find and record. These differences might include attention to investigating spatial movement and inter-relation movement between people and objects—for example, investigation of attachment and identity to place, investigation of cultural artifacts or historical or policy documentation pertaining to past places.

One example of a method tailor made to unpack space and place is that developed by Lisa Given and Gloria Leckie in their recent study of social activity and public libraries. The authors developed an observational method for assessing how individuals use and think about the academic library and other campus spaces. This method was combined with qualitative interviews and digital photos to assess the effect of space on students' academic lives. The findings indicate design and planning changes to enhance libraries as vibrant public spaces.

Academics and Their Research

Given the many thousands of professional human geographers employed in universities throughout the world, together with the large numbers of other social scientists and theorists whose work engages with space and place, any overview of researchers and their projects or interests will be incomplete. Nevertheless, to illuminate the character of this research, it is possible to provide three names, their disciplinary backgrounds, and an example of their research interests.

The British cultural geographer Phil Crang published a paper in the mid 1990s titled "It's Showtime" that is now somewhat of a modern disciplinary classic in his discipline. Demonstrating that economic geography does not have to be undertaken at the scale of regions, industries, and workforces, Crang's study mapped the sociospatial features of a workplace through an ethnographic (participant observation) study of waiting work in a restaurant based in South East England. The workers in Crang's study performed in front-public spaces, ultimately for their own financial gain (i.e., through short-term tips and long-term promotion). At times, however, the workers hid in private back spaces or even masqueraded (appearing to be doing something work orientated while not) in order to avoid work. The popularity and wider relevancy of Crang's study is its articulation of everyday geographies of work at the scale of rooms, scales many would recognize to be as part of their own working lives. On a theoretical level, the study demonstrated that, despite

considerable workplace regulation and surveillance, workers are not passive, powerless, and disenfranchised in the face of corporate power.

In 2000, two health geographers in New Zealand, Robin Kearns and Ross Barnett, published a groundbreaking paper titled "Happy Meals in the Starship Enterprise." Starship is a children's hospital located in Auckland (already with an obvious iconographic and commercial name) that was the site of controversy when a proposal was unveiled to open a McDonald's restaurant within its atrium. Through interviews with hospital management and data collected from media coverage and advertising, the authors analyzed the competing views and interests. These were broadly along the lines of those who believed that the hospital should provide a slice of real life for children and also facilitate commercial enterprise and those who believed that it is wrong to feed "bad" food to sick kids. The study demonstrated how hospital spaces are becoming economically and morally contested and also, in terms of globalization, Americanized.

Canada-based British health geographer Gavin J. Andrews and British sports sociologists Mark Sudwell and Andrew Sparkes published a novel paper in 2005 titled "The Gym in British Bodybuilding Culture." Through an ethnographic study of a gym (including participant observations and interviews conducted by Sudwell), the authors investigated how bodybuilding culture and place are coproduced. The participants in their study used the gym as a narrative resource to learn and advance, while it also acted as a crucial setting for identity, community, and hierarchies. Importantly, the gym also included its own internal spaces and spatial routines connected with rules and rituals that reinforced and reproduced bodybuilding culture. Meanwhile, the authors also studied perceptions and use of public space outside the gym by those with bodybuilding bodies and attitudes. From a disciplinary standpoint, the authors used the example to argue that geographers should study fitness and fitness places.

PLASTIC ARTS IN QUALITATIVE RESEARCH

See ARTS-BASED RESEARCH

PLAYBUILDING

Playbuilding is a process in which a group of researchers or actors uses dramatic techniques in all stages of the research process. It has a unique method of performance generation and style of production that differs from a variety of existing theatrical research presentations including readers theater and ethnodrama. Robert Donmoyer and June Yennie-Donmoyer translate traditionally collected data into a readers theater format that is usually performed live. In this theatrical genre, a narrator reads descriptions with analysis and a number of others read edited verbatim transcriptions from research participants.

Ethnodrama employs more theatrical techniques than readers theater. Matt Myer uses staged readings with minimalist sets to present research findings. Jim Mienczakowski and Johnny Saldaña's productions contain more elaborate dramatic action with the presenters or actors having their lines memorized. All four researchers have strong dramatic backgrounds, and in every case, they adapt traditional qualitative data into theatrical forms of dissemination.

Joe Norris, who also had roots in both theatre and qualitative research, takes a different approach. Using a Canadian theatrical genre called collective creation, more widely known as playbuilding, he integrates theatrical techniques throughout the entire research process of generating, interpreting, and presenting the data. The performed scenes are not adapted from other texts; rather, they are the texts themselves. Norris along with Donmoyer considers scene (readers theater) construction as a simultaneous means of data collection, analysis, and dissemination.

History

Although the origin of the collective creation genre is obscure, perhaps having its roots in the agit-prop theater of the 1920s, Theater Passé Muraille is credited with generating the first major Canadian production. A troupe of actors descended on the small farming community of Clinton, Ontario, interviewed its town folk, and constructed a play about their lives. Although not considered qualitative research at the time, the actors conducted a quasiform of participant observation and interview process with the intent of telling these peoples stories on stage. Alan Filewod has documented theater companies that have followed Theater Passé Muraille's lead.

Those in educational settings, Glenys Berry and Joanne Reinbold, for example, used collective creation as a means of teaching improvisational skills, a variety of dramatic forms, and giving students a voice in their learning. Their productions were often written by the actors or participants about issues that were important to them. Like a focus group, they assembled to examine a specific issue, topic, or theme. Unlike a typical focus group, they used theater as the medium of articulating their own thoughts and meanings as they researched their own lives. The performances were not always structured in a narrative form; rather, they were a series of vignettes presented as variations on the theme. Growing up, substance use, sexuality, suicide, prejudice, and bullying were often topics that were chosen.

Methodology

Norris saw the potential of this approach as a qualitative research methodology and along with his graduate and undergraduate students, formed Mirror Theater, a social issues theater company. A topic was chosen, and the research rehearsals began with the implied question, "What are our lived experiences with this theme, either as participants and/or witnesses?" Gathered in a circle, the actors would begin with personal stories as a means of exploring the range of issues within the topic, getting to know one another, and establishing trust. In addition to the above topics, the politics of student teaching, equality and respect on campus, school life, and the nature of qualitative research were studied. Diane Conrad used a similar methodology to assist at-risk youth in articulating and communicating their stories.

The rehearsal process is an emergent integrated spiral of storytelling, scene construction, scene analysis, discussion, and recording. At the beginning of each rehearsal, actors are provided with blank file cards and markers; during rehearsals and throughout the circle-discussions they would record their thoughts and stories on these cards, articulate them to the group, and place them in the center of the circle. These could be scene ideas, emergent themes, catch phrases, or metaphors. At the end of the rehearsal, the cards are placed in a file folder labeled "To Be Filed." At every third or fourth rehearsal, these cards would be collectively sorted and placed into file folders labeled "Themes/Issues," "Metaphors," "Scene Ideas," "Rehearsed Scenes," "Quick Scenes," "Research," and "Technical Information." The act of sorting enables a review of previously discussed material.

When rehearsal discussions reach a saturation point, potential scenes are identified and the cast members self-select scenes that they would like to work on. The scene construction process can take anywhere from 15 to 30 minutes, after which each group presents their scenes to the entire cast. The scenes are discussed, and other emergent themes and ideas are written on the file cards. At times, these scenes act as evokers, eliciting forgotten stories from the cast members' memories. These are also recorded. A short outline of the scene and who were in it is written out on a sheet of paper and filed as "Rehearsed Scenes."

These scene constructions have two important elements. First, the scenes are constructed so that they portray the problems and the complexities of the idea. Later, when performed, the audience will be asked to

analyze the scene and make suggestions to improve the presented situations and characters' lives. This process ensures the pedagogic approach that Norman Denzin encourages. In a constructivist manner, the audience joins the cast in understanding the phenomenon. Scenes are constructed to encourage this type of discourse. Second, a variety of dramatic styles is encouraged. One scene could be mimed, another could be a series of frozen pictures or tableaux, and another use percussive instruments to represent the tone of the experience. Norris suggests in "The Use of Drama in Teacher Education: A Call for Embodied Learning" a number of ways to generate and present dramatic material.

In the production "Warts and Beauty Marks," data were generated by having the cast members participate in a guided imagery to recall their experiences from the first day of school. In small groups, they retold their memories. Each group was instructed to create a composite scene—one using mime to tell a day in the life, another using mime but with an added narrator, a third was a slide show of tableaux on the day's events, and a fourth was a slide show on a common theme. All scenes were recorded, but not all were polished into performance quality. Since many scenes do not make it to the final presentation, polishing at this time is considered inefficient. In this case, a composite scene of ideas from all presentations was performed in the final production. One group of actors provided a series of frozen pictures or tableaux of the day's events while others provided typical dialogue and gave the characters' inner dialogues.

These rigorous research rehearsals usually go on for approximately ten 3-hour sessions until a saturation point is reached and/or a deadline is looming. The scene construction is considered data generation, albeit immediately translated into a performance piece. The underpinning belief is that any data collection device, including questionnaires and interviews, does not record but constructs meanings. Creating scenes and eliciting memories through drama is a different but a no less valuable way of creating understandings than more traditional means. Anna Banks and Stephen Banks claim that any research that denies its literary elements, denies itself. The playbuilding genre recognizes that its processes structurally frame knowledge. This framing is true of all research, including ANOVAs and *t* tests that represent opinions and behaviors as numbers and manipulate them mathematically.

The process then narrows with the question, "Based upon our conversations and scenes, what do we want our play to be about?" This process is similar to the

What's the Fine Line?

This picture is taken from the scene "What's the Fine Line" in the play with the same title. It employs a form of gibberish in which the only word used by both actors is the word "no." It demonstrates how variations in body language and inflection change the dictionary meaning of the word. This scene toured for a number of years yielding many valuable audience discussions on miscommunication on the part of both senders and receivers.

Female: (Sees boyfriend playing video game and tickles him.)

Male: (Laughing) No.

Female: (Pauses then snuggles next to him.)

Male: (Absorbed by the game responds firmly.) No!

Female: (Dejected stands, walks behind him and covers his eyes.)

Male: (Looses the game and with remorse for his player moans) No. (He faces her and starts to tickle her.)

Female: No. (The scene escalates. . .)

Playbuilding.

seeking of overarching themes in traditional qualitative research. All file folders are reviewed at this time for the selection of dominant themes and scenes. New scenes may be written based upon the themes chosen, and the selected rehearsed scenes are then cast and polished. Performers in the original scenes may not be in the final scene as cast members' priorities vary when the workload is shared. However, all do comment on each scene that their peers present. A spirit of co-authorship is encouraged throughout the process. Once polished, a sequence of themes is chosen, usually with a strong humorous opening and a thought-provoking conclusion. One guiding principle is that the scenes collectively provide a balance of thesis and antithesis, inviting audience members to seek and form synthesis.

Working With an Audience

The playbuilding process concludes with a live performance after which cast and audience members enter into dialogue using popular theater techniques, including those of Augusto Boal. Through forum theater and simultaneous dramaturgy, audience members make suggestions to rework the scenes. At times, audience members confirm the scenes as representing

their lives, and at other times they provide new scenes. A scene from Mirror Theater's "One of These Things Is Not Like the Other" examined how the song taught exclusion by removing difference. During their tour of *Fair Play Rulz* that included this scene, some audience members reported that this song was sung to them by peers and siblings as an act of exclusion, confirming the validity of the scene. A remount of Mirror Theater's show *What's the Fine Line?* contained a scene provided by a previous audience. Junior high students co-created a scene on how sexism was made manifest in coed inclusionary sport.

Working with an audience continues the research spiral by confirming and adding scenes. It is a dialogic element that acts as a continuous research renewal process. Playbuilding as a research method creates a spiral of data generation and data presentation in a metaphorical manner that invites audience participation. The participants co-create the product with the researchers or actors, making playbuilding a form of participatory research.

PLURALISM

Theoretical pluralism occurs whenever qualitative researchers draw on more than a single theory as a theoretical framework to guide decisions about the research design and to make sense of their research findings. In this entry, the nature, rationale for, benefits, and risks of theoretical pluralism in qualitative research are illustrated by identifying the limits of single theory research and by highlighting the potential contributions of theoretical pluralism. In addition, the entry highlights some of the challenges of theoretical pluralism, such as selecting appropriate theories and accounting for differences. Although it is acknowledged that every researcher brings a multitude of

formal and informal, stated and unstated, theories to any research endeavor, for the purposes of this entry, theory refers to formal, published, theories.

The Nature of Pluralism

The goal of theoretical pluralism is not to produce a single theory that explains all aspects and attributes of a phenomenon; rather, it is intended to integrate and organize alternative theoretical perspectives in order to develop a broader perspective about the phenomenon of interest than is possible with a single theory. Theoretical pluralism can be considered as scholarly inquiry because it generates new or expanded theories to explain certain phenomena. It can occur in a variety of ways, but in each case it is intended to provide stronger theoretical support to the research than what is available in a single theoretical perspective.

Rationale for Pluralism

In recent years, researchers have recognized that many of the phenomena they are studying are too complex to be framed within a single theory. For instance, common explanations of race do not sufficiently explain why adolescent suicide is more common in some ethnic groups than in others. Practitioners in a variety of practice fields have long complained that research has lagged behind the advances in practice. One reason for this is that researchers have tended to rely on single theories to explain practice phenomena; these do not accurately reflect the changing realities of practitioners' worlds. Some of the current theories are focused on the individual; these are inadequate to explain multifaceted phenomena, such as health, at a societal or population level. In addition, in most areas of study, there now exists a plethora of theories, each with its own concepts, language, and underlying assumptions, but there is a lack of critical comparison, integration, and synthesis in this body of theory, resulting in conceptual clouding and ambiguity. For example, concepts such as social capital have been obscured because the various theories that represent the concept differ greatly as to whether it is considered an attribute of a community or a person, and there is considerable variation in how it is operationally defined. Finally, there are new areas of study that have previously drawn on generalized theories but are now requiring a more distinct and differentiating theory than what has been previously articulated. These concerns have given rise to the need for theoretical pluralism.

Forms of Pluralism

The most common form of theoretical pluralism is when theories that pertain to a common phenomenon are blended together to form a single theoretical framework. For example, three theories of motivation (one that refers to attributions made about ability, another that discusses motivation as a socially constructed phenomenon, and another that proposes that motivation is the result of reinforcements from authority figures) could be used to form a theoretical framework for a study about students' motivation to study for exams. The concepts and constructs of the separate theories could be organized into a single whole; that is, a new theory that incorporates the components of all three theories. Such a study would then include research methods that examined how individual students perceived their academic success or failure, the social and contextual influences in students' motivation, and how teachers' interactions with students reinforced, negated, or fostered students' motivation to study.

Theoretical pluralism can also occur as separate stages in qualitative research; that is, the same research questions are asked in each stage, but a different theory provides the lens through which the research is designed and interpreted. Pluralism in this approach is most often used to reveal the unique contributions of each theory in explicating the phenomenon under investigation; each theory provides a different angle or lens with which to regard the phenomenon of interest. For example, a researcher could decide to study the experience of widowhood in two stages. In the first stage, a theory of bereavement could be used to frame the study. In the second stage, a theory of transition could be used. After both stages were completed, the researcher could examine the research findings to determine how assuming these different lenses affected the portrayal of the experience of widowhood. Reflecting on the implications of the differences and similarities in the research findings of both stages will foster theoretical clarity and at times lead to the development of new theory that incorporates the research findings and the foundational theories.

The Selection of Theories

Theories that are used to form a pluralist theoretical perspective in qualitative research should be mutually informative about the situation, behaviors, or experience that is under investigation. Together, they should provide a way to organize the research so that it

incorporates a broader theoretical perspective than that provided by a single theory. Ideally, each theory should illuminate the phenomenon from a different angle or with a different lens. For example, stigma theory may contribute to the design of research that focuses on why someone who is mentally ill perceives discrimination in health care, but theories of organizational culture may explain why it is that such discrimination occurs most often in hospital emergency departments. Although most formal theories lend themselves to theoretically pluralist research, the qualitative researcher might consider using theories that emerge from the findings of other qualitative research studies, such as those that emerge from grounded theory research.

Selecting the theories to frame the research requires that they fit the research question(s) and that they permit a broad investigation of relevant concepts. The selection of theories in pluralist research is a partisan choice and a political process. It is often based on the researchers' experience with the theories and on their personal sensibilities. This decision is also affected by researchers' beliefs about the fit of the theory to their understanding of the phenomena they are studying and their attitudes about the credibility and popularity of the theory in their field of study. Few graduate students, for example, choose a theoretical framework for their thesis that has been highly criticized or discounted in the literature as lacking scholarly integrity.

Qualitative researchers should consider asking the following questions in selecting theories for pluralist research:

- Is there an appropriate fit between the theory and the research problem, aims, and context of the research?
- What is the likelihood that using the theory will lead to new insights?
- How much work and cost (in terms of money, time, and energy) will incorporating the theory into methodologies require?
- How well does the researcher understand and feel comfortable with the theory? If the researcher is not familiar with the theory, is there a readily available resource to teach him or her about the theory?

Benefits of Pluralism

The benefits of theoretical pluralism include that it can lead to theory development, expansion, and/or clarification; it can foster researcher consciousness;

and it supports the aims and processes of interdisciplinary research.

Contributions to Theory

One of the basic assumptions underlying theoretical pluralism in qualitative research is that no theory offers in itself a complete picture of any phenomenon. A pluralist approach can enable qualitative researchers to address the limits of a single theory by supplementing it with other theories that focus on elements that have been excluded or overlooked in that theory. For example, theories that concentrate on the individual may not include aspects of the broader context that influences the individual's responses and behavior. Conversely, theories that examine phenomena from a macro perspective are likely to overlook how people's understanding and experience of social phenomena influences how they act in particular contexts. Because social phenomena usually entail a combination of individual, societal, and other factors, in-depth explications of these phenomena cannot be limited to a single perspective. Consequently, research that draws on both micro and macro theories can provide a portrayal of the phenomenon under investigation that acknowledges both the complexity and the contextual basis of human behavior. Such research is critical to the development of theory that incorporates the complex and multidimensional nature of many of the phenomena researchers study.

Theoretical pluralism can lead to new insights about the phenomenon under study and ultimately to revisions and improvements in the theory. For example, a researcher may use particular practice theories to frame research about the medication errors in hospitals; however, the research findings may suggest elements of this phenomenon that the theories do not address, such as how medication errors were handled in the health care practitioners' basic education program. Several advances in theories, such as theories about stigma and racism, have been prompted in just this way.

One of the benefits of theoretical pluralism is that it provides a basis for cross-theoretical comparisons in their application to the study of various phenomena. It brings theories into relationship with one another, establishing their connections and highlighting their differences. In most areas of investigation, there exists an abundance of models or theories explaining the phenomenon of interest. Often, these hold competing perspectives on the research topic. Theoretical pluralism provides a forum for a comparative

assessment of theories and consequently promotes the development of new or expanded theories

Theoretical pluralism can also provide a unifying framework for theoretical concepts that are often used in research but are not sufficiently clear to guide research. For example, in community-based research, concepts such as empowerment, partnership, or community are commonly used as theoretical frames to justify including representatives of the community in all facets of the research; however, the relationship between these concepts is unclear. Research that used all three theories might make this relationship transparent.

Contributions to the Researcher

Theoretical pluralism can lead researchers to become theoretically conscious. It contributes to researchers' consciousness by helping researchers acknowledge competing theories and the limitations of any single theoretical perspective. It requires that researchers learn new paradigmatic and theoretical languages, as well as the social and political aspects of theories. Researchers adopting a pluralist approach must be prepared to entertain new ways of thinking about the phenomena they are studying.

Harry Wolcott advises qualitative researchers to entertain theories as they do ideas in their research projects; he suggests that such a process will lead to a significant personal and academic transformation. The reflexivity that is required for researchers to select theories outside of their usual theory base fosters a deepening of the researchers' capacity to recognize their ethnocentric views in relation to theoretical perspectives and to acknowledge that they have certain ways of avoiding or discounting theory that appears at first glance to be contrary to those perspectives.

A theory is a way of making sense of a phenomenon, and it provides a lens through which researchers can understand and explain that phenomenon. Unfortunately, once researchers have learned a theory as one way of interpreting a phenomenon, they often are hard pressed to see the phenomenon in any other way. Theoretical pluralism helps qualitative researchers to move outside of the theories they know and to open their minds to new ways of seeing the phenomenon—that is, new theories. In addition, theories move in and out of fashion. Some theories that were once touted as insightful and explanatory are now in obscurity. Theoretical pluralism allows researchers to move beyond allegiance to a single theory as the "best" and to view each theory as having a distinct contribution to make to the field of study.

Contributions to Interdisciplinary Research

Pluralism both contributes to interdisciplinarity in qualitative research and is congruent with the tenets of interdisciplinary research. In practice, the theoretical frame of qualitative research is often selected on the basis of what the researcher views as common sense, trendy, familiar, and pragmatic. Although it is possible to draw on theories from one's own discipline in qualitative research, true theoretical pluralism requires researchers to move beyond their comfort zones to consider theories in other disciplines and/or other fields of study. As such, theoretical pluralism is in keeping with interdisciplinary research because it reflects a commitment to move beyond silos of knowledge. This move can lead to the development of theories that are alternatives to those that currently dominate any discipline. For example, researchers in the field of chronic illness typically use trajectory or transition theories to frame research about how people with chronic illness change in their response to the disease over time. Theories from other fields that might have equal relevance (e.g., transformational learning from education) are often overlooked because the researcher does not know about them and/or is unwilling to entertain them.

Unfortunately, researchers tend to stick to the theories they know and have learned within their own discipline or field of study. A broad systematic search of interdisciplinary literature can be a first step in locating unfamiliar theories. Another important step is to consult with those who are more familiar with the theory. One benefit of interdisciplinary research is that the researchers are likely to know a myriad of theories that they can draw upon for pluralist research.

Challenges of Pluralism

There are significant challenges to the enactment of theoretical pluralism in qualitative research. These include too much pluralism, too much or too little difference, the lack of standards of rigor in theoretical selection and in the application of theoretical pluralism in the research, and the lack of receptivity of others toward pluralist approaches.

The Amount of Pluralism

There is a risk that theoretical pluralism will be considered as the panacea for all qualitative research. Qualitative researchers should consider, however, that

there is a danger of including too many theories in any one research study and that not all research requires a pluralist approach. More is not necessarily better, particularly if the theories do not contribute in a significant way to the understanding of the phenomenon under investigation. An eclectic synthesis of too many theories can result in overly complex research designs and a superficial treatment of the phenomenon under investigation, as well as can tax the researcher, who attempts to design the study in a way that is methodologically congruent with all the theories.

A pluralist theoretical framework should function as a closet organizer, permitting the researcher to organize the theoretical concepts and constructs so that the research objectives are achieved. If it results in making undue work for the researcher by unnecessarily complicating the research process and blurring the phenomenon under investigation, it is possible that the inclusion of theories has been too ambitious, and the researcher should select fewer theories that are complementary to the research goals.

The Amount of Difference

There are varying notions about the level of difference and similarity between the theories that should exist in a pluralist approach to qualitative research. One school of thought is that the theories should share similar paradigmatic, epistemological, and ontological assumptions, and these in turn should be congruent with the methodology the researcher has selected. These authors argue that selecting theories that differ too much (e.g., with competing paradigms) will result in overly inclusive research in which the researcher is unable to effectively organize the theories into a coherent whole. Others propose that pluralist researchers should deliberately select theories that differ because it is in the differences that new theoretical insights lie. For example, research that has a modernist approach will differ in its philosophical and epistemological assumptions from one that has a post-modernist paradigm; however, blending the two in one study can permit the research to tap into insights that might be invisible in a monoparadigmatic approach to qualitative research.

Receptivity to Pluralism

A criticism of pluralism is that theoretical pluralism will produce a soft and mushy science that

contributes little to understanding particular phenomena. Although a growing number of qualitative researchers are exploring theoretical pluralism as a way of generating new theoretical developments and insights, not all researchers will share the view that such research has a place as scholarly inquiry.

Pluralism can threaten the traditions and conventions of disciplinary or academic cultures. Many researchers have been socialized to believe that their research will have more legitimacy and credibility if they become experts in particular lines of inquiry, using a single theoretical perspective. Consequently, reviewers of research proposals that propose theoretical pluralism may perceive the research to be unscholarly or lacking in scientific integrity.

Qualitative researchers who use theoretical pluralism in their research should account for the role of the various theories in their research. Researchers who adopt a pluralist approach should make clear in manuscripts and proposals why they chose such an approach, how it was enacted, how they dealt with any contradictions that exist between the theories, and how a pluralist approach has or will contribute to the investigation in a way that extends the benefits of a single theoretical perspective.

POETRY IN QUALITATIVE RESEARCH

Poetry in qualitative inquiry refers to the use of poetry written by participants and/or by researchers themselves through all stages of research. For example, scholars in the field known as *ethnopoetics* have studied verbal arts from around the world, transcribing poetic traditions and analyzing texts and performances, particularly those borne among Indigenous communities. Other poetic scholarship draws on elements of poetic craft such as meter, rhyme, form, image, and metaphor as interpretive tools for analyzing qualitative data, for example, thinking through provocative metaphors and similes to describe a piece of discourse or observed event. Perhaps the most overtly poetic activity qualitative researchers engage in is their own written poetry based on experiences during data collection and analysis. Qualitative inquirers are more likely now than ever before to find research about poetry and/or research that includes data poems in scholarly journals and books. Poetry offers scholars a means to say what might not otherwise be said, creating a more engaging and passionate form of social science.

Despite a long tradition of figurative language and poetic representation in all types of scientific research to express novelty, such as the clockwork metaphor for the solar system and the pump metaphor for the heart, qualitative researchers in general and ethnographers in particular have been the most avid and publicly reflexive about using poetry and other expressive forms in research. However, despite many qualitative researchers who are advocates and public users of poetic research methods, there is still very little written about how this approach takes place and the specific techniques used by poet-researchers. Scholarship that merges qualitative inquiry with poetry is still emerging, and there are many questions regarding poetic craft and its applications and use as researchers develop theories and heuristics for qualitative understanding. What possibilities does poetry offer for data collection, analysis, and presentation, and what impact might poetic scholarship have on the public and political community at large?

Poetry and Qualitative Research

Poets often refer to visits from the muse and her ability to see truth before the writer sees it. However, most

Ghetto Teachers' Apology

I'm afraid, sweet Wilmarie, we've lied.
 We didn't teach you how to hide
 your Rite Aid salary from Wel-
 fare in a Dominican bank. We didn't tell
 you how to find a roommate or put a lock
 on your bedroom door or how to walk
 after sundown by yourself, how to slouch
 at your brother's funeral, patched
 bullet holes in an open casket in your living room.
 We never told you,
 like your boss, you can't speak English,
 or like your cousin, you can't speak Spanish.

We didn't tell you how to live on
 \$5.50 an hour or that at seven-
 teen you'd be an orphan. We didn't want to sour
 our hopes and fictions, we wanted you to flower,
 and prove us wrong. Sweet Wilmarie,
 we're sorry.

We didn't live on your side of town
 between crack houses and crackdowns.

We're not like you, we didn't know how to survive
 behind shatter proof glass with those pretty brown
 eyes.

Melisa Cahnmann-Taylor

writers will also agree they are much more active in the creation process than this romantic image suggests. Below I describe some of the devices poets use to sustain and fortify their original impulses that have also been useful to qualitative researchers. Though not an exhaustive list, I highlight central devices such as meter, rhyme, form, image, and metaphor that make important contributions to a qualitative researcher's interpretive frame and presentation.

Rhythm and Form

First and foremost to any poet and valuable to the qualitative researcher's craft is a heightened sense of language, from the sounds of phonemes, prosody, tone to syntactical structures of word order to the way phrases and sentences are ordered to create images, meanings, logic, and narrative. Though many poets have broken free from the strict confines of sonnets and villanelles from the past, elements of formal craft such as meter, rhyme, and repetition appear in the work of most free verse poets from Walt Whitman to Gertrude Stein to Allen Ginsberg. Formal elements of craft are critical to all poets because their existence offers the writer techniques to play with for greater effect.

Meter, Greek for measure, is a term used to describe the patterns of stressed and unstressed syllables in a line. For example, *cre-áte* and *in-spíre* are iambic words because they have unstressed syllables followed by stressed ones (often represented as "U/"), making up what is called a *foot*. Thus, Shakespearean iambic pentameter (five iambic feet) is often rhythmically associated with the *daDum daDum daDum* we hear in a heartbeat, for example, such as in the following line from *Hamlet*, "Or thát the Éverlásting hád not fíx'd/His cánon gáinst self-sláughter! Ó God! Gód!"

Qualitative researchers such as discourse analysts and microethnographers have a tradition of analyzing speech for its rhythm and meter, pitch, and tone. Experience in the study of sound patterns in music and poetry may allow researchers to develop what poet Richard Hugo called "obsessive ears," enhancing our ability to notice, name, and make sense of both regularities and irregularities in the stress patterns of everyday speech in research settings. Poetic interpretations of participant speech fall within a tradition of qualitative scholarship that recognizes the relationship between different ways of talking and social identity, equity, and access to cultural, linguistic, and educational capital.

In addition to assisting analysis, the study of written poetry forms may enhance a researcher's presentation of recorded data, building on previous transcription conventions to best represent the authenticity and dimensionality of an observed interaction. A researcher who is exposed to various poetic approaches to line breaks can exploit the possibilities to control representation and effect. For example,

poets work alternatively with end stop lines, lines that end with a period, comma, or semicolon, or with enjambment where one line runs into the next. Researchers too might use end stops, punctuation, white space, and short lines to slow down a transcript and focus visual and auditory attention. Alternatively, a researcher might enjamb lines of a transcript to convey the speed of an interlocutor's contribution and use long overlapping lines to show motion in turn taking. Taking in the many different visual layouts of poems on the page offers researchers new ways to represent interview data that respect the tone and movement of the original conversation in ways that may not yet have been imagined in qualitative research. Poetic researchers pay attention to the rhythms of speech in communities where they carry out inquiry and learn how to adapt that speech to the page so that they learn to ask new questions and use poetic structure to represent and interpret complexity in research settings.

Image and Metaphor

Another shared aspect of craft in poetry and qualitative research is the documentation of everyday details to arrive at concrete universals. Images, anecdotes, phrases, or metaphors that are meaningful are those that keep coming back until the researcher-poet is sure the concrete detail means something more than itself. A poetic approach to inquiry requires what poet Robert Bly refers to as associative leaping, deep images that connect the conscious and unconscious parts of the mind. By taking observation notes both in and away from the field, poetic researchers accept the imagination and the unconscious are vital forces that shape and contribute to research discoveries.

Just as poet William Carlos Williams wrote, "So much depends upon a red wheelbarrow," highlighting the importance of a telling detail, so too good qualitative researchers (e.g., Laurel Richardson, Jane Piirto, Rishma Dunlop, among others) incorporate poetic images and metaphors drawing attention to the rhythms of everyday speech and images of the ordinary, particular, and quotidian. Increasing the use of ordinary language and concrete, resonating images and decreasing the use of academic jargon and theoretical abstraction, we are more likely to communicate intellectual as well as emotional understanding. We may enhance the

visibility and impact of our projects, and with hope, increase our influence on those who lead social change.

Conclusion

All phases of a qualitative research project can benefit from poetic sensibilities. By reading poetry and implementing poetic craft, researchers can enhance their abilities to listen and notice in the field during data collection, creatively play with metaphor and image during analysis, and communicate with more liveliness and accuracy when representing data to larger audiences. A poetic approach to inquiry also understands that writing up research is a part of a critical iterative feedback loop that informs ongoing decision making in the field.

The available traditions for analysis and write up of research are not fixed entities, but a dynamic enterprise that changes within and among generations of scholars and from audience to audience. We cannot lose by acquiring techniques employed by poetic researchers. We must assume the audience for our work longs for fresh language to describe the indescribable emotional and intellectual experiences in and beyond our field sites. We may not all write great popular or literary poems, but we can all draw on the craft and practice of poetry to realize its potential, challenging the academic marginality of our work. As an alternative to purely linear ways of thinking, the free associative nature of poetry offers a polyphonic, multidimensional, and insightful form of social science writing to engage more diverse audiences.

POLITICS OF QUALITATIVE RESEARCH

As Howard Becker said in a classic article, it is not a question of whether social scientists take a political position; it is a matter of whose side we are on. In other words, all research is political inasmuch as it comes out of a particular view of the world, makes claims about reality, and supports or refutes existing knowledge claims. Qualitative research, which generally makes no pretense of disinterested objectivity, has been more likely than quantitative research to be labeled as political. Qualitative researchers have risen to this challenge and engaged in a variety of discussions regarding the politics of their work. Over the past several decades, the discussions of the politics of qualitative research have primarily revolved around three distinct yet interrelated strands: the qualitative–quantitative debate, the question of the relationship between researcher and researched, and the evidence-based movement.

Qualitative–Quantitative Debate

At its heart, the quantitative–qualitative debate has been about different ways of seeing and approaching the social world. Those on the quantitative side for the most part have followed the Enlightenment tradition that emphasized the supremacy of rational thought and the ability of people to control both the natural and social worlds through the acquisition of knowledge. Knowledge in this case meant observable facts that led the researcher to uncover general laws that could help to predict human behavior. Qualitative researchers, meanwhile, believe that it is neither possible nor desirable for researchers to stand outside of a social world of which they are necessarily part. The quest for objectivity and neutrality that is fundamental to quantitative work is all but unimportant to most qualitative researchers. Knowledge is seen as situational and provisional. Acquiring knowledge will help researchers to better understand the human condition and explain how things have developed or persisted in particular ways. Rather than seeking to find cause-and-effect relationships that might be used to predict, and perhaps control, patterns of interaction, most qualitative researchers have sought to understand the complexity of social life. Although it is certainly possible to do qualitative research from a positivist perspective, for the most part qualitative researchers have built their work on postmodern understandings of the world.

Although some have characterized the qualitative–quantitative debate as a dialogue, it might be more accurate to describe it as a struggle on the part of qualitative researchers for legitimacy and place. For years, qualitative research has suffered from accusations of being unscientific and unreliable. This criticism has meant, for example, that unlike their quantitative counterparts, qualitative researchers have routinely included sections in their articles and books justifying their methodology. By the end of the 1990s, researchers from a number of social science disciplines were proclaiming an end to the “paradigm wars,” but recent developments indicate that it is probably more accurate to say that an uneasy truce had been declared. Both qualitative and quantitative researchers seemed to have agreed that a variety of methods are required to adequately investigate the range of questions we have in relation to the social world. What was not resolved was the divergence between the epistemological positions that undergird

the two research traditions. As the current debate over evidence-based research has shown, “scientific” inquiry continues to be portrayed as superior to “naturalistic” inquiry. In other words, the privileging of research designed to control and predict, as opposed to research that seeks to understand, remains strong in our research communities.

Qualitative researchers are concerned about what knowledge is being uncovered as a result of their work, and they are concerned with having their work taken seriously by their colleagues and by other policy actors. As a result, they have over the years sought to establish rigor in a variety of ways. Some have discussed the importance of the credibility of the results. They have encouraged the use of strategies such as constant comparative method, using a variety of data collection methods, and returning transcripts and analyses to participants to verify conclusions. Others have talked about establishing the trustworthiness of the research by describing all aspects of the research process in sufficient detail. This description could include recounting the events that took place, the influences on the study, specifics of the analytical process, and the actions of the researcher. More recently, some have talked about bricolage as a way of establishing the value of qualitative research. Building from postmodern understandings, bricolage requires that researchers approach a topic from multiple disciplinary perspectives, which implies employing multiple methods of inquiry as well as diverse theoretical and philosophical underpinnings in the work.

Relationship Between Researcher and Researched

In the positivist paradigm, the researcher is the expert, a neutral investigator who stands apart from his or her research subjects. Qualitative researchers, having rejected this position, have needed to come to terms with their relationship to both the research and the researched. In terms of the research, qualitative researchers generally declare their relationship to a topic of research and uncover some of their biases before embarking on a study. They talk about strategies to minimize researcher bias or ways to foreground the perspective and commitments of the researcher so that the research process is as open and transparent as possible. Most acknowledge that this is a good starting point, but it is insufficient in and of itself as a way to think about the entirety of the research activity.

The relationship with the people who are part of the research has led to an ongoing conversation among qualitative researchers about power relations, insider versus outsider knowledge, and the purposes of research. This conversation, sometimes labeled *the politics of the gaze*, asks researchers to think about who is looking at whom and for what purpose, who is explicitly or implicitly in the more powerful position in the situation, and what consequences this dynamic has for those in the less powerful positions. It asks us as researchers to question many aspects of our own undertakings including why it is important to do particular kinds of research, who will benefit from the research, who has the right to do different kinds of research, and how best to ensure the participants in the process are respected. It has, in some cases, led to a sustained engagement between researchers and members of minoritized groups (e.g., some First Nations communities and researchers in Canada) but this type of collaboration does not come easily, and its continuation cannot be taken for granted.

Qualitative researchers from various marginalized groups have extended arguments related to the politics of the gaze to ask if any methodologies developed for and by members of the dominant groups can ever be appropriate for the study of issues of importance to minoritized groups. From the perspective of many people from marginalized groups, research as a term and an activity is inextricably linked to imperialism and domination. To use Audre Lorde’s words, many marginalized peoples believe, “The master’s tools will never dismantle the master’s house.” This sentiment and the explicit relationships of exploitation and oppression that are written into it have resulted in yet another set of political discussions and activities aimed at developing new methodologies that grow out of knowledge traditions that may be called Indigenous, traditional, or marginalized. The purpose of such activity is to find ways to confer legitimacy on perspectives and knowledge that have generally been devalued and excluded from the public realm.

This second aspect of the politics of qualitative research, while engaging qualitative researchers in productive conversations about the meaning and ethics of research, has done little to enhance the aura of qualitative research to those outside the tradition. Intertwined as it has been with other conversations about representations of minoritized groups, it has raised concerns about censorship and limiting academic

freedom. Moreover, it has reinforced in the minds of some who are not social science researchers and who remain heavily influenced by the positivist assumptions that are woven into the fabric of most Western cultures that qualitative research is messy and biased and therefore not to be trusted. The threads from this aspect of the politics of qualitative research have also become part of the complex political tapestry that surrounds what is currently known as *evidence-based research*.

Evidence-Based Research

Starting in the 1990s, the term evidence-based research began to appear more and more frequently in the vocabulary of policy developers and research funding bodies in a number of Northern and Western countries. The term itself seemed benign enough. It seemed to suggest that research findings should be taken seriously only if they were supported by evidence. Quickly it became clear that it was linked to larger political and economic changes of the day.

The late 1980s ushered in an era of neoliberalism and globalization. Neoliberalism refers to an ideology that privileges the economic model of the free market. It posits that the market is the best model for structuring all relations in society, particularly those between governments and citizens. Although it advocates minimizing state intervention, there are certain ways in which the state has become more involved in public sector activities than it was previously. One of those ways is through control of what counts as “real” research.

Globalization is the name given to the current phenomenon of the spread of political and economic ideas and practices throughout the world. Many researchers have noted that globalization, rather than being a haphazard collection of ideas, is built on neoliberal principles. As early as 1999, noted educational researcher and sociologist Martin Carnoy warned that globalization would have a significant impact on educational practice, especially in five areas: (1) the organization of work, (2) strengthening ties between education and capitalism, (3) growing emphasis on international comparisons as a measure of accountability, (4) introduction of information technologies in ways that would transform the field, and (5) new struggles over the meaning and value of knowledge. Similar lists could have been developed for other social science related fields. Within this

framework, research that is of value to those in power is primarily that which will help to predict, control, and replicate results.

The only evidence that is considered worthy in evidence-based research, therefore, is that which is gathered through positivist-inspired quantitative studies; in other words, the evidence that counts is evidence that can be counted. Not surprisingly, throughout most Northern and Western countries, state agencies that provide contracts and grants to researchers have increasingly turned their back on qualitative researchers. In addition, policy developers have relied to a greater extent on the work of quantitative researchers to support their policy decisions. The lack of support for qualitative research also means that there is less financial and political support for emerging scholars pursuing qualitative traditions, and they will, therefore, be disadvantaged in the quest for tenure at research universities. Quite clearly, then, it is not only the current state of qualitative research, but also the future of the tradition that is at issue.

Qualitative research, particularly critical qualitative research, has come under progressively heavier fire. Nowhere is this more evident than in the struggle in the United States over the terrain of educational research. In 2002, the National Research Council (NRC) issued a report on educational research that favored the positivist paradigm. It stated that social science research in general and educational research in particular had become so muddled that it was of little or no value in terms of helping to shape the direction of policy. Therefore, in order to be funded, educational research would henceforth be evaluated on the basis of experimental or quasiexperimental design, and random field tests would effectively be the gold standard. Although the report goes on to justify this position on the basis of science and rationality, many critical qualitative researchers have challenged this stance.

For example, Patti Lather and Yvonna Lincoln have both, in different contexts, argued that the position the NRC takes is ironically unscientific in that it refuses to examine alternate views of evidence, analysis, or purpose. According to Lather’s analysis, the neoliberal mind-set, with its predisposition for managerialism, consumerism, and accountability, invariably leads to a kind of proceduralism that is compatible with positivist research traditions. Additionally, it imposes a rigid frame around what counts as research. Understanding the complexity of

real life becomes far less important than producing research results that appear to justify particular policy positions. In other words, officially sanctioned research becomes little more than a political tool.

Lincoln's analysis calls attention to the fact that three groups of people have seemingly joined forces in this recent attack on qualitative research. The first is a group of what she characterizes as traditional conventional researchers who want to rehabilitate what they see as the awful reputation of social science research. The second is a loose-knit group on the political Right who subscribe to a neoliberal view of the world. The third is often identified as the religious Right. The latter group tends to be guided by neoconservative ideology, a part of which is a longing for a mythical "golden age" when conservative values reigned supreme and issues of power and privilege had not yet surfaced. Thus, the attack on qualitative research has become part of a larger campaign against social historians, feminists, multiculturalists, post-modernists, and others who have questioned the conventional Western canon and other manifestations of power and of privilege.

Although the foregoing example comes from education in the United States, it finds echoes in other fields and other geographic locations. Critical qualitative researchers have drawn criticism because of their arguments that objectivity and value-neutrality in research are myths and that conventional science has served to reinforce the structures of power and privilege that exist in society. They have gone some way toward legitimizing the knowledge and traditions of marginalized groups. The existence of qualitative traditions has created a space for researchers from marginalized groups to enter into the academy and to challenge existing representations of themselves and others. All of these endeavors are highly politically charged. Consequently, the recent backlash against qualitative work in general is as closely related to the perception that minoritized groups are destabilizing taken-for-granted power structures as it is the demands of the neoliberal-inspired state.

Conclusion

From this brief account, what must certainly be obvious is that research is always and forever a political enterprise. Because of the predominant societal perspective of qualitative research, positioned as it is alongside critical and questioning movements, it will

more often than not be characterized as political, whereas quantitative work within a positivist paradigm will be characterized as scientific and therefore neutral.

What distinguishes the current political debate surrounding qualitative research from previous debates is that it has involved people from outside the research community and that it is so clearly part of a larger movement against all manner of critique and dissent. Qualitative researchers are increasingly becoming activists within and outside of the academy, forming their own links and coalitions with other outsiders who continue to challenge the status quo.

POPULATION

Looking beyond how population is often construed in everyday life (i.e., as every person who resides in a

given country, town, state, or province), population as a concept in research methods refers to every individual who fits the criteria (broad or narrow) that the researcher has laid out for research participants (e.g., all individuals who took Sociology 101 at the University of Victoria in 2001).

Conceptually, population is perhaps most easily understood when it is contrasted with the concept of a sample. A sample is different from a population because it includes only a portion of the population. In the case where the researcher uses a sample of participants, the researcher may have decided that it is not financially or chronologically feasible to study the whole population of, for example, unwed mothers in Canada. Hence, he or she may choose instead to study a subset of that population (i.e., a sample).

Because qualitative researchers tend to study smaller numbers of people in great depth, it is perhaps more common for them to study small samples. An example helps illustrate why this tendency is the case. It is not feasible to complete an in-depth, qualitative, interview study of the full population of unwed mothers in Canada. Even if it were theoretically possible to interview this full population, the analysis of the transcripts would be completely unwieldy. That being said, as mentioned earlier, a population can be a very small group as well—particularly if the criteria for the group being studied are very tightly defined. In this next case, the qualitative researcher may indeed study the full population. For example, perhaps the researcher in this instance is interested in examining the experiences of students enrolled in a new and experimental early education program. In this case, there may be only 10–12 students, and it is, therefore, realistic and perhaps important to get the perspective of everyone participating in the program so as to more accurately examine the successes and failures of this experimental program.

In essence, whether qualitative researchers decide to study a population or a sample from the population, the choice should reflect which approach will provide the answers they require from their research question. For example, they should consider whether a sample of unwed mothers can provide the insight they are seeking into the experience of being an unwed mother or whether a sample of students in a new and experimental educational program can fully answer the questions related to this program's successes and failures. With this in mind, qualitative researchers can decide whether they need to collect data from the full

population (i.e., all eligible participants who meet the study criteria).

PORTRAITURE

Portraiture is an artistic process. Framed by the traditions and values of the phenomenological paradigm, portraiture shares many of the techniques, standards, and goals of ethnography. Portraiture is a suitable methodology for capturing the essence of the human experience as portraitists seek to record and interpret the perspectives of the people they are studying. Portraiture allows the researcher to organize a narrative around central themes from the data and write layered stories where study participants are the subjects, not the objects, of the research.

In *The Art and Science of Portraiture*, Sarah Lawrence Lightfoot and Jessica Hoffman Davis define five essential features of portraiture: context, voice, relationship, emergent themes, and aesthetic whole.

Context

Portraitists view human experience as being framed and shaped by the setting. The context of a portrait is the setting—or where data collection happens. The context takes into account the physical, geographic, temporal, historical, cultural, and aesthetic nature of the research site, participants, and their experience. The context becomes the reference point to place people and action in time and space and as a resource for understanding what they do and say.

The internal context is the physical setting. In portraiture methodology, personal context, or the place and the stance of the researcher, are made clear.

A historical context considers the origins and evolutions of each participant.

Voice

In portraiture research, the researcher's voice is evident throughout the research—as witness, as interpretation, as preoccupation, as autobiography, as discerning others or listening for the voices of other identities or feelings, and as voice in dialogue through interviewing and having informal conversations with participants.

The researcher may use voice as witness to express the outsider's stance, to look across patterns of action and see the whole picture or portrait. In this way, the researcher is acquiring knowledge about her or his participants, but as a witness to the experience being captured and from a position on the boundary.

Voice as interpretation underscores the role of the portraitist for this is where she or he makes sense of the data. In making an interpretation, the portraitist must be vigilant about providing enough descriptive evidence in the text so that the reader might be able to offer a different interpretation of the data. Thick description contributes to authenticity by providing enough description so that readers will be able to determine how closely their situations match and can be generalized to the research situation. Using multiple data sources, repeated observations, and interviews provides the qualitative researcher with rich data for making the interpretative voice evident.

Voice not only seeks to witness the participant's stance through new eyes, but also it is used as preoccupation, or the ways in which the researcher sees and records reality. This concept of voice could also be viewed as the personal context or the researcher's perspective of the story, as it reflects the researcher's disciplinary background, theoretical perspectives, intellectual interests, and understanding of relevant literature.

Voice as autobiography also reflects the life story of the portraitist. In this sense, the researcher's perspectives, questions, and insights are inevitably shaped by her or his own developmental and autobiographical experiences. The researcher uses these experiences as resources for understanding and as sources of connection and identification to participants.

Listening for others' voices refers to how the portraitist seeks out and tries to capture the varying identities or feelings that may be captured while observing

or interviewing participants. When the portraitist listens for voice, she or he observes very closely, watching for the ways in which the actor's movements and gestures speak much louder than the words. For example, in the margins of observation protocol, the researcher could make notes of participant's gestures and expressions.

Voice in dialogue chronicles the developing relationship between the researcher and participant. It refers to the presence of the portraitist's voice discerning the sound and meaning of the actors' voices and sometimes entering into dialogue with them. Most qualitative research methods include voice in dialogue through interview and informal conversations with participants.

Relationship

Portraits are created, formed, and sketched through the development of relationships. Portraitists must try to forge a relationship during the first site visit and maintain that relationship throughout the research process, and maybe even beyond the study period. The relationship between the researcher and participant serves as the researcher's road in the search for goodness. That is, portraitists search for what is working, what is happening, and why rather than focusing on the identification of weaknesses. Relationship also considers the ethic of care the researcher takes in conducting her or his research and in being empathic to participant experiences. Relationship acknowledges the indebtedness toward the participants in the giving of their time, space, and personal experience. Finally, relationship considers the research boundaries that must be set by the researcher and the participant.

Emergent Themes

The development of emergent themes reflects the portraitist's first efforts to bring interpretive insight, analytic scrutiny, and aesthetic order to the collection of data. The themes give the data shape and form. They are consistently born from the data. In most qualitative research, emergent themes are constructed by first listening for repetitive refrains that are spoken frequently and persistently. Then, the researcher listens for resonant metaphors, poetic and symbolic expressions that reveal the ways participants experience and illuminate their realities. The qualitative researcher may also listen for the themes expressed through

cultural and institutional rituals and seem to be important to organizational continuity. Later, she or he uses triangulation to weave together the threads of data converging from a variety of sources. Finally, the researcher constructs themes and reveals patterns that are contrasting and dissonant by the participants.

The Aesthetic Whole

Portraits, the product or the aesthetic whole of portraiture, have four dimensions: conception, the development of the overarching story; structure, the sequencing and layering of emergent themes that scaffold the story; form, the movement of the narrative of the story; and cohesion, the unity and integrity of the story. Portraitists begin their investigations with a perspective, a framework, and a guiding set of questions that are a result of their previous experience, their reviews of the literature, and their conceptual and disciplinary knowledge. The aesthetic whole is the actual portrait that evokes context, voice, relationship, and emergent themes of the research. As a picture or painting, the aesthetic whole is that which is placed inside of the frame.

POSITIVISM

Positivism is the codeword for a package of philosophical ideas that most likely no one has ever accepted in its entirety. These ideas include a distrust of abstraction, a preference for observation unencumbered by too much theory, a commitment to the idea of a social *science* that is not vastly different from natural science, and a profound respect for quantification. Like empiricism, to which it is

closely related and with which it overlaps to a considerable degree, positivism is the label for a series of claims rather than any single claim. Moreover, many of these claims are analytically separable and do not entail one other so that it is entirely possible to accept some and not the rest. Inevitably, then, it is sometimes difficult to attach the label, without qualification, to any particular position or writer or even to identify the central ideas when several distinct positivisms (12, according to Peter Halfpenny) can be differentiated. But this problem has not prevented some methods writers in the social sciences from referring to positivism as a paradigm, implying that it makes up a quite determinate set of ontological, epistemological, and metaphysical beliefs, all locked together in an unbreakable structure that must, therefore, be rejected or embraced as a whole. This view requires a certain finessing of philosophical history, so this entry will begin with some excerpts from positivism's checkered career before returning to its role in social scientific methodological writing and in particular, its influence on qualitative research. Given that the history of positivism and the history of empiricism are entangled, it might be a good idea to read this entry alongside the corresponding one on empiricism.

Philosophical Positivism

Origins

The term was coined by Auguste Comte, but even for him it has several different connotations. It refers, in part, to a theory of history according to which every branch of knowledge passes through three stages (the theological, the metaphysical, and the positive state—when explanations by appeal to unobservable entities are finally abandoned) and which asserts that improvements in knowledge are responsible for historical progress. For Comte, positivism is also the assertion that there can be a science of society aiming at universal laws akin to those in the natural sciences; the name of a proposed secular religion, involving the worship of society, and with its own priesthood and church; and, less strangely, the label for a unity of science thesis claiming that all the sciences can be integrated into a single system. But perhaps the central thread in Comte's positivism, at least from the point of view of the subsequent history, is its empiricism, the view that the only source of knowledge

is experience. This idea is taken from the British empiricists and leads (as it did with John Locke, Bishop Berkeley, and possibly David Hume) to the view that there can be no knowledge of any reality beyond experience. It also led Comte to acknowledge the impossibility of obtaining absolute truth. This knowledge turns out to be a perennial positivist theme and is worth noting in the light of a familiar tendency to claim that positivism involves a commitment to absolute truth as well as knowledge with certainty. At any rate, the pivotal nature of empiricist ideas in positivist thought means that positivism is, in effect, a variant of empiricism.

A project frequently associated with positivism is that of quantification; indeed, for some writers, positivism and the quantitative paradigm are more or less synonymous. The incorporation of statistics into positivist thinking is normally attributed to Émile Durkheim, who built on Comte's empiricism by combining the idea of a science of society with the tradition of social physics. This tradition had developed during the 19th century and involved the collection of statistics for largely administrative purposes. What was innovative about Durkheim's proposal was the claim that statistics could be used to construct and test social theories, not just for the purposes of administration or reform. This claim has since become entrenched in popular understandings of positivism, and as a result, Durkheim's work (particularly *Suicide*) is recognized as one of the classic examples of positivist sociology.

Logical Positivism

However, the most iconic version of positivism is associated with the Vienna Circle and the school of logical positivism that emerged from it along with an affiliated group in Berlin. The circle's 1929 manifesto emphasizes two fundamental commitments: to empiricism (i.e., there is knowledge only from experience) and to logical analysis, by means of which philosophical problems and paradoxes would be resolved and the structure of scientific theory made clear. It is, of course, the second of these commitments that represents logical positivism's distinctive contribution to the empiricist tradition.

Empiricism, then, was a premise of logical positivism, but there was much debate as to what counted as the experiential foundation of knowledge. For Ernst Mach, an important influence on the Vienna Circle,

this foundation consisted of, quite literally, the scientist's own sense impressions, although some logical positivists held that sensations were not themselves the basis of science, but that *protocol sentences*—sentences recording those sensations—were. Later, however, this position was abandoned, at least by some positivists, in favor of the view that the experiential building blocks are in fact sentences that record not sensations, but the behavior of observable objects (e.g., measuring devices). In replacing sentences about sense impressions (which could be known to be true) with sentences about physical objects (which could not), this group of positivists effectively gave up the idea that knowledge could be certain and that there could be such a thing as absolute truth.

The logical analysis component of positivism has been based on developments in formal logic since the 19th century. Instead of a system of generalizations about psychological processes, logic was now seen as a formal symbolic language, empty of any empirical content that could be used to define precisely the conceptual relations between sentences. This development provided the logical positivists (or so they believed) with a means of translating theoretical sentences into sets of statements about experience and enabled them to organize the whole of scientific knowledge into an axiomatic system. These projects eventually broke down, as the positivists were the first to accept, partly because the translations were not forthcoming and partly because of the realization that no account of experience, no set of observations, can be theory-neutral. So, theoretical sentences cannot be translated into an observation language because observational terms are already theory-laden. Even so, two ideas persisted: first, that there are logical relations between theory and observation and second, that explanations consist of law-like generalizations from which the occurrence of specific events can be deduced. The latter is known as the *covering law* model.

Verifiability

The combination of empiricism and logical analysis leads to the principle for which logical positivism is best known: verifiability. This concept was an attempt to define a criterion capable of distinguishing between statements that are meaningful and those that are not (i.e., nonscientific, metaphysical statements). There were various formulations of this principle, but

the basic idea was that any statement is literally meaningless whose method of verification cannot be specified in terms of experience. An associated principle, verificationism, held that the meaning of a statement just is its method of verification.

Verificationism eventually failed for the same reason that other logical positivist projects failed. Yet its position as a defining principle in the movement was strong enough to confirm the positivists in a form of antirealism. For example, if subatomic particles are not directly observable in experience and if it proves difficult or impossible to translate statements about them into the language of observation, then these statements cannot be regarded as meaningful. In which case, belief in the existence of subatomic particles is at best an optional extra. In fact, almost all the logical positivists were antirealists in this sense: They were, at the very least, noncommittal about the actual existence of unobservable entities. The same is true of their attitude toward law-like generalizations of the form *all X are Y*. Statements of this type cannot, strictly, be verified, as it is impossible to observe all Xs, so some logical positivists were equally skeptical about the meaningfulness of universal laws.

Summary

Like empiricism, then, positivism is a family of claims and concepts on which different authors have placed varying degrees of emphasis. It shares with empiricism a commitment to making experience the test of all knowledge and is skeptical about the idea of an unobservable reality that includes entities and forces not discoverable in experience, a skepticism that extends even to laws of nature. In its later forms, positivism adds to empiricism an enthusiasm for statistics—indeed, for quantification in general—and the assumption that if a statement is meaningful, then it can, by definition, be subject to scientific testing and verification (an assumption subsequently weakened or dropped). It also attempts to translate what is known into formal languages, including mathematics, and to organize scientific theory into logical structures. However, if there is an overlap with empiricism, there is also common ground with American pragmatism, which had a similar preference for experience, verifiability, antirealism, and operationalism. This common ground largely explains why the logical positivists were accorded such a favorable reception in the United States following their flight from Nazi Europe in the 1930s.

It is noticeable, though, that the resonances of positivism, as well as its variety, are now often ignored. The term frequently signifies what is regarded as an exaggerated respect for the natural sciences and is inevitably associated with quantification. Moreover, it is usually assumed that positivists believed in a determinate reality and in the possibility of a correspondence between that reality and representations of it. This image of positivism, approaching a caricature, has been boosted by postmodernism, which portrays it as a reactionary force, committed to oppressive universal truths, a chimerical objectivity, and foundational narratives. In this guise, it is a convenient foil for a great deal of recent writing on social scientific methodology.

Positivism and Social Science

In contemporary methodological writing, positivism is apparently dead, yet it still receives constant criticism; it is significant that the most influential examples of modern social theory, such as critical realism, constructivism, hermeneutics, and structuration theory, take a critique of positivism as their premise. Recently, however, it has become clear that positivism is still a pervasive influence—although this influence is more marked in some social scientific disciplines than it is in others—to the extent that comments have been made about its surprising longevity. It is a visible force in American sociology and political science, has dominated the American history profession until the 1980s, and survives in various guises in economics. The record in sociology is particularly interesting, with a marked difference between the British and American sociological communities being evident, according to recent research by David Gartrell and John Gartrell. From the 1960s to the 1990s, British journals became less positivistic, so the evidence suggests, while the American journals became more so. There appears to be something of a discrepancy, then, between the pronouncements of social theorists and sociological research practice, at least in the United States.

Can Qualitative Research Be Positivist?

The study just referred to takes as its criterion for positivism an emphasis on measurement, the testing of generalizations, and the determining of relationships between variables using statistical analysis. So it

would seem that qualitative research, by definition, cannot be positivistic. This definition does appear to be one use of the term reflected in the familiar claim that qualitative and quantitative research represent different paradigms, with the quantitative paradigm often identified with positivism. The justification for this claim, where it is not simply derived from the assumption that positivism equals numbers, is that doing quantitative research entails commitment to a particular ontology and, specifically, to a belief in a single, objective reality that can be described by universal laws. In contrast, it is suggested that qualitative researchers, almost *ex officio*, do not share this belief: They see the universe as inherently subjective, socially constructed, more subtle and complex than mathematics can accommodate, and comprising multiple realities. On the other hand, those who are skeptical of this position ask why the use of quantitative methods, or any other technique, should presuppose beliefs about the universe at all. They point out that tools and instruments are not usually regarded as having philosophical views built into them: using a spoon, for example, does not commit one to the claim that the world consists entirely of fluids and small particles. So why should the use of specific research methods, for specific purposes, commit one to the claim that the universe is subjective or objective, multiple or singular?

The alternative is to take the distinction between positivist and nonpositivist as independent of the distinction between quantitative and qualitative, with the consequence that qualitative research can be positivist. Given this view, the various inquiry paradigms—positivism, postpositivism, critical theory, constructivism, the participatory–cooperative paradigm, and so on—can all be mapped onto qualitative research, each with its distinctive ontology, epistemology, methodology, and values and each manifested in a particular way of conducting qualitative studies.

Paradigm Tables

This mapping is evident in the tables that have become a familiar feature of qualitative methodological writing, especially by authors who draw on the work of Yvonna Lincoln and Egon Guba. Typically, the paradigms are represented in the columns while the rows represent inquiry issues on which different stands can be taken. For example, the positivist account of the nature of knowledge might be verified hypotheses established as facts or laws; the postpositivist

version might be nonfalsified hypotheses that are probable facts or laws; the critical realist view might refer to structural–historical insights; the constructivist position might involve individual reconstructions coalescing around consensus; and so on.

One unfortunate feature of these tables, irrespective of the intentions of the authors, is that they imply a certain rigidity in the idea of a paradigm. It can appear, at least to the novice, that each column is a vertical tramline from which there is no prospect of escape. Acceptance of what positivism says about one of the inquiry issues irrevocably commits one to accepting what it has to say about all the others because every paradigm is in effect a package deal. Accept realism, for example, and one is thereby committed to accepting dualism, reductionism, absolute truth, certainty, correspondence, knowledge by accumulation, and an extrinsic ethic “tilting toward deception.” Once the positivist column has been entered, there seems to be no way out. It is a little like getting married and finding oneself stuck with an entire family. Yet it is clear from the history of positivism that there is no such rigid structure, that it is possible to be a positivist without being a realist and without believing in correspondence, dualism, or certainty. To this extent, paradigm tables oversimplify the philosophical issues they try to elucidate and demand that one embrace or reject in its entirety something misleadingly called positivism.

Parallels Between Positivism and Qualitative Methods

In fact, there are several positivist ideas that sit comfortably with the claims of other paradigms and with the convictions of some qualitative researchers. For example, the positivist’s instinct is to stick with the observable phenomena and to distrust any theory that purports to give an account of reality. This instinct is quite consonant with what qualitative methodologists recommend, whether they are grounded theorists (who say that theory must be semantically tied to data), phenomenologists (who aim at an atheoretical description of phenomena), or constructivists (who present multivocal accounts, building toward the achievement of consensus rather than a theoretical evaluation). In all these cases, there is a preference for not going too far beyond the data and for not invoking theoretical, but unobservable, social forces such as class, power, socialization, or culture. Even the multiple

realities favored by constructivists are not too distant from the position arrived at by some logical positivists. Rudolf Carnap's mature view, for example, was that there are a number of different linguistic frameworks in terms of which the world can be described and that the choice between them is conventional and pragmatic, a matter of what is suited to a particular purpose. Consequently, all standards of correctness, validity, and truth are relativized to the rules and principles associated with whichever framework has been adopted. This view is not one that constructivists should find uncongenial.

Conclusion

This is not, of course, to deny that other positivist instincts, such as the preference for quantification and formalism, are at odds with those of qualitative researchers. But this is part of the point. There is no single thesis that counts as positivism, no single criterion that defines it; and of the variously assorted claims that belong to the positivist family, some are compatible with alternative paradigms such as constructivism, while others are not. To this extent, the concept of a paradigm, the concept of an encapsulated and rather rigid set of ontological, epistemological, methodological, and ethical beliefs, is itself a social construction, and (arguably) not a particularly helpful one. Instead of a fluid, historical, evolving, and internally contested discourse—which is what positivism is—it creates the image of a coherent, unified, and highly inflexible creed. Conceivably, however, the recent reexamination, and partial rehabilitation, of positivist thinkers will serve to unsettle this image, and will prompt qualitative researchers to discover what they can learn from positivism, however unlikely that may currently seem.

POSTCOLONIALISM

Postcolonialism is a broad theoretical approach that examines the past and present impact of colonialism and racism on social, political, and economic systems. It focuses on the ways particular groups of people because of notions of race or ethnicity have been excluded, marginalized, and represented in ways that devalued or even dehumanized them. Postcolonial theorists not only examine the position of people who have been colonized, but also analyze the impact that the process of colonialism has on those people who benefited from colonial acts such as dispossession, violence, and the promotion of racist ideology.

There are a number of major postcolonial theorists who have had a huge impact on the ways key concepts developed as an intellectual discipline: Frantz Fanon, whose groundbreaking work emphasized the effects of colonialism on the psyche; Edward Said, who developed the notion of “Orientalism”; Gayatri Spivak, whose work on the “subaltern” has been enormously influential; and Homi Bhabha, who has emphasized the value of psychoanalytical concepts such as ambivalence and hybridity in the study of colonialism. More recently, however, the field of postcolonial studies has been characterized by a

commitment to unpacking the complex connections between “race,” ethnicity, gender, sexuality, and many other forms of social stratification. These works tend to move beyond an additive model of identity, instead examining the specific ways in which various forms of inequality intersect in particular discourses and in particular historical locales.

Debate Over Definitions

There have been significant debates over the term *postcolonialism*. In general, however, the term postcolonialism refers to ongoing effects of historical racism, as well as the changing forms of oppression embedded in contemporary international relations, following the national liberation movements of various majority world countries. *Postcolonialism* is used to indicate the end of colonialism, but new forms of colonialism, as well as new challenges to the legacies of colonialism, are also examined within this area. In this sense, postcolonial criticism is understood as examining the relations of domination between and within nations, races, or cultures, recognizing the historical roots of such practices within colonialism.

In postcolonial studies, colonialism is not conceived simply in terms of military and economic expansion. It has important social, cultural, and religious dimensions as well. For instance, the export of cricket to colonial outposts by the British is a classic example of the way sport can be an element of colonialism.

Postcolonial studies also tend to be aware of Eurocentric assumptions within language and practice. For instance, postcolonial scholarship tends to avoid the use of the phrase “developing country” because it might be taken to imply that they are in some ways behind the “more advanced” countries in the West. Such language is problematic because it does not validate the economic, social, or political development of countries on their own terms and also seems to imply the ethnocentric assumption that the Western pattern of development is somehow superior to all others.

Colonialism's Effects on the Psyche

The effect of colonialism on the human psyche was the subject of a number of books by Fanon. Whether writing about his own experiences growing up in Martinique, examining the effect of racism on the

choice of sexual partners by women of color, or discussing the effects of the Algerian war of independence, Fanon consistently emphasized the damaging effects of racism and colonialism on the self-image and psyche of both colonizers and colonized people. However, he did not believe that people of color were destined to experience the same dehumanization as previous generations. As Fanon comments in *Black Skin, White Masks* (1991, p. 230), “I am not the slave of the Slavery that dehumanized my ancestors.”

Fanon also believed that colonialism was responsible for the creation of specific mental pathologies and disorders. For instance, Fanon (1991) described one person with “marked anxiety psychosis of the depersonalization type,” (p. 261) and another with “accusatory delirium and suicidal conduct disguised as ‘terrorist activity’” (p. 273) as a result of their involvement in the Algerian war.

Fanon was very concerned to show the effects of colonialism on the ways in which people from different countries, ethnicities, and cultures interact and the way that stereotypes of “the Negro” are a direct result of colonialism. He also emphasized the way access to colonial languages and adoption of elements of colonial cultures mediated the effect of inequality and dispersed relative privilege on particular groups of colonized people.

Fanon consistently emphasized the violence associated with both colonization and decolonization (a term he used to describe the achievement of political independence by formerly colonized countries). He highlighted the violence and exploitation of the Indigenous people by settlers, and he also argued that decolonization could be achieved only through a violent revolution in which colonized people overthrew the colonizers in a “murderous and decisive struggle” (p. 28)

Orientalism

Said’s book *Orientalism* was a landmark work: It is widely regarded as one of the reasons why the whole field of postcolonial studies became a recognized academic discipline. Said argued that the whole idea of “the Orient” was an imposed, thoroughly European notion. It did not stem from the diverse cultures found in Asia; rather, it is an ideology through which European countries demonstrated their dominance. He believed that the idea of the Orient was produced and managed by European countries in a way that

reflected their political, social, economic, military, ideological, and scientific power. Orientalism, therefore, places the West in a position of superiority over the Orient.

Said suggests that the phrase *the Orient* was applied to Asia or the East and was meant to be a catch-all phrase that was inclusive of geographical, moral, and cultural factors. Orientalism had cultural, political, and economic effects: It reflected the power, domination, and hegemony of the West (which he referred to as *the Occident*), over the Orient. Orientalism has an in-built arrogance: Like other forms of colonialism, Orientalism assumes that the colonizers (in this case, the West) know what is in the best interests of the colonized (in this case, Asia). Orientalism was not simply aimed at Asia: It was also important in terms of the ways people in the West understood themselves and their country.

Said emphasized that Orientalism not only justifies colonial acts after they have occurred, but also justifies colonization in advance. That is, it helps people in colonizing countries to develop an imperialist spirit and also promotes disrespect for the people in non-Western countries. Some of the prejudices that Orientalism helps to promote include the image of people from non-Western countries as childlike, irrational, depraved, and different, in contrast to the supposed Western traits of maturity, rationality, morality, and normality. For instance, Said compared the ways in which Islam is represented by the Orientalists as symbolizing terror, devastation, barbarians, and the demonic, whereas the West is seen as civilized, Christian, and originating.

Said's work was extremely influential because it challenged the way many scholars had previously understood Asia and the Middle East. It emphasized their reliance on secondary texts rather than on the original sources in non-English languages, and questioned their authority, leading to an increased emphasis on the ways in which people in colonized countries understood and responded to the challenge of colonialism.

Orientalism is a landmark text in the field of postcolonial studies. It has, therefore, been the subject of a great deal of academic discussion. One of the most common criticisms of this book is that it does not place enough emphasis on the way that colonized people resisted the process of Orientalism. It seems to give too much power to the West and its power to construct a dominant image of the Orient without

recognizing that people from non-Western countries have spent a great deal of time and energy challenging the biases colonialism promotes and reproduces. Said admitted that this was a problem with his book and tried to rectify this problem in his later work, most notably in his book, *Culture and Imperialism*.

In *Culture and Imperialism*, Said developed his thoughts on the importance of discursive and cultural domination within colonialism. He focused specifically on 19th- and 20th-century literary representation and narrative as an essential element of colonialism. He argued that such cultural practices attempt to justify colonialism by positioning colonized people as somehow subordinate or inferior, but also suggested that colonized people also mobilize cultural resources to challenge and resist such discourses and assert their own history and identity.

The Subaltern

One focus of Spivak's work is the way the Third World (and, in particular, Third World women) have been represented and silenced within Western discourse. She has employed the concept of the subaltern to describe the situation of Third World women, and the concept of the subaltern has gained a great deal of popularity in postcolonial theory, largely due to her use of it. However, Spivak was not the first theorist to use the term the subaltern; it had also been used by Indian historians collaborating under the Subaltern Studies project, and they had been inspired by the earlier use of the term by the Italian Marxist Antonio Gramsci.

Spivak argues that the subaltern cannot speak; that is, she argues that any attempt by Western scholars to represent or articulate subaltern experience is problematic because it runs the risk of speaking on behalf of the people being studied (which is a similar dynamic to colonialism itself). Furthermore, it also runs the risk of exaggerating the degree to which the subaltern is a unified, homogenous group. Instead, she emphasizes their diversity while recognizing that there is sometimes a need to use the rhetoric of a unified subject as a form of what she calls *strategic essentialism*.

The term subaltern seems to have a number of potentially contradictory meanings for Spivak. She sometimes seems to regard it as all the members of a society who do not make up the elite; but at other times (e.g., when she talks about the subaltern

within the subaltern) she seems to mean the groups who have attained political dominance. Indeed, the ambiguity of the term subaltern is one of the themes of Spivak's work: She argues that it is not possible to construct an unproblematic category of the subaltern whose interests can be identified and represented. Instead, Spivak emphasizes the heterogeneity of the subjects who occupy the position of the subaltern.

A characteristic feature of Spivak's work, unlike some other postcolonialist writers, is her attention to the dynamics of gender. Her work has been incredibly influential in encouraging other scholars to explore the ways in which gender, and to a lesser extent sexuality, operate in colonial and postcolonial contexts.

Ambivalence and Hybridity

Homi Bhabha has profoundly influenced the development of postcolonial theory. Bhabha's contribution to postcolonial theory lies in his emphasis on those in-between moments that unsettle the power relationships involved in colonialism. Bhabha's work suggests that viewing colonialism in terms of binaries (whether they are black–white binaries or Western–Eastern binaries) is incredibly simplistic and naïve. Instead, he suggests that cultures and identities are characterized by in-between moments, hybridity, ambivalence, and uncertainty. For Bhabha, hybridity is politically produced in the process of colonialism. It occupies an ambivalent space between the colonial power and its subjects.

Rather than simply looking for direct and overt opposition to colonialism, Bhabha suggests that other responses (such as uncertainty, ambiguity, ambivalence, and contradiction) may be equally important forms of resistance to colonial domination. Bhabha examines the cultural issues associated with liminality and ambivalence because he is interested in those in-between moments within colonialism that initiate new sites of identity, new collaborations, and new conflicts over identity.

Bhabha does not believe that ethnic or cultural identities are preexisting, homogeneous entities. He also believes that it is too simplistic to suggest that cultural difference simply involves polarities. And he certainly does not believe that particular ethnic groups have preexisting cultural traits. Instead, he suggests that these identities are thoroughly affected by power relationships and that all identities are performative.

That is, people negotiate and perform their identities in an ongoing, reflective, and complex manner, albeit within certain economic, cultural, and political constraints. Identities are always influenced by cultural, territorial, and psychological factors; they rarely exist in the simplistic manner suggested by colonialist ideology. Likewise, he suggests that cultural identities are always incomplete, open to translation, and capable of negotiation and change.

One form of resistance to colonialism that Bhabha emphasizes is mimicry. He believes that when colonized people mimic colonizers, they demonstrate the ambivalence inherent in colonial discourse, and they also challenge its authority. Mimicry by colonized people indicates that they partially represent and recognize the colonized, but it also demonstrates their resistance to colonialist discourse. Through mimicry, colonized people reinscribe the meanings of colonialist discourse, subtly challenging its meaning. This means that colonialism does not involve a simple, unilateral power dynamic, but instead a process of displacement, distortion, and dislocation.

In terms of theoretical frameworks, Bhabha's approach relies on a combination of Lacanian psychoanalysis, engagement with deconstruction (an analytical approach often associated with the work of the French philosopher Jacques Derrida), and postmodern ideas about performativity and identity. His emphasis on ambivalence, contradiction, hybridity, and liminality has opened up many new areas for study—providing a new framework for studying the patterns of recognition and disavowal that are involved in the negotiation of racial, cultural, and historical differences.

Beyond Additive Models of Identity

The complex ways in which colonialism and postcolonialism intersect with various forms of social stratification have been an important focus of recent postcolonial study. But integrating experiences from colonial and postcolonial contexts does not simply mean adding them on to preexisting understandings of concepts such as race, culture, or ethnicity (or more broadly, other analytical categories such as gender, sexuality, or disability). Instead, such work challenges scholars to fundamentally rethink the analytical categories and essentialisms contained within many sociological concepts. For instance, studies of colonial desire have challenged basic understandings of

sexuality, race, eroticism, exoticism, fetishism, conquest, domination, and violence.

Postcolonial studies of AIDS are another example of the attempt to explore the ways in which colonialism intersects with various forms of prejudice, such as racism and sexism. For instance, scholarship has emphasized the racist discourses that attribute contamination and disease to particular populations (such as the process of attributing AIDS to people from Haiti and their alleged bestiality in the early stages of the AIDS epidemic). These racist images have been laden with sexist messages also with specific emphasis on the alleged hypersexuality of Black women. By highlighting such prejudices, postcolonial scholarship has identified important power dimensions that affect broader discourses of public health, gender, sexuality, and international relations.

The study of transnational identity, ethnicity, culture, and language has also become a major area of recent scholarly interest. The liminal positions of various groups, in the context of transnational migration, have also been incorporated into some postcolonial research. Questions of home, exile, diaspora, and cultural identity have, therefore, become very important themes of such scholarship. Also, acculturation and creolization (the development of new social or linguistic practices as a result of cross-cultural contact) have been an emerging area of studies of such transnational immigration.

Experiences in the contact zones between nations and cultures, or in the borderlands, have also been a major focus for recent postcolonial scholarship. The borderlands (literally and metaphorically) are sites of transition and displacement where dominant assumptions are unsettled and new hybrid forms of power and identity emerge. However, borders are sites of exclusion where national boundaries are articulated, examined, and policed. Decisions about inclusion and exclusion at the borders are important statements about conceptions of the nation and its citizens.

Another theme of recent work is to identify hidden forms of power—such as the forms of privilege associated with Whiteness. For instance, the ways in which Caucasian ethnicity influences the standpoint and position of researchers and of community members have become emerging areas of scholarly interest. Likewise, the inclusion and exclusion of various ethnicities within the broader discourse of Whiteness (such as the interstitial position of Jews in this regard).

Qualitative Methods Used in Studying Postcolonialism

Robert Young's (2001) cross-national study of the development of postcolonialism is one example of the way in which qualitative methods have been used to study the development of specific national anticolonial movements and their interaction with the history and legacy of colonialism. Young's broad-ranging study covers Europe, Africa, Asia, and Latin America—but what is noteworthy in terms of its methodology is its deliberate attempt to recognize and incorporate the diversity of experiences that have occurred in various postcolonial situations. Young's approach, like that of some (but certainly not all) postcolonial theorists, draws heavily on—and emphasizes—Marxist economic themes in various transnational contexts. Young's transnational research is the exception rather than the rule, however. In general, the scholarly study of postcolonialism tends to focus on specific national contexts—and may involve field research on a particular topic—so that the researcher can record (as close as possible) “authentic” Indigenous perspectives on the topics being investigated. When working with some Aboriginal communities, this means that scholars have an obligation to describe how they came by certain information, what access they had to the community being studied, and how they conducted any fieldwork with this community. Fieldwork with Aboriginal communities in a postcolonial context has additional ethical obligations—ensuring that their rights (including their right to be free from harm, their right to be consulted on projects that affect their lives, and their right to confidentiality and privacy) are upheld.

Conclusion

Postcolonialism (the study of the ways in which past and present societies are influenced by a history of colonialism) is a theoretical approach that is gaining in popularity as a result of the need to theorize cross-cultural contact in the context of colonialism and globalization. Although early postcolonial critics, such as Fanon, tended to characterize the power relations as involving colonizers and colonized subjects, later work tended to move away from such simplistic binaries. Such later work has emphasized the importance of studying hybridity, ambivalence, and areas of intense contact such as the borderlands, in order to

develop a more sophisticated and nuanced approach to postcolonialism. The complex ways in which postcolonialism intersects with categories of gender, sexuality, and other forms of social stratification has also been a topic of growing scholarly interest in recent years. Qualitative research in this field tends to emphasize the situatedness of the researcher and the nation state being examined. Overgeneralization beyond the realms of one particular postcolonial context is particularly frowned upon in this area of study.

POSTMODERNISM

Perhaps the most radically transformative intellectual movement (or perhaps, more accurately, movements) of the latter part of the 20th century, postmodernism nonetheless defies ready definition. The term, used by Daniel Bell, Jean Francois Lyotard, Mark Poster, and others to describe contemporary, mediasaturated late-capitalist society is also widely, even indiscriminately, used to describe the work of a range of influential Continental philosophers and social thinkers, such as Michel Foucault, Jacques Derrida, and Jean Baudrillard. Postmodernism in the social sciences is strongly associated with a range of approaches to social research, including discourse analysis, post-structuralism, social constructivism, critical theory, feminist and queer theories, and so on. Indeed, ideas associated with postmodernism have become so all-pervasive in contemporary academic discourses, and its proponents and critics have become so numerous,

that its influence can be seen in virtually all areas not only of the social sciences from anthropology and sociology to information behavior research and knowledge management, but also of the academy as a whole.

Despite or perhaps because of this wide-ranging influence, a coherent definition of postmodernism remains problematic. Many of the key writers associated with it propound markedly different theoretical approaches or epistemological positions, while the research approaches and methodologies employed by postmodern researches range from textual analysis and deconstruction to interviewing and ethnomethodologies.

The term postmodernism is perhaps itself significant—indicating, as it does, not an affiliation with a particular philosophical viewpoint, but rather a desire to transcend the limitations of the modernist viewpoint that has dominated Western academic discourses since the Enlightenment. If postmodern writers and approaches can be said to have anything in common, despite their manifest heterogeneity, it is their critique of the core values and belief systems that have underpinned modernist approaches—such as rationalism, objectivity, and the idea of scientific as social progress.

One important area of ambiguity surrounding the term postmodern relates to the fact that it is widely—and ambiguously—used to describe both a socio-historical epoch (contemporary Western, postindustrial society) and an (admittedly related) paradigm shift in the late 20th-century academy.

Postmodern Society

Baudrillard argues that while the modernist period of the 19th and first half of the 20th centuries was dominated by industrialization, mass production, and commodification, contemporary postmodern society has become a postindustrial mass-media society where the emergence of new information and communication technologies allows the virtually unlimited reproduction and transmission of signs and symbols. Drawing on semiotic theory, he argues that the resulting continuous and ever-changing flood of signs and simulations has led to a hyper-real society where the distinction between the real and the unreal has become meaningless. This new hyper-real, postmodern society, he argues, is a “second revolution” as radically transformative of late 20th-century society as

the industrial revolution was of the 19th. He further argues that this radical transformation of the nature of knowledge and reality has rendered all existing modernist social theories obsolete.

Similarly, Lyotard in his *The Postmodern Condition* (1984) also argues that the emergence of computers and information and of communication technologies (ICTs) has radically transformed the social order of contemporary Western society. He argues that the emergent ICTs have undermined existing, modernist conceptions of knowledge and legitimacy. Recent developments in the sciences, as well as the emergence of intellectual movements such as feminism and action research have also, he argues, undermined the authority of existing meta-narratives, whether positivist, hermeneutic, or Marxist. Postmodern society is, therefore, defined by an incredulity regarding meta-narratives. For Lyotard, postmodern society is characterized by heterogeneity—a proliferation of different discourses and disciplines in the arts, sciences, and popular culture and a consequent decline in the hegemony of prevailing modernist social and political ideologies.

Like Bell and Baudrillard, Lyotard also sees postmodern society as dominated by postindustrial capitalism. Further, he argues that if industrial capitalism saw the commodification of agricultural and industrial goods, then postmodern capitalism is characterized by the commodification of knowledge.

Its association with developments in the contemporary West raises the question of whether postmodern ideas and theories are relevant only in that particular sociohistorical context. As commentators such as Steven Seidman have pointed out, debate about the emergence of a radically different postmodern society has occurred in the context of the Western democracies with their well-developed ICT infrastructures and advanced capitalist economies—and even there, largely among academic writers, many with strong associations with the radical social movements of the 1960s and 1970s. The question of whether the idea of a postmodern society has any relevance outside the developed world remains an open one.

Since one of the key principles espoused by postmodern thinkers such as Foucault and Lyotard has been a critique of teleologies—the idea that a single theory can provide a universal explanation—postmodernists would have no difficulty in accepting the notion that postmodernism is itself the product of a particular sociohistorical context and that different contexts will inevitably require different solutions.

Postmodern Theory

What is clear, however, is that postmodernism's critique of prevailing modernist approaches, its problematizing of many of the key assumptions underpinning 20th-century academic research practices, has caused many researchers to fundamentally reevaluate their way of looking at the world. As such, it marks a major paradigm shift, particularly in the humanities and social sciences.

Historical Antecedents: Modernism and Its Critics

The major research paradigms of the 19th and first half of the 20th centuries in both the sciences and the social sciences, such as Marxism and scientific empiricism, were the product of modernist world-views. The historical and philosophical antecedents of modernism can be traced to the work of late 17th- and 18th-century Enlightenment philosophers such as René Descartes and Immanuel Kant, who were themselves drawing on and adapting ideas from classical philosophy.

Drawing on classical traditions of logic and rhetoric, as well as the Aristotelian tradition of the importance of observation, a strong rationalist tradition emerged during the Enlightenment. From this emergence evolved the principles of positivism, scientific objectivism, and empiricism that underpinned the development of the modern sciences and social sciences, from biology to sociology.

In the modernist, rationalist view, science was constructed as producing a truth superior to anything that had gone before, rendering all previous belief systems obsolete. The “objective” scientific researcher employing the tools of empiricism was seen as uncovering “facts”—unraveling the mysteries of the physical and social worlds—discovering and describing and “capturing” aspects of “reality,” which in this positivist paradigm is seen as objective, external, and observable. The philosophical basis for such modernist approaches is *Cartesian dualism*—a distinction between the observing mind and the object of research—as is a tendency to view language as an essentially neutral tool for the representation and transmission of scientific discoveries. From this approach developed the idea of scientific progress—that science offered humankind not only the means to understand both the physical and social worlds, but also the

opportunity to create a new, better society in which old problems and prejudices would be swept away.

Modernist social science was perhaps best exemplified by the influential Chicago School of the 1920s and 1930s, a positivist school that aimed to develop social theory and research methodologies based on scientific principles of deductive analysis.

The origins of postmodernism are complex, but important historical antecedents of the movement include the work of the 19th-century philosophers Friedrich Nietzsche and Ludwig Wittgenstein, as well as the work of the linguist Ferdinand de Saussure.

Nietzsche's radical perspectivism, his rejection of positivism was an important influence on postmodernist thought. Nietzsche rejected rationalists' claims that they could describe objective reality, arguing that all scientific facts are—and can only ever be—interpretations. This argument is central to postmodern perspectives on the nature of knowledge.

Wittgenstein's work in *Tractatus Logico-Philosophicus* (1922) on the primacy of language—"The limits of my language mean the limits of my world"—is also clearly a core influence on postmodernism, which is frequently referred to as the linguistic turn in social theory. Saussure's structuralism, although in many ways a quintessentially modernist approach to defining the nature of language, was nonetheless an important influence on the work of such key postmodern writers as Foucault, Baudrillard, and Derrida. Saussure's vital contribution to the development of postmodernism derives from his contention that the relationship between the signifier and the signified—between symbol and what it represents—is a purely arbitrary one.

Knowledge and Power

If modernist social science was defined by the development of meta-narratives—teleologies or foundational theories, such as Marxism, claiming to have explanatory power across all time periods and cultural contexts—then, as Lyotard (1984) points out, postmodernism is defined by incredulity regarding meta-narratives. Postmodern critics point out that rationalist meta-narratives are not universal or objective, but are themselves the product of a particular sociohistorical context. A number of postmodern critics, such as Foucault, have pointed out that modernist discourse emerged from the 18th-century battle between humanist ideas and traditional religious worldviews—and

the political battle between the emerging industrial bourgeoisie and the traditional aristocratic and ecclesiastical ruling elites. Modernism emerged as a means of making sense of the social, political, and intellectual challenges of a changing world.

Similarly, postmodernists such as Lyotard argue that the social and political upheavals of the 1960s and 1970s—civil rights, student and labor movements, the rise of feminism, gay rights, and so on—have raised serious questions about the equity and objectivity of modernists' social theories and institutions. They ask the question, "Who has been excluded or marginalized by the 'universal' narratives of 'equitable' Western social discourse?" They argue that just as the industrial age required a new way of looking at the world, which was modernism, so must contemporary postindustrial society, which problematizes this worldview and requires the development of new theories, new paradigms, to meet the challenges of a postmodern world.

Postmodernists explicitly reject the totalizing claims of modernism. The work of Foucault is particularly important in this context. Although Foucault rejected identification with postmodernism, in an ironic example of his own principle of death of the author—that meaning is not dictated by authors but constructed by audiences—he has become one of the writers most strongly identified with the movement and one of the most important influences on postmodern theories and approaches.

For Foucault, meaning—whether in a text or a natural or social phenomenon—is not discovered, as positivists believe, but constructed. He argued that knowledge is not objective, to be measured in terms of its supposed correspondence to an external reality. Rather, it is a social construct, the product of the shared beliefs and interpretive practices (what Foucault called the discursive rules) shared by a particular community at a particular social point in space and time.

Foucault and other postmodern theorists, thus, reject the Cartesian dualist worldview of an objective material world and a subjective consciousness, instead regarding even apparently individual meaning-making—the creation, acceptance, rejection, and reinterpretation of knowledge as intersubjective. Postmodernists argue that knowledge and understandings, the sense-making processes, are never truly idiosyncratic, rather they are inextricably linked to social context. People learn through experience how to construct meaning in

different contexts and what they hold to be true will reflect (although not necessarily agree with) the beliefs and understandings of those around them. Furthermore, all discourse communities—whether nuclear physicists or 10-year-olds on the school playground—develop shared sets of social practices (discursive rules) by which the validity of a particular truth claim can be tested, accepted, modified, or rejected and a shared understanding negotiated.

These social processes of collective meaning-making Foucault called “the Battle for Truth.” He argued that the dynamics of discursive practice—the rejection, acceptance, reaffirmation, and reinvention of truth claims—are both the product and the producer of power relations. For Foucault, knowledge and power are inextricably linked, two sides of the same coin. Any acceptance of a knowledge claim as valid or true by a discourse community generates power-knowledge (*pouvoir-savoir*) within that community and will affect the subsequent sense-making processes of members of that community.

Scientific discourses from this perspective are, therefore, seen not as the privileged discoverers of objective facts, but the product of power-knowledge relations within and between scientific communities and their sociopolitical context. Discourses are sites for generating social agreement but also resistances—changing circumstances and the dynamics of discursive interaction must inevitably give rise to new discourses and new ways of looking at the world.

Like Foucault, other key postmodern thinkers’ work is also characterized by a rejection of modernist paradigms and grounded in a fundamental reconceptualization of the nature of language, signs and symbols, and knowledge and power.

Further developing Saussure’s insights, Derrida developed his poststructuralist deconstructionist approach. Derrida argues that since all meaning is contextual and based on difference, any philosophical or social theory that claims to uncover a fundamental truth is inherently flawed. His deconstructionist approach is, thus, a “method for revealing the radical contextuality of all systems of thought” (Dickens & Fontana, 1994, p. 8).

Deconstructionism has been influential in a number of areas of the social sciences, such as sociology and anthropology, where it has been used to question the authoritative status of traditional ethnographic texts and techniques. The technique has also been used by feminist researchers, for example, to analyze patriarchal discourses.

Critics and Criticism

Postmodernism has also attracted a great deal of criticism, both from within the academy and from politicians and the mass media. This criticism has no doubt been exacerbated by postmodernism’s long-standing association with the left wing—many of its leading figures such as Foucault, Derrida, and Baudrillard come out of the French postwar Marxist tradition—but not all criticisms can be attributed to political and social conservatives. Continental postmodern writers in particular are frequently accused of being impenetrable and obscure. This criticism may at least in part be attributed to the fact that their work was written in the context of European philosophical and intellectual traditions and debates that the majority of English language readers are unfamiliar with.

Another criticism of postmodern writers such as Foucault, Derrida, and Baudrillard is that while their work is grounded in a critique of teleologies, they have simply replaced modernist teleologies with meta-narratives of their own. It certainly has to be acknowledged that in developing their theories, postmodern authors have not—and can not—entirely exempt themselves from the discursive and rhetorical practices of post-Enlightenment Western scholarly life. It is perhaps ironic that Foucault, the champion, along with Barthes, of “death of the author” has become perhaps the most cited author in the social science and humanities literatures.

Among the most important critics of postmodernism has been Jurgen Habermas. Habermas interprets the heterogenous nature of contemporary societies as an extension of the modernism state. He sees modernism as an incomplete project and regards postmodern theories as anti-Enlightenment, even fascist.

There has been widespread criticism of postmodernism’s cultural relativism, which has been characterized as nihilistic, even morally bankrupt. This critique seems to be based on a belief that if all discourses are social constructs and the product of social agreement, then repressive and discriminatory discourses must be just as valid as emancipatory ones. Foucault argued that this was not the case. Rather, in recognizing gender, race, social class, and so on as social constructs, postmodern perspectives can form the basis for political debate and societal change.

Research Implications

In questioning the fundamental truths that have underpinned Western academic practice for centuries,

postmodernism requires social researchers to question and radically redefine their identity. Some critics, such as Baudrillard, even suggest that given the modernist origins and assumptions of disciplines such as sociology, postmodernism requires the “death” of the social sciences as we know them.

Others take a more optimistic view. Lyotard argues that postmodern ideas can liberate, reinvigorate, and reinvent the social sciences. Postmodern social science, its proponents argue, involves abandoning the absolute standards and grand meta-narratives of the modernist tradition in favor of more pragmatic, limited, and sociohistorically located forms of social enquiry.

So while modernist, positivist approaches saw research as a window on the world, with the objective social researcher applying research methods with appropriate rigor in order to discover and capture the reality of the phenomenon being investigated, postmodernists demand researchers recognize the social or constructive nature of the research process itself. Postmodern researchers such as Jaber Gubrium and James Holstein, for example, argue that interviewing needs to be seen not as a mechanism for accessing the participant’s consciousness, but as an interactional event. Postmodernists argue that the rhetorical nature of the research interview needs to be recognized—that it is a narrative produced by the interaction between researcher and researched, produced in a particular discursive context, embedded in power relations. Postmodernists argue that social researchers must reject the totalizing claims of modernist approaches and recognize that all research is a partial and sociohistorically located construction.

Postmodern perspectives have been applied to an enormous range of sociocultural contexts and phenomena: from Foucault’s archaeology of the discourses and institutions of the Enlightenment and the classical world, through Lyotard’s macrosociological analysis of contemporary society, through more microlevel or localized interview-based studies (such as the work of Gubrium & Holstein in sociology), to autoethnographies. Postmodernism should, thus, be seen as a sensibility or worldview not confined to any particular discipline or methodological approach.

Postmodern principles require researchers to be more reflective on their research practices, more conscientious in describing the influences on their work and the power relations that underpin any research process: between researcher and researched, between researcher and their field, and so on. These principles

also imply that researchers should reject the modernist tradition of seeing the researcher as a neutral, objective observer and write more openly about their own role in shaping the research process. Some postmodern researchers, such as the sociologist Laurel Richardson, even argue that social researchers should cast off the straitjacket of modernist academic prose in favor of rhetorical forms that allow researchers to more openly engage with their emotions.

The issues raised by postmodern theories have thus engendered a widespread debate about the nature and limitations of social research, the effects of which are still being played out throughout the social sciences.

POSTPOSITIVISM

Postpositivism describes an approach to knowledge, but it is also implicitly an assessment of the nature of reality. Thus, it is both an epistemological and an ontological position. It may be simplistically defined

as those approaches that historically succeeded positivism (e.g., realism), but more rigorously, it may be understood as a critique of positivist epistemology and ontology in which positivist claims concerning both the objective nature of reality and the ability of science to discern that reality are rejected.

Positivism and Its Critics

Positivism is a position in the philosophy of science that emphasizes the importance of observation for the growth of knowledge and thus considers the measurement of phenomena as central to the development of understanding. In its more sophisticated characterizations, however, it recognizes the need for a theoretical framework within which to structure data. Karl Popper, the philosopher of science, argued that theories should be tested against data with the intention of their falsification and subsequent replacement with improved theoretical models. In this way, science would contribute a closer and closer approximation to the truth of how phenomena work and the causal relations between these phenomena. Positivism has been widely applied in the natural sciences, where empirical observation is used to generate theories and models that can be generalized. This approach rejects nonobservable (and hence untestable) sources of knowledge as unscientific.

Positivism can be criticized for ruling out various sources of understanding of the world including those deriving from human experiences, reasoning, or interpretation as inappropriate for scientific enquiry. In the social sciences, these sources of understanding (e.g., qualitative interview data) are of great importance as bases for the growth of knowledge, and many areas of social scientific enquiry would be impoverished without recourse to such sources because this interpretative work is itself the subject of interest. A second criticism is that positivism ignores context and attempts to establish generalities independent of setting. In social science, setting is often an integral component of activity and as such, cannot be discounted—indeed, claims to knowledge require full contextualization. A third criticism is that as social order emerges from the sense making of human beings it will be largely contingent upon value-perspectives, and it is problematic to describe a single truth concerning the nature of the social world. Finally, positivism is committed to removing subjectivity from knowledge growth and thus denies any role for reflexivity among researchers.

For these reasons, positivism has been widely criticized since the inception of social science and has been largely replaced with postpositivist epistemologies (theories of knowledge) and ontologies (theories of the nature of reality), particularly in qualitative research. For postpositivists, while the pursuit of knowledge remains an aim of social scientific enquiry, the concept of an absolute truth may be seen as an aspiration rather than as something that can be discovered once and for all. Understanding rather than explanation is sometimes regarded as the objective of postpositivist enquiry, and this objective is often further constrained by acknowledgments of context and contingency. Furthermore, in postpositivism the role of the researcher as interpreter of data is fully acknowledged, as is the importance of reflexivity in research practice.

The Roots of Postpositivism

Postpositivism can be defined broadly to incorporate approaches to knowledge growth rejected by positivism as unscientific, such as psychoanalysis, Marxism, and astrology. However, this entry will restrict itself to examining the rival ontological and epistemological approaches to the theory and practice of social research that are both opposed to and critical of positivism.

An early manifestation of postpositivism in the social sciences can be found in the work of Max Weber, the late 19th- and early 20th-century sociologist. Weber developed the concept of *Verstehen*, or understanding, as a hermeneutic technique by which knowledge of the social world is to be gleaned. At the root of Weber's concept is the recognition that social realities need to be understood from the perspective of the subject rather than that of the observer and in totality rather than in isolation. However, to achieve this perspective, it is insufficient simply to try to imagine oneself in another's position or to interpret another's responses to a research instrument from the basis of the researcher's own assumptions about what these responses may mean. Rather, researchers need to recognize that actors are active subjects who are productive of their social reality, not simply the objects of social forces. The process of *Verstehen* involves understanding the intention and context of these social realities for the subject herself or himself. For social researchers to gain knowledge about actors in a field will require that the meanings and interpretations

of those subjects are fully acknowledged and understood. Understanding rather than causality is the key element to this approach.

This perspective offers the basis for both an interpretivist social science that recognizes the need to understand and interpret the meanings of subjects in order to make sense of the social order and a constructivist (or constructionist) approach in which social reality is seen not as objective and independent of actors, but as emergent from individual or collaborative constructions of concepts, values, beliefs, ethics, and norms of actors within a social field. The stability of social order derives not from social structures and independent forces, but from the customary habits of thought and shared meanings of actors that create a sense of continuity and order. Although these customs may be based in rationalizations, it is also possible to extend these constructions to encompass emotional or affective responses. Consequently, for the social researcher, *Verstehen* would require understanding not only rational thoughts and reflections, but also the affective components that contribute to the constructions of an actor's or groups of actor's social reality.

Methodologically, it will require a degree of empathy with the actors that a researcher is trying to understand and as a result, an element of reflexivity about the processes by which constructs are generated and deployed in the constitution of social reality. These elements have been highly influential in the development of social science research in the 20th century and have underpinned the development of movements including symbolic interactionism, social constructionism, feminist, and postmodern approaches in the social sciences. In all these approaches, the constructed and multiple character of the social world is acknowledged, and the need for reflexivity is seen as central to the enterprise of both research and social engagement.

Development of Postpositivist Ontologies

During the mid-20th century, Weber's postpositivist approach to the study of society was linked to phenomenology (the study of the structures of consciousness) to establish the basis for a sociology of knowledge that questioned many of the tenets of positivism and thus the objectivist approaches to social research that derive from the latter. Names associated

with this development include Alfred Schutz, Thomas Luckmann, and Peter Berger, but this development can be discerned also in Thomas Kuhn's philosophy of science, which recognized the social production of all scientific knowledge in both the natural and social sciences. This body of work underpins many elements of postpositivist research including the main strands of interpretivism, constructivism, and reflexive approaches, as well as many threads within the sociology of science and technology.

Drawing both on Weber's notion of *Verstehen* and upon phenomenological concerns with the collaborative nature of meaning, Schutz offered not only a perspective on the construction of reality but also an agenda for social research. He argued that knowledge and social reality are results of the sense-making work of human beings, but that these do not simply emerge out of individual rationalizations, but are constructed collaboratively between subjects and that, therefore, this intersubjective social production of knowledge (and the consequent social distribution of knowledge) should be the object of research.

He suggested that, unlike the objects of study in the natural sciences, those studied in social research are active, sense-making human beings, who are engaged in interpreting and ascribing meaning to their world in interaction with each other. Yet this description also applies to the social scientist, who is a further active interpreter of the same social world inhabited by those she or he would observe and understand. The social scientist is differentiated only by her or his aspiration to objectivity, in theory at least deriving from an interest that is purely intellectual.

Schutz pointed out a consequence for social science that is both methodological and epistemological. Researchers need to acknowledge their own interpretative work as they analyze the social worlds they are researching and to recognize that in making sense of an actor's sense making, they impose a second level of interpretation that is subject to *Verstehen*. This issue is critical for social researchers, especially those using qualitative interpretivist approaches, as they must recognize that their human, rationalizing, constructivist activity is behind their analyses of actors' life-worlds. This limitation may lead to accusations that these analyses are no more than relativistic interpretations. Schutz was keen to find ways to ensure that social science interpretations were congruent with actors' own interpretations and imposed the requirement that the former's interpretations should be comprehensible by

the latter and thus consistent with the understanding that an actor would impute to a social phenomenon.

Schutz's analysis has a further consequence. Because social science is part of the social world, the theories and models propounded by social scientists may contribute to the very social reality that is being researched. This possibility is the double hermeneutic of social science, according to sociologist Anthony Giddens.

This approach to the social scientific enterprise encompasses the main features of postpositivism. First, it acknowledges that the objects of study are engaged in an ongoing project of producing the social world, and therefore, their sense making must become part of the subject matter of a social science, ruling out a simplistic limitation of study to social facts and accepting the context-specificity of knowledge. Second, it recognizes that the tools of study in social science are human beings' own capacities as interpreters of the world. As such, these instruments work by means of exactly the same processes of intersubjective meaning-attribution that the social scientist seeks to study. Although there may be an aspiration to objectivity by the social scientist, this aspiration inheres only in her or his detachment from the practical commitments and interests of her or his subjects, not from some essential difference in her or his ability to interpret free from values, norms, and so forth. This problem leads to the third feature, the need for social scientists to be reflexive about their interpretative work, both to aspire to detachment but at the same time to accept its ultimate impossibility.

Realist Postpositivism

These elements of a full-blown postpositivist social science acknowledge both the ontological nature of social worlds as based in phenomenology and the epistemological constraints that result from the limitations that this ontology imposes on knowledge growth and the pursuit of truth in social science. The inevitable relativism that follows from fully adopting the postpositivist stance has been problematic in the social sciences, as its practitioners have been keen to retain some aspirations toward learning the truth about the social world. This problem has led to two contrary perspectives within postpositivism that can be broadly described as realist and constructivist. The former adheres to the notion that there is some objective reality to the social world, while acknowledging

that the Schutzian analysis of social science as interpretative and therefore ultimately subjective sense making precludes the discovery of that reality once and for all. All that can be achieved is the aspiration to knowledge through rigor, multiple data and theory analyses, building and testing. Constructivists, by contrast, consider not only that objective knowledge is impossible because of these problems of interpretation, but also that given that the world is variously constructed by human beings with their context- and interest-specific views of the world anyway, that reality is itself multiple, contingent, and value laden. Constructivists would contend that realism cannot, therefore, be considered a postpositivist position.

The roots of the realist ontological compromise can be discerned in the work of Schutz's phenomenological contemporaries and sometime collaborators Berger and Luckmann, although it has been further developed to establish contemporary critical realism. Berger and Luckmann argued in *The Social Construction of Reality* and other works that the social world has a dual character. On one hand, it is the outcome of the constructive work done by human beings as they seek to make sense of the world. On the other, because this work is done intersubjectively with other people, it achieves a kind of independence and, over time, accretes a "commonsense" reality with layers of institutionalization, tradition, and socializations. Within these relatively stable meanings, people's sense making becomes progressively trammled, until the social world has the appearance of objective reality with a semblance of continuity that also limits the meanings that can be attributed to objects. This limitation renders the social world available to enquiry independent of the human agency that constitutes it. Subsequent realist perspectives have built on this idea to argue that society is not created by individuals, though it is reproduced and transformed by them. Rather, the enduring social structures, processes, and institutions (e.g., class stratification and liberal democracy) are always the conditions of human agency and amount to an independent social reality to be studied objectively and potentially fully described.

This realist position, however, does not simply recapitulate positivism. Although realism considers there is an objective social reality that could be discerned were social researchers to possess sufficiently sophisticated tools, realism recognizes that when it comes to studying the social world, our tools (human understanding and interpretation) are inevitably value laden,

theory laden and context dependent. All that can be hoped for is that by continual efforts toward methodological rigor, triangulation from various data sources, and meticulous analysis of data that an approximation to truth can be derived and generalized.

Constructivism and Poststructuralism

The tensions within realism between individual interpretations of the world and an independent social reality that is still reproduced and even transformed by agency do not exist for constructivist and poststructuralist approaches. Although drawing to an extent upon phenomenological approaches (but with a background within but also in opposition to anthropological structuralism), these perspectives reject any notion of an objective reality to the social world independent of human action and thought and conclude that we cannot seek to study society and social action in the same way that a natural scientist would study a chemical reaction. The basis for this conclusion, broadly speaking, inheres in the primacy of language as the mediator of the human experience of reality.

Poststructuralist thinking is highly skeptical about truth and antagonistic to any assertion that one or another interpretation of reality is the only way in which it may be understood. Power and authority, often vested in archives of ascribed knowledge, underpin attempts to persuade groups and cultures to one view or judgment, for example, to a particular perspective on sexuality, form of worship, models of health, and so forth. Language comes to serve these authoritative bodies of knowledge so that they become more and more closed to challenge, and according to Jean-Francois Lyotard, may serve to effectively silence contrary voices. Furthermore, Michel Foucault argued that sources of power and systems of knowledge work together to create subjectivities in those whom they seek to persuade. However, poststructuralist approaches also recognize the unending potential that human subjects have for resisting these bodies of knowledge, and the entire history of human society can be understood as the struggle between power and resistance to control over what counts as knowledge and what it is to live ethically. The aim of poststructuralism has in general been to expose these power plays and claims to truth and thus to undermine them and offer alternative ways of thinking about the social world.

Constructivist and poststructuralist ontologies are consequently interested less in the continuities within

the social order and more with the fluidity of meanings that are held by social actors. They emphasize the extreme context-specificity of knowledge, suggesting that truth depends entirely upon point of view and that multiple truths may be said to exist concurrently within groups or communities that operate doddering systems of thought or have different commitments. Epistemologically, this means that knowledge is entirely dependent on context and indeed that the role of the researcher (with all her or his baggage of culture, norms and values) in constructing knowledge about a research setting must also be fully accounted for.

These perspectives have been highly influential within qualitative research, and in their strongest forms (e.g., James Clifford and George Marcus's collection *Writing Culture*) have sought to expose the processes and rhetorical devices whereby qualitative fieldwork has been translated into (realist) social science knowledge. These include the techniques by which the researcher's view is privileged over that of the researched (who sometimes appears in realist texts as a "cultural dupe," unable to discern the reality of her or his own situation and doomed to false consciousness), and the politics of the academy, which considers social theory as superior to the practical knowledge held by participants in a field setting. Constructivism variously argues for research that is context sensitive, engaged with the practical needs of the subjects of research, and committed to supporting resistance to power and authority. It is critical of social science knowledge that does not reflect on its own production and its own values and assumptions.

Constructivism approaches to ontology and epistemology also underpin various other strands in social theory that are not explicitly poststructuralist in provenance. Some feminist researchers, for example, have adopted this stance to critique both the ontological status of social reality as constructed by patriarchy, and the epistemology of positivism and realism in which (male) knowledge about the social world is claimed as truth. These perspectives emphasize the importance of reflexivity for researchers, both in understanding data and in acknowledging their own identities and subjectivities. Broadly, these approaches embrace relativism in knowledge growth, emphasizing the value of a research practice that is sensitive to difference and does not seek to establish "grand narratives" of theory and social modeling. They further embrace reflexive knowledge in addition to empirical data as sources for exploring the social world and

potentially transforming and improving the lives of those they research.

Summary

Postpositivism is a critique of both the ontological and epistemological foundations of theories of knowledge. It is a range of perspectives that have in common a rejection of the positivist claims to be able to discern a single social reality and to observation as the sole technique for its discernment. Realism and constructivism both recognize that our ability to know the world is constrained by the need for interpretation by researchers of data. Constructivists, however, also reject any sense that there is an independent reality that is there to be uncovered and consider instead that the social world is a consequence of authoritative claims to know the truth. The purpose of research, in the latter perspective, is exploratory and transformational.

POSTREPRESENTATION

Postrepresentation is primarily concerned with the extent to which researchers disclose authorial presence or

“voice” within their work. For the purposes of this entry, we can operationally define it as the process of transforming subjectively collected data into an inter-subjective narrative. This transformation is brought about through the researcher’s use of his or her own lens of experience being used as a filter for subjectively collected data taken from the participants of the research.

Because qualitative researchers are a part of and not apart from their studies in qualitative inquiry, qualitative research approaches lend themselves particularly well to the explicit inclusion of the author’s first-person perspective (i.e., the personal voice). In qualitative research, the researcher’s voice is always present, so the phenomenon of postrepresentation is avoided only in autobiographical and autoethnographical accounts, where the researcher either is the participant or is deeply entrenched in the relationship of the phenomena of interest.

Narrative, Truth, and Rigor in Postrepresentation

By employing a narrative style, the researcher attempts to represent the subjects of research by describing his or her interpretation of the phenomenon of interest. Was the authorial presence balanced? Did it increase the reader’s understanding of the research? How relevant is the author’s perspective to the reader’s understanding of the data? Researcher and reader are enlightened and enriched by the inclusion of the researcher’s voice, the researcher through self-awareness and the reader through the representation revealed by the author. Balance can be gained through determining how much or how little authorial presence is relevant to the effective portrayal of the participant’s reality.

Valid representation of their informants, participants, or co-researchers concerning the phenomenon of their inquiries is a primary purpose qualitative researchers seek in presenting their studies. The measures taken for achieving validity or trustworthiness of qualitatively collected data have been largely constructed to maintain this representation using credible procedures. These procedures, including rich thick description, member checks, prolonged engagement, persistent observation, peer debriefing, and inquiry audits, are all situated to promote and maintain that representation.

Held within the need for such procedures are two unrelated phenomena: (1) under-representation, where

the participant's experience with the phenomena is captured in an incomplete manner thus under-representing the nature of the phenomena under study and, (2) postrepresentation, where the participant's experience or perspective is interwoven within the researcher's perspective of the experience. To the novice qualitative researcher, under-representation appears more imperative—"Did I get 'it' right?" In this regard researchers employ a variety of verification processes in order to avoid under-representation and to gain epistemologically credible products from the research. To the practiced qualitative researcher, postrepresentation appears unavoidable and more critical in terms of producing meaningful research. "*Did I tell it right?*" captures the central postrepresentation dilemma. In the former "it" is the central concern; in the latter it becomes the "I." On one hand there is epistemology (it) and on the other, axiology (I).

The challenge of postrepresentation begins as the qualitative researcher employs the use of the personal pronoun by using first-person accounts. While this is an acceptable and useful practice in producing readable qualitative narratives, postrepresentation holds that the products of qualitative research are fictive narratives concerning the phenomena of interest because of these first-person accounts. The evidence for this is accounted for when one considers the researcher as the tool for data collection within qualitative studies. That being the case, all data are scrubbed through the researcher's values and currently held reality, which may or may not be close to the values and reality of those being researched.

Postrepresentation: Challenge and Critique

Postrepresentation represents both a challenge to and critique of qualitative inquiry. Epistemology can be defined as the study of the nature of knowing or knowledge. Ontology, on the other hand, is often referred to as the study of reality. The challenge for qualitative researchers is to position their findings epistemologically within the nature of reality (ontology). The critique centers upon the philosophical paradox of achieving the truth concerning the phenomena of interest. In the qualitative case this is represented as subjective truth while in quantitative designs the representation is objective truth. The difficulty present in qualitative research, and not present in quantitative designs, is that due to the researcher's presence this subjective truth is transformed within the researcher-participant relationship

into an intersubjective disclosure that is less related to a singular essence of "truth" and more representative of the reality surrounding the phenomena of interest than either the researcher or participant could capture or articulate on their own. The "I" of both the researcher and the participant is resituated as the "we" of this co-revealed inquiry. It should be noted that the more typical phraseology of "co-revealed" in this case would likely be "co-constructed." The concept of "co-reveal" is purposed to situate postrepresentation as an ontological construct. Truth becomes the perennial problem as these narratives become seen as essentially fictive yet very real.

In their attempt to be representative, qualitative researchers create postrepresentation by replacing the singular experience of the of the researcher with a new intersubjective reality created by the researcher and participant in relationship.

Postrepresentation as a Developmental Model

Postrepresentation can be seen as an attempt to use the perspective of transpersonal studies, which seeks a balanced development of the intellectual, emotional, spiritual, physical, social, and creative expression aspects of a person's life. Transpersonal studies seek to honor transformative human experiences. Interdependently and intersubjectively situated transpersonal dialogs represent a universality of the human experience. Postrepresentation is a transpersonal developmental construct in two key regards. It invites the reader to join in the developmental leap or learning, and it globally attempts to move the researcher-subject relationship from an epistemological center to that of an ontological center.

Qualitative researchers are also participants within a developmental scheme aimed at achieving some higher level of consciousness concerning the subject of their inquiry. The engagement (interviews, observations, or hermeneutical analysis) immediately makes apparent an intersubjective bridge from which all experiences or co-experiences must travel.

Postrepresentational development resolves the epistemological and ontological constraints of abstract reasoning by allowing that the reflective knower can indeed know himself or herself. In that regard postrepresentation does not preclude representation but deepens it. It suggests a relational construct for research that would intentionally probe the intersubjective

experience in order to directly illuminate the nature of reality. Practices such as setting intentions or meditation aid in positioning the researcher within the setting.

The great hope of representation is that different faculties of a subject (sensibility, imagination, memory, understanding, reason) can be portrayed in harmonious accord. Postrepresentation holds this harmonious accord is not the complete reality. In postrepresentation, the artist should not reveal that which we can already see but that which we cannot yet see, thus rendering visible that which remains logically or empirically invisible.

POSTSTRUCTURALISM

Poststructuralism refers to a range of theoretical perspectives that can be seen to move away from the tenets of structuralism, although poststructuralism has to be

regarded as being more wide ranging and theoretically nuanced than a straightforward oppositional positioning of structuralism–poststructuralism would suggest. Poststructuralist research practices do not look to identifying participant responses that can be seen to give rise to essentialist or uniquely privileged accounts that discover “the truth” of a situation. Instead, emphasis is placed on identifying meanings that are context specific and that relate to the varying discursive practices operating. This entry reviews the theoretical basis of poststructuralism. Next, it examines the similarities and differences between poststructuralism and other qualitatively orientated research methods. Last, it examines some of the critiques that have been brought to bear on poststructuralism.

Theoretical Underpinnings

There are various viewpoints on the relationship between poststructuralism and postmodern perspectives. Some scholars (such as Sarup, 1993) maintain that there are so many similarities between poststructuralist and postmodern orientations that it is difficult to distinguish between them. However, others (such as Huyssen, 1990) insist that there are significant differences and that combining the two is misleading and results in an unhelpful form of conceptual blurring.

Poststructuralism is a broad term, but generally focuses on exploring concepts such as relativity, plurality, fragmentation, and antifoundationalism. Comprehensive and prescriptive ideological frames or meta-narratives that clearly define and place boundaries around certain forms of knowledge are rejected. All-embracing theoretical frameworks such as Marxism, liberalism, psychoanalysis, and economic rationalism can be seen as examples of structurally orientated meta-narratives that poststructuralist perspectives both interrogate and deconstruct.

Poststructuralist perspectives tend to concentrate on the operation of language, the production of meaning, and the ways in which knowledge and power combine to create accepted or taken-for-granted forms of knowledge and social practices. Theorists such as Michel Foucault and Jacques Derrida have proved to be particularly influential, although neither would have regarded himself as a poststructural theorist. Derrida (1978), for example, rejected the idea that meanings could ever be fixed and developed the concept of *différance*. He maintained that meaning can be

produced only by the ongoing juxtaposition of the signified (meaning) and signifier (sound or written image) in discursive contexts. This concept has influenced poststructuralist perspectives in that meaning can never be regarded as being fixed or stable, but has always to be seen as ever changing and fluid. Meaning can be produced and temporarily fixed only in specific contexts. In relation to research, words and temporary meanings acquire a particular significance and are open to constant and continuing interrogation and analysis.

Foucault's view of power and knowledge has also served to shape poststructural perspectives. Unlike the structuralist views of power that focus on the hierarchical operation of institutional and positional power, Foucault developed a social relational view of power. According to Foucault, power operates from the "bottom up" in an ever-present, low profile manner in daily social relations or *micropractices*. He maintained that to understand how power is operating, micropractices or everyday social relations have to be viewed in their discursive contexts. This view makes it possible to pay attention to the historically specific relationships between combinations of power, language, and institutional practices in order to open up the knowledge bases that inform the taken-for-granted to critical scrutiny. Foucault tended to regard the operation of power within daily social practices as being manifested in a piecemeal and localized way. He maintained that it emanated from forms of disciplinary power exercised in disciplinary institutions such as the army, prisons, monasteries, and hospitals. He held that such institutions produce microtechniques for objectifying and regulating those inside. He saw these techniques as definitive of modern power and drew attention to two main types, which he called *synoptic* and *individualizing*. According to Foucault, synoptic visibility is associated with forms of unidirectional maximum surveillance that, for example, enable prison warders to continually survey the inmates via a one-way, 24-hour gaze. Individualizing visibility related to the power and technologies of "experts" who, by means of expert knowledge systems and confessional practices, control and mold the subject. However, he also identified how power operates to control and surveil the expert. He argued that the more seemingly powerful experts appear to be through their positioning in relation to dominant discourses, the more they are subject to processes of self-amplification. As a result, those with the most to gain

within a dominant discourse because of the way they have been positioned within it are voluntarily more constrained by regulatory aspects than others occupying less privileged positions. They, as a result, become docile bodies. Foucault associated disciplinary forms of power with biopower, which he regarded as the integration of microtechniques into global microstrategies. He also developed concepts of genealogy and eventalization. Genealogy refers to understanding the conditions that make certain social practices acceptable at particular points in time. Eventalization, in turn, is associated with a process whereby the self-evident is deconstructed to reveal, layer by layer, the factors that assured its social dominance during a particular historical juncture.

When considering views of the self, poststructuralist orientations reject the idea of an essential or core self that remains the same in all situations. In contrast, emphasis is placed on decentered subjects, where subjectivity is regarded as changing, complex, and contradictory. It is always influenced by social relational as well as by biographical forces and by discursively constituted experiences. Identities cannot be viewed in a unitary way and subjects are regarded as having a shifting core that continually changes in relation to context. As a result, there can be seen to be a continual discursive struggle taking place for the temporary determination of a subject's identity, with different subjectivities being continually created by competing discourses and social practices.

Both Foucault's and Derrida's contributions to poststructuralist ways of thinking have a clear bearing on poststructuralist research practices. Derrida highlighted the importance of meaning and linked the formulation of meaning to different and shifting contexts. Foucault interrogated and deconstructed social practices and events in order to analyze how they came to be dominant at a particular point in time. Similarly, the decentering of the structuralist unitary subject has also had a significant impact. The ways in which these theoretical perspectives have informed poststructuralist research analysis will now be considered

Poststructuralist Qualitative Research Analysis

Poststructuralist analysis has drawn from phenomenology and ethnography in terms of the attention paid to subjective meanings and to the emphasis placed on

people adopting different roles and giving different sets of meanings and accounts in differing situations. Hermeneutic analogies, which regard social phenomena as texts, are also utilized, and it is accepted that a number of different readings of the same text are possible. Reflexivity and the positioning of the researcher in relation to collecting and analyzing the material are also important and the varying ways in which the researcher can be positioned have to be subject to ongoing attention and comment. In addition to the interpretation and analysis of texts, methodological rigor is attended to by providing ongoing detail about the analysis and the presentation of differing readings of the text. Poststructuralist analyses are also used to critique notions of experience where experience is viewed in an essentialist manner and where experience is associated with individuals accessing the "truth" of a situation. As Maynard (1994, p. 23) asserts,

There is no such thing as "raw" experience. Poststructuralist thinking clearly demonstrates that the very act of speaking about experience is to culturally and discursively constitute it. People's accounts of their lives are culturally embedded. Their descriptions are, at the same time, a construction of the events that occurred, together with an interpretation of them.

Researchers utilizing poststructuralist forms of analysis also pay attention to social constructionist tenets. Social constructionist perspectives are not unique to poststructural orientations, and some exponents have provided a poststructuralist emphasis (e.g., Edley & Wetherell, 1997; Macnaghten, 1993) while others (e.g., Berger & Luckmann, 1966; Harvey, 1992) have maintained a structuralist focus. The range of social constructionist interpretations within poststructuralist perspectives is wide ranging. There are top-down forms of analysis that position the subject within discursive regimes in order to examine the operation of contributing discourses. In turn, bottom-up approaches have drawn from ethnomethodology and conversation analysis to concentrate on conversational and linguistic devices so that the operation of interpretative repertoires can be identified.

Poststructural analysts are concerned with the detailed examination of texts, with a very broad definition being given to what is meant by a text. As highlighted, particular attention is paid to language,

meaning, power-knowledge frames, discursive interplays, and constructions of self, although other areas can also be the subject of detailed interrogation. Different researchers place emphasis on different areas. However, the integral association of linguistic practices with social practices can be seen to be a common feature, with the study of these connections facilitating the mapping out of interpretative repertoires or discourses. Meanings are also related to specific contexts. However, one area of difference is that for some researchers linguistic form would have a greater relevance than linguistic context. For other researchers this ordering would be reversed and for others still, both areas would be emphasized. Linguistic form concentrates on aspects such as grammar, cohesions, style(s), and the linguistic resources utilized. Rhetorical devices and the ways in which particular constructions have been used to create legitimacy are also attended to. Analyses that focus on content and form rather than on form and content pay attention to language to the extent that the significance given within the text to experiences and events within the text are socially and culturally available linguistic resources and practices. However, the main aspect of the analysis is not to concentrate on a repertoire, conversation analysis, or the operation of discourse in grammar, but to critically interrogate social relationships and social practices.

Textual analysis places emphasis on processes of deconstruction. As with social constructionism, it is important to highlight that other theoretical approaches such as critical theory also utilize deconstructive techniques. However, a major difference between poststructural orientations and critical theory, for example, is that critical theory aims to deconstruct to uncover the truth of a situation, while poststructuralist analysis focuses on taking apart the endless layers that are seen to constitute social reality.

In terms of the analytical techniques involved in carrying out deconstructive textual analysis, within poststructuralist orientations researchers pay detailed attention to the different voices of the respondent(s) manifested in the text and to emotional tones, styles, and levels of intensity. Points within the text where variation, contradiction, and paradox are apparent are also emphasized. Attention is paid to interpretive shifts and the ways in which the subject develops the account or deals with prompts introduced by the researcher. Similarly, omissions and gaps within the text are closely scrutinized, as what is not said or

attended to can be seen to be as revealing as that which is said and included in the text. Differences and tensions within and between texts are also studied in detail and the researcher engages in an ongoing interpretative process, simultaneously and reflexively reading the text in association with their own positioning. With regard to deconstructive readings, Flax (1990, p. 38) notably commented,

Deconstructive readers are disrespectful to authority, attentive to suppressed tensions or conflicts within the text and suspicious of all “natural” categories, essentialist oppositions and representational claims. In a deconstructive reading one looks for what has been suppressed within the text. . . . Given the premise that the Real is always heterogenous and differentiated, it follows that whenever a story appears unified or whole, something must have been suppressed in order to sustain the appearance of unity . . . recovering the suppressed allows the strains and self-division that are an at least equally important part of the story to reappear.

The use of poststructuralist analytical processes and techniques will produce many different readings of the texts. These readings will variously concentrate on recurring themes, contradictions, and the identification of patterns in the ways in which participant experiences are articulated. Readings will also place emphasis on absences, avoidances, inconsistencies, and contradictions. Some readings will demonstrate a concern with function and consequence and will focus on formulating hypotheses about the function and effect of what has been said in the text. Such hypotheses will then be tested by searching for further textual material. If supported, these hypotheses will continue to be built upon; if not supported, they will be disregarded.

In any research project, the question of sample size has to be carefully considered. Research designs utilizing quantitative orientations and survey or experimental research approaches rely for their reliability, validity, and generalizability on the statistically amenable way in which the sample has been formed. However, the situation with regard to poststructuralist forms of deconstructive textual or discourse analysis is somewhat different. The aim is to generate enough texts to address the research question or the area of focus, and emphasis may be placed on a poststructuralist deconstructive interrogation of just one text. As highlighted, methodological rigor is attended to by

considering the positioning of the researcher, the provision of ongoing detail about the analytical process, and the posing of different textual readings. In relation to matters concerned with representativeness, it has to be borne in mind that the site of the analytical investigation is the textual frame within which the participants speak, rather than the participants themselves.

Critiques

Poststructuralist perspectives and associated forms of analyses have been subject to considerable critique. Proponents regard poststructuralist analyses as a means of overturning accepted knowledge frames and opening up all areas for re-analysis. Deconstructive analyses allow surface layers to be peeled away, not to reveal an essentialist core but to draw attention to pervasive, insidious, and constitutive aspects that require interrogation and critique. However, others have drawn attention to how relativity, plurality, and antifoundationalism make it impossible to recognize and address inequality and forms of oppression. Deconstructive critique, which remains forever in process, has been seen as dangerous and as moving attention away from those absolutes associated with extreme injustice and poverty. As everything becomes plural, all claims are relative and none can be seen to claim validity. It therefore becomes difficult to take an ethical position and to recognize and address social justice.

POWER

Power is one of the most important and widely used concepts in the social sciences. Nevertheless, widespread as this concept may be, there is far from general agreement upon its definition. To begin with, there is not one basic concept of power, but two: *power to* and *power over*.

Power to may be defined as having the ability to affect things. For example, power to can be understood as what enables individuals to move their arms, to dream, to get out of bed in the morning, and, generally speaking, to proceed through life as unique individuals. It is also worth noting that power to is the wellspring from whence human agency derives. Important as the notion of power to may be, social scientists often gloss over this individual-level instantiation of power in favor of focusing their attention on the phenomenon of power over.

Power over may be defined as occupying a position of dominance or command over others. Thus, power over implies an essential social relationship; this power, no doubt, accounts for the penchant among social scientists to give power to short shrift. Nonetheless, despite the inclinations of social scientists, it is essential to acknowledge that social power (i.e., power over) cannot exist in a vacuum. Human beings must be endowed with intrinsic capabilities to affect things (i.e., power to) or else manifestations of interrelational social power become untenable.

The Three Faces of Power

If the definition of power was not already complicated enough, scholars have also argued that social power is a multidimensional phenomenon that can be exercised simultaneously on three distinct dimensions: the individual, organizational, and cultural dimensions of power. Employing this terminology, or what we might refer to as the three faces of power, we can say that an exercise of power takes place when *A* gets *B* to do something that *B* would not otherwise do. The key indicators that an exercise of power has taken place are as follows:

1. An identifiable (i.e., often, observable) conflict of interests emerges between two or more distinct parties, that is, *A* versus *B*. (Whether or not such conflicts are observable in the traditional sense is a matter of additional debate.)
2. As a result of their conflicting interests, the distinct parties engage in a power struggle, that is, they call upon their power to overcome the will of their opponent(s).
3. One of the contestants emerges victorious—or paraphrasing Max Weber, the more powerful succeed in achieving their goals despite opposition. Therefore, the victorious can be described as having power over their opponents.

Individual-Level Power

To identify an exercise of power, one must first specify a relevant counterfactual. A counterfactual is a conditional in which the antecedent is false and the consequent states what would have been the case had the antecedent not been false. For *A* to have exercised power over *B*, it must be that case that if *A* had not exercised power over *B*, *B* would have done *X* (or would not

have done *X*). That is, a relevant counterfactual refers to a situation where one may detect the interruption of an actor's interests by the imposition of another set of interests. According to these criteria, identifying exercises of the first face of power is relatively straightforward. That is, observable conflict (i.e., individuals visibly manipulating the behavior of others) serves as a clear example of a counterfactual. According to this definition, power relationships exist only when *A* can be observed or identified as getting *B* to do something *B* would not otherwise do. Therefore, one may recognize exercises of the first face of power in situations such as boxing matches (i.e., two opponents, fighting each other in a ring), parents sending reluctant children to bed, or police hosing down protestors with water cannons (and thereby forcing the protestors to retreat).

Organizational Power

However, in the case of the second and third dimensions of power, identifying a relevant counterfactual becomes more complicated. Exercise of the second (or organizational) dimension of power still implies a conflict of interests between distinct parties. However, organizational power contests take place on an entirely different scale than struggles between individuals. Because, by definition, organizations tend to be larger and mightier than individuals, it is possible for organizations to exercise power over their adversaries with enhanced complexity and sophistication. Although organizations are perfectly capable of exercising the first dimension of power (e.g., employing security officers to dispatch the unruly), organizations can also manipulate power struggles without visible demonstrations of force by making nondecisions. Nondecisions are conscious choices made by organizational agenda-setters that tend to thwart challenges to decision makers. Therefore, power brokers can suppress challenges to their authority by designing organizational agendas to advance the interests of the powers-that-be while silencing adversaries. For example, political parties often enhance the perception of unanimity by failing to yield podium time to radical splinter groups during national conventions. In this way, power over may be exercised quite effectively without creating unseemly episodes of visible conflict.

Cultural Power

Exercises of the third (or cultural) dimension of power are even more complex. Briefly, the third

dimension of power works as a remarkably effective macrolevel social glue because of the way that it encourages individuals to apply themselves insatiably to the pursuit of those things that extant cultural systems are designed to provide. For example, the "tastes" of even 21st-century Americans are shaped to instill a passion for such "typically American" things as baseball, hot dogs, apple pie, and Chevrolets. Conveniently, the same taste-shaping forces facilitate the reproduction of the cultural context within which voracious consumers are embedded: Our hunger for automobiles effectively sustains the viability of numerous global industries that are bent on satisfying consumer desires, for example, petroleum, steel, shipping, and so on. Therefore, the third face of power can be perceived as a thoroughly enveloping blanket of power that steers microlevel individual behavior toward goals that bring about the reproduction of prevailing sociocultural macrostructures.

In conclusion, power is a multidimensional force that operates within (power to) and between (power over) individuals on three distinct levels: individual, organizational, and cultural. Although exercises of power at the organizational and cultural levels are somewhat more difficult to observe, they nevertheless may be identified and analyzed by anyone with a well-developed sociological imagination.

PRAGMATISM

As a philosophical movement, pragmatism was first introduced through the works of Charles Sanders Peirce (1839–1914), and then further developed by

William James (1842–1910) and John Dewey (1859–1952). William James was the first to use the term *pragmatism* in print; however, he credited Peirce with formulating the concept in the early 1870s. The central notion of pragmatism focuses on the nature of truth. In its simplest explanation, pragmatism holds that truth is found in “what works,” and that truth is relative to the current situation. However simple these statements may be, they created some of the most heated and widespread debate concerning the value and “truth” of pragmatism as a philosophy. Its earliest critics, emanating from the European continent, saw pragmatism as a quaint American philosophy of little value. Later it was viewed by many quantitative and qualitative researchers as an attack on epistemology. What made pragmatism a lightning rod for criticism was, first, its softening of the nature of truth, which made the empirical sciences less certain of their moorings; and, second, its subtle shift toward a separation of truth and reality, or, more accurately, a separation of epistemology and ontology. As James was quick to point out, pragmatists speak of how truth is not ready made and therefore uncertain or relative. Adding to that was the ontological bridge contained within the philosophy of pragmatism that held that we and reality “make” truth.

Pragmatism is derived from the Greek word *pragma*, meaning action. Interestingly this is the same root from which words like *practice* and *practical* are created. Pragmatism is often seen as the practical philosophy in which truth is not seen as an absolute but a moveable and usable construct for understanding the nature of reality. Therefore, a chasm formed between empirical scientists, and the methods, truths, and philosophies they held as certain, and the pragmatist who maintained a blatant disregard for the certainty of empirically revealed truths. Pragmatists selected their truths by their functionality. If a truth or theory could be easily seen as practical, the pragmatist was an early adopter; if not, it simply became unusable. Thus the pragmatist was often seen as having an ability to put theory into practice.

In the end, as was William James’s complaint, the pragmatist is simply unable to make truth a representation of reality, which was what the empiricist desired. Reality, according to the pragmatist, is to be revealed and experienced. Truths, portable or otherwise, were relative or practical only as long as they provided a tool for that reveal. Truths were easily seen as mutable and relative to an interpretive dialog. This

was of great concern to the epistemologist and to the empirical sciences. Pragmatism when treated as an epistemological construct fails at every measure because it violates too many empirical conventions. For that reason it is quite easy to attack pragmatism. However, when pragmatism is treated as an ontological construct it is exceptionally informative and nearly impossible to attack using any epistemological razor.

Pragmatism's Impact on Qualitative Research

To understand the full measure of pragmatism on qualitative methodology, it is necessary to reveal its full philosophical weight. In its earliest formations pragmatism moved away from an epistemological center held by both quantitative and qualitative research. As it shifted toward a more ontological rendering, it also reached out to axiological (beauty, aesthetics, values) aspects that had been formally dismissed by the quantitative researcher: Research is to be value free, and dismissed by way of simple blanket inclusion by the qualitative researcher: Research is value laden. Neither side of the epistemology debate formally probed the issues of values even though this issue was the key to the separation of the objective–subjective dichotomy. The pragmatists, however, insisted that because truth is relative or situational it can best be utilized as a way of forming signposts or landmarks concerning the nature of reality.

The pragmatists’ rendering of reality positioned it not as holding an objective view, as held by the quantitative researcher, or a subjective view, as held by the qualitative researcher. Since objectively and subjectively positioned methodologies were both contained within the epistemological domain, they both sought to discover either a verifiable or generalizable truth. The pragmatists, because of their move toward ontology, saw the world differently. The dichotomy that had formed between the objective world and the subjective world seemed for the most part inconsequential. The pragmatists found no value in absolute objectivity or absolute subjectivity, seeing neither as sufficient for understanding the nature of reality. The pragmatist pointed out that the affinity between quantitative methodologies and qualitative methodologies may be more deeply rooted than is commonly thought. In parts, this perspective was formed when the pragmatists positioned their philosophy as being *value informed*. This immediately positioned pragmatism as an ontologically centered philosophy not unlike other such positions

articulated by the philosophical hermeneutics of Hans-Georg Gadamer, the early transcendental renderings of phenomenology by Georg Wilhelm Friedrich Hegel, and the phenomenology of perception presented by Maurice Merleau-Ponty. This philosophical position held by pragmatism yielded an intersubjective rendering of the truth in that ontology was seen as relational and situational. The “we” or relationships aspect would hold that truth is co-created by way of intersubjective relationships. This co-created truth is epistemologically valid because it is co-constructed by the collective experience. It is through this relational construct that the nature of reality is revealed.

The pragmatist would hold that for all our methodological cleverness in design and approach to research, the focus has remained upon epistemology and as such is perennially flawed. The epistemologist would likely say “rightly so” since the true nature of inquiry is to discover how we come to know what we know. The pragmatic retort is informed by William James: “true ideas are those that we can assimilate, validate, corroborate, and verify. False ideas are those we cannot” (1907, p. 97). In reading this construct do not forget that the center of pragmatism is held within ontology, so its usability is being gauged not by its ability to render a truth but by its ability to assist in revealing the nature of reality. As such, it is important to avoid the epistemological trap of misconceiving the whole notion of pragmatism; for example, that it is only “a re-editing of positivism,” or that it is “primarily an appeal to action,” or that “the pragmatists cut themselves off from the right to believe in objective realities,” or that “no pragmatist can be a realist in his epistemologies,” or of the many others misconceptions concerning a concrete and practical way of seeing things—the reality of things. The pragmatic notion is that truth is always just in front of us. It has no history or future. Truth is always present, it is always now, and concerns itself with how we use it now to understand our realities—our historical and emergent goodness; our capabilities, capacities, propensities, power, and potential to embrace one another in relationships of values and beauty. Any attempt to give truth a prevailing or privileged position in these dimensions immediately freezes our realities’ and our values’ relevance and consequently and immediately arrests our development toward our full potential and toward full humanity. This immediately reveals the added dimension of humanistic and transpersonal psychology influences contained within the pragmatist philosophy.

In some ways the pragmatist philosophy was poison to both quantitative and qualitative approaches to research. The pragmatist has often been referred to as a pacifist seeking to bridge the two paradigms that are seen by the purist as incompatible. Pragmatism is seen as a theoretical position that privileges practice and method over reflection and deliberative action. In short, pragmatism links theory and practice, but it is the practical and experiential that is essential to the relational construct of pragmatism. Epistemology would privilege the findings of our research while ontology and pragmatism would privilege the direct usability and suitability of that knowledge in revealing the intersubjective nature of reality.

Beyond the humanistic and transpersonal implications of pragmatism are the deep ecology constructs found within this philosophy. Pragmatism purposes a deep probe into the intersubjective interactions between people and their environment. Ecology, as a comparison, is defined as the study of the interaction between an organism and its environment. Accordingly, all subjects, objects, and the interaction of subjects with subjects (intersubjectivity) and subjects with objects (interobjectivity) are taken into consideration in the inquiry. Consequently, pragmatism is positioned at three distinct intersections with other fields: philosophy (particularly an ontologically centered philosophy), humanistic and transpersonal psychology, and deep ecology.

Pragmatism is a very purposeful stance that engages the totality of philosophy; beauty (axiology), goodness (ontology), and truth (epistemology). As a way of priming their understanding of the nature of the ecology, pragmatists do not seek an epistemology (truth) and then following that retreat to ontology (reality/goodness). The pragmatist begins with a deep probe into the values and value complexes (axiology) held by subjects and the researcher and then positions them squarely within the ecology (reality/ontology) itself. It is from the emergent intersubjective and inter-objective interpretation that epistemology emerges within a pragmatic philosophy. Truth is relative to the nature of reality from which it was tendered. In this regard, truth is not only what works within the prevailing reality but also relative. Pragmatism gives reality a privileged position.

The Compatibility Thesis

The compatibility thesis states that qualitative and quantitative methods are compatible in that they are

both largely epistemologically centered methodologies that can be equally useful in probing the nature of reality. This position would hold that researchers do not choose their method of inquiry and then construct the appropriate problem, but that researchers locate the problem and then choose the appropriate methodology. The primacy given to the location of the problem is precisely what positions the pragmatic approach within the ecology (reality). The centrality and utility of pragmatism are found in its open ontological stance within the nature of reality—open to both the prevailing values (axiology) and currently held truths (epistemology). Ontology takes on an active transforming process in that within the intersubjective frame of reference, values are engaged and new understanding (new knowledge) is formed or revealed, thus repositioning epistemology as a following construct (truth is relative or transformative), and therefore truth is found in what works within the ecology. Or said another way, theory and practice are spanned effectively through pragmatism. Pragmatists take a philosophical viewpoint and position their probe at the intersections of subjectively and objectively held knowledge seeking to understand the nature of reality, whereas traditional qualitative and quantitative approaches take the epistemological position, choosing to construct or deconstruct either inductively or deductively new or existing knowledge. The epistemologist is seeking finite knowledge while the pragmatist is seeking universal knowledge.

The other central difference between the focused intention of the epistemologist and that of the universality of pragmatism is the belief by pragmatists that values (axiology) or value complexes play a very large role not only in the conduct of the research but also in its interpretation. They are less concerned about inductive or deductive approaches, choosing a holistic or ontological approach to revealing the nature of reality. Thus, unlike epistemologically centered research, pragmatic research is driven by anticipated consequences as given by the search for the practical.

Pragmatism Defined

Defining pragmatism accurately is difficult due to its complexity and emergent nature. The complexity is held by its intersectional relevance to multiple disciplines (deep ecology, philosophy, humanistic and transpersonal psychology, and education) and its emergent

nature held by its ontological center. In its roots in humanistic and transpersonal psychology, pragmatism is above all else an endeavor that seeks to liberate the will to pursue the purposes of self-actualization. In deep ecology, it is seeking a sustainable and grand synergistic society. In philosophy, it is seeking a return to a holistic rendering of beauty, goodness, and truth. In education, it is seeking the truth of what works.

In formalizing a definition for pragmatism, it is essential to return to the central argument that truth is subject to change. There are, according to Émile Durkheim, two central arguments contained within pragmatism: (1) Truth changes over time because reality changes, and (2) Truth changes through space because people have differing ideas. Definitions have generally been formulated in a dual fashion, splitting the philosophical aspect and the practical aspect. A composite rendering would produce the following:

Pragmatism. An American philosophical movement consisting of varying but associated theories marked by the doctrine that practical consequences are the central criteria of knowledge. Originally developed by Charles S. Peirce and William James, pragmatism is seen as the function of reflective thought and relationships to guide action and that truth is relative to the practical consequences of any belief. [adapted from <http://dictionary.reference.com/browse/pragmatism>]

The practical, matter-of-fact way of accepting the facts of life and approaching or assessing situations or of solving problems. [adapted from <http://dictionary.reference.com/browse/pragmatism>]

Criticisms

The criticisms aimed at pragmatism are generally sourced from the epistemological view of truth. In that regard, the general conclusion is that pragmatism is much less an undertaking to encourage philosophical action than it is an attack on theoretical thought. Critics would contend that the pragmatist is impatient with any rigorous scientific or intellectual discipline. Pragmatism seeks to free thought much more than it seeks an action and therefore is often seen as duplicitous. The desire of pragmatism, as William James would position it, is to “make the truth more supple.”

The other major criticism is made by those who see quantitative and qualitative research as being

incompatible. Since pragmatism wishes to bridge this gap, its position is held as unattainable and as an assault on the truth. Because the pragmatist maintains that reality is a co-construction of thought and relationship, reality is seen as apperception itself. In the process, they attach to thought and relationship the same power and the same qualities as given by empirical scientist from their more rigorous methodologies. Pragmatism, because it attempts to link the subjective and objective worlds, is found to be incompatible with either. Pragmatism therefore is seen as lacking the basic characteristics that one has the right to expect of any philosophical doctrine.

Methodological Implication

The key methodological implication for the qualitative researcher begins with the formation of the statement of the problem. Prior to that formulation, pragmatists would not select their research tools (i.e., quantitative, qualitative, or mixed methodology). Since the problem itself emerges from the nature of reality the pragmatist enters the field of inquiry with a practical problem-solving attitude. Therefore the pragmatist avoids Abraham Maslow's concern: "I suppose it is tempting, if the only tool you have is a hammer, to treat everything as if it were a nail." (*The Psychology of Science*, 1966.) For the qualitative researcher this perspective must signal the possibility that the problem emerging from the ecology (reality) may indeed be unsuited for the myriad of qualitative-based research designs.

The other methodological implication emerges as the pragmatists close their inquiry. Since the whole purpose of pragmatic approaches is to locate practical and usable solutions to the stated problem, the research would close with this direct articulation. This direct articulation is ontologically centered and as such is significantly distant from epistemological theories, hypotheses, propositions, suppositions, or verifiable narratives. In short, the pragmatist does not work around the truth of the problem but instead attacks the very nature of the problem by seeking a direct intervention or solution without regard to the epistemological rules of validity, reliability, or other issues surrounding the trustworthiness of data. Ontologically, it signals a problem being solved or a solution being constructed. Epistemologically, this signals a fatal weakness for this approach in that it cannot be validated or verified.

PRAXIS

Praxis refers to a particular philosophy used to guide and conduct research. Like action researchers, those who engage in praxis-oriented research involve the community or group under study in the research process. However, praxis is distinct in that its explicit goal is to empower marginalized peoples and help them challenge their oppression. Engaging in praxis is not a path for the harried researcher interested only in quickly collecting and analyzing data. Praxis-based research is a long process that involves establishing mutually beneficial relationships between the researcher and members of the community of study.

Though the effort and time investment may be great, the payoff has the potential to be huge. By engaging in collaborative research, researchers may help participants acquire the critical tools to transform their own lives. This entry examines the historical development of the concept of praxis and then explores the role it plays in contemporary research. It also describes implications of praxis for both researchers and participants and discusses the practices that characterize it.

Theoretical and Historical Definitions of Praxis

This section describes the evolution of the definition of praxis from the work of the ancient Greeks to the philosophy of Karl Marx and then the work of Paulo Freire. The section concludes with a discussion of the differences between praxis and other similar theories.

Ancient Greek Roots: The Work of Aristotle

The earliest known reference to praxis is found in the writings of Aristotle, who identified three different types of human activity: *theoria*, the production of truth; *poiesis*, a goal-oriented action; and *praxis*, action that is an end to in itself. Aristotle did not privilege one activity or view one to be in opposition to another. He understood each to be suited to different situations with different purposes and end goals. Poiesis, for example, is typically associated with the scientific method. Those engaged in poiesis aim to produce theoretical or scientific knowledge using tools such as proof or analytical reasoning to lead to a tangible result. The resulting knowledge is expressed in universal propositions and is true across all situations.

In contrast, the goal of praxis is not the knowledge obtained through an end result or the production of an object, but rather the knowledge produced through action. For Aristotle, the goal of praxis was to produce a morally worthwhile good. Whereas poiesis is defined through the production of a value-free object, praxis is defined as the production of a value-laden and moral good. Unlike the universal knowledge produced through poiesis, knowledge produced through praxis is concerned with the local and the particular. That is, it cannot be universalized across all situations. Those who employ praxis use their knowledge of a particular situation to understand a more general problem.

Early Philosophers: Marx and Gramsci

Marx wrote about praxis mainly during his early years, when the bulk of his scholarship concentrated on philosophy, as opposed to later in his life when he focused on economics. In his 11th thesis on Feuerbach, Marx takes other philosophers to task, criticizing them for not translating their theorizing into concrete action, writing, “philosophers have only interpreted the world in various ways; the point, however, is to change it” (Glass, 2001, p. 16). Thus, Marx issued one of the earliest calls to action, arguing that people could challenge the status quo. Like Aristotle, who divided human action into various realms, Marx subdivided praxis into two distinct categories. The first type of praxis derives from the capitalist market and refers to the unreflective labor that enables capitalism to thrive. Those who participate in the market automatically engage in this form of praxis, which simultaneously reproduces itself and oppresses the majority of those who participate. The second form of praxis offers an opportunity to challenge the capitalist, involuntary praxis. As Marx describes, this form of praxis is enacted through labor that has the potential to emancipate workers from, and challenge, the status quo.

The Italian writer Antonio Gramsci followed in Marx’s footsteps. Imprisoned by Mussolini due to his involvement with the Communist Party, Gramsci spent his time in prison writing thousands of pages on history and Marxism. His essays were later published as *The Prison Notebooks*. In his writing, he often refers to a “philosophy of praxis.” Many argue that he used this phrase as a stand-in for Marxism since prison censors did not allow such discussion to appear in prisoners’ correspondence. More recent scholarship suggests that Gramsci saw Marxism and a philosophy of praxis as two separate, though highly related concepts. For Gramsci, the philosophy of praxis describes the struggle that people undertake to obtain a critical perspective. Like Marx, Gramsci argued that such a philosophy generally stemmed out of the class struggle and was more easily accessible to those in the proletariat. Such a position—that praxis was for the disenfranchised—is critical in the works of future theorists, including Freire.

Recent Critical Conceptions: Paulo Freire

Perhaps the most influential figure in the development of praxis is Freire, the Brazilian-born educator

and theorist who developed his theory of praxis after working with Brazilian peasants in the mid-20th century. Freire began by teaching illiterate peasants to read, but later transitioned into advocating for conscientization (or consciousness-raising), a process of empowerment for marginalized people. Freire argued that oppressed groups had internalized society's power structures and accepted the inevitability of marginalization. Not only had they implicitly accepted the existence of power hierarchies in society, but they also were actively engaged in trying to climb up the hierarchy. In other words, marginalized groups accepted their oppression by striving to become the oppressor. Freire argued that such a practice failed to challenge existing power structures and continued the reproduction of inequalities.

For Freire, the way to challenge oppression was to engage in praxis, which he defined as "reflection and action upon the world in order to transform it" (Freire, 2000, p. 51). Mere activism was insufficient. Those engaged in praxis needed to engage in reflection to understand their position in society and how they used their position to perpetuate a cycle of oppression. A key element of praxis calls for oppressed groups to engage in dialogue with one another. Such a process challenged the imposition of norms by the ruling group and involved oppressed groups in formulating a solution for their own liberation. This dialogue was facilitated by a leader, possibly one from an external community. Through praxis, the distinction between leader and community members (or teacher and students) dissolved. The teacher's knowledge ceased to be privileged. Teachers and students engaged together to create knowledge originating from the oppressed group's experience. Freire's notion of praxis involved a community of individuals from a marginalized group coming together to recognize their own oppression and create strategies for change.

A Family of Critical Theories

The theory of praxis is one of a few theories that push researchers to engage in action-oriented research. Other theories, including critical theory and feminist theory, also focus on marginalized populations. Feminist theory places women's oppression at the center of inquiry and focuses on ways in which women have been excluded from positions of power. Despite this shared focus on oppressed

populations, feminism and praxis emerged from distinct theoretical origins. However, in recent years, some feminists have drawn upon the work of Freire to inform their own practice. In contrast, critical theory and praxis stem from the work of Marx and his followers. Like praxis, critical theory promotes human emancipation from all forms of oppression. Critical theorists vary in the type of oppression they focus on: some focus on freedom from capitalist oppression while others are concerned with freedom from racial oppression. All are concerned with freeing people from the conditions that disempower them. Freirean notions of praxis typically focus on working with the poor and uneducated to provide them with the tools to overcome their oppression. Unlike critical theory, praxis is primarily concerned with helping the uneducated emancipate themselves. Upon emancipation, these groups then help the privileged seek emancipation. Though critical theory and praxis share the same general goals, praxis tends to focus on one particular population and provides concrete guidelines on how to achieve emancipation from oppression.

Praxis in Research and Method

The goals of praxis remain similar to those espoused by Freire and his followers. Praxis involves a commitment to challenging the status quo and helping people from marginalized communities understand their oppression. Although the research project may be used to accumulate data and build better theory, social transformation remains the primary goal.

The definition of praxis in research continues to evolve. Whereas Aristotle perceived no inherent conflict between poiesis and praxis, current proponents of praxis point to a divide between the two traditions. Praxis arises out of the need to challenge the universal norms that characterize poiesis and the scientific method. Such norms were developed out of a privileging of the positivist paradigm, which is characterized by the search for objective knowledge and truth. In contrast, praxis is based on the idea that knowledge is not objective, but rather is socially constructed. In positivist research, the objective researcher enters the field to discover new knowledge about a problem or a population. Such a scenario tends to result in the researcher's worldview being imposed upon the research site and the findings conforming to the researcher's expectations and experiences. Researchers who engage

in praxis recognize that such a tradition has privileged the dominant group and way of thinking. As a result, existing knowledge is incomplete as it has typically excluded the perspectives of those not conducting the research. Praxis-based research seeks to include the voices of those who have been excluded from mainstream research. This type of inquiry tends to lead to new definitions of the researcher and researched. The rest of this section discusses four areas that a researcher engaging in praxis might consider: (1) the role of the researcher, (2) participants, (3) method, and (4) audience.

The Role of the Researcher

Although researcher and participants may be engaged in research as collaborators, this relationship does not absolve the researcher from assuming a leadership role. The researcher still enters the research site with more technical expertise than participants. The researcher may also possess a sense of critical consciousness that has been denied to participants. Particularly in the beginning stages of a research project, a researcher may exhibit more of a leadership role in challenging participants to consider the research problem from a new perspective. Like Freire, who recognized that oppressed groups may not necessarily be aware of the ways in which they were marginalized, researchers may need to challenge participants to adopt an alternative perspective to evaluate their lives. Part of the process of engaging in praxis-based research is arming participants with the critical tools to transform their lives or their community. The researcher takes a more directive role in challenging participants to consider topics that they had typically neglected or by helping them learn to critically analyze a situation.

This help is one of the real paradoxes of praxis-based research. Praxis necessitates that all research arise out of the experiences of the community being studied. However, members of marginalized groups may not possess the theoretical tools to engage in critical analysis or to identify the ways in which they are oppressed. In fact, they may have internalized their oppression and fail to perceive societal inequalities. Researchers committed to praxis need to find a balance between being directive and being responsive to community needs. Ultimately, researchers ensure that the research arises out of the needs of the community and reflects their experiences and equips them with

the tools to continue to engage in analysis and action long after the research has ended.

Participants in Praxis

Given its reliance on the social construction of knowledge, praxis-based research is generally a communal undertaking. No longer can a researcher expect to be able to adequately represent the experiences of a community of others. As a result, praxis calls for researchers to engage in collaborative inquiry with participants. In such an arrangement, the researcher recognizes the authority and knowledge that resides with community members. No longer need the researcher be looked to as the arbiter of knowledge definition and production. Community members who engage in praxis-based research simultaneously are trained to see themselves as sources of knowledge and capable of contributing to research. Often, nonacademics envision research as something best left to professors. Praxis-based research, however, functions by way of mutual cooperation. Ideally, the distinctions between researcher and researched will disappear as members of each group share their knowledge, teaching one another and engaging in the construction of knowledge together.

Method

Not only do researcher and participants engage in inquiry together, but the research problem arises out of the experiences of the community members. Researchers committed to praxis do not impose their own agendas upon the community site. Rather, they seek to understand the lives of participants and develop research that arises out of participants' experiences and concerns. Co-defining the research with community members helps prevent researchers from imposing an ill-fitting theory to explain participants' experiences. To ensure this equal participation in the research process, praxis-based research is characterized by three practices: (1) reciprocity, (2) reflexivity, and (3) dialogue and negotiation.

Reciprocity

Engaging in collaborative research necessitates that a foundation of trust be established among all participants in the research process. Reciprocity is one way to achieve this goal. Achieving reciprocity in the

research process occurs through recognition that researchers and participants are interdependent; researchers need participants as much as the participants need the researchers. Researchers seek to establish mutually beneficial relationships, or relationships through which all parties gain. Such an undertaking is in marked contrast to the typical method of research in which researchers are often seen as entering the research site, taking what they need, and leaving nothing in return. Through praxis, all parties benefit. For the researcher, the gains include the obvious—data collection—but also the less tangible—growth through reflection. For community participants, the potential for change is great. As discussed above, researchers help participants develop critical consciousness and learn to question their situation. Gains also occur on an even more mundane level. Researchers may provide day-to-day assistance, specific to the needs of the community, in ways that help all involved in the project benefit.

Reflexivity

A researcher might establish reciprocity by helping participants learn to think critically. Critical thinking helps participants and researchers develop reflexivity. Reflexivity is particularly important for those engaged in praxis as it forces participants to evaluate their actions and the way in which their own experiences might shape their interpretations of the research outcomes. Reflexivity helps those engaged in research gain insight into the research process. Reflexive participants learn to analyze their lives and their positions within society from a new perspective. For researchers, reflexivity helps remind them not to impose their own agendas upon the research site. It also highlights a researcher's position within the world and the ways in which knowledge is socially constructed. Being reflexive has the potential to remind researchers that they cannot engage in research alone, but rather their research needs the voices of their participants to truly gain an understanding of the study site.

Dialogue and Negotiation

Since praxis-oriented research emerges out of collaboration between researchers and participants, dialogue and negotiation help facilitate this partnership. Dialogue encourages all parties to engage in critical reflection and may help participants better understand

themselves and their collaborators. Dialogue also provides the tools for collaborators to engage in negotiation, a process crucial for producing accuracy in interpretations. The researchers and the participants are likely to possess different perspectives and may interpret the same situation through different lenses. Researchers engaged in praxis negotiate with participants throughout the research process. They negotiate with participants from the onset of research when establishing roles and responsibilities. They negotiate with participants when performing data analysis to reconcile varying interpretations of the same situation. They may even submit an initial draft of a written report to participants to receive feedback and negotiate their final interpretations of the data. Since praxis is built upon the collaboration of researchers and researched, dialogue and negotiation ensure that all parties are involved and represented in the research from start to finish.

Audience

Although praxis has recently seen an increase in popularity among researchers, not all disciplines readily embrace its use. Given its historical roots in Freire's work, education has the lengthiest tradition of employing praxis-based research. Fields such as nursing, public health, social work, and public administration also have had praxis emerge as an emphasis and focus in the literature. Discussion of praxis is largely absent in literature in science and engineering. Given that the focus of praxis is to partner with communities to create change, scholars in the physical sciences have seen less of an opportunity to employ such methods in their research. Although praxis-based research is reported in academic journals, it also has a considerable tradition in appearing in popular texts. Like Freire, who wanted to reach a wider public, many who employ praxis write in clear, stripped-down prose to allow their ideas to be accessible to all.

PRIVACY

Historically, privacy has been defined as the right to be left alone. An increasingly technological society has extended privacy to include rights to be free from surveillance, to make private communications, and to have autonomy and control over one's own body.

Most research ethics codes have established the need for privacy for research participants. Privacy is also a fundamental human right enshrined in the Universal Declaration of Human Rights. Although most people have an expectation of privacy in their lives, it is also understood that social, political, and technological changes are threats to privacy: Increased population density, antiterrorism initiatives, and the internet all pose challenges to privacy. When privacy is lost, it is often impossible to retrieve.

The moment a researcher begins to collect information from participants, privacy is being encroached upon. When researchers offer to respect the privacy of participants, they are giving participants the right to decide how much information to share and how it will be used. This discussion usually takes place through the process of informed consent. That is, participants are given an explanation about the kind of personal information they

are being asked to share, how that information will be protected from other parties, what the information will be used for, and how it will be used.

A common way to protect participant privacy is by offering confidentiality—an assurance that information shared with a researcher will not be disclosed in a way that can publicly identify the source. This can be accomplished by using the least amount of personal identifiable information to complete the research purpose. Researchers should code information about participant identity and store it separately from non-identifying data. Sometimes it is unnecessary for a researcher to know the true identity of a participant, and therefore a pseudonym can be employed.

Research that involves sensitive topics has the greatest privacy imperative. George Radwansky, former Privacy Commissioner for Canada, has said that information in health research must remain within the program of study and must not find its way into the hands of an “individual's employers, insurers, relatives or acquaintances, governmental or law enforcement authorities, marketers or any other third parties.”

The internet's ease of use as a research tool and the vast amount of information it offers has attracted many social scientists. Researchers may decide against disclosure of their presence on the internet, which raises issues around deception. The capacity to assume anonymous or pseudonymous identities is available to researchers and participants, which can confuse distinctions between reality and cyberspace. The sense of privacy that can be felt through the internet may be more illusion than reality. The internet also poses challenges with respect to informed consent processes, not least because researchers cannot easily verify age, mental capacity, and characteristics relevant to sampling. There is controversy about the expectation of privacy on the internet. Some researchers argue it is a public space and offers no expectation of privacy, and others point out that many internet users regard their chat rooms as private personal spaces where like-minded people interact.

PROBABILITY SAMPLING

Probability samples require that every member of the overall population have a known chance of being included in the sample. The most basic form of probability sampling is simple random sampling, where every member of the population has an equal chance of being included in the sample. Thus, a simple random sample of 100 people from a population of 10,000 gives each person a 100 to 10,000 or .01 probability of being in the sample. Another common form of probability sampling is stratified sampling, which divides the total population into separate subsets or strata (e.g., racial groups or geographical locations) before drawing random samples from each of these strata. In both cases, probability sampling ensures that the size of any subgroup in the population is the only thing that influences how often its members are included in the sample.

For quantitative research, probability samples have two main advantages. First, they allow statistical statements about the accuracy of the sample's numerical results. For example, a political poll may say that there is a 95% likelihood that its results are within 3% either way of the actual population value. Second, they are necessary for tests of statistical significance. For example, the results from a survey may show that the scores for men and women are so far apart that there is only a 5% chance that the difference is due to having drawn an unusual sample. These statements about a 5% chance of error or 95% degree of confidence explicitly recognize that probability samples are not always accurate. Instead, they make it possible to say precisely how likely it is that the sample does accurately represent the population. The results are thus generalizable within statistically well-defined limits.

For qualitative research, probability samples typically require information that is not likely to be available in most studies. In particular, if there is no way to count all the members of the original population, then there is no way to know what proportion of the total population is represented by any given sample. And even if the population size is known, there may not be any realistic way to give every member of that

population a known probability of being included in the sample. As a further limitation, an accurate probability sampling requires a relatively large sample size, and the accuracy of generalizations from probability samples declines rapidly for small samples.

For quantitative research, the statistical analyses that are possible only with probability samples justify the demands of knowing the population size, determining the probability of selection for each sample member, and gathering large samples. In contrast, for qualitative research, statistical analyses are not only of little interest but also are largely impractical due to the small sample sizes in those studies. Instead, most qualitative research concentrates on pairing purposive selection procedures to define the population of interest with nonprobability techniques to select the actual data sources for any given study.

PROBES AND PROBING

Probing is a specific research technique used by interviewers in individual and group interviews and focus groups to generate further explanation from research participants. Probing may be achieved nonverbally with pauses or gestures, or verbally with follow-up questions. Effective and efficient probing in interviewing relies on the interviewer's ability to actively listen to what interviewees have said and judge if further information is necessary to making meaning from what has been said, and then judiciously probe for further descriptions concerning the topics of interest. Methodologists who provide directions for how interviewers can ask interviewees for further explanation, clarification, or elaboration of their responses agree that mastery of this technique is critical for "good"

interviewing—whether using standardized survey protocols or open-ended interview guides.

One of the most extensive discussions of probing in interviewing has been provided by Raymond Gorden, who has outlined seven forms of probing questions that may be used by interviewers to manage the topic of interview talk. The silent probe—in which the interviewer refrains from commenting—allows interviewees to take up the topic of the talk in ways that are meaningful to them and is the least intrusive prompt. However, interviewers must be able to identify when it is useful to pause to allow interviewees to continue, and when participants have completed their turns. In the latter case, if participants are seeking direction from the interviewer, misplaced pauses may interfere with the flow of talk. Encouragement to speakers to continue may be conveyed by head nods, gaze, facial expression, gestures, and words such as “mm” and “uh huh.” Next, particular probes call on interviewees to provide immediate elaboration. For example, interviewers can request further information about the topic by asking questions such as, “Tell me more about that.” “What happened then?” Probes for immediate clarification, in contrast, request further information about particular topics. For example, this could include questions such as, “You mentioned *x*, tell me who was involved at that time?” or “What happened after you had completed *y*?” Probes involving retrospective elaboration orient the interviewee to earlier talk and seek further information. For example, the interviewer might begin by stating, “Earlier you mentioned that you were involved in *z*; thinking back to that time, tell me more about that.” Similarly, probes focused on retrospective clarification seek specific information about earlier talk. For example, “You talked earlier about the very first time you heard about *y*. Describe that event in detail—Was anyone with you at the time? What was that like for you?” The final form of probe outlined by Gorden is that of mutation. In this kind of probe, the interviewer uses prior talk to expand the topic into a new area. For example, “You’ve told me how you became involved in *z*, and what that was like for you. Tell me about your friends’ responses to that.”

As Gorden has explained, clarification probes exert more control over the topic than elaboration probes. That is, clarification questions specify the topics that participants should provide further information about; elaboration probes seek more information, while not specifying what kind. Whether interviewers should

seek further elaboration and clarification immediately or retrospectively is another question to be considered. Here, general guidelines for good practice are useful: Interviewers should avoid interrupting interviewees, should pose probes using participants’ words wherever possible, and, in probing, interviewers should show that they have been actively listening to participants.

In asking follow-up questions, novice interviewers may resort to the use of formulations, rather than using effective probes. Formulations are a conversational resource that speakers use to show they have been listening and understanding prior talk. In formulations, speakers summarize, delete, and transform various aspects of prior talk. A more effective way of probing for clarification than formulating the researcher’s understanding of prior talk is to use the interviewee’s own words. For example,

You’ve talked about the problems you’ve had with *y*.

Tell me more about that.

Or

Describe the kinds of things that you do.

For researchers who would like to use formulations in interviews as a way of checking their understandings of prior talk, the following question may also be useful:

From what I’ve heard you say, I understand *x*. Have I understood that correctly?

As Stewart and colleagues have pointed out, probes are an essential technique in eliciting further information from participants of focus groups. In focus groups, moderators can also use probes to give the next turn to other members of the group and ensure participation of group members. For example,

Does anyone else have something to add to that?

Is anyone able to provide a specific example of that?

In focus groups, moderators are advised to avoid creating conflict by posing questions that may lead to disagreement and defensive responses from group members. Rather, probes can be formulated that allow for different perspectives among group members:

What are other views on that?

In learning how to use probes effectively, novice interviewers must attend to several issues simultaneously. First, interviewers must listen attentively to interviewees, paying attention to the issues of relevance for the purposes of examining the research questions. Second, interviewers must learn how to pose follow-up questions that purposefully elicit further information that will provide data to understand the topic. This involves recognizing points in the talk in which interviewees have provided insufficient information about topics, used terms that may need to be defined, or avoided answering questions in detail. Third, interviewers must mindfully pose probes without interrupting the flow of interaction and disrupting the interviewer–interviewee relationship. To sum up, in qualitative interviews, effective use of probes entails selecting the topics about which the researcher needs more information, asking probes that seek further information without providing possible responses in the questions, and using probes in a way that invites interviewees to provide more information without transforming interviews into an interrogation. Probing, then, is a skill that requires careful listening, sensitive question-posing, and attentive timing.

PROGRAM EVALUATION

To evaluate is to determine the value of something, that is, to determine its merit, worth, or significance. Program evaluation is the systematic application of research to inform evaluative judgments. It involves the systematic collection of empirical information about the activities, characteristics, and outcomes of programs to make judgments about the program's merit or worth, improve program effectiveness, and/or

inform decisions about future programming. *Merit* refers to the intrinsic value of a program, for example, how effective it is in meeting the needs of those it is intended to help. In schools, this means determining to what extent students are learning what they need to know. *Worth*, in contrast, refers to extrinsic value to those outside the program, for example, to the larger community or society. A welfare program that gets jobs for recipients has merit for those who move out of poverty and worth to society by reducing welfare costs. *Significance* involves determining the relevance and importance of evaluation findings, for example, the extent to which one can confidently attribute observed outcomes to the program intervention. In all these cases, program evaluation is undertaken to inform decisions, clarify options, identify improvements, and provide information about programs and policies within contextual boundaries of time, place, values, and politics. Program evaluators use a variety of social science research methods to gather information, including qualitative methods. Qualitative methods have become widely used in program evaluation, often in conjunction with and to illuminate quantitative patterns, but also to contribute to in-depth understandings of program processes and participant outcomes.

Variety in and Standards for Program Evaluation

Evaluation research is characterized by enormous diversity. From large-scale, long-term, international comparative designs costing millions of dollars to small, short evaluations of a single component in a local agency, the variety is vast. Contrasts include internal versus external evaluations; outcomes versus process evaluations; experimental designs versus case studies; mandated accountability systems versus voluntary management efforts; academic studies versus informal action research by program staff; and published, polished evaluation reports versus oral briefings and discussions where no written report is ever generated. Then there are combinations and permutations of these contrasting approaches.

Despite this diversity, the professionalization of evaluation has led to standards for judging the quality of evaluations. The standards published by the Joint Committee on Standards in 1981 identified four areas of quality for judging evaluations: utility, feasibility, propriety, and accuracy. The rationale for this framework

was that an evaluation should not be done if there is no prospect for its being useful to some specific intended users. Moreover, it should not be done if it is not feasible politically and pragmatically (including financially). Evaluations also have to be conducted fairly and ethically. No matter how technically rigorous an evaluation study might be, by the criteria of the standards, if the findings from an evaluation are not used, it is an inadequate evaluation.

Moreover, the standards established the value and appropriateness of both quantitative and qualitative approaches. Indeed, in the section of the standards on accuracy, there is a standard on qualitative analysis and one on quantitative analysis. They are worded identically to be sure that in no way were the standards seen as preferring one approach over the other:

Analysis of Quantitative Information—Quantitative information in an evaluation should be appropriately and systematically analyzed so that evaluation questions are effectively answered.

Analysis of Qualitative Information—Qualitative information in an evaluation should be appropriately and systematically analyzed so that evaluation questions are effectively answered.

Purposes of Evaluation

Evaluation findings typically serve three primary purposes: rendering judgments, facilitating improvements, and/or generating knowledge. Judgments are undergirded by the accountability perspective, improvements are informed by a developmental perspective, and generating knowledge contributes to theory formulation and testing. These are by no means inherently conflicting purposes and some evaluations strive to incorporate all three approaches, but one is likely to be dominant in any given effort and prevail as the primary purpose informing design decisions and priority uses. Confusion among these quite different purposes is often the source of misunderstandings in an evaluation and can become disastrous at the end when it turns out that different intended users had different expectations and priorities.

In judgment-oriented evaluations, specifying the criteria for judgment is critical. Different stakeholders will bring different criteria to the task of judging a program's effectiveness. Summative evaluation constitutes an important purpose distinction in any menu of alternative evaluation purposes. Summative evaluations

judge the overall effectiveness of a program and deal with the problem of attributing measured results to the program intervention. Summative evaluations are particularly important in making decisions about continuing or terminating an experimental program or demonstration project. As such, summative evaluations are often requested by funders.

In contrast to summative evaluations, improvement-oriented (formative) evaluations often use an inductive approach in which criteria are less formal as one searches openly for whatever areas of strengths or weaknesses may emerge from looking at what's happening in the program. Qualitative methods can be especially useful for this purpose. Improvement-oriented evaluations aim to determine which participants are making good progress, which are not doing so well, and what kinds of implementation problems have emerged. The formative evaluator looks for unexpected consequences and side effects. It is especially important to gather data about how staff and clients are interacting, and about staff and participant perceptions of the program, finding out what they like, dislike, and want to change. Data on perceptions of the program's culture and climate may be part of the evaluation. The evaluation may examine how funds are being used compared with initial plans and how the program's external environment is affecting internal operations, looking for efficiencies that might be realized. In formative evaluation, it is especially important to gather evaluative feedback from program participants who receive services and to take that feedback seriously.

One classic metaphor explaining the difference between summative and formative evaluation is that when the cook tastes the soup, that's formative; when the guests taste the soup, that's summative.

Both summative and formative evaluations involve the instrumental use of results. Instrumental use occurs when a decision or action follows, at least in part, from the evaluation. Evaluations are seldom the sole basis for subsequent summative decisions or program improvements, but, when well done, they can contribute, often substantially, to programmatic decision making.

Special Contributions of Qualitative Evaluations

Certain purposes, questions, problems, and situations are more consonant with qualitative methods than

others. Understanding what people value and the meanings they attach to program experiences, from their own personal and cultural perspective, are major inquiry arenas for qualitative evaluation. This requires interviews to capture participants' perspectives.

Document analysis and review of program files can also be an important area of qualitative evaluation. However, in-depth reviews of the quality of care for participants in programs can draw on case files only if those files contain appropriate and valid information. When files are to be used for evaluation purposes, program staff need special training and support in how to gather and report highly descriptive qualitative data in program case files.

There are many aspects of programs that can be measured quantitatively, for example, counting the number of people who enter a program, the number who leave, and the number who receive or report some concrete benefit from the program. However, many attributes of programs do not lend themselves to counting. For example, school outcomes can be looked at both in terms of quantity of change and quality of change. Quantity of change may involve the number of books read, a score on a standardized achievement test, the number of words spelled correctly, and the number of interactions with other students, the teacher, or people of a different race. Each of these dimensions has a corresponding quality dimension that requires description rather than scaling. Thus, to find out *what it means* to a student to have read a certain number of books invites in-depth, qualitative interviewing and observation. In addition to counting the number of words spelled correctly, qualitative evaluation focuses on what spelling means to the student. How is spelling integrated into the student's approach to writing? How does the student think about spelling, approach spelling, feel about spelling? The answer to such questions requires description of individual students' perspectives and situations such that the meaning of the experience for the students is elucidated.

The same distinction holds with regard to programs that emphasize deinstitutionalization, for example, community mental health programs, community corrections, and community-based programs for the elderly. It is possible to count the number of people placed in the community. It is possible even to measure on standardized scales certain attributes of their lives and livelihoods. It is possible to have them subjectively rate various aspects and dimensions of quality of life. However, to fully grasp the meaning of a

change in life for particular persons it is necessary to develop a description of life quality that integrates interdependent dimensions of quality into a whole that is placed in context: What is their daily life like? Who do they interact with? How do they perceive their lives? How do they make sense of what they experience? What do they say about the path they are on? How do they talk about their quality of life? What do they compare themselves to when deciding how well they are doing? These are areas of qualitative inquiry that support quality enhancement efforts and insights.

To understand what happens to people in programs, participants' stories are important. It is through these stories that we come to understand how program staff work with clients and each other or with family and friends of their clients and how what goes on contributes to outcomes. Stories depict how participants grow and change in response to program interventions and other forces in their lives. There is a depth and richness to such evaluation stories that numbers alone cannot capture. Getting into case details better illuminates what worked and did not work along the journey to outcomes—the kind of understanding a program needs to improve.

Qualitative Syntheses of Findings About Effectiveness

As the field of evaluation has matured and a vast number of evaluations has accumulated, the opportunity has arisen to look across findings about specific programs to formulate generalizations about effectiveness. This involves synthesizing findings from different studies. An early and important example of synthesis evaluation was Lisbeth Schorr's *Within Our Reach*, a study of programs aimed at breaking the cycle of poverty. She identified the patterns of successful programs as follows:

- offering a broad spectrum of services;
- regularly crossing traditional, professional, and bureaucratic boundaries;
- seeing the child in the context of family and the family in the context of its surroundings, that is, holistic approaches;
- coherent and easy-to-use services;
- committed, caring, results-oriented staff;
- finding ways to adapt or circumvent traditional professional and bureaucratic limitations to meet client needs;

- professionals redefining their roles to respond to severe needs; and
- overall, intensive, comprehensive, responsive, and flexible programming.

Such generalizable evaluation findings about principles of effective programming derive from qualitative syntheses of diverse case studies. Such extrapolations have become the knowledge base of the field of evaluation research. Being knowledgeable about patterns of program effectiveness allows evaluators to provide guidance about development of new initiatives, policies, and strategies for implementation. These kinds of lessons constitute accumulated wisdom—principles of effectiveness that can be adapted, indeed must be adapted, to specific programs, or even entire organizations.

(which help participants to express themselves non-verbally) or from a variety of creative techniques. Nowadays, the term *projective technique* is commonly used to refer to a range of creative or enabling tasks, and the term is used in this broader sense here.

Projective techniques are research tools or approaches designed to access thoughts, feelings, or needs that are not easily accessible to research participants and/or to the researcher. They also provide permission for participants to express embarrassing or antisocial views by projection—attributing these views to other people. In this way, unacceptable ideas can be expressed, but personally disowned. Projective techniques, therefore, offer a structure for participants that makes it easier for them to access thoughts and emotions that are difficult to verbalize or difficult to express publicly. They can be invaluable in certain research situations, especially when we need to get beneath the top of mind or rational data. They enable access to hidden aspects and layers of respondents' experience and help translate the intuitive, the emotional and nonverbal into concepts that can be explored in the research situation.

Many projective techniques are directly borrowed from clinical psychology practice and are embedded in particular theoretical approaches. But to commercial researchers, what matters is their usefulness in developing understanding and answering the research question. They can generate additional layers of data that are difficult or impossible to access through conventional discursive means.

Projective techniques can be used in a wide variety of situations, for example,

- to obtain fresh perspectives on heavily researched markets,
- in new product or brand development or brand repositioning,
- in developing advertising strategy, and
- to evaluate courses/conferences when there is limited time and access to research participants.

Material generated through projective techniques can enable client or creative teams to develop a more holistic understanding than would be possible by verbal input alone. Visual and auditory material, music, drawing, word associations, and drama can provide a rich understanding of target markets and their relationships with brands and organizations.

The range of projective techniques is extensive. They can be very simple, incorporated into standard

PROJECTIVE TECHNIQUES

Historically, projective techniques were differentiated from related approaches such as enabling techniques

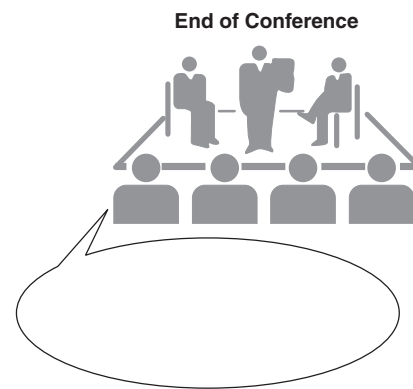

research approaches, and used without preplanning. Alternatively, they can be complex and time consuming, requiring prior preparation, specific materials, training, and experience. Projective techniques can easily be adapted to fit the needs of almost any project.

Some examples of projective techniques are as follows:

- *Personification*: If this chocolate bar came to life as a person, who would it be?
- *Market Mapping*: Group a collection of products together according to those that you see as similar in feel.
- *Bubble Drawings*: Cartoons in which speech or thought bubbles are filled in by participants, for example, what is the shopper thinking about X brand?
- *Life Graphs*: Draw a graph of a particular experience, for example a plane journey, noting the highs and lows, when and why these happened, and how you experienced each stage.
- *Collages*: Working as a group, construct a collage that represents how you feel about organization Y, using pictures from magazines, words, drawings.
- *Psychodrawing*: Draw a picture of your relationship with money.
- *Role Play*: Two people, one takes the role of the bank manager, the other plays the customer looking for a loan. Play out the conversation.

Perhaps the most important thing to remember when using projective techniques is that they are a means to an end, the end being greater understanding. The materials produced through using such techniques are not the findings. It is essential to explore with participants what they mean; why they have represented a brand or organization in such a way. Projective techniques work most effectively and have greater validity when research participants themselves interpret the outcomes. Equally, it is important to be clear on their usage. For instance, with sophisticated consumers, it is sometimes easier and more effective to talk about brand imagery rather than spend precious time on projective techniques.

Projective techniques can be used in many different types of research, but they are particularly useful in a group context, because there is time, because it is a relatively secure and less exposed environment for research participants, and because they can work in supportive teams. When exploring brand issues, a

Thought Bubble. This is an example of a thought bubble used to capture experiences at the end of a conference—useful when interviewing time is tight.

group context is particularly relevant in that brands are culturally defined. Accessing shared meanings and taken-for-granted assumptions within a group context is therefore more appropriate than using individual interviews.

It is very important that projective techniques are introduced at the appropriate stage in the research process. If introduced too early in the process, when participants are establishing the group, they may not engage participants. Too late in the group and participants may be flagging. Ideally, projective techniques should be introduced when the group is warmed up and enthused about the topic under discussion. Projective techniques change the style and energy of the group. Often they speed up the process and increase involvement. Participants may need a quiet period afterwards to reenergize.

In order to encourage participant involvement, it is important to introduce the particular technique appropriately. Participants need to be given a simple, clear explanation in a clear and confident manner. They need to feel that what they are being asked to do is reasonable, makes sense, and could be interesting. Projective techniques have value only insofar as they encourage people to talk in different ways.

Projective techniques work in different ways; some allow consumers to identify implicit structures, for example, the differences and relationships between brands. Others present consumers with materials they must react to, leading to discussion, or they disrupt the taken-for-granted world, which forces consumers to behave in different ways or explore new possibilities.

They are an invaluable part of the qualitative armory and enable richer, deeper, and more creative understanding of how research participants' understand their worlds.

PROJECT MANAGEMENT

A project is a nonroutine, one-time effort undertaken to create a specific measurable outcome, namely a product or service. Project management has been described as both a discipline and a process concerned with the successful completion of a defined project from inception to completion. The process involves planning, coordinating, and executing all project tasks and associated resources with specific attention to time, cost, scope, and quality.

A research study is a project. Large or small, funded or unfunded, research projects involve significant planning from initial proposal design to data collection to publication of results. Increasingly, large external research grants and contracts are requiring project-management expertise as a condition of funding. Qualitative researchers would benefit from adopting project-management techniques as an integral part of their research.

History

Although not formally labeled examples of project management, evidence of successful project management throughout history ranges from the building of the pyramids to the construction of the Eiffel Tower to advances in the industrial world. During the previous century, the main disciplines engaged in adopting and popularizing project-management practices came

from the construction, manufacturing, engineering, and defense industries. The establishment of the Project Management Institute (PMI) in 1969 was instrumental in promoting the profession of project management and working to standardize terms and processes across a spectrum of corporations and organizations. In recent decades, information and technology, computer system development, pharmaceutical, and financial companies have contributed to advances in the discipline of project management. Today, project management is rapidly being adopted across a wide spectrum of industries, both large and small. Project management is also being adopted for personal use such as planning a vacation or a wedding. For qualitative researchers, project management could be used to coordinate tasks such as budgeting, hiring research assistants, obtaining appropriate certifications and approvals, collecting and analyzing data, submitting reports to agencies, and preparing presentations and publications.

Phases of Project Management

Typically, the process of project management involves five phases. The labels used to describe these five phases vary somewhat in the literature; however, the generally agreed principles of project management according to the PMI are initiating processes, planning processes, executing processes, monitoring and controlling processes, and closing processes. During Phase I, initiating processes, the project objectives are defined. Details concerning the overall scope of the project are documented in order to keep the project manageable. At this phase, qualitative researchers may determine the size of the project (regional or national focus) as well as general timelines (e.g., expected deliverables at the completion of a 3-year research grant). Phase II, the planning process, involves detailing all of the activities to be accomplished in order to successfully complete the project. Work breakdown structures are created to illustrate the hierarchy of all work units, subprojects, tasks, subtasks, and the interdependencies among these components. Time estimates and cost factors are carefully considered as well. During this phase, qualitative researchers plan all tasks, responsibilities, and time estimates associated with the project. Once finalized, this plan is considered the baseline plan. During Phase III, the executing

Figure 1 GANTT Chart

Source: Microsoft Project 2003 screen shot; reprinted by permission of Microsoft.

Note: This is a screen view of a GANTT chart, used to plan and monitor progress in a qualitative research project.

process, the activities detailed in the baseline plan are implemented. In Phase IV, the monitoring and controlling process, progress is compared with the baseline plan. Any problems that arise are dealt with by adding, deleting, or adjusting activities to work toward successful completion of the project. For example, the time estimated to transcribe and analyze the interviews may have been underestimated, so adjustments would be made to keep the project on track (e.g., reduce the number of interviews, or hire additional assistants to transcribe and analyze data). The baseline plan is not changed, but revisions and progress are documented. This phase provides flexibility in an emergent research design as the research path evolves. The final phase, the closing phase is an often overlooked but vitally important aspect of project management. This phase allows for reflection and evaluation of what went right and what needed improvement. The changes made during Phase IV are reviewed in preparation for subsequent projects.

Techniques and Tools

Tools and techniques used to facilitate the project-management process for both small and large organizations range from paper-based templates to software and web-based products. The most accepted format to view project planning and progress is to use a GANTT chart. This type of bar chart was first developed by Henry Gantt in the early 1900s and allows users to visually monitor all scheduled project activities and their progress. Figure 1 is a sample GANTT chart

showing the baseline plan and progress bars from Phase IV of a qualitative research project.

Benefits and Challenges

The benefits of using project-management techniques as well as software and web-based tools include improved organization and time saving. Schedules and responsibility assignments are prepared early in the planning process. Monitoring progress as the plan is implemented ensures that problems are recognized early and appropriate modifications to the project are introduced with attention to time, scope, and cost. Project-management tools also facilitate improved communication among members of a given project team. Continual communication and reflection throughout the project cycle facilitate success of the current project and provide the groundwork to ensure that the lessons learned will benefit future research project planning. Qualitative researchers can use project-management tools to manage a single research project or a range of related or unrelated research projects. Project-management plans could also facilitate student-supervisor communication and progress monitoring.

Implementing project-management techniques and tools does not guarantee project success. The challenges are to ensure that the project objectives designed in Phase I are realistic and achievable. As the project moves through the five phases, project managers must be prepared to revise plans, scale down projects, or potentially end the project, if for example the original assumptions and projects were overly ambitious, the time estimates unrealistic, or delays unforeseen (e.g., difficulty accessing the research site, turnover of research assistants). Using software or web-based tools, one must be careful not to become overly consumed with managing the plan, making constant adjustments and micromanaging team members rather than managing the actual project. Implementing project-management techniques to facilitate the management of a research study will improve over time as researchers continually learn from one project to the next. Researchers will become more adept at estimating time associated with various tasks (e.g., obtaining ethics clearance, analyzing data, preparing manuscripts) resulting in successful research planning.

PROLONGED ENGAGEMENT

Prolonged engagement refers to spending extended time with respondents in their native culture and everyday world in order to gain a better understanding of behavior, values, and social relationships in a social context. The immersion of the researcher in the culture of the respondents on a long-term basis involves the development of congenial relationships between the researcher and members of the respondent community. The notion of prolonged engagement is most associated with traditional anthropology studies, such as those of Margaret Mead, but it is becoming increasingly used in a variety of qualitative research studies in an effort to move beyond the “observer” role of the researcher to one of engagement.

The use of prolonged engagement allows the research study to go farther in the investigation of certain phenomena that cannot be adequately explored with short-term study designs. By becoming engaged in and learning the cultural environment through experience in the natural everyday world of respondents, researchers can explore multiple constructions of reality and become familiar with the variety of ways that respondents interpret experiences. Spending sufficient time in a culture provides a more appropriate basis for determining the relationships between empirical results and the way individuals behave, speak, and interact in the natural setting of everyday life. While intensive interviewing on a short-term basis can provide valuable data about respondents’ culture, prolonged engagement goes beyond the words of respondents to the deciphering of meaning of language narratives and social interactions. In essence, researchers who employ prolonged

engagement seek to become members of the community, going beyond what respondents tell them in initial interviews to discover more fully things that go unsaid in the early stages of all human encounters.

The purpose of this method is to spend longer periods of time both in the world of the respondent and their community in order to better understand contextual meaning through the eyes of the ones who know it best. The world reality of the respondents can be more fully explored and experienced by the researcher through prolonged engagement, rather than “sitting on the sidelines” of the research setting. Explanations are clarified through repeated encounters, the researcher can understand to a much greater degree what is being said and not said, thus focusing on the topics related to the focus of the research study. The research study then becomes a joint experience between researcher and subject, allowing for greater understanding for both in how a phenomenon is experienced over time.

Issues Related to Prolonged Engagement

Prolonged engagement involves significant commitment and investment, not only for the researcher but also for the respondents as well. Erving Goffman, who advocated such an approach in his classic ethnographic research, believed that to truly learn a community’s culture, the researcher must effectively penetrate the community circle, even to the point of becoming a member. Goffman noted that by going beyond the traditional, superficial, and formal researcher-subject encounters, researchers subject themselves to the life circumstances of those being studied. He further asserted that the researcher must actually be authentically bound to the group or community. He explained his conception of prolonged engagement in this way:

You’re empathetic enough—because you’ve been taking the same crap they’ve been taking—to sense what it is that they’re responding to. To me, that’s the core of observation. If you don’t get yourself in that situation, I don’t think you can do a piece of serious work. (Goffman, 1989, p. 126)

Although not all researchers agree with Goffman’s position concerning the degree of going completely “native” in a community in order to produce valid research, prolonged engagement provides the ideal

foundation for the emic researcher who desires to go beyond simply describing the range of experiences of “typical” respondents to one of cultural immersion in the research setting. This occurs through being engaged on a long-term basis with respondents in their world as both researcher and respondent evolve in shared interactions. In other words, the sights and sounds of the world of the respondent, which had initially been unknown and foreign territory to the researcher, become familiar and comfortable. Prolonged engagement in a community requires extensive involvement in the culture and, as such, is more appropriate for specific research topics, especially those related to the discovery of cultural meanings. For example, the case study of specific events in a community’s history may employ prolonged engagement as the most appropriate approach for the study design and purpose.

Methods of Prolonged Engagement

In order to effectively engage with a community on a prolonged basis, the researcher must first find a way to effectively gain entry and membership in the community, establish a trust relationship with the respondents, and then commit to remaining as an active member participant for sufficient time to understand, and become a part of, the every day lives of the respondents. It is only at this point that the researcher can effectively explore, analyze, and interpret the data derived from the fieldwork of the research study.

As the researcher slowly gains acceptance into the community, he or she must constantly remain focused on the issues and focus of the research study’s purpose. This can be one of the most challenging aspects of prolonged engagement: remaining objective while still interacting and being a part of the culture under examination. By defining the complexities and culture of the group, the researcher begins to learn the unique and often secret language common in all communities in order to decode meanings that are reflected in the communication and actions of the members. The researcher using the method of prolonged engagement is in somewhat of a contradictory position: although seeking to become a part of the community, he or she must also remain focused on the purpose of the engagement, which is to more fully understand and explore the culture as an objective participant.

Social scientists have traditionally relied on informants and “insiders” in field research, and prolonged engagement involves similar techniques. The

researcher must gain confidence and trust, to provide more fully native insights and explanations that are not always apparent to the community outsider. Prolonged engagement allows for ample time and community involvement in the identification of those who can best represent the authentic views according to the study’s focus.

Validity and Reliability Issues of Prolonged Engagement

When researchers are up close and personal in the lives of the community and its members, the rigorous criteria of credibility, reliability and validity become intrinsically linked. The value of any research is to demonstrate what many researchers refer to as truth value. Through multiple encounters and learning the native language of the members of the community, as well as exploring the variety of ways that respondents express themselves, the researcher further establishes validity. The multiple constructions of reality of the respondents should be well represented through repeated encounters and immersion in the community’s rituals and everyday interactions. By clarifying contradictions or misinformation injected either by the community members or by the researcher, as well as analyzing differing perspectives, credibility is enhanced. The focus of the study guides these constant comparisons and contrasts as well as allowing for the identification of those elements in the situation that are most relevant to the study’s focus and purpose. By pursuing the specific issues related to the research study, the researcher can focus on validating them in detail and document them as they evolve.

To do this, the researcher must demonstrate that these multiple constructions are adequately described in the native words of the respondents and are deemed credible by the members themselves. This can be achieved by the use of member checks as a means of requesting the community members to validate the interpretations of the researcher. This occurs simultaneously with data collection, as analysis of members’ expressions, words, behaviors, and interactions are tested with the members themselves. If the analysis and conclusions of the researcher using prolonged engagement as a research strategy are recognizable to community members as adequate representations of their own “version of reality,” credibility is more likely to be established in the final results of the study. This can be done through formal means, such as repeating words back to the

respondents, clarifying terms unfamiliar to the researcher in the respondents' own words, and verifying interpretations of the researcher with the community members. It is critical to ask continuously for clarification and verification from diverse members of the community about their worldview in order to avoid misrepresenting and losing in translation the meaning of important concepts critical to the study's purpose. Such checks and rechecks help the researcher "connect the dots" of the cultural milieu and represent more accurately how the findings relate to the purpose of the research. Credibility and validity can also be demonstrated through less formal means, such as using thick descriptions of narratives and a variety of examples from interactions between the researcher and community members in the final report. As a final note, it is even more important when using prolonged engagement as a method that the researcher acknowledges an estimate of his or her biases that may exist due to the type of intimate engagement between the researcher and the community.

Ethical Issues in Prolonged Engagement

Because of the intimate and personal relationships formed during prolonged engagement, researchers must be especially vigilant that the members of the community comprehend the purpose of the study and their role in the research. Transparency between researcher and the community is essential. While knowledge about the community's culture is critical to understanding individual behavior, values and the construction of meaning, detailed descriptions, and quotes and narratives should be restricted to the aspects of the study focus. This can be a daunting task, as all researchers who have conducted field studies know, since most of the data collected is of interest to both the researcher and community. Building trust and dealing with sensitive issues between the researcher and members of the community must be a constant consideration and respected as such. Statements made about a culture in the final report should be consistently phrased in terms that are acceptable to the community. Trust and rapport can be established only if the researcher takes a genuine interest in the community and its members, learns the native language and rituals, attempts to truly understand the cultural nuances of the community, and has genuine respect for the members of the community and their way of life.

PSEUDONYM

A pseudonym is a fictional name assigned to give anonymity to a person, group, or place. Many ethical codes outline the importance of anonymity and confidentiality, and researchers routinely use pseudonyms as a means to this end. Pseudonyms are very useful for research in sensitive topics, particularly with regard to deviant or criminal behavior. When pseudonyms are used, it is important that this be clearly identified in any dissemination of findings.

Although pseudonyms are usually assigned to those who take part in research, researchers themselves occasionally employ a pseudonym. For example, in Sjaak van der Geest's anthropological research on marriage, death, and witchcraft in an African village, she gave pseudonyms to the village and participants. Later, she published her work under a

pseudonym because her university colleagues could have easily determined the name of the village and the small number of people living there.

Pseudonyms can be effective in protecting confidentiality and anonymity, but their use presents both practical and ethical issues. Although the researcher or participant may determine a pseudonym, care should be taken to consider whether the name may redefine the pseudonymized person's character. For example, in his doctoral dissertation, Francisco Ibanez-Carrasco retold the story of a student who had sued a university, and he pseudonymized the student as "Rogue," but otherwise portrayed the student positively. When participants choose their pseudonyms, problems can occur when a sample is sufficiently large that they select the same names. This can be problematic for researchers during manuscript preparation if participants cannot be contacted to approve new pseudonyms.

A general rule about the presentation of data is that individual respondents should be able to recognize themselves, but a reader should not be able to recognize the respondent. Therefore, it is ethically important that participants not be offended by pseudonyms that detract from how they see themselves or others. For example, in narrative research participants may take great care to share intimate and detailed accounts about themselves and persons they care for. Researchers should be sensitive to this and consider how participants might feel if they see themselves and others lost in a randomly selected pseudonym. In some research, such as that dealing with loss and bereavement, participants may actually prefer to have themselves and their loved ones presented as who they really are.

Researchers have been criticized for the overuse of pseudonyms and engaging in a form of ethical paternalism for assuming that participants must be anonymized. Many research participants do not wish to be anonymous. They participate in research because they anticipate a benefit, such as the hope that their contributions are valuable enough to make a difference and that they will be recognized for it. Anonymizing through pseudonyms defeats such a benefit, not only for individuals but entire communities if their geographical locations are concealed.

PSYCHOANALYTICALLY INFORMED OBSERVATION

Psychoanalytically informed observation as a research method derives from the method of infant observation as it was established in the 1950s by child psychoanalyst Esther Bick in her teaching of child psychotherapy trainees at the Tavistock Clinic in London. Infant observation is now a widely established method in psychoanalytic training. An appropriation of the principles of this method for research purposes, observing people of any age, in any relational, group, or institutional setting, affords a method that transcends reliance on what participants say—a reliance characteristic of most contemporary social science research. For any research broadly interested in identities and relational dynamics, the method can ensure that affect, unconscious intersubjectivity, and embodiment are not ignored and that identity change over time remains in view.

Classically, the infant observation method involves the observer visiting the new mother (or other primary caregiver) and baby at a regular time each week for one hour over a 2-year period. Supervision is essential as strong feelings are stirred up in observers during the process. The observer intervenes as little as possible, while recognizing that her or his presence has effects on the family. The observation is as naturalistic as possible in not selecting in advance any categories of behavior. Note writing is deferred until after the hour and emphasizes fine detailed description kept distinct from making theoretical inferences. The notes provide the basis for discussion at a weekly supervisory seminar group, enabling the observer to go beyond her or his single viewpoint and reveal and learn from transferences that are inevitably produced as a result of powerful identifications. The emotional significance of the observation experience provides a central vehicle for learning about babies' early self-development.

Stephen Briggs used the method to follow six babies of at-risk mothers. He identified characteristic and persistent patterns in the way that mothers and babies managed anxiety. This method, adapted for use as a formal qualitative research tool, provides a qualitative case-based and in-depth method for studying the extra-discursive alongside what people say. For example, as part of a research program into identities, funded by the United Kingdom Economic and Social Research Council, a research team investigated the identity processes involved in becoming a mother for the first time. Psychoanalytically informed observation was used alongside free association narrative interviews in order to open up for exploration the aspects of becoming a mother that are less conscious and therefore less capable of being expressed directly through language. Six observed mothers were part of a group that was interviewed three times over the baby's first year. The observational focus was the mother–baby couple; this being based on the principle derived from object relations psychoanalysis concerning the relational nature of subjectivity. The many other relationships affecting new mothers' identities were often also observable.

In this method, the ontology of research participants—including researchers—is consistent with the epistemology that guides the method in producing data and their analysis. Both are based on psychoanalytic premises, namely the effectivity of a dynamic unconscious and the relational, affective, and embodied nature of subjectivity. In contrast to epistemologies based on rational cognitive assumptions, psychoanalysis uses a method based on using one's subjectivity as an instrument of knowing. Different conceptualizations of reflexivity, objectivity, and validity underpin this methodology. This is reproduced in the style of note-taking, in which any experience that engenders a notable emotional response is attended to and recorded as such, and in the way that the group works with data. Observers' notes, each set developing a unique case as the mother's identity changes over her baby's first year of life, provide the material for discussion at weekly seminars attended by the observers, the seminar leader, and the researchers. Seminar notes provide a preliminary pass at making sense of the observation data and constitute another layer of data available for analysis.

Compared with interviews, observation data reveal the strains and conflicts associated with becoming a mother that she may not talk about or even be consciously aware of. They also register the deep emotional bonds that are often expressed in embodied ways.

PSYCHOLOGICAL GENERALIZATION

Psychological generalization refers to cognitive processes employed by both producers and consumers of qualitative research. Producers of research, for instance, engage in psychological generalization when they make sense of what is happening within a case or a collection of cases.

Within-Case Psychological Generalization

A psychological approach to within-case generalization was first articulated by the German historian Wilhelm Dilthey during the advent of the social sciences in the mid 1800s. Dilthey argued that the social sciences required a different methodology than the physical sciences because social scientists studied worlds of meaning that had been constructed by human beings.

Thus, according to Dilthey, the goal of social science is to understand the different meanings that both were created by and, in turn, influenced people and shaped events in different historical eras. Dilthey argued that researchers could do this by engaging in a hermeneutical process, that is, a circular approach to inquiry in which generalities were inferred by looking at particulars (e.g., cultural artifacts such a historical period's legal code or popular works of art) and in which inferred generalities, in turn, permitted social scientists to see particulars in new and richer ways. These enhanced perceptions of particulars added additional depth and dimension to general statements about a historical era or a particular culture, and these new general insights, in turn, shed additional light on the meaning of particulars.

Dilthey argued that social sciences could do all of the above because they were human beings studying other human beings. Because of this shared humanity, social scientists could understand social phenomena psychologically. Unlike scientists who studied physical phenomena, social scientists could use their own life experiences, along with their imaginations, to make sense of other historical eras and the general meaning implicit in the artifacts these eras produced.

Most contemporary qualitative researchers accept some variation of Dilthey's view of how within-case generalizations are generated. They have, however, also developed a range of strategies—for example, triangulation, member checking, peer debriefing, audits—to reassure skeptics that their psychologically generated within-case generalizations are not merely figments of researchers' imaginations.

Generalizability in Psychological Terms

Contemporary researchers also have used variations of the psychological generalization notion to redefine generalizability in psychological terms. Robert Stake, for example, has written about naturalistic generalization, and Yvonna Lincoln and Egon Guba have articulated the notion of transferability. Both notions rely on the research consumer's psychological judgment.

In addition, Robert Donmoyer used schema theory to reconceptualize generalizability in psychological terms and, in the process, to answer a long-standing question about the utility of studying atypical cases. He argued that outlier cases can be useful because such cases require consumers of the research to not only assimilate the details of a case into their existing cognitive structures, but also to expand their existing structures to accommodate the idiosyncratic elements of the case. This accommodation process leads to cognitive structures that are both more integrated and more differentiated than they were before the accommodation occurred; such structures, in turn, should produce more sophisticated perceptions and action.

PUBLISHING AND PUBLICATION

Publication refers to the act of circulating written results in order to disseminate and communicate these findings within academic and/or professional circles, or the broader public. Increasingly, scholarly publications are distributed electronically as well as in print. For researchers outside of academia, publications may be reports, articles in professional journals, or other avenues that disseminate research to colleagues, agencies, government institutions, or related bodies. For researchers within academia, the quality and sustainability of individuals, departments, and universities is largely based on publications in international refereed journals and books. A central part of being an academic researcher is publishing and disseminating results, often encapsulated in the mantra “publish or perish.” Publication prowess is furthermore often tied to funding opportunities and resource allocation in addition to providing substantial returns in terms of career mobility and recognition. This entry defines the central features of publishing and publications, with a focus on academia.

The Writing and Publishing Process

Publishing begins with the writing process, which should be based on clarity. Numerous articles and books can aid researchers in producing high quality manuscripts (see Further Readings). It is also essential to avoid fundamental mistakes like spelling errors, follow standard style guidelines (available from general texts such as William Strunk and Elwyn Brooks White's *The Elements of Style*), and keep the level of competence of readers in mind. Finally, avoid numerous footnotes or endnotes, write concisely and logically, remain focused, and show a command of the secondary literature.

To achieve success, it is advisable to first engage in an internal review (advisors, coworkers, discussion groups), look for a suitable journal or publisher, and submit a professional manuscript. After the manuscript has been submitted, it is generally sent for peer review and often undergoes a double-blind review process (i.e., both author and reviewers are anonymous). This process of peer review and revision is intended to maintain the quality of the publication;

however, some have argued that peer review is more reminiscent of a lottery than a rational process, or (at worst) a process that forces authors to “sell their souls” by editing to suit others’ intentions or risk not being published at all. Authors are then informed of the editorial decision, receive comments, and if the article has received a “revise and resubmit,” have the opportunity to revise the manuscript. If the revised article is accepted, it is usually copyedited prior to being typeset and distributed through print and digital means.

The Citation and Journal Impact Factor Indexes

In the increasingly competitive academic system, the journal impact factor and citation indexes have emerged as the central evaluation device in many academic institutions across most disciplines. These tools were developed by Eugene Garfield and presented in his 1955 paper, “Citation Indexes for Science: A New Dimension in Documentation Through Association of Ideas.” Quantitative and seemingly more objective indicators in the form of journal impact factors and citation indices were developed as a practical and cost-effective tool to serve these evaluation goals. Evaluation often takes place using publication counts, number of citations, and the prestige of journals.

The journal impact factor is a quantitative measure of journal quality in the form of an index that charts the frequency with which articles from a journal are cited. The impact factor is a simple calculation that covers a 3-year period calculating the average number of times published papers are cited for up to 2 years after publication. The impact factor for a journal in 2005 is calculated as follows:

A = total number of times articles published in 2003–2004 were cited in articles published in 2005

B = total number of articles, reviews, proceedings, or notes published in 2003–2004

Therefore, the 2005 Impact Factor = A/B.

In a similar manner, the impact of individual researchers is also assessed via a citation index. The Institute for Scientific Information in the United States produces citation information by recording the number of times each publication has been cited within an allotted period and by whom. This information is published in the form of a citation index.

Numerous researchers across multiple disciplines have criticized whether these indicators are a valid measure of scientific quality. For instance, particular journals with a broader focus, more review articles, or English language often fare better. Others have argued that it is questionable whether the impact factor measures the quality of publications. Further limitations include the 3-year window in calculating impact factors and the fact that only a few key articles are repeatedly cited. Other key criticisms are the general limitation/bias of the database to English language, reliance on journal articles alone at the expense of books, and inclusion of incorrect and self-citations. There also appears to be a great deviation in the way that scientists in different cultures and disciplines “do science,” which affects these indicators. Several studies have shown that scholars in the United States appear to be more prone to self-citation and citing one another, that disciplines such as psychology have longer reference lists (thus, more citations), or that other disciplines such as the medical sciences publish shorter articles, frequently with more coauthors. Other factors that may distort indicators include the absolute number of researchers and journals within certain disciplines, the number of authors, citation habits, article length, and speed at which results become obsolete.

The reliance on these indicators has several consequences. Librarians may use them to select relevant journals or book series for their collections. Researchers may seek to publish their work only in journals with a high citation index, even when other, specialized journals may be more useful for the dissemination of ideas. As a result, specialized fields or unpopular topics may become marginalized or local topics and non-English language contexts may not be well represented in the published literature. On the other hand, the positive impact of this system is that researchers must think in international terms, their work will be more widely disseminated, and they will receive more feedback on uses of their own work.

PURPOSIVE SAMPLING

To say one will engage in purposive sampling signifies that one sees sampling as a series of strategic choices about with whom, where, and how one does one's research. This statement implies that the way that researchers sample must be tied to their objectives. A second implication follows from the first: There is no one best sampling strategy because which is best will depend on the context in which researchers are working and the nature of their research objective(s).

Purposive sampling is virtually synonymous with qualitative research. However, because there are many objectives that qualitative researchers might have, the list of purposive strategies that may be followed is virtually endless, and any given list will reflect only the range of situations the author of that list has considered.

Nevertheless, some specific objectives and interests characterize qualitative research. For one thing, qualitative researchers are less often interested in asking about central tendency in a larger group (e.g., "What do most people in this population think about an issue?"), and much more interested in case study analysis—why particular people (or groups) feel particular ways, the processes by which these attitudes are constructed, and the role they play in dynamic processes within the organization or group. Embedded in this is the idea that who a person is and where that person is located within a group is important, unlike other forms of research where people are viewed as essentially interchangeable. Research participants are not always created equal—one well-placed articulate informant will often advance the research far better than any randomly chosen sample of 50—and researchers need to take this into account in choosing a sample.

The general theme here is that the biggest questions all researchers need to ask themselves are what they

want to accomplish and what they want to know. The appropriate sampling strategy will follow from that. Some examples of the kinds of purposive alternatives available include the following:

Stakeholder Sampling: Particularly useful in the context of evaluation research and policy analysis, this strategy involves identifying who the major stakeholders are who are involved in designing, giving, receiving, or administering the program or service being evaluated, and who might otherwise be affected by it.

Extreme or Deviant Case Sampling: Sometimes extreme cases are of interest because they represent the purest or most clea-cut instance of a phenomenon researchers are interested in. For example, if researchers were interested in studying management styles, it might be most interesting to study an organization that did exceptionally well and/or exceptionally poorly.

Typical Case Sampling: Sometimes researchers are interested in cases simply because they are not unusual in any way. For example, years ago Howard Becker and some of his colleagues were interested in studying how medical students were socialized into the profession. They did their research at the University of Kansas Medical School precisely because there was nothing unusual about it, and for that reason it was probably typical of the medical school experience.

Paradigmatic Case Sampling: A case is paradigmatic when it is considered the exemplar for a certain class. For example, if one wanted to study the management of professional sports teams, the paradigmatic case in hockey of a successful franchise would be the Montreal Canadians; for baseball it would be the New York Yankees.

Maximum Variation Sampling: Searching for cases or individuals who cover the spectrum of positions and perspectives in relation to the phenomenon one is studying, and would include both of the previous categories, that is, both extreme and typical cases plus any other positions that can be identified.

Criterion Sampling: This involves searching for cases or individuals who meet a certain criterion, for example, that they have a certain disease or have had a particular life experience. For example, a colleague of mine is doing research with men who have been clients of sex workers.

Theory-Guided Sampling: Researchers who are following a more deductive or theory-testing approach would be interested in finding individuals or cases that embody theoretical constructs. As this could be considered a particular type of criterion sampling, it also illustrates the overlaps that can exist between these categories (e.g., theory-based sampling might also lead the researcher to look for particularly intense or extreme cases).

Critical Case Sampling: Here the researcher might be looking for a decisive case that would help make a decision about which of several different explanations is most plausible, or is one that is identified by experts as being a particularly useful choice because of the generalizations it allows, for example, recent findings that life exists at the bottom of the ocean where there is no sunlight, bitter cold, and immense pressure, suggests that life can exist almost anywhere.

Disconfirming or Negative Case Sampling: With this strategy the researcher is looking to extend his or her analysis by looking for cases that will disconfirm it, both to test theory and simply because it is often from our failures that we learn the most. The general principle here is, “If you think your results are not

generalizable or the existence of a particular kind of case will undermine all that you ‘know’ to be true about a phenomenon, then look for that kind of case.”

These do not exhaust the possibilities but illustrate some of the strategic lenses through which purposive sampling can be considered. The general principle, however, remains, “Think of the person or place or situation that has the largest potential for advancing your understanding and look there.”

Q METHODOLOGY

Q methodology is a composite of philosophy, concepts, data-gathering procedures, and statistical methods that provides perhaps the most thoroughly elaborated basis for the systematic examination of human subjectivity. Central to this enterprise are the meanings and understandings that individuals bring to their endeavors. This preservation of the person's perspective (rather than submerging it in categorical averaging) has rendered Q methodology attractive to investigators who are partial to qualitative methods. In addition, it takes advantage of the leveraging power of sophisticated statistical procedures that often reveal patterns within subjective perspectives that can be overlooked by even the most sensitive and discerning eye.

Q methodology was invented in 1935 by William Stephenson (1902–1989), who initially received a doctorate in physics and then later in psychology at the University of London while serving as the last graduate assistant to Sir Charles Spearman, inventor of factor analysis. He subsequently served as director of the Institute of Experimental Psychology at Oxford, underwent psychoanalysis with Melanie Klein, and after World War II, accepted a position at the University of Chicago; later he became a distinguished research professor in advertising in the School of Journalism at the University of Missouri. His *The Study of Behavior* is the most thorough statement concerning his innovation, which has been applied in a wide variety of fields and more recently adopted as a method for qualitative analysis.

Although fortified by the mathematics of factor analysis and often presented as a purely quantitative method, Q methodology was advanced by Stephenson as the basis for the systematic study of subjectivity in which self-referential meaning and interpretation are central. It therefore shares many of the same goals with qualitative analysis and is contrapuntal to R methodology, which is the study of all that is objective.

Phenomena

Central to Q methodology is the concept of *concourse*, a term denoting the volume of common communicability with regard to any topic. During the Iraq War, for instance, assertions similar to the following were made and were collected from sources such as the media, interviews, and the internet: “The focus should be on Afghanistan rather than on Iraq,” “Saddam Hussein knew how to make weapons of mass destruction and could have passed this information on to terrorists,” “The war in Iraq was the right thing to do,” and so forth repeatedly and all in ordinary language. Or to take another example, consider comments similar to the following made by Koreans in reference to their own national identity and abstracted mainly from English-language books, chapters, and articles: “We are a sentimental and lyrical people,” “Our goal is to establish stability and happiness by first establishing proper relationships in all aspects of life,” the corpus of communicability comprising an ongoing cultural dialogue. Or, consider comments similar to the ones taken from interviews with Uruguayan farmers concerning their participation

in a dairy herd improvement program: "I don't believe milk prices are likely to increase, so I don't think I will participate to keep records," "If we want the producers to participate, we have to help them to become more efficient," and so on. Or consider possible ruminations of a single authoritarian personality in the course of prolonged in-depth interviews: "Some of the old rules help keep us in line," "It's stuck in my head that homosexuality is wrong," "There's not enough kindness," and so forth. Or consider the concourse of communicability attending the quantitative-qualitative debate itself, drawn from the professional literature: "Research is influenced to a great extent by the values of the researcher," "Quantitative and qualitative paradigms operate under different ontological, epistemological, and axiological assumptions," "Students should be pragmatic and use both kinds of techniques," and so forth, each proposition a pristine element in the grand debate and a matter of shared communicability understandable to all attending to it.

Statements of this kind are limitless and subjective in that they are matters of opinion and understanding rather than fact and explanation, and they constitute the phenomena of a science of subjectivity. Such statements can be obtained from interviews, publications, and any other source. But concourse is not necessarily restricted to talk. Photographs, advertisements, posters, music, and even foods and odors have been taken as phenomena to be examined. Concourse is more general than the related concept of discourse, which constitutes a special case. Whereas terms such as discourse and narrative imply coherency and a mainly linear storyline, concourse applies as well to inchoate ramblings of the kind encountered in daydreams, personal musings, and free associations.

Instrumentation and Observation

A universe of communicability on any topic typically numbers into the hundreds or thousands and is unlimited in theory. For purposes of study, therefore, the concourse is typically represented by a Q sample of 30 to 60 statements, which are frequently structured in terms of some conceptual framework. In the study of Korean identity noted previously, for instance, the hundreds of statements gathered into the concourse were first divided into (a) traditional and (b) modern values, each then subdivided into statements focused on (i) personal characteristics, (ii) philosophical and religious concerns, (iii) social relations, and (iv) political

orientations. Six statements were then selected from each of the resulting eight cells for a Q sample of 48 statements. The statements are printed on standardized cards (one statement per card) and are administered in the form of a Q sort, which requires participants to rank the statements, usually from agree to disagree. Just as the Q statements are matters of subjective opinion, so also is their ranking. The operation of Q sorting, therefore, effects a quantification of qualitative preference and constitutes the focal observation. The Q sort also nullifies consideration of validity insofar as it represents a person's own point of view for which external criteria are of no importance. There is no correct way to do a Q sort.

As in grounded theory, participants are selected in terms of their theoretical saturation. In the study of Korean identity, for example, participants were purposely selected to ensure a wide age range, diversity in terms of social class and education, and both males and females. To take another illustration, a study of physician-assisted suicide included participants selected according to whether they were experts (e.g., medical ethicists), authorities (religious leaders, politicians, journalists), had special interests (doctors, hospice workers, persons near death), or were representatives of the social classes. Beyond their use in facilitating the selection of interviewees, however, categories based upon respondent characteristics are of little interest and rarely enter into subsequent analyses. The goal in the sample of both statements and participants is representativeness, that is, to effect as much diversity as possible among participants as well as the statements to which they respond. Since the application of Q technique resolves responses into functional types, the number of participants is comparatively small, usually fewer than 40. Q can also be applied in the study of single cases.

Analysis

Q data can be analyzed using either of two dedicated software packages, PQMethod and PCQ. Each Q sort produces a set of scores (typically ranging from +4 to -4) representing the degrees of preference for all statements, and each person's subjective response is then statistically correlated with every other, the magnitude of the correlation coefficients indicating the degree of similarity among the various perspectives.

The factor analysis of the correlations reveals the number of qualitatively different ways in which the

various Q sorts have been organized, that is, the number of different viewpoints (or attitudes, identities, narratives, schemata, etc.) that are inherent in the population. Were all participants to organize the Q statements in essentially the same order (an indication of a commonly held outlook), then all of the correlations would be highly positive, and only one factor would be in evidence. At the other extreme, were all participants' views idiosyncratic, then there would be as many factors as persons, each factor representing a unique view. Usually, two to five factors prevail depending upon the degree to which the audience is segmented, each of the factors representing a perspective held in common by a subset of the participants. In the study of Korean identity, for instance, three factors emerged from the data, indicating three perceptions of the character of Koreans from among the Korean people themselves. These factors are natural categories that are beyond the investigator's control. Factor analysis as employed in Q methodology is outside the exploratory–confirmatory distinction and rests primarily on abductive rather than hypothetic-deductive logic.

Q sorts provided by the persons comprising a factor—that is, Q sorts demonstrating a high degree of commonality—are merged to provide a single composite Q sort, there being as many composite Q sorts as there are distinctly different views. Therefore, what began as many separate Q sorts (one representing each participant's vantage point) ends as just a few factor Q sorts (usually only three or four of them), one for each of the response types. The factor arrays are composed of the scores associated with each statement within each of the factors, and these scores provide the basis for factor interpretation.

It is significant that the factors in Q methodology are purely inductive, their number and character being indeterminate a priori. Faced with volumes of interview transcriptions, the qualitative analyst who inevitably has to place responses into categories (often with the assistance of content-analytic procedures) is never wholly free of uneasiness that the categories, despite conscientious effort, have been influenced in some way by observer bias. In Q methodology, on the other hand, the factors that emerge through analysis of the data are solely the function of the Q sorters themselves. Consequently, the factors are grounded in more than just a conceptual sense: They are wholly naturalistic inasmuch as they are inextricably tied to and emerge from the concrete operations of the participants.

Interpretation

In conventional research, trait measures and scale items are assumed to have fixed meanings (e.g., as measures of authoritarianism or anomie), and this eliminates the need for interpretation, but in Q methodology the meaning and significance of each statement is entirely in the hands of participants, thereby rendering a posteriori interpretation inescapable. In this hermeneutic phase, the investigator's interpretation of the factors that have emerged from the data is both facilitated and limited. First, the investigator is constrained by the factor scores—that is, the scores (typically from +4 to –4) registering the degree of agreement or disagreement with the statements within each of the factors. Moreover, any interpretation of a factor must comport with the entire pattern of scores, that is, the pattern of all statements constrains the meaning of particular statements. Second, interviews are normally taken following each Q-sorting session during which the participant elaborates on the reasons for having arranged the statements in this particular way, and these interviews provide auxiliary information concerning the coherency of each factor. What began as undifferentiated concourse, therefore, ends with a set of factors, or patterns of meaning, that explain why the volume of subjective communicability displays this particular form and content.

Taking the above-mentioned study of Korean identity as illustrative, the 40 Q sorts obtained condensed into three factors, which were interpreted as realistic, alienated, and idealized viewpoints. The meanings and significance of these dimensions were based on examination of the patterns of statements (as determined by the factor scores) supplemented with personal interviews. In general, the concourse of subjective communicability gives rise, via Q sorting and factor analysis, to underlying dimensions, which in turn denote the cultural geometry inherent in the concourse.

Resources

Additional information about Q methodology can be found at the Q website (www.qmethod.org), where the PQMethod and PCQ software packages can also be accessed. Ongoing research is facilitated by an online discussion group (Q-Method@listserv.kent.edu) and by annual meetings of the International Society for the Scientific Study of Subjectivity. Three journals

specialize in Q-related studies: *Operant Subjectivity*, *Journal of Human Subjectivity*, and the Korean language *Q-Methodology and Theory*.

QUALITATIVE HEALTH RESEARCH (JOURNAL)

The journal *Qualitative Health Research (QHR)* was established to provide a forum for exploring the experience of patients, caregivers, and families in illness and health; for caregiving; and for the administration of health care. Introduced as a quarterly journal by Sage Publications in 1991, *Qualitative Health Research* was the first journal specializing in qualitative inquiry for health professionals. As of 2008, it has been published 10 times a year as a full-sized, two-column journal of 1,500 pages per volume.

The journal's mission is both to contribute to the enhancement of health care and to further the development and understanding of qualitative research methods as they contribute to clinical practice and to the education of health professionals. To achieve this goal, in addition to publishing unsolicited research articles, *QHR* is organized into several special, but peer reviewed, sections: Pearls, Piths, and Provocation; Computer Monitor; Teaching Matters; and Knowledge Utilization. The journal also contains solicited keynote addresses from the Qualitative Health Research and Advances in Qualitative Methods annual conferences and book reviews. "End Notes" is space for short, solicited and unsolicited commentaries, and each issue has an editorial.

In every second issue, a special topic is addressed. Recent topics include relationships in health care (Vol. 15, No. 6), narratives and discourse (Vol. 15, No. 7), perspectives on qualitative evidence (Vol. 16, No. 3), family care (Vol. 16, No. 5), and identity issues (Vol. 17, No. 2).

One interesting issue was Qualitative Proposals (Vol. 13, No 6), which included examples of proposals by Tony Kuzel and information on submitting a small grant by Janice Penrod, resubmitting and responding to reviewers by Margarete Sandelowski and Julie Barroso, and criteria for committee evaluations of proposals by Janice Morse.

QHR ranks as one of Sage Publications' 10 top journals (of approximately 350). Its 2005 ranking on the Thomson Scientific (formerly ISI) journal list was 23 of 39 Health Policy and Services journal listings, with an impact factor of 0.938. *QHR* is indexed in the major social science and health indexes, including Academic Search–EBSCO, Applied Social

Sciences Index & Abstracts (ASSIA), CINAHL database (Cumulative Index to Nursing and Allied Health Literature), Current Contents: Social & Behavioral Sciences, MEDLINE, Psychological Abstracts, PsycLIT, and Sociological Abstracts.

QUALITATIVE HEALTH RESEARCH CONFERENCE

The Qualitative Health Research (QHR) Conferences are organized annually by the International Institute for Qualitative Methodology (IIQM). The first conference, in 1991, was held to launch the journal *Qualitative Health Research* (Sage Publications). These conferences provide an important forum for the discussion and dissemination of qualitative research results pertaining to health, and are attended by qualitative researchers worldwide.

Plenary and keynote speakers are international leaders in the field. In the 2006 conference, Carl Mitcham's (Colorado School of Mines, USA) closing plenary address, "Philosophical Challenges of Qualitative Research," spoke to the challenges of qualitative research and how qualitative research "struggles against the tide of quantitative methods." James Waldram (University of Saskatchewan, Canada) presented on the ethical and methodological issues of conducting research with imprisoned sexual offenders.

Panel discussions are lively: For example, the panel discussion "Building a Career Using Qualitative Methods" from the 2006 conference included viewpoints from Jeanie Kayser-Jones (University of California at San Francisco), John Engel (Northeastern Ohio Universities) and Julianne Cheek (University of South Australia).

The conferences are usually organized into sessions around topics. Sessions of four presentations, often

with a discussant, make possible some coherence for those with special interests, but the presentations are also coordinated so that participants can move between sessions to hear papers of particular interest. Sessions from the 2006 QHR Conference in Edmonton, Alberta, for instance, addressed topics such as cognitive impairment (including papers on people who live alone and have dementia by Lorna de Witt; on caring for relatives with dementia by Anne Neufeld, Kaysi Eastlick Kushner, and Gwen Rempel; on marriage relationships and dementia by Judie Velnes; and on a phenomenological study of losing one's memory by Karen Ann Parsons). Seminars are collections of presentations submitted as a set by participants, who are often members of the same research team (e.g., "Transitioning Out of the Sex Trade: What Makes a Difference?" presented by researchers from Counseling Psychology, Trinity Western University, Langley, British Columbia, Canada) or who have wanted to address a special interest topic in greater depth, such as "Engaging in Collaborative Health Research With Aboriginal Communities" by Fay Fletcher.

Pre- and post-conference workshops (and some in-conference sessions) focus on methodological training and issues in conducting qualitative inquiry so that new researchers are mentored into qualitative health research by international experts. For example, sessions are often held on grounded theory, phenomenology, or focus groups, or on using various qualitative software programs. Special sessions for graduate student networking are usually offered.

Recently, these conferences have been held at the following sites: 13th QHR Conference, Seoul, Korea, in June 2007; 12th QHR Conference, Edmonton, Alberta, in April 2006; and the 11th QHR Conference in Utrecht, the Netherlands, in May 2005.

Information about forthcoming QHR Conferences may be found on the website for the International Institute for Qualitative Methodology or by a search of the internet using the conference name.

QUALITATIVE INQUIRY (JOURNAL)

Qualitative Inquiry is an interdisciplinary, peer-reviewed journal that focuses on qualitative methodology. The journal provides a forum for social scientists to share their work and to discuss practical and theoretical issues regarding the treatment and advancement of qualitative research. Since its initial publication in 1995, *Qualitative Inquiry* has published articles across disciplinary, racial, ethnic, gender, national, and paradigmatic boundaries, presenting research from a variety of academic disciplines including anthropology, communication, cultural studies, education, evaluation, family studies, gerontology, health, history, management, medicine, nursing, psychology, and sociology.

One aspect that distinguishes this journal from others in the field is its emphasis on publishing new forms of qualitative inquiry, which often defy the format, methods, and contents used in more traditional periodicals. A reader perusing a typical issue of *Qualitative Inquiry* may find photographs, papers with a methodological focus, short stories, poems, and ideological debates about qualitative research. Although this diversity may pose some challenges to those accustomed to traditional textual forms, the thread that unites all these perspectives and formats is the search for tinkering with, dialoguing, or reflecting on topics and issues across the social sciences. Examples of articles published in recent issues include “Only a Piece of Meat: One Patient’s Reflections on Her Eight-Day Hospital Experience,” by Elaine Feder-Alford; “Reading and Writing Womanist Poetic Prose: African American Mothers With Deaf Daughters,” by Valerie Borum; “The Participant as Ally and Essentialist Portraiture,” by Klaus G. Witz; “Balancing the *Berimbau*: Embodied Ethnographic Understanding,” by Neil Stephens and Sara Delamont; and “Found Poetry as Literature Review: Research Poems on Audience and Performance,” by Monica Prendergast.

Qualitative Inquiry—a bimonthly journal—also publishes special issues on specific topics. A case in point was the 2002 issue on the events following the terrorist attacks on New York City and Washington, D.C., on September 11, 2001. This issue included mostly short pieces—between 300 and 1,000 words—that ratify the journal’s commitment to publish work that radically reformulates social science and is responsive to social justice issues. That same year, in

an effort to provide a space for the many submissions the editors received on the topic of September 11, 2001, the editors decided to publish a second issue on the same topic. This action alone exemplifies the participatory, collaborative, innovative, and responsive nature of this journal.

QUALITATIVE REPORT, THE (JOURNAL)

The Qualitative Report (TQR) is an English language, online, open-access journal devoted to qualitative, critical, action, and collaborative inquiry and research. *TQR* serves as a home for researchers, scholars, practitioners, and other reflective-minded individuals who are passionate about ideas, methods, and analyses permeating qualitative, action, collaborative, and critical study. *TQR*’s pages are open to a variety of forms: original, scholarly activity such as qualitative research studies, critical commentaries, editorials, or debates concerning pertinent issues and topics; news of networking and research possibilities; and other sorts of journalistic and literary shapes that may interest readers.

In 1990, Nova University and Northern Illinois University, two institutions of higher education in the United States, launched *TQR* in response to emerging needs in the psychology, counseling, psychotherapy, social work, and marital and family therapy communities that were just beginning to adopt qualitative research methods. From 1990 to 1994, the journal was published in paper form with limited circulation. In 1994, *TQR* was published solely by Nova Southeastern University (formerly Nova University) as an online publication, and its website also became home to web-based resources that provided visitors with information on qualitative research websites, online papers, and syllabi.

In becoming an online publication, *TQR*’s existing community was joined by colleagues from public

administration, information technology, business, health care, human services, political science, geography, nursing, education, architecture, law enforcement, and others who submitted their papers to the journal and who subscribed to the publication. In addition, going online led to an increase in papers from international authors—now representing 40 different nations.

The journal's leadership team, Ron Chenail from Nova Southeastern University, Sally St. George and Dan Wulff from the University of Louisville, and Maureen Duffy from Barry University, upholds the journal's mission to mentor authors and to support them throughout the entire paper development process. In doing so, *TQR* works as a virtual learning environment dedicated to helping all authors produce papers of excellence and distinction. The hallmark of *TQR* is not its rejection rates, but rather its commitment to assist authors to improve their texts to the highest quality. The journal's success in meeting this mission was exemplified by its 2005 grant from the Open Society Initiative in recognition of *TQR's* editorial support of authors from developing and transitional countries.

QUALITATIVE RESEARCH (JOURNAL)

The journal *Qualitative Research (QR)* is published by Sage Publications (United Kingdom) and first appeared in 2001. Its founding editors are Paul Atkinson and Sara Delamont. The founding book reviews editor was Amanda Coffey. All of the editorial team is from Cardiff University, which has a long tradition of qualitative research in the social sciences. *QR* appears four times per year. There are four associate editors—one for continental Europe, one for Australasia, and two for the Americas—and an international editorial board. Atkinson and Delamont were invited to start *QR* by Sage after they had edited the *Handbook of Ethnography* with Amanda Coffey, John Lofland, and Lyn Lofland.

QR is committed to publishing papers of the highest quality that advance or reflect upon methodological or epistemological aspects of qualitative research in the social sciences. A full range of qualitative methods is represented: focus groups, participant observation, all types of interview, documentary analyses, audio and visual recordings, and narrative, conversational, and discourse studies. The editors do not seek to promote narrow or sectarian perspectives on the conduct of qualitative research. *QR* is intended to be multidisciplinary: Papers from anthropologists, economists, educational researchers, geographers, historians, psychologists, and sociologists are all eligible, as are papers that cross those and other disciplinary borders. The journal recognizes the increasing significance of qualitative social research in a diverse range of substantive and disciplinary fields—including education, health and nursing studies, business and management, urban studies, and film and music studies.

Given these commitments, there are two fundamental requirements for publication. First, papers must advance the discussion of methods or methodology. *QR* does not publish papers that are primarily devoted to reporting empirical research. Second, papers must be of interest to an international readership. Papers based on empirical research should always be contextualized so that readers from countries other than the research site can gain insight from them.

The book review section, which regularly contains excellent reviews of a wide range of books, many of which are not being evaluated in other journals that either eschew reviews altogether or ignore methods books when commissioning reviews, is a key part of the journal. *QR* is one of the few academic publications in which those books are reliably reviewed.

QUALITATIVE RESEARCH, EVOLUTION OF

See EVOLUTION OF QUALITATIVE RESEARCH

QUALITATIVE RESEARCH, HISTORY OF

Qualitative research has a long and vibrant history in the social sciences, health sciences, and humanities. Qualitative research has meant different things at different times across its history. The development of qualitative research has been heavily influenced by the variety of subdisciplines. Although the work for the Chicago School in America in the 1920s and 1930s highlighted the central role of qualitative research in social research, a range of other disciplines was also responsible for the rise and continued development of qualitative approaches, including history, medicine, nursing, social work, and communications. Subdisciplines of social sciences, health sciences, and humanities, including cultural anthropology, symbolic interactionism, Marxism, ethnomethodology, phenomenology, feminism, cultural studies, and postmodernism, each with its own theoretical leanings, its own conception of reality, and its own methodological preferences, have played significant roles in the continued development of qualitative research. Despite their differing theoretical assumptions and methodological preferences, these disciplines and subdisciplines are united in their reasons for employing qualitative research—to identify, analyze, and understand patterned behaviors and social processes.

Vidich and Lyman's History of Qualitative Research

Although some historical accounts have taken as their starting point the development of qualitative research in the beginning of the 20th century, for example, Norman K. Denzin and Yvonna S. Lincoln's "Seven Moments of Qualitative Research," other accounts begin their analysis with the development of qualitative approaches in the 17th century. In their now classic historical account of qualitative research, Arthur J. Vidich and

Stanford M. Lyman split the history of qualitative research used by sociologists and anthropologists in ethnographic research into a series of interconnected stages. This continuum begins with initial encounters by early ethnographers and ends with the unique theoretical and practical considerations characterizing contemporary qualitative research.

Early Ethnography

The beginnings of qualitative research, according to Vidich and Lyman, are located in the work of early ethnographers during the 17th century. Qualitative research during this period involved the Western researcher observing the customs, practices, and behaviors of "primitive" societies, to understand *the other*. During this period, the other was often regarded as a non-White person living in a society considered less civilized than the society to which the observer belonged. Such interest in "primitive people" was exacerbated by the problems experienced by explorers during the 15th and 16th centuries when attempting to account for people they discovered in the New World. Difficulties occurred when explorers attempted to explain the existence of such groups according to received biblical accounts and explanations regarding the history of geography and the origin of humankind. Acknowledging racial and cultural diversity and the limitations of religious (i.e., Christian) teachings to account for this diversity, early ethnographers sought to locate such diversity into new theories of racial and cultural historical origins.

Colonial Ethnography

Qualitative research during this second phase (17th to the 19th century) was regarded in terms of colonial ethnography. During this period, ethnographic descriptions and analyses, written by Western explorers, missionaries, and colonial administrators, were deposited in church archives and/or local and national archives. Many of these early writings sought to civilize the world. These accounts are regarded by some contemporary ethnographers as biased, and attempts are made to separate more recent ethnographies from earlier Western reports. Colonial administrators, fostering a type of colonial pluralism, created a new type of anthropology, which did not focus on natives and their social processes, and highlighted the positive preservation effects of indirect rule. This period would

later shift in emphasis to encapsulate Auguste Comte's comparative method and theories surrounding the social evolution of culture and civilization. These evolutionary theories led to the creation of a cultural classification system handbook to guide the ethnographers' observations and provide the basis for the classification of traits. Ethnographic findings based on this classification of cultural traits were housed in the Human Relations Area Files at Yale University. The two main themes of this period—colonial ethnography and evolutionary schemes and cultural traits—were challenged by decolonization movements in Africa and Asia and critiques of ideas related to the primitive. This phase saw the introduction of new terms such as *underdeveloped* and *third world*. Research opportunities available to the ethnographic researcher decreased dramatically as ethnographers were regarded as partially responsible for the underdeveloped nature of third world countries. Ethnographers thus turned their attention to linguistic analysis, American society, and the files based at Yale University.

Ethnography of the American Indian as Other

During this next phase (late 19th to early 20th century), American ethnographers focused on American Indians, who were still regarded as primitive and as representing a specific other. These others were researched to shed light on prehistoric times. This period also saw a shift in the perspective of ethnographers, from ethnographies written by missionaries to those written exclusively by anthropologists, for example, those writing after the creation of the ethnology section of the Smithsonian Institution or for the Bureau of Indian Affairs (BIA).

Ethnography of the Civic Other

During the early 20th century and up to the 1960s, the religious beliefs, practices, and customs of Black, Asian, and European immigrants who had arrived on American soil during the early days of industrialization were a source of worry for White American citizens who were concerned with the future development of the American Protestant society. Initial efforts to preach a social gospel in the settlement houses were hindered by the sheer number of new urban inhabitants. In order to deal with these increasing numbers

and to identify the numbers of each denomination, nationality, and race, statistical surveys were implemented. The desire to incorporate immigrant groups into existing Protestant communities resulted in the first qualitative community analysis by W. E. B. DuBois—*The Philadelphia Negro*. Interviewing 5000 Black immigrants, the researcher sought to boost the status of Black immigrants through the Quaker community in which they were located. Church-led and corporate-sponsored community studies and ethnographies of the ethnic other exploded during this period. It was during this period that ethnography and qualitative research were professionalized. Through the work of the University of Chicago's Department of Sociology, ethnography was recognized as a particular method of social research. Community studies were conducted by those connected to the Chicago School, including Robert Park, Robert Redfield, and William Foote Whyte, among others. However, Chicago School sociologists soon discarded any Christian or religious research impetus, celebrated heterogeneous communities, and conducted research driven by a humanistic moral agenda. Using qualitative and sometimes quantitative methods, Park provided accounts of large American urban communities that were created toward the end of the 19th century and developed assimilation theories and race relations cycles. Due to the methodological tools used by Foote Whyte in his account of Italian Americans in Boston in *Street Corner Society*, this period also saw the introduction of participant observation as an appropriate qualitative research technique.

Ethnography of Assimilation

Debating and challenging the processes of assimilation and amalgamation, post-1960s (1950–1980) ethnographies and ethnographers included Native Americans, African Americans, Latinos, and Asian Americans seeking to take control of the study of their own groups. Attention shifted away from how to measure assimilation and acculturation, as identified by Park in the earlier phase, toward a consideration of a range of other topics, including the importance of individual character.

Ethnography Today

As with other areas of the social sciences, health sciences, and humanities, qualitative research from

the mid-1980s onward was influenced by poststructuralism and postmodernism. Assumptions regarding the role of the observer and the observed that underpinned many of the qualitative approaches during the above periods were challenged from the mid-1980s. In many contemporary ethnographies, the researcher is not regarded simply as an observer of history, for he or she plays a significant role in the creation of history. Reflective practice plays a fundamental role in postmodern ethnography as the researcher reflects and critiques his or her personal engagement with the research topic and subject. Some postmodern ethnographers have extended their focus of analysis of lived experience to representations of real life in, for example, media images. Contemporary modes of representing qualitative data include drama and poetry or presentation of unedited extracts of talk without commentary to remove the presence of the author.

The historical analysis developed by Vidich and Lyman suggests that the history of qualitative research is based on the ways in which researchers have defined social research in terms of their values, hopes, religious beliefs and political and/or professional ideologies. Over the centuries covered by this historical account, qualitative research has been released from the ideologies that focused the attention of early ethnographers. Qualitative research has flourished since the 17th century, and points of view, the reasons for conducting qualitative research, and subjects for study have broadened. Whereas the historical analysis offered by Vidich and Lyman is a comprehensive and detailed account covering four hundred years, other historical accounts have been written covering substantially shorter periods in history.

Denzin and Lincoln's Seven Moments of Qualitative Research

The historical analysis offered by Denzin and Lincoln focuses on the developments in qualitative research from the 20th century onwards. Their analysis identifies seven moments in the development of qualitative research. These seven historical moments can be viewed as supplementing the developmental periods identified by Vidich and Lyman.

Traditional Period

During the first moment (1900–1950), which corresponds with Vidich and Lyman's second and third

phases, qualitative researchers sought to provide valid and objective accounts of the alien "other". Qualitative research involved the researcher entering the field and then returning with observations and comments about strange societies and peoples. Some scholars, such as Renato Rosaldo, describe the qualitative researcher during this period as the *lone ethnographer*. The lone ethnographer was committed to objectivism, imperialism, monumentalism, and the timeless nature of the societies studied. Influential figures in this period include Bronislaw Malinowski and Margaret Mead. Although the image of the lone ethnographer represented the beginnings of classic ethnography, this image is not applicable to contemporary ethnography. Some contemporary qualitative research does, however, reflect the view that the researcher is capable of constructing theories about the societies and peoples studied, a view that was evident during this first moment.

Modernist Age

The second moment (1950–1970), dubbed the golden age of qualitative research, saw a shift toward making qualitative methods as rigorous as quantitative approaches. This shift is evident in Harold S. Becker, Blanche Greer, Everett C. Hughes, and Anselm L. Strauss's *Boys in White*. Subjects explored during this moment included deviance and social control in specific settings, such as classrooms, and in society more generally. New interpretive theories (such as ethnomethodology and feminism) and a shift to giving the underclass a voice and presence also characterized this moment. This golden age drew to a close toward the end of the 1960s with the publication of Barney G. Glaser and Anselm L. Strauss's *The Discovery of Grounded Theory*.

Blurred Genres

This moment (1970–1986) is characterized by pluralism, open-endedness, and interpretive approaches, or what Denzin and Lincoln refer to as genre diaspora. During the third moment, the qualitative researcher had a wealth of methods and theories to choose from—from semiotics to neo-Marxist theory, and from critical theory to postpositivism. Disciplinary boundaries between the social sciences and humanities became blurred as social scientists employed theories, methods, and concepts previously the preserve of humanities. Ethical and political considerations in

social research came to the forefront, as did a range of data collection and analysis techniques (from personal experience to documentary methods) and different strategies for reporting research findings (from case studies to biographical research). Further, possibilities were provided with the introduction of computers in assisting data analysis. The researcher's presence in the research text was also questioned and problematized during this period through the writings of Clifford Geertz, among others.

Crisis of Representation Period

As a consequence of the blurred genres period, the fourth moment (1986–1990) witnessed an increase in reflexive research practice. Research led by feminist and racial and ethnic concerns gathered momentum during this period. The crisis of representation occurred as a result of these new research trends destabilizing the assumptions that had previously underpinned qualitative research. The researcher's ability to capture social experiences was questioned due to the view that such experience is created in the very act of writing the research text. Further, long-entrenched views of the most appropriate ways in which to evaluate qualitative research were destabilized through problematizing concepts such as validity and objectivity.

Postmodern Period

The fifth moment (1990–1995) attempted to address the crises characterizing the previous period. Innovative approaches to ethnographic writing were introduced, and the perception of the distant observer was eroded. Situation-specific and localized theories replaced grand theories and narratives.

Postexperimental Period

The trends occurring in the postmodern period continue in the postexperimental period (1995–2000) through the use of poetry, drama, and multimedia techniques in ethnographic writings.

The Future

New researchers across a number of disciplines are continuing the more reflexive and interpretive approach to qualitative research.

Although Denzin and Lincoln separate the history of qualitative research into these seven linear moments, the moments are not isolated and unitary but are interconnected. Earlier moments influence later moments, and some of the trends and beliefs of earlier moments are evident in later periods. Movement through the seven moments illustrates how qualitative research is no longer bound by an objective positivist perspective and how contemporary qualitative researchers have a wide range of methods, theories, and paradigms from which to choose.

Qualitative Debates in German-Speaking Areas

The forementioned historical analyses have largely focused on the development of qualitative research in Anglophone countries. However, methodological developments in European countries, for example, Germany, have been particularly significant in the continual development of qualitative research. During the 1960s, American sociological critique concentrated on quantitative social research and quantitative techniques. German methodological discussions later took up such critiques in the 1970s. American methodological debates resonated in German-speaking areas as a number of influential American methodological texts (on ethnomethodology and symbolic interactionism) and critiques from the mid-1960s were translated and imported, making them available for German methodological debates.

German methodological discussions during the 1960s, according to Uwe Flick, placed fair treatment of research participants and objects at the forefront of methodological discussions, argued for research openness and flexibility, and called for a delay of any theoretical creation or development until the end of the research process when research participants and objects would demonstrate their "true colors."

From the end of the 1970s, methodological debates broadened out and lost their dependency on the translation and import of American texts. The role and position of interviews in empirical research dominated methodological debates during this time.

From the beginning of the 1980s, German methodological literature and methodological development focused on two specific qualitative approaches—the narrative interview and objective hermeneutics. In his review of German methodological literature, Flick observes that from the middle of the 1980s concerns surrounding the validity and generalizability of qualitative

findings and their presentation dominated German methodological debates, and, more recently, textbooks have been published on the history of qualitative research in German-speaking locations.

Other Important Historical Developments

Reflecting wider sociopolitical developments and feelings, based on distrust of authority and control, and on a celebration of individualism and personal freedom, qualitative research has experienced a renaissance since the 1960s (in the United States) and 1970s (in German-speaking countries). The second half of the 20th century saw an increase in the amount and strength of criticisms directed toward positivism, which until then had dominated social research. These nonpositivist or antipositivist attitudes resonated from a variety of subdisciplines, including cultural anthropology, symbolic interactionism, Marxism, ethnomethodology, phenomenology, feminism, cultural studies, and postmodernism. Critiques of positivism included attacks on the manner in which the methods used in the natural sciences were incorporated into social research, the ways in which reality was conceived and identified, the relationships between the researcher and the researched, the manner in which research was designed and executed, and the methods of data collection and data analysis employed. Positivist social theory and social research lost momentum and popularity as a result of such critiques.

Another increasingly prominent discussion evident in some social sciences, health sciences, and humanities methodological literature from the mid-1970s centered on the use of mixed methods. Advocating methodological pluralism, some researchers, such as Abbas Tashakkori and Charles Teddlie, argue for mixed method or multimethod approaches, including within-method and between-method mixing. Instead of taking a philosophical approach to methodology, mixed methodologies are often employed by pragmatic researchers who allow the nature of the research problem to dictate the methods employed for each research study. Although traditional stereotypes and assumptions about distinctions between quantitative and qualitative research have not been fully removed, for some scholars, such as Clive Seale, recent debates over mixed methods suggest that the future lies in dropping the terms “qualitative” or “quantitative,” research so that it is referred to simply as research.

A Note on the Limits of Historical Accounts

Historical accounts that navigate and review past events are often criticized for their artificiality, and their content depends on the authors’ methodological preferences, interpretations, and experiences. Although such limitations are recognized, these limitations should not detract from the importance or significance of historical accounts in contributing to our understanding of the development of qualitative research.

QUALITATIVE RESEARCH SUMMER INTENSIVE

The Qualitative Research Summer Intensive is the signature event for ResearchTalk, Inc., a qualitative research consulting company based in Bohemia, New York. This 5-day event features a series of professional development courses covering various aspects of qualitative analysis. Courses are taught by leading scholars in the field of qualitative research. Course content is defined by an explicit focus on the intersection of theoretical foundations and practical skills and is divided into three areas: qualitative approaches, foundation courses, and applied skills.

These courses introduce core approaches to qualitative analysis. Instructors use real data examples to illustrate applied use of ideas presented in class. Course topics include the following:

- autoethnography
- case study
- ethnography
- grounded theory
- phenomenology
- multidimensional qualitative analysis

Foundation courses cover basic knowledge common to most qualitative approaches and provide core skills allowing participants to move forward with their qualitative projects. Course topics include the following:

- introduction to qualitative analysis
- integrating qualitative and quantitative approaches
- building a codebook and writing memos
- moving from codes to findings

Applied skills courses focus on how-to aspects of qualitative research and offer theoretical foundations and practical tips for performing key functions

integral to any qualitative project. Course topics include the following:

- conducting qualitative interviews and focus groups
- focus groups: tips and pitfalls
- integrating software into qualitative analysis
- writing rites for qualitative research

Past Presenters

Presenters at the conference are leading scholars in the qualitative research field. Past presenters have included Mitch Allen, Elijah Anderson, Kathy Charmaz, Adele Clarke, John Creswell, Leslie Curry, Kathleen DeMarrais, Carolyn Ellis, Valerie Janesick, Udo Kuckartz, C. Deborah Laughton, Ray Maietta, Douglas Maynard, Paul Mihas, David Morgan, Patricia Munhall, Judith Preissle, Jean J. Schensul, Robert Stake, and Tom Wengraf.

QUALPAGE

QualPage is arguably the oldest website of internet resources for qualitative researchers. It began in the early 1990s as a Gopher site developed by Judy Norris, who was then on the nursing faculty at the University of Alberta in Canada. She initially designed the site for students in her qualitative research classes, but found that other qualitative researchers wanted to link it to their own websites. In 1995, she redesigned QualPage as a complex collection of web pages pointing to the variety of internet resources available for qualitative researchers. In preparation for her retirement, she transferred the ownership and management of QualPage in 2003 to Judith Preissle and to the faculty at the University of Georgia, where the Qualitative Interest Group contributes to its maintenance and development.

The QualPage website maintains a page of announcements of conferences, workshops, and other events of

interest to qualitative researchers around the globe. The remaining pages organize internet resources in occasionally overlapping categories: recent books, disciplinary sites in areas like anthropology and sociology, discussion forums, electronic journals, sites on various research methods, multimedia resources, professional organizations related to qualitative research, links to proceedings and online papers, sites on philosophical sources relevant to qualitative research, publishers who regularly produce material on qualitative research, resources for computer programs used by qualitative researchers including links to the major providers, and a collection of other resources. Visitors to the page are invited to contribute new material through an email address maintained for that purpose: qualres@uga.edu. The pages on proceedings and online papers and on theses and reports have links to material already accessible to the public on the internet so material with legally restricted circulation, such as much copyright material, is avoided. Norris's original vision of the page as a site where researchers freely share and circulate their materials and resources remains the goal of QualPage.

QUALRUS (SOFTWARE)

Qualrus is a computer-assisted data analysis software program that was developed by Idea Works with some advice from Howard Becker. It is flexible and adaptable for different theoretical approaches. Qualrus uses advanced artificial intelligence to facilitate coding and analysis, but the user interface is less convenient than some of the alternatives available. Qualrus handles many different forms of data including video, html, graphics, and audio files.

The coding process in Qualrus is relatively involved. The coder selects a segment to code and then opens the Coding Form. Several codes can be selected at one time by holding down the control key, but two further clicks are required to code the segment. To code the next segment, the Coding Form has to be reopened. There are no coding shortcuts, codes cannot be dragged and dropped, and in-vivo coding is not possible.

A key feature of Qualrus is the suggestion of appropriate codes. Suggested codes are based on rules such as user-defined synonyms, a previous correlation between codes, or a code used in the preceding segment. Codes are suggested only; the analyst can choose to select or ignore the suggested codes and can change some of the suggestion criteria. This feature can be very helpful; the software may suggest relevant codes and identify relationships between codes that the coder has overlooked.

Codes are displayed in the margin with overlapping codes shown in different colors. The colors are controlled

Qualrus Screen View

by the program rather than by the user. It is not possible to print out the coded transcript. From the Code Editor, code details and all segments for a particular code can be quickly retrieved or printed. Clicking on any segment takes one back to the Qualrus Viewer, but the need to move between these two screens increases the distance between the analyst and the data. A useful feature of Qualrus is the network interface, which can be viewed from the Code Editor. The nodes on networks are clickable so that the researcher can quickly trace the connections between codes.

Qualrus has many sophisticated analytical tools including a statistical tool that displays individual and coincidental code usage; a coincidental code explorer, which enables quick inspection of all segments where co-occurrence does or does not occur; a tool for categorizing codes; a hypothesis testing tool; and a tool that reveals the extent to which the coding of each coder coincides with the program's advice. Qualrus also allows the researcher to write coding scripts using a special scripting language. These give the technically minded analyst unparalleled flexibility and can be used for auto coding, but this feature is less user friendly than the auto coding in some alternative programs.

QUANTITATIVE RESEARCH

The term *quantitative research* refers to approaches to empirical inquiry that collect, analyze, and display data in numerical rather than narrative form. Not surprisingly, quantitative research is often viewed as the antithesis of—and, at times, even a foil for—the qualitative type of research that is the focal point of this encyclopedia. The qualitative–quantitative distinction, however, can be a bit misleading. This entry first reviews issues related to this distinction and then examines these differences.

Caveats About the Qualitative–Quantitative Distinction

The qualitative–quantitative distinction is a bit misleading in part because many quantitative researchers are interested in and study the qualitative aspects of phenomena. To study qualities quantitatively, of course, quantitative researchers translate gradations of quality into numerical scales that are amenable to statistical analysis.

The quantitative and qualitative labels also are misleading because qualitative researchers can never totally avoid quantification. Whenever they use terms such as *sometimes*, *often*, *seldom*, or *never*, for example, they are employing a form—albeit an exceedingly imprecise form—of quantification.

Furthermore, some qualitative researchers actually move beyond primitive forms of quantification by administering questionnaires and reporting results in the form of descriptive statistics. This sort of numerical data is employed in some qualitative studies to triangulate qualitative findings and/or to determine whether or not the insights gleaned from a limited number of in-depth interviews are reasonably consistent with the views of those who were not able to participate in what is often a time-consuming and labor-intensive interview process.

Thus, the qualitative–quantitative distinction is not a completely clean one. Still, quantitative and qualitative approaches to research do normally exhibit some rather pronounced—and quite significant—differences. These differences become apparent when quantitative and qualitative researchers' differing views of reliability and validity are examined.

The Qualitative–Quantitative Distinction: Reliability and Validity

Reliability and Validity in Quantitative Research

Quantitative researchers invariably embrace the concepts of reliability and validity. *Reliability* is viewed as a property of the instruments (e.g., tests and observation schedules) that quantitative researchers use to measure the phenomena they are studying. An instrument is considered reliable if it consistently produces the same results when administered to the same or comparable individuals. Quantitative researchers normally employ measures of consistency to determine the reliability of a particular instrument.

Quantitative researchers also are concerned with validity and they normally employ measurement to assess the extent to which a study and the study's key components are valid. Both internal and external validity are assessed.

Internal validity refers to whether an instrument used in a study actually measures what it purports to measure. An instrument's internal validity can be assessed in a number of ways: by correlating the instrument's results with the results produced by another better established instrument that presumably measures the same phenomena (*concurrent validity*), by determining whether the results accurately predict something that the instrument's results would be expected to predict (*predictive validity*), or by determining whether empirical studies support—or fail to support—reasonable hypotheses about the theoretical construct that an instrument makes operational and measures (*construct validity*).

Quantitative researchers also, at times, rely on more qualitative procedures to assess an instrument's validity. They might, for instance, ask a panel of experts to review the contents of an instrument and make a judgment about the instrument's *content validity*. Quantitative researchers also, at times, claim that the validity of an instrument is self-evident; in these situations, the instrument is said to have *face validity*.

Quantitative researchers also are concerned about the external validity of their studies. *External validity* (which also is referred to as *generalizability*) refers to the likelihood that a study's findings will apply to the larger population represented by the study's sample. Once again, statistical procedures are employed to assess the degree to which a study exhibits this second general type of validity. Specifically, statistical procedures are used to determine the extent to which a study's results might have occurred by chance. If the likelihood that chance produced a study's results is low, the study is said to have high external validity.

Qualitative Researchers' Views of Reliability and Validity

Quantitative researchers' constructs of reliability and validity are problematic for qualitative researchers in part because they represent rules of a research game that qualitative researchers cannot possibly play. For example, in most qualitative studies, the researcher is the primary—and in some cases, the only—instrument;

in such situations, quantitative researchers' formal reliability assessments cannot be performed.

Some qualitative researchers, however, also object to traditional notions of reliability and validity on philosophical grounds. For example, the concept of triangulation—which often is seen as an analog for reliability in the qualitative tradition because it entails looking at multiple data sources—frequently has a significantly different meaning than reliability. Sandra Mathison, for example, noted in the 1980s that qualitative researchers who assume that different people construct different meanings of the same events should not expect interview results to be consistent across individuals or subgroups, even within the same organization. Consequently, qualitative researchers should not aspire to produce consistent—that is, reliable—findings; rather, their task is to document the different ways different individuals and subgroups have constructed reality and to make whatever sense they can make of these different constructions.

Qualitative researchers also have redefined quantitative researchers' notions of validity. Once again, this redefinition has occurred, in part, for pragmatic reasons: Quantitative researchers' external validity or generalizability game, for example, simply cannot be played when one is studying a single case—or even a small number of cases—as those who employ labor-intensive qualitative methods tend to do.

But again, qualitative researchers also have philosophical reasons for rejecting quantitative researchers' thinking about validity. Qualitative researchers, for instance, tend to assume that contexts are idiosyncratic and ever changing. If one assumes this, there is little reason to play the external validity game because findings will never apply to other individuals or contexts than the ones that were studied in anything but a heuristic way. Even the individuals and/or contexts that were studied are likely to change over time, according to many qualitative researchers.

Thus, some qualitative researchers have reconceptualized quantitative researchers' notion of external validity-generalizability in more psychological terms by talking about the *transferability* rather than the generalizability of findings. The transferability notion, for instance, assumes (a) that all research findings are merely working hypotheses about what is likely to happen when similar things are done in even apparently similar contexts and (b) that only the consumers of research can determine whether a finding is likely to be transferable to their situations.

Qualitative researchers also normally have rethought quantitative researchers' notion of internal validity. Once again, some sort of rethinking was required: Equating internal validity with the results of statistical analyses of instruments makes absolutely no sense in single-case or limited-case studies that employ the researcher as the study's primary instrument. Consequently, qualitative researchers, especially in fields where quantitative researchers' notions of validity have not been challenged on philosophical grounds, have been forced to invent procedures like member checking as analogs for the statistical procedures quantitative researchers use to assess concurrent, predictive, and construct validity.

One should not push the member checking analogy too far, however, for as was the case with the reliability and external validity concepts, quantitative researchers' notion of internal validity also has been challenged by qualitative researchers on philosophical grounds. This philosophical challenge, in fact, reflects a fundamental disagreement among many quantitative and qualitative researchers about the nature of social phenomena and consequently about how those who study social phenomena should do their work. The next section attempts to unpack this fundamental disagreement.

The Qualitative–Quantitative Distinction: Causal Versus Constructivist Perspectives of the Social World

Historically, influential quantitative methodologists such as E. L. Thorndike, Thomas Campbell, and Julian Stanley embraced a cause-effect view of social life and promised to provide valid knowledge about cause-and-effect relationships. Such knowledge, they argued, could be used in the real world not only to predict, but also to control events. Consequently, knowledge of cause-and-effect relationships could make decision making in a variety of policy and professional contexts rational rather than political.

Experimental and Quasi-Experimental Designs

The agenda alluded to above, of course, required not only quantification, but also the use of experimental research designs. Researchers, in other words, could determine only which treatment worked best—and

consequently which policy option or professional practice should be implemented—if they went beyond establishing statistical correlations between variables and instead placed research subjects into control and experimental groups and conducted experiments. Of course, if experiments are to produce valid results, experimental researchers must randomly assign research subjects to control and experimental groups. They also must institute sufficient controls so that the only differences in the treatments that control and experimental groups receive are those related to the independent variable being studied.

Employing random assignment and instituting tight controls in the real world can be difficult and at times even impossible. Consequently, many experimental studies are conducted in laboratory settings. This certainly is the situation in fields like experimental psychology where virtually all studies employ experimental designs.

Unfortunately, laboratory results do not always hold in real-world contexts. The developmental psychologist Urie Bronfenbrenner coined a term to characterize the problem: He indicated that results generated in artificial settings such as laboratories lack *ecological validity*.

To correct the ecological validity problem, many quantitative researchers have conducted quasi-experimental studies in real-world settings. In principle, at least, findings from these studies exhibit ecological validity; the trade-off, however, is less control over such things as the assignment of research subjects and the standardization of treatments than one has in laboratory settings.

Many quantitative researchers have argued that this trade-off is worth making. In the 1960s, for example, Thomas Campbell and Julian Stanley published a handbook chapter titled “Experimental and Quasi-Experimental Designs for Research.” The chapter later was published as a monograph. The monograph has influenced thinking in a number of social science fields.

In their chapter-monograph, Campbell and Stanley described 12 threats to a study's internal and/or external validity and suggested how these threats are likely to play out in different experimental and especially quasi-experimental designs. They indicated, however, that these threats do not mean that quasi-experimental studies have to be abandoned as long as (a) consumers of research are aware of and take into account the likely threats associated with different quasi-experimental designs and (b) consumers do not expect a single study to produce definitive results.

Indeed, Campbell and Stanley argue that, despite the flaws that individual experiments might exhibit, the only way we have to resolve disputes in the policy and practice domains is to rely on the cumulative insights that experimental studies provide about cause-and-effect relationships. Later, quantitative researchers developed meta-analysis techniques to systematically analyze the sometimes contradictory findings from different studies and produce what some take to be statistically validated cumulative results.

Cronbach's Evolving View of Research Design and Cause-Effect Generalizations

Campbell and Stanley provided a tempered, but still quite positive view of the likely contributions of quantitative research that employed experimental and quasi-experimental designs. Another giant among quantitative methodologists, Lee Cronbach, came to a very different conclusion about the potential of experimental and quasi-experimental studies. Cronbach's thinking on the topic evolved over a number of decades in response to the failure of quantitative methods, in general, and experimental and quasi-experimental designs, in particular, to produce the definitive result that quantitative researchers (including Cronbach) had promised to produce. It is instructive to trace the evolution of Cronbach's thinking.

By the mid-1950s Cronbach had taken note of the failure of researchers in his field of psychology to produce even useful probabilistic generalizations that linked causes with effects. At that point, however, he suggested that the problem could be remedied if researchers would stop looking at the effects of treatments in a general way and instead examined the effects of treatments on individuals with particular characteristics or (to use Cronbach's terminology) aptitudes.

By the 1970s, however, after Cronbach and other psychologists had spent roughly 20 years trying to discover what Cronbach called aptitude \times treatment interactions, Cronbach concluded publicly that this goal could not be accomplished. The problem was not that the social world was not as law-like as the physical world, Cronbach contended at this point. Rather, the problem was that the social world was too complex for experimental studies to ferret out law-like relationships between independent, intervening, and dependent variables. The phenomenon of culture, along with the fact that cultures were constantly

changing, added to the complexity problem, according to Cronbach.

Cronbach did not recommend completely abandoning the search for generalizations in his writings during the 1970s. Instead, he recommended that quantitative researchers add a qualitative component to experimental studies so qualitative researchers' thick descriptions could be used *ex post facto* to generate grounded hypotheses about what produced any atypical results. Cronbach suggested that these hypotheses could contribute to clinical understanding; such understanding would have to substitute for the experimentally validated generalizations that researchers had traditionally sought but failed—and would continue to fail—to produce due to the complexity of an ever-changing social world.

In the 1980s, Cronbach reversed his earlier position about the lawfulness of social phenomena. He argued that action in the social world was constructed, not caused, and indicated that those who expected social science eventually to produce definitive cause-effect generalizations were, in effect, waiting for Godot, the character in the Samuel Beckett play who never appears.

Qualitative Researchers' Views of Cause-Effect Explanations

By the 1980s, Cronbach had embraced a position that also has been adopted by many qualitative researchers, including qualitative researchers who worked in the symbolic interactionist and ethnomethodology traditions within sociology. Those who had been socialized into these traditions also rejected cause-effect explanations and like Cronbach in the 1980s, they assumed (a) that human beings act on the basis of the meaning that they attribute to events and (b) that meaning is both constructed—and constantly reconstructed—as human beings interact. Because of this constant reconstruction process, symbolic interactionists and ethnomethodologists argued that it does not make sense to treat socially constructed meanings as intervening variables in a cause-effect explanatory framework.

Many other qualitative researchers also have rejected—or at least radically reconceptualized—the role of cause-effect generalizations in social science research. An example of reconceptualization can be found in anthropologist Clifford Geertz's discussion of the thick description approach to ethnography. Geertz treated theories—including theories

about cause-and-effect relationships—as rhetorical tools for doing thick description rather than as end products of ethnographic research. He argued that when theoretical generalizations about cause-and-effect relationships are stripped of the rich, concrete details of particular cultures, they become little more than commonsense—and consequently exceedingly pedestrian—truisms.

Causation as a Functional Fiction

Philosopher of social science Peter Cohen has provided a somewhat different take on the causation versus constructivism debate that has occurred between many qualitative and quantitative researchers and also to a lesser extent within the quantitative research community itself (see the discussion of Cronbach's evolving views above). Cohen indicates that the notion of causation in the social world may, indeed, be a fiction, but he argues that it is nevertheless a highly functional—and even perhaps an indispensable—fiction.

Cohen notes, for example, that it would be difficult, if not impossible, to create public policies if we totally rejected cause-and-effect thinking. Similar arguments could be made about activities such as counseling, teaching, leading, and presumably any other social activity in which someone acts with the intention of influencing others.

Rethinking Possibilities for Mixing Qualitative and Quantitative Research

Viewing quantitative researchers' talk of causation as a functional fiction has implications for mixing quantitative and qualitative methods in research studies. To be sure, some mixing of methods has always been tolerated. Indeed, as noted above, even deeply committed constructivists normally have not objected to using descriptive statistics to triangulate qualitative data. Constructivist-oriented qualitative researchers, however, often viewed experimental designs that attempted to ferret out cause-and-effect relationships as indefensible, and they almost never incorporated inferential statistics—which contemporary researchers often employ in lieu of using difficult-to-implement quasi-experimental designs—into their studies.

If quantitative researchers are no longer seen as making an ontological statement when they employ experimental or quasi-experimental research designs, a major barrier to a more extensive approach to mixing

methods seemingly has been removed. Furthermore, inferential techniques such as multiple regression and hierarchical linear modeling, when used with nonexperimental data, technically cannot address issues of cause and effect. Consequently, those who employ these techniques in nonexperimental research cannot legitimately make causal claims, even if they wanted to do so. This fact should open the door even further for the mixing of quantitative and qualitative procedures.

Views of Quantitative Research Today

Of course, not everyone today views the concept of causation as a functional fiction. Indeed, many influential policymakers continue to expect quantitative researchers to produce knowledge about cause-and-effect relationships that will, in essence, dictate which policies and programs should be implemented. Many quantitatively oriented researchers also continue to promise that experimental studies can, in fact, produce such knowledge.

Some rather striking examples of all of this can be found in the field of education. For instance, the head of the Institute of Education Sciences, the federal agency that funds educational research in the United States, recently declared randomized trials (i.e., experimental or quasi-experimental studies in which research subjects are randomly assigned to control and experimental groups) the new gold standard in federally funded research.

Similarly, a committee of prominent educational researchers set up by the National Research Council (NRC, the research arm of the National Academies of Science) to define what constitutes scientific (and by implication, fundable) research in education made the search for theoretical knowledge that links causes and effects a defining property of scientific research and relegated qualitative research to the hypothesis generation role that it was forced to play in the educational research field prior to the qualitative revolution in the final quarter of the 20th century. Ironically, the NRC committee's report, *Scientific Research in Education*, was dedicated to that circumspect—and quite visionary—quantitative methodologist and researcher, Cronbach.

Thus, the traditional battle between qualitative and quantitative researchers has not ended. Truly thoughtful individuals on both sides of the qualitative–quantitative methodological and philosophical divide, however, at

this point understand that neither qualitative nor quantitative research can provide truth in any absolute, definitive sense because even the most rigorous empirical inquiry is rooted in a priori assumptions that cannot be proved empirically. Thoughtful individuals also understand, however, that each approach to inquiry—and in certain situations some combination of qualitative and quantitative procedures—can serve a heuristic function and can provide insight that is useful for accomplishing some—but of course not all—purposes.

QUEER THEORY

Queer theory emerged during the 1990s, influenced by queer social activist aims to expose and to challenge heterosexism, homophobia, and transphobia. Its interdisciplinary development in academe has been heavily influenced by poststructural feminism and other post-foundational, multiperspective theoretical discourses. These discourses have had currency across a spectrum of academic disciplines and areas of study including anthropology, sociology, and cultural studies. Queer theory continues to develop and build on these discourses. It is a multifaceted theoretical and creative space for contestation and discovery. Queer theory contests, interrogates, and disrupts systemic and

structural relationships of power that are historically caught up in heteronormative attitudes, values, and practices, as well as heteronormative ideological, linguistic, existential, and strategic conventions and constructs. These power relationships have variously defiled or dismissed sexes, sexualities, and genders not sanctioned by heteronormativity. Heteronormativity presumes and values heterosexuality (or the opposite-sex attraction between a biological XY male and a biological XX female) as the norm against which other sexualities have historically been labeled deviant. This entry engages queer theory in its opposition to heteronormativity by discussing the meaning of queer, the emergence of queer theory since the early 1990s, and the relationship between queer theory and research.

The Meaning of Queer

Historically, *queer* has been a derogatory term used to diminish sexual-minority persons and assault their integrity and dignity. Including lesbian, gay, bisexual, trans-identified, intersex, and two-spirited individuals, queer represents a diverse and at best loosely configured spectral community across sex, sexual, and gender differences. Queers have different histories, identities, identifications, needs, and desires that set them apart not only from heterosexuals, but also from one another. The interwoven historical, social, and cultural thread connecting queers across differences is marginalization. For some, the terms *trans-identified*, *intersex*, and *two-spirited* may be new. Trans-identified describes individuals whose gender identity does not conform to the simplicity of the male-female, two-gender model. Intersex depicts individuals who may possess both male and female biological sex characteristics. Two-spirited is an Aboriginal term used to refer to persons whose bodies are believed to have both a masculine and a feminine spirit.

In terms of its etymology or history as a word, queer has long been used to connote someone odd, curious, different, peculiar, strange, or unusual. Since the early 1990s, beginning with the U.S. grassroots activist group Queer Nation, queer has been reclaimed as a proactive and public term that is more encompassing and expansive than the limited and problematic descriptor *gay*. Queer is a fluid concept with multiple meanings that collapse identity politics delimited by static understandings of sex, sexuality, and gender—nonconformist heterosexual desiring and acting can also be considered queer. Sexual minorities

use queer to describe themselves and their social and cultural geography in terms they set out within a politics of hope and possibility. As part of a language of visibility and representation, the term queer is now linked to empowering those disenfranchised by sex, sexual, and gender differences. As a concept and a way of naming, queer by nature and intention resists the inimical prescription and inscription of sexual-minority characteristics and differences found in heteronormative classification. It exposes heteronorms that limit meanings, positionalities, and possibilities. These countercultural dynamics seek to resignify the concept of queer to proclaim the visibility, vocality, and transgressive politics of those long shamed and silenced by heterosexism, homophobia, and transphobia. The new queer colloquial chant, made popular by Queer Nation, is “We’re here. We’re queer. Get used to it.”

Queer understands that queers have been shattered by a heteronormative society and a heterosexualizing culture. In an effort to transgress the unacceptable in the history of the gay liberation movement that started in 1969, queer rejects lesbian and gay concerns with assimilation and integration into heteronormative society, which can be coded as “passing straight.” It also rejects the conception of gay and lesbian as stable, unitary, and essentialized identities since such an understanding reinscribes the power of the heterosexual–homosexual binary to defile or dismiss homosexuals. Queer is about grappling with sex, sexual, and gender differences as a spectrum of fluid subjectivity markers. Queer and all it encompasses moves and shifts, challenging notions of citizenship and what it means to be, become, and belong. In this sense, queer marks diverse disenfranchised positionalities that variously lie beyond what by convention has been morally, politically, socially, or culturally accepted and acceptable in civil society.

The Emergence of Queer Theory as a Field of Study

Queer theory assumes a spectrum of fluid sex, sexual, and gender differences that are always in a state of becoming; being is never fixed and belonging is never a certainty. In a queer context, differences, representations, expressions, and desires are considered dynamic, multiple, and varied, which makes queer theory a volatile formation. Queer theory depicts how ignorance of queer often leads to fear of queer and actual and/or symbolic violence toward queer (or

those perceived to be queer) persons. It works to dissolve dominant social binaries that subjugate women and queers in particular: public–private, male–female, and heterosexual–homosexual. For example, queer theory challenges us to understand such differences as intersexuality (anatomic sex differentiation such that a person is neither specifically a biological XY male nor XX female) and transsexuality (dissonance between one’s biological sex and intuited gender). As it focuses on ontological and epistemological facets of queer, queer theory is counter expression as expression. It resists categories limited by heteronormativity and engenders positionality as fluid and spectral. It exposes how queers have been historically, socially, culturally, and politically dislocated in a disenfranchising heteronormative world as it works to revitalize queerness (being, believing, desiring, acting queer).

William G. Tierney and Patrick Dilley, both influential in the emergence of queer theory in education, provide this useful summary of the purposes of queer theory. First, queer theory exposes the heteronormative nature of power. Second, queer theory works to empower queer voices in order to interrupt heteronormative power. Third, it interrogates language in the intersection with knowledge, experience, and action. Fourth, it deconstructs the heteronormative notion of natural as well as institutional processes of legitimating and sanctioning certain ways of being in the world. Fifth, queer theory engages power in intersections where sexual orientation and gender identity encounter other relationships of power, including race and class. Sixth, queer theory considers research itself to be a form of cultural politics, and it considers how the researcher-writer is positioned and implicated in relation to knowledge production, exchange, and distribution.

Eve Kosofsky Sedgwick, Judith Butler, Teresa de Lauretis, Diana Fuss, and Michael Warner are considered key theorists in the emergence of queer theory. Published in 1990, Sedgwick’s *Epistemology of the Closet* is usually considered the founding text in queer theory. In this text and the subsequent *Tendencies*, published in 1993, Sedgwick engaged queer not only to name and represent a spectrum of sexual-minority differences, but also to speak to issues of race, ethnicity, and postcolonial nationality in ways that leveraged queer in the interests of exploring the intricacies of language, positionalities, and power relationships. In her work, Sedgwick hypothesized that modern figurative, commonsensical constructions of sexual identities, which situate lesbians or gay men either

between genders (inversion models) or as discrete genders (gender-separatist models), are rhetorically meaningless because they ignore the complexity of multiple sexes, sexualities, and genders and their subjectivities, identities, identifications, desires, and agencies. Queer takes this complexity as a given. As Sedgwick sees it, acknowledging anything less than the complexity of queer reduces sexual-minority studies to inutility, incoherence, and prejudice.

Another text published in 1990, Butler's groundbreaking *Gender Trouble: Feminism and the Subversion of Identity*, is also most influential in the emergence of queer theory. Butler queered theory by confronting the indeterminacy and messiness of gender inside and beyond the binary constriction and purported categorical fixity of male and female. In keeping with a queer standpoint, she considered how best to trouble gender, moving analysis beyond presumptive heterosexuality and the hegemony of a masculinist sexual economy. Butler, conceiving what she called a performative theory of gender, had readers question the positionalities of women, the dynamic complexities of language and power, and the fictions marking the constructions of the body, sex, sexuality, and gender from a masculinist gaze.

In 1991, de Lauretis edited *Queer Theory: Lesbian and Gay Sexualities*, while Fuss edited *Inside/Out: Lesbian Theories, Gay Theories*. These pivotal texts in the emergence of queer theory further marked a move toward transgressive queer studies that contests the limited identities and identifications as well as the assimilation and integration of sexual minorities associated with lesbian and gay studies. In her theorizing, de Lauretis articulated a transgressive politics of queer resistance that is still collaborative, interactive, and participatory. As she set out terms of engagement in these politics, she cautioned readers to remember history amid moves to meet sexual-minority demands for vocality, visibility, and representation. In her writing in *Inside/Out*, Fuss argued that binaries associated with patriarchy like male–female and heterosexual–homosexual are socially, culturally, and historically based on an inside–outside binary that places limits on sexual desire, identity, and expression. As these binaries work to order what is “normal”, Fuss asserted that they also symbolically eradicate diverse positionalities contained between their binary ends. For example, the heterosexual–homosexual binary leaves bisexual, intersexual and transsexual persons out. Paralleling Butler's standpoint, Fuss set this task for queer theory as it worked to bring standard binaries to the point of

collapse: to challenge the hegemony of heterosexuality as a compulsory identity, practice, and institution that is deemed legitimate and necessary against the purported pathology of homosexuality. For Fuss, this meant interrogating the systematic construction of language, subjectivity, and repression that designates the construction of exclusion, oppression, and repudiation in a masculinist sexual economy. In contemporary queer theory, such work is enhanced when we intersect differences in sex, sexuality, and gender with differences in other relationships of power to consider how heteronormativity and homophobia impact, for example, queers of color, poor queers, variously abled queers, and other multiple subjects.

Two other key texts in the emergence of queer theory are Warner's edited collection *Fear of a Queer Planet: Queer Politics and Social Theory* and Butler's *Bodies That Matter*, both published in 1993. In his text, Warner pondered what queers want and took the novel stance that queer studies ought to gain vitality not from rethinking the social, but from rethinking the meaning of sexuality as a subjective formation that impacts how queer is constructed. From this perspective, he challenged queer theory to interrogate how ideology and social structures impact the sexual order and how heteronormative language, themes, and concepts lack utility and limit possibility in developing queer theory. Butler also called for such interrogation in *Bodies That Matter*, situating queer as a discursive term with historical and revisionist meanings that are always constructed through and against the grain of heteronormativity. She cautioned queer theorists to consider what it means culturally and politically to take back a term historically associated with accusation, pathology, insult, and deviance. Butler also emphasized that queer is a term that can divide despite its intended expansiveness. For example, queer is divisive in its common association with a predominantly White sexual-minority movement and with youth resisting the delimitations of lesbian and gay while seeking a more expansive term to include a spectrum of sex, sexual, and gender differences. In this light, Butler argues that queer will always be volatile, discursive, political, open to redeployment from earlier usage, and never entirely owned.

From Queer Theory to Queer Research

Since they emerged only during the 1990s, queer theory and queer studies lack a significant history of

research traditions. Qualitative research methods that focus on investigating everyday experience and making meaning have proven advantageous to queer research bent on social and cultural change at the grassroots level. Queer research is still coming to terms with ethical, strategic, and methodological aspects of research on sexual minorities and their everyday experiences in culture and society. Thus researchers who engage in queer research are mediating research terrain that is in genesis as they take up matters of research design, methods, ethics, and research politics. During the 1990s, much queer research focused on textual and linguistic analyses. In this period, queer research largely failed to engage in dispositional, relational, and contextual analyses of the ways medical, educational, and other institutions and their heteronormative practices affect sexual minorities. There is still an urgent need to conduct queer research and to queer heteronormative research by challenging heteronormative ontological, epistemological, methodological, and textual aspects of inquiry. These aspects are embodied and embedded in contexts, relationships, dispositions, concepts, constructs, assumptions, and affiliations that perpetuate heteronormativity and limit utility and possibility in research on sexual minorities. Thus, for queer theorists, applying queer theory to research practice intersects academic studies with advocacy. This engagement involves exposing queer exclusion and derision historically embodied and embedded in the heteronormative knowledge-culture-language-power nexus. It also involves counteracting characterizations and representations of queer that stereotype and demean persons along a spectrum of sex, sexual, and gender differences. This requires taking detours through queer history and culture as spaces to encounter what queerness incorporates and how queerness has been treated.

Historically operating within a heteronormative paradigm, research in medicine, education, and other disciplines has usually been biased to the detriment of sexual-minority persons. For example, medical science has traditionally diagnosed those categorized homosexual as individuals who engage in aberrant or deviant behavior outside heteronormativity. Although gay liberation coupled with demands for more scientific rigor in research into homosexuality led to the American Psychiatric Association's (APA) 1973 decision to depathologize homosexuality, the current categorization of gender identity disorder as pathological is still used to legitimate inhibiting the development of homosexuality. As another example, sexual minorities

have fared no better in educational research. In his typology depicting researchers' understandings of the locatedness of sexual-minority youth, Ritch Savin-Williams demonstrated that the APA's 1973 decision had little initial impact on educational research. During what he categorized as the first stage of research on sexual-minority youth (1970s and 1980s), emphases were placed on deviance, pathology, and the need for specialized medical intervention. During his second stage (1980s and early 1990s), emphases were placed on sexual-minority youth as at-risk for social problems, including increased drug and alcohol abuse, homelessness, violence, and suicide. Emphases in his third stage (late 1990s and the early 21st century) appear more positive. Research has focused on education for social change to counter the social, cultural, and political marginalization of sexual minorities. Building youth capacity and resiliency have been focal points. However, Savin-Williams notes that third-stage research remains largely assimilationist in nature and that the heteronormalizing structures of mainstream education remain largely intact.

Queer research has been critiqued for its apparent failure to link the fluidity of the concept queer to the concreteness of social activism and cultural work focused on sexual minorities. Queer research needs to interrogate the politics of research in general and focus on researcher subjectivities and positionalities and how they influence research processes and outcomes. It also needs to critique the designs used in mainstream research in medicine, education, and other disciplines that have been historically heteronormative and homophobic in their everyday practices. This need is in keeping with queer theory's critique of dominant power and interests and the ways they maintain heteronormativity. From this perspective, queer research has to be a reflexive engagement with the researcher, the researched, social dynamics and power plays, and the cultural politics and practice of research engagements.

A key challenge in queer research is to dissolve public-private, male-female, and heterosexual-homosexual binaries that carry the weight of history and limit utility and possible outcomes in queer research. Another key challenge is to work in the intersection of relationships of power where queer as a construct intermeshes problematically with constructs of race, class, and other relationships of power that have their own histories of excluding queer. Queer has to be understood and mediated in intersections with other relationships of power, and more queer research is needed to understand how heteronormative discourses

on race, gender, ethnicity, age, ability, and class contribute to queer exclusion and homophobia. For example, more queer research is needed to help us understand historically and culturally why a heterosexual Black male might assimilate a White supremacist's misogynous and homophobic masculinity. Understanding how the knowledge-culture-language-power nexus works in intersections where racism and homophobia have been normalized is crucial to cultural work to dismantle compulsory heterosexuality.

Queer research also needs to continue to gaze inward and investigate how disenfranchising forces like heterosexism, sexism, classism, racism, ableism, and ageism infect queer culture just like mainstream culture. Queer research is needed to investigate issues of language and power at play when, for example, a gay male seeks a straight-looking, straight-acting partner, a lesbian avoids a bisexual or transsexual woman, a gay male uses sexist language smattered with demeaning references to "she" and "her," a gay White male avoids a two-spirited male in a gay bar, a professional gay male dismisses another gay male who works in sales as a "retail queen," and a younger gay male calls an older gay male an "old queen." In all this queer research, we need to be open to possibility and learning outside the heteronormative box. Here we might start from the open stance suggested by William Shakespeare's description of sexual ambiguity in *Twelfth Night* when Clown says to Sebastian in Act IV, "Nothing that is so, is so."

QUOTA SAMPLING

Quota sampling uses key categories in the larger population to specify how many members of the sample should fall into each of those categories or combinations of categories. This sampling is a nonprobability technique because it requires only that the quota for each category be met without any further attention to how those sample members are actually located. For example, a study of social service organizations might set quotas for both the number of public and private providers and the number of larger and smaller agencies in the sample. Similarly, an interview study might select participants using a two-by-two table for gender and age so that one quarter of the informants were younger women, one quarter were older men, and so on.

Survey research originally used quota sampling as a quicker and cheaper alternative to random sampling, but abandoned this approach during the 1950s because of the potential for producing unrepresentative samples. Quota samples are not truly generalizable because even though the quota-based categories may match their size in the larger population, the sample may be unrepresentative on other characteristics outside the quota system. For example, in the population of older people, there are more women than there are men, but adjusting the quotas for a study of this group to reflect gender accurately would not ensure that the sample was representative with regard to income, health, frequency of family contacts, and so on.

In contrast, quota sampling in qualitative research is a specific technique for selecting a sample that has been defined using a purposive sampling strategy to define the categories of data sources that are eligible for a study. As a technique for selecting a sample in qualitative research projects, quota sampling is often connected to stratified sampling as a specific approach to purposive sampling. In particular, stratified sampling often breaks the population into theoretically specified categories for comparative purposes, and

these categories would then be matched by quotas for data collection.

Another important use for quota sampling in qualitative research is not to create a representative sample, but rather to avoid bias on key characteristics, by assuring their inclusion in the sample. For purposive sampling, this process is much more likely to set quotas that match important substantive categories from study, rather than demographic or background characteristics that are not directly relevant to the topic of the study. For example, a study of how health affects older men and women would set quotas for gender and poor versus good health and then investigate how other factors, such as income and frequency of family contacts, operated within the key categories of interest. This

demonstrates how quota sampling assures that the most important population categories will be adequately represented in the sample.

R

RANDOM SAMPLING

In random sampling, every data source in the population has an equal chance of being included in the sample. Because random samples are probability samples, this creates the possibility for generalizing to a larger population, but this generalizability is not absolute. To see that random samples are not automatically representative of the population from which they are drawn, consider the example of flipping a coin five times. This will produce a random sample of all the possible outcomes, but it is still possible to obtain either five heads or five tails—which definitely are not “typical” results.

The key point is that the statistics associated with random sampling simply define the probability of getting an unusual result rather than guaranteeing that the sample will actually match the population (e.g., in flipping a coin five times, there is a 6.25% chance of getting either all heads or all tails). In addition, the ability to make accurate generalizations from random sampling is highly dependent on sample size. In qualitative research, however, the sample sizes are typically so small that even random sampling would yield too little accuracy for meaningful generalizations. For example, a random sample of 20 people would have virtually no value for representing any sizable population—regardless of whether the data are quantitative or qualitative.

For some cases, the use of random sampling in qualitative research comes closer to what is technically known as “random assignment.” In particular,

after a purposive sampling process locates a set of eligible data sources, the next step might be to use random selection in deciding which cases to study. Although this use of probability sampling would eliminate what are known as “selection effects” by ensuring that the size of a group in the larger population is the only factor that influences how often its members appear in the sample, it once again does not guarantee a representative sample—especially when the sample size is small. For example, if a researcher wants to select 5 people to interview from a pool of 30 eligible cases that are evenly divided between men and women, random sampling will produce results that are at least 80% male or female more than a third of the time (to be precise, 37.5% of such samples will have at least four men or four women). As this example demonstrates, random sampling is an inefficient method for creating representativeness in small samples. For many qualitative studies, a nonprobability sampling method, such as quota sampling, would be a better strategy for making certain that a small sample was well balanced with regard to the characteristics that are most important. Although quota samples are not generalizable, a small size sample will make that consideration irrelevant for most practical purposes; hence, the more important goal is to avoid producing a sample that is obviously different from the population on some crucial characteristic.

RAPID ASSESSMENT PROCESS

Rapid assessment is defined as intensive, team-based qualitative inquiry using triangulation, iterative data analysis, and additional data collection to quickly develop a preliminary understanding of a situation from the insider's perspective. Rapid assessment allows a team of at least two researchers to investigate complicated situations where issues are not yet well defined and where there is not sufficient time or other resources for long-term, traditional qualitative research. A call for this type of more rapid qualitative research was implicit in the declaration in *BusinessWeek* magazine in June 2006 that "ethnography is the new core competence." The article described the use of ethnography to "develop a deep understanding of how people live and work" (p. IN10) but was accompanied by the observation that most researchers do not have the time or the resources to do it. Although there is greater recognition of the need for qualitative inquiry and for results that can be used quickly, there has also been increased attention given to the resources needed and time associated with traditional, long-term qualitative research. There are issues concerning participation and related ethical issues associated with rapid assessment.

Basic Characteristics

Rapid assessment allows a team of at least two individuals to gain sufficient understanding of a situation in 1 to 6 weeks to make preliminary decisions for the design and implementation of applied activities or additional research. Rapid assessment can also be used for monitoring and evaluation. Usually rapid assessment should not be used for estimating numbers or percentages. Rapid assessment has been used in areas as diverse as wetlands evaluation, citywide needs assessment, early childhood care evaluation, monitoring of home ownership patterns among minorities, client satisfaction assessment at clinics in Africa, marketing studies, and landscape planning.

Results are different from those produced by longer-term fieldwork. In some cases, intensive interaction by a research team over a short period may produce better results than those produced by a lone researcher over a long period. Rapid assessment will almost always produce results in a fraction of the time and at less cost in comparison with traditional qualitative research.

Although the 1- to 6-week time period for rapid assessment is recognized as arbitrary, there is growing consensus among practitioners that it is extremely difficult to complete the process of data collection, data analysis, and additional data collection as part of an iterative process and to then prepare a report in less than a week. "Rapid" does not mean "rushed." Schedules must be designed with sufficient flexibility that the team can take full advantage of unanticipated opportunities.

Triangulation is a critical element of rapid assessment. Triangulation is a metaphor employed by social scientists for the use of data from different sources, the use of several different researchers, the use of multiple perspectives to interpret a single set of data, and the use of multiple methods to study a single problem.

Rapid assessment shares many of the characteristics of ethnographic research but differs in two important ways. First, more than one researcher is always involved in data collection. Second, more than one researcher is involved in an iterative approach to data analysis and additional data collection. The intensive teamwork for both the data collection and analysis is an alternative to prolonged fieldwork associated with traditional qualitative research.

Rapid assessment process (RAP) is one way of reducing the costs and speeding up the process. Terms such as rapid appraisal, rapid assessment, rapid rural appraisal, and participatory rural appraisal, as well as the acronym RAP, have been widely used to identify other rapid research methods based on the use of teams with results produced in several months or less. Quick ethnography is another approach for speeding up the process based on using greater structure for the process and taking between 30 and 90 days.

Data Collection: Intensive Teamwork

There are usually two to six individuals on the RAP team, and the team needs to be multidisciplinary and

diverse and must include at least one “insider” as well as “outsiders.” Rapid assessment cannot be done by one researcher. The assumption is that two sets of eyes and ears are better than one and that the use of different techniques can help to make the best use of the extra eyes and ears. Also, the assumption is that two heads are better than one in figuring out what has been seen and heard and in making decisions about what should be asked in the next round of data collection. Sensitivity to cultural differences is essential, and team diversity improves cultural sensitivity and helps to establish credibility with local communities. The success of RAP depends on the quality of the teamwork.

Semi-Structured Interviews and Directed Conversations

Rapid assessment is based on talking with people and getting them to tell their stories. The acronym RAP communicates the essential ingredient for successful implementation. The objective of rapid assessment is to communicate with participants using their vocabulary and rhythm and is *not* to get answers to questions. One definition of RAP is to talk freely and frankly. Although the process is often identified as a “semi-structured interview,” it is better thought of as directed conversation. Directed group discussions involve the entire team talking with one or more local participants and is *not* sequential interviewing by individual members of the team.

Individuals with whom the RAP team talks are purposefully selected. They are not a sample. They are selected not because they are believed to be average but rather because they are believed to represent the diversity found in the local situation. The RAP team should seek out the poorer, less articulate, more upset individuals and those least like the members of the RAP team.

Other Techniques for Data Collection

In addition to semi-structured interviewing, other specific techniques are chosen from among a wide range of techniques based on the specific topic being investigated and the resources available. Observations and team interaction with respondents based on what is seen and heard are necessary. All interviews should be conducted in a setting where listening can be combined with observing.

Iterative Analysis and Additional Data Collection

Rapid assessment explicitly divides research time between blocks used for collecting information and blocks used when the RAP team does data analysis and considers changes in the next round of data collection. Beginning on the first day, time is scheduled for team interaction. Usually more time is spent on team interaction than on data collection. The constant shifting between data analysis and additional data collection is an iterative or recursive process. An iterative process is defined as a process in which replications of a cycle produce results that approximate the desired result more and more closely. For rapid assessment, the replication of the process of data collection followed by analysis and additional data collection contributes to the goal of understanding the situation under investigation from the perspective of the local participants in the system.

Each rapid assessment must adapt the data analysis process to the specific setting. An approach that has worked for many rapid assessments and that can serve as a beginning point for modification involves (a) coding the data, (b) displaying the data, and (c) drawing conclusions. Analysis is an ongoing process that begins with, or even before, the first round of data collection and continues through the preparation of the report.

The Issue of Participation and Ethics

Rapid assessment is a type of participatory action research. There is widespread consensus on the value of the participation in the research process by members of the local community. However, there are ethical issues related to participation that have often been ignored. These issues are almost always aggravated by inappropriate instances where problems are identified and solved at the local level without the involvement of outsiders. Rapid assessment assumes that decision makers should be part of the effort to identify and address issues and that often this involves outsiders who control resources. Even when outside decision makers are not part of the research effort, it is critical that the research effort be designed with sufficient rigor to allow them to make decisions based on the results.

The most serious negative consequence of an excessive focus on participation is the shifting of the burden onto the poor and the relinquishing by outsiders of their

responsibilities to promote development with equity. Even when such a shift does not occur, participation can raise unrealistic expectations in local communities. Closely related to raising unrealistic expectation is “bogus empowerment” that occurs whenever someone is asked for his or her input but there are no intentions of using it.

One of the major challenges of rapid assessment is to promote inventiveness and creativity concerning implementation without losing rigor. Other challenges include overselling it, confusing “rapid” with “rushed,” and failing to implement it rigorously. The overall challenge is to embrace the potential of rapid assessment while recognizing its limitations.

Participant observation raises a unique set of issues associated with rapport due to the length and complexity of the relationships involved in this method. Once the participant observer has access to the study site and research participants, the creation and management of relationships becomes an ongoing issue with this method of data collection. In this case, the creation of rapport often begins with a process of trust building, but once relationships are established, issues of reciprocity and mutual obligation become increasingly important. In particular, the kind of “prolonged engagement” that is often seen as essential for high-quality participant observation is likely to require rapport across a web of relationships that goes well beyond the dyadic relationships that are usually considered in discussions of rapport.

In contrast, nearly all studies based on interviewing involve more transitory relationships where the collection of data is the primary basis for interaction—with extended oral histories being the most notable exception. Thus, concerns with rapport in interviewing center on the need to build an appropriate relationship within a relatively short period of time. Hence, the way the researcher describes both the nature of the project and the procedures for the interview itself sets the stage for the rapport building that occurs in the subsequent interaction. In particular, it is frequently helpful to let the participants know the extent to which the interviewer will be primarily a listener, an active questioner and facilitator, or even a relatively directive and agenda-driven data collector because the nature of rapport will be different in each of those approaches to qualitative interviewing.

Among the factors that affect rapport in both participant observation and interviewing are the topic of the research and the amount of self-disclosure that it requires from the participants, the ability of the researcher to protect the participants’ privacy, the nature of the research setting, the extent to which the researcher has an “insider status” or other preexisting contacts with the participants, and the extent to which the participants perceive themselves as similar to the researcher. As this list indicates, rapport in research relationships can be a complex issue. Furthermore, these factors often occur in combinations that may have strong effects. Most notably, the combination of the research topic and the degree of similarity between the researcher and the participants can have a powerful effect on rapport, especially when the topic involves contested social boundaries such as race, gender, and sexuality.

RAPPORT

Rapport refers to the degree of comfort in the interactions between the researcher and research participants. For participant observation, rapport refers to the quality of the relationships that the researcher makes at the field-site. For interviewing, it refers to the relative ease of exchanges between the interviewer and interviewee(s).

Overall, the concept of rapport is a good illustration of the classic claim that the qualitative researcher is the “research instrument” because the quality of the research often depends on the quality of the researcher’s relationships with the participants.

RAW DATA

Raw data can be broadly defined as information collected by a researcher to understand phenomena under investigation. Raw data include words that participants use, diagrams of environments, observations, documents, memos, transcripts of focus groups, and pictures. Any information collected by the researcher, before any manipulation (e.g., analysis) has been conducted, is considered raw data. From a sociological perspective, raw data are viewed as a window into the human experience. Hence, the qualitative researcher can collect two types of raw data: (1) narratives, open-ended interviews, and discourses; and (2) information collected from methods that elicit systematic information from respondents.

Qualitative research can generate enormous amounts of raw data. Thus, before any data have been collected, it is essential for the researcher to design a method of arranging, organizing, and categorizing the raw data as they are being collected. When choosing a method of organizing the raw data, the researcher should keep in mind the importance of where or by whom the raw data were produced. Therefore, having a coding method for tracking where or by whom the raw data were produced is paramount.

The most important principle when working with raw data is ensuring their accuracy. Raw data need to be as correct, thorough, and complete as possible. The qualitative researcher has the responsibility to ensure

that the raw data are an accurate reflection of the participant’s voice. To check the accuracy or trustworthiness of the raw data, member checking can be used. For example, to undertake member checking of raw data from an interview, after the interview has been audiotaped, the researcher transcribes the data so that they are in written text. This text, or a portion of the text, then can be member checked by asking the interviewee to read through the text to determine whether it accurately and adequately captures her or his voice. Member checking the raw data actually can provide additional raw data, especially if it leads to the transcript being modified or expanded.

Raw data in qualitative inquiry have many unique features. Most notably, raw data provide naturally occurring information that allows the researcher to increase his or her understanding of the phenomena. Furthermore, raw data tend to be collected in close proximity to the actual situation such as via direct observation or interview, with the influence of the local context forming part of the data rather than being ignored or manipulated. In addition, raw data often yield rich descriptions that are contextualized and reveal complexity. Also, raw data often are collected over a long period, allowing for in-depth analyses of institutional, historical, psychological, and social processes.

REACTIVITY

Reactivity, also known as the observer effect, takes place when the act of doing the research changes the behavior of participants, thereby making the findings of the research subject to error.

Different types of reactivity have been identified. One of the first to be noted, the Hawthorne effect, is

associated with experiments conducted by Elton Mayo at the Westinghouse Electric plant in Hawthorne, Illinois, during the 1920s and 1930s. Modifications in working conditions (e.g., changes in lighting) were introduced, and it was observed that productivity increased after each modification. Mayo hypothesized that workers were responding to increased attention received as being part of the experiment and knowing they were being observed rather than to the changes in work process. The Hawthorne effect encompasses changes in behavior arising from knowledge about participation in research. Another type of reactivity is the novelty effect, which involves changes in behavior due to the introduction of something new in the research setting (e.g., the presence of the researcher). Novelty effects usually disappear with passing time. The placebo effect has been well documented in drug trial research but also can occur in other research settings. Finally, reactivity may result from demand characteristics, with participants doing what they think the researcher expects them to do or what will please the researcher.

A number of factors have been seen to influence the degree of reactivity. Conspicuous observers, or those who place themselves in the middle of the activities, are more intrusive than those who stand to the side. Characteristics of the observer (e.g., age, race, gender, dress) that differ substantially from those of participants are likely to cause more reactivity. Characteristics of participants may also influence behavior. For example, children usually return to naturally occurring behavior more quickly than do adults. Reactive behavior usually decreases as time passes, a process known as habituation. It is postulated that this return to normality arises from the development of rapport and trust between participants and the researcher and the fact that it is difficult to sustain unnatural behavior for a long period. Participants' understanding of the purpose of the research may cause reactivity. For example, if participants believe that the researcher is trying to document socially unacceptable or deviant activities, they may hide these behaviors.

In qualitative research, reactivity is usually seen as being inclusive of the researcher as well as the participants. The researcher keeps reflexive notes that document how his or her own behavior and understandings may have been affected by the research process. Reactivity is regarded as being inevitable in any research process that involves interaction among participants, the

researcher, and a setting of interest. Reflexive analysis helps to uncover and respond to reactivity in appropriate ways.

READERS THEATER

Readers theater is a genre of drama in which actors hold scripts, staging is kept simple, scenery is limited to things such as stools and ladders, and costumes (if used at all) are little more than articles of clothing (e.g., a hat, a scarf) intended to suggest, rather than literally represent, a character. Certain qualitative researchers have used the readers theater genre to display their data.

The use of the readers theater genre to display data is part of a larger movement within both the theater and research communities to translate qualitative data into drama. Different names (e.g., performance ethnography, documentary theater, data-based readers theater) have been used to characterize the products that have been created, and each form of data-based theater has its own unique characteristics.

The most obvious defining characteristic of the readers theater genre is the convention of actors holding scripts during performances. This convention is used even in well-rehearsed professional productions where actors have memorized scripts because readers theater is by design a stylized, rather than realistic, form of drama. Readers theater productions exhibit other forms of stylization as well. When actors enter or exit a scene, for example, they are unlikely to literally walk on or off the stage. More often than not, they simply turn toward or away from the audience to symbolize entering or leaving, respectively.

Why this focus on symbolization and stylization? Theater scholars indicate that readers theater is a presentational, rather than representational, type of theater. Whereas representational forms of theater attempt to portray action realistically, presentational forms ask audience members to fill in what has been intentionally omitted onstage and, in the process, to co-construct with the actors the meaning of the work. Some social scientists who advocate the use of the readers theater genre to display qualitative data have even compared the holding of scripts and the genre's other stylization techniques to the distancing devices that playwright Bertolt Brecht used to ensure that audiences do not get so emotionally caught up in his plays that they forget to think and analyze.

This emphasis on promoting thinking and analysis as well as empathic understanding makes readers theater an especially appropriate form of drama for use in academic contexts. Of course, the genre also offers a more practical benefit in that because scripts do not need to be memorized and staging, scenery, and costumes are simple (or nonexistent), a readers theater script can be rehearsed relatively quickly and presented at research conferences and in other venues where the performance of data can be used to stimulate a rich discussion of the issues implicit in the script.

conducted. Realist ontologies (assumptions about the nature of reality) range from the view that the world of objects and social structures exists independent of human experience to the idea that, although the world exists independent of any one person, human perception is such that our reality is a preinterpreted one. Realist epistemologies (theories about what counts as knowledge) range from the view that the world can be known directly through the senses to the idea that internally consistent interpretations of reality can count as knowledge if bounded by, and revisable in light of, interactions with the world. Holding a realist ontology does not always commit a researcher to a realist epistemology.

Realism has often been associated with quantification, but it is compatible with many qualitative methods and is the position of choice of many qualitative researchers. In this entry, realism as a philosophical position influencing the development of research methodology is first set in context. Positivist philosophies of science are then outlined, and naive and scientific realism are explored. The nature of postpositivist science is then considered along with subtle, analytic, and critical realism. Finally, the relation of critical and standpoint theory to forms of realism is explored. Although these subdivisions can be identified and described, the dividing line between positions is often a matter of emphasis. Moreover, what is described under each heading can contain contradictions because some stances have more than one strand.

Realism in Context

Realism as an overarching philosophical doctrine is the position that we should strive to understand the world from an objective point of view. In this, realism is a radical counter to religious and authoritarian truths and, as such, was defended by Galileo. Realism brought an optimism that the world is knowable and that this knowledge could be value free, and it has dominated Western thought since the 18th-century Enlightenment. Throughout the 20th century, antirealist positions have made headway into the philosophy of science, particularly the social sciences, arguing for the impossibility of human objectivity. The impact of antirealism and modified realism on social science has gained momentum since the 1960s, evolving into what is sometimes referred to as the “turn to language” or “reflexive turn” in relation to qualitative methodology. However, forms of realism are still

REALISM

Realism refers to a range of ontological and epistemological positions within which research may be

compatible with contemporary understandings of science that incorporate an element of interpretation into what counts as knowledge and are adopted by many qualitative researchers.

Realism and Positivism

Positivism

Positivism is a hugely influential philosophy of science associated with a 19th-century model of the physical sciences. It is empiricist in asserting that the world exists of observables that are knowable through sensory experience, aspires to the discovery of universal causal laws through the identification of statistical regularities, and commits to value neutrality. The ontology proscribed to positivism ranges from the naive realism that the world exists of objective material things to the more complex position that although there is a real world to be discovered, it can be apprehended only imperfectly and probabilistically. The epistemology of positivism is tied to the scientific principle of verification that specifies rules for what counts as knowledge, in particular confirming sensory experiences through replication. However, although an objective stance is sought, positivist empiricism admits a certain subjectivity through restricting the knowable to the experienceable. In fact, during the 1920s and 1930s, logical positivists introduced elements of epistemological relativism, arguing that the truth of a statement was always internal to a culturally produced linguistic framework of meaning. Moreover, although strongly associated with quantification, the role of interpretation in statistical analysis is acknowledged in logical positivism, inductive theory generation accepted as a stage for scientific inquiry, and qualitative methods not disqualified *prima facie*, particularly in the social sciences.

Many authors suggest that since the mid-20th century, positivism has no longer been held as a coherent philosophy of science, even though the language of positivism may still be entrenched in most scientific disciplines. It is argued that the idea of empirical science offering a solid foundation for knowledge has been successfully refuted. For example, postmodern and constructionist perspectives argue that methodology is never neutral, that guiding ideals such as objectivity are value laden and untenable, and that methods used to study the social world of self-conscious agents must differ from those used in the natural sciences.

However, in dismissing and “othering” positivism, qualitative researchers may be oversimplifying this complex philosophy, which in some forms actually anticipated postpositivist science. Moreover, some qualitative methods themselves involve elements that might be considered positivist, including the search for universal causal laws in analytic induction, the verificational aspects of grounded theory, and the strict empiricism of conversation analysis.

Naive/Commonsense/ Descriptive/Crude Realism

Naive realism asserts the ontology that, under normal conditions, things are just as we perceive them to be and asserts the epistemology that true knowledge can be identified through its correspondence with reality. Arguably, it is the commonsense philosophy adopted tacitly in daily life. Naive realism is an unsuitable position for inquiry into things that are not directly perceptible, but in itself it is compatible with both quantitative and qualitative methods and is drawn on within both positivist and postpositivist theories of science.

In qualitative methodology, naive or descriptive realism is most associated with naturalist ethnography and symbolic interactionist research in the tradition of Erving Goffman and Herbert Blumer. The methodology of naturalism requires an immersion and co-participation in the social environment under study in its natural state. The empathic understanding gained is the basis for knowledge of the context investigated. In focusing on cultural meanings, as opposed to universal laws, naturalism was developed as a counterpoint to positivist science but maintained the claim that social reality can be apprehended directly. This naive realism has been attacked by Thomas Kuhn, who argued that all scientific knowledge is relative and provisional. Moreover, naturalism has been derided by postmodern perspectives arguing that “descriptively real” texts of research findings are a rhetorical construction imposing univocality on what is a multiperspectival social world. However, there is an argument that, in using a basic process of human sensemaking (i.e., intersubjectivity), immersive understanding has a claim to be able to produce knowledge of social life.

Scientific Realism

Scientific realism accepts the broad ontological and epistemological postulates of naive realism and

adds a commitment to the scientific method as the best mode of inquiry into the nature of reality. The natural sciences are often held as exemplifying methodological procedures, and some qualitative researchers, particularly during the 1920s and 1930s, sought to emulate them. This included pioneers such as Florian Znaniecki, Herbert Blumer, Bronislaw Malinowski, and Alfred Reginald Radcliffe-Brown. However, striving to emulate the natural sciences is fraught with problems from the start because there is no one true method. Even physics has been shown to have divergent underpinnings, including positivist, conventionalist, and realist interpretations, among others. However, although scientific realism is heavily associated with positivism, postpositivist approaches are developing a modified version in critical realism.

Realism and Postpositivism

Postpositivism

Many argue that contemporary science is dominated by postpositivist positions that favor quantification and the search for causation, although amenable to certain forms of qualitative method, and includes a concern with subjectivity and meaning. In general, postpositivists are ontological realists in being willing to accept the existence of an independent reality. However, they espouse a more explicitly skeptical epistemology than do positivists, doubting that reality can be known in a direct way but having faith that language is in some way referential. Even so, postpositivist epistemology is nonfoundationalist in the sense that truth is considered so only relative to a paradigm. However, a major principle of postpositivist science is falsificationism; that is, the principle that knowledge claims must be tested empirically in conditions under which such claims could be refuted. Hence, in subjecting beliefs to empirical test, postpositivists allow that the world sets constraints on what can be accepted as truth even if human understanding requires this to be interpreted within a contemporaneously acceptable framework of meaning. Moreover, postpositivists argue that some beliefs are just more plausible than others and that evidence (e.g., consistency of account, set of associations), although not proof of truth, helps to provide this credibility. Some critical perspectives argue that postpositivism can be an overly conservative philosophy by awarding the power of truth determination, however provisional, to contextually dominant paradigms of knowledge.

Postpositivism has developed positions that attempt to claim the middle ground between realism and relativism—subtle realism, analytic realism, critical realism, and Kantian soft or “transcendental” idealism (because the latter does not identify as a realist position, it is not explored further here).

Subtle Realism

Ethnography is one of the oldest forms of qualitative method in the social sciences, and the reflexive turn during the late 20th century had a particularly profound impact on ethnographers, leading to a critical examination of its foundations. In response, Martyn Hammersley articulated a position termed *subtle realism*, and David Altheide and John Johnson articulated a position known as *analytic realism*.

Subtle realism, argued to be applicable to social science research in general, is a middle ground between the naive realism of naturalism and the relativism of constructionist and postmodern approaches. Subtle realism shares the naive realist ontology that the world consists of independent phenomena but argues that we do not have direct access to them. In terms of epistemology, subtle realism agrees with naive realism that the world is knowable but adds that our understanding always relies on cultural assumptions and is, at best, a selective representation; that is, one of many possible valid accounts. This is a correspondence theory of truth but one that allows that, because we have no direct access to reality, we can never have absolutely certain knowledge. Hence, subtle realism requires that researchers make explicit the relevances on which their accounts are based. For example, accounts must be plausible given our existing knowledge, have credibility as the kinds of accounts that might reasonably be expected given the conditions of the research, and have relevance to issues of human concern.

Analytic Realism

Altheide and Johnson’s analytic realism is a humanistic approach to qualitative methodology, particularly ethnography, focusing on what they called the empirical world of lived experience. Like subtle realism, analytic realism rejects the dichotomy of realism and relativism, although Altheide and Johnson argued that analytic realism places the stronger emphasis on knowledge verification. Ontological assumptions concern the social world,

and this is conceptualized as interpreted rather than literal. Epistemologically, interpretation is accepted as a valid way of knowing even though knowledge is considered relative to a perspective and it is accepted that different researchers, and research conducted at different points in time, may come to different conclusions. So, although analytic realism shares with naturalism a faith in immersive understanding, it includes a particular concern with the interpretive validity of research accounts and is careful to specify criteria increasing the validity of reports. Criteria include clear delineation of the research context and method, reflexive reporting, and attention to the multivocality of members' perspectives. Such procedures do not ensure the objective truth of findings given that the report is considered to be truth only as the researcher has come to understand it, but they make the researcher's claims better open to evaluation.

Critical Realism

Critical realism is a position under development by a growing number of proponents but is associated most with Roy Bhaskar. Writings on critical realism often stress the position as an ontology, although it does have epistemological implications and may even be considered a philosophy of science.

The ontological position of critical realism states that the objects of the world consist of the emergent properties of physical and social entities, although our beliefs and expectations influence the way we perceive and theorize these objects, particularly in the social sciences. Hence, as an epistemology, critical realism accepts a perspectival theory of knowledge situated within a socially and historically relativist theory of science. However, some forms of knowledge are argued to be more plausible than others, and critical realism accepts the importance of empirical investigation, with Bhaskar arguing for a form of naturalism in the social sciences. This substantiates the interpretation that Bhaskar views critical realism as a development within scientific realism that jettisons some of its more positivist assumptions. That is, in viewing meaningfulness as the key element of social life, critical realists eschew the use of quantification and experimental control in the social sciences. Moreover, although accounts of the social world are believed to be grounded in practices with an underlying structure and logic, critical realism is nonreductionist in arguing that the best explanations are not necessarily at the level of most basic empirical elements and mechanisms.

The final defining characteristic of critical realism is that it is also a moral philosophy that places human emancipation as a central concern of science. Bhaskar has argued that social science theories, developed through empirical investigation, can show certain beliefs, or ideologies, to be false and can demonstrate how they have been generated within transitory, and hence changeable, social relations and structures.

Critical realism has been critiqued as being too vague and too general to be a convincing philosophy of science. Moreover, it is argued that faith that the social world is grounded in knowable, extra-theoretical deep structures seems to be at odds with Bhaskar's commitment to scientific relativism associated with Thomas Kuhn's theory of paradigmatic shifts in the nature of the objects and processes with which science populates the world.

Realism and Critical Approaches

Critical Theory

Critical theory has had an influence on social science from the 1960s onward, incorporating a backlash to the perceived value neutrality of positivism and the perceived failure of interpretive, or hermeneutic, social science to recognize macrostructural constraints. Critical theory is emancipatory in its aims and focuses on the critique of ideology; that is, on revealing historically created distortions in understanding that influence everyday life. In general, three versions of critical theory can be identified: Marxism, the Frankfurt School version of Marxism, and positions influenced by feminism (as well as by Marxism).

Ontologically, critical theory allows that the world exists of real objects but that reality can take on different meanings within different, humanly constructed symbolic fields. Hence, critical theory has a nonfoundational epistemology, believing that there is no theory- or value-free knowledge given that human understanding consists of socially and historically situated patterns. However, critical theory retains the idea that knowledge can be objective by defining objectivity not in terms of correspondence with an independent reality but rather in relation to explicating the shared patterns of culturally and historically developed understandings.

This peculiarly historical and political emphasis, and strength with which discourses are understood to be constitutive of the world, makes critical theory difficult to match easily with subtle or analytic realism—or, perhaps, even critical realism. Although it has a

realist ontology, the discursive emphasis of critical theory can make it difficult to ground research findings as truth. Moreover, it seems inconsistent to claim that one truth is more empowering than another when the interests of one oppressed group may well be in conflict with those of another.

Standpoint Theory

The political and emancipatory elements of critical theory are shared by standpoint theory, which commits to the empowerment of oppressed groups informed by feminism but also stances such as antiracism and anti-colonialism. The ontology of standpoint theory is the acceptance of a materially real world. However, just as critical realism is sometimes presented as a particularly sophisticated ontology, the emphasis of standpoint theory is its epistemology. Standpoint epistemology provides a more secure grounding for truth claims than does critical theory through espousing a stronger foundationalist stance, although this foundationalism is complex and has been described as “fractured.” That is, truth claims are grounded in a material world understood to set boundaries on what is possible, whereas it is accepted that many different interpretations of this world are plausible and valid within the different contexts provoking them.

An important aspect of standpoint theory is the attempt to democratize knowledge production through approaching participants as experts on their own experience and for researchers to incorporate a reflexive awareness about how their own biographies and actions influence the knowledge produced. This does not *prima facie* exclude quantitative methods, but it tends to be more compatible with qualitative approaches. However, standpoint research does tread a precarious and (arguably) contradictory line between knowledge as construction and knowledge as experience. Some researchers argue that standpoint research produces more objective knowledge than do traditional methods through its revelation of otherwise ignored values and frameworks of power. This has been critiqued most pertinently by postmodern feminists, who argue that this glosses over the problems of accepting that differing accounts of the world may be true relative to their context, particularly when power relations between members of an oppressed group differ. For example, one may ask whether it is possible even for research on women by women to democratize the research process and produce value-free

knowledge when the actors have many different social identities, each with potentially different structural power relations—ethnicity, sexual orientation, class, and so on. In support of standpoint theory, in good research such tensions are not dismissed but rather incorporated reflexively as dilemmas to be explored as part of understanding the complexities of lived experience.

Conclusion

Realism covers a range of complex ontological and epistemological positions within which research can be conducted. The philosophy of science is in continual development, and new and modified realisms are under debate. Many of these are relevant to qualitative research even if the perception can be that these methodologies are dominated by relativist, social constructionist, and postmodern perspectives. Realist positions offer qualitative analysis grounding for research findings—sophisticated, complex, and compatible with the ethos of many qualitative methods. Critical realism, in particular, is gaining advocates as a strong foundation for forms of discourse analysis, and other qualitative researchers, perhaps most notably in the phenomenological and humanistic traditions, are drawn to realist positions, allowing them to argue that they access the lived experience of those they study.

REALITY AND MULTIPLE REALITIES

The nature of reality has long been the topic of philosophical debate. In general, the debate falls along a continuum. At one end, reality is objective, existing independent of us. It is out there, waiting to be discovered. At the other end, reality is subjective, continually being co-created by us. It is dynamic and changing. What the researcher believes about the nature of reality is critical. The questions asked by the researcher who falls closer to the objective end of the continuum will be different from the questions asked by the researcher who falls closer to the subjective end.

The nature of reality is related to discussions of ontology, epistemology, and methodology. Ontology has to do with our assumptions regarding how the world works. Epistemology has to do with how we know what we know. Methodology has to do with how we go about investigating reality and making knowledge claims. What we believe leads to questions about our relationship to the world, how we understand it, and how we study it. Some people believe that the world shapes us and that we react to what is happening around us. Others believe that we shape the world and can control our own destinies. Still others take a stance somewhere in between these two views.

Perspectives on the Nature of Reality

There are many perspectives on the nature of reality. They can be traced through the development of scientific thinking through the ages. For purposes of illustration, three major periods are briefly described: prescientific revolution, scientific revolution, and postmodern.

Before the scientific revolution (pre-1500s), reality was commonly conceived of as both natural and supernatural. A natural world co-existed with a spirit world. Reality consisted of both worlds. Not everything that happened had an explanation; thus, a degree of mystery was acceptable. Primary sources of knowledge were mysticism and revelation. With the rise of the scientific revolution, the degree of mystery that could be tolerated changed.

The scientific revolution is linked closely with the Enlightenment following the Middle Ages. The emphasis was on rationality, science, and reason. People such as René Descartes and Isaac Newton proposed that there were natural laws to explain reality

and that those laws could be discovered. Descartes advocated deductive reasoning, coming to conclusions based on observable facts using reason and logic. Newton explained the principle of gravity, dispelling myths associated with that phenomenon. In addition, he suggested that the universe was like a giant clock and that if we understood its parts, we would understand the whole. This kind of thinking formed the basis of the scientific method and has been dominant for centuries. It is the basis of the positivist objective approach to research.

Recently, the positivist approach has been challenged by postmodern thinking. Postmodern thinking argues that the scientific method, as it has been advocated, has not served us well. The idea that the whole can be understood from its parts leads to fragmentation of systems and thinking. The postmodern approach suggests that the whole is greater than its parts. Deductive reasoning provides only partial explanations, and it is possible to understand the general by studying the particular. The possibility that there are multiple realities is presented. This is a more subjective approach to research.

Objective and Subjective Nature

As noted, reality can be seen to fall on a continuum between the objective and the subjective. At the objective end of the continuum, because reality exists independent of beliefs and perceptions, it can be identified and studied. We can confirm what is there through observation, experimentation, and measures. Meaning is fixed and verifiable. It does not need to be interpreted; it can be proven and tested. There are universal norms for truth and morality. Reality is predictable because people will react to what is around them, and those reactions can be predicted. Reality can be dissected and studied in fragments. There is an answer, and it can be found. Deductive modes of reasoning are used. Knowledge is stable. Bias should not influence the research. These are often the premises in quantitative research where a hypothesis is tested to see whether it is correct.

At the other end of the continuum, reality exists in many forms. It is co-created, and our understandings of reality are being constructed continually. Meaning is pluralistic and diverse. It is made, not found. Something exists only when it is experienced and ascribed a meaning. Experience and intuition are used to study holistic, interactive complex systems that can

be described and interpreted in many ways. Reality is unpredictable and can be challenged. Deductive modes of reasoning are used. Knowledge shifts and changes over time. It is accepted that bias will influence the research. These are often the assumptions in qualitative research. There are many possible interpretations; a qualitative study is presenting one of many.

Because the researcher is the instrument in qualitative research, what the researcher believes about the way the world works becomes crucial. These beliefs will guide the direction of the research, the methodology chosen, data analysis and interpretation, and how the study is presented.

Researcher as Instrument

The researcher brings his or her views, values, beliefs, feelings, and assumptions to the research. When the researcher is the instrument, all of these have an effect on how the research is conducted. In addition, the gender, race/ethnicity, age, sexual orientation, and politics of the researcher will accompany him or her into the research setting. The researcher has a place in the research. That place needs to be made explicit. The researcher's personal and social perspectives shape the decisions that are made about the research. The topic chosen, who will be asked to participate in the study, the questions asked, the approaches to data collection and analysis, how the report is written, and what gets presented all are decisions made by the researcher. Those decisions are influenced by what the researcher brings to the research in the first place.

As an example, consider that two researchers are studying the topic of employee retention. Both want to know what the organization can do to generate higher retention rates. Researcher A sees this as a problem that can be solved. By understanding what the organization is doing wrong, corrections can be made. Study participants are those who have given notice that they will be leaving the organization. There is a postulation that by understanding why employees are leaving, the organization may learn what can be done to improve retention. Interview questions are designed to discover what is motivating the participants to leave and, from their perspective, how the organization could encourage employees to stay. Researcher B recognizes that several employees have been with the organization for many years. Perhaps by learning why they have been there so long, organizational strengths can be identified and expanded. Study participants are

those who have been with the organization for more than 10 years. Interview questions are designed to understand why they have worked there for so long and, from their perspective, what the organization offers employees.

Neither research design or approach is wrong; the two are different. Both designs or approaches will address the question of employee retention, but in different ways. Because they are asking different questions, the researchers will get different answers. This illustrates that the perspective of the researcher is one of many. Participants in both studies will also be providing perspectives, making for multiple realities.

Multiple Realities

It is important to remember that qualitative research is not designed to prove something; rather, it is designed to generate working understandings. A universal explanation is not being sought. Although a possible explanation may be presented, it is recognized that this is one explanation and that there could be many others. Qualitative research honors the idea of multiple realities.

One way in which the idea of multiple realities is honored is through the place of the researcher in the research. The researcher is not objective. It is expected that the researcher will bring biases to the research. Qualitative research addresses this by calling for the researcher to disclose his or her biases and explain how they may have affected the research. There also is acknowledgment that the researcher provides only one perspective.

Those who participate in the study provide additional perspectives. Each person who participates in the study provides a different view on the topic being investigated. Each brings his or her own assumptions, beliefs, and perspective. This is commonly shown through the use of different quotes from participants. Quotes may show that participants do not agree on the topic and/or that they have had different experiences. Consistency is not necessarily the goal. Dissonant points of view are acceptable. Qualitative research frequently illustrates the complexity of multiple realities.

A third way in which multiple realities are honored is through flexible guidelines. Due to their emergent nature, qualitative methodologies tend to be malleable. For example, there is no one correct way in which to conduct a phenomenological study. Although there are guidelines for conducting phenomenological studies, there is not a set procedure that must be followed.

Whereas quantitative research generally seeks to prove, measure, and verify, qualitative research generally seeks to understand, illustrate, and describe. Quantitative research lends itself to developing theories that explain and can be used to predict the future. Qualitative research lends itself to accessing the meaning made by others and describing how those meanings were created.

Four Broad Orientations

As stated earlier, what the researcher believes about the nature of reality is critical to qualitative research. This is demonstrated through a very broad brushstroke of four general orientations to research: positivist, interpretive, participatory, and critical orientations. (It is important to note that these are very general orientations to research and are not the only ones. They are used here for illustrative purposes.)

Positivist Orientation

The positivist orientation to research depends on a rational view of the world. This view tends to believe that reality is fixed and has an orderly pattern. There is a truth, and it can be found. It is most commonly associated with quantitative research but can be revealed in qualitative research, particularly through the use of language. The language tends to be factual and authoritative, in the third person (e.g., “the researcher”), and full of concrete details, and the voice of the author is dominant. What is discovered through the study tends to be expressed in informative statements; it may read like a documentary. A purpose of this orientation is to transform knowledge by supplementing the existing knowledge base. Using the study of employee retention as an example, the research question from this orientation might take the form of a sort of hypothesis: People leave organizations for reasons, and these reasons could identify factors that contribute to employee retention. Implicit in this question is an assumption that there are identifiable factors that can be discovered and explained. Unlike with a quantitative study, the working hypothesis would not be tested but instead would be used to gather data.

Interpretive Orientation

An interpretive orientation seeks to understand the world from the point of view of the individuals. Truth

must be understood from the perspective of each individual. No perspective is right or wrong, and all are presented. More than one reality can exist. The voices of those who participated in the study are primary. Although the researcher’s voice is present, it is in the background. The language of the study has a personalized empathic tone, is multivocal, is rich in description, and may be in the vernacular. What is learned from the study may take an arts-based form such as narrative, poetry, drama, photography, collage, or dance. An aim of this orientation may be to evoke individual transformation. In the study of employee retention, the research question here might be the following: How have long-term employees (those with 10-plus years of service) experienced the organization? The intent behind such a question would be to understand the workplace from long-term employees’ points of view. There is an assumption that there is something in these individuals’ experiences that has led them to stay with the organization for so long. By tapping into these experiences, the employees may gain a deeper understanding of why they continue to work for the organization and the researcher may gain an appreciation of what the organization is doing to retain employees.

Participatory Orientation

In the participatory orientation, the researcher is an active participant in the study. Reality is not fixed; rather, it is co-created and, therefore, can be re-created. A common goal of this orientation is to improve the setting by having people take charge of their own circumstances. The research is collaborative; participants may be co-researchers and co-authors. The research is not about or on people; rather, it is with people, blurring the line between the researcher and the researched. The researcher’s perspective may be presented alongside the participants’ perspectives. The language of the study has polyphonic and pragmatic qualities. What is discovered from the study may include an autobiographical or autoethnographic component, communicating the experience of the researcher. A desired result of this orientation is to transform the setting through taking action guided by the study. In this type of research, using the example of employee retention, the question may center more on the individual than on the organization. The inquiry might be around what the role of the individual employee is in retention. Besides understanding individuals’ role and increasing their awareness of self-responsibility, the aim may also be

for individuals to take a more active role in creating an inviting workplace.

Critical Orientation

The critical orientation puts the focus on structures, such as political and economic, and issues, such as knowledge and power. Here reality is seen as being shaped by issues of knowledge and power. An assumption is that knowledge and power can be used to oppress as well as to liberate. The purpose of the research is to raise consciousness and to prompt questions of power, economy, history, society, politics, and exploitation. Rather than maintain the status quo, it seeks to upset it. The research is directed toward illuminating issues of marginalization. It is purposely provocative, working toward the transformation of not only individuals but also entire systems through questioning their structures. What is learned from the study is expressed through a call to action. In the example of the study on employee retention, a research question from this orientation might focus on a specific issue. For example, the role of gender in employee retention might be explored to ascertain whether the organization is experienced differently by male and female employees and how the organization may be inadvertently (or even deliberately) set up to favor one gender more than the other.

Each of the preceding orientations provides a different perspective and will lead to different interpretations even when studying the same topic. The question is not one of which orientation is correct; all orientations have their place. The question is one of which orientation the researcher has chosen and why. Different orientations illuminate different things, providing different kinds of understandings. The researcher's ontological, epistemological, and methodological assumptions will influence which orientation he or she gravitates toward. Thus, it is incumbent on the researcher to understand and disclose his or her position on the continuum between objective and subjective reality.

RECIPROCITY

Reciprocity concerns balanced patterns of giving and taking between people. Research relationships are not necessarily reciprocal, but good research ethics practice requires that researchers consider what they take from research participants as well as what they give to them. There are several dimensions to this issue, including the different conceptualizations of what is given and taken, the rights and responsibilities of each party in research relationships, and the practicalities of building rapport.

Inviting people to participate in research always involves asking them to give up their time, and this may vary from a short one-off period (e.g., to be interviewed) to a substantial longer-term commitment (e.g., to participate in a longitudinal study). In addition to their time, people are being asked to share some aspects of themselves and their lives, such as their knowledge, views, and experiences. The research “bargain” is not only that honest and undistorted access to these often private realms is granted to the researcher but also that the data collected about them may be put in the public domain in some form of publication.

In turn, researchers are expected to include an assurance that the material collected will be treated ethically (e.g., through a commitment to treat the material as confidential and to anonymize participants when publishing findings). Researchers may also give something to participants through the opportunity to reflect on their lives and by providing a voice in the

wider public domain. There is, however, potential for misunderstanding and disagreement about the extent to which that voice should be reported uncritically; researchers rarely give participants a veto over how they are represented in research reports, although giving them the opportunity to comment on draft reports is more common.

Researchers may seek to compensate participants in further ways. Payments to participants may be presented as recompense for their time and trouble, although setting the levels for such payments is problematic. Concerns also exist about the impact on research if participants' motivation is financial. The idea of give and take can lead researchers to respond to participants' revelations by revealing similar aspects of their own lives. This may be done for practical reasons as well as for ethical reasons; for example, research inquiry may take the form of conversations in which the norm is for both parties to contribute equally, thereby building rapport.

Concern about the potentially exploitative nature of research relationships has prompted extensive consideration of what participants get from involvement in research. The opportunity to be listened to and given a voice is generally a more important motivation than the prospect of direct material benefit. Furthermore, the desire to contribute to the research process may be altruistic; therefore, the absence of reciprocity is not necessarily a problem provided that participants are given due consideration and respect at all stages of the research process.

RECONSTRUCTIVE ANALYSIS

Reconstructive analysis is the theoretically guided process of explicating the initially implicit components, structures, and/or generative rules of meaning. Jürgen Habermas introduced the expression “reconstructive

sciences” during the 1970s to distinguish reconstruction from inductive empiricist methods of inquiry. Reconstruction works from the implicitly grasped know-how of an insider and internally moves this knowledge into explicit form.

The Intersubjective and Pragmatic Basis of Meaning

Intersubjectivity as Position-Taking

In everyday life, people act meaningfully and understand the meaningful acts of others through forms of implicit and culturally contingent know-how. Meaning resides most primordially through the process of position-taking with other possible subject positions as constructed contingently within specific cultures. Individuals may take on several subject positions at once as well; for example, a woman with children who works part-time while attending school may take on subject positions of mother, employee, and student in her various life roles. Position-taking—intersubjectivity—is a process that has always already occurred as soon as it is noticed and is more primordial than objectivity or subjectivity. Uses of language, signs, symbols, and the like depend on more basic structures of intersubjectivity through which actors automatically juxtapose a cluster of subject positions in the experience of their own actions (including thoughts) and those of others. A wink, a gesture, and an upward cast of the eyes all convey meanings specific to social contexts because those addressed by such acts automatically position-take with assumed possible positions from which the acts came, with what their own position appears to be from the possible positions of the actor, and with any number of third-person uninvolved positions from which the act would be understood if observed. The same is true of fully linguistic acts. Misunderstandings and acknowledged ambiguities of meaning occur because the subject positions one automatically takes may or may not accord with those taken by others in the situation.

Typifications and Interactive Settings

Preinterpretations of social contexts are provided by cultural typifications, the most basic structures through which position taking occurs. Each such preinterpretation is constituted internally by the juxtaposition of

multiple subject positions such that each person finding herself or himself within the situation can anticipate the possible subjective states and actions of others as well as the anticipations that others have regarding one's own possible states and actions. An encounter with a stranger in a hallway, an arrival at a prearranged location with friends, and an accidental bump with another while walking together are three examples of a huge number of typifications that every culture provides its members. Typifications enable people to initiate interactions with each other and to mutually establish more specific interactive infrastructures—called “settings”—in the process.

Reconstructive analysis will always begin by acquiring an insider's position in relation to typifications and settings, so that the researcher learns to position-take with others as her or his participants routinely position-take with each other. The researcher must acquire forms of communicative know-how that are taken for granted by the participants. The next step is to articulate these forms of implicit knowledge discursively and/or facilitate the process of explication from the side of the cultural members. Validation of the resulting formulations must come from their ability to win the recognition of cultural insiders and from their fit with subsequently experienced expressions and actions. Typifications and routine interactive settings can be explicated by articulating their norms, role sets, power relations, and other intersubjectively constituted features if doing so serves the purposes of a study.

Meaning Fields

All meaningful expressions are usually experienced as a range of possible meanings, not as a singular unambiguous meaning, by people in everyday life. With an insider's understanding of typifications and settings, the qualitative researcher is able to make meaning fields for particular expressions and acts explicit, representing the range of possible meanings that her or his participants experience. A meaning field can be explicated by assuming the actor's position and expressing the act again several times with more words added to semanticize the differences in possible meanings. Conjunctions and disjunctions (e.g., and, or, or/and, and/or) are used to display the range of possible meanings.

As a very simple example, given a well-understood specific context, typification, and relationship history, the greeting “Hello, Mary, how are you today?” said

with a smile and in “friendly” tones could have the following meaning field:

“I'm pleased to see you!”

(or/and) “Let's talk a little.”

Much context familiarity, both with the stream of previous action and with the culture and site of interest, must be attained to articulate meaning fields for specific acts. A skilled researcher takes note of meaning fields mentally when coding data or otherwise analyzing them; it is neither necessary nor possible to explicitly reconstruct meaning fields for all items in a data set, but it is necessary to be aware of them in the same way that one's participants are.

Criticizable Validity Claims and the Validity Horizon

Categorical Distinctions

Ludwig Wittgenstein's work on meaning clarified its nature to reside in implicit, culturally contingent competencies for responding to it. The competency to respond includes three formal modes simultaneously at one's disposal: (1) as would be appropriate for one familiar with the culture who was just addressed by the act (second-person position), (2) as the actor herself or himself had just acted as when one mimics or otherwise reproduces the act of another for some purpose (first-person position), and (3) as one who describes the act from an uninvolved observer perspective (third-person position). Hence, given a shared typification and setting, the act “Hello, Mary, how are you today?” is understood if one can respond in the modes exemplified by “I'm just fine, how are you?” (second-person response), “Hello, Mary, how are you today?” (first-person reenactment), and “He said hello and asked me how I am today” (third-person description). These three formal categorical distinctions are fused together in a moment of holistic understanding and differentiated in one direction or another by the actual response (both in action and thought) that comes next.

Meaning-Constitutive Validity Claims, the Validity Horizon, and the Identity Claim

These three distinctions, based on what Donald Davidson called “the basic speech situation” of having

two or more subjects within an assumedly shared preinterpreted context, form the basis for three basic attitudes fused as potentialities within the understanding of meaningful action: an expressive attitude, a norm-conformative/nonconformative attitude, and an objectivating attitude. Habermas identified these three attitudes and pointed out that with every act, an actor demarcates herself or himself with three “world relations”: a relation with the actor’s own inner states, a relation with an assumedly shared domain of social norms, and a relation with a world to which there is multiple access from assumedly shared third-person perspectives.

Reconstructive analysis can be used to articulate the cultural milieu through which actors take on world relations and demarcate their identities. The first step is to become cognizant of the array of validity claims that constitute meaningful acts. Every expression of meaning is constituted by a cluster of claims falling into four categories: subjective, normative, and objective validity claims and the identity claim. An act such as “Hello, Mary, how are you today?” is constituted in part by claims such as the following: “I am feeling friendly toward you” (subjective claims referencing the intentions and feelings of the actor), “I am acting toward you appropriately” (normative claims referencing a shared social order and culture), and “We have just met for the first time today, we are people who know each other from previous meetings” (objective claims pertaining to objective or objectivated features of the interactive context). In addition, this act carries claims about the identity of the actor, perhaps as follows: “I am a polite and friendly woman and a good friend.”

Every meaningful expression can, in principle, be reconstructed as a horizon of validity claims falling within the three categories of subjectivity, normativity, and objectivity, and it can be arrayed along a continuum of foreground to background relations. This is called the “validity horizon,” and it is the most precise articulation possible for a meaningful expression. In our example of greeting Mary, foregrounded claims would include the subjective claim of feeling friendly toward Mary and happy to see her, intermediate-level claims would include the subjective desire for friendly interaction of uncertain duration as well as a normative claim that Mary ought to respond to this greeting, and backgrounded claims would include the objective claim of previous familiarity with each other.

Validity horizons will reveal backgrounded claims that occur frequently in the typical actions of cultural

insiders such that an entire worldview or ideology is instantiated and reproduced in routine social interactions and practices. In addition, the identity claims of actors will draw on cultural milieu supplying identity components in structured relations. Components related to gender, sexual orientation, race, class, and many other things are often within culturally specific relations of opposition, contrast, and hierarchy that maintain power relations in a social order. Reconstructive analysis, therefore, can be used to reveal forms of cultural power as well as deep-seated ideologies and beliefs that are embedded within a form of life.

Internal Critique

The insight that meaningful action demarcates an actor through three basic world relations establishes a theoretical ground for conducting sociocultural critique in qualitative research. The demarcation of the self with every act can be fruitfully analyzed in accordance with George Herbert Mead’s distinction between the “I” and the “me.” The “me” part of the self is the identity claim mentioned earlier. A chronic feature of all meaningful expression (although it is very backgrounded in many acts) is the claim that the actor is such and such kind of person (usually meaning that she or he is not another possible kind of person). But the “I” part of the self pertains to the fact that actors hold themselves and others responsible for their actions. One is never simply one’s roles and identity claims; one is also the *author* of one’s roles and identity claims. Similarly, one does not simply make validity claims with every act of meaning; one implicitly takes on the obligation of providing reasons for these claims if they are contested by others or of changing one’s position if others give good reasons for doing so. Meaningful actions are produced in relation to existential needs for being a *somebody* (having a “me”) as well as for being trustworthy, responsible and accountable in relation to at least some reference groups (the “I” feature of the claimed self).

Hence, the validity claims constitutive of meaning are inherently criticizable. Ultimately, this means that people in everyday life themselves are capable of criticizing the norms, identity repertoires, beliefs, and interpretive structures of their own culture. Reconstructive analysis becomes a form of critical qualitative research when it brings to light implicit and/or explicit forms of sociocultural criticism made

by cultural members themselves. Internal standards for critique include the relation of norms and identity repertoires to human needs for self formation, development, and emancipation as well as the relation of beliefs to actual experiences of an objectivated world.

Reconstruction of Semantic and Pragmatic Structures

The validity horizon is the most precise, but never an exhaustive, articulation of meaning for singular expressions. Thematic analysis of cultures, discourses, and ideologies takes the usually backgrounded portions of typical meaningful expressions to reveal interpretive generalities within a form of life. Such generalities are also embedded within broadly distributed semantic and pragmatic structures that can be investigated independently.

Semantic structures are instantiated through culturally distinctive uses of words and phrases whose meanings depend on relations to other categories through relations of opposition, contrast, similarity, analogy, metaphor, and homology. Use of the word *dude* within a particular group will have meaning dependent on how members implicitly contrast the term with alternative words such as *person*, *man*, *woman*, and *guy*. Each use of a word such as *dude* can instantiate a different semantic structure, and insiders implicitly grasp which structure is in play according to the context of interaction. Reconstructive analysis brings common semantic structures of this type into explicit discourse. Ultimately, the meanings carried by instantiated semantic structures can be fully articulated as validity horizons; the validity horizons of particular expressive acts are delivered in part by the semantic structures instantiated by the acts.

Similarly, ways of talking and acting deliver meanings in culturally structured forms. Insiders are aware of roles played by themselves and others through at least implicit understandings of whole structures of roles that exist in relations of similarity and contrast. The pragmatics of interaction—proxemics, pacing, gesturing, patterns of eye contact, and so on—all deliver portions of the validity horizon through culturally generalized structures. Reconstructive analysis can be used to explicate the distinctive pragmatic structures of a form of life as well as the distinctive semantic ones.

Examples of the use of hermeneutic reconstructive analysis include Mark Dressman's "On the Use and

Misuse of Research Evidence: Decoding Two States' Reading Initiatives"; Barbara Korth's "Gendered Interpretations Veiled With Discourses of Individuality"; and Mary-Ann Hardcastle and colleagues' "Carspecken's Five-Stage Critical Qualitative Research Method: An Application to Nursing Research."

RECRUITING PARTICIPANTS

In qualitative inquiry, *recruitment* refers to the process whereby the researcher identifies and invites (recruits) participants to join the study. Qualitative researchers strive to include participants who meet the study criteria and who represent the richest and most complex source of information (data) relevant to the phenomena being studied. The specific research questions will guide the choice of the research design that is best suited to address the study objectives.

A major element of the research design involves developing guidelines as to who will be recruited for the proposed study. "Inclusion" and "exclusion" criteria address who will be approached (involving criteria such as age group, diagnosis, geographic location, and ethnic background) and, on occasion, when they will be approached (e.g., requiring participants to be at a specific disease stage). Careful design of a sampling

strategy and recruitment scheme will help to ensure maximum discovery and knowledge about the phenomena under study.

Two key elements that must be addressed are the appropriateness of the sample being recruited (are participants who can best inform the research being identified and enrolled in the study?) and adequacy (are there enough data collected to develop rich thick descriptions of the phenomena under study?). If the answer to the last question is *no*, then theoretical saturation of the data has not occurred and further recruitment or revision of the inclusion criteria, based on data collected to date, is indicated.

Specific strategies include snowball recruitment, where nomination of other potential participants is made by those already enrolled in the study, and use of media approaches, such as paid advertisements in newspapers, posting and/or mailing of informational flyers, and publication of information about the study through online sources (e.g., chat rooms, discussion boards). Use of the internet for recruitment and implementation of data collection is receiving increased attention, but as with all recruitment strategies, it must first make sense in terms of the research question and not be used primarily for ease of access by the researcher.

In developing a recruitment strategy, researchers must carefully consider who they may be excluding by the strategy they will be adopting. For example, in the previous example of online recruitment, studies have shown that minorities, persons of low socioeconomic status, those with internet access issues, and socially isolated adults all may be underrepresented in this type of scheme. Use of existing agencies, service organizations, and/or social groups that involve the target population is another avenue for recruitment. This has the advantage of efficiency because the groups or agencies are already serving an identified population that meets all or most of the study's criteria. However, researchers must again examine the issue of who would not be reached if the recruitment strategy is overly reliant on this approach. Use of more than one recruitment strategy can assist in widening the potential audience and participant pool.

Barriers to recruitment may include certain groups' fear and/or mistrust of research and researchers based on historical wrongs such as may be found among some African American groups who know of the deceptive research practices used in the 40-year Tuskegee Syphilis Study in the United States. It can be challenging to engage in research when the

researcher's cultural background and that of the participants are not similar. There may be a lack of pre-existing knowledge by the community about the area of research proposed in the current study. Providing information about the study to interested community members through an informal orientation and question-and-answer period would be a prudent first step in recruitment.

All of these barriers can be addressed, but the qualitative researcher is well advised to plan additional time to implement these strategies. To overcome fear and mistrust issues, it is important to build strong coalitions and networks based in the culture and community. This entails finding key contacts and champions for the research who can then vouch for the researcher and the research and also assist in recruitment of initial participants. In transcultural research, having key contact people who are willing to serve in this liaison role is crucial for the success of participant recruitment and the overall study. In this context, the researcher not only is the "knower" of the research question and focus of the study but also must be sensitive to the need to "be known" by the community so that trust, veracity, and mutual respect can be ascertained and developed. It is vital to determine the cultural institutions and groups that are most trusted and seek to involve key contacts from these organizations in the study. For example, when engaging in research with members of the African American population, studies have involved local churches that serve this population as well as beauty salons and barbershops that serve African American clientele. Both ministers from these congregations and shop operators have been involved in recruiting participants for various qualitative studies with success based on the trusting interpersonal relationship these individuals have built up with members of the target population.

Other issues in recruitment may involve dealing with gatekeepers—those who have influence with or power over potential participants and who can either serve to facilitate contact or prohibit participation. There are also cost issues to consider. Placing advertisements in newspapers, reproducing and mailing out informational flyers, and making payments of stipends to cover participants' costs are examples of budgetary items that must be planned in advance depending on the recruitment strategy chosen by the investigator. Legal and regulatory issues need to be considered. Institutional ethics boards' approval of the research plan, including the strategies for recruitment, must be received before any research activities commence.

Qualitative investigators must be aware of laws and regulations that may restrict, for example, health care facilities' sharing of data relevant to recruitment of the desired sample. In summary, recruitment is a critical element of the qualitative research plan, requiring careful consideration of inclusion/exclusion criteria and development of strategies to most effectively access the population of interest for recruitment purposes.

RECURSIVITY

Recursivity refers to the cyclical nature of qualitative research where all procedures can be undertaken repeatedly until a specified condition is met. For example, in a qualitative study, data are collected and then analyzed. Based on the results of this analysis, the researcher might decide to collect data from a new source. If this decision is made, the researcher collects data from the new source and then conducts a type of analysis. The process of collecting and then analyzing the data continues until saturation is reached—that is, until no new or relevant information data emerge. This repeated cyclical process is recursivity. As such, recursivity refers

to nonlinearity of the qualitative research process, reflecting a nonstatic research design. Moreover, recursivity indicates an emergent research process in which the design and procedures unfold as the study proceeds. Recursivity represents a dynamic process of inquiry, yet at the same time it reflects a process that is methodical, logical, and cumulative.

Another example of recursivity in qualitative research is when the researcher considers the research focus and then analyzes the data; subsequently, the researcher might go back to the research focus, reflect on the data collected, and consider the possibility of reformulating the research focus based on the data collected. The research focus might or might not change based on the collected and analyzed data. Either way, the qualitative researcher then takes the original or new research focus and collects further data. In addition, recursivity helps the qualitative researcher to return to the sample as needed and to loop back and forth between data collection and analysis in a carefully constructed and documented manner so that others (e.g., researchers, peer debriefers whose goal is to legitimate the interpretations and conclusions made) can examine or replicate the path or audit trail left.

These are only a few examples of recursivity; there are many instances of recursivity in qualitative research. The recursive nature of qualitative research creates a basis for results to emerge from the data. Therefore, new decisions can be made throughout a study. The process of recursivity allows the researcher to look at the collected information in a holistic manner, moving from an inductive mode of inquiry to a deductive mode of inquiry and then back to an inductive mode of inquiry. This movement from inductive to deductive reasoning and then back to inductive reasoning allows the researcher to be open to unexpected results. Therefore, the researcher is open to the potential of building new constructs and integrating them within the existing results, creating linkages among results, and developing explanations for conclusions found within a study.

REDUCTIONISM

Reductionism is a viewpoint that regards one phenomenon as entirely explainable by the properties of another phenomenon. The first can be said to be reducible to the second. It is a mere epiphenomenon of the second. It is really just another name for the second. It has no distinctive properties that require a distinctive theory or methodology.

For example, biological reductionism claims that the mind is explained entirely by physical properties of the brain, that the mind is physical, that what we call *mental* is really just another term for the brain, that mental/mind is actually only an epiphenomenon of the brain, that it can and should be studied by neurophysiologists, that there is nothing distinctively psychological about the mind, and that treating the mind as having properties distinct from those of the brain is an illusion.

An opposite form of reductionism is sociological reductionism. This reduces psychological phenomena to epiphenomena of social factors. In this view, psychology is determined entirely by nationality or social class. There is nothing to psychology besides the properties it acquires from one's nationhood or class. In this view, one may speak of U.S. psychology as a homogeneous phenomenon or lower-class psychology as a homogeneous phenomenon because no other factors determine psychology; it is reducible to social state or social class.

Another form of reductionism that bears directly on qualitative methodology is quantitative reductionism. The claim here is that qualitative characteristics of personality, emotions, and reasoning are entirely expressible in quantitative terms. An example is the notion of intelligence. IQ is construed as an entirely quantitative dimension. IQ can range from low to high. The only meaningful way to discuss IQ is in terms of its quantitative amount. IQ is reducible to quantity. Psychologists are concerned with operationalizing intelligence and measuring it, not with discussing theories about what it is.

Reductionism denies complex multiplicity and heterogeneity in favor of a single kind of phenomenon or factor. For example, biological reductionism construes the mind as continuous with the single realm of neurophysiology. It does not recognize the mind as a complication of neurophysiology that introduces a new kind of phenomenon.

Quantitative reductionism similarly simplifies psychology by recognizing only one order of reality, the quantitative order. Qualitative complexity and multiplicity is reduced to simple quantitative differences.

Alternatives to Reductionism

There are two alternatives to reductionism. Both of them emphasize that there is more than one order of phenomena. *Dualism* postulates separate orders of phenomena. René Descartes's postulating of a mind that is separate from the body is the classic dualistic alternative to reductionism. In this case, a separate realm of the mental stands apart from the physical body. In this view, the mind cannot be reduced to the body or be explained in physical terms. Studying the mind requires special theories and methodologies that are different from those that are applicable to physical phenomena.

Dialectical emergence is a second alternative to reductionism. It also recognizes that phenomena are complex, multifaceted, and heterogeneous. They are not reducible to single properties and processes. However, it postulates that these distinctive characteristics are related to others. They are not independent as in dualism.

The classic example of emergence is the relation of water to its elements, oxygen and hydrogen. Water is composed of these elements; it is not independent of them. Yet oxygen and hydrogen are gaseous molecules, whereas water is a liquid. Although water depends on its constituents, it has a qualitatively new property—liquid—that cannot be understood in terms of its gaseous components. A new field of study is necessary to study the distinctive emergent liquid quality of water.

In analogous fashion, an emergent conception of the mind argues that it is grounded in neurophysiological processes; however, it emerges from them and is a distinctive form of them with distinctive properties. The mind is capable of willing action, thinking, predicting, comprehending, and even controlling the brain and the body. These are acts that are qualitatively

different from their constituent neurons, just as water is qualitatively different from hydrogen and oxygen. A special field of psychology to study these emergent, distinctive mental qualities is warranted.

Qualitative Methodology

Qualitative methodology overcomes the simplification of positivism by acknowledging that psychological phenomena are qualitatively different in different individuals and cultures. Shame, introversion, attachment, intelligence, depression, love, memory, self-concept, and reasoning are not single, simple, invariant quantitative dimensions.

Many different kinds of intelligence have been identified by Robert Sternberg. Abstract, syllogistic logical reasoning is different from reasoning based on empirical experience. In the latter, deductions are made from what one has personally experienced, not from abstract logical rules. Romantic love is different from puritanical love in colonial America.

Qualitative methodology includes complex procedures for investigating complex, variable qualitative characteristics of psychological phenomena. It avoids discounting or simplifying complexity, multiplicity, and variation. Of course, qualitative procedures organize complex data into meaningful categories. They also summarize trends in the data. However, these organizing procedures respect the complexity of phenomena. They simply categorize similar complex issues together and distinguish them from different complex issues. Organizing data does not necessitate reducing them to simple, singular, invariant quantitative dimensions.

REFLEXIVITY

Reflexivity can be broadly described as qualitative researchers' engagement of continuous examination and explanation of how they have influenced a research project. It plays a key role in many types of qualitative methodologies, including feminist research, participatory action research, ethnographies, and hermeneutic and poststructural approaches. However, the extent to which researchers engage in reflexivity depends on the methodological approach they have adopted for their study.

There are essentially four types of reflexivity adopted by qualitative researchers, and the form used is dependent on the methodology adopted. Reflexivity, therefore, can be viewed on a continuum. On the objectivist end of the reflexivity continuum is the approach of "bracketing" adopted in descriptive phenomenology. Similar to bracketing, "ethnomethodological indifference" adopted in ethnomethodology is also placed on the objectivist end of the reflexivity continuum. Both of these approaches to reflexivity reflect positivist influences. In achieving this type of reflexivity, researchers keep a diary of the thoughts and feelings that influenced their methodological decision making throughout a study.

A broader view of reflexivity is evident in epistemological reflexivity where researchers are required to ask questions of their methodological decision making and are encouraged to think about epistemological decisions regarding the research and its findings. This form of reflexivity is evident in philosophical hermeneutics and in grounded theory. Similar to the objectivist type of reflexivity, researchers adopting epistemological reflexivity can keep a journal to assist in their understanding of prior assumptions, beliefs, and attitudes.

The third type of reflexivity moves beyond the mere recording of a journal to one where the reflexivity is critical and embraces an examination of the political and social issues that inform the research process. This type of reflexivity is employed in, for instance, critical ethnography and critical hermeneutics.

The fourth type of reflexivity is that espoused by feminist researchers. This form of reflexivity embraces the reciprocal nature of the researcher-participant relationship and challenges the notion of neutrality in this relationship. The researchers and informants become partners in the researchers' endeavor, and

the researchers use their own experiences and reflections to illuminate important meaning. Both researchers and participants, therefore, undergo reflexivity. This view of reflexivity suggests an intimate reciprocity between researchers and participants and could be considered problematic. However, in the case of research investigating sensitive and private aspects of people's lives, the endeavor to create a successful interview can be compared with the processes employed by, for instance, counselors and therapists.

Achieving reflexivity is not a straightforward endeavor. It requires consideration and examination of decisions made at each stage of the research process, and the extent to which such examination is adopted depends on the methodology adopted. Current discussions on reflexivity reflect the need for qualitative researchers to be explicit in their actual practice of reflexivity so as to avoid it appearing to merely address the need to make a qualitative study appear more rigorous.

about our interdependency as well as our freedom, our emotions as well as our reason, and our unique situation as well as our human commonalities. It involves finding the fitting responses to our ethical questions.

A fitting response is one that is suitable, balanced, and harmonious and that takes into account the immediacy and complexity of the particular situation and our moral responsibility within it. The answer to “How should I act?” is discovered not solely by oneself but rather in dialogue with others. We cannot know ahead of time, and with great certainty, how we should act. This does not mean that “everything is relative” or that “anything goes.” Rather, it is acknowledged that we need to be sensitive to the whole of a given situation, to be inclusive in our dialogue about it, and to be aware of the effect of our contributions on it.

Interpersonal and societal relationships are influenced by the dynamics of power. It must be recognized that persons marginalized and/or stigmatized due to factors such as poverty, gender, and illness can be disadvantaged in serious ways. They may, for instance, have less opportunity to give voice to their concerns, or they may find that their concerns are not given priority by others. A relational ethics approach to ethical action underscores the need to address issues of power and vulnerability.

Relational ethics is informed by the work of philosophers and scholars such as Zygmunt Bauman, Robin Dillon, Han-Georg Gadamer, Sally Gadow, Raimund Gaita, Emmanuel Lévinas, Knut Løgstrup, John Macmurray, H. Richard Niebuhr, Charles Taylor, and Arne Vetlesen. Ethics, as espoused in their works (among others), is not based in a disengaged process of moral reasoning conceived as objective and existing outside the situated reality of human existence. There is instead acknowledgment of the primacy and ethical significance of our relationships to one another and of the need to understand humans as embodied beings situated within families and communities.

RELATIONAL ETHICS

Relational ethics is a contemporary approach to ethics that situates ethical action explicitly in relationship. If ethics is about how we should live, then it is essentially about how we should live *together*. Acting ethically involves more than resolving ethical dilemmas through good moral reasoning; it demands attentiveness and responsiveness to our commitments to one another, to the earth, and to all living things. Ethics is

Relational Ethics Research

Research in relational ethics began during the early 1990s at the University of Alberta in Edmonton, Canada, as an interdisciplinary project in health ethics led by Vangie Bergum (a nurse) and John Dossetor (a physician) and funded by the Social Sciences and Humanities Research Council of Canada. This initial project evolved in response to the dominance of the notion of the autonomous person within North

American bioethics. Although respect for the autonomy of the individual is highly valued in Western societies and is important to the key concepts of rights and freedoms, the idea of the self-contained separate person, free from external constraint, does not capture the inherently social nature of human lives. Overemphasis on autonomy can create a false picture of a person's actual situation in everyday life. Although it acknowledges the value of independence, it ignores the way in which independence is an aspect of our *interdependence*.

The aim of this first project was to explore ethical action in health care from the perspective of relationship and responsibility, rather than autonomy, and to describe what this change in focus might look like as a foundation for health care. The interdisciplinary research team used interpretive inquiry to examine actual health care situations using testimonials from those involved, documentaries, or published descriptions. Artwork (e.g., photography, painting), poetry, and literature that captured aspects of caring for others were used to enhance the researchers' understanding of ethical relations. The core elements of relational ethics that emerged from this inquiry were mutual respect, engagement, embodied knowledge, attention to the interdependent environment, and uncertainty/vulnerability. These results, as well as the research process, are described in Vangie Bergum and John Dossetor's *Relational Ethics: The Full Meaning of Respect*. This initial project inspired other health ethics research, including studies in mental health care, genetic counseling, the moral distress and compassion fatigue of health professionals, and the challenges of establishing ethical relationships in forensic psychiatric settings.

Relational Ethics in Research

To ensure that research is conducted in an ethical way that minimizes risks and maximizes benefits to participants, international, national, and local guidelines have been developed. These guidelines, usually based strongly on the concept of informed autonomous consent, are crucial tools for researchers. From a relational ethics perspective, however, although these guidelines are necessary, they are insufficient. Some of the most serious violations in the past have occurred despite guidelines and laws governing research. A common factor in such violations has been the attitude of researchers toward their participants or

“subjects.” Some researchers have acted on their subjects in ways that they would never contemplate or tolerate in relation to themselves or their own loved ones. Genuine respect for those enrolled in their studies has been absent. When research misconduct is conceptualized as fabrication, falsification, and plagiarism, the significance of ethical relationships in research—with colleagues, assistants, and students as well as with participants—can be diminished. A relational ethics approach demands otherwise.

Criticisms of Relational Ethics

Attention to context and the recognition of embodied knowing in relational ethics incite criticisms of relativism and lack of impartiality and universality. In addition, the emphasis on relationship confuses some critics who wonder whether relational ethics means that it takes two to be ethical. This is not the case. There is, however, recognition that the individual learns to be ethical in relationships with others.

RELATIVISM

Relativism does not refer to a unitary doctrine but rather announces a cluster of viewpoints. There are,

however, two deeply interrelated points central to all discussions of relativism. The first is the claim that our experiences, moral judgments, claims to knowledge, and so on can be understood only relative to something else such as particular languages and particular social and cultural practices. The second is the denial that there can be any universal or apodictic truths.

The Greek Sophist Protagoras generally is considered to be one of the first to broach the issue of relativism. Plato, in the *Theaetetus*, attributed to Protagoras the well-known and oft-cited phrase “Man is the measure of all things: of things that are that [how] they are and of things that are not that [how] they are not.” Since that time, relativism has been an ongoing major theme in Western thought and has posed a central problem in both moral philosophy (axiology) and the philosophy of science (epistemology). Over the past few decades, the discussions of moral relativism have become even more pronounced and expanded beyond philosophical discourse to public discussions in general because of what are referred to as the “culture wars.” In discussions in the philosophy of science, especially concerning the nature and purpose of social research, a similarly intensified debate has arisen over the implications of relativism. These discussions have centered on some of the concepts of greatest importance to social researchers, qualitative researchers in particular, such as the definitions to be accepted for objectivity, subjectivity, and truth as well as the criteria to be used for judging the quality of research.

Types of Relativism

In the philosophical literature on relativism, various terms are used to broadly denote two different types or categories of relativism. The first type, as introduced briefly in the introductory paragraphs, is most commonly described using the paired terms descriptive–normative, cognitive–ethical, and epistemological–moral, all of which refer to basically the same differentiation. Normative, ethical, and moral relativism state that what we accept as morally correct or incorrect varies from society to society and even within different segments of a society. There are no moral/ethical principles that are accepted by all people across societies or even by all members of any particular society. The validity and force of ethical and moral injunctions are context dependent, and there are not, and cannot be, any enduring universal ethical and moral strictures. This form of relativism does

not allow for the possibility of an objectivist basis for moral/ethical judgment. Moreover, moral relativism obviously stands in conflict with the moral absolutes associated with religious doctrines.

The second type of relativism, cognitive or epistemological relativism, holds that there are no universal truths or truths about the world that stand outside our use of language; that is, there are no extra-linguistic truths. This claim is based on the idea that although we may accept that there is a world out there independent of our interests and purposes, as per common sense, the languages we use to depict that world are not out there independent of us. Relativists argue that because truth can be understood only within a language, there are no inherent or given characteristics of the world and, as such, there can be no ultimate fact of the matter. All that can be said about the world is that there are different ways of interpreting it—interpretations that are time and place contingent or, put differently, are relative to time and place. Although epistemological relativism is less widely held than is moral relativism, it recently has gained increased attention from, most especially, social researchers. As the implications of the idea of no theory-free knowledge have been more fully realized, arguments over epistemological relativism have become far more common in the philosophy of social research literature.

Finally, very often when the concept of relativism is encountered in the literature where it is not the subject of direct philosophical analysis, such as in many of the discussions among both quantitative and qualitative social researchers about the quality of research, it is not formally defined. Almost always, however, the implicit definition is that of “anything goes” in the sense that relativism means that no moral stance can be judged as superior to any other moral stance and that no claim to knowledge can be defended as better than any other claim to knowledge. Those who define relativism in “anything goes” fashion further argue that relativism is a very serious problem because it undermines the idea of truth and, as such, it is a major step toward intellectual (and moral) nihilism or anarchy.

Relativism as Self-Refuting

Among numerous, often philosophically complex, objections to relativism, the most common one is that relativism is not a defensible position because it is logically self-contradictory. The argument can be summarized as follows. To say that all things are

relative is an absolute or nonrelative statement. Hence, relativism is logically self-refuting and, thus, falls before the very relativity that it seeks to defend. This line of argument, which has been widely accepted, again can be traced back to Plato's comments on Protagoras in the *Theaetetus*.

During recent years, various philosophers who have held, or who are claimed by others to hold, a position of relativism have responded to this charge of relativism as self-refuting. Although nearly everyone agrees that, given conventional logical canons, relativism is indeed self-refuting, philosophers such as Richard Rorty and Hans-Georg Gadamer have argued in one form or another that this makes no difference.

Rorty, adopting a pragmatist stance, began with the point that relativism generally refers to three views: an "anything goes" view that states that all beliefs are equally good, a view that there are as many meanings for truth as there are procedures for justification, and a view that there is little more to be said about truth than to describe the procedures employed by particular social groups to justify claims to knowledge in any particular area of inquiry. He stated that pragmatists adopt the third view in that they think we should drop the traditional view that truth is defined as the correspondence between language and reality and should realize that truth is best thought of as a compliment paid to people with whom we agree. He added that when truth is defined in this way, it is not a theory of truth in the conventional sense because there is no interest in attempting to ground knowledge claims. Put differently, Rorty concluded that because pragmatists do not have a theory of truth and are not interested in theories of truth, they cannot as such have a relativist theory of truth. Once one gives up on epistemology or theories of truth, the idea that relativism is self-refuting is of no particular concern.

Gadamer, in a very sophisticated elaboration of philosophical or ontological hermeneutics, likewise dismissed the importance of the idea of relativism as self-refuting. Gadamer argued that we must understand the historicity of our own understanding. Given that all human experience of the world is by nature verbal, it is apparent that people with a particular language and cultural tradition perceive the world in a way that is different from that perceived by people with a different language and cultural tradition. Although this does not mean that communication is impossible across languages and cultures or across time, it does mean that the idea of a "world in itself,"

or a world beyond language, is not possible. From this point, he added the idea that these different views of the world are not, or cannot, be relative to some sort of world in itself. The world is the same as the views in which it is presented. Although Gadamer agreed that the self-refuting argument is itself irrefutable, he argued that this point simply misses the main point in that it does not express any insight of consequence or achieve anything of interest. Moreover, the argument doubles back on the arguer because it calls into question the fundamental truth in the claim about the historicity of all understanding. In the end, one can interpret Gadamer as considering the self-refuting argument as a kind of "bowl you over" attempt to push back on those who argue that there can be privileged knowledge or knowledge that is over and above considerations of time and place.

A third response to the self-refuting argument is an extension of the positions taken by Rorty and Gadamer. John K. Smith stated that relativism should be redefined to mean nothing more than the fact that we, as humans, are finite. Once this redefinition is undertaken, it is clear that there is no point in thinking of relativism in terms of a theory of knowledge; relativism is nothing more than an acknowledgment of our finite condition of being in the world. We cannot see or understand the world from a "God's-eye" stance or from outside of a time- and place-contingent language and cultural practice. If this is so, the idea that relativism is self-refuting is of no consequence because relativism is not something that can be transcended; rather, it is a condition with which we, as finite humans, must learn to live.

When relativism is redefined as an acknowledgment of our presence in the world as finite beings, as opposed to "anything goes" or "all things are equal," two additional considerations are usually offered to justify this different understanding. First, there is the negative point that relativism as anything goes requires for its meaning a viable concept of the absolute. There is what is called a dyadic relationship between these concepts, meaning that if one term cannot be made sensible, the same is so for the other term. This is the case in this instance because we have no defensible prospect for making sense of the absolute; accordingly, we have no prospect for making sense of anything goes.

Second, in a more tangible sense, the reason that "anything goes" relativism is meaningless is because all of us already do make judgments and will continue to do so for a very long time so far as anyone can see.

It is impossible to conceive of how anyone could lead a life without preferring some things over other things. As such, the conventional definition of relativism in the “all things are equal” guise is at best an abstraction with no practical import.

Relativism and Criteria

The most important issue that discussions of relativism have brought to the forefront for social researchers, most especially qualitative researchers, is that of how to judge the quality of research and how to adjudicate among different claims to knowledge. For quantitative social researchers, given their empiricist and realist philosophical dispositions, there has been a general agreement that there is a two-stage process appropriate for judging the quality of research. First, judgments about good versus bad research are based on whether or not the researcher employed the proper methods; this judgment is then followed by a judgment as to the value of the findings in a practical and/or theoretical sense. The collapse of the logical empiricist theory of knowledge because of internal contradictions concerning verifiability, along with serious doubts about the viability of the correspondence theory of truth, an increasing understanding of the implications of no theory-free knowledge, and so on, has led most philosophers of social inquiry to hold that we can no longer think of researchers as able to have direct access to social reality and, with the proper use of certain methods, depict that reality as it really is.

In the wake of these philosophical changes, two different positions have developed on the issue of criteria for judging research. One perspective is referred to as neorealism. Neorealists, having accepted that there is no direct access to reality and no absolute methodical criteria by which to judge the quality of research, have elaborated a position based on a dual set of commitments. On the one hand, they argue for the idea of a real world that is independent of interests and purposes; on the other hand, they acknowledge that our knowledge of this world is fallible in the sense that we can never really know whether we know this world as it really is. They believe, in other words, in a realist ontology and a constructivist epistemology. The main thrust by the neorealists has been to elaborate this dual commitment in a way that would prevent relativism, especially a relativism of “all things are equal” or “anything goes.” Their concern is that if

relativism is not prevented, all disputes over claims to knowledge can, and will, be resolved only through a resort to power.

Martyn Hammersley is one of the more prominent research philosophers who has attempted to elaborate criteria for judging qualitative research that are not method-bound and are not time and place contingent (relative to a particular set of social/cultural practices) and, thus, avoid the threat of relativism. Hammersley accepted what he called a modified correspondence of truth based on a subtle realism and stated that we can retain the empiricist concept of truth, but not in a naive sense. This led him to elaborate the criteria of plausibility and credibility. The former refers to a judgment as to whether a research result is likely to be true given our existing knowledge. The latter refers to whether a result can be deemed credible given the circumstances of the research and the nature of the phenomena under study. In the end, Hammersley argued that it is reality itself that must be called on, albeit in a subtle or indirect way, to judge the quality of research and to adjudicate among different claims to knowledge.

Most of the discussions about the validity of qualitative research also are undertaken from a neorealist philosophical perspective. The work of Joseph Maxwell on the different aspects of validity is another example of the neorealist approach to the issue of criteria. For Maxwell, as for others who have discussed the validity issue, descriptive validity is the key issue because it involves the basic issue of the factual accuracy of a research account. The validity question at this level is whether the researcher made it up, distorted things, missed things, or got it right. Although he recognized that description is not theory free or independent of a researcher’s effective history, any disagreement among researchers at the descriptive level can be resolved, at least in principle, by the data or the reality itself. Again, as with other neorealists such as Hammersley, although there is no direct access to reality, it is still claimed that reality itself can be called on to judge the quality of research and to adjudicate among claims to knowledge.

The relativists argue that the neorealists have not made good on their position, especially on the point that social reality itself can do the work they desire from it. Their main contention is that the implications of no theory-free knowledge, which has forced them to accept that one can never know, or know if one knows, reality as it really is, mean that there is no

possibility that reality itself can be an independent referent point for judging the quality of research and for adjudicating among different knowledge claims. Any criteria used for judgment can be contingent on time and place or on the familiar forms of justification only relative to particular times and places. This is relativism, but not a relativism of “anything goes” because, as noted, relativists argue that the concept means nothing more than the recognition that we, as humans, are finite beings.

For relativists, the issue of criteria should be thought of in terms of a list of characteristics that define what is considered good versus bad inquiry. Such a list of items is open-ended in the sense that it always can be added to and subtracted from. Moreover, any list of characteristics that is brought to a judgment of research can be only partially articulated, with some items being more or less specified and others resisting such specification. There always will be a surplus of meaning that stands beyond our grasp or beyond our language. Finally, the items on the lists are changed not through abstract discussion but rather in the continual application to actual inquiries. As new forms of inquiry come along, this opens up the possibility that our lists must be modified to accommodate the new or else the items on the list remain and the new is rejected as not even being research. Just such a dispute has occurred over the past few decades over whether to change/modify the criteria for judging research and accept qualitative research or to keep the traditional empiricist criteria and reject or devalue this approach to inquiry.

Finally, relativists add that although judgments cannot be grounded extra-linguistically, this does not allow that researchers are exempt from engaging each other in open and unconstrained conversation in the attempt to justify claims to knowledge. Relativists argue that researchers have a moral obligation, in their attempts to persuade others to accept their knowledge claims and define the quality of research the way they do, to be open to having themselves persuaded by others. The idea that researchers must learn to live with uncertainty and the absence of the possibility for final vindications does not mean that judgment is to be abandoned.

RELIABILITY

Reliability, in the field of research, is broadly described as the dependability, consistency, and/or repeatability of a project’s data collection, interpretation, and/or analysis. Reliability is viewed very differently in qualitative research from how it is viewed in quantitative research. In the quantitative domain, reliability is specifically characterized as the extent to which multiple researchers arrive at similar results when they engage in the same study using identical procedures. In these conditions, differences in results are described as measurement error. Therefore, from a quantitative perspective, reliability is specifically defined, sought, and measured, and it is accepted as an essential indicator of a study’s quality (along with measures of validity and generalizability).

In contrast, because of the paradigmatic and methodological diversity of approaches that comprise the field, reliability has not been described with such uniformity in qualitative research. Whereas many qualitative researchers describe parallel concepts such as credibility, dependability, confirmability, and consistency as appropriate qualitative correlates to reliability, others avoid the purposeful quest for reliability altogether. Those who overtly seek credibility and dependability often assert that such aims support the rigor of qualitative work and ensure that studies avoid “haphazard” subjectivity. Three of the commonly cited indicators of credibility and dependability are methodological coherence (the appropriate and thorough

collection, analysis, and interpretation of data), researcher responsiveness (the early and ongoing verification of findings and analyses with study participants), and audit trails (a transparent description of all procedures and issues relative to the research project). Such strategies are commonly employed by qualitative researchers to demonstrate systematic attention to reliability-related issues.

On the other hand, some have asserted that purposeful attempts to demonstrate reliability are counterintuitive to much of the work that emanates from the qualitative domain. They point to the interpretive subjective nature of qualitative work as a defining hallmark of the field—one that can be undermined by rigid reliability concerns. At the heart of this position is the notion of reflexivity. Whereas quantitative researchers (and some qualitative researchers) attempt to minimize—indeed eliminate—researcher effects so as to maintain objectivity, most qualitative researchers embrace the notion of reflexivity—the idea that researchers' backgrounds, interests, skills, and biases necessarily play unique roles in the framing of studies and in the collection, analysis, and interpretation of data. Researchers are seen as visible, biased integral players in the process. This depiction of “researcher as instrument” in the project flows naturally with the claim that the richness and meaningfulness of qualitative research is largely dependent on its creativity and originality. Rather than seeking to standardize interview/testing procedures so that any researcher (who is detached and neutral) might gain the same results, the unique identities of both researchers and research participants are transparently identified and purposefully centered. Repeatability, from this perspective, is neither desired nor possible.

Therefore, it is evident that reliability, like many other concepts in qualitative research, is best approached on a case-by-case basis. Although many specific steps can be taken to support the credibility of one's research, such efforts should not compromise the deeper methodological and paradigmatic meanings that underpin this work.

REPLICATION

Replication refers to researchers conducting a repeated study of a project that typically has been published in a peer-reviewed journal or book. This is not the same, however, as duplication. All qualitative research hinges on the unique characteristics of people, locations, cultures, and genres. Consequently, no two qualitative studies ever will be identical. Nonetheless, researchers can, at times, locate participants with demographic variables similar to an original qualitative design, ask similar questions, and assess data for codes similar to an original data collection. This integrated process entails a research protocol called replication.

Ethical guidelines of research associations often require that researchers make available their data (without names or identities) to future researchers wishing to replicate findings. Consequently, researchers may access the very questions posed to participants (if documented) or may even review the recorded transcripts for how the participants replied to the questions (if ethics approval received during the initial study allows for such review). Codes are made available for later researchers to use in future research when samples are similar. When conducting a replication study, researchers give due credit and acknowledgments to the original researchers who made their design and/or data set available to the replicators. As such, scholars who replicate previous studies avoid plagiarism or otherwise simply rehashing previous researchers' work.

All research is context specific. For quantitative researchers, findings are based on sampling distribution theory. Namely, one may generalize the findings of a study to the degree that the sample appropriately matched the population from which it was drawn. Consequently, findings from a quantitative study may (in theory) be applied to others who possess relatively similar characteristics of the individuals in the original study.

Qualitative researchers, in contrast, typically use criterion sampling. This means that participants are selected based on a set of prescribed criteria established by researchers. Participants possess the variables of interest for study—and may or may not represent others in the population from which the sample was drawn. Due to this choice of sampling methodology, qualitative researchers likely will always have a weak case for external validity when focusing solely on one individual study.

From the preceding context, replication is the key to qualitative research external validity. A qualitative finding is reflective of its context in the sense that one knows for certain only that it represents the views of the participants. Few question the internal validity of qualitative research (as a whole). Consequently, if external validity will be established for a qualitative finding, then replication represents the most likely means of this to be manifested.

Replication is a cornerstone of quantitative research because it detects fraud or findings that lack internal validity. If a study cannot be replicated, then it is said to be an outlier or a fluke or to contain methodological flaws. Without replication, a study's findings can never be certain. Because the participants typically were drawn at random, representing the larger population in the characteristics of interest, future studies—using new random samples—should generate relatively similar results.

Qualitative research, despite its lack of random representation, can nonetheless show external validity. When researchers conduct future qualitative studies using participants who are generally similar to the original qualitative sample (i.e., same criterion used for participant selection), one logically could expect to find similar results. For example, suppose that a qualitative researcher in Canada shows findings that families of children with attention deficit hyperactivity disorder (ADHD) struggle mostly during the first hour after children come home for school. Further research studies in the United States, using participants similar in characteristics to the ones in the Canadian study, may yield similar results. When such replication occurs, it strengthens the external validity of the original study's findings.

Qualitative researchers will never possess the same sophisticated levels of generalizability to their findings as do quantitative researchers. Recall that findings are context specific. Consequently, the findings of one qualitative study will depend to a large measure on the context in which the participants reside and interviews were administered. A follow-up study, although using a similar sample, likely will not show duplicate results. All of the variables in qualitative research are not controlled, with only the independent variable being manipulated, as is true with quantitative research. The participants from the second study will be selected based on criterion variables, not random selection or random assignment. Consequently, the reality is that duplication simply is unlikely.

When findings are replicated, even with quantitative studies the results are never identical. There are

chance and random variables, fluctuating the results to varying degrees. If quantitative researchers show the probability of repeating results 95 of 100 times, this generally is considered to be successful replication in the social sciences.

Although qualitative research will never reach this level of sophistication, future replications of general findings do, nonetheless, strengthen an original study's external validity. Generalizability should not be viewed as an on or off button—something that either exists or does not exist for a research study. Rather, external validity should be understood as a volume button—something that exists on a continuum. In other words, it is not a question of whether or not a study possesses external validity but rather a matter of how much external validity it possesses. In short, when general qualitative findings are replicated by future qualitative studies—at least in overall principles—qualitative research can be stated to possess a measure of external validity.

An additional value of replication studies is that they may further illuminate previous qualitative studies. One finding can be viewed as a “dot” on a page. When another study is conducted, using a generally similar sample, and researchers show similar conclusions from the study, the two dots may form, connecting a line. When a third researcher conducts a similar study, showing similar results, even more confidence is placed in the original study because observers can (figuratively) connect three dots. The more qualitative studies that are conducted, showing relatively similar findings, external validity is increased proportionately.

In addition, patterns may become observed over time as qualitative studies are replicated. For example, after two studies show comparable findings, one may assume that the two dots form a straight line. However, after conducting, say, nine similar studies, observers may discover a pattern among the findings that previously was undetectable. For instance, the dots actually may form an arc rather than a straight line.

REPRESENTATION

Representation refers to fully understanding and expressing the lived experience of research participants and including the multiple realities, interpretations, experiences, and voices emergent from all individuals and all angles. Michael Quinn Patton suggested that qualitative researchers should aim for balance, fairness, and completeness in their research in a way that reports the lived experience as it actually exists to the people being studied.

One challenge in ethnographic and narrative methods is to ensure that the people and context studied are adequately and sufficiently represented. Many researchers of vulnerable populations would argue that no one has the moral “right” to represent, or speak on behalf of, another person. Some would suggest that experiences must be written from the inside such as through autoethnography. Others contend that it is possible to represent study participants so long as rigorous attempts are made to include their own voices and interpretations.

Such attempts would include multiple, or mixed, methods to triangulate (or, as Laurel Richardson said, to crystallize) the data. Crystallization recognizes that reality is multidimensional, deep, and complex and that understanding is necessarily partial. Thus, multiple methods are used to find other ways of looking at the data—to find other interpretations and explanations. A multimethod design contributes to research rigor by enabling the researcher to more fully understand the lived experience of the people or context being studied.

Methods that directly include participants’ voices and interpretations might include interactive techniques such as interactive interviewing, interactive focus groups, and co-constructed narratives that allow study participants to give their own accounts of their own experiences. Ethnographic techniques such as close observation over a long period allow time for a relationship to develop between the researcher and the researched, giving the researcher additional empathy toward and understanding of the people being studied. In addition, methods that simultaneously let the

researcher investigate the system as a whole while studying the interplay between individuals within the system can allow the research to more fully represent both the people and the context under study. Conversely, more unstructured methods such as unstructured interviews and diaries let participants express their experiences in their own natural language and setting, thereby giving them full voice.

Qualitative researchers also ensure that they are representing the voice of their participants by conducting member checks at the conclusion of the study. Member checks involve a process of providing study participants with the research findings and giving them the opportunity to voice agreement or disagreement with the research as reported. All of these processes focus on the interpretive knowledge of the people, context, or culture being studied rather than that of the outside researcher.

REPRESENTATIONAL FORMS OF DISSEMINATION

Representation, according to *Webster’s Online Dictionary*, can be defined as the act of representing or state of being represented or as something that represents as (a) an image or likeness of something, (b) an account or statement (as of facts), (c) an expostulation or protest, or (d) a presentation or production (as of a play). Dissemination can be defined as the act of dissemination or the state of being disseminated, diffusion for propagation and permanence, or a scattering or

spreading abroad (as of ideas, beliefs, etc.). This entry first reviews the history of qualitative research in terms of the eight stages identified by Norman K. Denzin and Yvonna S. Lincoln. Next, it describes four approaches to such work: thematic, narrative, performative, and visual. Finally, the entry explores some of the issues that arise in the evaluation of qualitative research.

Evolution of Qualitative Research

During earlier times of qualitative research, the ways in which researchers represented their work took the form of expository distanced texts where the researchers' stances, biases, and assumptions were masked in an authorial voice that presented "findings" posited as an unrefuted reality. This is typically no longer the case. The influences of postmodernism, feminism, and critical theory, among others, have dramatically changed qualitative research beliefs, values, and practices that evolved through what Denzin and Lincoln described as the eight moments of qualitative research. Although these phases are not totally discrete or absolute in terms of time, they do provide a useful context for thinking about how our notions of representation have expanded and changed over the years.

The first of these moments is known as the *traditional phase* (1900–1942), when ethnographies about others from distant lands were presented as objective depictions of reality. James Smith and Phil Hodgkinson suggested that this kind of research was predicated on a "spectator theory" of knowledge that resulted in a colonizing kind of research that presented a largely Western, and often misguided, understanding of other peoples and cultures. The *modernist phase* (1947–1970s) followed. During this time, qualitative researchers experimented with new interpretive approaches and attempted to formalize their methods so that qualitative work could match the rigor and legitimacy of quantitative methods. The phase that Denzin and Lincoln referred to as *blurred genres* (1970–1986) occurred as qualitative research was burgeoning and gaining in stature and acceptability. According to Jerome Bruner, narrative forms of doing, knowing, and representing were acknowledged as the natural way in which humans make sense of their lives and, therefore, as the most appropriate for describing human activity. These approaches took hold, and the relational aspects involved in this type of research brought questions of ethics to the forefront.

From the mid-1980s until 1990, a "rupture" occurred in the fabric of qualitative research. Known as the *crisis of representation*, a term that emerged from the work of George Marcus and Michael Fischer, it marked the realization that all aspects of the research process—from the inception of a study, through the creation of field texts, research texts, and interpretive working documents, to the creation of a public text—are a series of constructions made by the researcher and do not represent the actual lived experiences of the participants.

Questions arose about gender, class, and race given that these areas were frequently glossed over or omitted entirely. There was a strong call for researchers to be more reflexive about their work by questioning and accounting for their assumptions and biases and by clearly situating their own voices in their work. Denzin and Lincoln suggested that this resulted in a "*triple crisis*" of *representation, legitimation, and praxis* that called into question the notion of representation as a mirror of experience; the appropriateness of the traditional criteria of validity, reliability, and generalizability used to legitimate research; and whether it is possible to make change if society is really a text. The face of qualitative research changed forever.

The *postmodern phase* (1990–1995) marked a period of experimental writing during which new forms of ethnographies emerged, of engagement in participatory research and inquiry into local understandings and specific situations. During the era of *postexperimental inquiry* (1995–2000), the qualitative research field witnessed burgeoning arts-based/arts-informed ways of expressing lived experience. Denzin and Lincoln suggested that during the seventh moment, the *methodologically contested phase* (2000–2004), there was a period of methodological conflict and retrenchment. They suggested that during the eighth moment (2005–), now or the *fractured future* to come, the key issues are, and will be, around the need to confront the methodological backlash associated with evidenced-based research and to reconnect research to social purpose by making it accountable and responsive to those it serves. If proven to be accurate, this future will continue to contribute to the evolving discussions about the possible kinds and practices of representation.

Cultures of Inquiry

Some qualitative researchers, such as Carolyn Benz and Jeremy Shapiro, align themselves with a "culture

of inquiry.” These researchers use or adapt the research methods typically associated with a particular tradition. The principal cultures of inquiry vary according to different authors but tend to include phenomenology, ethnography, auto/biography, gender studies, cultural studies, historical research, action research, critical theory research, narrative inquiry, and arts-based/arts-informed research. More frequently, however, qualitative researchers choose their methods as a response to the kinds of questions they are posing, and they borrow and adapt approaches from various traditions to conduct their studies. The approaches chosen have implications for the kinds of representational forms present in their work and, ultimately, for where the work can be published or presented.

Interpretive Approaches and Representational Forms

The approaches used to analyze and represent research directly affect how it is understood, where it may be published, and what audiences it will attract. Although there is much overlap and blurring of boundaries among interpretive approaches and representational forms, for ease of discussion, qualitative methods can be clustered into four basic approaches: thematic, narrative, performative, and visual.

Thematic Approach

In the thematic approach, traditionally used in ethnographic and phenomenological work and carefully explained in the work of Pamela Maykut and Richard Morehouse, the field texts produced by the researcher are separated into units of meaning that are systematically compared and contrasted with each other and subsequently reconstructed into large themes that are woven together to tell the research “story.” The final representational forms tend to be written in the voice of the researcher interspersed with excerpts from field texts used to persuade readers that the proposed explanation is a plausible one. These forms still remain the most frequent type of representation in qualitative research and, as such, continue to dominate in journals and at conferences in spite of postmodern understandings.

Narrative Approach

As pointed out earlier, all qualitative research is story based, but there are different ways of

eliciting/constructing research stories. As Susan Chase suggested, these tend to take a variety of forms that center on understanding lives by those who live them. Narrative inquiry maintains the context in which a story is told or embedded, and it tells a short or extended story about something significant or relates a life story from its inception. Jerome Bruner, Jean Clandinin, and Michael Connelly argued that it is a distinctive way of thinking and understanding that is unique and embodied.

In narrative inquiry, researchers use different approaches to cull stories of their participants from their field texts, as seen in the work of Constance Fischer, Frederick Wertz, William Labov, and Carl Rhodes. These result in many and varied representational forms. Some products resemble the more traditional texts produced by phenomenological and ethnographic researchers. Others concerned with issues around voice and representation turn to various literary genres as ways of communicating their work to engage, evoke, and disrupt ways of thinking and knowing. These include different forms of fiction such as that of Tom Barone and Rishma Dunlop; found and autobiographical poetry such as that of Corinne Glesne, Carl Leggo, Lorri Neilsen, Monica Prendergast, Laurel Richardson, and Anne Sullivan; and scripts and textual collages, and combinations of these, as in the work of Carol Mullen, Patrick Diamond, Joe Norris, and Johnny Saldaña, to name a few.

There is, however, still resistance to these evocative narrative forms, although less so than there was a decade ago. Certain journals, such as *Qualitative Inquiry*, and special-interest groups at conferences, such as the arts-based special interest group at the American Educational Research Association, have done much to promote this type of work and make it visible.

Performative Approach

Performance texts/representations mirror many of the variations of narrative work just described. Saldaña pointed out that a good research story is needed to incorporate the art and craft of theater so as to perform a successful rendition of participant experiences. Furthermore, Norris suggested that the beauty of drama is that it integrates all aspects of meaning construction, including the use of word, number, image, gesture, and sound. Denzin concluded that because performance has so much potential, during the past

decade or so there has been increasing interest in this genre as a means to counteract criticisms of traditional representation, to exploit the integrative aspects of meaning, and to permit the engagement, accessibility, and participatory dimensions that drama or performance elicits. James Mienczakowski showed the emancipatory potential in performative ethnography, and Saldaña's collection of performance works suggested how ethnodramas can give voice to previously silenced people and stories. Performances portrayed as readers theater and other similar forms that transform data into a script that is then read aloud to an audience, often using the participants as "actors" and/or involving the audience, have become more frequent at large research conferences and have shown the evocative and pedagogical potential of performative inquiry.

Visual Approach

Anthropologists have been using visual images in their research since before the turn of the 20th century. At first, still photographs were used. Then, with the advent of moving pictures, film was employed more extensively to provide greater detail and a "truer picture" of what transpires in other cultures. An entire field of visual anthropology was developed based on the use of visual images in research. In her work, Fadwa El Guindi has discussed how film and photographs were used as a means for recording and analysis, for elicitation and discovery, for reconstructing dimensions of culture, and for representing ethnographies. As mentioned earlier, when researchers became more critical of how others were being studied—in part because of the growth of cultural studies—and realized how subjective research really is, there was a growing awareness that visual texts (like all texts), although powerful and seductive, are socially constructed. Therefore, as Gillian Rose suggested, visual imagery is never innocent.

There has been a renewed interest in visual inquiry because of the increasingly visual nature of our society and because new technologies provide a wide variety of interesting representational possibilities. In addition, arts-based/arts-informed researchers such as Elliot Eisner have shown that we see and understand differently when we examine a phenomenon through a visual lens. A growing number of arts-based/arts-informed researchers are using photographs, films, collage, painting, sculpture, and combinations of these to understand their work and represent it to others.

More and more, researchers are using visual images as a means of reflexivity (to self-monitor and reflect on the research process), as a means of elicitation (to evoke responses from participants and/or elicit deeper understandings in the analyses), and as forms of representation that are disseminated publicly. Two approaches in particular have been gaining momentum.

Photo Elicitation

The first of these is photo elicitation, or "PhotoVoice," developed by Caroline Wang. It uses photographs taken by research participants to record and reflect on social needs, promote critical dialogue, and ultimately reach policymakers. It has been particularly successful in situations where people are marginalized because it is inherently participatory and collaborative and is used in action research endeavors to signal inequities and to initiate and promote social change.

Collage

The second visual approach is that of collage. The word *collage*, a term that refers to a genre of art derived from the French verb *coller* (meaning "to stick"), is the process of cutting and sticking found materials (often pictures from popular magazines) onto flat surfaces such as heavyweight paper (e.g., card stock). The roots of collage date back at least 1,000 years, but collage became acknowledged as an art form at the turn of the 20th century when artists such as Pablo Picasso and Georges Braque used this medium to challenge the traditional artistic conventions, the elitist nature of art, and the notion of a single reality. As Donna Davis has shown, working in this nonlinear and intuitive way, feelings are articulated before ideas and, as a result, implicit assumptions of the researcher and/or participants can be revealed. In addition, collage evokes embodied responses and uses the juxtaposition of fragments and the presence of metaphor and ambiguity to engage viewers in multiple avenues of interpretation. Besides these substantive aspects of collage, the use of cutting and sticking found images can produce a sophisticated product and, it can be argued, can do so with less technical skill than is required in other visual art forms. As a result, however, as with all of the arts-based/arts-informed modes of inquiry, it raises issues of quality. Resistance to arts-based/arts-informed inquiry is

about whether it can count as research and about who should be using these approaches in their work. In general, however, the dissemination of visual representational forms is far easier and less costly with the existing digital technologies, and possibilities for using varying representational forms are increasing with the growing number of online journals.

Representational Issues

When qualitative research got its “wings” during the 1980s, the issues that researchers faced were about validity, reliability, and generalizability—criteria that characteristically had been used to judge quantitative work. Critics of qualitative research, whose philosophical perspectives were based on positivist assumptions, questioned how qualitative research could be valid and/or reliable when the work typically involved single cases and/or a small number of participants and established no controls for variables to test a priori hypotheses. The usefulness of research was questioned if it could not be replicated so that results could be generalized. As qualitative research evolved, researchers spent less and less time countering these criticisms, arguing that in qualitative work, different criteria must be used for assessing the quality of the work. Largely because of the work of Eisner, it is now generally agreed that qualitative research is judged on its *credibility*, on its *plausibility* (whether or not what is represented provides a plausible explanation), on its *transparency* of process, on the apparent *reflexivity* of the researcher, and on its *utility* (how the work can be accessed and actually used to better the human condition). These criteria are demonstrated when the researcher spends extended time with participants in the field, develops and maintains a relational and ethical approach to the work, uses multiple forms of data for analysis, incorporates participant perspectives and voices, and addresses biases and assumptions that are brought to the work.

More recently, with the burgeoning interest in arts-based/arts-informed research, some other issues have surfaced. As mentioned earlier, these are about the quality of the art form and about who should use arts-based/arts-informed approaches and why or why not. This is a slippery slope. On the one hand, great strides have been made in legitimizing arts-based/arts-informed work during the past decade or so, and it would be a shame to diminish representational possibilities by condoning less than acceptable work. On the other hand,

gatekeeping can create elitism and privilege and can reverse the postmodern gains that have countered modernist ways of thinking and doing. Excellent discussions that merit examination have taken place. Richardson suggested that the criteria for judging arts-based/arts-informed research should include the quality of its contribution as well as its aesthetic merit, its reflexivity, and its emotional and intellectual impact. She also suggested that the notion of *crystallization*, or the combination of symmetry and substance seen through a series of “multiple refractions,” should replace any notion of validity. Other work, done by Anne Bamford as well as Eisner and Barone, reflects similar criteria that are nuanced according to the arts-based/arts-informed genre in which the research is situated. What is needed is more discussion and agreement about some basic criteria as well as more specificity and/or elaboration as to how these relate to the existing genres. These exchanges will no doubt carve out new and interesting notions about how to judge research quality as new territories and possibilities emerge.

Sources for Publications

Most journals (e.g., in education) are willing to publish qualitative research. Until recently, however, it has always been more difficult to find journals that are receptive to alternative representational forms or arts-based/arts-informed work. This situation is changing, partly because new technologies make publication of this research easier, particularly as it relates to visual work, but mostly because there is much more receptivity to these burgeoning genres. A few of a growing number of these journals include the *International Journal of Education and the Arts*, *Qualitative Inquiry*, and the *International Journal of Qualitative Methods*.

RESEARCH DESIGN

Put simply, research design refers to the way in which a research idea is transformed into a research project or plan that can then be carried out in practice by a researcher or research team. However, research design is more than just the selection of methods or techniques to be used in collecting data for a particular study. Rather, the term refers to and encompasses decisions about how the research itself is conceptualized, the subsequent conduct of a specific research project, and ultimately the type of contribution the research is intended to make to the development of knowledge in a particular area. Importantly, the process of developing a research design combines three broadly connected and interdependent components: the theoretical, methodological, and ethical considerations relevant to the specific project. This entry explores these in more detail.

The theoretical understandings and assumptions about research held by a researcher and/or research team provide an overarching frame that shapes and influences the research design at every point. For example, if a design is qualitative in nature, then one can assume that the researcher has a commitment to, and has identified the need for, some form of naturalistic interpretive approach to inquiry so as to explore or address the particular substantive focus or question. Such a commitment will influence all parts of the research design, from the way in which the aims and objectives of the research are thought about and articulated, to the methods/techniques/approaches used in collecting the data, to the analytic processes undertaken with respect to the types of theoretical lenses that are applied to the data collected.

However, qualitative designs vary with respect to how theory is explicitly used in a particular study. In some research designs, a specific theory may provide the organizing construct for the entire research design. For example, in a study design that is overtly Marxist in orientation, Marxist theory and traditions will shape and influence that design at every point. Other qualitative research designs may use theoretical concepts, as opposed to entire theories, to shape the design. These theoretical concepts may be derived from one or a number of theoretical traditions to provide the focus for the study and/or as a vehicle to explore a topic of interest. For example, the concept of power might be used as the overarching theoretical construct in a certain research design. The understanding of power in use may draw on one, two, or several theoretical traditions or variants thereof. In such a research design, power provides a theoretical lens or perspective to guide the study, which might be exploring, for example, the outworking or use of power in a particular substantive area. Similarly, gender or class as concepts can provide a theoretical lens or frame in qualitative research. In addition, some research designs may employ combinations of these concepts—for example, in a study looking at the effects of power in a group of women living in a particular social situation or setting.

Another type of research design is one in which the researcher collects and analyzes data with the goal of generating or deriving theory from the study undertaken. Thus, the generation of theory constitutes an endpoint to the research. Yet other study designs, such as (but not invariably) those that are submitted for funding, might not explicitly refer to theory at all in

“Alone in a Crowd”: A Study of Managing Loneliness

The aim of the research is to provide understandings of loneliness that can inform support and service provision targeting older Australians managing loneliness. Specific objectives related to this aim are the following:

- Identify and describe older people’s and service providers’ perceptions and understandings of loneliness;
- Use this in-depth knowledge to inform the development of solutions to assist older people to manage loneliness;
- Work with support/service providers and older people to implement, evaluate, and refine the identified solutions;
- Develop and disseminate recommendations designed to promote wide uptake of the identified solutions at the individual, organizational, professional, educational, and policy levels.

Source: Cheek, J., Moyle, W., Ballantyne, A., Stanley, M., Corlis, M., & Oxlade, D. (2007–2009). *Alone in a crowd: Supporting older Australians managing loneliness*. Funded by Australian Research Council Linkage Grant.

the proposals that outline the research designs to the funding bodies. However, as discussed, such studies do in fact draw on the theoretical traditions that inform qualitative research generally. Thus, there is a great deal of variation in the way theory is used in the design of qualitative studies. It is not a case of one way necessarily being better than another way of using theory. Rather, the key point is that theory does inform the design of all qualitative research, and it is important that this be taken into account and acknowledged in the research design.

Once the theoretical parameters of the research have been established, other parts of the design can be developed. The issue/question/problem that prompted the researcher to identify the need for the research in the first place must be refined into a clearly articulated succinct statement that is able to provide a precise focus for the research design. Part of this process of refinement must involve searching the research and other literature to identify previous studies that are relevant in terms of the substantive and/or methodological foci. This enables the researcher to ascertain what has already been undertaken in the area, and this knowledge can then be used to refine the focus of the

proposed study in terms of what has been found and how it was done. It also ensures that the proposed study has not already been conducted elsewhere.

When the focus of the study has been refined, it is then possible to develop clear aims and objectives for the study. Simplifying in the extreme, the aims and objectives of a study refer to what the study hopes to achieve. Often this information is presented as a series of related and sequential points pertaining to the proposed design. The accompanying sidebar, excerpted from the *Alone in a Crowd* study, is an example of the aims and objectives from a funded research project in the area of care for older persons.

In this example, the aim makes clear that the research design will provide understandings of loneliness and then use these understandings to influence practice in the area of support and service provision for older persons. The objectives then articulate the inter-related steps that will be achieved to meet this aim.

The aims and objectives of a study also provide a framework for choosing the specific methods and techniques for data collection. In a tight and refined research design, it should be possible to cross-link and relate every part of the study design, including the data collection techniques, back to what the research is attempting to achieve as expressed in the stated aims and objectives. For example, if the design involves the use of interviews, then why interviews are an appropriate method to use, what type of interview is being used, and who is being interviewed should be apparent from, and congruent with, the aims and objectives of the research. The following excerpt, taken from the grant application for the *Alone in a Crowd* study, demonstrates how the chosen methods, in this case interviews and focus groups, relate to the overall aim of the study and, more specifically, to the first objective:

In-depth interviews and focus groups will be used to build a comprehensive description of older people’s and service providers’ perceptions about loneliness (Objective 1). The interviews and focus groups will be semi-structured, and initial probes have been developed around six areas:

1. What the participants perceive and understand loneliness to be;
2. Important factors contributing to loneliness;
3. How older people manage loneliness;

4. The effect of loneliness on the health and well-being of the older person;
5. What assists or could assist older people to manage loneliness;
6. Perceived barriers to managing loneliness.

However, it is not enough simply to state the proposed methods; the way in which these methods will be used must be spelled out clearly in the research design. Regardless of the method being employed, clear descriptions of what will actually be done must be given. Depending on the actual design, this might be information about who the research participants are and the criteria that will be used to select them. Which sources of data (e.g., documents) will be investigated and why? Which technique (e.g., type of interview) will be employed to actually collect the data, and what probes will be used in such interviews? Similarly, the equivalent level of detail must be given for other forms of data collection. Methods are not simply techniques to be followed or applied prescriptively, acritically, and slavishly. They need to be used with care, and both their choice and the way they are used within the research design require a large degree of reflection and reflexivity on the part of the researcher.

How the analysis of the collected data will be conducted is another crucial part of the research design. Here the researcher must consider and be clear about what he or she is going to do with the data collected. How will they be organized, and why will they be organized in that way? Exactly how will the researcher go about doing the analysis? A particular theoretical and/or methodological tradition, such as some form of grounded theory or phenomenology, may have already established relatively clear principles of analysis that will provide the basis for an analytic framework within which to work. If not, or if the research design is more eclectic with respect to its underlying theoretical influences, then it is important that a clear and overt link be made between those theoretical influences that shape and influence the concept of the study and the mode of analysis adopted. Such synergy and connection between the theoretical frames shaping the research and the actual data collected enables the analysis to move beyond the descriptive (as useful and important as that may be in its own right) toward deeper and richer theoretically informed understandings that link with existing knowledge and can extend and develop that knowledge.

Furthermore, both influencing and embedded in the design and conduct of qualitative research at every point must be ethical considerations. Such considerations are integral to the research design and go beyond simply meeting the requirements of an ethics review board. Steinar Kvale identified three important ethical issues to consider in any research design: scientific responsibility on the part of the researcher, the relation of the researcher to the participants in the research, and the independence of the researcher when reporting and interpreting the results. Ethical issues also arise at a more practical level in the research design concerning the way in which data are actually collected. For example, if the design necessitates the involvement of people, then issues of confidentiality and anonymity for participants, informed consent, and the possible effects of the research on participants will need to be considered. In his book, *InterViews: An Introduction to Qualitative Research Interviewing*, Kvale provided a useful overview of ethical questions to ask at the start of a research study, and although his focus was on interviews, these questions can be extrapolated to other types of qualitative research study design.

Research design, thus, is much more than simply identifying techniques that will be used to collect data. It involves theoretical, methodological, and ethical considerations that shape both the design and what the research is aiming to achieve. Research design also involves a degree of reflexivity on the part of the researcher with respect to acknowledging the underlying theory and/or theoretical assumptions that have shaped his or her perspectives and understandings of the research focus and process.

RESEARCH DIARIES AND JOURNALS

Research diaries are documents written by individuals to keep a record of ongoing events in their lives and in their surrounding social environment. Andy Alaszewski argued that to constitute data for empirical research, diaries generally need to be contemporaneous, personal, and kept regularly and also must feature entries that include emotions, beliefs, interpretations, interactions, events, and activities. Different types of diaries exist. Logs contain records of activities and events, often in minute details, but feature no personal or intimate information. Journals are diaries written with a narrow audience in mind—the writer himself or herself. Memoirs are similar to journals in both content and form, but their intended audience encompasses both contemporaries of the author and posterity. The latter are often intended for publication and, therefore, may include artistic elements and fictional components. Distinctions between journals and memoirs are, however, difficult at times, and for that reason the words *diaries* and *journals* are used interchangeably in this entry.

Historically, research diaries and journals have developed as user-friendly technologies of recording have become more easily available. In today's society, diaries and journals have become somewhat omnipresent thanks to high levels of literacy; the cultural emphasis on self-disclosure, self-awareness, and introspection; and, of course, the ease of publicizing personal memoirs on new media of communication such as the internet (e.g., blogs, online diaries).

Qualitative researchers employ diaries and journals in two main fashions: as tools of data collection and as data. In other words, researchers may explicitly commission people to keep diaries and journals, or they may collect diaries and journals kept by people out of their volition. Regardless of their solicited or unsolicited origin, many different research strategies may employ diaries and journals. For example, they may be used as part of: fieldwork; unstructured, semi-structured, and structured interviewing; action research; evaluation research; textual analysis; and case study research. In addition, diary- and journal-derived data are amenable to interpretation from a wide variety of analytic perspectives.

Research diaries and journals have been used predominantly in biographical and historical research. Diaries and journals serve well the purpose of providing researchers with documentary evidence in the form of

raw historical and biographical material because they are personal, situated, intimate, and capable of offering insight into the lives of marginalized oppressed people or groups otherwise neglected by traditional versions of objective political and cultural history. Diaries and journals are also commonly used in ethnographic research because they are known to offer vivid depictions of the flow of everyday life experiences and to work well as thickly descriptive chronicles rich with insights into taken-for-granted social interactions. Finally, research journals and diaries have been used to record mundane activities and experiences otherwise inaccessible by researchers. For example, diary entries solicited through structured open-ended survey questions have shed light on time management activities, division of household labor, frequency of sexual activity, and so forth. Similarly, researchers have used diaries and journals to benefit from the deeply reflexive nature of writing over time; compiling diaries allows individuals to ponder the meanings of routines, rituals, identity, and even sensory perceptions.

Recruiting writers for diaries and journals is a complex activity driven primarily by the research design and research objectives. Many issues pertaining to sampling are common to other qualitative research methods and, therefore, are not discussed here. Other issues are, however, idiosyncratic to diary research. The selection of research diarists must be done while taking into consideration issues such as basic competencies in record keeping and literacy, understanding of the context of interest to researchers, and motivation to begin and continue journaling activities.

Researchers who rely on archived or otherwise publicly available diaries, journals, and logs have different sampling dilemmas to consider. In these circumstances, literacy, understanding, and motivation are obviously irrelevant issues, but in cases where multiple choices among archived records exist, researchers must carefully interrogate themselves to determine what diaries are likely to provide the needed information and whether recent or historical diaries (or a mix) better satisfy research needs. Finding archives where diaries are kept, or finding groups of people more likely than the general population to keep journals, can also be a challenge.

Diary data collection varies primarily in relation to the desired degree of control researchers wish to achieve. On the one hand, unsolicited diaries are most desirable when intrusion is seen as problematic, but they offer the lowest degree of control. On the other

hand, structured questionnaire-type journals offer the highest amount of control, but considerable training and incentives may be required for their use to be effective. The diary–interview method offers an intermediate solution. In this approach to data collection, diaries are linked to both preliminary and follow-up interviews after diary completion. Analysis of diary data is highly variable across different research projects. Typical analytic strategies may include content analysis and grounded theory, narrative analysis, interpretive biography, and structural linguistic analysis.

The advantages of using research diaries are numerous. Diaries are extremely flexible in that they can be used within a variety of research designs and strategies, they can be used as data whether they are solicited or unsolicited, and they can be used together with other research methods of data collection. Furthermore, diaries and journals can allow researchers to reach groups otherwise difficult to access, they can aid in recording intimate or private behaviors, and as a form of record keeping they compensate well for problems arising from selective memory or limited recall. On the other hand, diary data may be costly to obtain—especially when diarists need to be trained—and they may be a source of bias due to sample selection limitations (e.g., the need to rely on literate and highly motivated samples). As for unsolicited diaries and journals, although researchers can benefit from being able to access personal information in respondents' own words without research intrusion, they need to deal with artificial elements such as diarists' needs for recording resources, the implicit conventions of the diary genre, and (once again) the requirement of basic skills such as literacy.

and scholarly research as a critical creative activity that employs modes of artistic expression both as methodological tools and as forms of representation. The researcher as artist is open to the experiences and lessons of artistic practices that provide fresh critical and experimental approaches that, among other things, empower research participants by offering alternative, more evocative, and nondominant modes of response to the process of data gathering. Thus, while employing established research techniques and methods, the researcher as artist may also use highly personalized autoethnographic accounts, poetry, storytelling, and nonverbal modes of artistic expression such as collage, dance, and drawing. For example, a researcher might ask informants to visualize responses as well as verbalize responses, a practice commonly used in the gestalt and art therapy context.

The tension in the co-existence of the notions of researcher and artist is resolved in the to and fro among the formation of hypotheses, the flashes of insight, and the operations of imagination in the indefinite nonlinear acts that can accompany the process of analysis. For the researcher as artist, modes of artistic expression become a constituent part of the analysis itself. By conceiving themselves as artists, researchers can avoid reification of consciousness and thinking. Artistic practices allow a higher degree of uncertainty, nonlinearity, and embracing the unpredictable. Thus, for the researcher as artist, the representations of research are not rigidly separated out into material objects or artifacts and the mental world of ideas and concepts; rather, conceptual elaboration is grasped in terms of perception and modes of representation that involve an emphasis on emotional knowledge as well as cognitive knowledge.

There is also the sense in which an artist is at the same time a researcher insofar as his or her research, very often in the form of journals, notebooks, and/or sketchbooks, fosters the production of works suitable for public performance or viewing.

The notion of the researcher as artist has its origins in the dissolution of a hierarchy among the arts, the use of the arts in the context of therapy, the multimodal nature of many works of art, and the postmodern relation of the artist to his or her work as only one reception among multiple interpretations. It is a notion that brings both artistic activity and research activity closer together as an expression of the essential tension between tradition and innovation whereby

RESEARCHER AS ARTIST

The characterization of the researcher as artist is based on the reconciliation between artistic practices

established paradigms are revised or replaced and research becomes a transformative and practical productive force.

RESEARCHER AS INSTRUMENT

Noted qualitative methodologist Norman Denzin described the social sciences as resulting largely from the “art of interpretation.” Perhaps the most important tool in the practice of this art is the researcher herself or himself. Qualitative methods rely much less than quantitative methods on “standardized” instruments and methods. Thus, the researcher is positioned quite closely to raw words and real life, and the researcher as “person” plays a more obvious, if not more profound, role in all stages of research. This does not mean that researcher characteristics are not also central to every stage of quantitative research, but whereas quantitative research attempts to minimize or even obscure these issues through standardized protocols and “objective” numerical outcomes, qualitative

research is more forthright concerning the ways in which all of research is a human endeavor.

Feminist standpoint theory explores and acknowledges that research is affected by researcher and other worldviews. Both the researcher and research participants are seen as present, and meaning is constructed and interpreted in the interaction between these two positionalities. Different qualitative researchers may look for, see, experience, and interpret data differently based on their experiences, skills, interests, and so on. As important as, if not more important than, researcher differences are the differences between the insider (emic) and outsider (etic) perspectives. This is not a question of competing truths but rather a question of the multiple stories and truths that exist simultaneously and are co-created by research itself.

The researcher also becomes an instrument through the relationships she or he builds with research participants. Rather than attempting to minimize these, feminist work (among others) stresses the importance of these relationships. Patricia Adler and Peter Adler examined how three sociological traditions also define different roles, and thus different researcher instrumentalities, and how each of these in turn produces potentially unique, but equally authentic, findings. Prolific ethnographer Michael Agar also wrote of the ways in which the ethnographer’s personality matters in ethnography—another example of how the researcher is an instrument of qualitative research.

The researcher is also an instrument in the collection and analysis of data. In nonlaboratory research, one cannot attend to all of the data present in even the smallest interaction; thus, narrowing the field of concentration is a function of who the researcher is. As David Fetterman wrote, “perception is selective,” and the researcher, steeped in personal background as well as theoretical background, makes this selection. The final stages of research are also a highly individual human enterprise. Qualitative research has no data-crunching software to impart an equation representing results. Rather, analysis, interpretation, and meaning-making come from the researcher, using all of her or his personal and professional skills, training, knowledge, and experience as an instrument to produce a coherent authentic picture of the research as the researcher saw and experienced it.

RESEARCHER–PARTICIPANT RELATIONSHIPS

A significant portion of qualitative research involves collecting data from research participants. The kinds of information that participants disclose in a research setting depend in part on the nature and quality of their relationship with the researcher. Researcher–participant relationships may fall anywhere along a continuum from distant, detached, and impersonal to close, collaborative, and friendly. The relationship between a researcher and participants may evolve and change over the course of a research project, especially if that research project progresses over an extended period of time, as is common in many forms of qualitative research. Important methodological and ethical considerations arise from the nature and quality of researcher–participant relationships.

Range of Researcher–Participant Relationships

In traditional positivist research, researchers present themselves as detached objective reporters and attempt to gather data that are standardized and narrowly constrained. Quantitative researchers strive to treat each participant identically as part of their attempts to maintain experimental control. Limited interactions between participants and researchers keep the research focused and reduce the chance of introducing confounding variables.

In contrast, in qualitative research traditions, researchers tend to gather wide-ranging and open-ended

data through personal interactions with research participants. In the process of data collection, qualitative researchers and research participants develop relationships that can shift and change over the life of a research project. Margaret Jane Pitts and Michelle Miller-Day investigated turning points in researchers' relationships with participants. Through open-ended surveys and detailed interviews with field researchers, they identified five possible phases in researcher–participant relationships. During the first phase, researchers emphasized their concerns with meeting the needs of participants with respect to the research, helping them to feel comfortable as research participants. During the second phase, researchers and participants began to consider their partnerships in the research and their interrelationships with each other. More personal relationships began to develop during the third phase, which involved connections in public or professional spheres outside of the research project. The fourth phase was characterized by close interpersonal relationships that were most often described as friendships. During the fifth phase, the personal relationships superseded the research relationships and there was a feeling of a true partnership. Researchers are not expected to progress through all five relationship phases in each research project or with every participant. The first phase is typically the only phase evident in research conducted over a short duration or involving few interactions with participants. Other research projects might involve movement toward increasingly closer relationships as evidenced by the other identified phases, but very few researcher–participant relationships ever achieve the level of true partnership evidenced during the fifth phase. A closer relationship is not a sign of a better research relationship or better research.

Researcher–Participant Relationships and Qualitative Research Traditions

To a certain extent, the nature and evolution of researcher–participant relationships are informed by the qualitative research traditions that inform the research.

Ethnographic Research

Ethnographic researchers often begin a research project by attempting to get a feel for a particular research setting by easing themselves into the situation, observing

from a distance, and getting to know some prospective research participants. A research project emerges and takes shape as the researchers gain familiarity with the research setting and interact with research participants over time. Ethnographic researchers establish close relationships with key informants who provide introductions to activities, events, and other people in the research setting. Over time, key informants become important confidants to, and often friends with, researchers. Ethnographic research is commonly associated with prolonged engagement in the field, which provides opportunities for researchers to develop close relationships with one or more members of the studied community. In community settings where ethnographic research is undertaken, a researcher's relationships with one participant may positively or negatively influence relationships with other participants. Lisa Russell provided an informative analysis of the challenges of establishing and maintaining relationships with both students and teachers in her ethnographic classroom research. To investigate student resistance to schooling, she needed to establish strong trusting relationships with students. At the same time, she also needed to establish collegial relationships with the teachers to secure their commitment to the research without negatively influencing the delicate relationships that she was building with the adolescent students.

Community-Based and Action Research

In community-based and action research, collaborative or participatory relationships are common. Research participants frequently contribute to defining the research project, including informing choices about the research questions, research methods, data sources, and data interpretations. Research participants in such projects may be seen as research partners or co-researchers. In these kinds of research, traditional power hierarchies between researchers and participants no longer prevail. Researchers and participants may be activists working together toward shared goals and are frequently seen as co-equal colleagues.

Interview-Based Research

In life history, narrative, and other interview-based research, researchers strive to document intricate details of research participants' lives. In these research approaches, researchers often attempt to give voice to participants such that the research reports are frequently

presented in participants' own words. These qualitative researchers attribute significant value and importance to the participants' experiences and perspectives, which often translates into respectful and engaged relationships that develop over repeated interviews.

Critical Scholarship

In critical scholarship, qualitative researchers question social structures and systems that promote inequity and injustice. Feminist or other critical scholars who are committed to social justice often undertake efforts intended to disrupt hierarchies and power relationships in society. These efforts may also carry over into the research process where researchers are critically conscious of the traditional power imbalances that favor social scientists over research participants. This critical consciousness may contribute to developing positive relationships with research participants because researchers are seen as advocates and allies.

Some forms of critical scholarship require researchers to engage with research participants who hold opinions that oppose the researchers' views. Researchers treat these research participants with respect but seldom develop close personal relationships with them. In some cases, maintaining distance from the participants may be necessary for researchers to adequately engage social and institutional critique.

Influences of Researcher–Participant Relationships

The different roles, positions, and relationships that researchers and participants adopt influence the data that are revealed in a research study. Whether close or distant, the relationship with the researcher affects what participants say. Some scholars have argued that close relationships between researchers and participants lead to "better" data, but this is not necessarily the case. There are different advantages and disadvantages associated with the different types of researcher–participant relationships in particular research settings. A tremendous amount of information can be learned through close personal relationships with participants, just as a great deal can be learned when researchers remain distant or even estranged from research participants.

Sumi Colligan became intimately involved with the women in the Karaite village where she conducted her dissertation research because she needed to rely on the women's assistance with showering and personal

grooming due to her physical disabilities. The necessary openness that Colligan displayed to these women led to reciprocal displays of openness from the women, which in turn allowed Colligan to explore the nature of openness in the Karaite religion. Colligan's close and intimate relationships with the women allowed her to learn about openness in the Karaite religion in a way that would not have been possible without her intimate relationships with the research participants. However, such positive benefits of intimacy are not always evident.

Intimacy and closeness may prevent researchers from challenging the status quo. Interviews conducted within the context of close relationships frequently rely on insider information and shared understandings that cannot easily be substantiated in research reports. Transcripts from such interviews are notoriously difficult to interpret because so much of the information is communicated without explicit verbal statements. It is impossible to gauge how much information is missed or misinterpreted because participants remain silent regarding issues about which they assume the researchers already know and because researchers fail to ask appropriate follow-up questions that would make this information explicit.

Scholars who have written about insider/outsider status frequently discuss the relative strengths and weaknesses of various configurations of researcher–participant relationships. Closer researcher–participant relationships are associated with research conducted by insiders, whereas more distant researcher–participant relationships are associated with research conducted by outsiders. However, insider and outsider status and the corresponding relationships with participants resist simple binary classifications.

Furthermore, there are times when outsiders are more appropriately placed to conduct research than are insiders, and there are situations where the researcher–participant relationship needs to remain relatively distant. For example, David Gordon found that a distant relationship with the members of the religious proselytizing groups that he studied was critical for the success of his research. Some researchers in similar situations have tried to hide their personal beliefs through evasion, lies, and covert actions, but Gordon did not feel comfortable with those approaches. As a nonbeliever, he felt that it was important to display his open, honest disagreement with the group's beliefs and used this as a way to engage conversations with the group members. This strategy kept him at a remove from the research participants, but it had a positive influence on

the research in that it led to an increase in rapport and acceptance from the group and a simultaneous decrease in his own feelings of psychological distress as a researcher in the setting.

Factors Contributing to Close Researcher–Participant Relationships

Although a range of relationships can exist between researchers and participants, several key features of qualitative research tend to promote closer relationships rather than distanced relationships.

To gather data from research participants, researchers must first establish rapport and build trust. Few research participants are comfortable in telling a stranger about their opinions and experiences, so they may need to get to know the researcher and the motives behind the research before they will disclose sensitive information. Research participants may become more forthcoming as they come to accept the researcher's presence and involvement in the research setting and start to see the researcher as a real person rather than some detached or distant evaluator. Such transitions are clearly evident in the five relationship phases identified in the study conducted by Margaret Jane Pitts and Michelle Miller-Day.

Beyond establishing rapport with research participants, the rich and thick descriptions that are the heart of qualitative research demand engaged and prolonged data collection. Qualitative researchers may be involved in a field-site over an extended period of time, observing and interacting with research participants. They may reinterview the same person or people multiple times, seeking in-depth understandings from insider perspectives. Qualitative researchers also regularly engage in forms of participant observation where they take on participatory roles in the research setting. Frequently, the research itself occurs in a setting where researchers are already engaged as teachers, therapists, or other community members. Through ongoing interactions in the research site over time, researchers and participants can naturally develop close relationships, possibly even friendships or true partnerships.

In much qualitative research, data collection and data analysis proceed simultaneously. This is particularly common when data collection occurs over an extended period of time. In such situations, member checking (i.e., where participants are involved in reviewing transcripts or written accounts of research) occurs on an ongoing basis and there are continuing opportunities for

research participants to contribute to data analyses. Research participants may extend their involvement in the research beyond the data collection period and may become involved as research partners or co-researchers.

Efforts to provide reciprocity for research participants also influence the resulting relationships that develop between researchers and participants. Reciprocity is about the need to give something back to participants. Frequently this is interpreted as providing small gifts or tokens of appreciation in exchange for participation in research. More fundamentally, Patti Lather described reciprocity as mutual negotiations of meaning and power. This requires a collaborative approach to research where participants are invited to negotiate interpretations of the data and to contribute directly to data analyses. Researchers who are committed to reciprocity try to avoid imposing their own meanings on the research and strive to decenter their roles as “experts” in the process. Full reciprocity involves a conscious commitment by researchers to using the research to help participants understand and change their situations.

Researcher–participant relationships are also fostered by the commitments that some qualitative researchers make to a relational ethic, which is particularly evident in feminist or community-based research projects. Researchers who ascribe to a relational ethic strive for collaborative, reciprocal, trusting, friendly, and connected relationships with participants. This commitment demands that researchers engage self-awareness, reflexivity, and interactivity throughout the research. In such research approaches, it is common for researchers to engage in self-disclosure in research reports and sometimes directly to participants during data collection. The resulting shared intimacies lead to close and personal relationships.

Qualitative researchers often include reflexive elements in their research. Some qualitative research is distinctly autobiographical or autoethnographic, whereas other research includes a self-study component to complement the experiences of other research participants. This emphasis on reflexivity increases the chances of self-disclosure from researchers during data collection, creating a two-way relationship with research participants.

Ethical Challenges

As with any other research decision, close relationships with research participants raise ethical issues.

Research ethics review procedures address preexisting relationships with prospective research participants. Such relationships can influence the ability of prospective participants to make free choices about participation. In such situations, researchers must take great care to avoid any subtle pressure or coercion and to ensure that decisions about participation are not seen to affect the preexisting relationship in any way. Institutional ethics review boards devote particular attention to research involving clients and service providers (e.g., patients and doctors/nurses, clients and therapists, students and teachers, athletes and coaches, parishioners and spiritual leaders) or individuals and their supervisors (e.g., managers, employers). Research involving family members or close personal friends is also subject to scrutiny.

In addition to considerations about how to ensure free choice, preexisting relationships may require a researcher to juggle multiple roles throughout the research and make judgments about when to act as researcher and when to act as employer, doctor, teacher, friend, and/or whatever other roles may be possible. These overlapping roles and relationships provide the potential for mixed messages and boundary violations. In most cases, nonresearcher roles must take precedence over researcher roles.

Preexisting relationships are relatively easy to document, and there are strategies in place to counteract the related ethical issues. Relationships that develop over the course of a research project are less predictable, and ethics review boards tend to provide limited guidance about the relevant ethical issues associated with emerging relationships.

Not all research participants will want to fully engage and develop close relationships, so researchers must be careful not to impose unwanted expectations. On the other hand, some research participants may be overly enthusiastic about developing relationships with researchers and may even forget the research-based nature of such relationships. Researchers' friendliness may be misinterpreted as friendship, leading to social invitations from research participants that researchers may perceive as undesirable or inappropriate. Negotiating exit from the research field may be particularly challenging in such situations because former research participants may wish to maintain relationships that they perceived as true friendships.

There may be ethical challenges even when a friendship is an equal and reciprocal relationship between a researcher and a participant, whether that

relationship existed prior to the research or emerged in the midst of the research. Researchers may be aware of the need to balance their roles as researchers and friends, but research participants tend to be less cautious in this regard. During the research, friendships may prompt research participants to disclose information that they would have preferred to keep private, sometimes not even wanting to acknowledge the information to themselves. Research participants may share information as friends that may then become entangled as data in the research project and may appear in written reports, leading to possible feelings of betrayal or deception.

The ethical challenges of researcher–participant relationships of an intimate nature can be particularly profound. For example, the so-called Brad Trilogy, a series of articles that Harry Wolcott wrote about a school dropout who he found squatting on his property, has spawned considerable attention to the issues of intimate relations in research. Wolcott documented Brad's life history, with a particular focus on the ways in which the school system had failed him. The young man lived for several years in a shack that he had constructed on Wolcott's property and willingly participated in a series of interviews. Two years after leaving the property, the young man returned and attempted to murder Wolcott. In the ensuing court case and in Wolcott's subsequent reports about Brad, he admitted to a sexual relationship with the young man that preceded the research relationship. Wolcott's admission prompted extensive scholarly discussion about morality and the limits of qualitative research.

Dynamic Researcher–Participant Relationships

There is a dynamic range of possible researcher–participant relationships in qualitative research that lead to corresponding methodological and ethical considerations. The reflexivity demanded of qualitative researchers means that relationships with participants have been recognized as influential to the research process and the resulting interpretations. Researcher–participant relationships are considered a topic worthy of study.

RESEARCHER ROLES

When undertaking qualitative research, the scholar/researcher has a multiplicity of roles and responsibilities, often enacted simultaneously. Many of these roles are so intuitive and commonly understood that they are rarely discussed in standard methods texts. However, other roles, particularly the role of the researcher in relation to study participants, have generated a great deal of controversy and angst and have been debated endlessly across all of the disciplines in which qualitative research has both epistemological and methodological acceptance. The goal of this entry, then, is to make visible the many roles of the

qualitative researcher and to provide a sense of the larger scholarly framework within which these roles are enacted and examined.

The researcher's roles are discussed in two sections. *Tacit roles* have to do with the knowledge and commonly understood practices that the researcher brings with him or her to the study concerning how scholarly research should proceed. In any of the tacit roles, the researcher is the recognized expert who must ensure that the research proceeds according to accepted standards and procedures. *Interactionist roles*, on the other hand, have to do with how the researcher conceptualizes and frames his or her role in relation to study participants and what effect the researcher's presence might have on the thoughts and actions of research participants and the knowledge that accrues from the study. The interactionist issues that arise are considered reflexively by the researcher, who then must make a decision about how best to proceed given the unfolding circumstances of the research.

Tacit Roles

The researcher's role begins at the stage of research conceptualization. At this point, the researcher takes on the role of an informed "ideas" person. The researcher uses his or her prior knowledge of an area of study within a discipline, or across more than one discipline, to propose a well-crafted and coherent project with clearly articulated research questions. The research project could be a stand-alone project for a limited time frame, or it could be part of a much larger program of study unfolding over a longer period of time, perhaps a decade or more. In either case, in the role of the "ideas" person, the researcher has a number of responsibilities, the understanding of which is internalized throughout the process of attaining a PhD and develops further as new research projects are undertaken. Because the vast majority of researchers do have a PhD, the responsibilities of the ideas person are well understood by all scholars but are rarely discussed. Some of them include the following:

- Keeping current and abreast of the scholarly literature (including philosophical discussions, theoretical developments, and research findings) related to the topic under consideration
- Maintaining a critical awareness of the issues/questions needing further examination
- Having a thorough understanding of the parameters of qualitative research

- Proposing a project that is manageable and can be completed successfully
- Ensuring that the research will be conducted according to accepted methodological and ethical standards
- Seeking appropriate funding so that an investigation can be done as fully and thoroughly as possible
- Ensuring that the research is meaningful in terms of its contribution both to the discipline in particular and to knowledge or society in general

The qualitative researcher maintains the role of ideas person throughout the study, constantly and reflectively blending the theoretical framework(s) of the study with the qualitative observations to provide new and/or unique interpretations of how participants come to develop certain meanings and practices within their social worlds.

Although the role of the ideas person is always present, once the research project begins, the researcher also may assume a number of other roles. Foremost among these are the rather overlooked, but very important, roles of research administrator and manager. All qualitative research projects, whether done as solo projects or by collaborative teams, have myriad administrative aspects such as keeping track of expenditures, hiring assistants and supervising them, paying attention to reporting requirements for grants, preparing survey instruments, organizing transportation, purchasing any necessary equipment and/or software, sending out advertisements or letters of contact and of thanks for participation, and a variety of other necessary paperwork. In some cases the researcher has a great deal of responsibility for these tasks, whereas in other cases a hired project director or another staff member looks after these details in consultation with the researcher. Nonetheless, even if not attending to all of these details himself or herself, the researcher needs to be cognizant of the progress made on administrative matters to ensure that the project moves forward satisfactorily.

Whereas there is some overlap with the administrative role, the managerial role is distinct and draws on slightly different knowledge and expertise. In the managerial role, the qualitative researcher must make ongoing and important decisions about the conduct and management of the research—decisions that could ultimately affect the legitimacy of the study's findings and contributions. Such decisions would include elements such as research location and timing, access to participants, supervision of research assistants,

daily problem solving, data analysis, and preparation of findings. In the managerial role, the researcher acts as the primary problem solver, perhaps needing to make a number of important decisions on a daily basis about the conduct of the research and the intellectual analysis/presentation of the resulting data. Without this crucial role, the research project could be adversely affected by a number of smaller or larger problems, such as a subtle drift away from the study objectives, errors in procedure, or the violation of ethical standards, any of which could have devastating consequences for the academic legitimacy of the study and the reliability of the findings.

Throughout the research project, from conceptualization to implementation to completion, the researcher also must take on the role of research ethicist. In qualitative research, ethical considerations are paramount and cannot be underestimated. The research must be conducted to ensure that human participants are informed and protected and that there generally will be no adverse affects from their participation (although it must be noted that this is not always completely controllable given that some study participants may feel various degrees of upset at recounting their experiences to the researcher). It is the researcher's responsibility to understand ethical issues and norms in qualitative research and to ensure that an appropriate ethics protocol has been approved by his or her institution and that the approved protocol is upheld throughout the research. The importance of ethical considerations must be communicated to research assistants, who must be trained to handle any ethical issues that might arise when working with human subjects.

Another important tacit role for the qualitative researcher is that of mentor. The most obvious mentoring role is with graduate students and other research assistants who are paid to work on the project. In such situations, the researcher may need to spend a certain amount of time instructing assistants in the best practices of the particular methodology being used, coaching them on a variety of issues (e.g., good interviewing or observational techniques, how to take good field-notes, what to expect and what to observe in a given setting) and allowing them to participate in data-related activities such as the development of coding categories and the actual coding and analysis of the data collected. Graduate research assistants also may be involved in helping to prepare the results of the study for conference presentations and possibly for publication. Involving graduate students in the various

stages of research does take additional time, but the researcher who is working with graduate students, particularly at the doctoral level, usually does feel some obligation to enable the students to learn from the project so that they will have a better idea about managing and conducting their own research projects later on as their academic careers progress. Similarly, the researcher who is a principal or main investigator may do a certain amount of mentoring with co-investigators who are less experienced with the administrative requirements and problem solving that accompany larger qualitative research projects.

Interactionist Roles

Qualitative research encompasses a wide range of methodologies, including everything from analysis of visual media and document interpretation to interviewing and various types of ethnographic observation of humans in their environments. Despite this range, there is a strong association of qualitative research with the latter two methodologies, involving either direct one-on-one contact with individuals who have agreed to talk about their experiences or the incorporation of the researcher into a setting where the people being studied are going about the business of daily life. Accordingly, the researcher roles that receive by far the most attention in the scholarly literature have to do with the ways in which the researcher interacts with study participants and his or her own reflections on those interactions. Although every qualitative research project is unique in some way because of the questions asked and the type of people studied, there are nonetheless many common areas of concern related to interactionist roles across a variety of very different qualitative studies.

There have been a number of different typologies of, and terms for, researcher roles in relation to the people they study. Lynda Baker, writing about observation as a qualitative research methodology, provides a very good summary of both the ways in which researcher roles have been conceptualized over time and the problems associated with each, including roles such as the following:

Nonparticipant: The researcher has no involvement with individuals and observes from a distance, sometimes via software or other electronic means.

Complete Observer: The researcher is present in the setting but only listens and observes and does not interact. His or her role as a researcher might not be known.

Observer as Participant: The researcher is present in the setting and primarily observes, although some brief interactions with participants may occur.

Participant as Observer: The researcher actively participates in a number of activities with the group, to the point where he or she may be identified as a friend or colleague.

Complete Participant: The researcher studies a group in which he or she is already active as a member but does not reveal his or her research role.

Complete Member: The researcher studies a group in which he or she is or has been active and reveals his or her role as a researcher.

Although the roles noted are discussed in relation to ethnographic observation, versions of them also may be evident when doing a study based on interviewing. Regardless of which role the qualitative researcher assumes and whether or not the research is based on interviewing, observation, or some combination of the two, there are a number of skills and qualities that the researcher must bring to these roles to be effective. Renee Fox, reflecting on her five decades as an ethnographic researcher, suggested that the skills that are paramount for ethnographic fieldwork include skills in observation, interviewing, recording, and remembering; the ability to be self-reflexive without narcissism; the ability to recognize empathically the connection between the researcher and the researched; interpersonal skills and an ability not only to listen but also to really hear what is said and meant; awareness not only of language but also of gesture and silence; an appreciation for the importance of the routine aspects of social life; and an unwavering work ethic for the many hours that are necessary to perform the emotional and mental labor required for detailed fieldnotes.

A key issue that always arises and must be navigated by the researcher is that of the “insider” versus “outsider” role. Insiders are individuals who either have experienced or have knowledge about the issues being studied (e.g., domestic violence) or have membership in the group being studied (e.g., persons with AIDS, a particular ethnic group). As insiders, study participants know firsthand about the concerns, feelings, social norms/conventions, beliefs, daily activities, and/or cultural practices related to the issue or group. Researchers who have no personal experience with a particular issue or are not members of a particular group are outsiders.

The insider/outsider dichotomy raises a number of dilemmas regarding the role of the researcher having to do with issues such as acceptance, trustworthiness, and the impact of insider or outsider status on the perceptions of participants. Some authors believe that it is essential to maintain some element of the outsider role (i.e., academic or intellectual distance) throughout the study, whereas others insist that the qualitative researcher’s role as an objective and dispassionate observer is not always realistic, achievable, or even desirable. Arguments have been made that, particularly if researchers are insiders, claiming any sort of objectivity or distance can actually inhibit accurate perceptions and observations. In such cases, researchers are encouraged to demonstrate their understanding of the complexities of the situation, thereby increasing the integrity of the study and their findings. Most researchers come to an awareness and acceptance of their insider or outsider status and deal with the implications of that status (and possible shifts in it) throughout their research.

The role as an insider or outsider is only one of many possible interactionist roles that might confront the researcher during the course of a qualitative study. Some of these additional roles may be assumed by the researcher, whereas others may be assigned to the researcher by participants. In the latter case, the researcher may need to actively discourage participants from thinking of him or her in a particular role that could be potentially harmful to the study, to the participants, and/or to the researcher. Some of the most common roles include the following:

Friend. Much has been written about the difficulties of having friends as participants or informants in a study or of using a friend as an access mechanism into a group. Nonetheless, particularly with a long and in-depth study, the researcher may develop a bond with at least one participant that develops into a true friendship. Although some authors think that there is nothing inherently wrong with a friendship arising from research, it may complicate the study in that the researcher then must be aware of how a developing friendship may alter the situation and/or the accounts of participants. The researcher also must come to terms with the fact that he or she cannot freely share everything about the research with a participant who is, or has become, a friend.

Mentor. On occasion, the researcher may take on a mentoring role with study participants. For instance,

in his study of African American high school students, Marc Hill noted that his previous role as a teacher caused some of the students to seek him out for advice and a sympathetic ear, thereby giving rise to a mentoring role that he had not anticipated.

Negative Agent. There is always the risk that the researcher's mere presence will alter the behavior of participants or the conditions of their social setting in some way. This can be particularly true in an intimate setting such as the home. The term *negative agent* was coined by Amy Jordan, who noted in her study of media use in the home that her presence as a researcher seemed to escalate the tensions among family members and/or cause them to rethink their roles in the family. It is very possible that the researcher may unwittingly take on a role as a negative agent by causing participants to reflect on their beliefs or their social conditions.

Parent. Particularly in qualitative research involving children, researchers who are themselves parents may come to feel a great attachment to their participants. Deborah Ceglowski, for example, described how she fell in love with one particular child during her research at a Head Start program and how she struggled to separate her researcher self from her parent self. This struggle also affected her role as a participant observer staff member at the program in that she sometimes felt that the full-time staff members were not doing what was best for this child.

Professional. A researcher who has a previous professional identity may find that the other role as a professional can aid him or her in gaining access to a community where that professional role is recognized. Because of the researcher's prior work experience, he or she may be regarded as a knowledgeable professional who truly understands the issues within a particular environment, and so participants are willing to really open up about their experiences in that setting. On the other hand, a researcher's prior professional role may arouse suspicion. Will participants' thoughts and feelings be kept confidential, or will the researcher impart information to management? In such situations, the qualitative researcher may need to work extra hard to reassure participants that a prior professional role does not in any way compromise participants' personal situation.

Social Activist. Although there is general agreement that an interventionist role is to be avoided, there are some instances where taking a social or political activist stance is the only way to move the research forward or is the only morally appropriate course of action. In their work within a Navajo community, Bryan Brayboy and Donna Deyhle noted that naming the racism that they observed and that participants recounted to them was the only way to develop a complete understanding of the educational problems faced by Navajo youth. Although there were repercussions to their stance, the authors nonetheless believed that to take any other position would have been irresponsible and would have weakened the research findings. Similarly, some researchers have found themselves taking a socially active role when participants are in a dangerous or critical situation.

Therapist. Of all the roles thrust on the researchers by participants, the role of therapist is the one that is universally disavowed and deemed to be the most problematic. Particularly when using a one-on-one interview methodology, the researcher may be privy to painful memories and incidents that participants have never disclosed previously. Similarly, in an observational study, the researcher may feel a great desire to intervene in a situation to improve things for participants. Fox referred to this as the "therapeutic temptation." Being regarded as a therapist puts the researcher in a precarious position because he or she is not trained as a therapist and the purpose of the research is not to provide therapy even when participants clearly need assistance.

Also frequently discussed in the qualitative literature is how the researcher's role is a component of the differing power or social relations between the researcher and research participants. Power imbalances can arise because of demographic differences between the researcher and study participants, including social class, race, ethnicity, and level of education. Power differences also can be related to a perceived inequality between the researcher (who is the authoritative figure and is in control of the study) and participants (who provide the raw material for the study). The qualitative researcher needs to build a bridge to the study participants so that they will trust him or her and will reveal aspects of the issue being studied or allow the researcher to observe their regular practices. The researcher builds this bridge by a number of means,

including demonstrations of empathy, nonjudgmental interest, caring, honesty, and openness. However, no matter how empathetic the researcher or how trusting the participants, there is still an unequal balance of power. The researcher is responsible for the study, and the participants might not be entirely sure what the researcher is going to do with the information given or the observations made or how the researcher will interpret and describe their accounts. Participants also may feel that they are not getting enough back or are not being adequately compensated for the disclosure of their life experiences to the researcher.

In situations where participants have come to view the researcher as an insider and/or a friend, the power imbalance may be even more apparent when the researcher suddenly seems to revert to the researcher role. Numerous authors have commented that their participants have become uneasy or disappointed when, during mundane and friendly conversations, the researchers began to take notes or pulled out a tape recorder. In these cases, participants often comment that the researchers put on their “researcher hat.” In such situations, participants can feel betrayed that the bond they feel is really not reciprocal and that it is only business as usual for the researchers. Similarly, the researchers may feel guilty that they have ruined critical moments in their developing relationships with participants. Many researchers have recounted that, having had this experience once, they ensure that they do not again revert to the researcher role during routine friendly encounters with participants. However, there are also just as many accounts of researchers running into the washroom or to another private place and writing down as much of those sorts of conversations as they can accurately recall. This illustrates the fine line in qualitative and ethnographic research between the researcher becoming so familiar to participants that they think of him or her as a normal part of their setting and the researcher using participants as a pathway into a particular worldview or set of practices.

Although much of the discussion about the researcher’s role centers on the researcher’s interactions with, and obligations to, participants, in some settings the researcher’s role may actually be co-opted and used by participants themselves. Often this happens when the researcher also has a professional identity (e.g., health care professional, engineer, teacher) that is recognized by participants. For instance, Carol Haigh and her colleagues suggested that some participants in their study of postoperative epidural pain

management used the researcher to further their own agendas such as by asking the researcher to bring their concerns/grievances about their care to someone in a position of higher authority within the clinical setting or asking for clarification of medical information given to them. The researcher should always be aware that participants may have their own reasons for participating in the research and that they have the right to question the researcher’s motives and practices.

Finally, it should be noted that the researcher has a reflexive role in conducting qualitative research. Reflexivity concerns the need for the researcher to reflect on his or her role(s) and on the general nature of the relationship between the researcher and the studied. Qualitative researchers understand that they need to think about the epistemological assumptions, theoretical frameworks, and personal values/beliefs that they bring to their research. This involves careful reflection on issues such as the way(s) in which researchers position themselves in relation to the study participants, the way(s) in which participants in turn position themselves in relation to the researcher, and the researcher’s interpretations of participants’ life experiences. Although a certain amount of reflexivity about the researcher’s role has always been a component of qualitative research, within the past 15 years or so, qualitative research has taken an unprecedented reflexive turn during which a reflexive lens has been brought to bear on virtually every aspect of the qualitative research process.

RESEARCHER SAFETY

The gathering and processing of qualitative research data brings important safety considerations for researchers. Qualitative research encounters often require researchers to meet participants face to face and discuss personal aspects of their lives and can require them to work alone. From design through to analysis and writeup, ensuring the safety of researchers is a crucial consideration that cuts across the research process.

This entry begins with an overview of the three key dimensions of research safety: physical harms, emotional harms, and societal harms. It goes on to focus on some of the practical steps that individual researchers, their managers, and their employing organizations can take to help ensure that researchers work as safely as possible during fieldwork.

Dimensions of Researcher Safety

Risks in the research process are not mutually exclusive, and neither are they isolated to particular fields of study. Rather, they are ubiquitous features that pervade qualitative research.

When meeting research participants face to face, unwelcome touch, physical or sexual assault, and attack by pets are risks that are likely to be remote but remain real. It is important to recognize that researchers will face and respond to risks differently.

The risk of attack for men is different from that for women. For example, women tend to be more at risk for sexual advance and threat compared with men, and young men may be more at risk for physical attack.

Emotional harms can take a number of forms. Harm may arise as a consequence of, or as a threat of, physical attack. It may also be caused by forming friendships and experiencing the feelings of loss when leaving the field. Or, the content of what is reported during the research encounter can be upsetting for researchers. Or, researchers may dwell on issues in their own lives longer than they normally would. For example, researching palliative care topics can raise issues that all people face in their lives at some point.

Some of the risks faced in society, such as accidents, general infections and communicable disease, and the theft of (or damage to) personal possessions, may be increased in some areas of fieldwork. There may, for example, be increased risk of crime, including the theft of (or damage to) personal possessions such as cars, in particular geographical areas or at specific times of day. And working within some health care settings, such as hospitals and laboratories, may pose increased risk of infection or communicable disease.

Ensuring Researcher Safety

Employers have a duty of care toward their employees. This requires employers to undertake risk assessments and to provide sound operating policies and protocols. Also, it is important for researchers to adhere to the requirements set out by their employers and for managers to ensure compliance.

A culture and ethic of safety awareness is important in all organizations. This can be brought about via education and training to enable researchers to feel prepared for the risks they may face in the course of their work. Training initiatives, therefore, may focus on general awareness raising through to risk assessments, role-plays, and diffusing difficult situations or managing challenging behavior. In the United Kingdom, the Suzy Lamplugh Trust works to provide guidance and resources to help everyone keep safe. An organization that is aware of the risks faced by its employees will encourage open communication and the alerting of potential threats. This will enable management action with appropriate revisions to operational policies and protocols as required.

There needs to be sufficient resources to ensure that any threats to researchers' safety are minimized.

Good Practices to Ensure Researcher Safety

To ensure researcher safety, the following practices can be implemented while planning, traveling to the meeting, and conducting the meeting, and follow-up after the research meeting.

Planning

- Consider working in research pairs or with an escort.
- Always make appointments.
- Leave written details of whereabouts, including the names of participants, address, expected start and end times of meeting, location of meeting, and travel arrangements, with manager. Information about participants should remain confidential and subject to data protection in the same way as researchers hold such information. The same principles should apply to family or friends aware of the researcher's activities.
- Prearrange a time to call manager after each interview, including ways in which the researcher can alert of threat by telephone. If threat is alerted, or contact cannot be made at the arranged time, the manager should phone the police immediately.
- Create list of telephone contacts, both in the phone memory and on paper.
- Carry a phone card.
- Fully charge personal alarms and mobile phones.
- Arrange debriefing sessions with manager or supervisor.
- Arrange research meetings in public buildings, and during the day, where possible.
- If arranging an overnight stay, use a well-located and reputable hotel.
- Acquire local knowledge of the research area. For example, home care teams and security officials are good sources of information.
- Establish the best site for both the participant(s) and the researcher(s) to meet.
- Plan routes to and from research sites, including phone numbers of reputable taxi companies.
- Have sufficient funds, including cash, to cover travel, subsistence, and unexpected expenses.

- Dress appropriately for the situation and avoid wearing expensive jewelry or carrying expensive equipment.
- If using incentives to participate, such as cash or gifts, take these only when they are required.
- Create a checklist of these practices and other study-specific needs such as notebooks and recording equipment.

Traveling to the Meeting

- Ensure that all practices on the checklist are met.
- Use reputable taxis if the researcher feels unsure about the area or it is late at night.
- Carry interviewer identification.

Conducting the Research Meeting

- Show identification.
- Establish identities of participants.
- Be cognizant of exit points.
- Do not conduct research if participants are intoxicated or appear to be angry or violent.
- Abandon the interview if the researcher feels unsafe in any way.
- Leave contact details for the researcher and the independent contact.

Follow-Up After the Research Meeting

- Use reputable taxis to return if the researcher feels unsure about the area or it is late at night.
- Contact manager.
- Conduct debriefing (undertaken with manager) as soon as possible after the research encounter.
- Alert colleagues handling the data to any areas of sensitivity.
- Share fieldwork experiences.
- Reflect on researcher safety at the individual level and for the research project as a whole.

Research designs need to make any additional costs explicit, especially to ensure adequate funding. For example, during fieldwork, resources may be required for transportation by taxis to attend research meetings (especially when visiting participants in their own homes or at night), paired interviews or payment for an escort when necessary, personal alarms, mobile telephones, lone worker telephone systems (i.e., systems that allow a telephone to be tracked remotely and have automatic

links with emergency services when required), immunizations, and counseling. Organizations must also have adequate insurance coverage. For example, insurance should cover researchers' personal possessions and personal injury while undertaking fieldwork.

The ubiquitous nature of risk requires individuals and employing organizations to take joint responsibility for ensuring safety at work. Risk assessments provide researchers with one key mechanism for identifying

early the difficulties they may encounter in the field. Employing organizations and research funders need to ensure that sufficient resources are in place to ensure that these risks can be managed effectively.

RESEARCHER SENSITIVITY

Using qualitative methods successfully requires researcher sensitivity. Researcher sensitivity refers to a host of skills that the qualitative researcher employs throughout all phases of the research cycle. For instance, the researcher needs to be sensitive to the impact that gender or class has on recruitment, data collection, and data analysis. The researcher also needs to be sensitive to issues of cultural and language differences. For example, the researcher needs to be aware that Muslim women are unlikely to participate in interviews with a male researcher and that in research with Aboriginal students, sensitivity regarding issues of cultural assimilation is a necessity.

The qualitative researcher also needs to be sensitive to nonverbal cues, such as changes in body language in interview contexts, and to informant interaction in focus groups. Likewise, the researcher needs to develop theoretical sensitivity—the ability to know when theoretical saturation has been reached. Theoretical saturation is the point in qualitative research where no new insights are likely to result from continued data collection and where data analysis accounts for differences as well as commonalities in the research findings.

Research with informants with Parkinson's disease provides further illustration of the use of researcher sensitivity in qualitative research. For example, an informant with Parkinson's disease copes with a variety of symptoms that may include exhaustion, muscular rigidity, and communication difficulties, all of which the researcher must be sensitive to and must account for in recruitment, data collection, and analysis. For instance, the qualitative researcher must understand that low response rates may mean that potential informants decline to participate in a qualitative study because qualitative research typically requires more energy from informants than do other types of research designs. Furthermore, the researcher must pay attention to the fact that increasing fatigue or muscle rigidity brought on by an informant's medication wearing off means that shorter interview times need to be scheduled and more follow-up interviews need to be conducted.

In addition, the qualitative researcher needs to be prepared for possible communication problems and may need to include family members or caregivers as participants in the interview. As a consequence, the researcher also needs to be sensitive to the impact of a third-party presence in the interview. Furthermore, the researcher needs to deal with the consequences of indecipherable audiotape recordings, large chunks of missing data, and very brief informant responses in research where there are communication difficulties. Moreover, researcher sensitivity in this case means an understanding of the interview as an interactive event where both the researcher and the informant are jointly responsible for any communication problems that may arise. The informant's speech should not be characterized as a "problem" that the "expert" researcher fixes; rather, researcher sensitivity allows one to see that problematic communication is something that is mutually resolved through the use of the communication skills held by both the informant and the researcher.

In addition to being sensitive regarding communication problems, conducting research with people living with illness means that the qualitative researcher must be sensitive to the meaning of silences in interviewing. Kathy Charmaz, a major figure in the area of qualitative research into chronic illness and disability, reminded us that what people do not say is as important as what they do say. Silence might mean that a topic is too painful to discuss and that the interview needs to move in a different direction. Alternatively, silence might mean that an informant is getting tired and that the interview should be discontinued. A period

Research With Vulnerable or Marginalized Groups

The need for researcher sensitivity is particularly highlighted in the case of research with vulnerable or marginalized groups such as people living with chronic illness or disability. For instance, many qualitative researchers have cautioned that in research with people who are ill, the researcher must be sensitive to the possibility that informants may experience the interview as traumatic. Although this is an important issue, it needs to be understood that researchers must also use sensitivity in order to avoid paternalism in their efforts to prevent harm. Equally important, they must be sensitive to the influence of members of various helping and other professions who may be present, especially in cases of research with people with chronic illness or disability. For example, in our focus group research with women with multiple sclerosis commissioned by a regional home care organization, Mary O'Connor, Julia Shelley, and I (Jacqueline Low) were asked by nurses and social workers to identify any participants who happened to cry during the focus group meetings. Home care representatives would then intervene with treatment for depression. We declined to do what they asked, instead offering to provide a list of available support services to all of the women who participated in the focus groups. We did so for three reasons. First, it is normal for people to express emotion when discussing emotional issues such as the experience of chronic illness, and such expressions of emotion should not necessarily be taken as signs of depression. Second, as social scientists, we had no specialized training, making any attempt on our part to diagnose depression inappropriate. Third, we also felt strongly that reporting women to the home care organization would have compromised researcher/informant trust and would have been antithetical to the philosophy of equal researcher/informant relations that underpins participatory action research.

of silence during the interview might even mean that it has become necessary to reconfirm informed consent before proceeding with the interview.

RESEARCH JUSTIFICATION

Research justification refers to the rationale for the research, or the reason why the research is being conducted, including an explanation for the design and methods employed in the research.

Elements of Research Requiring Justification

Traditionally in research conducted within any paradigm, researchers have been expected to provide an explanation about why the research is necessary. To explain the overall purpose, aims, and objectives, a rationale is constructed and may illustrate how the research endeavor addresses gaps in the existing knowledge base, contributes a new dimension or perspective, or generates theory about a phenomenon that has not been explored previously.

Another aspect of research for which one might sometimes find justification in any description is the choice of methods employed to generate data; for example, the explanation for selecting interviews, focus groups, or participant observation. Such explanations might include the opportunity to orientate to the participant's perspective through in-depth responses, to

probe and clarify, and to ask for examples in the case of interviews.

However, it is less common in accounts of research to find an explicit rationale for the choice of research paradigm (e.g., qualitative, quantitative, postmodern, critical/subtle realist). This may be because authors are less critically reflexive about the overriding perspective they bring to their research endeavor or simply because this has not historically been expected or required in accounts of research. Certainly, the word limits imposed by editors and publishers on contributors to some journals often preclude detailed consideration of one's ontological position.

Another area within qualitative research where explanation or rationale may sometimes appear to be lacking is choice of approach or methodology (e.g., grounded theory, narrative approach, discourse analysis). This is sometimes because the explanation is implicitly woven into the description of the methodology. For example, in writing about one's choice of grounded theory as the theoretical underpinning in a research project, one is likely to allude to the lack of prior research or theorizing about the social process being explored and to cite the work of Barney Glaser and Anselm Strauss in explaining how theory will be created and that it will be rooted in, or "grounded" in, the data generated. Thus, the implicit justification for the choice of grounded theory may be that no theory currently exists to explain a particular social phenomenon or that changing cultures and practices mean that existing theoretical explanations need to be tested and challenged with reference to new data.

Why Justification Is Considered Necessary

In posing the question "Why am I doing this research?," perhaps the most obvious response is "In order to answer a particular research question," and indeed the intellectual and/or practical problem prompting the research endeavor should feature prominently in any account of it.

In considering why qualitative research particularly is being carried out, the explanation is likely to include reference to a social phenomenon requiring in-depth investigation that will provide rich, complex, and detailed information about not only the object of inquiry but also the context in which it occurs. The justification may include an acknowledgment that the

exact form of the inquiry is likely to be flexible and at least partly dependent on emerging ideas and theories once the project has commenced.

Linda Finlay, for example, described how an interest in and a desire to learn more about the personal experiences of people with multiple sclerosis led her to adopt a phenomenological approach involving case studies with people diagnosed with this condition. The aim of the researcher working within an existential-phenomenological tradition is to ask "What is this kind of experience like?" Finlay carried out in-depth interviews with her participants. She believed that it was important to remain open to their stories as they emerged and used questions such as "Can you describe a typical day?" and "Can you describe that particular incident in more detail?" to elicit detailed personal accounts about how multiple sclerosis affects people's lives—their roles, their aspirations, their relationships, and ultimately their sense of self. Finlay showed how phenomenology can illuminate the depth of individual experience and provided a convincing justification for the use of qualitative research approaches in general and phenomenology in particular.

An important point here is that the way in which the research problem is described, the research question is framed, and the description of the subsequent methodology and methods is adopted to address the question should be ontologically coherent. For example, a discourse analyst is unlikely to be interested in exploring people's beliefs or attitudes but will be interested in how talk and text function in the social world to perform certain actions and the resources that inform how these texts are constituted.

In reality, the answer to the question of why someone is involved in a particular research project is likely to be complex. Jennifer Mason, for example, argued that it is important to include the sociopolitical context and moral/ethical dimensions in thinking about why research is being carried out. For example, research carried out as part of a master's or PhD program is undertaken in part to fulfill academic requirements and enable the researcher to gain the degree. Research carried out within a feminist or participatory framework is likely to have additional sociopolitical objectives around giving a voice to groups often disenfranchised in more traditional sorts of research. In acknowledging these additional motivations, Mason argued that one is more likely to recognize tensions and conflicts, to think reflexively about one's own role

in the research, to plan systematically, and to behave ethically.

How the Case for Research Is Made

The way in which research justification is provided depends to a large extent on the form of text in which it is required. One of the important considerations is the space or word length that one has available to create a rationale for research enterprise. However, there are different conventions about the sorts of material to include in constituting a rationale that are also contingent on the type of text being produced. This section addresses research justification in three types of documents: research proposals or plans submitted as part of funded grant applications, papers or articles, and dissertations or theses.

In each of these three types of documents, the literature review will play a key role in establishing the rationale for the research study to be undertaken. Shane Thomas identified a number of ways of achieving this. First, there is a need to demonstrate that the question the research project has been designed to answer has not been addressed previously. This can be achieved by demonstrating that one has carried out a systematic and thorough search of the literature, often using electronic resources. In this instance, it is usual to include the keywords used to search, the electronic databases included, and the years covered. Use of previous literature to demonstrate that other eminent researchers have considered the same area and topic to be worth investigating is also a compelling way to justify one's study. Researchers frequently identify areas for further research toward the conclusions of their studies, and these can be cited in support of one's own case.

A second form of justification used to support the case for research is to illustrate that a lot of people are affected by the problem to be investigated and that it consumes a lot of resources and/or has unfortunate consequences (e.g., creating a burden of disability, resulting in chronic pain). In research exploring older people's perceptions about falls, falling, and interventions to prevent falling, for example, most researchers in this area will cite the frequently quoted statistic that one in three people over 65 years of age falls every year. This may be accompanied by information about the potential consequences of a fall such as fractures, anxiety, and admission to a nursing home.

Another strategy that may be used in support of a particular research study is to show how, by addressing

this one specific research question, insight might be provided into other problems of a similar nature. For example, evidence-based guidelines have recently been published on the Prevention of Falls Network Europe (ProFaNE) website (www.profane.eu.org), suggesting ways of increasing older people's uptake of and adherence to fall-prevention strategies. In making a case to investigate how and why older people respond to these suggestions, for example, it would seem reasonable to argue that such research might shed light not only on perspectives in relation to fall prevention but also on other public health issues affecting older people such as cardiovascular fitness and the benefits of regular exercise.

In addition to the practical benefits to be accrued from undertaking research, one can argue that important insights will be gained in terms of theory development, which in turn might also have a broader impact. To pursue the previous example, one could argue that by further developing theory around adherence to fall prevention interventions by older people, such as the barriers and facilitators to adherence, one might develop theoretical insights that would be useful in relation to other health interventions for older people such as medication.

Finally, Thomas described the case for improved services or treatment as a strategy to provide a justification for research. Much research in the public domain is funded through government bodies or charities. For example, in considering health research in the United Kingdom, the Department of Health, through its research and development initiative, has funded a considerable amount of health-focused research, as have the medical charities such as the Parkinson's Disease Society and Action Medical Research. The usual process of applying for research funding is to submit a grant application, often accompanied by a research proposal, in response to a call for proposals issued by the funding body. These may have specific remits and objectives or, alternatively, may ask applicants to identify their own focus, but they identify general criteria that the applications should fulfill.

In writing a grant proposal, one of the primary considerations that the funding body will be checking is that the application expressly meets the aims of the call for proposals. This is usually considered both by considering the aims and objectives of the proposal and by reviewing the introduction, background, and literature review to ensure that a well-argued, well-evidenced,

and robust case has been made. The funding body will also scrutinize the proposed methods and funding details to ensure that the proposed process appears realistic, is likely to meet the objectives, and seems feasible. The experience of the researcher, particularly in managing previous funded research projects, is also pertinent.

The focus in applications for funded research, then, is on demonstrating that, as a researcher, one is familiar with the field of study, knows of relevant previous research and can see the potential to contribute a new and valuable perspective, has the capacity to successfully organize and conduct a research study, and is likely to disseminate findings effectively. These considerations will be closely linked with the funding organization's own mission and objectives. Because the reviewers might not have expertise in the specific methodology being proposed, the focus perhaps tends to fall on the practical use and application of the research and the capacity of the applicant rather than on more abstract theoretical concerns.

In written papers or articles, the researcher as author may be able to focus more on the justification for using a particular methodology to address a specific question and, depending on word length, may be able to expand on the previous literature in the field. Whereas experienced and well-resourced grant-awarding bodies may expect detailed critique and justification of the research approach to be adopted, editors of highly respected peer-reviewed journals will certainly expect these points to be addressed, albeit succinctly.

Research dissertations and theses clearly have longer maximum word limits, thereby permitting researchers/authors to write in depth. However, conventions surrounding how this is addressed in theses are also subtly different in comparison with the texts described previously. To clearly demonstrate to examiners that the authors/students clearly understand the nature of what they are doing and the traditions within which they are working, justification of all elements of the research is required, including the aim and purpose, paradigm, particular methodology adopted, methods used, and form of analysis. For students, therefore, the production of the literature review is a key opportunity to demonstrate a critical capacity and the ability to marshal one's arguments effectively.

RESEARCH LITERATURE

Research literature can be defined as written reports from research studies. There are many types of research literature, with published research articles representing the most common source for research literature. Other sources include dissertations, books, and internet websites.

Published research articles, for some, are considered the most trustworthy type of research literature. When identifying articles, it is most important to consider the origin of the work. For example, some published research literature articles have the added benefit of being peer reviewed. Peer review is a process whereby literature is read and reviewed by others, and the reviewers must deem the work to be worthy before it can be published. Typically, the reviewer does not know who the author(s) is and vice versa, a process known as a double-blind review that reduces undue reviewer bias. Another important aspect to consider in regard to the origin of the work is who the author(s) is. In most areas of research, there are existing research literature articles written by authors who have published repeatedly in the area. Knowing who these authors are for a given area that is being investigated can assist researchers in identifying relevant research literature.

Dissertations are another source of research literature. Dissertations typically are considered as published works and can be found in databases such as ERIC. Using dissertations as research literature can assist researchers in knowing what new researchers in the field are investigating. Also, dissertations often

contain studies that have not been published but contain helpful information. It is important to remember that the review process for dissertations can be inconsistent; there are no agreed-on standards across colleges or universities for quality of dissertations. Thus, faculty members who serve on the committee for the student who wrote the dissertation often are the only readers and the only ones who have judged the dissertation to be worthy.

Books, which represent another type of research literature, can be very helpful for researchers, especially when broad topics are being investigated because most books include general information. There are many books available that are conceptual in nature, thereby not reporting specific research findings. When using books as research literature, it is necessary to remember that, unlike some research articles, books are usually not peer reviewed and can include opinions of the author(s) that are not based on research findings.

Internet websites are another helpful source of research literature. Checking the internet for information regarding the topic under investigation can help researchers to identify other researchers' work. For example, by searching the internet for the topic of interest, one might find research literature based on studies. Furthermore, the internet is beneficial in helping to identify other sources of research literature (e.g., books).

There are many places to search for research literature. Library databases, such as ERIC and PsychInfo, include many published research articles. The internet website Google Scholar can help researchers to identify peer-reviewed articles, abstracts, books, dissertations, and theses.

Being careful readers and remembering that just because works are published or appear on the internet does not mean they represent reliable sources can assist researchers in locating relevant research literature.

RESEARCH PROBLEM

The research problem addresses what researchers perceive is wrong, missing, or puzzling, or what requires changing, in the world. Presentations of the research problem typically set the stage for the study that will be, or that was, conducted by offering evidence that the problem exists and for whom and by establishing the significance of the problem and why it requires formal inquiry. The research problem, the details of which are fleshed out in a literature review that critically addresses what is known and yet to be known about the problem and how it has been conceptualized and studied to date, leads directly to the research purpose(s) and research question(s).

The research problem may be a clinical/practice, theoretical/disciplinary, or methodological problem. An example of a clinical/practice problem is that virtually perfect medication adherence—as conventionally defined in the health sciences literature—is required to prevent the transmission, and development of resistant strains, of HIV. Although numerous studies have indicated that adherence is sporadic, few of them offer explanations for this state of affairs that are useful in practice. The research purpose, therefore, is to study adherence practices in a group of HIV-positive patients to explain the circumstances for taking or refusing medication. An example of a theoretical/disciplinary problem is that medication adherence has typically been treated in empirical health sciences research as a behavior characterizing individuals whereby they either take or do not take medications as physicians prescribe them. Because of this narrow view of adherence, the findings of empirical studies of medication adherence have been inconsistent, contradictory, and inconclusive. The research purpose, therefore, is to study medication adherence as located in a larger arena of patient work as this is conceived in the sociology of work. An example of a methodological problem is that researchers in the health sciences are increasingly calling for the incorporation of qualitative methods into systematic reviews, yet few methods have been

developed or tested to accomplish this. The research purpose, therefore, is to develop methods to synthesize qualitative and quantitative research findings in targeted domains of health sciences research.

Because of the fluid and emergent nature of qualitative research design, the research problem that set the stage for a study might not be the one, or might not be conceived in the same way, as the problem researchers come to see as the study proceeds. For example, the clinical problem initially conceived to be imperfect medication adherence may be reconceptualized as a theoretical problem as researchers question the validity of understanding adherence as located in the individual. Accordingly, one kind of problem may become another kind of problem, and the research problem may both set the beginning stage for and become a finding of a study. Like research purposes and questions, research problems in qualitative research are both the stimulus to and the outcomes of inquiry.

RESEARCH PROPOSAL

Research proposals are documents prepared for two primary purposes: to help researchers articulate their plans for research and to convince others (e.g., funders, colleagues, supervisors) that the plan for a research study is sound. In essence, then, the research proposal is a plan for intended research.

Parts of a Research Proposal

Typically, there are several fundamental parts of any research proposal. One key piece is the justification for the research, which addresses the purpose of the research, answering the “so what?” question. This is where the researcher has the opportunity to make the

case for the research, whether resources are being requested or not. This case should be made as convincingly as possible, with reference to both short- and long-term potential interest and value. Justifying the importance of the research requires that the research questions be contextualized in terms of a larger research problem and tied to larger questions of theoretical and/or practical importance. That context includes reviewing the literature to indicate what has been researched in the area to date and to demonstrate a need for further research; that is, for the particular piece of research being proposed. Specific research objectives may or may not be expected; however, the proposal must articulate the specific research questions that the study will address. These questions should flow logically from the research problem or context. The overall research design articulates how the research questions will be addressed. In this section, the methodology or theoretical perspective to be taken should be explicated. Will the study take a constructionist or phenomenological approach? What is the theoretical lens through which the study is being conceived? What will be the theoretical basis for data analysis and interpretation?

In addition, specific data collection methods are also described, including addressing the questions relating to what, where, when, how, and about whom data will be collected. Will people be involved as research participants? If so, how will principles of ethical research conduct with people be upheld? The researcher should be aware of where formal ethics approval needs to be obtained and should either have that ethical approval included as part of the proposal or indicate an intention to obtain approval. Known limitations and parameters of the study, as well as assumptions on the part of the researcher, should be stated. Qualitative research proposals should address the methods being employed to ensure trustworthiness (e.g., triangulation of methods, member checking). Sometimes expected venues for dissemination of the research results are articulated in the proposal. A timeline for the study is a useful addition to help the researcher think realistically and ensure feasibility. The final logistical element is to make clear what other resources are needed to complete the work (e.g., funding, personnel, equipment, supplies). These logistical elements must be carefully considered and researched to ensure accuracy; this kind of precision is important to demonstrate competence on the part of the researcher. The role of the principal investigator

(presumably the author of the proposal) should be made clear, whether the researcher is conducting the study alone or with the assistance of others. Sometimes a proposal includes some description of the principal investigator's background, which provides assurance of the experience and skill set necessary to ensure success of the proposed study.

The relative emphasis on each of these aspects of the research proposal depends on the situation. For a doctoral student proposing his or her dissertation research, each aspect may be weighted relatively equally, and close scrutiny will be paid to each section. Often a more mature researcher exerts less effort articulating specific methods in a grant application, for example, if his or her research track record indicates experience with the methods proposed.

The different parts of the research proposal also must be conceptually and logically consistent. The research questions should flow plausibly from the research problem and the literature review. The methodological approach should be consistent with the way in which the research questions are posed, and the specific data collection methods should be consistent with the methodological approach. A clear and logical link between the research questions and the data to be collected should be evident; that is, the data should be expected to address the questions to be explored. The proposed methods for data analysis also should be logically consistent with the methodological approach.

The Written Document

A proposal may consist of only a few pages, or it may be extensively detailed; in all cases, however, a proposal should be written so that others may comprehend it. Research proposals require careful attention to detail and clear concise writing. A proposal must be organized logically and should be presented consistently both conceptually and in its presentation. Subheadings are a useful addition for the reader. Proposals outline plans for the future, so future tense is appropriate. Often proposals are written for an "educated audience" rather than experts in a particular field, especially for grant applications. Thus, jargon should be avoided, and concepts and language specific to the field must be carefully defined. Even concepts for which definitions are considered to be widely shared should be carefully defined both to ensure conceptual clarity for the researcher and to ensure mutual understanding by others. In general,

care should be taken to ensure that the writer makes as few assumptions as possible about the substantive background and knowledge of the intended reader. Most important, a proposal must be written and presented in such a way that the proposed study appears to have excellent potential for successful completion. Therefore, it is good practice to obtain feedback on draft versions to ensure completeness and accuracy.

A research proposal ultimately is judged on whether a sufficient and convincing argument has been made for the research study. That argument must be conceptually strong, the study plans must be feasible and logical, and the researcher must be judged as competent to carry out the specified plans.

RESEARCH QUESTION

Research questions designate what researchers want to understand about the research problem that led to their study. Research questions further specify the stated purpose of the study, which in turn addresses the stated research problem.

In contrast to quantitative studies, in which research questions are always specified prior to study, in qualitative research they may be the result of having entered the field of study and, thereby, arriving at the relevant questions to ask. Whereas research questions in quantitative research restrict, and commit researchers to, the variables that will be addressed, research questions in qualitative research are broad enough to permit the discovery of the specific experiences, events, artifacts, concepts, or other empirical and/or analytic subjects that will ultimately be the focus of study. In keeping with the interactive and

emergent nature of qualitative research design, and the cyclic and data-derived nature of qualitative analysis, research questions are ultimately the outcomes of the concerns, curiosities, and fascinations that first led investigators to enter a field of study and that they later developed while in the field.

Qualitative research questions often signal initial theoretical orientations toward a target experience or event even when such orientations are never explicitly stated. The very way in which research questions are posed reveals researchers' preconceptions and proclivities toward the target of study. For example, to ask why one group of people does not use hospice care is often to assume that the group should, and it is also not to ask why other groups of people do use hospice care and why they should not. Qualitative research questions also tend to signal initial methodological orientations toward the study of a target phenomenon even when they are not explicitly stated. When research questions are asked about the nature of experiences and events, how and why things came to be, and how sense or meaning is made of an event, a desire is being communicated phenomenologically, theoretically, narratively, or otherwise interpretively to describe or explain that event or experience. For example, phenomenological research questions tend to address what it is like to be, to have, or to live questions in the interest of developing feeling understandings of experiences, whereas grounded theory questions tend to address social (inter)action in the interest of theoretically modeling social processes.

Research questions are usually distinguished from the questions researchers actually ask participants in interviews or in the course of field observations or ask of data in the course of analyzing them. Although the questions participants answer and the constant questioning process that defines qualitative data collection and analysis are in the service of answering research questions, they are not equivalent to them. For example, the interview question asked of participants, "Tell me about your routine day," is in the service of the research question, "How do people with chronic illnesses manage their lives?"

RESEARCH SETTING

The research setting can be seen as the physical, social, and cultural site in which the researcher conducts the study. In qualitative research, the focus is mainly on meaning-making, and the researcher studies the participants in their natural setting. The contrast with postpositivist, experimental, and quantitative research settings lies in the fact that here the investigator does not attempt to completely control the conditions of the study in a laboratory setting, instead focusing on situated activities that locate her or him in the context.

For example, in traditional ethnographic studies, the observer becomes immersed in the community that she or he is studying. Historically, through the colonial project, such settings were where the "natives" lived in the study of "other" cultures conducted by missionaries and state-sponsored researchers, a tradition continued later by Western anthropologists. However, Indigenous research practices are now framed against imperialist oppressive research, raising questions of power and privilege at the intersection of race, gender, caste, class, and sexuality. These play a significant role in determining the subject of study, the participants, and thereby the setting. Ethnographic research now emphasizes the embeddedness and reflexivity of the researcher in the cultural setting of the participants. In such studies, the influence of cultural behavior in the understanding of a phenomenon gets recognized and, therefore, is central in defining the setting.

Linda Tuhiwai Smith, among others, has redefined research practices through challenging who studies whom and where. Research setting, then, can refer to a geographical site where the participants of a study reside. Or, it could be a group that is being studied. It could be the everyday lives that we live and study, the films that we watch, the texts that we analyze, the feelings that we interrogate, the bodies in which we reside, and the myriad interpretations and constructions of reality and the world that we, as researchers, are constantly trying to negotiate and "re-present." More recently, performance (auto)ethnography has introduced the idea of the self as the context and setting for

research. Through the use of “mystory” and other formats, researchers such as Norman Denzin have talked about their selves, turning points in their lives, their epiphanies, and their times of trouble in reflexive ways using various techniques of telling. They have situated their selves and their bodies as the sites of research and study.

Participatory collaborative research now considers the setting as beyond the group that is performing and conducting the research in dialogue with the researcher and has moved toward including the larger sociocultural field in which we lie embedded as researchers and participants with the goal of social change. Global ethnographies talk about how the global is embedded in the local; thus, when we talk of a specific local research setting, we also need to acknowledge that the setting is now truly global. These local–global studies, illustrated in the work of Michael Buroway and others, now emphasize the need for multiple sites and settings in understanding larger issues that challenge our world and remain the focus of qualitative research practices.

RESEARCH SUBJECTS

See PARTICIPANTS

RESEARCHTALK, INC.

ResearchTalk, Inc., provides consultation and professional development for qualitative researchers throughout the United States and Canada, with emphases in the areas of research plans, fieldwork, analysis strategies, results presentation, and software skills

integration. The company is based on Long Island, New York, and was founded in 1996 by Raymond C. Maietta, the company’s president.

Research Plans

ResearchTalk helps clients to design data collection and analysis strategies that provide insight about the processes that guide decision making and daily activities. By introducing more involved, open-ended discussions with respondents, researchers begin to understand better how and why people develop attitudes and engage in behaviors.

In the Field

Fieldwork should yield rich descriptions and explanations of behaviors and attitudes via thoughtful discussion and observation strategies with respondents. ResearchTalk works with clients to establish a window into the day-to-day lives of participants. In-person sessions, such as face-to-face interviews, focus groups, and on-site evaluations of a phenomenon typical of ethnographic fieldwork, can provide this window.

Analysis Strategies

Maietta created the “Sort and Sift, Think and Shift” qualitative analysis method. Sort and Sift emphasizes strategies to attain deep familiarization with data as an initial step in data analysis. This phase defines the creation of document and case profiles, codebooks, and memo-writing strategies. ResearchTalk works with clients from the beginning of, or deep into, a project to compare early project goals with emergent issues that arise during analysis. Some researchers apply techniques included in the Sort and Sift method, whereas others use methods familiar to qualitative researchers, including grounded theory, phenomenology, and ethnographic methods.

Results Presentation

Communication of key findings presents unique challenges to qualitative researchers. Frequently researchers wait to “finish” analysis before working on final presentation of qualitative information. Alternatively, building memos and visual diagrams throughout the life of a qualitative analysis project can result in an evolving presentation of materials in sync with data analysis.

ResearchTalk works with clients to develop tools with qualitative software, Word, Excel, and PowerPoint that provide opportunities to think out loud and refine ideas that emerge throughout an analysis.

Software Skills Integration

ResearchTalk's software integration strategies introduce users to software via necessary components of any qualitative analysis project. This approach ensures that software does not redefine how analysis proceeds but instead serves as a complementary tool for data organization and access. The focus, then, remains on the substance of the data and the analyst's responses to it.

Websites

ResearchTalk, Inc.: <http://www.researchtalk.com>

RESEARCH TEAM

A research team involves all of the individuals who contribute directly to a research project. Research teams can vary in size from an individual researcher working one on one with a student assistant to large-scale projects involving multiple co-investigators, collaborators, student assistants, nonstudent assistants, and technicians working across numerous sites. In participatory research approaches, research participants themselves may be considered as co-researchers and, therefore, as members of the research team.

Research teams may work on a single time-limited research project, a parallel series of research projects, or a range of ongoing projects. Regardless of size, composition, and duration, research teams can function in collaborative, hierarchical, or distributed ways. Team members may include academics and nonacademics from similar or diverse employment situations, disciplinary backgrounds, and career stages. Consistent with the emphasis on reflexivity in qualitative research, some teams include distinct roles for team ethnographers to document the collaborative process, to facilitate team functioning, and to contribute to effective evaluation of the collaborative work.

As research teams increase in size and complexity, leadership within the team becomes increasingly important. Any member of the team may fulfill a leadership role on a temporary or continuing basis. Strong leadership is essential to the project management process, including coordinating team members' activities, monitoring progress toward research goals, redirecting efforts as the research plan evolves, and maintaining clear communication within the team. Leaders also play important roles in assuaging tensions or conflicts that may arise within the team.

Research teams are well advised to develop written policies about teamwork and authorship principles. As a general guideline, the order of authorship should reflect (so far as possible) relative contributions to a particular publication regardless of the authors' respective roles in the research project. In some cases, authorship credit may be granted to the research team as a collective such that the work is published under the research team name rather than under individual team members' names.

Research teams provide clear opportunities for mentorship. Experienced researchers are well placed to facilitate the learning and development of junior researchers, including community members and students, as they work together on a research team. More broadly, research teams provide space and opportunity for all team members to contribute to the learning of other team members regardless of status and experience. Researchers who appoint student research assistants to their research teams are ethically obliged to ensure that the research assistantships are educative. Student research assistants provide necessary labor that is needed to complete the research, and they typically receive some form of financial compensation, but they are also expected to learn new skills and aptitudes through the project and to receive appropriate credit for their intellectual contributions. Student assistants require appropriate task assignments and adequate supervision.

RESONANCE

Within an interpretive tradition of qualitative research, resonance refers to a researcher's posture of openness and receptivity toward potential meanings embedded in text. It serves as an important ontological and epistemological counterpoint to the postpositivist stance of objective analysis of data.

Texts as representations of human experience are assumed to be social constructions imbued with meaning—by the author of a text and those who resonate with it. As Elliot Eisner suggested with the concept of *connoisseurship*, it is a researcher's sensibilities that allow him or her to see the nuances of a text with an "enlightened eye." Barney Glaser and Anselm Strauss, in formulating grounded theory, offered the term *theoretical sensitivity* to connote a similar capacity of researchers to engage insightfully with texts of a social phenomenon. Writing within a tradition of existential phenomenology, Hans-Georg Gadamer argued that "our sensitive-spiritual existence is an aesthetic resonance chamber that resonates with the voices that are constantly reaching us" (p. 8). As Gadamer's observation suggests, resonance is not an analytic technique. Rather, it stems from our very existence, our way of being and relating in the world. Thomas Schwandt, drawing on Deborah Kerdeman's interpretation of Gadamer, pointed to the relational nature of understanding and the transformative possibilities that arise when researchers are open to the "other." The quality of openness to voices that are reaching the researcher's ear might be likened to a finely tuned musical instrument capable of picking up and reverberating with external vibrations. In extending this musical analogy, it is useful to consider resonance in concert with *dissonance* and *consonance*. As Maureen McCarthy Draper explained, "*dissonance* refers to intervals or chords that create tension because they are unstable and therefore generate the energy to move—the opposite of *consonance*, in which sounds are relatively stable and free of tension" (p. 46). Resonance connotes a capacity to hear both

consonance and dissonance—the harmonies and disharmonies. Reverberating with the consonance and dissonance within a text allows researchers to discern a multiplicity of potential meanings associated with the phenomenon under study. Through a richly nuanced representation of these meanings, an inquiry may strike a responsive chord in others, thereby allowing for what Robert Stake called *naturalistic generalization*. Vipassana Esbjorn-Hagens and Rosemarie Anderson, in describing intuitive inquiry in psychology, used the concept of *resonance validity* to describe this mode of extending meaning beyond the specific context of a study to a broader, more universal audience.

RESPONDENT

Respondents are those persons who have been invited to participate in a particular study and have actually taken part in the study. This definition applies to both qualitative and quantitative studies. However, respondents of a qualitative study have special roles in that not only are their answers in aggregate important to the study, but also their respective voices are essential to the study's evolution and findings.

Respondents are derived from the sample that is constructed for a qualitative study. In designing the sample, the researcher focuses on potential respondents who have some level of familiarity with the

phenomenon under investigation. Furthermore, in recruiting individuals, the qualitative researcher must be keenly aware of what aspects of the study (e.g., subject matter, length of interviews, incentives) will encourage individuals to accept or decline the invitation to become respondents. These issues are important when considering which type of respondents are best suited for the study—adults, children, parents, men, women, cancer survivors, educators, prisoners, union members, and so on.

In most qualitative research, the aim is to give voice to the individuals or respondents who decide to participate in the study. When the study focuses on populations that are difficult to access or have special human subjects considerations or restrictions, the qualitative researcher must take all of these factors under consideration when developing a sample that will generate enough respondents to conduct an adequate analysis to explore the topic under investigation and address the research questions posed.

This concern raises the question of how many respondents are enough. For quantitative studies, statistical formulas typically dictate the minimum number of participants needed. In qualitative studies, there are no hard-and-fast rules to indicate when a qualitative researcher has reached the optimal number of respondents and may stop data collection at 10, 20, or 50 respondents. In addition, the number of respondents required is often dictated by the type of qualitative approach used for the study (e.g., 10 for phenomenology, 20–30 for grounded theory), timelines, resources, and the investigator's personal limitations and intuition regarding the costs and benefits with respect to recruiting more respondents. For a graduate student, the guiding factor may ultimately be the dissertation committee's recommendation or the student's defense date.

Although this may appear to be a real quandary, it is not. All respondents, whether their involvement comes by way of formal or informal interviews, observations, journal writing, email exchanges, or chat rooms, add to the wealth of data so that new knowledge is gained. When new knowledge declines with each additional respondent, the researcher has most likely reached the appropriate point at which data collection may cease.

Finally, *respondent*, *participant*, and *informant* are terms used to characterize individuals who participated in a qualitative study. All three terms convey a very sterile, impersonal, and distant relationship with

individuals who give of their time and voice to the researcher who wishes to better understand and learn something new about a particular human experience. As such, the term *respondent* falls short of communicating this very important aspect of qualitative research. The term *participant* comes much closer to capturing the true meaning and aims of qualitative inquiry. Nevertheless, in the end, the investigator must determine which term best suits the study.

RESPONSE GROUPS

Response groups are a research and pedagogical tool that can be useful in a wide range of contexts, including peer debriefing and interpretation of data. Response groups have derived from the work of literacy researchers and educators in relation to reading, writing, and oral communication. Response groups enable a community of researchers/participants to share perspectives and also support the notion of research and writing as a collaborative venture. Through participation in response groups, researchers both provide and seek oral feedback to their data or their formulating ideas and analysis. Development of a community fosters awareness of audience for researchers, and knowledge of audience enables researchers to become more aware of possible strategies for interpretation and response to interview and document data. Effective data analysis and interpretation is enhanced through anticipation of an audience, and response groups provide a real audience and genuine reactions from a community of researchers/participants.

Writing response groups encourage writing as an activity of social and communicative nature, and they provide not only a genuine audience but also a real

purpose for which to write. The writing of research findings becomes a purposeful activity that is located within a research community and provokes action. Response groups enable researchers to have their writing responded to in a constructive processual manner through participant or peer debriefing.

Writing and research writing in particular are interactive activities and should be purposeful and meaningful; researchers need to continually remember who they are interacting with and the purpose of their research. Hence, response groups have, until recently, been conceptualized as face-to-face encounters, with members of the group being close together in such a way that all voices can be heard and shared. Writing is shared in a variety of ways, including reading aloud, distributing printed copies prior to the response group meeting, and sharing copies at the time of the meeting. Response group members read or listen to the text being discussed before responding.

Since the more recent developments of technological tools, computers have provided an alternative way to conceptualize response groups. A new social organization via online interaction has enabled a variety of peer collaborations and communities of researchers and participants to develop.

Literature response groups involve communities of learners in exploring issues and genuine questions related to common research interests in relation to their own lives. Through response groups, readers are invited to extend and revise their thinking about concepts or theories. Response groups as part of a process of learning from literature encourage prolonged involvement with a concept or theory.

Response groups have provided an approach for encountering data in process rather than only as a product. Response groups can, by virtue of the existence of real and meaningful interaction, encourage development and revision of ideas and of ongoing interpretation and depth of understanding of findings so as to best reach the intended audience in the most engaging ways possible.

RESULTS

See FINDINGS

RHETORIC

Rhetoric is the “art” of persuasion, of convincing the hearer or reader of a particular line of argumentation. Handbooks of classical rhetoric constitute a codification of practically any expression possible in words. At the same time, classical rhetoric is based on an engagement with the audience as recipient and recognizes that the situatedness of communication includes the writer/speaker, the audience, and text.

Together with grammar and dialectic, rhetoric formed part of the ancient *trivium* that was the basis of education from ancient times until well into the 19th century. However, as early as the 16th century, rhetoric began a period of progressive narrowing and decline until it fell into complete abeyance. During recent times, the power, complexity, and subtlety of rhetoric as a feature of all discourse and of persuading a particularly constituted audience has produced, among other things, a view of all texts as representations that are the product of the reworkings of other texts and an understanding of the research practices of human inquiry as essentially rhetorical.

An approach to data in terms of genre, difference, definition, division of an assertion into its parts, etymology, and comparison corresponds to the “places” or “topics” of rhetoric that operate as potential guides to choices, possibilities, and alternative ways of thinking about data. When, for example, a qualitative researcher thinks about the kind of questions that will obtain “rich” data, he or she is engaging with the first step of rhetoric—invention. Integral to further steps of rhetoric are models of organization, arrangement, contiguity, and amplification. The latter, for example can take several modes such as providing examples, the use of icons, visual devices (e.g., diagrams), concordant authorities and theories, cause and effect, and detailed description and repetition with modifications.

Much of the data of qualitative research is in the form of partial situated knowledge from which the researcher, in the process of analysis, moves from the known to the unknown, abstracting some distinguishing mark or

governing metaphor. Metaphor is one of the main figures or tropes of rhetoric. However, this is not to say that rhetoric can be mapped directly onto qualitative method; rather, it serves to deepen the researcher's thinking about the possibilities of representation in terms of style, the articulation of knowledge, and the production of rational modes of inquiry based on different argumentative structures.

RHYTHMANALYSIS

Rhythmanalysis is based on a conception of people, places, and things as having rhythms in relation to our minds and bodies. This places an emphasis on repetition, measure, and the way things are linked—their rhythm—rather than their fragmentation, the way individuals and groups create “moments” as part of social relationships and individual consciousness, and how the repetition of these moments creates situations. It is useful to think of rhythmanalysis in terms of the metaphor of wave patterns of the social, spatial, and temporal and how they mutually shape one another, absorb each other, fade, return, and travel through each other unhindered, producing a polyrhythmic field at the center of which are the rhythms of the body and mind in place. The body

itself is conceived of as polyrhythmic and subject to both normal and disruptive rhythms in its physiological, psychological, and mnemonic functioning that, unlike the overt rhythms of gesture and expression, are often concealed.

Thus, rhythmanalysis is of particular relevance for the analysis of the disjuncture between biological and natural or cosmic rhythms and the imposed rhythms of technology and of socioeconomic organization and production. Another area of particular relevance for rhythmanalysis is knowledge founded in a conflation of the body–mind duality, knowledge that is embodied and is, in part, engendered by the situatedness of practices and the production of space. Thus, rhythmanalysis attempts to uncover the ways in which, for example, the production of place mobilizes the rhythms of interiority and action and changes social relations. An example of this would be the way in which the workplaces of artists, architects, designers, and writers involve the construction of a set of configurations and rhythms of activity that exceeds the traditional view of creative activity as place independent in favor of one that emphasizes the relations between the inside and the outside, the internal world and the external world. The way in which artists produce the space of their practices, the linear nature of their daily routines, the cyclic nature of their processes, and the detailed investigation of processes of idea generation, modification, and development is sometimes described as a drafting process.

From this, it will be understood that rhythmanalysis is often practice related. The diversity of rhythms in practices is concealed, and the efficacy of rhythmanalysis hinges on the way the hidden aspects of the multiple strands of the social, temporal, and spatial are unraveled and grasped. This requires a close study of the details of everyday life that raises questions as to the nature of change and repetition. The analysis of repetition with modifications, but also returns that reintegrate at another level what has been surpassed, is one of the key activities of rhythmanalysis.

Thus, rhythmanalysis involves a notion of repetition that produces difference in a cyclical notion of time rather than a linear one. The cyclical is manifest in social organization, and the linear is manifest in daily routines. In cyclical time, new cycles are produced from completed ones.

The notion of internal and external measure is also important in rhythmanalysis. External measure would be the time of the clock that is imposed on internal

measure as the differentiated sense of lived time that is present in the way we repeat actions but with a qualitative difference. In general, rhythmanalysis involves a differentiated conception of time that is interwoven with the production of space in which we act and react to objects and people.

Research itself has its rituals that create their own particular rhythmic repetition of acts in a certain sequence that initiates, sustains, or brings things to a close. A good way to start rhythmanalysis is to examine one's own rhythms of intellectual and creative activity and how they are interwoven with place and the way repetition supervenes on them as a source of difference and renewal, thereby constituting rhythmanalysis in its reflexive dimension as an exploration of the researcher's relationship to place and things and of the rhythmic passage through mediations and changes as self-knowledge.

The diversity of rhythms in places and practices is concealed, and the efficacy of rhythmanalysis hinges on the way the multiple strands of the social, temporal, and spatial are unraveled and grasped. The difficulty is one of comprehending the role of each rhythm in the whole rather than in isolation. This does not preclude the identification of a determining or co-coordinating rhythm that may indeed be expressed as a governing metaphor or trope. Thus, rhythmanalysis by definition adopts a multidisciplinary approach, often one that engages with philosophical perspectives on the nature of time and space or place. A difficulty in rhythmanalysis is that, on the one hand, repetition enables the analyst to grasp a given state of things in a prospective and retrospective way because they are repeated with modifications but that, on the other hand, materials, actions, texts, and other data must during the process of analysis be elevated qua presentation to a state of simultaneity. This makes simultaneity not so much a temporal category as a function of presentation that can be approached in many ways; for example, collage and microcomputer applications such as hypertext.

Rhythmanalysis has a sound philosophical basis in phenomenological perspectives that allow consciousness to become reflective and reveal the interwoven nature of the substrata of human activity, the imbrication of the subject in the "other," and the situated nature of practices. Nevertheless, since its inception, and partly because of its combination of poetry and science, rhythmanalysis has produced theoretical, conceptual, and procedural difficulties. However, in the light of more recent developments in the area of

qualitative research methods, Henri Lefebvre's fragment, "Rhythmanalysis of Mediterranean Cities," provides an outline of a potentially powerful approach to arts-based research worth revisiting.

RICH DATA

The term *rich data* describes the notion that qualitative data and their subsequent representation in text should reveal the complexities and the richness of what is being studied. Although it is never possible to comprehend all dimensions of a phenomenon, the qualitative researcher seeks to understand what is being investigated as deeply as possible and to situate it within the context of time and space rather than in isolation. As a result, time is an important investment in qualitative research. Prolonged engagement with research participants and sites enables the researcher to get a sense of the multifacetedness of what is being examined. The amount of time actually spent in the field depends on the specific project. Some qualitative projects can be completed in months, whereas traditional ethnographies require at least a year

in the field. However, the amount of time required to fully understand a phenomenon can be infinite.

Equally important to qualitative research are the kinds of data being collected. The qualitative researcher typically triangulates data by collecting multiple kinds of data that usually, but not exclusively, include interviews, observational fieldnotes, researcher journals, documents, and other kinds of artifacts. Interviews tend to be open-ended so that participants can share their thoughts and perspectives as fully as possible. Observations and artifact collection lead to better understanding of a phenomenon in the moment, over time, and through various perspectives. Examining different types of data regarding the same phenomenon enables the researcher to better understand the complexity of what is being studied and increases the trustworthiness of the data as well as the interpretations of the researcher. Various kinds of data also help the researcher to understand the richness of the phenomenon being examined.

Collecting rich data, however, is for naught unless the rich data are subsequently interpreted and represented. Quality qualitative research is often described as having rich “thick description,” in the words of Clifford Geertz. Rather than merely recording events, people, and places, thick description seeks to present and explore the multifaceted complexities of the situation being studied, the intentions and motivations of the actors involved, and the context of the situation. By doing this, rich thick description engages readers. It should also give readers a sense of the complexity of the reality about which they are reading only a partial representation. This kind of description is achieved in numerous ways, including the telling of rich involved stories, the use of lengthy quotations from participants and written documents, and the inclusion of researcher fieldnotes and journal entries. In short, rich thick description builds on rich data to grab readers, giving them a sense that they are there, experiencing what the researcher is representing.

RIGOR IN QUALITATIVE RESEARCH

As a concept, rigor is perhaps best thought of in terms of the quality of the research process. In essence, a more rigorous research process will result in more trustworthy findings. A number of features are thought to define rigorous qualitative research: transparency, maximal validity or credibility, maximal reliability or dependability, comparativeness, and reflexivity.

Transparency, as its name suggests, refers to clarity in describing the research process. Here researchers are providing their audience with a thorough description of the steps taken in conducting their research. They are, in effect, providing an audit trail. This accomplishes two main things. First, if others want to replicate the research to see whether they achieve similar results, they can. Second, it enables readers to assess whether the method chosen was the most appropriate for answering the chosen research question.

Because a valid or credible study requires that the data be represented fairly and accurately, the representation of the data also affects the rigor of a study. Various means can be used to help enhance credibility. First, looking for and citing negative cases is important because doing so illustrates that researchers are not just looking for cases that support their theory. Second, member checks can also add to the credibility of qualitative research because they indicate that researchers have confirmed their findings with the individuals from whom they have collected the data (i.e., the people whose ideas are being represented).

When a study is reliable or dependable, similar participants and research methods should generally lead to similar results. One way to attend to this issue is to use more than one coder to see whether the same kinds of themes result from their analyses. Furthermore, regular discussions of coding results with colleagues can also be a means for improving dependability. This helps to assess whether researchers' interpretations are in line with what others are thinking.

Comparability is yet another criterion that helps to denote the rigor of a qualitative study. In essence, researchers should be comparing the various cases with one another so that they can build a theory that represents all of the voices present in their findings. Furthermore, it is also of value to compare findings with the findings of other research scientists so as to relate what has been found back to the broader research context.

Finally, a rigorous qualitative study is built on the notion of reflexivity. Here researchers must account for the fact that their presence has some influence on the research findings, and they should attempt to report how they, as the primary research instrument, may have influenced the study's results.

Using these criteria for building a rigorous research study will enable qualitative researchers to report results that are considered as both useful and credible by their peers.

RISK

Risk is a value-laden concept that can be viewed positively or negatively. Risk-averse scientists will postpone a space shuttle launch when weather conditions threaten human life, whereas successful entrepreneurs are often praised for risk taking. In qualitative research, risk refers to the chance or probability that harm or injury may occur either in the course of the research or as a consequence of the research. Therefore, risk is a consideration for researchers, participants, and research ethics boards. Risk in qualitative research is a controversial and often misunderstood concept, particularly because the hypothetical *chance* of harm is frequently seen as an *actual* harm.

Researchers should consider risk during the design of research protocols, and they should attempt to determine whether a methodology presents real unwanted harm or injury to participants. Harms may include invasion of privacy, violation of confidentiality, damage to reputation, and physical injury. Researchers and ethics boards should be aware that their perceptions of risk may vary from those of research participants. It is prudent to understand risk from the perspective of those

who participate in research based on comprehensive information about foreseeable harms.

The type of research presents different capacities to weigh risk against actual harms. For example, in experimental research, the harms caused by applying force to a person's body can be measured in terms of pain as well as tissue and bone damage. In qualitative research, however, risk is much more difficult to assess and often involves looking to future harms for which there is little or no evidence. Anthony Giddens called this "manufactured risk"—that is, "new risk environments for which history provides us with very little previous experience" (p. 3). Although we live in a risk society, researchers have not dedicated research to measuring the risk of actual harm in social science research. Instead, institutions such as research ethics boards focus on managing and avoiding manufactured risk.

Many research ethics codes outline a two-level standard for risk assessment: minimal risk and greater than minimal risk. Minimal risk is defined as the degree of harm or discomfort that research participants would encounter in their routine daily lives relative to the research design. Minimal risk research demands a lesser degree of ethical scrutiny than does research that exceeds the minimal risk standard. Research in the greater than minimal risk category should be evaluated on the basis of the actual harms that may arise from the research against the benefits of the research. Benefits include immediate benefits for research participants and prospective benefits to scientific knowledge and society.

A challenge in any risk-benefit analysis in qualitative research is that all risks and potential benefits cannot be known at the outset. Therefore, research participants should be advised of reasonably foreseeable harms and benefits. In general, most qualitative research presents little or no risk to participants, and in most cases risk can be managed effectively through appropriate methodologies.

S

SAMPLE

A sample is the set of actual data sources that are drawn from a larger *population* of potential data sources. Within the broad process of *sampling*, choosing the actual sample is the second step in a two-step process, which begins with defining the population that is eligible for inclusion in the sample. Approaches to selecting samples are typically divided between *probability sampling* and *nonprobability sampling*, where the former uses a group's size in the population as the sole influence on how many of its members will be included in the sample, while the latter concentrates on selecting sample members according to their ability to meet specific criteria.

Issues With Terminology

The prominence of survey sampling as a technique for defining samples has created a tendency to identify the entire concept of sampling with this one approach to selecting data sources, but discussing qualitative research within the framework created by survey sampling can easily be misleading. In particular, describing a set of data sources as a "sample" seems to invoke an implicit image of random sampling as a gold standard for assessing all approaches to sample selection. Yet random sampling is primarily of value for creating statistical generalizability, which is far more relevant in quantitative rather than qualitative research.

A different source of confusion in sampling terminology is the tendency to attach the words *sample* or *sampling* to every aspect of the process, including

issues that involve the definition of the relevant population rather than the selection of a sample from that population. This confusion is most obvious in misguided comparisons between *random sampling* in quantitative research and *purposive sampling* in qualitative research. In that case, the parallel phrasing of the two labels makes it difficult to recognize that random sampling is about selecting a sample from a population, while purposive sampling is about defining the population of eligible data sources, prior to selecting the actual sample.

Uses for Samples in Qualitative and Quantitative Research

Although it is undoubtedly too late to modify the overly broad use of the words *sample* and *sampling*, it is important to avoid using them in ways that obscure the differences between qualitative and quantitative research. In particular, qualitative and quantitative research emphasize different sample selection procedures that are specifically adapted to the purposes and goals that guide each kind of research. Because the goals of quantitative research typically include generalizing estimates to populations and conducting statistical tests, this leads to an emphasis on probability-based sampling with large *sample sizes*. In contrast, qualitative research emphasizes inductive theory building, subjective understanding, and detailed, holistic data, and these goals are often best met through intense investigations of small, systematically selected samples. Overall, samples in qualitative research need to be judged according to how well they serve the purposes of a specific study,

rather than being judged by criteria that apply to other goals.

- Patton, M. Q. (2001). *Qualitative research & evaluation methods* (3rd ed.). Thousand Oaks, CA: Sage.

SAMPLE SIZE

The sample size is the number of data sources that are actually selected from the total population. Basic principles of statistical sampling demonstrate that the accuracy of an estimate from a *probability sample* is strongly influenced by the size of the sample itself. The importance of sample size in determining the accuracy of the results is the reason that larger samples generate more precise estimates and smaller samples produce less accurate estimates—regardless of the size of the larger population.

Table 1 illustrates how sample size affects accuracy in the case of estimating a simple percentage (e.g., percent male) with *random sampling* in a population where the actual proportion is 50%.

Thus, for a population that is divided 50–50 between men and women, 95% of all the samples of size 10 would produce an estimate that fell somewhere between 19% and 81%, while 95% of all estimates from samples of 25 would fall between 30% and 70%, and so on. This table makes it easy to see why surveys typically rely on samples of 500 and over, because it takes that many observations to produce estimates that are accurate within the desired range of 3–4%. In contrast, the table also shows why random sampling is seldom of much practical value with small samples, since even a random sample of 100 is only accurate to 10 percentage points either way.

Table 1 How Sample Size Affects Accuracy in the Case of Estimating a Simple Percentage

Sample Size	95% Confidence Interval
10	19%–81%
25	30%–70%
50	36%–64%
100	40%–60%
250	44%–56%
500	46%–54%
1,000	47%–53%

Although qualitative researchers are seldom interested in results that can be expressed as percentages, the real point is not whether it makes sense to estimate simple percentages, but whether it makes sense to try to estimate *anything* with a small sample—regardless of whether it is a random sample. In particular, it is common to hear criticisms of the lack of *generalizability* in qualitative studies because they do not use *probability samples*, but this argument overlooks the fact that small samples seldom have any practical value for generalizability—regardless of whether they are random samples.

In most qualitative studies, the goals of the research emphasize an in-depth and highly contextualized understanding of specific phenomena, and such goals are well-suited to small sample sizes. For these purposes, qualitative researchers are well justified in using criteria such as *saturation* or redundancy in the data collection, rather than statistical criteria, as a standard for determining sample size—especially when the alternative is to be “drowning” in more data than it is possible to analyze.

SAMPLING

Sampling is the process of choosing actual data sources from a larger set of possibilities. This overall process actually consists of two related elements: (1) defining the full set of possible data sources—which is generally termed the *population*, and (2) selecting a specific *sample* of data sources from that population. Note that this definition is stated in general terms that apply to both qualitative and quantitative research, because it is nearly always necessary to work with a sample of data sources rather than attempting to collect data from the entire population. Beyond that similarity, however, the very different goals of qualitative and quantitative research lead to equally different procedures for selecting data sources from a larger population. It is thus important to understand the differences between the logic of purposively selecting a small number of sources for intense analysis in qualitative research, as opposed to the emphasis on randomly selecting large samples for statistical analysis in quantitative research.

Defining the Population

All samples must be drawn from some larger population, and that requires a prior definition of the population. In practical terms, every research project has to consider which kinds of data sources will be eligible for the study, regardless of whether those data sources consist of people to be interviewed, sites to be observed, or texts and other media to be examined. Stating the eligibility criteria that determine whether a given data source is included in the total population is technically known as defining a *sampling frame*. For example, a study examining “inner-city schools” must begin by defining which schools belong in that population, and this outlines a sampling frame that determines whether any given school is eligible for inclusion in the study.

In qualitative research, issues related to defining the overall populations are generally treated as part of *purposive sampling*, which inherently requires an explicit definition of the kinds of data sources that are of interest. In essence, determining which data sources met the goal of purposive sampling for a qualitative study is equivalent to defining a set of eligibility requirements for the population (i.e., creating a

sampling frame). Hence, the concept of purposive sampling falls within the broad process of defining the population of potential data sources.

Qualitative researchers have also developed a number of more specific techniques for defining eligible populations through purposive sampling. Among these are *theoretical sampling*, which selects cases according to their ability to advance research goals such as theory development; *maximum variation sampling*, which examines a wide range of different cases within the population of interest; and *stratified sampling*, which divides the overall sample into specified subsets for comparative purposes. Each of these techniques amounts to a strategy for implementing the goal of purposive sampling, in order to meet a specific set of research purposes. Taken together, these strategies facilitate the in-depth interpretation of a systematically selected set of data sources, which is one of the hallmarks of qualitative research.

Selecting the Sample

Once a population has been defined, the next task is to select the members of the population that will be included in the sample. The most basic division between different procedures for selecting samples is based on producing either a *probability sample* or a *nonprobability sample*. For a probability sample, each member of the population has a known chance of being included in the sample, and *random sampling* is the best-known means for accomplishing this. Probability samples are required for statements about either the accuracy of sample estimates or the statistical significance of results.

When there are problems with counting all the members of the original population, or giving every member of that population a known probability of being included in the sample, then it may not be practical or even possible to generate a probability sample. These kinds of problems are obvious for what are known as “hidden populations” where the members do not want to be recognizable because they violate some legal or cultural standards (e.g., undocumented immigrants). But it can be just as difficult to draw probability samples in many non-hidden populations (such as cancer patients, non-governmental organizations, or media stories on crime, and so on). In those cases, the only option is to use a nonprobability sample.

Among the most common ways of selecting nonprobability samples are *convenience sampling*, which accepts any eligible case that can be found; *quota sampling*, which specifies categories within the sample and states how many people should be included in each category; and *snowball sampling*, which uses an initial set of data sources as the basis for locating additional data sources. It is important to note that this list does *not* include purposive sampling because, as stated above, that is properly part of the process of defining the population rather than the process of selecting a sample from that population. In practice, almost all qualitative research does rely on nonprobability samples, but this has little connection to the use of purposive sampling. Instead, this reliance on nonprobability samples is often due to the difficulty of even locating data sources that meet eligibility criteria, let alone counting the total size of the population from which that sample is drawn. In addition, the need to collect detailed, in-depth data typically leads to small *sample sizes* where there would be no point to doing statistical analysis. Thus, the common use of nonprobability samples in qualitative research matches an approach to data collection and analysis strategy that typically relies on the careful interpretation of a small number of very rich data sources.

SAMPLING FRAME

A sampling frame defines the members of the *population* who are eligible to be included in a given *sample*—in the sense of drawing a boundary or frame

around those cases that are acceptable for inclusion in the sample. This terminology is most common in survey sampling, where it is associated with a countable listing of all the data sources in the population that are accessible for *sampling*. For example, a sampling frame might be all the registered voters in a state or all the public schools in a local district. The actual sample would then be drawn from the population defined by this frame.

Survey sampling thus involves a two-step process that begins by defining a set of inclusion criteria for the overall population (i.e., the sampling frame), typically followed by drawing a *random sample* of respondents who meet that definition. For example, the footnotes that accompany most “random samples” of the U.S. population often show that they are actually limited to something like the English-speaking, noninstitutionalized, civilian residents of the U.S. who are over the age of eighteen. This means that almost all *generalizable* surveys explicitly exclude several categories of potential respondents, and thus the sample only represents the population defined by that frame.

In qualitative research, the process of *purposive sampling* is logically similar to defining a sampling frame in survey research. In both cases, the key goal is to specify the set of data sources within the general population that will be eligible for inclusion in the study. In particular, both of these procedures are included in defining the population of potential data source, prior to selecting the sample of cases that will be studied. Although purposive sampling typically defines a narrow set specific of cases, it is also the case that many quantitative studies are aimed at very specific populations, and thus use equally restrictive sampling frames. In other words, when surveys target specific populations, they also use a process of purposive definition that only includes the data sources that are of interest to that particular study. Thus, to revisit the earlier examples of sampling frames, a survey that was interested in the long-term voting habits of people who did not belong to a major party might start with all the registered voters, and then reduce that list to independent voters who participated in at least three of the last four major elections. Or a survey that was interested in students who had above-average school performance despite a below-average socioeconomic background might use both of those factors to define a sampling frame of potential respondents. By comparison, a qualitative researcher who wanted to pursue either of

those topics would follow a similar process of “purposive sampling” in order to define the set of people who were eligible for that study.

SECONDARY ANALYSIS

Archived qualitative data are a rich source of research material that offer researchers, teachers, and learners opportunities to revisit, rework, and verify data—both their own and those created by others—and also to compare with other data materials. They provide opportunities to study the raw materials of recent or earlier research to gain both methodological and substantive insights. New data are typically expensive to collect, so using already collected sources can save costs as well as avoiding duplication of research effort and investment. But unlike secondary analysis of questionnaire data, the practice for qualitative data is far less well-established. What can older data offer the secondary analyst, and are there specific problems to overcome? This entry introduces some of the key issues.

Qualitative data are collected across a range of academic disciplines, often with varying techniques or emphasis. Typically, qualitative studies aim to capture lived experiences of the social world and the meanings people give these experiences. Often a range of methods and tools are utilized in the field and the kinds of data collected vary with the aims of the study and the nature of the sample. Data that could potentially be reused from a study include interviews, in-depth or unstructured; group discussions or focus groups; fieldwork diaries and observation notes; diaries; personal documents; and photographs. These data may also be created in a variety of formats: digital, paper (typed or hand-written), audio, video, and photographic.

To some extent the scope and format of data determine their potential for secondary analysis. A large collection of recorded and transcribed in-depth interviews with detailed fieldnotes may offer greater potential for reanalysis than a more focused set of semi-structured interviews. Audiovisual materials are possibly the least reexploited resources in the social sciences.

The ways that qualitative data can be reused are similar to those used for the secondary analysis of questionnaire data, yet there are different and more challenging theoretical, epistemological, methodological, ethical, and practical problems for the potential user to consider. While there is a well-established tradition in social science of reanalyzing quantitative data, for qualitative data this is not the case.

Approaches to Secondary Analysis

Louise Corti and Paul Thompson identify six approaches to secondary analysis that are based that on anticipation of the original data creators and experiences of users.

Description

The possibilities for using data descriptively are extensive—contemporary and historical attitudes and behaviors can be gleaned from data—at the individual, organizational, or societal level. Transcribed interviews with selective samples of the population can complement official sources of information such as newspapers and public documents. Significant data created now will in time become a valuable potential historical resource—methods of secondary analysis thus become historical research methods. The latter are better practiced and documented, requiring the new investigator to examine the provenance of the material and assess the veracity of the sources. This may be an unfamiliar practice for contemporary social researchers.

Comparative Research, Restudy, or Follow-Up Study

Qualitative data can be compared with other data sources or be used to provide comparison with other contexts, over other periods of time, and across other social groups and cultures. In Britain the original returns of the population census have been preserved

as public records and have proved an invaluable resource for measuring trends. Classic UK restudies include Seebohm Rowntree's repeated surveys of poverty in York and Llewellyn Smith's (1930–1935) repeat of Charles Booth's (1891–1902) poverty survey in London. Comparison brings greater power to answer research questions; for example, when a data set can be combined with data beyond its own sample or geographical limitations. Equally, respondents in original studies that have been preserved can be followed up to form a longitudinal study, sometimes with the involvement of the original investigators and typically requiring new ethical approval. An example of a prospective follow-up study is Glen Elder's Children of the Great Depression (1974), based on both new fieldwork and a reorganization of the earlier interviews and participant observant of the Berkeley and Oakland cohorts interviewed on a regular basis since the 1920s.

Reanalysis

Reanalysis of qualitative data allows both for new interpretation and new questions to be asked of data. New perspectives can be applied and new analytical methods and tools employed. Typically, the "richer" the original research material, the more potential there is for further exploitation. Secondary analysis is particularly valuable for studying sensitive topics or hard to reach populations, where access may have been difficult to negotiate or data hard to collect.

Research Design and Methodological Advancement

A study of the research methods of an original qualitative investigation can help in the design of a new study or the development of a methodology or research tool. While description of a study's methods are often included in books or journal articles based on a study, the details tend to be brief. Consulting documentation and notes of the original sampling methods, data collection, fieldwork strategies, interview guides, and analyses notes can offer insight into the history and development of the research.

Verification

Archived data can be scrutinized with scientific rigor to support or challenge a set of findings or to

appraise the method. The practice of opening data for inspection is becoming increasingly important in the natural sciences, with the aim of encouraging more transparent research. While "replication" can be used to check findings, true scientific replication is not possible with qualitative research as studies are not controlled in the same way as in experiments.

Teaching and Learning

The use of authentic data in teaching substantive or methodological perspectives across the social sciences adds interest and relevance to a program. Students who gain their experiences of qualitative data analysis from the use of archived data from a well-known published study can gain a good understanding of the complexity of data analysis, and develop critical appraisal of the strengths and weaknesses of the data collection strategies or analytic approaches used by the principal investigators.

Difficulties in Reusing Data

The seven key issues that present themselves as difficulties in both reusing and sharing data, as identified by Corti and Thompson are:

1. ethical and consent considerations and constraints;
2. representation, coverage, and context of the research and fieldwork—a problem with the reflexive and implicit nature of qualitative data collection and analysis;
3. unfamiliarity with the methods of secondary qualitative analysis;
4. lack of time to get fully acquainted with research materials created by others;
5. lack of infrastructure for accessing data sets in area of interest;
6. misinterpretation of data and exposure of one's own research practice through sharing data that might bring unwelcomed critique;
7. threat to intellectual property rights in data and methods.

The most significant issue currently being debated in the consideration of secondary analysis is of that data and original context. The basic argument lies with the belief that qualitative data cannot be used

sensibly without the accumulated background knowledge and tacit understanding that the original investigator had acquired in “being there.”

But the loss of context in archived data should not be viewed as an insurmountable barrier to reuse. Indeed, there are very common and accepted instances where research data is used in a “secondhand” sense by investigators themselves: principal investigators writing up their final analyses and reports may not have been directly engaged in data collection. Similarly, researchers working in teams rely on sharing their own experiences of fieldwork and its context. In both instances, the analyzers or authors must rely on fieldworkers and co-workers documenting detailed notes about the project and communicating them—through text, audio, and video. But documentation of the complete research process can help recover the original fieldwork and analysis experience. Representation of audiorecorded interviews are affected by the method of transcription, which can vary between disciplines and individuals: while sociologists typically want to capture the words, conversation analysts and sociolinguists are more concerned with documenting the paralinguistic features of speech, such as pauses or laughter.

However, the views of qualitative researchers themselves on these matters are by no means homogeneous. While a minority are opposed to sharing what they see as personal “possession” and a means for their own future publication opportunities, many view further exploitation of data as offering significant added value and as a right, through public investment in funding the original study.

SECONDARY DATA

Secondary data are preexisting data that have been collected for a different purpose or by someone other than the researcher. These data may have been gathered originally for another research study or for administrative purposes. Secondary data may be available through government agencies, researcher-contributed databases, public or private archives, institutional records, or arrangements with individual researchers. Researchers may use secondary data to investigate new research questions, corroborate or extend the original analyses, or compare to other (primary or secondary) data sources.

The practice of using secondary data is well established in quantitative research traditions where large-scale databases and data depositories provide ready access to censuses, national and international educational assessments, and other numeric data on a multitude of topics. In contrast, secondary data has a more recent history in qualitative research traditions, with the first methodological publications about secondary analyses of qualitative data appearing in the mid-1990s.

Technological advances, interdisciplinary opportunities, pressures for increased research productivity, and encouragement for large-scale projects may all contribute to researchers' decisions to use secondary data. Public funding agencies have developed policies to explicitly encourage data archiving and data sharing as part of their mandates toward openness, accountability, and public ownership of data.

Conducting research using secondary data can entail considerable savings in time, money, and labor compared to gathering firsthand data. Reliance upon secondary data can also reduce intrusions into

research participants' lives because the data that they supply in a single research study could inform a broad range of research projects, thereby maximizing potential societal benefits and scholarly contributions.

There are, however, considerable ethical and methodological issues that researchers must consider before using secondary data. A major challenge of secondary data is the potential to undermine the autonomy of the individuals who provided the original data by limiting opportunities for those individuals to provide informed consent to participate in this secondary research. Privacy legislation and ethics review board procedures consider the extent to which the data are identifiable, the potential harms that research participants could face, the relationship between the purposes for the original data collection and the current research project, the expectations that the participating individuals would consent or object to the research, and the potential social good of the research. To the extent possible, individuals engaged in data collection for research or administrative purposes should consider possible secondary uses of those data and seek permission at the data collection stage.

Another challenge for qualitative researchers using secondary data is the limited relationship with the participants and context for the data. Secondary research conducted by a different researcher undermines the close relationships between researchers and participants that are a key feature of qualitative research. A new researcher who was not involved in the original research study will not know what information the original respondents considered sensitive and will therefore be unable to calculate risks involved in divulging sensitive information. This may explain why qualitative research undertaken with secondary data typically involves researchers who have some firsthand knowledge of the original research.

SECONDARY PARTICIPANTS

A *human participant* is a living individual whom a researcher obtains data about through interaction with that individual or with private information that identifies that person. A *secondary participant* is someone who was not initially designated as a primary participant in a study, but about whom information is gathered from persons who are primary participants. Secondary participants are created when individuals provide information about other people whom they know or to whom they are related. Because secondary participants were not initially recruited for the study, they have not given consent to be studied.

Secondary participants are routinely created when social scientists and educators ask questions about the behavior and beliefs of participants' family members and associates. Ethnographers learn information about members of communities where participants live, interact, or work. Epidemiologists studying communicable diseases or infection risks request the identity of all persons with whom participants interact over specific issues, such as sharing of needles or drugs, eating similar foods, or engaging in risky sex or similar recreational activities.

Crucial is whether or not secondary participants are human participants from whom researchers must obtain informed consent for use of data about them. If a person "about whom" information is sought cannot be identified, even by the researcher, then the person is *not* a secondary participant and informed consent is not required. However, if the secondary participant reasonably can be identified, researchers may have to obtain their informed consent, especially if the information about them is private, sensitive, or significant. Since no worldwide consensus exists regarding how to handle issues of consent, researchers should check on the regulations governing ethics issues in the country granting approval.

When researchers use network, reputational, or snowball sampling to identify potential research participants, individuals may become unconsented secondary participants because such sampling gathers information "about" individuals, and renders them "identifiable." In addition, since ethnographers and qualitative researchers usually can identify their primary participants, if primary participants name specific people in their network, researchers will have information about those people relative to the reasons for their participation in

specific activities. They are, therefore, secondary participants. Their consent may need to be obtained before data about them are recorded and used in the research, unless an ethics review board has granted a waiver of informed consent.

Researchers must exercise particular care if they have access to private, sensitive, or significant information—anything a potential participant might not want, or expect, to be disclosed or that could put them at risk if disclosed to others. Risks include experiencing emotional, financial, legal, political or physical harm, or embarrassment for violating social or cultural norms or taboos. It derives from disclosure of

- Abusive treatment of the participant by parents or relatives
- Abusive treatment the participant has inflicted upon others
- Participation in illegal or unethical acts
- Illegal, antisocial, or nonsocial behavior
- Drug use and sexual behavior
- Communicable diseases or stigmas
- Interactions with people whom participants are forbidden to contact
- Engaging in tabooed activities

Risks are especially likely when the culture of the researcher differs from that of the participants, since risks and what constitutes normative or even legal behavior differ across societies. Thus, consent may need to be obtained from secondary participants

- when they are identifiable;
- when private, significant, or sensitive information is obtained about them—such information is not if a participant’s mother likes or dislikes comedy movies, but could involve data from the mother’s medical records, if the participant’s mother were involved in antiwar protests, or if she used recreational drugs; and
- when the researcher plans to use the information as data for his or her study.

To avoid creating secondary participants, researchers can avoid asking participants for names and direct relationships. When using network sampling, they can ask existing participants to give potential participants information about the study; those individuals can then contact the researchers themselves if interested in participating. This can be difficult in nonliterate societies; where finding key

members of social networks is crucial to solving a social problem, whether or not they give consent; or where taboos forbid such contacts. Procedures for obtaining informed consent from secondary subjects are identical with those used for consenting primary subjects. If the potential secondary subject does not provide consent, then the researcher cannot use any information collected about them.

SELECTIVE CODING

Selective coding is a late phase of analysis in the grounded theory approach to qualitative data as presented by Anselm Strauss and Juliet Corbin, when explanations of phenomena (e.g., events, actions, processes) are emergent. Open coding, the earliest phase of identifying and labeling concepts in raw data (e.g., interviews, fieldnotes, art), sets the stage for axial coding, where the dissected data is reassembled as the researcher develops and relates categories. Axial coding is succeeded by selective coding where the analyst selects a central (core) category as a vehicle for the integration of the other major categories thereby developing and refining theoretical claims.

Linking (integrating) categories is essential to developing a story about “what is happening” in the data (explaining phenomena) and relies on the choice of a central category that represents the major theme or “essence” of the research. The central category should be highly frequent and salient, and it should be possible to relate all the major categories uncovered in

the data to it. For example, a central category that might emerge from a study of children of incarcerated offenders is heightened deviant behavior. Other major categories uncovered might be types of deviance, seriousness of the act, and childhood phase. These (and many others) would be linked to the central category in an attempt to develop a theoretical scheme to better understand and explain the deviant activity. The choice of the core category and the explanation provided is the researcher's interpretation of what is happening. It is almost certainly not the only possible interpretation of the data, but one of several different, equally logical possibilities.

Techniques are offered to help researchers commit to a central category (often said to be difficult but key to theory development) and relate other major categories to it. These include writing an initial sketch of the main story concerning what is at issue in the data, using diagrams, and making use of notes kept throughout data analysis (memos). Through the process of category integration, a theoretical scheme emerges.

In refining the theory, the researcher aims to insure that the major categories' properties and dimensions have been adequately uncovered—that *density* has been achieved. For example, in studying children of incarcerated offenders, if the researcher notices that female delinquent children have been more sparsely coded than males, more data concerning this category would need to be gathered. Also, in addition to weeding out less relevant concepts, the researcher is advised to make sure the derived theory is both logical and consistent with the raw data analyzed, checking to see how well it “fits the data” in terms of explaining the central phenomenon.

In generating theory grounded in data, it can be difficult to determine when to stop searching for more detail. The guideline for when to stop collecting and analyzing data is when new aspects of categories no longer emerge and no new relationships are discovered in analysis (theoretical saturation).

There is some disagreement among grounded theorists about when selective coding should occur. However, seeking a central, organizing category as the core of a storyline (one that integrates major categories) seems to be a generally agreed upon approach to theoretical development.

SEMIOTICS

Semiotics is the doctrine, or general science, of signs. Simply put, a sign is anything that can stand for some other thing. Just about anything that we can perceive somehow can act as a sign, so long as it can point away from itself and toward something else. Therefore, most of the time when we are doing semiotic research, we are not collecting signs per se. Instead, we are looking at how things stand in relation to other things, and how those mediated relationships help us understand things better. These points will become clearer as we gain further understanding of semiotics itself. To that end, we will start with its history. This entry will then explore semiotics as language and as logic, closing with a specific section on the role of semiotics in qualitative research.

Semiotics in History

Semiotics, although a fairly new field, nonetheless has quite a substantial history. The Stoics were the first to explore sign relations. While little is known of their logic per se, it is known that they were interested in mediated and unmediated relationships, and how they varied.

There was also an extensive semiotic presence in Christendom, from its earliest roots through the Middle Ages. St. Augustine in particular was quite interested in the action of signs. He is one of the first thinkers to draw a distinction between natural signs and conventional signs. Natural signs, for Augustine, were those signs that occurred in the world. Such things as footprints (signs of someone walking around) and smoke (as a sign of fire) are natural signs. Conventional signs are those things that are signs because they function as such within culture. Words are conventional signs, and so are red octagons on poles telling people to STOP.

Language and other conventional signs were important topics of inquiry among many medieval thinkers. One important debate was over the nature of names. Did names indicate the presence of universal properties, or were they merely labels? Also, there

was quite an extended discussion over what sort of system constituted a language. Human speech was accepted as a language, of course, but what about the barking of dogs? Did a language have to do more than just communicate to be a language? These debates helped form some of the most important questions in contemporary semiotic theory and research.

It is not until we reach the 20th century, however, that we have an explicit formal doctrine of semiotics. Interestingly enough, though, it turns out that there were two independent doctrines of semiotics formed at roughly the same time. The first branch, which we also sometimes call *semiology*, was born in the work of Swiss linguist Ferdinand de Saussure. The second branch was formed in the United States by logician and philosopher Charles Peirce. We will look at each approach in turn.

Semiotics as Language

Saussure was a revolutionary linguist who died in 1913 at an early age. Because of his early demise, he left no systematic treatise of his work. Therefore, his students, in tribute to him, pooled together their class notes to create his *Course in General Linguistics*. This work served as the basis for the development of his model of semiotics.

Before Saussure, the main emphasis of linguistics was historical. That is, linguists were interested in tracing the origins, migrations, and evolutions of various language families. Saussure took a completely different approach. Suppose, he said, we set aside the historical nature of language and just look at language as a complete and self-contained system. Furthermore, he said, suppose we look at not just any particular language, but language itself as an abstract system. He called this abstract system *langue*, to distinguish it from speech, which he called *parole*. He envisioned *langue* as the universal abstract core around which all actual languages are built. Linguistics, he argued, needed to understand *langue* before it could understand languages *per se*.

In order to build a theory of *langue*, Saussure needed a set of ideas more basic than those of language. He set aside the notion that words, phrases, and sentences were the basic units of language. Instead, he argued, all these forms depended upon a single, more abstract form. That single abstract form he called the *sign*.

For Saussure, the sign was a single entity with two necessary and complementary parts. Every sign

consisted of a *signifier* and a *signified*. The signified is the object of the sign. For Saussure, it was not the actual object itself in the world, but a concept of the object in a person's mind. For instance, the object of the sign "tree" is not an actual tree somewhere, but the concept of a tree that the perceiver of the sign summons forth when presented with the sign. The signifier is that thing that causes the person to summon up the concept in the first place. In our example above, the signifier is the word *tree*. According to Saussure, every sign consists of a signifier and a signified, and these cannot be separated. So, a signifier without a signified is not a sign—for example, a random string of letters is not a word, and therefore not a sign *per se*.

Language is a privileged sign system according to Saussure. While it is not the only sign system, it is the model and ideal form of all other sign systems. Saussure went on to say that all links between words and objects are arbitrary. This means that meaning in language is always a matter of convention, or knowing the proper codes. This notion of code and language pervades the Saussurean model of semiotics, which is also known as *semiology*. Followers of Saussure often look for the presence of codes, and hence a "language," among various sorts of phenomena.

Semiologists are semioticians who use the basic ideas of Saussure to discover and decode various systems of signs in both nature and culture. There are a number of famous and important semiologists in a variety of fields. Roman Jakobson explored the codes of the formal properties of language and meaning, and Kenneth Pike did the same for phonetics and phonology. Claude Lévi-Strauss uncovered patterns of kinship and behavior in anthropology. Jacques Lacan took a semiological approach to psychology and psychotherapy, and Roland Barthes used semiological codes and patterns to explore popular culture.

Currently, most semiologists practice in such areas as comparative literature and cultural studies. Finland, France, Estonia, Italy, and other Continental areas continue to embrace and expand semiological thought. Perhaps the most important contemporary semiotician with at least a semiological bent is Umberto Eco.

Semiotics as Logic

Within the Anglo-American world, semiotics is most often characterized by the work of the American logician and philosopher Charles Sanders Peirce. Peirce, who died in 1914 at the age of 75, was the founder of

both Pragmatism and the American version of semiotics. For clarity, we will call Peircean semiotics “semiotics” and Saussurean semiotics “semiology.”

Peirce was an original but often daunting thinker. Part of the difficulty in understanding Peirce lies in grasping his basic points and assumptions. Peirce was first and foremost a logician. But logic was not just a tool for thinking for Peirce. Logic was a fundamental property of nature, and the glue that holds together reality. This power of logic is best seen in Peirce’s work in his model of signs.

For Peirce, a sign is a triadic entity whose nature is based on logical concepts. The three irreducible components of a sign are the *sign*, the *object*, and the *interpretant*. But before we can discuss them, we need to review a few basic concepts.

One of the key relations in logic, especially logic as applied to the empirical world, is the notion of *contingency*. A contingent relation describes how one thing might lead to another thing. We can describe a contingent relationship in the following formal manner:

If A, then C

“A” stands for the *antecedent*, or literally, that which comes before. “C” stands for the *consequent*, or that which comes after. Consider the following simple example: If “you drop a 1,000-pound weight upon your toe,” then “you will smash your toe.” The dropping of the weight is the antecedent, and the smashing of the toe is the consequent.

Peirce would call this simple sort of relationship an unmediated relationship. These sorts of relationships happen all the time, and they are the basis for, among other things, simple Newtonian physics. But not all relationships in the world are unmediated. There are any number of relationships that are not only mediated, but are necessarily mediated. By that, Peirce means that they cannot be reduced to some more basic subset of unmediated relationships. For these sorts of relationships, we need a different (although related) formal model:

If *O*, by *S*, then *I*

Here, *O* stands for the object, *S* for the sign, and *I* for the interpretant. Each of these terms has their own unique properties. We can see these properties by comparing them to the antecedent and the consequent from the unmediated relationship.

Let us start with the sign. In all semiotic situations, the sign is that part of the relationship that is manifest. In the case of humans and other animals, it is the part of the relationship that is actually present and perceived (it is important to note that, for Peirce, semiotic relationships do not necessarily depend on perceivers, but this part of semiotics is well beyond the scope of this entry). That is, it is the part of the relationship we directly attend to. But we do not just attend to it for its own sake. It also directs us in some fashion to the object.

Unlike the sign, the object is never present. If it were, then there would be no need for the sign. The object would just stand as an antecedent in its own right. For our example, let us suppose that our sign is a piece of paper with the words *a 1,000-pound rock* written upon it. Because we understand English, these words direct us to the absent object, namely the 1,000-pound rock. Unlike Saussure, Peirce had no problem with the actual object being a real existing rock and not just a concept of a rock. Of course, it could be a concept of a rock as well. There are also a number of systematic ways that a sign directs us to an object, but those details can be found elsewhere. The important thing to remember is that the sign is acting as an antecedent, but only as a stand-in for the object.

The interpretant, therefore, is the mediated consequent. That is, it is the consequent we get when we let the sign stand in for the object, instead of letting the object stand as an antecedent on its own terms. We can clarify this with a simple and trivial example. Suppose we drop the sign, or the piece of paper with the words written on it, on our bare foot. The consequences will be much different than if we had dropped the actual object on our foot!

For many circumstances, especially when dealing with human beings, the mediation involved becomes a matter of making sense of how to deal with the object as represented by the sign. That is, the act of mediation very often deals with making or discerning meaning. In these cases, the interpretant is most often characterized by an act of interpretation. But it is a mistake to simply equate the interpretant with interpretation (Peirce’s choice of terms here does not help matters, by the way). Sometimes we have to make meaning out of a mediated relationship, but other times, we need to discern meaning that was not immediately apparent but is nonetheless important. In that case, the interpretant is much more of a discovery than an interpretation.

Semiotics takes a very sophisticated stance to the topic of meaning in research and theory. Unlike, say, radical constructivism, semiotics does not assume that the world is meaning-poor. It acknowledges that there is much meaning already in the world, waiting for us to discover it. It also acknowledges that we are constantly engaging in a process called *semiosis*. Semiosis is the act of working with signs to make sure that we understand the world as completely as we possibly can. Whether we find meaning or make meaning, the goal is the same—to live in a world that makes perfectly good sense. Therefore, semiotics also acknowledges that meaning is not just a pleasant or comfortable part of our lives. To the contrary, the drive to meaning is compulsive and consuming. We cannot live in a state that Peirce called *genuine doubt*, where we are not sure of what something or some circumstance means. Our very survival may depend on getting from genuine doubt to true understanding as quickly as we can. When applied to research, this means that researchers can never be casual about the topic of meaning. Our efforts to try to live in a world free of genuine doubt colors everything we do, and it can affect our research efforts if we are not careful. In fact, one of the most important things a semiotic researcher can do, if need be, is to purposely suspend the need to resolve genuine doubt in order to get at deeper and more subtle issues.

There are not as many practicing semioticians as there are semiologists, but there is important work here nonetheless. Thomas Sebeok was the most important semiotician of our era. His work on expanding semiotics into work especially with animal behavior was very important. Ireneus Eibl-Eiblsfeldt combined the ideas of ethology with semiotics in his research of human behavior. John Deely has contributed important theoretical and historical research contributions. John Josephson has systematized and extended much of the current work on abductive reasoning, particularly into the realms of expert systems and artificial intelligence. In education, there is the lively Special Interest Group in Semiotics and Education that has been part of the American Educational Research Association for over 20 years.

Semiotics and Qualitative Research

Before we talk about semiotics in qualitative research, we need to make a few distinctions about research directions in semiotics per se. Most important, there

are important research differences between semiology and semiotics. Semiology assumes that signs are a vehicle of communication, and that in semiological research we engage in a conversation with the world. Semiotics focuses on the logical relations inherent in signs, and in semiotic research we use signs to reveal and discern the world. Both aspects are important in the overall project of semiotic research.

How do we use semiotics in qualitative research? There are few specifically semiotic research tools. Instead, semiotic research is motivated by a set of fundamental assumptions about research and the world. Note that these assumptions move back and forth between semiology and semiotics:

The world can be read just like a text. One of the great legacies of medieval Christendom is the notion that God was the author of two books. The first book, obviously enough, was the Bible. The second book was the World. Medieval thinkers often assumed that the world was full of lessons for our edification. Actually, this notion can be found as far back as the fables of Aesop. Today, we are not just looking for morals and lessons. We are interested in how the world can come together as a coherent and meaningful whole and in the implicit and explicit codes that allow this to happen.

The world is always talking to us. Peirce once insisted that the world was perfused with signs. Since we are always searching for meaning in order to avoid genuine doubt, we are always drawing guidance and affirmation from the world. Therefore, there is usually a meditative or even contemplative dimension to semiotic research, where we allow the order of the world to come to us on its own terms.

The world is rich in meaning. Semioticians go beyond the notion that we make all the meaning we find, either singly or collectively. We share Peirce's sense that there is some form of logical order to the world, and that there are things in the world that are meaningful on their own terms, and not necessarily on ours. Stepping outside our own personal or cultural frames of meaning can be one of the most exciting forms of semiotic research.

The presence or absence of specific things often serve as clues to the nature of reality. One good way to think of semiotic researchers is to compare them to detectives. Signs are often clues and symptoms and

omens of things. Our job is to find them in intelligent and creative ways. Numerous semioticians have argued on the semiotic nature of the work of Sherlock Holmes. Eco also created the archetypal semiotic detective in William of Baskerville, the hero of his best-selling book (and movie) *The Name of the Rose*.

Although semioticians assume the world can be understood, we do not necessarily assume that it can always be understood easily in human terms. This awareness is a summary of all the points above. Simply put, semioticians try not to impose order on things, unless they are things we are supposed to impose order upon. Most of the time, we watch, learn, synthesize, and organize. If we are patient, we are often rewarded with startling, and even beautiful, insights.

At this time, semiotics is important to qualitative research mainly as a related discipline. Should qualitative researchers choose to employ some of the perspectives listed above, the links between semiotics and qualitative research might become more explicit over time. In the meantime, there are important periodicals that can keep the interested qualitative researcher informed on the latest ideas within semiotics. The flagship semiotic journal is *Semiotica*, the official journal of the International Association of Semiotic Studies. *The American Journal of Semiotics* is the journal of the Semiotic Society of America. The Special Interest Group in Semiotics and Education publishes the *International Journal of Applied Semiotics*. Finally, Toronto, Canada, has been a hotbed of semiotics in North America, and the Toronto Semiotic Circle publishes a number of important source journals, including the long-running *Semiotic Review of Books*.

SEMI-STRUCTURED INTERVIEW

The semi-structured interview is a qualitative data collection strategy in which the researcher asks informants a series of predetermined but open-ended questions. The researcher has more control over the topics of the interview than in unstructured interviews, but in contrast to structured interviews or questionnaires that use closed questions, there is no fixed range of responses to each question.

Researchers who use semi-structured interviewing develop a written interview guide in advance. The interview guide may be very specific, with carefully worded questions, or it may be a list of topics to be covered. The interviewer may follow the guide to the letter, asking the questions in the order they are given, or the researcher may move back and forth through the topic list based on the informant's responses. In either case, the topics of the interview guide are based on the research question and the tentative conceptual model of the phenomenon that underlies the research.

Semi-structured interviews use many kinds of open-ended questions. Some questions may ask for relatively concrete information such as, "What did the doctor tell you about your mother's diagnosis?" Or they may ask for more narrative information such as, "How did you come to be the person who is taking care of your mother?" In addition to questions directly related to the concepts under investigation, semi-structured interviews also use a variety of probes that elicit further information or build rapport through the researcher's use of active listening skills. For example, the question, "What did the doctor tell you about your mother's illness?" might be followed up by a paraphrase such as, "So the doctor never used the word *dementia*?" or by a reflection such as, "It sounds like you were pretty upset." Similarly, the question, "How did you come to be the person taking care of your mother?" could be followed up by a neutral probe such as, "Can you tell me more about what that was like?" Or if the response was lengthy, by a brief summary statement.

Semi-structured interviews are especially useful in research questions where the concepts and relationships among them are relatively well understood, such as in typological analysis; in contrast, unstructured interviews are more useful when the identification of important concepts is one of the research aims, such as in phenomenology. Because of the degree of structure in this interview format, the resulting text is a collaboration of investigator and informant. In order to ensure interpretive validity, the interviewer must avoid leading questions such as, "What was the main benefit of your mother's stay in the respite unit?" A better question would be, "How would you evaluate your mother's stay in the respite unit?" The latter question does not lead the informant into providing only one kind of evaluation. For both unstructured and semi-structured interviews, the development of rich, relevant data rests on the interviewer's ability to understand, interpret, and respond to the verbal and nonverbal information provided by the informant.

SENSITIVE TOPICS

In qualitative research a sensitive topic presents a threat to the researcher, the participants, or the community to whom the participants belong. This threat is sufficient to create significant problems for doing the research and/or disseminating the data.

Topics that are typically regarded as sensitive include studies on sexual health or deviant or illegal conduct, as well as studies where the population under research is in a significant power imbalance with the wider population. It is important that researchers recognize that individual topics are not inherently sensitive, but that their social contexts make them so.

The sensitivity of a research topic may arise in several ways. Research may intrude into the private sphere

of a participant's life, as in the case of exploring sexual intimacy or religious beliefs. Depending on the cultural context, such intrusions may or may not be perceived by participants as threatening. For example, questions about homosexual behavior may not be viewed as particularly sensitive in some liberal communities, whereas they may be highly intrusive within communities that proscribe homosexuality. In other words, conduct that is considered acceptable in one community may be defined as disreputable in another community, and thus cause participants to fear that they will be judged or that harm may even be brought to the reputations of their community. A consequence of this fear may be a reporting bias, which has implications for data collection as well as reliability and validity.

There are a number of strategies available for managing and reducing the sensitivity of a topic. Participants should receive appropriate information to properly give informed consent. Such information should anticipate potential harms and explain how they will be prevented or minimized. Researchers should also build trust with participants and relevant communities by explaining the value of a study and showing that its purpose is not to bring judgment or stigma. Participants need to believe that a researcher has their interests in mind as well as the search for knowledge. To this end, researchers have a responsibility to consider in advance how they will report and disseminate findings.

Some research topics are so sensitive that researchers may have to give unconditional promises of confidentiality to participants in order to gain their trust. On occasion, researchers have faced legal threats to force disclosure of confidential data, which can have a chilling effect on the ability to conduct research as well as place participants and researchers at risk. In such situations, researchers need to anticipate the threat to themselves and participants and must know in advance what they will do to manage such threats.

Researchers need to be sensitive to the culture and values of their participants in order to build trust and understand whether or not they will perceive a topic as sensitive. This need requires diligence in all stages of research design, from problem identification, to data collection, to the reporting of findings. Researching sensitive topics demands careful consideration and management of ethical issues in order to maximize data quality while minimizing harm.

SENSITIZING CONCEPTS

Sensitizing concepts are constructs that are derived from the research participants' perspective, using their language or expressions, and that sensitize the researcher to possible lines of inquiry. Sensitizing concepts are distinctive, natural terms used within a researched population that the researcher can also use to develop more generic, social constructs that are useful in studying other social settings. For example, a researcher might adopt the concept *detective work* to describe the process by which a medical professional might interpret clues about a patient's illness and will then use that concept to characterize other professional–client interactions (such as a university counselor trying to gain insight about a student's stated intention for dropping a course).

Historical Lineage

Symbolic interactionism provides the essential epistemological source of sensitizing concepts. Herbert G. Blumer's *Symbolic Interactionism: Perspective and Method* deals with sensitizing concepts. Based on approaches by pragmatist philosophers, such as James Dewey, symbolic interactionism highlights experience and interaction in particular. In understanding this experience, the researcher must grasp the meaning with which the social actors infuse their understandings and actions. Sensitizing concepts are a logical and even an essential methodological consequence of this premise.

However, it was not until the early 1950s that Blumer coined the term *sensitizing concept* to bridge the prevailing gap (or grave shortcomings) in the then-current theories' all-too-evident separation from the empirical world.

Sensitizing concepts offer three important benefits in qualitative research. First, they are an important methodological device with which to enter the world of meanings of a researched population. Second, they offer the means to transcend the seemingly inherent problem of accumulating unique case-specific data.

Third, they allow the researcher to pay attention to developing concepts that are empirically grounded.

Usefulness in Approaching Empirical Instances

According to Blumer, sensitizing concepts give the user a general sense of reference and guidance in approaching empirical instances, suggesting helpful directions along which to look. Sensitizing concepts are starting points in thinking about a class of data about which the social researcher has no definite idea. A concept is usually provisional and may be dropped as a more viable and definite concept emerges in the course of research. According to this approach, meanings are best captured by using sensitizing concepts that contain the words and thoughts that research subjects use to explain their world. As a case in point, a study of northwest Icelandic fishermen shows that they regularly spoke of “going South.” This expression sensitizes the researcher to the practice employed by fishermen to negotiate policy changes in Reykjavik, Iceland's capital in the south of the country. “Going South” captures local initiatives to effect changes, the need to travel to Reykjavik—that is, from the periphery to the center—and the importance of engaging politicians and marine biologists when lobbying for change.

Potential to Transcend Unique Data

Blumer's 4,300-word essay, “What Is Wrong with Social Theory?” decries the aridity of contemporary social theory removed many times from the empirical world, treating social actors as irrelevant.

Blumer, however, had not intended sensitizing concepts to be definitive in the manner of offering a clear-cut identification of a particular class of data. For him there is an advantage in using sensitizing concepts rather than definitive ones. Because sensitizing concepts do not create closure during one's research, he thought they would be most useful in studying empirical instances. Such an inductive approach to the study of micro phenomena allows one to derive generic statements from what constitute unique data from unique settings.

Some Illustrative Examples

Every researcher will have come across sensitizing concepts that allow him or her to enter the realm of the studied population, shedding light on meanings distinctive

"How I Learned What a Crock Was" by Howard S. Becker (1993)

Howard S. Becker reports on a segment of research on medical students that led him to discover "crock" as a viable sensitizing concept.

As I've already said, my discovery of what the word "crock" meant was not a lightning bolt of intuition. On the contrary, it was guided by sociological theorizing every step of the way. Like this. When I heard Chet call the patient a crock, I engaged in a quick but deep theoretical analysis. I had a piece of theory ready to put to work here. . . .

So, when Chet called the patient a crock, I made this theoretical analysis in a flash and then came up with a profoundly theoretical question: "What's a crock?" He looked at me as if to say that any damn fool would know that. So I said, "Seriously, when you called her a crock, what did you mean?" He looked a little confused. He had known what he meant when he said it, but wasn't sure he could explain it. After fumbling for a while, he said it referred to someone with psychosomatic illness. . . .

But, as a good scientist, I wanted to check my finding out further, so I held my tongue. The next patient we saw, as it turned out, had a gastric ulcer, and the attending physician made him the occasion for a short lecture on psychosomatic illness, with ulcer the example at hand. It was quite interesting and, when we left the room, I tried out my new knowledge and said to Chet, "Crock, huh?" He looked at me as though I were a fool, and said, "No, he's not a crock." I said, "Why not?" He has

psychosomatic disease, doesn't he? Didn't you just tell me that's what a crock is? Didn't we just spend ten minutes discussing it?" He looked more confused than before and another student, eavesdropping on our discussion, undertook to clear it up: "No, he's not a crock. He really has an ulcer."

. . . we ended up defining a crock as a patient who had multiple complaints but no discernible physical pathology. That definition was robust, and held up under many further tests.

But my problem was only half solved. I still had to find out why students thought crocks were bad. What interest of theirs was compromised by a patient with many complaints and no pathology? When I asked them, students said that you couldn't learn anything from crocks that would be useful in your future medical practice. That told me that what students wanted to maximize in school, not surprisingly, was the chance to learn things that would be useful when they entered practice. . . . A crock presented no medical puzzles to be solved.

. . . Learning what a crock is was thus a matter of carefully unraveling the multiple meanings built into that simple word, rather than the Big Ah-Ha . . . This little ah-ha may have a lesson for us when we experience the Big Ah-Ha. Intuitions are great but they don't do much for us unless we follow them up with the detailed work that shows us what they really mean, what they can really account for.

Source: Retrieved January 2, 2007, from <http://home.earthlink.net/~hsbecker/index.html>

to that world. Dan and Cheryl Albas have made use of the term *aces* as used by students, opening up fruitful lines of inquiry and analysis. The term *desk science* in research by Will C. van den Hoonaard offers insights into how fishermen view the work of marine biologists. One of the better known examples of a sensitizing concept is Howard S. Becker's discovery of the use of *crock* by medical students. Becker followed a team of medical students in a teaching hospital, and when he heard one student say that a patient was "a crock," Becker followed through on the usage of this term and asked that student, "What's a crock?" Through successive visits to other patients and talking with more students, he realized that students were defining a *crock* as a patient with many health-related complaints but no discernible physical pathology. Crocks were, according to the medical students, not useful for their training in medicine. These patients had no apparent pathologies.

Thus, the medical students rated patients according to their usefulness in training. Nothing medical could be learned from these crocks. Medical students need only to talk to them (patients) to make them feel better. What is more, crocks took a lot more time than students had at their disposal. The patients often had a long medical history with multiple diagnoses, or surgeries: it just took a lot of precious time to get the patients' full accounts. Becker's cluing in to the off-the-cuff usage of a particular term revealed the wider aspects of the education of medical students, establishing what patients were deemed useful to their training, the problem of time, and what constituted healing.

Current Appeal and Use

Sensitizing concepts are experiencing a rebirth of sorts. A wide variety of disciplines are invoking them,

such as nursing, recreation and leisure studies, sociology, demography, social work, communication, and adult education, although virtually no introductory textbook in sociology makes an explicit reference to sensitizing concepts. Even textbooks that explicitly adopt the qualitative-research approach also ignore sensitizing concepts. Nevertheless, the use of sensitizing concepts is now so widespread and commonplace that many social scientists today no longer feel the need to articulate their indebtedness to Blumer.

SERENDIPITY

Serendipity is a distinctive type of inductive discovery. Robert Stebbins defines it as the quintessential form of informal experimentation, accidental discovery, and spontaneous invention. Robert K. Merton and Elinor Barber observe that serendipity can either refer to finding something of value while searching for something else or to finding something sought after in an unexpected place or manner. Serendipity contrasts sharply with a neighboring type of discovery with which it is sometimes confused; namely, exploration. The second is a broad-ranging, purposive, systematic, prearranged undertaking. And whereas serendipity is

highly democratic—at least in principle anyone can experience it—exploration is more narrowly select, the province of those creative people who are trained to routinely produce new ideas. In certain fields of serious leisure and professional work, artists, scientists, and entertainers, for example, routinely explore while, in some forms of casual leisure, people at play (both children and adults), sociable conversationalists, and seekers of sensory stimulation never do this. This observation holds equally well for many nonprofessional fields of work. For this second group, discovery can only come by way of serendipity. For the routinely creative group, however, discovery, though occasionally serendipitous, is nonetheless far more likely to flow from exploration.

Merton, one of a small number of social scientists to discuss serendipity in detail, first ran onto its sociological manifestation during his research on the social organization of Crafttown, his pseudonym for a suburban housing community composed of over 700 families. In this largely working-class community, he observed that a sizeable proportion of its residents were affiliated with more civic, political, and other voluntary organizations than in their previous places of residence. Serendipitously, he noted further that this increase in group participation had occurred also among the parents of infants and young children. This finding contradicted commonsense knowledge, for it is well known that, particularly on the lower socioeconomic levels, youngsters commonly tie parents down. In turn, this situation prevents them from actively participating in organized group life outside the home. This anomalous fact emerged well beyond Merton's original program of observation.

Recently, in a far more detailed examination of serendipity than found in Merton's earlier study, Merton and Barber explore its nature, history, and application in the humanities and social sciences. They observe that serendipity as a term first appeared in a letter written in 1754 by Horace Walpole to Horace Mann. Walpole coined *serendipity* based on his familiarity with the fairy tale *The Travels and Adventures of Three Princes of Serendip*. Serendip is the ancient name of Ceylon (today, Sri Lanka), and the three princes were sons of Jafer, at the time philosopher and king of that country. Serendipitous discovery is evident in places in the tale.

SITUATEDNESS

Situatedness refers to involvement within a context. There are two types of situatedness. The first type refers to the involvement of the researcher within a research site. Qualitative researchers should be aware of the situated nature of the contexts in which they collect data. The word *situated* refers, therefore, to the researcher's physically being on site and consequently to research shaped by personal relationships and by linguistic, biographical, historical, political, economic, cultural, ideological, material, and spatial dimensions. A researcher who is keenly aware of the situated nature of researchers can be said to be reflexive.

The second instance of situatedness refers to exactly the same phenomenon, but to a different subject: not only are researchers situated in the contexts they study, but so are the social agents whose lives are being investigated. Thus, situatedness means involvement of social beings with symbolic and material dimensions of sites and with the various social processes occurring in those domains. In sum, situatedness refers to the quality of contingency of all social interaction. As such, it stands in sharp opposition to the universal, determinist, atomistic, and absolute pretensions of classical positivism.

Situatedness is a tricky affair because of the diverse, contradicting, dynamic, uncertain, and constantly shifting ways of being involved in social domains. Different individuals are situated within contexts in different ways—depending on their definition of the situation. For example, teachers and students may share a common understanding of their context (the classroom), but their different perspectives, values, goals, identities, or biographies may make their conduct, experiences, or feelings different. Furthermore, regardless of their role as students, different pupils are oriented toward different classroom situations in different ways: for some, learning may be fun; for others, it may be but a family

imposition; and for others, a physical struggle. As their situatedness in the classroom context and in the various situations typical of this context varies, so do students' and teachers' interactions in relation to grading, attendance, effort, and so on. Because multiple ways of being situated in a context always exist, researchers need to be aware of the multiplicity of voices, possibilities, and interpretations existent within a research site. Since researchers are also situated, they need to reflect on how their observations and interpretations are outcomes of their interaction with that environment.

Over recent years, researchers have engaged in numerous debates over the nature of knowledge. According to some scholars, reflexivity of one's situatedness is unnecessary, difficult, or even impossible, and as long as the researcher's conduct in the research site is made predictable by following precise procedures for gathering and interpreting data, no problems occur. Others believe that reflexivity of one's situatedness as researchers is necessary to avoid bias. For them, the situatedness of knowledge works as a limitation of research based on its contingency. Finally, for a third group, research-derived knowledge is so inevitably embodied, so clearly positioned by such markers as race, gender, class, identity, time, and space that writing about knowledge can be nothing but a modest, relative, partial, relational, standpoint-based narrative—a story with no claim of authority higher than the stories that research participants may tell about themselves.

SNOWBALL SAMPLING

Snowball sampling uses a small pool of initial informants to nominate other participants who meet the eligibility criteria for a study. The name reflects an analogy to a snowball increasing in size as it rolls downhill.

This approach to locating research participants is almost always used as a form of nonprobability sampling (although some epidemiological research

applies techniques from social network analysis to variations on snowball sampling as a way to estimate the total size of populations). Snowball sampling is a useful way to pursue the goals of purposive sampling in many situations where there are no lists or other obvious sources for locating members of the population of interest, but it does require that the participants are likely to know others who share the characteristics that make them eligible for inclusion in the study. This method is particularly useful for locating hidden populations, where there is no way to know the total size of the overall population, such as samples of the homeless or users of illegal drugs.

The typical process for a snowball sample begins with interviewing an initial set of research participants who serve as informants about not only the research topic but also about other potential participants. In some cases, the process of snowballing that follows the initial interviews is indirect in the sense that these original sources mostly supply information about how to locate others like themselves; that is, where such people are likely to congregate, how to recognize them, and so on. In classic snowball sampling, however, the initial informant often assists in recruiting additional participants into the study. Depending on the number of people sought, this process of using earlier informants to locate new informants may go through several rounds. For example, a single initial informant might put the researcher in touch with three other sources who might assist in locating seven more new sources, and so on.

In practice, snowball sampling poses a distinct risk of capturing a biased subset of the total population of potential participants because any eligible participants who are not linked to the original set of informants will not be accessible for inclusion in the study. The best defense against this problem is to begin with a set of initial informants that are as diverse as possible. This variation on maximum diversity sampling increases the likelihood that the subsequent links in the snowballing process will reach different segments of the total set of eligible participants.

SOCIAL CONSTRUCTIONISM

The phrase *social construction* typically refers to a tradition of scholarship that traces the origin of knowledge and meaning and the nature of reality to processes generated within human relationships. The term *constructivism* is sometimes used interchangeably, but much scholarship associated with constructivism considers meaning-making as taking place in the individual mind, as opposed to a product of human relationships. Social constructionism has grown from three separate movements: a critical or ideological critique of dominating discourse, a literary-rhetorical critique of realism, and a social critique that emphasizes the communal origins of knowledge claims. The social constructionist position has significant implications for traditional research methods, both in questioning their authority and in opening up new possibilities, especially in the domain of qualitative inquiry. In qualitative research, social construction brings into specific focus three significant relationships: the researcher's relationships with the subjects of research, with the audience, and with society more generally.

Origins

Although one may trace the roots of social constructionism to early philosophers, such as Giambattista Vico, scholars often view *The Social Construction of Reality* by Peter Berger and Thomas Lukmann in 1966 as the landmark volume. Yet, because of its theoretical origins in social phenomenology, this work has largely been eclipsed by more recent scholarly developments, particularly three quite independent movements. In effect, the convergence of these movements provides the basis for social constructionist inquiry today.

The first movement may be viewed as critical and refers to the mounting ideological critique of all authoritative accounts of the world, including those of empirical science. Such critique can be traced to the Frankfurt School, as well as to other Marxist enclaves, but today is more fully embodied in movements associated with feminist, multicultural, anticolonial, gay

and lesbian, and antipsychiatry groups. The second significant movement, the literary-rhetorical, demonstrates the extent to which scientific theories, explanations, and descriptions of the world are not so much dependent on the world in itself as on discursive conventions. Traditions of language use construct what one takes to be the world. The third context of ferment, the social, may be traced to the collective scholarship in the history of science, the sociology of knowledge, and social studies of science. Here the major focus is on the social processes giving rise to knowledge, both scientific and otherwise.

Basic Tenets

The aim in this entry is not to review the emergence of these three movements. Rather, what follows is a brief outline of several of the most widely shared agreements to emerge from these various movements. To be sure, there is active disagreement among participants in these various traditions. However, there are at least three major lines of argument that tend to link these traditions and to form the basis of contemporary social constructionism. This discussion will prepare the way for a brief account of the relationship between social construction and movements in qualitative methods.

The Social Origins of Knowledge

Perhaps the most generative idea emerging from the constructionist dialogues is that what one takes to be knowledge of the world and self finds its origins in human relationships. What one takes to be true as opposed to false, objective as opposed to subjective, scientific as opposed to mythological, rational as opposed to irrational, moral as opposed to immoral is brought into being through historically and culturally situated social processes. This view stands in dramatic contrast to two of the most important intellectual and cultural traditions of the West. First is the tradition of the individual knower, the rational, self-directing, morally centered, and knowledgeable agent of action. Within the constructionist dialogues, one finds that it is not the individual mind in which knowledge, reason, emotion, and morality reside, but in relationships.

The communal view of knowledge also represents a major challenge to the presumption of truth, or the possibility that the accounts of scientists, or any other group, reveal or approach the objective truth about what is the case. In effect, propose the constructionists,

no one arrangement of words is necessarily more objective or accurate in its depiction of the world than any other. To be sure, accuracy may be achieved within a given community or tradition—according to its rules and practices. Physics and chemistry generate useful truths from within their communal traditions, just as psychologists, sociologists, and priests do from within theirs. But from these often competing traditions there is no means by which one can locate a transcendent truth, a “truly true.” Any attempt to establish the superior account would itself be the product of a given community of agreement.

To be sure, these arguments have provoked antagonistic reactions among scientific communities. There remain substantial numbers in the scientific community, including the social sciences, which still cling to a vision of science as generating “truth beyond community.” In contrast, scientists who see themselves as generating pragmatic or instrumental truths find constructionist arguments quite congenial. Thus, for example, both would agree that while Western medical science does succeed in generating what might commonly be called “cures” for that which is termed “illness,” these advances are dependent on culturally and historically specific constructions of what constitutes an impairment, health and illness, life and death, the boundaries of the body, the nature of pain, and so on. When these assumptions are treated as universal—true for all cultures and times—alternative conceptions are undermined and destroyed. To understand death, for example, as merely the termination of biological functioning would be an enormous impoverishment of human existence. If a nourishing life is of value, there is much to be said of those who believe in reincarnation, the Christian dogma of “a life hereafter,” or the Japanese, Mexican, or African tribal views of living ancestor spirits. The constructionist does not abandon medical science, but attempts to understand it as a cultural tradition—one among many.

The Centrality of Language

Central to the constructionist account of the social origins of knowledge is a concern with language. If accounts of the world are not demanded by what there is, then the traditional view of language as a mapping device ceases to compel. Rather, a Wittgensteinian view of language is invited, in which meaning is understood as a derivative of language use within

relationships. Given that games of language are essentially conducted in a rule-like fashion, accounts of the world are governed in significant degree by conventions of language use. Empirical research could not reveal, for example, that motives are oblong. The utterance is grammatically correct, but there is no way one could empirically verify or falsify such a proposition. Rather, while it is perfectly satisfactory to speak of motives as varying in intensity or content, discursive conventions for constructing motivation in the 21st century do not happen to include the adjective oblong.

Social constructionists also tend to accept the view of language games as embedded within broader forms of life. Thus, for example, the language conventions for communicating about human motivation are linked to certain activities, objects, and settings. For the empirical researcher there may be assessment devices for motivation (e.g., questionnaires, thematic analysis of discourse, controlled observations of behavior) and statistical technologies to assess differences between groups. Given broad agreement within a field of study about the way the game is played, conclusions can be reached about the nature of human motivation. As constructionists also suggest, playing by the rules of a given community is enormously important to sustaining these relationships. Not only does conformity to the rules affirm the reality, rationality, and values of the research community, but also the central purpose of the profession itself is sustained. To abandon the discourse would render the accompanying practices unintelligible. Without conventions of construction, action loses value.

The Politics of Knowledge

Social constructionism is closely allied with a pragmatic conception of knowledge. That is, traditional issues of truth and objectivity are replaced by concerns with that which research brings forth. It is not whether an account is true from a god's-eye view that matters, but rather, the implications for cultural life that follow from taking any truth claim seriously. This concern with consequences essentially eradicates the long-standing distinction between *fact* and *value*, between *is* and *ought*. The forms of life within any knowledge-making community represent and sustain the values of that community. In establishing "what is the case," the research community also places value on its particular metatheory of knowledge, constructions

of the world, and practices of research. When others embrace such knowledge, they wittingly or unwittingly extend the reach of these values.

Thus, for example, the scientist may use the most rigorous methods of testing intelligence and amass files of data that indicate differences in such capacities. However, the presumptions that there is something called individual intelligence, that a series of question and answer games reveal this capacity, and that some people are superior to others in this regard, are all specific to a given tradition or paradigm. Such concepts and measures are not required by "the way the world is." Most important, to accept the paradigm and extend its implications into daily practices may be advantageous or injurious to various people, depending on how they are classified.

This line of reasoning has had enormous repercussions in the academic community and beyond. This effect is so especially for scholars and practitioners concerned with social injustice, oppression, and the marginalization of minority groups in society. Drawing sustenance in particular from Michel Foucault's power-knowledge formulations, a strong critical movement has emerged across the social sciences, a movement that gives expression to the discontent and resistance shared within the broad spectrum of minorities. In what sense do the taken-for-granted realities of the scientist sustain ideologies inimical to a particular group (e.g., women, people of color, gays and lesbians, the working class, environmentalists, communalists, the colonized) or to human well-being more generally? Traditional research methods have also fallen prey to such critique. For example, experimental research is taken to task not only for its manipulative character and its value-neutral stance, but for its obliteration of the concept of human agency.

These three themes—centering on the social construction of the real and the good, the pivotal function of language in creating intelligible worlds, and the political and pragmatic nature of discourse—have rippled across the academic disciplines and throughout many domains of human practice. To be sure, there has been substantial controversy, and interested readers may wish to explore the various critiques and their rejoinders. However, such ideas also possess enormous potential. They have the capacity to challenge oppressive organizations, broaden the dialogues of human interchange, sharpen sensitivity to the limits of traditions, and incite the collaborative creation of

more viable futures. Such is the case in qualitative research as it is in the global context.

The Liberation of Methodology

Given these themes in social constructionist scholarship, what are the major implications for research methods in the social sciences? There are two broadly resounding challenges: First, no authoritative statement about the nature of things stands on any foundation other than its own network of presumptions. All attempts to credit (or discredit) a given research practice rely on historically and culturally situated agreements within a given community. In terms of research methodology, nothing is required by the nature of things because all methods are born out of presumptions about such matters. In effect, it is the presumptive base, generated within a given community, that makes requirements on methodology. What is learned about the world through employment of a given method will necessarily construct the world in terms of its base. Thus, within the social sciences the subject-object dualism embedded within much logical empiricist metatheory is congenial with a concept of persons as responsive to causal inputs (e.g., behaviorism). Both the positivist metatheory and the associated theories (i.e., behaviorist, cognitivist) give rise to methods of experimentation. In contrast, the humanist assumption of personal agency is more congenial with phenomenological research methods. If persons are defined as harboring unconscious motives, as in psychoanalytic theory, then practices of interpreting dreams and fantasies are upheld.

In effect, the constructionist dialogues serve a profoundly liberating function. They remove the privilege of any group to establish the necessary and desirable in methods of research. In broader terms, they relinquish the grip of methodology as the royal road to truth. Methods themselves do not provide guarantees of objective knowledge, so much as they attest to one's commitment to the realities, values, and practices of a particular community.

Yet, there is a second major outcome of social constructionist ideas for research methods. It is not simply the demise of authority that is hastened by constructionism, but the creation of an open field of possibility. Thus, to understand all knowledge claims as socially constructed is not to render them false or insignificant. Again, it is to recognize that each tradition, while limited, may offer us options for living together. In this

way constructionism invites a posture of curiosity, where new methodological amalgams are invited. In recognizing that the realities of today depend on the agreements of today, researchers realize enormous possibilities for methodological innovation.

These two outcomes of the constructionist dialogues have incited intense and broad-ranging controversy within the social sciences and have added force to an enormous creative surge in research methods. At present there are a myriad of questions, dilemmas, and possible trajectories that remain open. In the following section, several more specific implications for qualitative methodology are sketched.

Qualitative Research as Social Construction

Although constructionism makes no necessary demands on either theory or method, many researchers are drawn to the possibility of developing methods congenial with its premises. In particular, the constructionist emphasis on the relational genesis of intelligibility and action stands as a dramatic alternative to the individualist worldview dominating traditional social science. If methods are used to create a conception of the real and the good, is the world community not better served by methods that bring the importance of relationship into prominence as opposed to separation? In this context, there are three significant relationships: the researcher's relationships with the subjects of research, with the audience, and with society more generally. In each case, concerns with relationships lend themselves to particular innovations in qualitative methodology.

Relationship With the Subjects of Research

In traditional research, a strong distinction is drawn between the researcher and the subject matter under study. On the individualist account, the researcher should remain distant and dispassionate, and any relationship with the subject should be standardized and impersonal. In this way, an objective stance can be maintained, and the researcher's theoretical orientation will not bias the research outcome. Yet, as many see it, such relationships can be both alienated and exploitative in character. They also eliminate the subject's voice from determining the conclusions of the research. These concerns with relationships are highly congenial with a variety of innovations in qualitative

methods. At the outset, the narrative movement in qualitative research was highly significant in opening a space for the voice of the subject to be heard. Removing the researcher's mediation altogether, autoethnographic methods enable researchers to use their personal experience to illuminate various life-worlds. In action research, it is largely the voices of those to whom the researcher offers services that determine its outcome.

Relationship With the Audience

Traditionally the relationship between researcher and audience is that of teachers to their colleagues. Researchers enlighten their colleagues through reports on their theories and findings. Although this tradition does build viable communities of practice, it is also problematic in its creation of boundaries between communities and in its discouragement of communication with the society at large. Further, the concerns of those under study are typically sacrificed to the conventions and values of the field. In effect, the professional guild uses its observations of society primarily to strengthen itself, with little offered to the society from which the research was taken. Such critique has fueled a variety of methodological developments. For example, some researchers have sought ways of writing collaboratively with their subjects. Others have turned to visual methods of expression, using photographs taken by participants. An active international research group now pursues performance modes of representation, live and on the internet, not only to enrich the rhetorical capacities of the sciences, but also to create forms that appeal to a broad general audience.

Relationship With Society

In traditional, truth-seeking research, the relationship of the science to society tends to be both distant and inconsequential. The researcher's task is to establish what is the case; applications are left to others (i.e., not creators, but users). In effect, communication with the outside world is minimal, as the concerns of the scientific community are not necessarily those of the society. Further, the traditional search for universal principles of human functioning carries with it a conservative politics. The focus is on what must endure as opposed to what can be changed. From a constructionist perspective all research serves the ends of those cultures or subcultures

in which it is spawned. And, to the extent that intelligibilities can be transformed, so may patterns of societal life. Thus, for the researcher, the pressing concerns of the society may be prime stimulators of inquiry, and the methods may be tailored to achieve social change. For example, critical discourse methodology is exemplary of research growing from societal concerns and liberatory in its ultimate political goals. Similarly, the myriad methodologies of participatory action research (PAR) are tailored to the specific, change-oriented investments of various, often marginalized groups in society.

SOCIAL CONTEXT

Social context refers to the specific setting in which social interaction takes place. Social context includes specific, often unique meanings and interpretations assigned by people within the given group. Understanding the social context of a particular setting demands that researchers seek to understand and interpret meaning according to those in the setting, rather than meaning according to the researcher.

Researchers face important considerations related to social context. First, researchers must understand that meaning and knowledge are socially defined. That is to say that the people in a particular group or population collectively define the meanings and significance assigned to symbols, words, objects, and actions. Thus, researchers must seek to understand what particular actions, words, and objects mean to people in a particular setting, as opposed to what these may mean to the researcher.

For example, a wave or wink in a particular culture or setting may communicate a warm greeting or friendly joke by one definition. In a different social context, however, these actions might signify a completely different message. In other words, the meaning of a particular action or behavior must be understood in relation to the setting and system of which it is a part.

Understanding of meaning in a particular social context requires that researchers understand that it may be impossible to separate this socially constructed knowledge from the specific setting. This impossibility leads to two issues of interest. First, making comparisons or generalizations across groups may be difficult or inappropriate and presents a much-discussed problem. Second, both qualitative research and social context demand that researchers report findings in the language used by the participants. Hence, social context is directly related to the language and descriptions used to report findings, which has been criticized in quantitative circles.

As researchers are themselves a part of a particular social context, they must be aware of their own experiences and perspectives and how this may influence their conclusions and interpretations of meaning. This situation has raised questions about the role of bias, which stems from the realization that there is no theory-free knowledge. The general thinking is that these points of view (or biases) cannot be eliminated completely; researchers should actively ask themselves questions such as, "What does this (action, word, symbol) mean to them?" Such a focus, while not eliminating bias, maintains the researcher's focus on the meanings defined by the participants, rather than on the researcher.

For example, researchers must be careful not to assign their own meanings to practices such as working, teaching, marrying, or sport. Rather, they must remember that understanding these actions requires an understanding of the meaning that individuals, not the researcher, assign to them. Only through the particular social context that is locally defined can meaning be understood.

The social context, including the researcher as part of that context, is an important consideration for all qualitative researchers. Most particularly is the realization that the interpretation of data must be contextualized if it is to be meaningful and understood by others.

SOCIAL JUSTICE

Social justice, broadly defined, refers to a condition whereby all people are afforded fair opportunities to enjoy the benefits of society. Although many different specific conceptualizations of social justice have been posited, most agree that it is directly related to and influenced by the larger social, political, economic, and educational schema of a society and that it exists in varying degrees in each given context. When arbitrary distinctions are made between individuals and groups in the assigning of basic rights, responsibilities, and opportunities, conditions of social justice are greatly diminished; when all members of society are given equal freedom to pursue their desired ends, social justice can potentially flourish.

Instances of oppression have severely infringed upon the development of socially just societies. Although effectively meeting the needs of some, inequitable and historically entrenched policies, rituals, customs, and habits disproportionately and pervasively punish others. Without consideration of merit, the chances that people have to achieve educationally, advance economically, and function socially are significantly dependent upon where, how, and/or to whom they are born. These drastic discrepancies are widespread and can be witnessed across the diversity of society's sectors. Conditions of social justice (those that maximize the fundamental rights and liberties of all people), then, are formidably contested by the injustices of the past and present.

Contested Territories

The inequalities and injustices that counter conditions of social justice are often identified in relation to specific issues of diversity. Among these are issues related to race or ethnicity, social class (socioeconomics), gender, religion, sexuality, and ability. Some common considerations in each of these contested territories are briefly described below.

Race or Ethnicity

Instances of racism at individual, institutional, and societal levels have long inhibited people from non-dominant racial and/or ethnic groups from achieving comparable social standing as members of dominant groups. The effects of racism can be seen in many areas, including education (e.g., students of color may be placed in less rigorous courses, score lower on standardized tests, and graduate from high school and college at lower rates), business (e.g., people of color may be drastically underrepresented in positions that pay the most and wield the most influence), and politics (e.g., especially at state and federal levels, politicians of color may struggle to gain necessary support and/or attention to get elected). In addition, broader indicators of social advancement adamantly confirm that people of color suffer the brunt of unjust systems. For example, people of color are incarcerated at exceedingly high rates, own homes at extremely low rates, and are often labeled—both overtly and covertly—as being deficient in comparison with the dominant White “norm.”

Social Class

The historical permanence of issues of poverty can, like those of racism, be witnessed throughout the various spectrums of society. Children who are born into low-income households may receive inadequate early-childhood intervention (related to health, nutrition, and psychosocial support), may attend schools that are significantly underresourced, may be exposed more frequently to violence, and may be stigmatized with predesigned places on the lower rungs of the social ladder.

Gender

In the midst of legislation and policies that call for equal opportunity in the educational, professional, and social sectors, many women continue to be treated unequally. In comparison with men, women are less represented in educational fields of math, science, and engineering; paid less for similar work; and are less represented in top-level corporate, civic, religious, and political positions. Among countless other indicators of injustice, these conditions demonstrate the continued centrality of gender oppression in contemporary society.

Religion

Social injustices related to religion have been particularly evident in recent years. Deep-seated historical and philosophical differences between members of different faiths have been played out visibly and violently on the world stage. Additionally, in conjunction with the violent actions of extremists who perversely purport affiliation with given religions, those who legitimately and peacefully practice certain faiths may be subjected to widespread distrust and religious profiling by others—including members of more socially accepted faith denominations.

Sexuality

Issues of injustice related to sexuality or sexual orientation have also been notably prevalent recently. From debates between national political actors, to seminars in college classrooms, to discussions at school board meetings, an emergent mainstream engagement with issues of discrimination based on sexual orientation has proved necessary due to the continued individual and societal-level demonstrations of heterosexism.

Ability

Inequities based on ability also continue to be problematic. These inequities are evident both in the way that those who have disabilities are treated (placed on the fringes of relevance in educational, professional, and social circles) and by whom is labeled as having a disability (with disproportionate frequency, students of color, those who are poor, and those whose first language is not English).

With acknowledgment that problems exist in each of these issue areas, a common perception remains that individual instances of overt disparagement and disrespect—microaggressions—are the primary manifestations of oppression and that society, as a whole, is basically fair. Such positions, which overlook powerful statistics of oppression such as those alluded to above, often point to significant legal advances in civil rights (such as *Brown vs. Board of Education*, the Civil Rights Act of 1964, and Title IX) in describing a level playing field that is only incidentally disturbed by distorted individuals. Although it is true that foundational civil rights legislation has helped establish environments of possibility (where there once

appeared to be no hope), it can be seen, upon honest examination, that the oppression that limits the emergence of a socially just society is much deeper and complex than what is written in law. Social justice can be approached only when such changes in writing are accompanied by fundamental transformations to institutional structures and societal rhythms. For although people from nondominant groups certainly continue to suffer from and are limited by microaggressions, they are most dehumanized by their still-extraneous role in the writing of society's master narrative. Until those of diverse races, ethnicities, social classes, religions, sexual orientations, and abilities are comprehensively included in this public conceptualizing of truth, it has been suggested that social justice might remain an abstraction that is theorized rather than a reality that is concretized.

Qualitative Research: Moving Toward Social Justice

Social justice, then, is an idealized condition that is contested on multiple fronts. The influence of historical oppression continues to hold a strong grip on all societies—even those who progressively seek the maximization of personal liberties for all.

Efforts to bring about greater social justice have certainly been witnessed in various political and activist movements throughout history (such as the multiple civil rights movements), but in the field of research, work directed toward social research has emerged with regularity only in recent years. Of particular note has been the mainstream development and wider dissemination of qualitative research (in its diverse forms) from alternative paradigms. It is evident that such work, when informed by critical theories and employing emancipatory methods, can become a key instrument in the purposeful pursuit of social justice.

Alternative Research Paradigms

Until recent years, mainstream acceptance and legitimization of much qualitative research was minimal. Quantitative research tenets such as validity, reliability, and objectivity—ones that are differently defined or altogether irrelevant in qualitative work—were labeled as rigid standards of empirical work, and any study that did not embody such tenets was quickly

disregarded as subjective fluff. Such evaluative standards were indicators of the dominance of positivist or postpositivist paradigms of inquiry—perspectives that seek to prove or disprove universal truths that apply to all people, regardless of their place in society. However, as scholars and activists escalated their analyses of social ills, alternative paradigms (which had long been placed on the periphery of academic discussions) have emerged as appropriate lenses through which mainstream social conditions can be viewed. These constructivist, critical, and postmodern perspectives investigate truth as a context-specific, fluid construction—one that varies and has unique meaning by time and place. They call for deep, qualitative investigations into the complex experiences of individuals and in that they center alternative views of social reality, naturally gravitate toward revealing conditions of oppression and advocating for social justice. Exceptional instances of such work can be seen in the corpuses of writing of Peter McLaren, Henry Giroux, Gloria Ladson-Billings, Michael Dantley, and Joel Spring, among others. Therefore, although quantitative work is still identified as the gold standard by many central power brokers (in politics, education, and research), the burgeoning qualitative niche that is informed by alternative paradigms has made notable efforts to increase equity and justice.

Critical Theory

Tenets of critical theory have guided much of this qualitative research that explicitly seeks the liberation and empowerment of oppressed groups. Housing a broad range of more specifically focused frameworks (such as feminism, critical pedagogy, cultural studies, and critical race theory), critical theory, broadly conceived, is usually distinguishable from traditional positivistic or postpositivistic perspectives in several ways: (a) it questions issues of power, (b) it is political in nature, (c) it centers the voices of those who have traditionally been silenced, and (d) it necessarily stimulates action.

Power. Critical theory questions systems and structures of power that perpetuate injustice. It is rooted in the core assumption that power is disproportionately distributed in most social schema and that those who are not from the dominant race, class, gender, religion, sexual orientation, and/or ability groups suffer from this reality. Critical theory seeks to reveal these power structures and to redistribute power more equitably.

Politics. Unlike quantitative research studies that espouse researcher detachment and neutrality, qualitative research projects that are informed by critical theory are forthrightly political. Activist researchers openly seek the transformation of oppressive political, economic, educational, and/or social institutions, systems, and norms that perpetuate injustice. From critical perspectives, the changes that are sought are radical ones that address the core causes of oppression. Rather than discussing superficial solutions to deal with the symptoms of injustice, critical theory investigates the overhaul of resource allocation and disposition formation. Critical theory, then, is oppositional by nature and serves as a guide in the public discussion of political transformation.

Voice. In its emancipatory work, critical qualitative research centers the voices of people from traditionally silenced and/or oppressed groups. Their voices are contextualized without being normalized in reference to dominant group standards. In other words, the voices of the oppressed are presented in authentic communion with each other as dimensions of an oppressive totality, rather than being focalized in comparison to the mainstream discourse on reality. The counterstories (depictions of reality that differ from those that are typically perpetuated by dominant groups) of social injustice victims are presented as true, insightful, and meaningful on their own accord. The centering of these words can bring awareness to those who remain unaware of the widespread, pervasive nature of systemic oppression and, as described by Paulo Freire, it often helps elevate the consciousnesses of the oppressed themselves—many of whom have been systematically denied visions of different futures. By uniting their words with others who are oppressed, they can forge a solidarity which might lead to transformative action.

Action. Whereas the purpose of quantitative research is usually to explain, predict, and/or control, critically oriented qualitative research seeks to critique and transform. Inferred here is a fundamental value in critical theory for both awareness and action. Critical research is not distinct from movements of social activism—it is a contributing element of them. The quality of critical research is indeed largely dependent upon its effectiveness in stimulating change.

Although critical theories have informally guided change movements for many years, it is certainly

apparent that the increased presence of critically oriented works in qualitative research has contributed to a wider escalation of social justice advances by many members of the academy in recent years. These theories of resistance have served to not only broaden societal understandings of issues of equity and justice, but also to inspire creative methodological alternatives for conducting research.

Methodology

Inferred in the discussion of critical theory is the relevance of procedural considerations in the social justice quest. Specifically, the means must be consistent with the desired ends. Research that seeks to free the oppressed must first vocalize the oppressed. Those who were systemically quieted must be strategically amplified. Accordingly, critical qualitative data are collected and analyzed through dialogue, dialectics, hermeneutics, and/or participatory methods. It employs research designs such as ethnographies, autoethnographies, case studies, phenomenologies, narrative analyses, and action research, which are reflective of the very purposes of critical work. Indeed, critical qualitative research has ethical and moral commitments in that it moves the broader research conversation toward social justice by being necessarily rooted in the creative, authentic participation of the oppressed themselves. This differs from quantitative research that relies upon detached experimentation, manipulation, or verification of hypotheses.

The Context of the Social Justice Movement

Efforts to bring about social justice, including critical qualitative studies, have not been carried out untested. In the broader society, social justice is conceptualized in highly diverse ways, and many of these conceptualizations are reflective of deeply entrenched, widely accepted, and often unconscious systems, mind-sets, and mores. It is difficult for members of dominant groups to critically reflect upon and ultimately admit to the extents to which they have benefited from privilege. Such admissions to the fundamental influence of oppression and inequality, which occupy important spaces in the greater societal turn toward social justice, can threaten fundamental conceptions of societies as genuinely democratic and

meritocratic. Indeed, those who are relatively comfortable with the status quo often see social justice movements as unnecessary, risky, or even dangerous, and they dispute policies and movements that might alter entrenched power structures. As a result, many people who do not suffer the brunt of institutional and societal injustice are often more likely to contribute to the social good through acts of charity—those that can provide temporary relief within the established social framework—than through acts of social justice—those that seek the transformation of the very framework itself.

Despite the discomfort that some of the established elite might feel about altering social structures so that all people might have equal opportunities to enjoy the economic, educational, and social benefits of society, many critical scholars and activists suggest that each person, regardless of his or her current position in life, can only be fully humanized (the actualizing of human potential) when all people are able to write their futures unencumbered by the weight of oppression. This perspective is one of dialectics and confluences. The burdens of the oppressed are seen as the burdens of all and the emancipation of the oppressed is the advancement of all. The destinies of all people, no matter how different in their current states, are seen as shared. In this light, a socially just society, one where all people have fair opportunities to thrive, is a complex tapestry of mutual economic, educational, and social interdependence.

SOCIAL NETWORK ANALYSIS

Social network refers to the pattern of partnerships that channel social interaction. Social network analysis addresses how such ties are patterned and how these patterns influence ongoing bonds.

Relations have patterns whether those relations are absent or present. This concept is effectively universal, outside of very small groups, because social interaction takes time. As time is scarce, individuals tend to specialize with relatively few interaction partners to the exclusion of nearly all others. Exclusion is more severe for specialized kinds of interactions or bonds and is more prevalent in larger populations. Exclusion engenders texture in networks because gaps ensure that “who is in touch with whom” is variable, not uniform.

Social network can be understood in terms of a metaphor where persons (including corporate persons such as states) are nodes, and relations among persons are lines that link those nodes. The metaphor is highly adaptable since nodes can be any kind of interaction partners, such as firms, congregations, or computers, while relations can variously refer to assorted modes of exchange, interaction, or social bonds. Networks are studied in many disciplines, from computer science to anthropology, by methods ranging from mathematical modeling to ethnographic observation.

The graphic device of a network map has considerable appeal. But to create such a map empirically, it is usually necessary to abstract bonds to a limited number of alternatives—for example, as absent versus present—without distinctions of degree.

Jacob Moreno’s sociometry is widely considered to be the pioneering application of the social network idea. Typical studies began with small populations confined by shared circumstances such as a classroom, dormitory floor, or correctional facility. Every individual could be asked about sentiments or attachments toward each of the others. These responses yielded patterns for which labels were devised. Individuals, termed egos, could be *isolates* with no ties or few ties, while *stars* had many ties. Multiindividual patterns were also apparent. Some nodes were connected to others by paths of varying

numbers of steps while others were disconnected and could not be reached, for example, by gossip. A set of nodes, each of whose members had ties to every other, was termed a *clique*. In many settings, multiple cliques were apparent, where two or more distinctive subsets were united by a thick knit of bonds, but where bonds were few (or absent) between different cliques and isolates were excluded from all cliques.

Georg Simmel's accounts of how triads differed from dyads sparked interest in how bonds are affected by surrounding bonds. Many roles, such as in-law or referee, are defined by joint relations to a bonded pair. Transactions, between marriage partners or contestants in a match, are influenced by mutual awareness of how third parties might intervene.

Such concerns help motivate studies of ego-centered networks of focal persons and the others to whom they are tied by frequent interactions and/or formal bonds. When different types of ties—such as kinship, coworkers, and friendship—are distinguished, bonds can be classified as single-stranded versus multiplex. Another concern is whether ego's alters (i.e., the others tied to some focal individual) are tied to each other or not. In turn, such patterns are examined as potential determinants of cohesion, individuality, and social support.

SOCIAL SCIENCES, QUALITATIVE RESEARCH IN

When one thinks of the social sciences, one typically envisions a group of academic disciplines that study various human aspects of the social world. The social sciences are distinguishable from the arts and humanities chiefly because social scientists employ the use of the scientific method in their studies of human groups, societies, and humanity.

Qualitative research in the social sciences involves the use of a variety of available qualitative methodologies.

Qualitative research, however, is a bit amorphous to define; the most obvious definition is that it is research that uses methods that are not primarily quantitative (numerical) in nature. Qualitative research may also be viewed as using various methods that embrace the quality or essence of something, some phenomenon, or even some event. Some people believe qualitative methods are largely subjective, where the researcher is used as the instrument of data collection or at least as a filter for capturing information on some subject. Other people suggest that qualitative research in the social sciences involves historical tracing or at least some sort of historical contextualization of whatever the researcher is investigating. Those with a more theoretical stance claim that qualitative research in the social sciences is guided by the orientations set forth in symbolic interaction.

Symbolic interaction is one of several theoretical schools of thought available in the social sciences. This orientation maintains that what humans do and say are the result of how they interpret their social world to have meaning; in effect, what people do and say has specific meanings communicated through mutually shared understandings of symbols, the most common of which being language. One reason for these various nuances in meaning for qualitative research in the social sciences is that various disciplines and fields commonly thought of as comprising the social sciences have sought to incorporate their own interpretations and perspectives on the methodological frameworks by which they plan and organize their research endeavors. In this manner, they seek to capture their own discipline's theoretical perspectives and epistemological orientations while using a qualitative methodological paradigm.

The Qualitative Methodological Paradigm

The design of any research study begins with an idea for the study and selection of a methodological paradigm. A paradigm is essentially a worldview, a whole framework of beliefs, values, and methods within which research will take place. Qualitative research places emphasis on understanding through looking closely at people's words, actions and interactions, and traces or records created by people. Qualitative research examines the patterns of meaning that emerge from systematic observations of people's words, actions and interactions, and traces or records. The task of the qualitative researcher, then, is to locate

these patterns in the words and actions of people and to offer interpretations of these patterns while staying as close as possible to the social constructions of the participants who originally experienced these words and actions. Thus, following a qualitative paradigm in the social sciences means seeking to allow patterns to emerge in the data in order to discover and better understand how the participants under investigation come to give meaning to things, what these meanings are, and to place into a contextual understanding what people say and do under certain circumstances or in specific situations, given the meanings attached to various objects, events, and phenomena.

What Are the Social Science Disciplines?

When one thinks of traditional social scientific disciplines, one is likely to consider anthropology, sociology, psychology, political science, and economics. During the past several decades, however, other fields and disciplines have begun to see themselves as part of the social sciences, slowly giving rise to recognizing other disciplines as part of the social sciences. These include criminology, nursing, public health, social work, education, English, history, women's studies, and even business and marketing. The lines of demarcation between fields of study and disciplines, then, have become blurred, but among the several linchpins that seem to hold them together as the social sciences, are their research methods. All of the new social sciences have incorporated the qualitative paradigm into their primary research strategies and offer discipline specific qualitative methods courses as part of their curriculums.

In truth, there are many ways to actually conduct qualitative research in the social sciences, depending on whether one considers discipline traditions or methodological orientations. For example, one can assert at least five major qualitative research traditions that are discipline related, which include cognitive anthropology, ecological psychology, ethnographic communication used in English and linguistics, holistic or naturalistic ethnography in education, and symbolic interactionism, commonly associated with sociology.

Cognitive Anthropology

The field of cognitive anthropology focuses on the study of the relation between human culture and human thought, rather than with material, artifacts, or phenomena. Cognitive anthropologists study how

people understand and organize the material objects, events, and experiences that make up their world as the people they study perceive it. Consequently, cognitive anthropologists explore how people make sense of reality according to their own Indigenous cognitive categories, not the analytic creations or interpretations of the researcher.

Ecological Psychology

Ecological psychology views the world as divided into two distinct domains: the environment and the person. This perspective offers a picture of the world as consisting of matter and material objects in motion, in the environment, and as distinct from a second separate dynamic cognitive realm. One can envision this second realm as that of mental phenomenon, a realm where materialistic accounts and natural law do not apply. What one might consider phenomena of psychological interest—such as perceptual experiences, thoughts, and emotions—are located in this realm of the person, yet the causes of these psychological phenomena should be understood as occurring in the material domain—the environment. Ecological psychology is sometimes described as an analytic framework that seeks to reveal functional relationships in the ongoing reciprocal interactions between the realms of the person and the environment.

Ethnographic Communication

Ethnographic communication examines language and its use. At the societal level, ethnographic communication examines what functions language serves. For example, many languages contain terms that serve a social identification function in society by providing linguistic indicators that may be used to reinforce social stratification or to maintain differential power relationships between groups. Linguistic features are often employed by people consciously or unconsciously to identify themselves and others and thus serve to mark and maintain various social categories and divisions. At the level of the individual and the group, then, ethnographic communication examines groups interacting with one another to understand how the function of communication may be directly related to the participants' purposes and needs. These may include categories of functions such as *expressive terms* (conveying feelings, sentiment, or emotion), *directive terms* (requesting or demanding), *referential*

terms (true or false statements, with propositional content), *poetic terms* (connoting a sense of aesthetics), *phatic terms* (offering notions of empathy and solidarity), and *metalinguistics* (referring to language use itself).

Holistic or Naturalistic Ethnography

Holistic or naturalistic ethnography has commonly become part of the research repertoire in the study of schools and education. This ethnographic process seeks to provide holistic and scientific descriptions of educational systems, processes, and phenomena within their specific contexts (as applied to educational research). It is loosely based on classical ethnography that tends to focus on an entire social group or organization; the goal of a holistic ethnography is the description of an entire cultural system, or in the case of its use in education, an entire educational process, school, or a classroom experience.

Symbolic Interactionism

Symbolic interactionism, or interactionism for short, as mentioned above, is one of the major theoretical perspectives in sociology. Interactionists focus on the subjective aspects of social life rather than on objective, macrostructural aspects of social systems. This forms the substantive basis for symbolic interactionism as a theoretical approach whose orientation is generally acknowledged to derive from the works of John Dewey, Charles Horton Cooley, George Herbert Mead, and Herbert Blumer, the last often considered the primary founder of symbolic interactionism. Interactionists base their theoretical perspective on the idea that humans account for meaning in two basic ways. First, meaning may be seen as intrinsically attached to an object, event, phenomenon, and so forth. Second, meaning may be understood as a psychological accretion imposed on objects, events, and the like by people. Thus, meanings are attached to objects, events, phenomenon, and so forth as part of the social process in which these items take place.

For interactionists, humans are pragmatic actors who continually adjust their behavior to the actions and reactions of other actors. People can adjust to these actions only because humans are able to interpret the actions of others; that is, humans are capable of denoting actions symbolically and treating these actions, and those who perform them, as symbolic

objects. This process of adjustment is aided by humans' ability to imaginatively rehearse alternative lines of action before acting—as if performing before an imaginary audience. The process is further aided by the ability to think about and to react to one's own actions and even oneself as a symbolic object. Thus, the interactionist sees humans as active, creative participants who construct their social world, not as passive, conforming objects of socialization.

Methodological Considerations

Methodologically, one can suggest a variety of traditional data collection technologies used by an assortment of social science disciplines; among the more common are biographical and autobiographical methods, case studies, participant observation, interviewing, oral histories and historical tracing, grounded theory approaches, and phenomenological discovery. Today, a number of innovative data collection strategies that once were considered splinter or off the mainstream have begun to appear in greater frequency; these include action research, photo-voice, visual ethnography and other photographic and visual recording techniques, and e-interviewing. Given the breadth and depth of qualitative research in the social sciences, it would be inappropriate to explain in detail all of these techniques here or try to associate any of them with a particular discipline or field of study in the social science. However, it would seem appropriate to at minimum briefly define each of the traditional strategies, and these definitions are offered below.

Biographical and Autobiographical Methods

Autobiography is perhaps the most widely accepted form of personal document in the social sciences. Most sources will suggest there are actually three major types of autobiography: comprehensive, topical, and edited. The comprehensive autobiography spans the entire life of an individual and includes detailed descriptions of one's life experiences, personal insights, and anecdotal reminiscences. Topical autobiographies, unlike the more well-rounded and complete description of experiences offered in a comprehensive autobiography, provide a more fragmented picture of an individual's life. The typical topical autobiography is more of an excision from the life of a subject than is the full life description. The edited autobiography involves the researcher serving as a kind of editor and

commentator who eliminates any repetition in descriptions, shortens lengthy discourse to more direct and crisper statements, and amplifies selected portions of the biography while deleting others.

Case Studies

Case studies can be defined in a number of ways. Some sources will define case studies as attempts to systematically investigate an event or set of related events with the specific aim of describing and explaining the phenomenon. Other sources may suggest case studies seek to examine a single setting, single subject, single event, or even a single depository of documents. Regardless of one's personal favorite, most definitions will indicate it is a method that involves systematically gathering enough information about some particular individual, social setting, event, group, or organization sufficient to permit the researcher to effectively understand how the subject of the study experiences things as he, she, or they operate and function in their group or setting.

Participant Observation

In general, participant observation involves the process of immersing oneself into the natural setting of some group of people from whom the researcher is not too different or from which the researcher may already be a member. Research is undertaken either covertly (where the researcher's identity as an investigator is kept secret) or overtly (where the group is informed that the researcher is undertaking a study of the group). The goal of participant observation is to gain an understanding of the various activities and experiences of those being observed in their natural setting. The research methods literature frequently describes includes at least three roles a researcher may take when undertaking observational research:

1. *Complete participation*, where the researcher is an active member of the group and participates in the full gamut of activities and social relationships available to him or her in the group being studied. Frequently, this orientation is undertaken covertly.

2. *Partial participant or participant as observer*, where the researcher may or may not be a full member of the group and where he or she may participate in many or even all activities of the group under study, but need not

participate in any. In most cases, the researcher's presence and identity as a researcher is known by the group (an identified researcher), and thus the researcher can bow out of certain activities if he or she chooses.

3. *Nonparticipant observation* involves an identified researcher intentionally not taking part in any of the usual activities of the group under investigation, maintaining instead a kind of watchful and professionally distant role and relationship with members of the group during observations.

Interviewing

This method may involve one-on-one or face-to-face type endeavors or groups of individuals simultaneously being interviewed by a single researcher or facilitator. Such groups are sometimes referred to as focus group interviews, whereas the face-to-face interviews are frequently described as in-depth interviews. Face-to-face interviews are sometimes placed along an imaginary continuum of rigidity of structure and are described as unstructured, semi-structured, and structured, where the least amount of formal structure is required of the unstructured interview and the greatest amount of formal structure is found in the structured interview format. Although face-to-face interviews encourage individuals to speak about their personal experiences and understandings of their social lives, the group interview makes use of the synergistic energy of the group to encourage people to talk about and to discuss their views and experiences, sometimes negotiating different understandings than some may have held prior to the group interview.

Oral Histories and Historical Tracing

Oral histories are literally the stories and eyewitness descriptions of individuals who have personal life experiences with certain events, phenomena, settings, and so forth. Although the ideal way to learn about this information is by listening to an oral historian, many researchers have recorded and/or transcribed the words of oral historians and created more permanent records of these oral histories. Given the growing accessibility of oral history archives on the internet, a kind of revitalization of this orientation has begun to occur in the social sciences during the past 10 years. It is now possible to locate and actually listen to—via the internet, for example—archived interviews with jazz musicians,

fishermen, townsfolk, and an assortment of other individuals making up a vast variety of social roles one might be interested in researching. Historical tracings tend to draw out their research investigation by examining various types of data typically classified as either primary or secondary.

Primary data are derived from sources such as oral historians, or their transcribed statements, or written testimony of other types of eyewitnesses. These tend to be the original artifacts, documents, and items related to some direct event, or outcome of an event, or some experience of an individual.

Secondary data are sources that include oral or written statements from people who may not have been immediately present during the event or phenomenon being described, but they convey information provided by others who were present or have knowledge about some specific research interest or subject.

Grounded Theory Approaches

Grounded theory is frequently described as a method where the theory emerges from the data itself rather than a priori. Grounded theory is sometimes described as a method that separates theory and data, but in fact, it should be more accurately described as a method that combines the two. Data collection, analysis, and theory formulation are intricately and reciprocally related, and the grounded theory approach incorporates explicit procedures to guide and ensure this. Thus, theory literally springs from and is anchored to the data.

Phenomenological Discovery

Phenomenology is generally understood as designating a philosophical movement that arose during the turn of the 20th century that proposed a radically different grounding for scientific study and theoretical construction. Originally applied to psychology, phenomenology has been adapted to most other disciplines of the contemporary social sciences. The original work on phenomenology is generally attributed to the writings of Martin Heidegger, Edmund Husserl, and George Wilhelm Friedrich Hegel, all of whom wrote at the turn of the 20th century. Methodologically, phenomenological discovery is the study of structures of consciousness as experienced from the first-person point of view of those experiencing some activity, event, or phenomena. Phenomenological discovery, then, literally can be

described as the study of phenomena—the appearance of things, or things as they appear, in one’s own experiences, or even the way one experiences things. Thus, phenomenological discovery seeks to examine the meanings things have in one’s personal experience and how these meanings may be shaped and/or used.

Future Directions for Qualitative Research in the Social Sciences

There are several fairly conspicuous similarities in all of the methodological technologies described in this entry, which tend to bind together all of these procedures under the qualitative paradigm. First, all of them tend to examine experiences of individuals under study—regardless of what specific data they seek to collect. Second, all of these orientations and methods seek to explain meanings. And third, none of these orientations or methodological strategies is restricted to any particular social scientific field of study or discipline. Rather, these orientations are extremely flexible and provide a means for being adapted and applied not only in different disciplines, but also over time as technology expands the horizons of qualitative research.

Although most people tend to associate computer technology and the internet with more quantitative number-crunching activities, in fact, qualitative research in the social sciences has reached out to embrace technology as well. Self-administered interviews, laptop computers, or e-interviews conducted entirely in real time and over the internet are fast becoming more common. Explorations of blogs permit investigators to conduct phenomenological explorations of the social worlds of people involved in a wide assortment of areas, fields, and occupations. Even participant observation can be undertaken in a high-tech fashion through the use of digital cameras either attached to a computer or connected by way of wireless transmissions to monitor a particular setting, individual, or group. As qualitative researchers in the various social sciences continue to move forward through the current millennium, it seems clear that they not only will continue to expand their orientations and strategies for data collection, but also will remain tied to the overall qualitative paradigm.

STATISTICS

Statistics is divided into two categories: descriptive and inferential. The objective of descriptive statistics is to describe or summarize the properties of data that a researcher has collected. Inferential statistics is for inferring from a sample to a population.

In general, the goals of qualitative research (i.e., to identify key trends or patterns and transferable findings and to study in-depth phenomena within small populations) are quite different from the goals of quantitative research (i.e., to discover generalizable results and to study across broad populations); therefore, the use of statistics is not the same in the two approaches. As with descriptive statistics, inferential statistics allow researchers using a multi or mixed method approach to provide another context, a richer picture or enhanced representation, in which to examine the phenomenon of interest. The inclusion of quantitative data can also enhance legitimacy (i.e., validity, credibility, trustworthiness, or transferability), although this may not be appropriate for some qualitative studies. Not all researchers agree with the mixed method approach.

Qualitative and quantitative researchers use three inference modes: abduction, induction, and deduction. Abduction occurs when one studies the facts, hunches, and data and develops general propositions from specific observations to devise a working hypothesis. Inductive reasoning occurs when one tests the working hypothesis. Deductive reasoning occurs when the

researcher begins with a premise (hypothesis testing) typically from a theory and makes inferences after testing that premise. In statistics, researchers deduce that two groups are not the same after observing a statistically significant difference test. Depending on the research being conducted, the three inference modes occur at different temporal locations during a research study. Traditionally, abduction and induction are associated with qualitative research, while deduction is associated with quantitative research.

Because making good inferences is paramount in research, the correct use of inferential statistics is important, when this appropriate. In many qualitative projects, trustworthiness of data is key to quality results; however, statistics may or may not play a role in this process. Therefore, it is imperative to understand a few key components of inferential statistics, such as sample, sampling error, and null hypothesis as related to statistical significance.

Statistical rigor begins with the sample of participants. The sample of participants is a representation of the whole population. Therefore, how the gathered sample relates to the larger population of interest is important. Political exit polling is a good example where a large number of participants answer a question, and an inference about the larger population of individuals occurs. Who was sampled and how they were chosen affects the quality of the results and inferences from those results.

The exit poll data collected, in quantitative terms, are variables. For example, individuals' votes (yes or no) on a legislative bill would be one variable—that is, how they voted. The proportion who voted yes is a descriptive or sample statistic. If every voter were asked how he or she voted, then that proportion is a parameter or population parameter because it concerns the whole population. The values typically calculated from a sample are termed statistics because the complete set of values for a variable from a population is rare. If the sample is representative of the population, then inferences made from those proportions would be considered valid and generalizable to the larger population.

Due to the issues of obtaining a representative sample, the concept of sampling error developed. The sampling error provides an estimate of the calculated statistic. This is why random sampling from the population is desired. If the sample is truly random, there is a reduction in sampling error. Increasing the number of participants will also reduce sampling error risk.

Similar to descriptive statistics, the types of data collected has an appropriate type of inferential statistic

to use. Data that are interval or ratio and normally distributed use parametric tests (e.g., a *t*-test). If these conditions are not met, nonparametric analysis is appropriate (e.g., Mann-Whitney *U* test, the nonparametric version of the *t*-test).

The test of statistical significance is a procedure for determining the probability of a particular result with specific caveats (e.g., that the null hypothesis, no difference between group A and B on phenomenon Y, is true, and random sampling and random assignment of participants occurs). A statistical test does not indicate the probability that the null hypothesis is true or false, does not give the probability that an alternative hypothesis is true or false, and does not indicate if the observed results will be replicated. A statistically significant test could be discussed in the results as plausible in relation to the null hypothesis. The tradition of rejecting the null hypothesis, a statistically significant observation, is too absolute in its conclusion.

Finally, sample size affects statistical significance; that is, the larger the sample, the more likely a statistically significant difference between groups or association between variables will be observed.

Integrating inferential statistics into a qualitative design can be categorized in two ways: sequential and parallel. In the first, sequential approach, a researcher conducts a qualitative study to identify theoretical issues and to develop hypotheses. Next, the researcher conducts a quantitative study with inferential statistical tests to test those hypotheses with a larger sample. Essentially, the qualitative study is performed to identify research problem areas and to determine which research questions should be investigated quantitatively. A second approach is where a researcher completes a quantitative study, first, because the domain is so large (e.g., community characteristics and student achievement across a whole state or province); quantitative information from that study can be used to refine the sample and identify potential research questions for a qualitative study. A parallel approach occurs when a researcher simultaneously conducts a qualitative and quantitative study. This approach has the potential to determine measurement problems and to identify unique aspects of both methods because data are gathered from participants with two methods.

STORYTELLING

The universe is made of stories,
not of atoms.

These two brief lines from Muriel Rukeyser's poem, "The Speed of Darkness," offer a succinct affirmation of the significance of storytelling for any discipline of the arts, humanities, and natural and social sciences. In effect, the so-called narrative turn in scholarly inquiry invites researchers to recognize how their particular forms of discourse are ordered as narratives; that is, to think of all discourse as taking the form of a story. Rukeyser reminds us that the worlds we inhabit (perceptual, existential, phenomenal, imagined, virtual, etc.) can for many purposes be understood as being composed of stories. The idea that the universe is made of atoms is just one of those stories.

Within the social sciences, the literature of historical inquiry took an explicit narrative turn in the 1970s, with representative works including Louis Mink's appraisal of history and fiction as modes of comprehension. However, during the same period, historians such as Lawrence Stone referred to the revival of

narrative as a new old history, thereby indicating the durability of storytelling in the historiography of Western societies. Other social scientists who added significant momentum to the narrative turn around this time include Richard Rorty, with his call to see the social sciences as continuous with literature; that is, as genres of storytelling that interpret other people to us and thus enlarge and deepen our sense of community with them. Donald Polkinghorne's book *Narrative Knowing and the Human Sciences*, and Laurel Richardson's work on narrative and sociology were similarly generative.

Alasdair MacIntyre provides an ethical imperative for disciplined storytelling in his influential study in moral theory, *After Virtue: A Study of Moral Theory*: "I can only answer the question 'What am I to do?' if I can answer the prior question 'Of what story or stories do I find myself a part?' . . . Mythology, in its original sense, is at the heart of things" (1984, p. 216). Some of the most powerful and practical examples of the relationship between ethics and storytelling can be found in the literature that deals with the place of storytelling and narrative structures in finding meaning in illness. For example, Arthur Frank's *The Wounded Storyteller: Body, Illness, and Ethics* examines the ways in which illness can be the beginning of a journey in which the teller calls others into a transformative narrative relationship: personal ethics become social ethics as the suffering individual brings others into caring relationships, which in turn draw attention to social structures and systems that might support such morally responsible relationships.

Some critics of narrative methods argue that sociologists should be story analysts rather than storytellers. For example, Paul Atkinson repudiates the narrative turn in the social sciences and argues that personal narratives, especially illness narratives, misconstrue the essential nature of narrative by substituting a therapeutic for a sociological view of the person. Responding to Atkinson and others, Arthur Bochner defends what he calls "narrative's virtues" and argues that critics who see narratives of suffering as privileged, romantic, and/or solipsistic cling to an idealized (and certainly contested) theory of social inquiry, a monolithic conception of ethnography, a masculine characterization of sociology, and an implicit resistance to the moral, political, existential, and therapeutic goals of deploying narrative methods in seeking deeper understandings of social problems and issues.

Donna Haraway demonstrates the generativity of the narrative turn for the natural sciences in her

critical history of primatology, *Primate Visions*. She argues that biologists observe the performances of organisms and that their testimonies to their experiences of these performances are the "facts" they transform into "truths" that are attested by their disciplined experience and made meaningful within their traditions of social relationships and organization. Thus, in the production of biological truth-claims, she insists that both biologists and organisms are actors in a storytelling practice.

French literary critic Gerard Genette suggests a tripartite framework for analyzing distinctions among literary works that can also be used for distinguishing between various aspects of storytelling: (1) rhetorical moves that create a particular narrative statement; (2) the events and situations that are being described, (that is, the larger story that is being told, given that the same events can be told in different ways); and (3) the act of narrating. In the field of educational inquiry, Carola Conle has demonstrated the utility of applying Genette's schema to the analysis of curriculum discourses-practices. Among other educational researchers who have embraced narrative approaches, Tom Barone's work on critical storytelling follows Rorty in connecting educational inquiry with other storytelling genres, including literary fiction and journalism.

STRATIFIED SAMPLING

Stratified sampling is a process that first divides the overall population into separate subgroups and then creates a sample by drawing subsamples from each of those subgroups. Within the overall process of sampling, stratification is related to the definition of the population because it requires a prior definition of categories within the population before it is possible to draw samples from those subgroups. This general process can apply to both qualitative and quantitative research. For survey sampling, stratification ensures the degree to which pre-selected subgroups in the population are represented in the sample—otherwise, a process of random sampling always includes the possibility that one of these groups will be substantially over or underrepresented, simply by the luck of the draw. For example, a survey of a city where the population is evenly split between three major ethnic groups might divide the sample into thirds, with each subsample drawn from a different ethnic group to ensure that the size of each group in the sample reflects its size in the population.

In qualitative research, stratified sampling is a specific strategy for implementing the broader goal of purposive sampling. In this case, dividing the larger population into subcategories that are relevant for the research goals ensures that the data will include cases from each of these categories. The simplest kind of stratification divides the overall sample into two distinct groups, but it is also possible to create more than two groups or to draw the subsamples from different points along a continuum.

The most common reason for using a stratified approach to purposive sampling is to do systematic comparisons between the categories that define the basis for stratification. For example, an interview project might examine how parents from the lower, middle, and upper socioeconomic sectors interacted with their children's teachers, while a participant observation project might compare schools where students from low-income families had either above- or below-average performance on standardized tests, or a media analysis project might examine written work from students whose teachers had either less than 2 or more than 5 years of experience. In each of these cases, the overall goal of purposive sampling includes the need to determine the similarities and/or differences between carefully selected subsets of the larger population, and the stratification of the sample makes this comparison possible.

For qualitative research, stratification has a distinct link to quota sampling as a means of selecting cases. Thus, when the purposive selection process calls for data from subgroups in the population, the next step is to select the members of those subgroups that will make up the corresponding subsamples, which amounts to setting a quota for the size of each subsample. For example, if the research design calls for a total of 20 men and women to be interviewed on some topic, then the research design implies a quota of more or less 10 men and 10 women in each subgroup. Of course, the emergent data from those interviews may point toward something other than an even split between the original categories, but the key goal is still to ensure that there are a sufficient number of data sources in each subcategory.

STRUCTURALISM

Structuralism is a theoretical concept that gained particular currency in the 1960s. It has been interpreted in

a number of different ways, but a common theme is the prioritization of the explanatory power of linguistic, social, and economic structures over individual agency and meaning. Emphasis is also placed on underlying processes and systems that determine individual action.

Theoretical Underpinnings

In order to review the contribution of structuralism to research, it is useful to briefly review theoretical understandings of this concept. Two key examples in relation to language and social relations can be taken from the writings of Ferdinand de Saussure and Louis Althusser.

Saussure (1916/1974) focused on the structure of language. He maintained that there is a pre-given structuring of language prior to its realization in speech or writing. He viewed language as comprising a set of signs, with each sign being made up of a signifier (a sound or written image) and a signified (meaning). He maintained that the connection between the two is arbitrary, rather than natural, and that each sign obtains its meaning from its difference from all other signs in the language chain. However, he made it clear that although both the signified and the signifier have no connections when considered separately, when combined, the connection is ratified, resulting in the production of an established fact. Structuralism in language for Saussure was associated with the combining of signifier and signified and with the concomitant fixing of meaning. He regarded this as a product of the conventions of a speech community.

With regard to social relations, structuralism is concerned with determining the real or essential structures that underlie social interaction. In this, the individual or the individual subject is decentered. Althusser (1971) argued, in his interpretation of Marxism, that individual agency and social life is predominantly determined by social structure. He used the term *ideological state apparatuses* to refer to the complex correlation of ideological and political forces within the economy. He maintained that ideological state apparatuses contribute to the reproduction of capitalist relations of exploitation and that language is the means by which the various ideological state apparatuses determine dominant meanings. Accordingly, Althusser argued that individuals are governed by ideological state apparatuses in the interests of the ruling class and by language in the form of

ideology in general. Ideology functions for the individual by interpellating; that is, recruiting or transforming individuals into subjects and agents. He put forward the view that ideology has the effect of making an individual unthinkingly accept their constituted subjectivity. As a result, individuals would perceive themselves to be in control of their own actions and the formulation of meanings, although, according to Althusser's structural analysis, this would be predetermined and inflexible.

Other key figures who have utilized structuralist perspectives include Jaques Lacan, Roland Barthes, and Claude Lévi-Strauss. Lacan used this orientation to explore the unconscious, and he concentrated on producing theoretical accounts relating to the identification of deeper, underlying psychological structures. Barthes, in turn, looked at ways of deconstructing and reconstructing objects in order to reveal the underpinning rules of functioning, and Lévi-Strauss sought to identify the structures that informed cultural systems and myths across societies. As part of this process, he claimed that the universal codes that he identified had an objective validity.

A predominant and deterministic emphasis on the discovery of underlying structures has been subject to considerable critique. Many have sought to emphasize a duality of both agency and structure, and Anthony Giddens, perhaps, provides the most famous example. Giddens promoted structuration theory as a way of not privileging either agency or structure in sociological analyses. In relation to the duality of structure, Giddens points to the interrelationship of both action and structure. He argues that individual actions are guided by social interaction and by an awareness of the overarching structural context. As a result, individual agency remains possible within a structural context where the interaction between the two determines both process and outcome. Michel Foucault conceptualized the relationship between agency and structure in a different way. He looked at how things came to be as they are. He focused on *how* questions, such as how relations between agency and structure have been discursively constituted, how agency is denied to some and given to others, and how structures could be said to have determined some things and not others. He sought by means of genealogy to explore how particular social practices achieved dominance at particular historical junctures. Foucault developed a social relational understanding of power that conceptualized social practices as those "places where what is said

and what is done, rules imposed and reasons given, the planned and the taken for granted meet and interconnect” (Foucault, 1981, p. 5). He maintained that everyday social practices have to be viewed in relation to their discursive contexts to ascertain the historically located relationship between power, language, knowledge, and institutional practices.

The Practice of Research

In relation to the practice of research, structuralism can be associated with positivism, which focuses on the methodology utilized by physical science applied to the social field, and to critical realism, which concentrates on a more qualitative engagement between conceptual deconstruction and reconstruction in the social arena. These connections will now be briefly explored, although it has to be borne in mind that these can be contested and have to be viewed flexibly.

Associations between structuralism and positivism can take a number of different forms, but commonalities include an emphasis on rational inquiry and on uncovering cause and effect, the achievement of objectivity, and the production of value-free knowledge, which is regarded as factual and incontrovertible.

Structuralist and positivist research methodologies predominantly utilize quantitative orientations. These orientations clearly have a different emphasis on qualitative approaches, but they can be used alongside qualitative data collection methods and data analysis techniques to interrogate research questions in different ways. The use of both qualitative and quantitative orientations has been referred to as mixed method or multistrategy research. In the social sciences, there are two main quantitative methodological approaches that predominate. These are social experimental approaches and surveys. With regard to social experimental approaches, there is a concentration on the testing out of hypotheses, the identification of independent and dependent variables, and the production of frameworks for the measurement and control of these variables. With regard to surveys, there are many different types. A questionnaire adopting a quantitative orientation is concerned with systematically collecting quantifiable data relating to a number of variables. The purpose is to statistically examine the data to discover associations and possible patterns or trends.

Qualitative researchers have critiqued structuralist and positivist forms of research for assuming that bias in the social arena can be eliminated. The uncritical

adoption of a particular ontological and epistemological position has also been disputed. The view that it is possible to achieve, by means of rational inquiry, the uncovering of underlying truths or indisputable facts has been interrogated critically. Qualitative researchers, particularly those who have drawn from the many strands of feminism, emphasize that ontological and epistemological positions and research frameworks have to be analyzed critically and that all knowledge claims have to be regarded as partial. Those who adopt a qualitative orientation have also highlighted how individual and group values influence not only what is researched but also how the findings are interpreted and applied. In this, attention has been drawn to unacknowledged power imbalances and to the gendered constructions of social relations. Objectivity is therefore regarded as a particular form of subjectivity dressed up in an unacknowledged universalizing disguise.

The ethical implications of structuralist and positivistic methods of inquiry have similarly been subject to criticism from researchers who adopt qualitative positions. It has been highlighted that as those taking part in positivist research projects are regarded as subjects and not as participants, there is the possibility that the subjects will not be treated with dignity and respect. It has also been contended that sample groups denied choice could be exposed to possible distressing experiences; that self-determination is, by implication, limited; and that subjects may not be fully informed about the purpose of the research. Ethics committees have been established to guard against questionable or unethical practices, but discussion continues between quantitatively and qualitatively orientated researchers about acceptable and unacceptable ways of operating. However, it has to be pointed out that the issues are not as clear-cut as they are sometimes presented. Qualitative researchers have argued that qualitative research has to emphasize factors such as rigor, range, depth, and progression to maintain credibility as well as ensuring an ongoing interaction with moral, social, and political agendas.

The association of structuralism with critical realism results in a very different form of research. Rather than attention being paid to discovering laws that govern human behavior, emphasis is placed on deconstructing or taking apart social phenomena to uncover essential underlying structures. These underpinning mechanisms cannot be revealed by empirical methodology alone, but by constant backwards and forwards

movement between the empirical data and the generation of theory. An example that can be given for illustrative purposes is critical social research as developed by Lee Harvey.

The main tenet of critical social research is that it is antiphenomenalist so that understandings of the real world cannot be formed on the basis of surface appearance. It is also totalistic, and it is contended that the social world cannot be understood independently of the wider social and historical context. Emphasis is placed on the importance of deconstructing existing social relationships to reconstruct alternatives that identify and critique oppressive social mechanisms.

Harvey distinguishes between research methodology, which describes techniques of data collection, and critical social research methodology, which is the point at which method, theory, and epistemology come together as part of the process of directly investigating specific concerns within the social world. According to Harvey, critical social research is concerned with an intrinsic critique of interpretative frameworks. In line with many qualitative orientations, Harvey rejects that knowledge is objective and fixed. Knowledge is viewed as not only dynamic and deconstructive, but also dialectical. Like Foucault, Harvey is concerned with exploring and critiquing taken-for-granted concepts, with placing events in historical context, and with making links between accepted knowledge claims and pervasive social structures. However, unlike Foucault, Harvey's approach has a clear political dimension. His view of power is hierarchical and top-down and is concerned with revealing oppressive structural mechanisms and what is really going on. This approach is designed to cut through ideological legitimations and to mount a political struggle against oppressive social structures.

In conclusion, structuralism, both theoretically and practically, provides a framework that can be used in a number of different ways. It can be allied with the differing perspectives of positivism and critical idealism and both quantitative and qualitative research methods can be utilized. However, structuralism is predominantly defined by an acceptance of underlying structures and rules which in a variety of ways determine individual agency. It also provides a clear point of reference for poststructuralist understandings.

STRUCTURED INTERVIEW

Structured interviews involve administering relatively standardized interview questions to all participants in a research study. This structure ensures that all persons are given equal opportunities to provide data across the same research constructs. Interviews are designed to draw from the interviewee constructs embedded in one's thinking and rationale for decision making. The researcher uses an inductive method in data gathering, regardless of whether the interview method is open, structured, or semi-structured. In all cases, inductively, the researcher wishes to understand what presently exists within the participants, helping them to articulate precepts such that they will be understood clearly by the journal reader.

Qualitative researchers often view interviews on a continuum. One extreme involves open interviews that utilize minimal structure. There is no direction given or hints as to what the researcher might suspect to find. The participant is encouraged to speak freely, taking the interview in whatever direction(s) he or she desires to go.

Structured interviews exist at the other end of the method pendulum. When using this method, the researcher typically has garnered tentative hypotheses regarding what the participant might contribute to the interview. These hypotheses might be generated via previous research, literature reviews, pilot studies, or a priori reasoning. It is important to note, however, that the researcher is not attempting to superimpose his or her own viewpoint onto the research participant or to

fish out perspectives that the participant does not innately possess.

Rather, structured interviews begin with some type of tentative hunch, targeting interview questions in that direction. For example, research studies may show that elementary school girls typically engage in verbal aggression in given circumstances. Does this aggression also hold true for, say, seventh graders? A qualitative researcher might employ structured interview techniques, following up on previous studies from elementary school children. Having some basis of comparison between the two groups may best be accomplished by asking both groups of individuals the same (or similar) questions in this example.

Among others, there are four occasions when qualitative researchers may choose to employ structured research methods. One includes comparison among groups (as previously mentioned). Second, structured interviews can be useful when conducting interview waves. Initiating contact with a participant, using structured questions can be followed up by open or semi-structured interviews later. Third, structured interviews are often used when the primary design of the project is quantitative research, but the researcher wishes to supplement the findings with an open-ended component. In such circumstances, quantitative researchers might be more comfortable with a structured approach to data collection, and interpretations may be more easily integrated into the quantitative findings. Fourth, structured interviews can be the method of choice when interviewing low-functioning individuals such as persons with developmental disabilities or homeless individuals who may have tendencies to ramble or otherwise deviate from the topic at hand. Structured interviews might help these participants focus on the subject and provide some security relating to why he or she is providing audiorecorded data to the researcher.

STRUCTURED OBSERVATION

Structured observation entails the collection of data according to a set of predefined rules and procedures. The structure of the observation and the predefined variables and their values are derived from the purpose of the study. Structured observation is a type of nonparticipant observation in that it involves direct observation of a setting without interaction with participants. More quantitative in nature, it is also referred to as systematic observation.

Structured observation uses observation schedules or checklists in which data are recorded according to predefined criteria as values of variables that have been explicitly defined to ensure consistency in data collection. It emphasizes factual measures (e.g., whether or not a particular behavior has occurred) over those requiring judgment or interpretation (e.g., application of a scale related to the intensity of a particular behavior). As observations are collected in real time, they have a temporal dimension and yield information about the duration, frequency, and sequence of events. Tests of interobserver agreement are conducted to ensure the reliability of data. Structured observation typically involves a strong investment in the development and the pretesting of variables as well as the training and monitoring of observers.

Because of the rigorous quantitative nature of the variables and data collection processes, structured observation is regarded as having the potential to yield results with high validity, making replication and generalization possible. If the same observation schedules and coding schemes are used, it enables comparison across two or more sites.

Structured observation allows for the collection of data (e.g., frequency of particular types of behavior, actions of very young children) that are not readily captured by other methods such as surveys or interviews. Structured observation is appropriate for data collection in both laboratory and natural settings. When combined with interviews, structured observation allows researchers to compare what people say with what they actually do. It is very useful for understanding processes and frequencies of behaviors within a given time period.

Structured observation is not appropriate for a research topic about which little is known, as it requires prior knowledge of the setting for the development of observation schedules. Unlike more flexible

forms of observation such as participant or unstructured observation, structured observation, with its pre-defined variables and processes, is not effective in capturing behaviors or other features of a research context that are unexpected. Reactivity can be a major problem and should be addressed through purposeful habituation and monitoring. Structured observation is difficult to implement in busy, complex settings where it may be hard for observers to focus on particular behaviors. This challenge can be overcome somewhat through the use of multiple observers, who may increase reactivity, and the strategy of focusing on one participant at a time, which may result in the loss of other data. Structured observation requires highly skilled, well-trained observers who are familiar with and can understand what they are observing.

SUBJECTIVISM

Subjectivism is a certain way of conceptualizing subjectivity. Subjectivity is what makes us subjects rather than objects. Subjectivity includes processes denoted by the terms *mental*, *mind*, *conscious*, *experience*, *agency*, *will*, *intentionality*, *thinking*, *feeling*, *remembering*, *interpreting*, *understanding*, *learning*, and *psyche*. These subjective processes comprise the activity of subjects. Without subjectivity, we would only be physical objects devoid of activity.

Subjectivity and Subjectivism

Subjectivity is understandable if we see how it develops over the phylogenetic scale. Lower animals' behavior is devoid of subjectivity. It is a direct, immediate association of a response with a stimulus. The response is determined by a biological program known as an instinct. More advanced animals progressively

develop subjective processes that mediate between stimuli and responses and increasingly determine the animal's response to stimuli. Subjectivity reaches its highest form in humans who think, plan, remember, feel, dream, imagine, anticipate, symbolize, decide, understand, learn, and initiate action on a level that is far more sophisticated, complex, and active than any other animals. Subjective functions determine how humans react to stimuli. Stimuli do not directly determine human reaction as they do in lower organisms.

For subjectivity to mediate stimuli it must be different from them. This difference justifies examining it as a particular order of things, a distinctive phenomenon. This examination is what subjectivism does. It examines the interiority of subjectivity, the active processes that are subjectivity and that determine behavior.

Subjectivism is one conception of subjectivity. Subjectivism construes subjectivity as the product of the subject, or individual. In this view, what we think, imagine, feel, remember, expect, understand, and strive for is entirely the product of ourselves. Subjectivity may utilize worldly things, but always on its own terms, for its own purposes, according to its own processes and laws.

Subjectivism in the Humanities and Social Sciences

Subjectivism has been the dominant view of subjectivity in many fields of scholarship.

Rene Descartes and Bishop Berkeley expressed the core notion of subjectivism. Descartes proposed that mind is distinct from body and world and is a realm of its own. Berkeley expressed this in his classic statement that the world is as one sees it. One's perception does not represent the world. Rather, the world is an expression of one's subjectivity. The processes and principles of one's subjectivity determine how one sees the world; the world does not influence one's perception of it. The direction is entirely from inside one's mind to the outside world.

Immanuel Kant similarly proposed that subjectivity cannot know the world because the two are separate domains. Subjectivity contains its own intrinsic laws, such as ethical principles, that structure one's perception of the world.

Historical discussions, especially intellectual history, often present events as the unfolding of ideas that

are freely decided by people. One hears that the prevailing outlook changed from a focus on national construction to a more international outlook. Philosophies, legal concepts, and marriage customs are thought of as exclusively rooted in thinking, perception, desires, motivation, and reasoning apart from conditions, structures, and resources.

Subjectivism is also a strong tendency in a branch of sociology known as microsociology. Erving Goffman proclaimed his work to be microsociological because it studied face-to-face social interactions. These he defined as interpersonal, face-to-face environments. His work is not about social organization and social structure that are the traditional concerns of sociologists. Anthony Giddens perceptively explains that Goffman's main concern throughout his writings involves individuals directly attending to what each other are saying and doing for a particular segment of time. Even when individuals are group members, their interactions are to be understood in terms of an immediate interpersonal encounter, not in terms of their membership of the group.

Goffman is not interested, for example, in the role of a doctor in relation to the wider medical community. His focus on face-to-face encounters leads him to concentrate on such interpersonal dynamics as mutual eye contact, body space, and details of the conversation acts (i.e., moves) such as turn-taking (timing), silences, and volume of speaking. This conversation analysis lacks a relation to the existence of social institutions including the power relations of who owns and controls them.

Subjectivism is also characteristic of many spiritual doctrines. Hindu yoga, for example, is a systematic method of physical postures and breathing exercises to help concentrate thoughts on a single object to systematically reduce the diversity and rate of flow of thoughts until it comes to a near stop. At this stage, a practitioner of yogic techniques is said to withdraw attention from the object of thoughts to thought itself and further onto the self-as-subject at the center of the universe of experience. Drawing attention completely to the self-as-subject epitomizes subjectivism.

Subjectivism in Psychology

Subjectivism takes various forms in the discipline of psychology.

Jerome Bruner believes that culture is symbolic meanings. He says that social realities are not bricks that we trip over or bruise ourselves on when we kick

at them, but that they are the meanings that we achieve by the sharing of human cognitions. In Bruner's world, we do not encounter and are not bruised by armies, wars, inequality, abuse, exploitation, pollution, global warming, power, poverty, wealth, disease, the world bank, congress, the CIA immigration quotas, emigration restrictions, or prisons. These are not real things out there in the world that directly affect us. They are simply meanings that become negotiated through interpersonal communication. We can readily change these concepts by simply renegotiating them with our colleagues.

Reducing social reality to symbolic meanings is subjectivism because it construes subjective experience as a self-contained realm.

Jaen Valsiner espouses a subjectivist view of agency. Formerly an advocate of Lev Vygotsky's sociohistorical psychology, he now asserts that culture is a set of suggestions that individuals can freely accept, reject, or modify as they wish. Valsiner replaces sociohistorical psychology with a new formulation called *co-constructionism*. In contrast to sociohistorical psychology, which construes the individual as profoundly affected by culture, co-constructionism grants primacy to the individual's decision about how to deal with culture. Acknowledging that his new position is a wholesale rejection of sociocultural psychology, Valsiner says that the logic of the argument supporting the relevance of the social environment in human development is reversed in the co-constructionist paradigm. According to the new paradigm, "most of human development takes place through *active ignoring and neutralization of most of the social suggestions* to which the person is subjected in everyday life" (Valsiner, 1998, p. 393, emphasis in original).

Valsiner even contends that babies construct their own personal goals. They utilize culture as an instrumental means for achieving their own goals; they do not adapt themselves to established culture as social scientists formerly believed.

Subjectivism in Qualitative Methodology

Subjectivism dominates qualitative methodology. It construes interactions between researcher and subjects (through interviews in particular) and the active interpretation of data—which are central features of qualitative research—as a license for the free exercise of subjective processes. The subject is free to express

whatever subjective idea he or she desires, and the researcher is free to subjectively interpret data.

The subjectivistic tendency in qualitative research (which is contradicted by an objectivistic tendency that is described in the entry on objectivism) claims that the world, including the psychological world of subjects, is unknowable. Consequently, the researcher constructs an impression of the world as he or she sees it, without regard for whether this subjective impression corresponds to any reality beyond. The researcher's subjectivity is a world unto itself, which is the classic definition of subjectivism. Validity and objectivity are irrelevant issues here, as is methodology. There is no point developing a rigorous methodology to apprehend and measure a singular psychological reality because it simply does not exist. Qualitative research, in this view, consists of researchers developing and comparing their own accounts of psychology.

This subjectivist approach to qualitative research is expressed by Ken Gergen's (2001) statement of social constructionism—postmodernism: "There is no means of declaring that the world is either out there or reflected objectively by an 'in here'" (p. 805).

The constructionist is not, then, interested in truth as a scientific outcome—or at least truth with a capital *T*—a universal or transcendent propositional network. There may be local truths, established within various scientific fields, within the various communities of humankind, and these must surely be honored from within the traditions of these communities. However, the future well-being of the world community depends on facilitating dialogue among these local traditions. Declarations of truth beyond tradition are, in this sense, a step toward tyranny and, ultimately, the end of communication (Gergen, 2004).

Gergen makes the following points on this issue: "To tell the truth, on this account, is not to furnish an accurate picture of what actually happened, but to participate in a set of social conventions. . . . To be objective is to play by the rules within a given tradition of social practices. . . . To do science is not to hold a mirror to nature but to participate actively in the interpretive conventions and practices of a particular culture. The major question that must be asked of scientific accounts, then, is not whether they are true to nature but what these accounts. . . . offer to the culture more generally" (Gergen, 2001, p. 806). "A postmodern empiricism would replace the 'truth game' with a search for culturally useful theories and findings with significant cultural meaning" (p. 808). "Arguments about what is really real are futile" (p. 806).

A strand of feminism amplifies this idea by repudiating the notion of a real world of phenomena that can and should be objectively apprehended. Instead, science is equated with the subjectivity of researchers. These feminists denounce scientific objectivity as nothing more than a political ideology that is promoted by men to oppress women. For instance, Liz Stanley and Sue Wise (1983) assert that objectivity is "an excuse for a power relationship every bit as obscene as the power relationship that leads women to be sexually assaulted, murdered and otherwise treated as mere objects. The assault on our minds, the removal from existence of our experiences as valid and true, is every bit as questionable" (p. 169). Stanley and Wise agree with Gergen's position that "there are many (often competing) versions of truth. Which, if any, is 'the' truth is irrelevant. And even if such a thing as 'truth' exists, this is undemonstrable" (p. 169). This position is subjectivistic because it places the subjectivity of researchers at the center of things and denies worldly phenomena apart from the researcher's subjectivity.

Subjectivism in qualitative research additionally accepts subjective accounts of subjects about their psychology as the object of research. The objective is to validate subjective interpretations, meanings, and understandings. This line of research does not seek to explain subjects' subjective accounts in terms of external influences, for this would deny originality and agency to subjects' subjectivity. Nor does this line of research seek to evaluate subjects' subjective accounts by comparing them to other sources of information—such as other people's accounts of the same psychological phenomenon. Subjectivistic research would not compare a child's account of her or his experience with her or his parents' account of her or his experience—for example, a daughter says she was unhappy five years ago and resented her parents, while the parents show photographs of her appearing very happy with them. For this kind of comparison too would challenge the originality and agency of the subject's subjective account. It might prove that the subject misinterpreted her experience or some other event. External data are eschewed by subjectivistic research because it transcends the pure subjectivity of the agent.

Howard Garfinkel's ethnomethodology, for example, abstains from judging peoples' statements as to their accuracy, adequacy, value, importance, necessity, practicality, success, or consequences. It only refers to conditions outside individuals when they do. If subjects do not mention social conditions, they are

not introduced by the researcher. Thus, even if people objectively fit the category of lower class (because of their education, occupation, income, family background), they may be discussed as middle class if this is how they subjectively see themselves.

These features of subjectivistic research are illustrated in a study by Dorothy Holland and colleagues on the ways in which college girls experience romantic love. From interviews, she reports that some girls pursue romantic love enthusiastically while others are ambivalent and others reject it. One girl, Sandy, sought romantic love, but had trouble establishing the kind of relationships she wanted with men. She also learned that a potential boyfriend from back home was involved with someone else. So she took a stronger interest in friendships and developed a special friendship with one person. Another girl, Karen, tried to make herself more attractive by suggesting to her boyfriend that she had many other suitors. Holland explained these strategies as based on personal decision-making processes that the subjects employed: These strategies were ones the women themselves had improvised or decided to use. Holland explains the subjects' approaches to love as stemming from personal traits such as their identification of themselves as romantically inclined and skillful. She does not indicate social reasons, models, values, or practices that might have influenced the subjects to adopt these strategies for dealing with love.

Discursive psychology, is another approach to research that is strongly subjectivistic. It typically treats speech acts as spontaneous constructions that reflect individual agency and constitute subjectivity. This treatment is subjectivistic because it construes subjectivity and discourse as spontaneously created worlds in themselves, uninfluenced by external events. Indeed, social phenomena are treated as discursive products; speech is not regarded as denoting worldly events. Culture and psychology are created by people as they speak; they do not stand over people and influence them. Although certain discourse analysts do link discourse to cultural influences, many treat discourse as an entirely subjective process free from external influences or evaluation.

Evaluation of Subjectivism

Subjectivism contributes to our understanding of human subjectivity and psychology because it emphasizes the active role that these play in generating behavior. Subjectivism prevents us from regarding people as mechanical, empty responders to stimuli—as behaviorism, positivism, and artificial intelligence

presume. Subjectivism corrects the widespread tendency in psychology to mechanically associate independent and dependent variables, with no consideration for subjects' active interpretation, comprehension, and/or anticipation. It also corrects social reductionism—discussed in the entry on objectivism—which reduces psychology to social structures.

Yet this contribution of subjectivism comes at a price. Emphasizing subjective activity so strongly and exclusively overlooks social and natural influences on subjectivity and psychology.

A balance can be achieved by acknowledging the activity of subjectivity along with social constraints that shape it. For example, in forming personal identity, individuals are highly active in the process of self-making; however, the materials available for writing one's own story are a function of one's public and shared notions of personhood. For example, American accounts of the self involve a set of culture-confirming ideas and images of success, competence, ability, and the need to feel good. Although making a self appears to be an individual and individualizing pursuit, it is also a collective and collectivizing one.

Cultural influences, content, and function can be seen in psychological phenomena. They can be seen in Karen's approach to love that Holland recounted earlier. Karen's strategy of enhancing her attractiveness by exaggerating her appeal to numerous men bears striking resemblance to a principle of free market economics—namely, that increased demand drives up the value of a commodity. Businesses often exaggerate the demand for a product in order to enhance its attractiveness and increase its price. Employees often exaggerate the number of job offers they have, or could have, in order to raise the value of their salaries. From Holland's brief description, Karen evidently imported this common business practice into her personal world of romantic love.

Subjectivity is permeated by cultural content; it is not a self-contained realm because subjectivity is oriented toward the world and laden with worldly content. Subjectivity enhances the organism's comprehension of the world and its ability to plan effective action within it. A self-contained subjectivity that created itself ex nihilo without any basis in or regard for the world would be of little service to the organism.

confound and muddle the analysis of data. Qualitative research increasingly challenges this conventional wisdom.

Qualitative researchers have aggressively examined the question of subjectivity and have suggested its positive contributions to the process of inquiry. Many frame the objectivity–subjectivity debate as conflict between Enlightenment and postmodern values. However, there are advocates for the positive influences of subjectivity in research in early Greek philosophy, among the Enlightenment philosophers (e.g., Immanuel Kant and Johann Wolfgang Goethe), as well as eminent 20th-century scientists. For example, in 1918, Albert Einstein claimed that if science was limited by objectivity, then it would not be capable of fresh thinking or producing original insights.

Since the 1990s, technological advances in the area of cognitive neuroscience have allowed researchers to use neural brain imaging to identify objective thinking as deeply contextualized within subjective thought. These findings suggest that subjectivity allows an individual to properly situate an objective problem and coherently apply the analysis to a real-world situation. The conventional conception of subjectivity diminishing objectivity is not an accurate representation of higher-order thinking. Instead, these new research findings support John Dewey’s claim that thinking in terms of the relationships of sensory qualities requires more rigorous thinking than the dispassionate manipulation of symbols.

Alan Peshkin championed the positive role of subjectivity in qualitative research. He argued that the subjective lenses of the researcher were a powerful and useful means for shaping data. The challenge to the researcher was to become aware, through self-reflection, how his or her personal subjectivity was driving the collection and analysis of data. Elliot Eisner extended this idea in his concept of connoisseurship and through his arts-based research methodology of educational criticism. Other arts-based research methodologies that regard positive subjectivity as foundational to inquiry include narrative storytelling and a/r/tography.

Recently, Tom Barone has argued for an abandonment of the terms *objectivity* and *subjectivity*. In light of current philosophical and scientific understandings, he argues for critical persuasiveness as a standard for research. According to Barone, whether research is objective or subjective misses the point. Research, whether it is rigorously objective or subjective, needs

SUBJECTIVITY

Subjectivity refers to an individual’s feelings, opinions, or preferences. It has traditionally been seen as the opposite of objectivity, which refers to dispassionate analysis and coolheaded reason. Therefore, a conventional view is to eliminate, or at the least avoid and constrain, subjectivity during the conduct of scientific inquiry. The presence of subjectivity can only

to be evaluated on its capacity to provide useful insights into addressing practical problems.

SUBJECTIVITY STATEMENT

A subjectivity statement is a summary of who researchers are in relation to what and whom they are studying. Researchers develop these from their personal histories, their cultural worldviews, and their professional experiences. The purpose of a subjectivity statement is (1) to help researchers identify how their personal features, experiences, beliefs, feelings, cultural standpoints, and professional predispositions may affect their research and (2) to convey this material to other scholars for their consideration of the study's credibility, authenticity, and overall quality or validity. Researcher subjectivities may bias, unbalance, and limit endeavors, but they may also motivate and illuminate inquiry. Although subjectivity statements may make audiences unfamiliar with qualitative design more skeptical of a research report, their absence makes knowledgeable audiences suspicious about what has been omitted.

A subjectivity statement is not the same as an autobiography, although it is built from autobiographical material. The emphasis is not the individual researcher per se, but the researcher in relationship to others, especially the research participants. Reflexivity, or researchers' contemplation of their

influences on their research, can be considered the process for which subjectivity statements are the product. For example, researchers studying fantasy gamers might summarize their experiences with games of all kinds, but especially those most similar to the games the participants are playing. A subjectivity statement may be a sentence or two in a journal article or several pages in a book. Subjectivity statements may be offered as separate or even appended sections in a manuscript. In contrast, many feminists and other qualitative researchers thread information about their participation and standpoints throughout their research reports. Researchers frequently, however, discuss their relationships with participants in publications separate from their substantive research reports, and anthologies of such material have been common.

Researchers develop subjectivity statements in different ways. One approach is the story of the research relationship from introduction to withdrawal from interaction. Another is more autobiographical, focusing on who researchers believe themselves to be as individuals, their backgrounds, and how these are related to those they study.

Researchers' subjectivity statements change over time as people accumulate new experiences and become transformed by their own inquiries. The content of subjectivity statements varies, but often includes researchers' ascribed characteristics such as sex or gender, race or ethnicity, socioeconomic status, and age and achieved characteristics such as education and occupation. Experiences relevant to the research and standpoints pertinent to those studied are those most important to specify. Statements may also include how researchers believe these characteristics and experiences delimit, enhance, or constrain the results of the study.

SUPERHYPERQUAL (SOFTWARE)

SuperHyperQual (SHQ) is a computer program that is used for qualitative data analysis, especially during the coding and conceptualizing phase of qualitative research. SHQ evolved from HyperQual, which was originally developed in 1989 for the Apple Macintosh computer using HyperCard. SHQ includes versions for both Windows and Macintosh computers. SHQ is an example of specialized computer programs dedicated to computer-assisted qualitative data analysis (CAQDA) that began to appear in the early 1980s when personal computers became widely available.

Programs such as SHQ typically have a number of common features. They provide a means to manage the data after the data have been collected from the field. Text data usually can be entered directly into the program; otherwise, the data are imported into the program from external text files. After the text data are edited and documented, the resulting data set is ready for analysis. From this point forward, all manipulation of the data is done electronically. Another common feature is qualitative data coding. CAQDA programs help the researcher perform the often tedious process of sorting a large volume of text data into collections (or categories) of small chunks of text that have some likeness in meaning as interpreted by the analyst. Because the categories are developed inductively and it may take

several revisions before the identification of the categories becomes stable, data coding with the assistance of a computer becomes essential for quality analysis. A third common feature is data output. CAQDA programs provide the user with formatted text data that can be easily incorporated into a research report. At a minimum, the user gets output (in either print or electronic form) of all the categories and their corresponding chunks of text, otherwise known as exemplars (of the category).

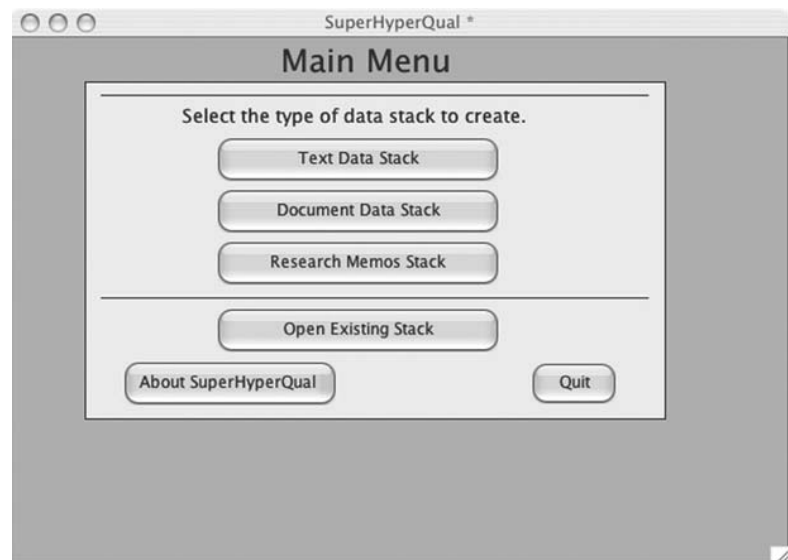

SHQ has all of these basic features. It allows the user to create a text database, to code the data using the mouse to highlight chunks of text, to manipulate the evolving coding scheme, to sort the codes, and to produce output text files that contain categories and their corresponding chunks of text. The program handles interview data, observations, and research memos.

SURVEY RESEARCH

Survey research is one of the most commonly used methodologies in the social sciences. Survey research refers to the set of methods used to gather data in a systematic way from a range of individuals, organizations, or other units of interest. Specific methods may include questionnaires (on paper or online), interviews (conducted by any method; e.g., individual interviews done face to face or via telephone), focus groups, or observation (e.g., structured observations of people using internet access stations at a public library). This entry focuses on methods most commonly associated with survey research: questionnaires (often used in quantitative research designs) and interviews (often used in qualitative research designs).

Many studies using more than one data collection method will include a survey method. For example, a quantitatively oriented questionnaire could be used to generate general understanding of a set of related questions, to identify interview questions for deeper qualitative investigation, and to identify possible interview participants. Alternatively, a questionnaire could be used to confirm the generalizability of results from a small interview study to a larger, more statistically representative sample. Timing of survey research is relevant to the data produced. For example a cross-section approach collects data at one point in time. Longitudinal survey research can sample data at different periods over a length of time to examine long-term trends.

Although some researchers believe survey research to be a wholly quantitative approach, this opinion is not universally shared. Data gathered from any survey method may be entirely quantitative, may be largely qualitative, or may be a mixture. For example, open-ended questions on a questionnaire or asked in an interview will produce text that may be analyzed qualitatively. Qualitative data gathered in survey methods tends to be in text form, such as narrative responses to open-ended questions posed in an interview or written responses to a “comments” item on a questionnaire. There are many ways in which open-ended text or commentary is analyzed, although content analysis (either quantitative or qualitative) would be a commonly applied analytic method. The value of this qualitative data collected during the course of a questionnaire can be particularly important to contextualize more quantitative responses and to add depth and richness to the data set. For example, a questionnaire

seeking data about service delivery in a nonprofit setting may include space for open-ended comments where respondents can indicate why they responded in certain ways or provide details not otherwise captured by closed response items. Responses to open-ended questions can provide detail about perceptions, opinions, personal experiences, and deeply held beliefs. Of course, written responses assume basic literacy on the part of respondents, as well as motivation to take the time required to write comments.

Open-ended questions provide greater freedom to the researcher in terms of how to frame the question, as well as granting greater freedom to respondents in the ways they choose to answer. Open-ended questions are often used in qualitative research to explore an issue or concept, to obtain natural wording, to add variety to a questionnaire, to obtain exact numerical data, and to provide respondents with opportunities for self-expression or elaboration. Open-ended questions may challenge respondents because they are more demanding and time-consuming to answer; however, the data obtained are typically richer than that generated from closed questions. Researchers often find that responses to open-ended questions require greater effort to record, code, analyze, and interpret than is the case for responses to closed questions. However, closed questions are easier and faster for respondents to answer, and responses to closed questions are easier for researchers to code and analyze, and they provide consistent response categories. Closed questions have many disadvantages including eliciting responses where no knowledge or opinion actually exists, oversimplifying issues, and forcing answers into possibly unnatural categories. It is important to ensure that response categories to closed questions are inclusive of all reasonably possible responses and are nonoverlapping.

Wording of Survey Questions

Wording of survey questions, whether these are posed on a written questionnaire or posed during an interview, is challenging and is one of the significant reasons why piloting drafts of questions is wise. Questions should use language that is meaningful to respondents, with an emphasis on simple, direct, jargon-free language. Ensuring that language is appropriate for respondents is critical to obtaining respondent cooperation and interest, as well as key to obtaining valid research data. Questions should be

clear and specific as well as applicable to all respondents (e.g., asking how old one's spouse is will not be applicable to respondents with no spouse). A question asking "What is your income?" appears simple, but is open to interpretation: Does this mean individual or family or household income? What is the time reference (last week, last month, last year)? And, should "income" include wages only, or tips and bonuses? Leading or loaded questions and abbreviations should be avoided. Asking "Do you believe there should be an amendment to the Constitution protecting the life of the unborn child?" uses loaded language that may bias responses. If questions have been translated from one language to another, that translation should be double-checked for unintended errors. Double-barreled questions are also to be avoided: "Do you plan to leave your car at home and take the bus to work during the coming year?" is asking two separate questions. Questions that include an implied alternative should be avoided; for example, "Do you think most manufacturing companies that lay off workers during slack periods could arrange things to avoid layoffs and give steady work right through the year?" implies the alternative that layoffs are unavoidable. Bias is also evident in questions that may entail social responsibility, such as "Did you vote in the last election?" It is better to start with a more neutral question such as "Were you able to get to the polls in the last election?" Researchers should be aware of order bias, since respondents will incline toward the middle in a list of numbers, extremes in a list of ideas, and the second alternative in a list of two ideas. It is also wise to rotate the order of questions in case order influences responses.

Question Sequencing

When structuring a survey, question sequencing must be considered. Survey instruments, whether questionnaires or interview schedules, should open with an introduction that provides a title or subject of the survey, identify the sponsor or organization conducting the survey, establish legitimacy of purpose, request cooperation and identify any benefits for respondents, and indicate the degree of confidentiality. In mail surveys, a return address and date for return should be provided. Opening questions should be pleasant, easy, interesting, broadly applicable, and relate to the introduction and study objectives. Sensitive items should be introduced at a point where respondents are likely

to have developed trust and confidence and should be introduced gradually by warm-up items that are less threatening. All items should be located in context; that is, a section where they are most meaningful in the context of other questions. Classificatory data, such as demographic data, is best placed at the end of a questionnaire. This type of data can be used to stratify respondents, to determine if respondents represent a cross section of the population, and to analyze the relationships, if any, between these demographic variables and the other variables. Question sequencing refers to the flow of items, which should follow the logic of respondents. Group questions similar in content together, aid respondents' memories with chronological lead-ins, and use transitions for continuity. For example, Part A: "Let's talk about your work experience. . . ." Follow this with Part B: "Now let's talk about your feelings about your job. . . ." Filter questions are used to select relevant respondents for the survey: for example, "Are you a resident or a visitor?" These questions will help eliminate a category of respondent not intended to be included in the study. Funneling questions is done by asking broad questions first, and then proceeding to more specific questions in the same area, while an inverted funnel sequence asks narrower questions first, followed by broader ones.

Appearance

Printed or online questionnaires need to consider layout. The general appearance should be interesting and easy to complete, with consideration for paper quality (if relevant), size, font, and color. Any front matter should create a positive first impression. Instructions should facilitate proper answering of questions, and illustrations, symbols, and mechanical devices should attract attention and guide respondents. The final section should provide opportunity for additional comments and include an expression of appreciation.

Online Surveys

Online surveys are increasingly popular because they can be logistically easier to handle for both the researcher and the respondent. This makes online survey research more cost-effective when balancing investment against the potential number of respondents who are not bound by geographical barriers. Online surveys can be more convenient for respondents,

although obviously access to a networked computer is required. Thus, online surveys may be practical for certain populations but not so for others; that is, those without digital access. Analysis of data gathered from an online survey may be greatly facilitated by moving electronic responses directly into analysis software.

Survey Sampling

Regardless of the specific survey method used, sampling (i.e., identifying potential respondents) is critical. A census refers to sampling an entire population or universe; that is, all members of a particular group, regardless of the size of the group. Populations do not have to be people, but may be organizations or pieces of text. The most important thing about samples is the degree to which they are representative; a sample must reflect the population that it purports to stand for. A random sample is a probability sample, where each case has an equal chance of being selected. Random samples are used when the intention is to seek external validity. A stratified sample is based on studying a certain attribute in a population. For example, individuals are categorized as to whether or not they possess that attribute, which may be based on gender, ethnicity, educational level, and so on. Proportional sampling is based on the proportion or percentage each group contributes to the entire population (e.g., to look at a group of people in relation to the proportion of their representation in a population). Cluster sampling usually refers to selection on the basis of geography; in this case, the sample is usually then structured in other ways, such as stratified, or random, or both. Nonprobability sampling, which is typical for qualitative research, includes convenience sampling (e.g., approach the first x number of people who appear in the grocery store). A quota sample is used when the researcher wants to be sure that the sample includes individuals with a number of characteristics. A sequential sampling approach involves choosing every n th item in a group.

Trustworthiness

Validity and reliability are important aspects of survey research. Internal validity is achieved when the survey's questions and answers accurately measure or reflect what the investigators want to know and are not distorted by some other factor. External validity refers to how representative a sample of the population is. In survey research, it is important to factor in the return

rate as well as the proportion of nonrespondents to know if there is a statistically significant difference between respondents and nonrespondents with regard to certain characteristics. Reliability refers to the consistency of data gathering in measuring whatever the survey purports to measure. To ensure reliability, the researcher looks at question wording to ask whether the questions really ask for the information in the best possible way or to ask if people from different groups understand the questions in the same way. Reliability can be improved by asking the same question twice on a questionnaire or by following up to check on similarity of response in an interview. Trustworthiness is equally important when using methods such as observation; for example, recording observations in multiple ways (e.g., using photography as well as individuals' visual observations) and using more than one observer are ways to increase trustworthiness.

Survey research is common because it is so flexible, open to researchers taking quantitative as well as qualitative approaches. Survey methods can answer a wide range of research questions, from the "who" and "what" to the "how" and "why." Because of this flexibility, survey research is appealing to inexperienced researchers and is, therefore, open to careless design and data collection practices. However, trustworthy survey research requires careful consideration of design and research conduct.

SYMBOLIC INTERACTIONISM

Symbolic interactionism (SI) is a sociological and social-psychological perspective grounded in the

study of the meanings that people learn and assign to the objects and actions that surround their everyday experiences. It is a theoretical perspective that was originally developed in the early half of the 20th century by scholars at the University of Chicago. SI is the most sociological of a range of social psychology traditions (others include cognitive sociology, discursive psychology, ethnomethodology, and rational choice-exchange theory) and was originally conceptualized by the philosopher George Herbert Mead, although he never used the term. The perspective was first given coherence by Mead's students from Chicago, who collected and, in 1934, published their notes from his social psychology courses in a book titled *Mind, Self, and Society*. In 1937, Herbert Blumer, one of Mead's students, coined the term *symbolic interactionism* and subsequently consolidated much of Mead's work into a distinct sociological perspective. Blumer's 1969 book, *Symbolic Interactionism*, is a collection of his own essays and is still widely acknowledged as a major statement on the perspective.

The term *symbolic interactionism* is comprised of two concepts: symbol and interaction. Symbol refers to any social object (e.g., a physical object, a gesture, or a word) that stands in place of or represents something else. Symbols are a uniquely human creation. No other animal has the ability to arbitrarily assign meaning; that is, make something into a social object. Interaction highlights the significance of interpersonal communication in transmitting the meaning of symbols. Through interaction, culture arises. Interactionists understand culture to be the ideas, objects, and practices that constitute everyday life. Howard Becker has noted that, on the one hand, culture preexists individuals' births and therefore, structures their lives. On the other hand, people are autonomous, interpretive beings who have the ability to negotiate, modify, or reject the meanings they learn, thus actively shaping culture. From a symbolic interactionist perspective then, human beings are active creators of symbols and culture. As one example, consider the symbolic meaning of communism. The word means very different things to different people in different places at different times. As a symbol, communism signifies an emancipatory political-economic model to some people, while to others it represents repression, collective poverty, and aggression. Each of these meanings, and many more, is learned by people through their interactions with other people, various media, and so on. Communism is not a tangible thing—it cannot be seen or touched—yet it is

a social object because it refers to a set of processes (ideological, political, economic) that occur in the world. Through symbolic interaction, human beings construct, share, resist, modify, or reject various aspects of the social world.

SI offered a radical conceptualization of sociological theory compared to the macro, structural, positivist sociology that dominated American sociology at its emergence in the 1930s. Rather than rely on quantitatively derived data that were collected through representative survey research and analyzed using statistics, symbolic interactionists primarily collect and analyze qualitative data from people's experiences in naturalistic settings (though some practitioners of the perspective, often called structural interactionists, use quantitative methods and experimental designs). SI has tended to be labeled as distinctly micro-oriented, rather than macro-oriented, although this label has changed in recent decades with the explicit push among some SI scholars toward meso-level theorizing. Another difference between SI and dominant sociology relates to epistemology. Dominant mid-century sociology was aligned with positivism, the epistemological assumption that the social sciences could be modeled after the biological and physical sciences to produce verifiable "facts" that explain social behavior and predict future behavior. SI, in contrast, is an interpretive perspective that allows for the agency inherent in human behavior and supports a methodology to study social behavior without demanding that it be definitively explained or predicted. One final contrast relates to the role of the researcher. Whereas positivist sociology believed in a value-neutral perspective—the social scientist's ability to separate values, beliefs, and interests from data collection and analysis—SI rejects the idea of a disembodied researcher and instead supports the idea that all science is done from a particular standpoint. The interactionist's job is to identify how bias, values, interests, and other intersubjective phenomena impact the research process and to acknowledge (if not highlight) that impact in her or his research questions, data collection and analysis techniques, and writing.

Pragmatist Roots of the Perspective

SI's theoretical paradigm owes much to pragmatist philosophers of the late 19th and early 20th centuries,

notably John Dewey, William James, and Charles Peirce. Pragmatism differed from classical rationalism, the dominant philosophy of that time, in a number of important ways, and understanding pragmatist epistemology and ontology provides an important step toward understanding the basic premises of SI. First, classical rationalism conceptualized reality in static, fixed terms. René Descartes argued that conscious, sense-based experiences were not to be trusted when studying reality. Rather, reality exists in an objective form that could be understood through deductive reasoning, separate of any sensory experience. Pragmatism, in contrast, conceptualized reality in terms of potentiality. Reality may be “out there,” but human beings can only understand its existence through sensory experience. Further, human beings are selective in what they notice about the world, thus different people may apprehend the same reality differently. For pragmatists, reality is what people make of it. Second and related to its conceptualization of reality, classical rationalism approached knowledge as separate from the knower. Some rationalists have argued that, given a basic set of scientific axioms, a person could deductively derive the rest of all possible knowledge in the world. In other words, rationalists believed that knowledge could be gained through reasoning alone. In contrast, pragmatists believe that reasoning cannot be separated from a person’s bodily experiences in the world. For pragmatists, knowledge is not a thing, but rather a process. From this, pragmatists argued against the rationalist assumption that an ultimate truth exists. Rather, pragmatists see the world as comprised of many truths that are carved out of reality by human activity. From this perspective, the role of science itself comes into question. For rationalists, science seeks to apprehend a static, objective reality and to comprehend it through its identifiable components. For pragmatists, however, science is value laden. If reality and truth are relative, then all scientists come to their research with beliefs, values, and morals that cannot simply be ignored or set aside. Science, for pragmatists, is a moral endeavor through which the human condition can be changed for better or worse. Scientists should not study the world for the sake of knowledge, but rather for the sake of improving the world in which people live. Scientists must also remain cognizant of the consequences of their research—this point is particularly germane to the fields of social scientific research.

Guiding Ontological and Epistemological Assumptions

The scholar primarily responsible for translating the philosophical ideas of pragmatism into a workable social science was George Herbert Mead. Mead developed a social psychology that held crucial insights for the development of SI. First, human beings are the only animals capable of using language, understood as a complex system of symbols, and thus, are uniquely capable of manipulating, negotiating, and even transcending their physical environment through its use. Second, Mead argued that the human mind is as much an active, ongoing process as it is a mental structure. Human beings not only communicate with other people, but also communicate with themselves (i.e., self-reflexivity). The human ability to see oneself as an object of communication gives rise to the mind, which is not intrinsic and psychic, but processual and social in nature. This argument is a very different social psychology than behaviorism, for example, which sees human behaviors as reactions to environmental stimuli. The human ability for symbol use and the process-oriented nature of human action also highlights human agency. Human beings do not simply react to stimuli (although some human actions have instinctual roots), but instead assign meaning to objects in the world and then, based on the meanings assigned, act toward those objects in specific ways.

Herbert Blumer used Mead’s work, along with that of other social scientists such as William Isaac Thomas and Charles Horton Cooley, to develop SI into a distinctly sociological perspective. Blumer highlighted three premises that are foundational to the perspective. First, human beings act toward things based on the meaning they attribute to those things. Nothing has inherent meaning; rather, all meaning is assigned. When a female student walking on campus hears footsteps behind her, she must attribute meaning to the footsteps, and to the larger social situation, before acting toward those footsteps. If she is in the middle of a crowded student center in the middle of the day, she may likely dismiss the footsteps as normal or unimportant. But if she is in a secluded part of campus at night and alone, she might attribute a menacing or dangerous meaning to the footsteps. Second, the meanings people attribute to things arise out of social interaction. The potential meanings a person assigns are not arbitrary, but are learned. People learn

the meanings of things through face-to-face interaction with other people or with the thing itself or through various forms of mediated interaction, such as television, magazines, music, or the internet. Elijah Anderson's research on interracial interaction, for example, highlights how White people's fear of Black males is socially learned and oftentimes unjustified. Many Whites learn to fear Black males (often, through mediated interaction) without having any significant contact with them. Third, the meanings people attribute to things are handled through an interpretive process used by a person in specific situations. When a female student hears footsteps behind her at night or when a White woman sees several Black males walking toward her on an otherwise empty sidewalk, she will decide how to respond to them based on her own experiences and/or knowledge of similar situations. Reading about recent assaults or muggings may give her reason to feel afraid enough to cry for help. Or she may decide to ignore the what she has read or heard surrounding such alleged threats and treat the footsteps or men as nonthreatening.

In addition to Blumer's three premises, interactionists have subsequently discussed a larger set of guiding principles for the perspective. One is the idea that all social life is intersubjective. Human experiences are inextricably social in nature. Symbolic interactionist research has studied how even a person's most private thoughts are learned and given meaning through group life. A similar idea highlights the centrality of emotions to social life. Symbolic interactionists do not define emotions solely in biological terms. Instead, they understand that people's bodies are comprised of biological and physiological processes that are shaped by, and in turn shape, social action. Social action is itself another key term for interactionists; Blumer called it the fundamental unit of sociological analysis. Symbolic interactionists do not study individuals; they study the social actions in which individuals engage. Social actions are actions that take other people into account and include visible behaviors, as well as inner actions such as thoughts and emotions. Because most human actions take account of other people, SI provides an inductive explanation of the creation, maintenance, and change in society. Through the alignment of social action, society is created on a moment-by-moment basis by people acting socially. In short, symbolic interactionists see society as interaction. It is this emphasis on social action that most obviously highlights SI as a sociological perspective.

Finally, because symbolic interactionists study social action, they support the development of sociological methods that enable researchers to grasp the meanings that people come to attach to such action.

Methodological Traditions

Most interactionists do not believe that conventional scientific methods such as large-scale surveys or experimental designs yield sufficient insight into the intersubjective construction of reality, the self, or society, preferring naturalistic inquiry—research that focuses on people's behaviors in natural social settings. According to Blumer, naturalistic inquiry consists of two phases: exploration and inspection. During the exploration phase, interactionists work to familiarize themselves with the topic at hand, generally by becoming an "insider" of a particular social world. Exploration is a flexible process that allows the research to progress inductively. In order to understand pregnancy, for example, an interactionist would explore the social world of pregnancy in great detail. The researcher might observe and interact with pregnant women or couples, as well as examine literature, television shows, films, or other popular sources of portrayals of pregnancy. The researcher might attend parenthood classes, interview expecting parents, or even record the process of pregnancy autoethnographically, either as a pregnant woman or through a significant other. Throughout the exploration phase, the goal is to learn to understand the topic being studied from the perspective of the people who are active participants of that world. What is sociologically significant about the data recorded becomes clearer in Blumer's second phase, inspection, which refers to the process of analyzing the data collected during exploration. Fieldnotes, interview transcripts, documents and other data sources are all scrutinized as the interactionist engages in the creative process of establishing sensitizing concepts: concepts that are grounded in what the interactionist thinks is most significant or relevant about the data and which offer an analytic frame for understanding the social phenomena being studied. Exploration and inspection are not temporally ordered, but overlap as the researcher continuously inspects collected data and modifies the exploration process as necessary.

The findings of such a study are usually written and disseminated as an ethnographic text. Ethnography was developed by sociologists such as Thomas and Robert Park, who worked at the University of Chicago during

the same time as Mead. The so-called Chicago School of sociology, referred to either as the spark behind SI or as the incarnation of SI itself, is best known for its legacy of ethnographic research on everyday urban life. Although Mead's and Thomas's work offered a coherent interpretivist approach to sociological research, Park turned his training in journalism and philosophy into a methodology for describing lived experience. Often-cited examples of this tradition include Thomas and Florian Znaniecki's (1918–1920) *The Polish Peasant in Europe and America*, Frederick Thrasher's (1927) *The Delinquent Gang*, Paul Cressey's (1932) *The Taxi-Dance Hall*, and William Foote Whyte's (1943) *Street Corner Society*.

Another important qualitative tradition that emerged from SI is grounded theory. Developed originally by Barney Glaser and Anselm Strauss in their 1967 book, *The Discovery of Grounded Theory*, grounded theory emphasizes the development of theory through method. Grounded theory is a more robust approach than Blumer's exploration and inspection because it moves beyond developing sensitizing concepts to generating inductively derived meso or macrolevel theories of the social world. Grounded theory consists of the researcher exploring and analyzing data from cases, coming up with provisional concepts to explain what is going on, then studying new cases to see whether the provisional concepts remain satisfactory. The researcher continues to study new cases until the point of saturation, at which point the concepts become valid and a theory may be constructed.

Theoretical Extensions

Using the methods cited above, and others, symbolic interactionists have engaged in many types of sociologically informed scholarship, from theoretical to applied, from apolitical to critical and action-oriented. The following stand as a sample of the variety of ways in which interactionist-informed research has developed over the past half-century. First, the sociological study of the self and identity took a new direction under the influence of Erving Goffman, whose dramaturgical perspective studies social interaction through theatrical metaphor. Goffman's work highlights the contingent and situational aspects of the self by studying how identities are strategically presented and manipulated by people in order to accomplish collective action. Second, the ethnographic study of delinquency, developed in the Chicago School, received a more critical

interactionist eye by Howard Becker, who developed labeling theory to illustrate the social roots and functions of deviance. In line with traditional SI tenets, Becker highlights how deviant behavior is culturally and situationally defined by people who collectively agree on social rules and then apply deviant labels to those who do not conform. A third example is Arlie Hochschild's theory of emotions and emotion management. Furthering Goffman's metaphor of people "acting" in situations, Hochschild studies the emotional work in which people engage as they go through everyday life. Making oneself feel sad at a funeral or smiling when one would like to scream are but two examples of how individuals modify their behaviors to conform to the larger social structure.

Each of these theoretical strands has led to new fields of sociological scholarship that are often populated by scholars who do not self-identify as symbolic interactionists, though their work is implicitly informed by interactionist theory. In recent years, some scholars have been more explicit in identifying the symbolic interactionist roots of their work. One example is the intersection of SI and feminism, which results in a feminist interactionism as practiced by scholars such as Sheryl Kleinman. Other interactionists such as Michael Schwalbe have drawn on neo-Marxian theory to develop a more critical interactionism that focuses explicitly on the social processes through which inequalities are constructed. A final example is Norman Denzin's interpretive interactionism, which blends SI and critical social theory (i.e., neo-Marxist, feminist, antirace) with postmodernist preoccupations including an emphasis on people's interactions with(in) mass, communication, and new media technologies.

SI is a perspective with broad sociological significance. It theorizes the self and identity, socialization and culture, community and collective behavior, deviance and inequality, and more generally society-as-process by studying the creation and communication of meaning. With the increasingly blurred boundaries between traditional social science disciplines, SI has the potential to make an even greater impact on fields such as education, gender and minority studies, cultural studies, psychology, and communication and new media studies, among others.

SYSTEMATIC SOCIOLOGICAL INTROSPECTION

Systematic sociological introspection refers to the process of thinking about thinking and feeling about feeling in a focused way in order to examine the lived experiences of the self. It is the primary method connected with autoethnographic writing, where researchers write about their bodies, thoughts, and feelings in evocative narratives that invite readers to experience their experiences. Systematic sociological introspection relies on ethnographic guidelines for recording and writing about experience and on phenomenological and sociological understanding for contextualizing and interpreting what that experience means. This entry focuses on the history of introspection in sociology and on the development and application of systematic sociological introspection in autoethnographic research.

Sociological insight has been built on the introspective methods of its forebears in philosophy and psychology. Yet modern theorists often have neglected Charles H. Cooley's affective orientation and introspective

method for George H. Mead's more cognitive emphasis and technique of understanding humans by studying what they do. The rejection of introspection as a technique, along with the neglect of introspection as an object of study in the form of thoughts and feelings, came from the idea that sociology should define as its territory rational action and social facts that exist outside of individual consciousness.

Sociologists also reacted against introspection because they viewed it as a psychological process that implied self-contained internal events. But the psychological approach ignored the socially constructed, processual nature of thoughts, feelings, and introspection. Viewed as process, introspection, like any thinking, is covert communicative behavior. As private, inner dialogue, it is enabled by publicly shared significant symbols and thus is inherently social. Psychologists who used introspection presented it as an inward activity, a way to investigate how an individual mind had constructed the world. Psychology deemphasized the self-dialogue inherent in introspection, underplayed the impact of shared symbols on people's response to their selves in inner conversation, and excluded the role of external norms and social structure.

Nevertheless, the gate in sociology never has been closed entirely to introspection. Some sociological traditions have maintained that understanding the meaning of one's own experience and empathically interpreting meaning in the experience of others constitute bases for inquiry. For example, Charles H. Cooley advocated sympathetic introspection, a process by which one comes to understand others by sympathetically ascribing to them one's own response in similar situations. Ethnographic, feminist, hermeneutic, and social constructionist approaches continue laying the groundwork for investigating emotions, thoughts, and subjective meaning.

In the past two decades, interpretive social scientists, such as Arthur Bochner, Norman Denzin, Carolyn Ellis, H. L. Goodall, Ronald Pelias, and Laurel Richardson more openly and passionately have embraced subjectivity as both a subject of study and a vital part of the methods for studying self and social life. Carolyn Ellis, for example, argues that introspection is a social process as well as a psychological one. Introspection is actively thinking about one's thoughts and feelings; it emerges from social interaction; it occurs in response to bodily sensations, mental processes, and external stimuli as well as affecting

these same processes. It is not just listening to one's voice arising alone in one's head; usually, it consists of interacting voices, which are products of social forces and roles.

Autoethnographers, in particular, call on introspection in writing their self stories. Though not everyone who writes autoethnography advocates a systematic or sociological methodological approach, many autoethnographers were educated and claim identities as ethnographers. Though their goal is to write evocative narratives, they often follow a process akin to steps taken in qualitative research. Thus, introspection, like autoethnography, intersects social science and humanities.

The following is a brief description of how to engage in systematic sociological introspection to write autoethnographic stories. Autoethnographers first write fieldnotes on the relevant aspects of their experiences. They include all the details they can recall, organizing their writing chronologically and using main events to structure the tale. Authors concentrate on emotions and dialogue, but they also describe places, colors, sounds, and movements. The first draft stays as close to the reconstructed events, fieldnotes, and emotional memory as possible. Embracing the multiplicity of selves that all human beings harbor, autoethnographers engage in recording the many competing voices in their heads and bring to consciousness their contradictory and ambiguous thoughts and feelings.

Using a process of emotional recall similar to the method acting of Lee Strasberg at the Actors Studio, writers imagine being back in the scene emotionally and physically. Revisiting the scene emotionally leads to remembering other details. The advantage of writing close to the time of the event is that it does not take much effort to access lived emotions; they are often there whether one wants them to be or not. The disadvantage is that being so involved in the scene emotionally can make it difficult to analyze from a more distanced cultural perspective. Yet both of these processes, moving in and moving out, are necessary to produce an effective introspective autoethnography.

In the next draft, writers develop a plotline that focuses more specifically on the topic of the project. Literary tropes of dialogue, scenes, and characters are important as are conveying thoughts and emotions constructed in the initial notes. These thoughts and emotions are further developed in the process of writing, which continues to stimulate memory and reexperience of the experience as well as provide context and meaning.

The stories, written as evocative narratives, invite readers into experience, and let them move with authors though their defenses and toward deeper levels of examination. Readers can move back and forth between being in the story of the author and returning to their own, where they might fill in or compare their experiences and provide their own sensitivities about what is going on. Readers should be able to feel the specificity of the author's situation, yet sense the unity of human experience as well as they connect to what happened to the author, remember what happened to them, or anticipate what might happen in the future.

An introspective autoethnography should not only probe thoughts and feelings but also provide details that help make sense of the experience in terms of the situational or historical context in which these events occurred. A successful autoethnography should stimulate conversations among those who write and read the text, which then act back on the text, making the interpretation and understanding ongoing with each conversation that takes place. The end result is narrative truth, which means that the experiences these narratives depict become believable, lifelike, and possible.

SYSTEMIC INQUIRY

Systemic inquiry is inquiry, research, or evaluation that is based on systems concepts or systems principles.

Systemic inquiry covers a wide range of methodologies, methods, and techniques with a strong focus on the behaviors of complex situations and the meanings we draw from those situations. It spans both the qualitative and quantitative research method domains but also includes approaches that fit neither category and both categories.

Origins

Although elements of systemic inquiry can be identified in writings since the Greek philosophers, systemic inquiry as we know it today derives from traditions established by people such as Ludwig von Bertalanffy, Warren Weaver, Norbert Wiener, and Gregory Bateson in the late 1930s and 1940s. Von Bertalanffy was a biologist who was interested in the extent to which biological concepts such as metabolism, isomorphism, growth, equifinality, nested systems, and steady state could be applied to other scientific domains. His interest developed into general system theory (GST) first promoted during the late 1940s. Around the same time, Weaver, a mathematician and engineer, was suggesting that science should distinguish between simplicity and what he termed organized and disorganized complexity. Also Wiener, Bateson, and others became interested in the idea of cybernetics—a more mechanistic version of GST that explores how feedback disrupts normal linear understandings of cause and effect.

By the 1960s these ideas, blended with parallel thinking from the organizational research and action research fields, had developed into a series of methodologies for assessing, problem solving, and intervening in complex, real-world situations.

Once established within the problem-solving and organizational research arenas, the ideas spread further into environmental, planning, social work, futurist, group dynamic, and other domains. By 2001, Eric Schwartz was able to identify 1,000 streams of systemic thought.

What Is Systemic Inquiry?

Any attempt to summarize a transdiscipline like systemic inquiry is fraught with difficulties. Despite its relatively simple origins, the field has sprawled into many directions so that no single, universally accepted theory has emerged, and neither are there universally agreed definitions of basic concepts such

as what is and what is not a system. Although we will find many definitions in the systems literature, many authors argue that single fixed definitions promote the kind of reductionist thinking that runs counter to systemic principles. Instead, they argue, the field should promote debates around methodological principles to create learning rather than fixed definitions—what Kurt Richardson calls “critical pluralism.”

None of this, of course, helps those entering the systems field to get a firm grip on the core elements. One way of understanding systems inquiry is through a series of historical perspectives of its development and application.

Gerald Midgley suggests that systems thinking and systems practice has evolved through a series of waves, or phases of research. Each wave related to a particular focus of the systems field and brought with it a new set of methods. Each wave emerged in response to critical evaluations of the logic and methods of previous waves. However, unlike real waves crashing on a beach, the foci and methods developed during the different waves of systems thinking did not disappear when a new wave came along. Rather, they continued to be developed in parallel with new ideas. Therefore, it is appropriate to talk about all the waves in the present tense.

In the first wave, based on methods developed directly from GST and cybernetics, the focus is on systems “out there” in the world. Improvements come about from changes in the components and relationships within those systems. Methods developed during the first wave are characterized by models of real-world interrelationships and interconnections. These models are validated by how closely they match patterns observed in the situation being studied. System dynamics is one of the best-known methodologies to emerge during this phase, and the influential sociological theories of Talcott Parsons are also associated with the first wave.

During the 1970s, the focus shifted toward using systems concepts to analyze situations from a variety of different perspectives. In this second wave, it became less important to model behavior and more important to understand the different meanings that can be drawn by taking account of multiple systems, each a logical consequences of a particular perspective on the situation. Proposals to improve a situation are based on debates, from the perspectives of these different systems, about desirable and feasible changes. An example of an approach to emerge during

this second wave is Peter Checkland's soft systems methodology.

The third wave, developed during the 1980s, embraced the idea that differences between people's perspectives about a situation are often tied up with power relations. Perspectives affect the boundaries we draw around a situation. Boundaries demarcate who or what is included in or excluded from an assessment of a situation and, thus, the necessary interventions. In other words, boundaries can reflect power dynamics within a situation. From this emerged the notion of boundary critique. The effects of power in defining the boundaries of an intervention need to be accounted for, and multiple options for setting boundaries should be considered. An example of a third-wave approach is Werner Ulrich's critical systems heuristics.

So the first wave tended to focus on interrelationships, the second wave promoted a focus on perspectives, and the third wave promoted a focus on boundaries. However, the third wave was also characterized by an interest in methodological pluralism. Thus, it is not unusual these days for inquiries to use simultaneously methods and concepts developed during all three phases.

Benjamin Lichtenstein provides another historical thread by focusing on the ideas associated with complex systems. He identifies over a dozen semidistinct conceptual strands that contributed to our understanding of complex systems. These strands include fractals, deterministic chaos, and catastrophe theory from mathematics; synergetics, self-organized criticality, and simulated annealing from physics and engineering; human systems dynamics from the social sciences; NK landscapes, autopoiesis, and emergent evolution from biology; dissipative structures from chemistry and thermodynamics; agent-based modeling, cellular automata, and game theory from computer and information science; and systems dynamics. Each of these fields developed models and methods to explore patterns of behavior that belonged to a collection of interdependent parts rather than any individual part of a system working in isolation.

Yet another way to understand the methodological richness of the systems field is by making a distinction between *system* and *situation*.

Some systems practitioners consider a system as a self-evident concrete entity—the filing system, the health system, simple systems, complex systems. These systems possess certain properties and behave according to specific rules. Methodologies associated

with cybernetics, system dynamics, and complex adaptive systems (CAS) tend to use this systems perspective to describe patterns of behavior.

Other systems practitioners argue that systems are not self-evident objects, but are human constructs we apply to a situation in order to make it comprehensible to us. We use systems constructs essentially as lenses through which we gain insights into the behavior of situations. Thus, systems are not viewed as real-world entities, but as mental constructs that help us understand the world. It is similar to distinguishing the glasses we use to view a landscape from the landscape itself. When we can put on different glasses and test them out, we know that by doing so we have not changed the landscape itself but have allowed ourselves the possibility of experiencing the landscape in a different way. Methodologies associated with soft and critical systems methodologies tend to reflect this focus.

Today many systems practitioners have a foot in both camps. They recognize that making a distinction between system and situation allows them access to a wide range of systems methodologies and the ability to investigate their most deeply held views of how the world operates.

Systemic Inquiry and Qualitative Research

Systemic inquiry tends to frame the research process and provides questions for the research process. With a few exceptions, it does not concern itself in theory or in practice with the kind of data used in the research process. If an inquiry needs quantitative data, then that is what will be used. If an inquiry needs qualitative data, then that is what will be used. In many cases, both forms of data will be used in a single inquiry.

Examples of Methodologies Based on Systems Concepts

System Dynamics

System dynamics provides researchers with the ability to explore the interrelationships between components of a situation, especially the consequences of feedback and delay. It thus provides insights into the behavior of a situation from the perspective of its dynamics.

The approach was developed by Jay Forrester in the 1950s and has been one of the highest-profile

systems methodologies. Essentially system dynamics does three things:

1. helps us explore rigorously the implications of feedback and delay on the accumulation of stocks (egg resources) and flows between them,
2. maps the possible relationships among parts of the situation that is being explored, and
3. allows researchers to play “what if” games with the way in which these relationships interact—often using computer simulation.

System dynamics focuses primarily on identifying the main components of a system (often called *stocks*), what flows between them, and exploring rigorously the effect stocks and flows have on each other over time. It, therefore, emphasizes the dynamics of a situation rather than seeks a single snapshot of it.

System dynamics depends more on the use of quantitative data than most systems approaches, although being interested in patterns rather than prediction, the conclusions drawn from system dynamics are often qualitative in nature.

Viable Systems

Stafford Beer conceived his viable systems model (VSM) as a biological cell analogy to explore the necessary relationships between five distinct management functions (or systems) in order to allow an organization to be viable within its environment:

System 1 is what the organization does;

System 2 is what glues the System 1s together (egg coordination);

System 3 is how it does it what it does (i.e., management);

System 4 is about gathering intelligence from the environment and dealing with environmental factors; and

System 5 is about strategy and, together with System 4, ensures that the organization continues to do what it is supposed to do, or needs to do.

VSM has been widely used in the knowledge management area because it promotes a focus on what information each system needs (and does not need) from the other in order for the whole organizational system to operate effectively.

Soft Systems Methodology

Soft systems methodology (SSM) provides researchers a means of drawing deep insights by looking rigorously at a situation from a variety of different systems perspectives. In particular, it provides a means by which these multiple viewpoints can be unpacked, reassembled, and assessed in a rigorous fashion. Given that these viewpoints will be present within the situation and will be informing people’s motivations and behavior, soft systems is a means of understanding and anticipating so-called unanticipated consequences.

SSM was developed by Peter Checkland in the late 1960s at the University of Lancaster in the United Kingdom. It was one of the first systems approaches to consider the importance of understanding how people draw meaning from what they observed.

At the heart of SSM is the notion that it is unhelpful to think of a particular situation as comprising actual systems. Most situations are complex messes that mostly do not adhere to any useful set of systems rules. Even when they do, different systems can be identified within a single situation depending on our perspective.

SSM essentially compares the real situation with understandings of what the situation might look like if it were only operating using systems concepts from a single perspective. What would a basketball game look like if it was only concerned with team skill? What would it look like if it were only about promoting a team’s sponsor’s product? This ideal system has six building blocks—the system’s purpose (transformation), what gives that purpose meaning (worldview), those who will benefit from this meaning (customers), those who provide the expertise to bring it about (actors), those who have the power to control the system (owners), and the environment that influences but does not control the system.

Considerable insights can be gained from comparing these different ideal systems with the real situation. Thus, systemicity is a property of people’s thinking about the situation rather than a property of the “mess” that is the starting point of an analysis.

Critical Systems Heuristics

Critical systems heuristics (CSH) draws researchers’ attentions to ethical issues, marginalization of people and ideas, and ideas of power and coercion in a situation. It helps researchers identify and critique the

consequences of boundaries set by those with power or expertise. Who or what is positively or negatively affected by those boundary decisions is a major part of any research undertaken from a CSH perspective. Of course the boundaries set by research itself are also subject to investigation and critique.

CSH was developed from the ideas of C. West Churchman, who felt that just looking at a situation from different perspectives was not enough. A mixture of coercion, homogeneity of view, and other factors will mean not all relevant perspectives will be considered or have equal value. Thus, the full consequences, both positive and negative, of taking a perspective may not be assessed. Churchman argued that those conducting an inquiry need to “sweep in” and consider issues that challenge any emerging consensus.

Werner Ulrich further developed Churchman’s ideas so that a critical systems inquiry will generate debates or dialectics along three dimensions:

- within each of 12 major components of a perspective (purpose, beneficiaries, measures of success, resources, decision makers, environmental opportunities and constraints, expertise, experts, assumptions, the systems “victims,” safeguards for those victims, and worldview),
- between these 12 components (especially between the first nine that generally take a positive view of the system and the last 3 that take a negative view), and
- between the actual state of each component in real life and what ought to be the state of each component.

Clearly the tensions between the *is* and the *ought*, and also the positive and negative views, and indeed between these two dimensions themselves, provide a

Figure 1 Elements Shaping the Purpose of a System

powerful analytical tool that strongly emphasizes the ethical boundaries of a research endeavor or planning exercise.

Activity Systems

Activity systems (often known as cultural–historical activity theory) draws its primary inspiration from cognitive rather than cybernetic concepts—especially Vygotskyian learning theory. Vygotsky’s ideas were taken up by Leont’ev (both based in the USSR), and introduced to the wider systems world during the 1980s by Yrjö Engeström. It is extensively used in teaching, knowledge management, and innovation research.

Activity systems is based on five key notions:

1. The starting point is a social situation with a defined purpose. This purpose is affected by a range of elements, in particular mediating artifacts (e.g., tools) used, which include language plus the rules and the roles people have that mediate and are mediated by the use of those tools diagrammatically (see Figure 1).
2. There are always multiple points of view, traditions, and interests that provide potential sources of trouble and sites for innovation.
3. A situation’s current features and dynamics can only be understood by exploring the impacts of past features and dynamics.
4. Changes in a situation are primarily driven by contradictions. These contradictions generate tensions within the system and can result in conflicts, problems, disturbances, or innovations.
5. These contradictions provide primary sites for learning and development. Consequently, there is the ever-present possibility of the situation being transformed by these contradictions. These transformations create further historical contradictions that provide further learning opportunities. In fact, the process is cyclical.

Complex Adaptive Systems (CAS)

CAS is the name for both a description of a particular systems behavior as well as the springboard for a wide range of systems methodologies and methods designed to bring insights into situations that display complex adaptive behaviors. A complex

adaptive system comprises independent, interconnected elements (or agents) that adapt their behavior according to the behavior of other elements within the system. Consequently, our understanding of situations requires research tools that allow us to explore patterns of behavior rather than predetermined fixed results.

These patterns are determined primarily by fixed rules that determine how an agent responds to another agent's behavior (as distinct from the potential more flexible rules in activity systems). Clearly the starting conditions affect the result. Consequently, the focus in CAS based research is to study the patterns and starting conditions to understand who the key agents are, what rules are applying to them and what affects the nature of their response.

Many methodologies and heuristics have been developed how to recognize and how to intervene in complex situations. For example:

- Agent-based modeling uses computer simulations to model rule-based behavior between agents (i.e., system components). Like system dynamics, agent-based modeling will often use quantitative data to draw qualitative conclusions.
- Cynefin developed by David Snowden uses cognitive theory and network theory's notions of centrality and connectedness to understand simple, complicated, complex, and chaotic patterns of behavior.
- Human systems dynamics developed by Glenda Eoyang seeks to understand patterns of self-adaptive behavior using three aspects of a system; containers that hold the agents, differences between the agents, and exchanges between the agents to explain complex behavior. A combination of small container, small difference, and limited exchanges results in simple, predictable behaviors. The opposite will result in complex, unpredictable behavior. In between lies possibilities of self-adapting, recognizable patterns of behaviors.
- Mapping a situation along two dimensions—certainty of cause and effect and agreement between agents—was developed by Ralph Stacey to understand complex patterns of leadership.
- A four-stage cycle of systems behaviors (birth–exploitation, maturity–conservation, creative destruction, and renewal–mobilization) was developed by Brenda Zimmerman.

TACIT KNOWLEDGE

Tacit knowledge is a construct associated with the thinking and writing of philosopher Michael Polanyi. Polanyi noted that we inevitably know more than we can say; he labeled this nonlinguistic, intuitive, and even at times unconscious form of knowledge *tacit knowledge*.

Tacit Knowledge and Qualitative Research

In the final quarter of the 20th century, certain advocates for using qualitative methods in social science research employed Polanyi's tacit knowledge construct to help make their case. In particular, they used the construct to argue that a perceived problem with qualitative research was, in fact, an asset. Transforming perceived liabilities into assets is a classic marketing strategy, of course. The slogan, "With a name like Smuckers, it has to be good," is an example of the marketing field's use of the strategy. Here, the markets have taken a name that could be seen as a liability and have turned it into an asset by creating a slogan that makes the name synonymous with "goodness."

For academics, the problem of "marketing" qualitative methods to skeptical social science communities in the final quarter of the 20th century was not in a name. Rather, the problem was that qualitative researchers' emergent designs and their normally informal research strategies (e.g., participant observation, the researcher as instrument, conversational

interviewing) were highly subjective, and traditional social scientists—who had been socialized to use supposedly objective procedures in the interest of minimizing error—viewed open-ended designs and subjective methods as problematic.

Qualitative researchers at times referenced Polanyi's notion of tacit knowledge to transform this perceived problem into a solution for a different problem that even many traditional social scientists had begun to recognize.

That problem was the complexity of social phenomena. Traditional researchers had become aware of the complexity problem when their traditional approaches to research failed to provide the sort of generalizable knowledge that traditional researchers had expected—and had promised—to produce. In the early 1970s, for example, evaluators who employed experimental and control groups to assess the effectiveness of programs began to understand that their a priori lists of independent and intervening variables did not capture a host of interaction effects and that their predefined dependent variables sometimes were less important than the unintended outcomes a program produced (and that their a priori designs, of course, did not address).

Qualitative research advocates argued that the complexity of social phenomena requires that researchers employ open-ended research designs and use research methods that allowed researchers to tap their tacit knowledge. Tacit knowledge, in other words, is needed to make sense of a level of complexity that prespecified designs and standardized—that is, quantitative researchers' so-called objective—methods will never be able to accommodate.

Minimizing and Managing Subjectivity

Of course, there is still a potential downside to relying on knowledge that is tacit and, hence, unavailable for public scrutiny and critique. Thus, qualitative researchers developed a number of procedures—for example, member checking, various forms of triangulation, peer debriefing, and audits—to move qualitative researchers' findings and interpretations beyond the tacit and subjective levels. In addition, a seminal article by Alan Peshkin, "In Search of Subjectivity—One's Own," suggested ways to manage one's subjectivity so it contributed to rather than interfered with a study's validity.

TELEPHONE INTERVIEW

Telephone interviews were first used in large-scale quantitative surveys. More recently the method has been applied to qualitative interviewing. As with any method, the use of telephone interviews is determined by the practical advantages and pitfalls associated with the method and with regard to the research topics and participants involved.

Free flowing conversations can be held and rich data obtained from telephone interviews. However, participants tend to answer briefly compared with face-to-face interviews. Researchers, therefore, need to probe to ensure questions and topics are fully addressed. There is an important and unresolved issue about social desirability bias generated through telephone interviews. On the one hand, use of the telephone can offer anonymity to participants, enabling them to talk freely, openly, and honestly. On the other hand, during interviews on the telephone it can be difficult to build up trust and rapport, as well as gain the full attention of the participant.

Some participant groups may be more difficult to engage on the telephone; they may be distrustful of using the telephone, especially when discussing potentially sensitive topics (e.g., illegal activities, health behavior). Telephone interviews may not be appropriate for participants when researcher–interviewee rapport is important and trust needs to be established. Once rapport and trust have been built up, telephone interviews may be used in follow-up work. Similar issues are raised with cold calling—referring to telephoning people for interviews with no prior warning—where it can prove difficult to recruit participants and obtain rich qualitative data.

The use of visual information and aids during telephone interviews (e.g., prompt cards, vignettes) and requests for participants to write or draw need to be carefully planned for. Materials should be sent in advance, researchers have to ensure participants have these available at the time of interview, and the discussion should be carefully managed to ensure the correct materials are being used.

The nuances of body language and other nonverbal cues associated with face-to-face interaction may be lost over the telephone, although voice and intonation remain important cues. It is important to recognize researchers' personal characteristics that may influence responses (e.g., age, ethnicity) are minimized over the telephone.

Telephone interviews can be a difficult method to implement with people with verbal communication difficulties, people who tire easily, or where third parties (e.g., translators) need to be involved. However, researchers can ensure participants set the style and pace of the telephone interview.

Researchers have less opportunity in telephone interviews to create good interview ambience, such as ensuring participants are comfortable and interview distractions are kept to a minimum. However, should participants be distracted, interviews can be rescheduled relatively quickly and easily.

Low administration costs are associated with telephone interviews compared to face-to-face interviews, which incur travel time and expenses. The method is widely recognized as cost effective, especially when interviewing participants across geographically dispersed areas.

TEXT

Text, which in its broadest sense is anything in written form, constitutes the basic medium through which most qualitative analysis is carried out. Texts for research purposes are generated in many different ways; some are naturally occurring (e.g., newspaper reports, minutes of meetings, or policy documents); some are created following the use of research methods such as semi-structured interviews or focus groups (through audiorecording and transcription) or produced by the researcher (such as fieldnotes within participant observation); and others are the consequence of a process of “translation” whereby a social phenomenon that is the object of study is turned into text. In this latter category, Ian Parker and colleagues include television programs, cities, film, gardens, bodies, and silence.

The epistemological status of a text is contingent on the set of assumptions and tenets underpinning the research endeavor for which it has been generated. In considering a transcription of a research interview, for example, researchers working within a critical realist paradigm (e.g., perhaps using grounded theory principles) might accept the transcript as a reflection of the research participant's perspectives or views. Those adopting a narrative methodology will view the product of the interview as a story and will be interested in sequencing and form. Researchers of postmodern persuasion (e.g., discourse analysts) will treat the text as constitutive in its own right and reject it as a neutral representation of research participants' cognitive processes (such as their beliefs or attitudes).

The processes whereby the social phenomena that are the objects of study are transformed into text are also largely determined by the assumptions

underpinning what the text represents. If one views text as the means of transmitting the spoken word, which itself is a transparent representation of views, beliefs, or experiences, then the process of transcribing audiorecorded material is largely a technical issue in terms of ensuring that an interview is audible and thus captured on a recording and then accurately word-processed. However, within a research methodology such as conversation analysis, talk and text are viewed as active and performative. In order to carry out the fine-grained analysis required for conversation analysis, many nonverbal elements of talk also need to be represented within text, including volume, inflection, pauses, and overlapping speech. A text prepared for a conversation analysis appears very detailed and may be virtually incomprehensible to a novice researcher in comparison to a transcription of an interview generated for a grounded theory study. With the challenge to the authorial voice of the researcher that accompanies a postmodern or post-structural position, it is incumbent on the investigator to foreground his or her own role and interaction with the process of creating the text, as it will be for the process of interpretation.

Traditionally, the process and findings of research have been represented as scholarly texts such as academic papers, books, or theses. However, the critical turn within social research means that more researchers are exploring different ways of presenting their research products, such as alternative textual forms (poems, stories, web-based material), visual forms (such as photographs and pictures), or performative media (such as drama).

TEXTQUEST (SOFTWARE)

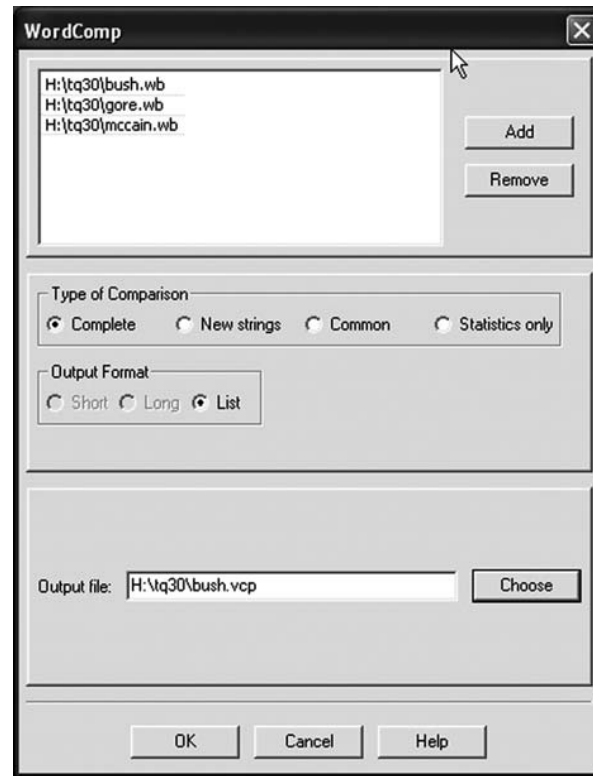

TextQuest is a language-independent program that supports quantitative and qualitative analyses of texts: wordlists, lists of phrases, and co-occurrences of words. All of these are sorted, ascending by alphabet and containing the character strings and their frequencies. Exclusion lists, selection by frequency, and selection by length are possible. Sort order tables for non-English languages are implemented.

TextQuest can also be used in qualitative analysis to examine the context of a search pattern and its display on a single line. The definition of a search pattern is not restricted to single words. One can define any part of a word, phrase, or co-occurrences of words as a search pattern. Also, the use of wildcards such as using a question mark or an asterisk is allowed. The context can be either the whole text unit or a selected part of displayed on a line. The length of the line is variable; for example, 60, 80, or 113 characters, per line.

The comparison of vocabularies is another module of TextQuest. A vocabulary can be a wordlist, a phrase list, or a list of co-occurrences. With version 3.0 or later, one can compare multiple vocabularies; for example, the speeches of 5 speakers on the same subject in one comparison instead of 10 one-by-one comparisons. Statistics include common entries of all vocabularies and exclusive entries related to the first vocabulary specified.

One form of a content analysis is a readability analysis based on mathematical formulas called readability indices. TextQuest offers 68 formulas for seven different languages. The results of these formulas can either be the reading class, the reading age, or an index value often between 0 (very difficult) and 100 (very easy). However, these formulas only measure syntactic variables like sentence and word length, number of syllables, or the occurrence of unknown words by comparing the text with entries of given word lists. The content of the text is not taken into account. All the formulas have implications regarding the language of the text and its genre.

The content analysis is very powerful. The search patterns can be defined as described above, and ambiguous or negated search patterns can be handled by interactive coding. The numeric results and the log files give complete control of the coding process. For statistical analyses, syntax files for SAS, SimStat, and SPSS are written.

A Screen View of the Word Comparison Module. In this module it is possible to compare many wordlists at one time; e.g. to compare speeches of different authors on the same subjects, or changes in the word use over time on newspaper articles. This example shows the module configured to compare three files.

TEXTUAL ANALYSIS

Textual analysis is a method of data analysis that closely examines either the content and meaning of texts or their structure and discourse. Texts, which can range from newspapers, television programs, and blogs to architecture, fashion, and furniture, are deconstructed to examine how they operate, the manner in which they are constructed, the ways in which meanings are produced, and the nature of those meanings. Sociologists, geographers, historians, linguists, communications and media studies researchers, and film researchers use textual analysis to assess texts from a range of cultural settings.

Textual analysis is a term used to refer to a variety of primarily qualitative methodologies or models. Research that focuses on the analysis of textual content will adopt either content analysis (both quantitative and qualitative approaches), semiotics, phenomenology, or hermeneutics. Research on textual structure and discourse employs different methodologies, including genre analysis, *mise-en-scène* analysis, narrative analysis, discourse analysis, structural analysis, poststructural analysis, or postmodern textual analysis. Each methodology has its own nuances, inflections, strengths, and weaknesses. A number of theoretical frameworks are available to researchers when interpreting any text. The framework adopted will depend on the researcher's preferences. Some researchers explore texts, their conventions and their relationship to realism, whereas others assess the construction and reinforcement of cultural myths.

The Glasgow University Group (1976, 1980) used a combination of textual analysis methodologies, including content analysis and semiotic analysis, to explore the ideology at work in the presentation of television news surrounding industrial reporting. Their textual analyses identified systematic biases against the working classes. More recently, textual analysis has been broadened to consider the ideological implications of both factual and fictional texts and their hybrid forms.

All texts, including this encyclopedia entry, have their own narrative structures and persuasive qualities and are designed to convey a preferred meaning. Textual analysis does not attempt to identify the "correct" interpretation of a text, but is used to identify what interpretations are possible and likely. Texts are polysemic—they have multiple and varied meanings. However, this semantic instability does not mean that readers can make a text mean whatever they wish it to

mean. Meaning is derived from the codes, conventions, and genre of the text and its social, cultural, historical, and ideological context—which can work together to convey a preferred reading of the text. Some textual analyses examine the interconnections of meanings both inside and outside the text. Thus, questions asked during textual analysis refer to the rhetorical context of the text (Who created the text? What are the authors' intentions? Who is the intended audience?), the specific textual characteristics (What topic or issue is being addressed? How is the audience addressed? What is the central theme or claim made? Is there evidence or explanation to support the theme or claim? What is the nature of this evidence or explanation?), and the wider context of the text (How does the text relate to other texts in the same genre or format?).

Textual analysis is a fruitful methodology that has increased understanding of the construction of textual meaning in variety of cultural texts. Through close and detailed scrutiny, textual analysis can provide rich discussion of presentational and structural specifics and subtleties that would remain unidentified if a cursory analysis was conducted. Textual analysis also benefits from that naturally occurring status of its data source. Texts exist in society before the researcher decides to analyze them. Therefore, insights into meaning construction and the ideological implications of texts are not subject to the biases that are evident when data sources are created for, or around, the research project. Texts are also readily available, which can quicken the research process and prevent ethical difficulties surrounding access (although some ethical considerations still apply; for example, regarding anonymity). Further, as textual approaches provide close analyses of texts, often only a small number of texts is required to create an adequate data set (with the exception of quantitative content analysis).

Critics of textual analysis have questioned the validity of the approach, arguing that a reading of a text echoes the perspective of the researcher and that the specific approaches used to analyze texts are as ideological as the texts themselves. Recognizing this, Paula Saukko proposes that textual analysts should highlight that a text can never be completely understood because all readings of texts are socially situated. Further, researchers should critically reflect on their own perspectives by subjecting them to the political and social inspection that would be conducted for all texts. This process involves being self-reflexive about favoring certain approaches to textual

analysis over others and about referring to other textual approaches as inferior. Alternatively, Saukko suggests that in order to highlight the political dimensions of interpretations of texts, researchers could adopt multiperspectival textual analysis by combining different textual analysis approaches, such as semiotics and postmodern approaches.

Texts are diverse in form, and this diversity is sometimes overlooked in textual analysis. Even within the same family of texts there will be wide variation. For example, media texts range from front covers of magazines to the latest blog entry, each with their own production and stylistic conventions. This variety should be taken into account when examining the production of meaning in texts and their likely interpretations.

A further criticism of textual analysis is that it is conducted in isolation—the text is all that matters, and it is the central, or the only, focus of analysis. This self-contained approach to analysis neglects the importance of the producer and reader in the construction of meaning. Combining textual analysis with methods that explore the institutional constraints on the production of the text (such as in-depth interviews or participant observation) and how audiences read the text (focus groups and in-depth interviews) prevents the risk textualizing the world—perceiving the world specifically in terms of texts—and acknowledges the world that exists outside of texts.

THEATRE OF THE OPPRESSED

Theatre of the Oppressed (TO) generally refers to a collection of unique improvisational and theatrical

forms developed by Brazilian theater artist and activist Augusto Boal. TO is a participatory and democratic approach to theater that critically examines social, political, and personal oppressions to develop emancipatory strategies. Selected qualitative researchers employ TO for such purposes as participant diagnostics, data-gathering methods, stimuli for participant reflection and dialogue, action research to create positive social change within communities, and therapeutic modalities with selected populations.

Forms of Theatre of the Oppressed

Boal's most well-known and widely used TO forms include games, Image Theatre, and Forum Theatre.

Boal's unique games function as physical warm-ups for more advanced work and serve as metaphors for the dynamics and inequity of power between individuals and social groups.

Image Theatre is based on Boal's theory that language sometimes obfuscates what people truly think and feel. Therefore, the participant's body is used as an expressive instrument to articulate his or her innermost attitudes, values, and beliefs through still and fluid images. An example is a group of incarcerated youth sculpting themselves into their representative image of justice.

Forum Theatre is an improvisational, participatory form in which a brief, prepared scenario is presented to an audience that illustrates an oppressive conflict, such as a teacher (the antagonist) unfairly accusing a student (the protagonist) of cheating on an exam. The scene ends unresolved so that audience members (called *spect-actors*) can replace the protagonist and replay the scenario several times with different tactics to overcome the oppression. The Forum Theatre event is facilitated by a *joker* who, like the playing card, can assume multiple roles as needed—facilitator, devil's advocate, discussion moderator, and so on.

Other forms of Boal's TO include: Invisible Theatre, the Rainbow of Desire, Legislative Theatre, and Aesthetics of the Oppressed.

Applications in Qualitative Research

Qualitative researchers, primarily from the fields of education, social work, and theater, have applied TO techniques with diverse groups of participants ranging

from Latina youth to inner-city secondary school students. Audio- and videorecordings of TO experiences can generate such data as the visual-symbolic representations of concepts produced through Image Theatre and the transcripts of Forum Theatre's spect-actor dialogue and debate.

THEMATIC CODING AND ANALYSIS

Thematic analysis is a data reduction and analysis strategy by which qualitative data are segmented, categorized, summarized, and reconstructed in a way that captures the important concepts within the data set. Thematic analysis is primarily a descriptive strategy that facilitates the search for patterns of experience within a qualitative data set; the product of a thematic analysis is a description of those patterns and the overarching design that unites them. Thematic coding is the strategy by which data are segmented and categorized for thematic analysis. Thematic coding is a strategy of data reduction, in contrast to the axial and open coding strategies characteristic of grounded theory research, which enrich and complicate data through the inclusion of analytic insights and inquiries used.

In thematic coding, the analyst frequently begins with a list of themes known (or at least anticipated) to be found in the data. When data for thematic analysis

are collected through semi-structured interviews, some themes will be anticipated in the data set because those concepts were explicitly included in data collection. Codes may also come from a beginning conceptual model, the review of the literature, or professional experience. At this stage of the analysis, coding categories are more heuristic than analytic; that is, coding categories serve as a receptacle for promising ideas. Promising ideas become coding categories through a rigorous process of analytic induction that includes both within- and across-case comparisons. First, an idea must show importance within an individual account. For example, in a study of family caregivers, one female informant may live in a house in which all of the bedrooms are on the second floor where she cares for her mother, who recently had a stroke and can no longer manage the stairs. The informant may tell stories about her mother's early life as a women's softball player, their lifelong close relationship, and her mother's current inability to remember names or faces. The stairs, the softball, and the stroke are key ingredients in this informant's account. Stairways and softball are unique to this participant, but environmental barriers to caregiving and the image of the care receiver are ideas likely to recur in other interviews. If they do recur, then environmental barriers and image of the care receiver become themes. Similarly, although not every informant may be caring for a family member with cognitive changes after a stroke, many caregivers may contrast the condition of their family member now and before the illness event, leading to a theme of change.

Coding facilitates the development of themes, and the development of themes facilitates coding. In coding, portions of data are separated from their original context and labeled in some way so that all data bearing the same label can be retrieved and inspected together. As noted by Renata Tesch, these data are decontextualized from their original interview and recontextualized into a theme. Coding categories are reconceptualized, renamed, reorganized, merged, or separated as the analysis progresses; categories are seldom static and never inviolate, as they are subject throughout the analysis to the search for alternative interpretations or disconfirming evidence. Data management strategies are needed that can handle coded data in ways that are both flexible and robust; that is, codes and categories must be easily reorganized, and search and retrieval capacities must be capable of managing large amounts of information. For these reasons, many qualitative researchers now use some form of qualitative data management software.

Although it is convenient to discuss coding, data management, the development and refinement of themes, and the identification of patterns across the data as though they occur sequentially, like steps in a process, in practice this is not the case. Rather, all of these activities occur throughout the project, although with more emphasis on coding and data management at the beginning of a project and more emphasis on identification of patterns as data collection winds down and the investigator's focus turns to analysis. For this reason, it is difficult to identify the point in the analysis at which thematic coding becomes thematic analysis. Throughout the analysis, the investigator considers the relevance of each theme to the research question and to the data set as a whole, thus keeping the developing analysis integrated. At the same time, as identification of themes progresses, the investigator also considers the relationship among categories. In this way, data that have been decontextualized through coding retain their connection to their sources and thus can lead to the ideographic (that is, case-based) generalizations characteristic of qualitative research. The processes of reintegration and connection to the source distinguish thematic analysis from qualitative content analysis. In the latter, coded data segments are analyzed without relation to the account from which they were drawn.

In order to develop useful generalizations from thematic coding, themes must be synthesized. The product of a thematic analysis is more than a list of themes and their descriptions. The product of a thematic analysis, like any qualitative analysis, includes both the important concepts and processes identified in the study and the overarching patterns of experience by which those concepts and processes are manifested. Ideally, a thematic analysis takes into account both patterns of commonality across all cases and the contextual aspects of the phenomenon that account for differences among participants; for example, a thematic analysis might include both the important concepts in a study of family caregivers and those concepts that influence the way care is provided. Although thematic analysis remains descriptive and is not designed to uncover an essential structure or develop a grounded theory, nevertheless, investigators are challenged to present findings that are both meaningful and useful.

THEMES

In qualitative research, data collection typically occurs to the point of saturation. Essentially, this means that researchers continue interviews to the point where little new information is shared by participants. In other words, people continue reporting essentially the same ideas and the law of diminishing returns is at work in the information-gathering procedure. Collecting more data, at that point, does not produce novel results.

Thematic analysis is one of many methods used to assess whether or not saturation has occurred in the data collecting process. Typically, reoccurrence is a prime means of analyzing data for themes. That is, researchers assess the interview transcripts for repeated statements, phrases, and words.

However, themes are not generated simply by counting words. Rather, themes are assessed by examining constructs that occur in the data. For example, the terms *anger*, *upset*, *frustrated*, or *mad* may be used by various participants, but all refer essentially to the same overarching construct. Computer-assisted software often can be helpful to qualitative researchers when assessing data for related ideas, using different words or phrases.

Themes typically are derived from codes generated by the qualitative researcher. Reading the material presented by the participants multiple times, using constant comparison among the ideas presented throughout the interviews, can become overwhelming to the researcher. Consequently, experienced qualitative inquiries involve researchers making memos to themselves as the data collection process occurs. These memos may involve hunches, impressions, or ideas for further exploration. Tracing through one's memos often prompts the researcher for potential reoccurring ideas.

These potential reoccurring ideas are coded, simply meaning that the constructs are physically noted (handwritten or in a software database). Sometimes what originally appeared to be a theme does not turn out to be aptly supported by the data. Those codes eventually are ignored or discarded. Other codes, however, occur repeatedly—both in terms of breadth, and, when appropriate, depth of occurrences. These reoccurring coded phrases, terms, and expressions (and the like) formulate constructs that seem to be shared by most or many of the participants of the study. When sufficiently grounded in the data collected, they become the study's themes.

Quantitative researchers sometimes overlook the inductive method of qualitative themes. As a hallmark, qualitative researchers use an inductive method of analysis. Most quantitative researchers begin with hypotheses that they attempt to prove or disprove statistically. Essentially, it is a deductive method. The researcher begins with a conclusion (null hypothesis) and goes to data for its support. Qualitative researchers, in contrast, are inductively driven. They begin with the data, and from it, develop hypotheses or conclusions. Most often, the themes generated from the data are the study's conclusions.

Finally, themes are assessed by qualitative researchers in more than just transcribed interviews. Triangulation involves sifting through documents, websites, test results, public relations materials—anything that might substantiate or negate the stability of themes found from participant interview transcripts. In other words, information from related documents should support the overall themes generated from the coded transcript data.

empirical or quasi-empirical theory of social and/or psychological processes, at a variety of levels (e.g., grand, mid-range, and explanatory), that can be applied to the understanding of phenomena. Qualitative research has often been criticized for not being guided by theory in its development and conduct. Additionally, students as well as experienced researchers who employ qualitative methods frequently have trouble identifying and using theoretical frameworks in their research (i.e., understanding how and what it affects in the process of conducting the research).

The confusion related to understanding and using theoretical frameworks stems from a wide variety of treatments of this topic by leading writers in the field. Many of the prominent writers on qualitative methods provide neither the depth of understanding nor the specificity needed to explicate the topic. In an attempt to address this confusion, this entry focuses on what has been written about the role of theory and theoretical frameworks in qualitative research, defining what a theoretical framework is, looking at how one finds and utilizes a theoretical framework in qualitative research, and addressing the effects of a theoretical framework on the research process.

What the Literature Says

While there is little disagreement about the role and place of theory in quantitative research, such is not the case regarding qualitative research. There is consensus neither about its role in qualitative research nor about its definition. Theory, though, has an unavoidable place for all but a few of the authors reviewed, and it plays a substantive role in the research process. An examination of the literature on this topic reveals three different understandings: (1) that theory has little relationship to qualitative research, (2) that theory in qualitative research relates to the methodology the researcher chooses to use and the epistemologies underlying that methodology, and (3) that theory in qualitative research has a pervasive role that affects all aspects of the research process. These categories of understandings are not exclusive, but help highlight the confusion that exists in the literature. Authors may lean toward more than one position. For example, an author may situate the role of theory within methodological paradigms, yet hint at the notion that theory has a much wider role to play. A brief review of each of these categories follows.

THEORETICAL FRAMEWORKS

Although the term does not have a clear and consistent definition, *theoretical framework* is defined as any

Theory Has Little Relationship

Some widely used textbooks do not discuss, nor even mention, theory in relation to qualitative research. Others mention theory, but confine the discussion to defining it as an attempt to develop a general explanation for some phenomenon or as primarily concerned with explanation. Several authors give short shrift to discussions of theory in qualitative research while acknowledging its relevance to a particular methodology. For example, in discussions of grounded theory, they hold that qualitative studies are done to discover theory because the researcher starts by collecting data and then searches for theoretical constructs, themes, and patterns that are “grounded” in the theory.

Theory as Related to Methodology

In sharp contrast to these works, where theory in relation to qualitative research is nonexistent or relatively modest, there is a substantive body of work that equates theory in qualitative research with the methodologies used in the conduct of the research and the epistemologies underlying these methods. These works are well known and are largely written about qualitative research specifically, rather than about research in general. Some authors in this category speak about theories emerging from naturalistic inquiry, not framing it.

Some researchers equate paradigms with theory and argue that these paradigms contain the researchers’ epistemological, ontological, and methodological premises that guide the researcher’s actions. These paradigms are identified as positivism and postpositivism; interpretivism, constructivism, and hermeneutics; feminism(s); racialized discourses; critical theory and Marxist models; cultural studies models; and queer theory. These paradigms clearly link theory to methodologies; however, it is also suggested that the study is widely affected by the linkage. Some writers of qualitative methods argue that case study research, in contrast to other qualitative research designs such as ethnography, requires identifying the theoretical perspective at the outset of the inquiry since it affects the research questions, analysis, and interpretation of findings.

Other writers of qualitative methods acknowledge that researchers bring paradigmatic assumptions (ontological, epistemological, axiological, rhetorical, and methodological) to the design of their studies, and may, in addition, bring ideological perspectives (postmodernism, critical theory, and feminism) that might guide a study. It is believed that with ethnography and

phenomenology, the researcher brings a strong orienting framework to the research, while in grounded theory, one collects and analyzes data before using theory. With biography and case study, a theoretical lens might or might not play a part, depending on the nature of the study and the disposition of the researcher.

Theory as More

As compelling as the work relating theory in qualitative research to methodologies and their underlying epistemologies, a body of work that, while not denying the influence of methodologies and their underlying epistemologies, suggests that the role of theory in qualitative research is more pervasive and influential than suggested by those who situate it methodologically. They contend that it plays a key role in framing and conducting almost every aspect of the study (e.g., development of purpose statement, research questions, data collection protocols and approaches, and analysis).

From this perspective, it would be difficult to imagine a study without a theoretical (sometimes called a conceptual) framework. We would not know what to do in conducting our research without some theoretical framework to guide us, whether it is made explicit or not. Researchers who hold this perspective call the theoretical framework the structure, the scaffolding, or the frame of the study. For some authors, the theoretical framework affects every aspect of the study, from determining how to frame the purpose and problem, to what to look at and for, to how they make sense of the data that are collected. In short, the entire process is theory-laden.

This position holds that without at least some rudimentary theoretical framework there would be no way to make reasoned decisions about what data to gather or to determine what is important from among the wealth of data and possibilities of approaches to analysis that exist. The theoretical framework can be rudimentary or elaborate, theory-driven or commonsensical, descriptive or causal, but it delineates the main things to be studied and the presumed relationships among them. The theoretical framework is constructed from the theories and experiences the researcher brings to and draws upon in conceptualizing the study. These theories, implicit and explicit, include grand theories such as symbolic interactionism and middle-range concepts such as culture, as well as preconceptions, biases, values, frames, and rhetorical habits.

Few of us can claim that we enter the field *tabula rasa*, unencumbered by notions of the phenomena we seek to understand. Theory (i.e., a theoretical framework), then, includes any general set of ideas that guide action, and that theory profoundly affects the conduct of qualitative research. Theory is pragmatically linked with the activities of planning a study, gaining entry into the field, recording observations, conducting interviews, sifting through documents, and writing up research.

Definition of a Theoretical Framework

As noted above, the term *theoretical framework* does not have a clear and consistent definition; in this entry, it is defined as any empirical or quasi-empirical theory of social and/or psychological processes, at a variety of levels (e.g., grand, mid-range, and explanatory), that can be applied to the understanding of phenomena. This definition of theoretical frameworks excludes what some writers have called paradigms of social research (e.g., postpositivist, constructivist, critical, feminist). It also does not consider methodological issues or approaches to be synonymous with theoretical frameworks (e.g., narrative analysis, systems analysis, symbolic interactionism).

Examples of what is meant by theories that can be applied as “lenses” to study phenomena might include Vygotskian learning theory, micropolitical theory, class reproduction theory, job choice theory, social capital, cultural capital, liminality, transformational learning theory, the arena model of policy innovation, and grief theory, to name only a few.

There are a wide variety of theoretical frameworks available for qualitative researchers to consider. These frameworks originate in the many different fields of study and disciplines in the social and natural sciences. Thus, the well-read qualitative researcher is alert to theoretical frameworks in economics, sociology, political science, psychology, biology, physics, and anthropology, to name but a few. Researchers should be open to considering the applicability of these frameworks to the research problem they seek to study. It is, indeed, this diversity and richness of theoretical frameworks that allow us to see in new and different ways what seems to be ordinary and familiar.

In defining theoretical frameworks, we must be cognizant that any framework or theory allows the researcher to “see” and understand certain aspects of

the phenomenon being studied while concealing other aspects. No theory, or theoretical framework, provides a perfect explanation of what is being studied.

How Do I Find a Theoretical Framework?

The problem of finding a theoretical framework is not confined to students or neophyte researchers. Even seasoned qualitative researchers have been known to have manuscripts returned to them with questions about the theoretical framework that guided their study. Students of qualitative research as well as experienced researchers sometimes find themselves at a loss in the process of selecting a theoretical framework. They often expect it to appear or to magically drop into their laps. Admittedly, finding a theoretical framework, especially one that works well for the phenomenon being studied, is not always an easy process. Although students or researchers may be lucky and find a theoretical framework quickly and painlessly, having one handed to them by a professor for their thesis or dissertation, by a colleague, or by co-researchers, the fact remains that in all likelihood students or researchers will have to actively search for a theoretical framework. No doubt, this pursuit will be characterized by much reading (e.g., in the fields of economics, political science, sociology, anthropology, psychology, and even the physical and biological sciences); possible discussion with colleagues; and finding, reflecting upon, and discarding several potential theoretical frameworks before one is finally chosen. Although some researchers use a particular theoretical framework for an extended period of time, others change frameworks with each study undertaken.

A good approach to beginning to find a theoretical framework might be to study a scholarly journal that requires its authors to identify the theoretical framework used. Typically, one will see a heading or subheading that is actually labeled as a theoretical or conceptual framework. Qualitative researchers are encouraged to spend some time looking at published research and identifying the theoretical frameworks used as a way to stimulate thinking about theories and their relationship to research projects. Additionally, qualitative researchers are encouraged to be persistent in the search for theoretical frameworks and to think beyond the confines of their disciplinary focus.

What Effect Does the Theoretical Framework Have on My Research?

A theoretical framework has the ability to (a) focus a study, (b) reveal and conceal meaning and understanding, (c) situate the research in a scholarly conversation and provide a vernacular, and (d) reveal its strengths and weaknesses.

Focus a Study

The ability of a theoretical framework to focus a study involves four issues. First, qualitative researchers often feel overwhelmed by the mountains of data (e.g., interview transcripts, documents, observation notes, and fieldnotes) that can be collected. By acting as a “sieve” or a “lens,” the theoretical framework assists the researcher in the process of sorting through these data. Second, the theoretical framework frames every aspect of a study from the questions asked, to the sample selected, to the analysis derived. The concepts, constructs, and propositions that are part and parcel of a theory help the researcher in formulating these component parts of the research process. Third, qualitative researchers are keenly aware of the existence of subjectivity and bias in their research. The theoretical framework helps the researcher to control this subjectivity by the self-conscious revisiting of the theory and a concomitant awareness that one is using a particular perspective. Fourth, the theoretical framework provides powerful concepts that may be used in the coding and the analysis of the data. In short, the theoretical framework forces the researcher to be accountable to ensure that the methodology, the data, and the analysis are consistent with the theory.

Reveal and Conceal Meaning and Understanding

The theoretical framework has the ability to reveal and conceal meaning and understanding. Theories can allow us to see familiar phenomena in novel ways, but they can also blind us to aspects of the phenomena that are not part of the theory. As part of theory’s ability to reveal and conceal, we should be cognizant that a theoretical framework can distort the phenomena being studied by filtering out critical pieces of data.

Researchers need to recognize this characteristic of a theoretical framework and give serious thought to what is being concealed. This ability to reveal and conceal makes it all the more important for researchers to tell their readers, if possible, what is concealed. This

concealment is, after all, the essence of a study’s delimitations. Although the choice of a theoretical framework clearly delimits a study, little recognition of this fact is found in theses, dissertations, or in journal articles.

Situate the Research in a Scholarly Conversation and Provide a Vernacular

In the process of advancing knowledge, the theoretical framework allows researchers to situate their research and knowledge contributions in a scholarly conversation. It allows them to talk across disciplines using the known and accepted language of the theory. It is this established language that assists in making meanings of the phenomena being studied explicit. The theoretical framework also provides convenient labels and categories that help in explaining and developing thick descriptions and a coherent analysis.

In reflecting upon this effect of the theoretical framework, it is important for qualitative researchers to learn the language of the theory being used and to use it precisely and clearly. It is also necessary to make every attempt to state their contributions to the scholarly conversation without overreaching appropriate parameters—parameters that will be dictated by the data they have collected and the analysis they have formulated. Part of participating in this scholarly conversation and documenting their contribution involves looking carefully at the relationship between their study and the theory they have used. Does their research support the existing theory, does it advance the theory in some meaningful and important way, or does it refute the theory? These are important questions that should not be avoided in this discussion.

Reveals Its Strengths and Weaknesses

No theoretical framework can completely and adequately describe or explain any phenomena. Researchers should be concerned about the power of a theoretical framework to be too reductionistic, stripping the phenomenon of its complexity and interest, or too deterministic, forcing the researcher to “fit” the data into predetermined categories. Other researchers have been concerned about the power of the existing literature on a topic to be ideologically hegemonic, making it difficult to see phenomena in ways that are different from those that are prevalent in the literature. Some have discussed the fact that strengths and weaknesses provide sufficient reason to employ multiple frameworks in one study.

Researchers need to be prepared for the strengths and weaknesses of a theoretical framework being revealed during the process of conducting a research project. Questions will be raised that need to be addressed. Whereas the “fit” of the theoretical framework for a study may become evident, it may in fact become necessary to discard the theoretical framework and start the process of searching for a new one. Researchers need to be wary of dropping data in light of assessing the strengths and weaknesses of any theory. It could be these data that help in the advancement of the theory or in its being refuted.

The relationship between theory and qualitative research remains complicated. The question remains, “Is it possible to observe and describe what happens in natural settings without some theory to guide the researcher in what is relevant to observe and to assist in naming what is happening?” Qualitative forms of inquiry demand that theory (i.e., theoretical frameworks) be used with imagination and flexibility. As John Dewey noted, it is part of our need to reeducate our perceptions.

THEORETICAL MEMOING

Memoing refers to the informal written records kept by qualitative researchers that reference ideas, hunches, hypotheses, research literature, and sundry observations about research questions, research design and methods, and theory as they arise in the process of a research project. *Theoretical memoing* refers to a specific subset of memoing that focuses on the theorizing aspect of research. Although memoing is described as an essential step throughout the process of conducting studies using grounded theory, it is also described by other qualitative researchers as a useful means to trace one’s development of theory from initial conception of a research project to publication of the findings. Given that theoretical assumptions underlie every aspect of a research project, theoretical memos provide an important record that researchers may use as a source of information, impetus for reflection, and record of analytic decision making.

Various descriptions of memo writing provide guidelines for how researchers can use theoretical memoing in their work, as well as exemplars of various types of memos. First, qualitative researchers can use multiple techniques to illustrate their developing understandings of how evidence may be generated, understood, analyzed, and represented. These include freewriting and drawing diagrams and concept maps. Second, qualitative researchers are advised to begin recording theoretical memos early—throughout the research design process, while conducting fieldwork, and throughout the process of data collection and analysis.

Advocates of theoretical memoing affirm that this technique assists researchers to develop researcher reflexivity, to make decisions with respect to data generation and research design, to make connections between the concrete details of evidence to abstract ideas and concepts, to support assertions and develop analyses and interpretations, to record the development of theory building, and to write and report findings. Although some scholars describe writing, coding, and filing theoretical memos on index cards, the introduction of computer-assisted qualitative data analysis software packages (CAQDAS) to the field of qualitative inquiry has facilitated quick and easy access to systematic forms of memo writing in the form of annotated texts, linked memo documents, and hypertext links among electronic documents.

The focus of theoretical memoing is on reflection, analysis, and interpretation, as well as how researchers

relate evidence to abstract concepts. Proponents of theoretical memoing recommend that researchers write with a focus on jotting thoughts down, rather than writing accurately. Researchers are advised to keep records systematically and include the date of memo writing and references to specific data and/or analyses, along with excerpts of relevant transcriptions and fieldnotes. Each theoretical memo is seen as a step in the generation of theory, and researchers are advised to be flexible, developing ideas further in later memo writing and using memos as a springboard for revising manuscripts for publication.

THEORETICAL SAMPLING

Theoretical sampling is a tool that allows the researcher to generate theoretical insights by drawing on comparisons among samples of data. The data can include population, events, activities, or even time periods. Barney G. Glaser and Anselm Strauss first significantly explained the term in *The Discovery of Grounded Theory* (1967).

Data remain opaque if the researcher develops no sensitivity among the potential differences and similarities among a variety of classes or samples of data. More important, the choice of data samples allows the researcher to impute the theoretical aspects of the research. For instance, data generated in a study of horseback riding by the disabled might lack depth and understanding if the researcher chooses to ignore the kinds of participants involved in the many aspects of this form of

horseback riding such as the disabled person (and this by age or gender), the parents or guardian of that person, the organizers of horseback riding events, and those responsible for dressing the horses. The researcher might also find it fruitful to conduct a theoretical sample of subgroups; namely, horseback riding of the disabled in rural, semirural, and urban settings. A theoretical sample would bring into relief a variety of experiences that can be compared to generate concepts and theory.

The typical basic research process often does not allow a researcher initially to set out the samples. Rather, as the researcher first deepens him- or herself in the field setting, the potentiality of creating theoretical samples becomes more obvious. The question, "How can I differentiate or compare data that would allow me to move my research to a more conceptual stage?" resembles a refinement of how a researcher can use data to advance conceptual thinking. Taking an example from thinking theoretically about research on a Florida retirement community, one would off-hand think of interviewing active and inactive members of the community. However, within the cadre of active members, members of the entertainment committee constitute the hyperactive ones, while on the inactive side, one would be forced to collect data from "snowbirds" and "snowflakes" who are intermittent visitors from the north. Without such dimensionalizing of the data, it would be hard to theoretically advance the data about the retirement community.

The two above examples also illustrate the timing of introducing theoretical samples in one's research. In some cases, theoretical sampling involves further differentiations among classes of data whether they pertain to activities, events, documents, or time periods. Observing street-level activities in a village, a researcher might feel compelled to derive a theoretical sample based on times of day. This type of theorizing can yield clues about the shape of public life in that village and lead the researcher to generate insights about "compact" time and "diffuse" time.

The theoretical sample is a simple, but highly effective tool that can spark further insights because it can save time. Moreover, the use of theoretical sampling forces the researcher into new directions, stretching the diversity of data gathered for the purpose of developing concepts and theories.

THEORETICAL SATURATION

Theoretical saturation signals the point in grounded theory studies at which theorizing the events under investigation is considered to have come to a sufficiently comprehensive end. At this point, researchers are comfortable that the properties and dimensions of the concepts and conceptual relationships selected to render the target event are fully described and that they have captured its complexity and variation. Theoretical saturation is the endpoint of theoretical sampling and is achieved via constant comparison analysis, the signature sampling and analysis strategy in grounded theory inquiry.

Although related to each other, theoretical saturation is different from data saturation (also called informational redundancy). Informational redundancy refers to data and occurs when researchers sense they have seen or heard something so repeatedly that they can anticipate it. Collecting more data is deemed to have no further interpretive value. In contrast, theoretical saturation refers to interpretations of data and occurs when researchers are satisfied their theoretical renderings of a target event will fit any other data about it that might still be collected.

The achievement of theoretical saturation is a function of the theoretical sensitivities researchers developed prior to and in the course of their studies and based on the judgments of other researchers. Theoretical saturation is, therefore, a process idiosyncratic to the researcher and study, and a product of communal evaluation as the audiences to whom a theoretical rendering is directed decide whether it has been achieved. When theoretical saturation is reached depends on such factors as sample variation, length of time in the field of study, and researcher experience. Moreover, because theories are always subject to revision, theoretical saturation represents what Barney Glaser and Anselm Strauss described as a pause in the never-ending process of theory development.

Illustration of Theoretical Saturation

What follows is a necessarily simplified illustration of theoretical saturation intended to clarify its defining

features. A researcher conducting a study to understand how HIV-positive women handle the stigmatization associated with HIV infection begins to theorize, from the interview data collected from HIV-positive women, two types of disclosure: managed and mismanaged disclosure. In managed disclosure, women stay in control of whether their HIV status will be revealed and what about it will be revealed and to whom. The researcher discerns what she or he initially takes to be four analytically distinct strategies women use in managed disclosure: (a) full disclosure, whereby women withhold nothing about their disease from anyone; (b) partial disclosure, whereby they reveal only some things about their disease; (c) selective disclosure, whereby they reveal information about their disease to some but not to other people; and (d) full concealment, whereby they reveal nothing about their disease to anyone. In mismanaged disclosure, women lose control of whether their HIV status is revealed, what is revealed, and to whom. These women are “outed” accidentally, as when they are seen entering a clinic serving only HIV-positive patients, or deliberately, as when a person to whom a woman has revealed her disease subsequently tells other people.

Theoretical saturation will have been achieved when this researcher—using theoretical sampling and constant comparison analysis—is able to answer a number of questions, only a few of which are featured here. For example, do the concepts *managed* and *mismanaged disclosure*, and *full disclosure* and *concealment*, and *partial* and *selective disclosure*, exhaust the variation in types and strategies of disclosure? Should the categorization of disclosure be refined to encompass additional types and strategies or to eliminate one or more of them? No matter the number of categories, are they both exhaustive and mutually exclusive? If the researcher decides to use a conditional matrix framework for analysis—one of a number of grounded theory coding families—does she or he have the data to describe the causes and conditions for, and consequences of, using these disclosure strategies? For example, do certain HIV-positive women (e. g., White versus African American, women in general versus just mothers, women diagnosed with HIV infection for more versus less than a specified period of time) prefer one strategy over another? Under what circumstances would a woman decide to disclose or conceal fully, partially, or selectively? Alternatively, if the researcher decided a process coding framework was a better fit to the data, can the

researcher show how women moved from one strategy to another, or cycled between strategies?

Theoretical saturation is achieved to the extent that this researcher's theoretical rendering is sufficiently developed to answer these and the many other questions that might be raised in analyzing such a dynamic process. Moreover, the achievement of theoretical saturation does not necessarily require that additional data be collected as the researcher, by virtue of engaging in the process of constant comparison analysis, will have developed the theoretical sensitivity to see in the data already collected what was not seen before. The researcher may come to see an incident a woman shared about telling others about her disease, not simply as yet another story about telling (i.e., as simply informationally redundant), but rather as an empirical example of the theoretical proposition that whenever a woman judges a person as having a right to know, selective disclosure of at least partial information ensues. The researcher might seek to "test" this proposition by theoretically sampling the data already obtained or data newly acquired for this purpose and, thereby, determine whether this proposition continues to hold or whether any negative cases exist to undermine it (e.g., an empirical example of managed disclosure when no right to know was deemed to exist). Theoretical saturation, thus, serves as a key criterion for validity in grounded theory studies.

THEORY

Theory is a term that is widely used in both everyday language and academic discourse, but its

precise meaning is vague and contested. A theory, in both everyday and scientific use, is normally used to denote a model or set of concepts and propositions that pertains to some actual phenomena; a theory can provide understanding of these phenomena or form the basis for action with respect to them.

Following Thomas Kuhn, qualitative researchers have generally accepted the view that all observation is theory-laden—that our understanding of the world is inherently shaped by our prior ideas and assumptions about the world and that there is no possibility of purely objective or theory-neutral description independent of some particular perspective. Thus, theory is an inescapable component of all research, whether or not it is explicitly acknowledged.

However, the explicit use of theory in qualitative research is quite different from that in the physical sciences and in much quantitative research. Qualitative researchers do not usually design their research primarily to apply or test formally constructed theories about the topics and settings they study. Instead, they normally seek to better understand these topics and settings through their investigations and to inductively develop theory about these from their data. Qualitative researchers generally acknowledge, and often explicitly analyze, the influence of their prior assumptions about these topics and settings, and they typically use insights or concepts taken from existing theories and relate their findings to these theories, but their research normally draws on these theories selectively and eclectically, rather than deliberately seeking to contribute to a particular theory.

An apparent exception to this understanding is the widespread use of critical theory, queer theory, and other such approaches in qualitative research. Although these approaches contain some premises about the nature of the phenomena being investigated, they function more as normative frameworks than as theories in the traditional sense, emphasizing particular goals for research and assumptions about appropriate methods for achieving those goals, as well as assumptions about the social context of research and the political and economic structures that shape its conduct and use.

Understanding qualitative researchers' stance toward theory requires further exploration of what a "theory" is. There are three characteristics of the concept of theory in scientific use that are important for this discussion:

1. Theory is abstract, and refers (at least in part) to entities or ideas that are hypothesized, abstracted, or inferred rather than being directly observable.
2. Theory is general; it refers not only to a single instance or case, but also to all instances or cases of a particular type.
3. Theory is typically explanatory; it tells us why things happen, rather than simply describing what happened.

All of these characteristics have created difficulties for the use of theory in qualitative research. Qualitative research has generally focused on concrete description and interpretation, rather than the development of abstract propositions. It has similarly been skeptical of the formulation of general propositions or models and has emphasized the importance of particularity and context. Finally, it has typically rejected the idea of causal explanation, emphasizing the role of interpretive understanding (Max Weber's *Verstehen*) rather than explanation in the human and social sciences. These three characteristics of theory, and their implications for qualitative research, are addressed below.

Abstraction

In the philosophy of science, the generally accepted definition of a theory during the first half of the 20th century, one taken from logical positivism, was that a theory consists of a set of abstract (ideally, mathematical) propositions, some of which take the form of "laws," that predict a range of specific events or results. Such theories constitute a deductive system that explains specific events by subsuming them under the theory; this system was known as the *deductive-nomological* model of scientific explanation. For many logical positivists, the abstract terms (e.g., photons, gravity, or social cohesion) employed in these statements or laws (known as *theoretical concepts*) were not thought to have any "reality"; they were simply useful constructs in subsuming or predicting observable events, and needed to be defined operationally in terms of the procedures used to apply and verify them. (The classic example is "intelligence is whatever intelligence tests measure.") Since such theories could not themselves be directly investigated empirically, the goal of research was to test the predictions derived from these theories, using empirical data.

In the social sciences other than economics (and, to some extent, psychology), this model of theory was never generally accepted. However, during the mid-20th century, its impact was reinforced by the dominance of highly abstract theoretical frameworks (for example, the theory of action proposed by Talcott Parsons) and by the view that the main purpose of research is to derive and test the prediction of such theories. Thus, despite the striking lack of success of the deductive-nomological model in generating theories in the social sciences that were equivalent in explanatory power to those in the physical sciences, this model continued to influence social scientists' thinking about theory.

As a consequence, many qualitative researchers rejected the use of abstract, formal theory in their work. Barney Glaser's and Anselm Strauss's concept of grounded theory, which endorsed the view that the inductive development of theory from data collected during an investigation was more important than testing prior theory, was a major statement of and influence on this development.

However, in philosophy, from about 1950 on, the deductive-nomological view of theory was subjected to severe criticism, from both inside and outside the positivist tradition, and was eventually abandoned or modified beyond recognition. It is now generally accepted that the formal, law-like, deductive conception of theory espoused by the positivists is not a valid understanding of the use of theory even in many of the physical sciences, and that the antirealist or instrumentalist view of theoretical terms is highly problematic. The social sciences in particular do not normally proceed by developing highly abstract, formal theories and empirically testing the implications of these theories. And while much quantitative research still employs the concept of operational definitions of theoretical terms, this view has never been widely adopted in qualitative research.

A less restrictive conception of theory is now widespread, one that sees theory as simply a set of concepts and the postulated relationships among these, a model or framework that has implications for understanding or action. Theories can range from highly abstract frameworks to models that are closely linked with observation and experience. In addition, there is a growing recognition that theories, like most of human thought, are to an important extent metaphorical rather than strictly logical in nature; they draw on what are usually unconscious metaphors from basic human

experiences. Such a conception of theory is much more compatible with qualitative research, which focuses on concrete situations, events, and meanings.

Generality

Closely connected with abstraction, theory is typically assumed to be general rather than particular; with the possible exception of history, the social sciences have treated theories as being applicable to more than a unique case. The range of generality extends from so-called grand theory, such as structuralism, psychoanalysis, rational choice theory, and Parsons's theory of action, mentioned above, through Robert Merton's middle-range theory, focusing on a more limited set of phenomena and backed by empirical data, such as reference group theory, social network theory, and Erving Goffman's theory of total institutions, to very specific theories of or hypotheses about particular types of phenomena or settings.

Qualitative researchers have tended to avoid broad generalizations about the issues they study. They have focused on specific, local understanding of the settings and activities they study and rarely claimed that they had developed propositions that applied to a wide range of settings or activities, as theory in the traditional sense would seem to require. The idea of generalizability itself has been problematic for qualitative researchers, and Egon Guba and Yvonna Lincoln's substitution of *transferability* for the traditional concept of *external validity* or generalizability has been widely adopted. For transferability, the traditional emphasis on developing a general theory from multiple studies is replaced by the idea that other researchers or practitioners can adapt and apply the conclusions of one study to their own particular situations. In particular, qualitative researchers have usually avoided claims that their theories are predictive in the ways that quantitative researchers have often endorsed.

However, other qualitative researchers did not abandon the concept of generalizability, or of theory, but adapted these to the requirements of qualitative inquiry. Robert Yin distinguished between statistical generalization and analytic generalization, the latter also described as generalizing to theory. He argued that qualitative case studies generalize in the same way as experiments in the natural sciences—not by applying statistically to some defined population, but by contributing to the development of a theory with wider applicability. Howard Becker made a similar

claim, emphasizing that such a theory identifies a general process, but does not predict results independent of context. Instead, it needs to be applied in conjunction with the specific social and cultural features of the setting in question, which can create very different outcomes. Yin's and Becker's approaches to theory employ the broader and more commonsense view of theory presented in the previous section: as a system of concepts and postulated relationships among these.

Explanation

Not all theories in the social sciences have explanation as their goal; some important theories (such as Talcott Parsons' theory of action) have been mainly typological, proposing a system of ideal or abstract concepts and the logical relationships among these. Such theories have tended to be fairly general and abstract and have not received much use by qualitative researchers, for reasons discussed above. However, explanation is generally felt to be an important goal of theory.

For most scientists, explanation is causal explanation; an explanation claims to describe what caused a particular result or state of affairs. This concept of explanation has been problematic for many qualitative researchers because the model of causation that is typically invoked is particularly uncongenial to qualitative research. This model, derived from Hume's regularity account of causation, holds that causal explanation consists simply of showing that the presumed cause is regularly followed by a given effect and that other plausible causes for this effect can be ruled out. Hume proscribed any reference to unobservable processes as being metaphysical. This view was incorporated by the logical positivists in their model of explanation, a model that has survived the demise of positivism and is a dominant influence on quantitative research.

As a result, it is widely held that only experimental research, or quantitative techniques such as structural equation modeling, can answer causal questions. The Humean regularity account of causation leaves no role for the major strengths of qualitative research—its ability to elucidate the meanings, processes, and contextual influences that are involved in particular events or situations. As a result, many qualitative researchers have either denied that they were making causal claims that were more than speculative or have argued that causality is not a valid concept in the social sciences (a particularly influential statement of this position was that by Lincoln and Guba). The latter

position fit well with the emerging interpretivist approach to social research, which focused on the elucidation of meaning rather than causal explanation (a distinction emphasized by Max Weber, although he did not see the two as mutually exclusive).

However, there is now a well-developed alternative approach to causation and explanation—one that sees explanation as the explication of the processes and mechanisms that result in a particular occurrence in a given context. This view, advanced both by philosophers and by social researchers, is often labeled *realist* or *critical realist* in contrast to both positivism and constructivism. It is very compatible with qualitative researchers' emphasis on process and on contextual influence and also with their emphasis on the importance of meaning, if meanings are taken to be real entities that can causally influence people's actions. Such a stance legitimates the explanatory role of theory in qualitative research and implies that adequate theories in the social sciences need to incorporate issues of meaning, process, and context, rather than simply stating relationships between variables.

Issues in Developing and Using Theory

In the more recent conceptions of theory outlined above, theory is a simplification of the world, but not necessarily a highly abstract, logical model; it is a simplification that can exist at many levels, and one that is aimed at clarifying and explaining some aspect of the world and our experience of it. A useful theory is not just a framework; it tells an illuminating story about some phenomenon, one that provides new insights and broadens our understanding of that phenomenon. This conception of theory is more compatible with, and gives greater prominence to, many of the issues that are central to qualitative research than are traditional positivist or neopositivist views.

However, such a conception of theory does not eliminate all problems with developing and using theory in qualitative research. Developing theory is not something that can be reduced to an algorithm; it is dependent on the phenomena that one wants to theorize about, and the specific goals, abilities, and paradigmatic commitments of the researcher.

First, it is important to recognize Chris Argyris and Donald A. Schön's distinction between a theory that a researcher states or explicitly applies (espoused theory), and the actual theory or theories that inform the research (theory-in-use). The latter is generally far

more extensive and complex than any espoused theory, and may require considerable reflection (or critique) to uncover.

Second, as postmodernists argue, no theory can completely characterize any social phenomena; it is always incomplete and leaves out alternative possible understandings. Thus, the acceptance of any theory privileges a particular view of the phenomena it addresses and can limit or distort the researcher's understanding. Becker has pointed out the ideological hegemony of dominant theories and how they can deform researchers' conceptions of the things they study, showing how such theories distorted his early research on marijuana use.

An awareness of alternative concepts and theories that are applicable to the phenomena being studied is thus an important counterweight to the ideological hegemony and deforming power of established theory. Such alternatives may be found in other fields, or in sources other than published literature, including the researcher's personal experiences, the unpublished ideas of other researchers, and thought experiments that attempt to generate such alternative ways of seeing these phenomena. However, as with theory-in-use, recognizing these as alternative ways of seeing is likely to require a reflective and critical perspective on existing theory, and assessing the theory in question relative to alternative plausible theories is one of the major tasks of any research.

Finally, the view of theory presented above implies that the testing of theory should involve more than simply making predictions from the theory and seeing if these are confirmed by research. It should also involve investigating the processes stated or implied by the theory, to see if these are actually operative for the phenomena in question. The ability of qualitative research to do this has been argued by many qualitative researchers, and this approach to theory provides additional support for these arguments.

THICK DESCRIPTION

The term *thick description* was introduced into qualitative research by the anthropologist Clifford Geertz, who borrowed it from the philosopher Gilbert Ryle. It has often been misinterpreted to mean rich, thickly detailed description, but neither Geertz nor Ryle used it in this way. Ryle developed this concept as part of an attempt to banish from philosophy the idea of “mind” as a separate entity from behavior. He argued that mental terms refer not to unobservable “ghostly” processes located in a “secret grotto” in the skull, but to aspects of people’s public behavior—not their bodily movements per se, but their dispositions, powers, and propensities to behave in particular ways in specific contexts. Mental terms thus describe behavior thickly, incorporating these propensities and contexts in the description as opposed to describing “thin” behavioral accounts—for example, describing someone as playing golf rather than as hitting a small white ball with a metal stick. Geertz added to this the idea that thick description incorporates the cultural framework and meanings of the actors, their codes of signification, providing an emic account grounded in the actors’ cultural context; thick description is thus the essential activity of ethnographic research.

Ironically, considering the importance of this concept for qualitative research, Ryle’s strategy of identifying mental terms with behavioral dispositions was an essentially positivist approach of attempting to eliminate theoretical terms referring to unobservable entities from philosophical and scientific discourse. It can be seen as a variant of what earlier positivist philosophers had called *logical behaviorism*. Geertz was not endorsing this position—his essay “Thick Description” is subtitled “Toward an Interpretive Theory of Culture”—but one of his goals in using the concept of thick description was to argue that ethnography did not require access to the inner thoughts and feelings of those studied and to assert the public, observable nature of the phenomena that anthropologists sought to interpret.

Logical behaviorism eventually foundered under a barrage of philosophical criticisms, but the term *thick description* has outlived its philosophical origins and taken on new meanings. More recent uses of this concept have tended to see thick description as inherently interpretive rather than descriptive, linking the term to the position that all observation is theory-laden and that descriptions are social constructions rather than reflections of some external reality. Thomas Schwandt (2007), for example, states that “to thickly describe social action is actually to begin to interpret it by recording the circumstances, meanings, intentions, strategies, motivations, and so on that characterize a particular episode. It is this interpretive characteristic of description rather than detail per se that makes it thick.” (2007, p. 296) Norman Denzin coined the phrase “thick interpretation” to emphasize the interpretive nature of this activity and has drawn on Geertz’s later work to support the inseparability of description and interpretation.

THINK ALOUD METHOD

See COGNITIVE INTERVIEW

THINKING QUALITATIVELY WORKSHOP CONFERENCE

Thinking Qualitatively is an annual event consisting of a series of workshops in conference format. Participants can mix- and-match workshops, creating their program from approximately 20 half-day or full-day workshops offered in six concurrent sessions.

Organized by the International Institute for Qualitative Methodology (IIQM), University of Alberta, Canada, the series is offered over a one-week period every summer. Participants are generally those who are new to qualitative inquiry, including many graduate students. Because of its flexibility, programs can be tailored to meet participants' own research interests and individual needs. Faculty consist of scholars affiliated with the IIQM, assisted by international guests. Previous keynote speakers have included Juliet Corbin, Phyllis Stern, and Arthur Frank.

The sessions are primarily at the introductory level, providing an excellent overview of the principles of qualitative inquiry (e.g., previous conferences have included sessions such as "Preparing Your Proposal," "Sampling," "Interviewing Techniques," and "Coding.") Qualitative methods are explicated with sessions on narrative inquiry, phenomenology, ethnography, interpretive inquiry, using videos, observational research, and grounded theory. The conference concludes with a one-day workshop on textual data analysis using a computer program, such as NVivo.

The weeklong series also includes a special session each day: a poster session is offered, so that registrants can circulate and discuss their own work, keynote presentations bookend the event, and panel discussions (such as "Doing a Qualitative Dissertation") are offered. Networking lunches provide opportunity for informal discussions with the faculty and for meeting new colleagues.

Participants agree that, while intense, Thinking Qualitatively is an excellent way to be mentored into qualitative research. The goal of the workshop series is to bring participants to the level that by the end of the conference they will feel confident enough to commence an actual qualitative project.

Information about Thinking Qualitatively may be found on the website for the International Institute for Qualitative Methodology or by searching the internet using the series title Thinking Qualitatively.

TRANSANA (SOFTWARE)

Transana is an open-source software program available via its website, www.transana.org, that facilitates computer-based transcription and management of media files. Available for both Mac and PC platforms, it was developed primarily for use with video data, but it can also be used with audio data. Transana provides integrated organization of transcription, coding, presentation, and analysis of audio and video data. It was first developed by Chris Fassnacht and is now developed and maintained by David Woods and colleagues at the University of Wisconsin's Center for Education Research. Transana has gained wide popularity for its low cost, availability, user-friendliness, and its increasing power to facilitate transcription, coding, and organization of large corpora of qualitative audio and video data.

Transana allows the user to play media files and simultaneously transcribe or code without switching applications or browser windows. The program also includes keyboard shortcuts that mirror the functions of traditional pedal transcribers (i.e., pause, stop, rewind, fast-forward), includes automatic rollback from zero to 5 seconds after pausing, and has shortcuts for fine-grained transcription superscripts. Users can also select media playback speed (from 1/10 to two times the original speed) and can insert timecode stamps in a transcription, allowing for easy access to key points in the media file or transcript.

In addition, Transana functions as a database, linking a transcription file (exportable in Word rich-text format) to a media file. Timecode markers, keywords, or other codes can be used to call up portions of the file or catalog and group relevant portions of data. Transana also includes a hierarchical organizing system for organizing multiple layers of transcripts or codes for the same media clips.

Transana is available in single- or multiuser versions, the latter of which provides database access to multiple parties across institutions. This ability allows for continued and shared consideration of the data in its original media format without sole reliance on transcripts alone. Making such a consideration of non-verbal interactions easily available to multiple parties opens data up to dispute-verification during coding, analysis, or dissemination. Transana also includes a presentation feature in which media clips can be

Transana Screen View. Transana's typical display including (clockwise from top left): Visualization window (shows audio waveform), video window, data window (shows database file organization), transcript window.

presented with overlain transcripts or codes. The ability to view video in tandem with codes and transcript keeps these analytic processes more visible and fluid and thus open to others' insights and opinions throughout entire process.

TRANSCRIPT

A transcript is a textual representation of an audio- or videorecording. Researchers who use interviews and focus groups tend to construct their analyses based on transcripts made from audiorecordings (and sometimes videorecordings). Similarly, researchers who videorecord observations often rely upon transcripts of those recordings in their analyses.

To create a transcript, transcriptionists often use foot pedals that control playback of the audiorecording

A Sample Transcript

Researchers make choices about the level of detail that is required or desired in the transcripts for a given research project. This sample interview transcript was generated from a one-on-one interview with a professor about her experiences as a researcher and a research educator (McGinn, 2007). The transcript emphasizes verbatim words exchanged between the researcher and participant, supplemented with notations for filled pauses (e.g., *um*), hesitations (pauses timed by the second), and laughter. Emphasis has been marked with italics. No attempt has been made to include extralinguistic or non-body language. Standard punctuation (e.g., commas, periods, and question marks) has been included to facilitate reading of the transcript.

Interviewer: When did you yourself start to feel like a researcher?

Participant: (8-s pause) Well, it's funny, you think about how you. Probably younger. I mean, I don't think the actual label is given to you, like it wasn't until my second year, research assistant, but I don't know, definitely in grade school. I guess when I first started doing projects and things. Like that independent study sort of first task I think, I think my first one was Grade 3 or Grade 4, I forget, but around there. It was that sort of *um* doing something, investigating something on your own away from, knowing that the teacher sort of was giving you that sort of freedom. I really see the research as starting to explore

different things on your own and trying to make sense of it.

Interviewer: So that on your *own*, investigating on your own

Participant: Yeah

Interviewer: Was what led to that feeling of researcher, sense of yourself as a researcher?

Participant: And just the excitement of finding something I think as well. So that

Interviewer: So the opportunity to do

Participant: Yeah

Interviewer: Something but then

Participant: Yeah.

Interviewer: The emotional reaction to doing it

Participant: Yeah, to finding something interesting.

Interviewer: All right. So what about for the graduate students, what do they have to do or feel to feel like researchers?

Participant: (5-s pause) Well, I think they again, I think they need to find that topic that will provide them with that feeling of excitement or discovery. I think that is the key to feeling like a researcher because (5-s pause) because if you're just doing a task for, that doesn't really mean anything to you I don't know if you really feel like a researcher. (laughs)

so that they can operate the audio controls without removing their fingers from the keyboard. Complete transcribing systems also allow adjustments to the speed of playback that do not affect pitch and to the length of the segment prior to a stopping point that is repeated when playback continues (i.e., backspacing).

In recent years, some transcriptionists have begun using voice-recognition technology to facilitate transcription. Common software programs include Dragon NaturallySpeaking, IBM ViaVoice, and iListen. Voice-recognition technology is designed to translate a single speaker's voice to text so that it is ideally suited to dictation of fieldnotes or diary entries from researchers or research participants. This technology has also been used with variable success to transcribe interviews and

focus groups, typically by listening to the audiorecording and dictating it into the computer. It is essential to compare the resulting transcript against the original audiorecording to address errors introduced through the dictation or by the software.

With or without the use of voice-recognition technology, transcriptionists are engaged in interpretive and constructive acts as they produce transcripts. Some scholars have, therefore, begun to analyze the influence of the transcriptionist on the research data and the resulting analyses. Regardless of recording quality or the transcriptionist's expertise, transcripts cannot fully represent spoken discourse or movement. Spoken discourse includes verbal content (e.g., words, word fragments, filled pauses such as *um* and *er*), prosodic information

(e.g., rhythm, intonation, pitch, volume), paralinguistic information (e.g., laughter, audible breaths, sighs), extralinguistic information (e.g., gestures, fidgeting, gaze), pauses, and various contextual cues. It is virtually impossible to document all elements of spoken discourse in a transcript for at least four reasons:

1. It is difficult to reliably identify all these components of speech.
2. There are no clear notation systems that can represent all this information textually.
3. Transcripts become less readable as additional speech elements are recorded.
4. Spoken discourse does not include punctuation or follow other standard grammar rules, yet transcriptionists naturally add these conventions as they type.

Transcripts are even more limited textual reproductions when it comes to movement and other visual information that is present in videorecordings. Researchers need to think carefully about which information is most important to their analysis and how to best document that information in transcripts to support their analyses.

TRANSCRIPTION

Transcription is the process whereby recordings of research conversations (interviews, focus groups) are turned into textual material (transcripts), which then become the primary data for subsequent analysis. Perhaps because transcription is so ubiquitous and taken for granted, its significance in the interpretive process is routinely underestimated. This is unfortunate because in the translation from richly textured lived experience to

audiorecording to two-dimensional written prose, the data are transformed in ways that have particular consequences for interpretation. This consequence is true even in cases where new developments in computerized software permit the researcher to work with and code audio material directly because ultimately most qualitative research is made accessible to others (published) in written form. This entry reviews issues related to transcription quality, identifies strategies for enhancing it, and discusses related ethical concerns.

Transcription Quality

Paying attention to the ways in which transcripts are generated and what they represent invokes two parallel discourses about transcription quality as an aspect of rigor in qualitative research.

Anticipating and Reducing Error

The first (and dominant) discourse on transcription in qualitative research holds that one must be vigilant in anticipating and reducing sources of error in the production of verbatim transcripts. Transcriber fatigue, poor-quality recordings (background noise, use of low-quality microphones and recording equipment, poor microphone placement), and difficulty understanding accents and culturally specific turns of phrase are said to lead to errors. When transcription is contracted out to individuals who are not affiliated with the study (as sample sizes of funded research studies grow), lack of familiarity with the subject matter, with academic and/or qualitative research, or with the interview itself can pose additional challenges, particularly when a background in nonresearch settings leads transcribers to tidy up the material (e.g., as with dictated correspondence). Even under ideal conditions it is possible to mistake words for others that sound very similar, leading to interesting reversals of meaning (e.g., *consultation* versus *confrontation*).

The Interpretive Nature of Transcription

A second discourse on transcription in qualitative research has more recently emerged that highlights the essentially interpretive nature of transcription. A more reflexive stance vis-à-vis issues of transcription accuracy is advocated. It is argued that, as the raw material from which transcripts are generated, even audiorecordings cannot be verbatim records of a research interview because they do not capture many elements of interpersonal interaction, nonverbal communication, and interview context that are essential

for the interpretation of what is said (hence, the growing use of videorecording). Elements of pace, tonality, affect (humor, sarcasm, excitement, hesitancy), and some elements of turn-taking and verbal communication that do not translate easily into text (e.g., laughter, paraphrasing or mimicking others, or the interviewer's use of *uh-huh* that may steer the interviewee, intentionally or unintentionally) are, in many cases, lost in translation from oral to written. Within this second, more postmodern, discourse on transcription, not only is the possibility of verbatim transcription called into question, but also its desirability, as issues of contextuality, voice, representation, authenticity, audience, and positionality are brought into consideration.

Strategies for Maximizing Transcription Quality

In practice, these two discourses are not as mutually exclusive as might initially be assumed. It is both possible and necessary to simultaneously maintain a reflexive stance that problematizes many modernist assumptions about transcription, without entirely abandoning claims to rigor (albeit inherently limited ones) made possible by availing oneself of opportunities to anticipate and prevent many of the more obvious sources of error described above. Potential strategies for maximizing transcription quality include (but are not limited to) (a) ensuring highest possible audio quality (e.g., minimizing background noise, appropriate quality and placing of microphone); (b) use of notation systems and conventions/instructions to guide transcription (on how to deal with pauses, laughter, interruptions, intonation); (c) selection and training of transcribers; (d) reviewing transcription quality (of a random or purposeful subsample; co-transcription to assess inter-staff reliability when more than one transcriber is being used); (e) interviewer and researcher involvement in transcription (particularly in pilot phase for early detection of problems, and sensitization of researchers to the interpretive work of transcription); (f) involving transcribers in research meetings and as key informants in the analysis of data; (g) member checking (having research participants review their own transcripts for accuracy—though it should be emphasized that the process and results are not straightforward, and many issues of presentation-of-self, selective recall, and self-censorship inhere in member-checking); (h) flagging ambiguous material during the interview (prompting for clarification); (i) using fieldnotes and

observational data to inform interpretation during and following transcription; and (j) reporting on transcription quality when writing up qualitative research.

Which of these strategies are employed and how they are used depends significantly on the kind of transcripts required to answer the particular research question(s) under investigation. The kinds of transcripts and attention to detail required for a conversation analysis will be very different from what is required for studies that focus more on what is said than how it is said. Indeed, in some studies verbatim transcription may be selective (focusing only on some passages, summarizing the others) or not at all required (e.g., listing of issues raised, brainstorming strategies for action).

Ethical Issues

In transcription, several ethical considerations deserve mention. One concerns the need to protect the anonymity of research participants by removing not only names but also other potential identifying information from transcripts prior to analysis, especially in cases where multiple research team members may have (or request) access to the data. A second concern is how interviewees are represented in published material. Because the spoken word has a different syntax, structure, and rhythm than written prose, an insistence on the use of verbatim quotes may inadvertently cast research participants as less articulate than if they had been asked to write on the subject. The potential consequences in cross-cultural research or research with marginalized groups (e.g., for reinforcing stigmatizing stereotypes) should not be underestimated.

Transcription is not just a phase of data preparation and data management; it is interpretive work that occurs early in the analysis phase of most qualitative research projects. As such, transcription calls for the same attention to reflexivity and rigor as other components of data analysis—perhaps more so, insofar as transcriptions involves the production of the raw material upon which subsequent analytic work is based.

TRANSFERABILITY

Due to the nature of the qualitative methodologies, it is not appropriate to have the large sample populations found in some quantitative studies, which might have a sample of 500 to 1,000-plus participants. With any study, there should be careful thought into selecting the participants with the inherent notion that they somehow represent the entire population. This being the case, researchers and readers can then begin to make connections from the revealed data to both local and entire community-level behavior and practice. These considerations are applied to qualitative methodologies through a process called *transferability*.

In quantitative research, generalizability suggests that the results of a given study can be applied across all environments related to the context being studied. For example, the results of a study looking at the impact of an educational campaign against drinking and driving among 400 14- to 18-year-olds in Idaho could be generalizable to all 14- to 18-year-olds in Idaho. Transferability implies that the results of the research can be transferred to other contexts and situations beyond the scope of the study context. For example, the results of a study exploring the decision-making process of 10 labor negotiators in conflict-intense situations could be transferred to police officers handling conflict-intense situations.

To increase transferability, qualitative researchers should focus on two key considerations: (a) how closely the participants are linked to the context being studied, and (b) the contextual boundaries of the findings. In the first consideration, the participants need to be relevant members of the community related to the study. If a study was about the impact of cultural capital and employment opportunities among new immigrants and only Chinese and Pakistani participants were selected, it would lack transferability because the original context is not being accurately measured. The other consideration is concern about providing a complete understanding of the context being studied

and ensuring that the research questions are appropriately answered. It is from here that readers can explore the research document and determine if the findings can be transferred to their setting or environment. So with generalizability, it is the researcher's responsibility to ensure that the findings can be generalizable to a larger context or the entire population. In transferability, it is the researcher's responsibility to paint a full picture of the context and then allow the reader to determine if the work is transferable to their context.

Qualitative researchers can use two strategies to increase the transferability of a study. The first is through thick description. Thick description means that the researcher provides the reader with a full and purposeful account of the context, participants, and research design so that the reader can make their own determinations about transferability. The other methodology is through purposeful sampling. Here, participants are selected because they most represent the research design, limitations, and delimitations of the study. Participants most consistent with the research design will enhance the potential that readers can assess the degree of transferability to their given context.

TRANSFORMATIONAL METHODS

Transformational methods are used to inspire positive social change. Researchers generally adopt transformational methodologies in their pursuit of social justice, socioeconomic or cultural equity, empowerment of marginalized individuals, or actions taken in a process of exposing and resisting hegemonic power structures. The ends of transformational research are not only taken as modes of restorative justice, but are also futuristic, formed in existentialist hope that the world we currently live in could be improved by breaking down power structures that result in oppression.

Defining Transformational Research

The twofold purpose of transformational research (variously referred to as emancipatory, revolutionary, or resistance research) is to change practice for the better while also revising stereotypes, habits of mind, and deeply held meanings that guide people's thinking about social and political issues. Research that is done for transformative purposes is *praxis-based*—that is, it involves a dynamic interplay between reflection and action, between knowing and doing. Its focus is the intertwining of research and practice. Thus, the transformative power of research resides in the potential for creative ideas and social constructions aimed to reform undesirable but common social practices. The essential characteristics of transformational research are described as being *subjective, relational, collaborative, interpretive, and performative*. Each of these distinguishing features is shared with many other qualitative methodologies, but transformational researchers also explicitly intended to advance particular moral and political standpoints.

Types of Transformational Research Methods

Transformational research methods fit within the common framework of qualitative research. The research is largely ethnographic and relies primarily on observations and interviews. However, each of these methods is tweaked and refined to serve the purposes of social transformation. Methods are used flexibly to accommodate the inquiry context and are tailored to meet the dynamics of locally determined participant research communities. No prescribed methods for interviews or observations hold fast across transformational studies, but instead, methods are structured by participant-researchers to best suit the context in which the research occurs. One of the hallmarks of transformative research is that its methods are used as avenues to include multiple representations, diverse voices, dynamic (and sometimes uncomfortable) revelations of culturally entrenched beliefs, assumptions, and stereotypes. It is necessary for the transformative researcher to adapt methods to the particulars of participant communities in order to best serve the ends of multiplicity and diversity. Another notable feature of transformative methods is that researchers make no claim to objectivity in taking up these research approaches—transformative researchers readily acknowledge that the

processes of doing research affect the people being researched.

Interviews

In most examples of transformative research, interviews are interactive, conversational, and dialogic events. All parties to the interview are encouraged to relate their thoughts, feelings, and beliefs about the topics of conversations. Personal narratives and stories about life's experiences are encouraged during conversational exchanges. The interviewer is not a distanced outsider in the interview and he or she is well aware that his or her own contributions to the interview might affect the content of the conversation. Similarly, empathetic understanding is the goal, with the interviewer telling of his or her own beliefs as a way to make connections with the person being interviewed. In most instances, researchers describe the interview process as a democratizing event that serves to give depth and breadth to representations of the voices of individuals in the community being researched.

Interviews in transformative research are sometimes also used to persuade or educate. That is, the act of interviewing may draw the interviewee's attention to particular issues associated with the research topic. An example might be when, in an effort to involve parents of children living in shelters as advocates for their child's rights in school, the researcher asks the parent questions that elicit comments about school equity. In some instances, the interview might become a conversation that is the catalyst for parental activism for children living in shelters. In this way, the interview process can itself be a transformational moment.

Additional interview methods that fit in this framework include cross-interviews in which co-researchers interview each other and instances when members of community groups interview other community members or when community members lead group dialogues.

Observations

Observational objectivity is not generally a goal for researchers working from within transformative paradigms. Thus, there is no attempt by researchers to create a balance between empathy and detachment. What comes into question is the extent to which researchers can actually be members of participant communities

in which research takes place. Many researchers see themselves as community members and may include life histories, descriptions of activities, photographs, and interview dialogues that represent their inclusion in community contexts. They see their role as community member rather than as being that of an inquirer about the community. Community membership varies in transformative research models along a continuum from indigeneity to concerned other. Some researchers address the issue of distance by including multiple participants as researchers of their own lives. Observations of daily living take place in journals and other reflective documentations of everyday experiences. As with interviews, in research that is deliberately designed to transform social practices, opportunities for observational studies are used to create dialogues. The goal is to generate diverse perspectives on what people believe has transpired during any given social event, to develop commentary on the meanings of body language and other physical social cues, and to understand diverse perspectives about the context, physical settings, or place in which the research is based. Observations are undertaken as a way to inspire imagination to embrace equity and social justice, to plan measures to enact imagined differences, and to take actions for the purposes of social change.

Reflections

Compatible methods include reflective practices such as analytical self-expressions, documentation of the researcher's own life history, and creating personal narratives (i.e., autoethnography). Transformational research frequently involves reflective consideration of the researcher's own subjective oppression. Because transformative research involves the researcher's own beliefs and feelings about social issues, it is one of the researcher's tasks to present autobiographical information and include in the research dialogue her or his beliefs, assumptions, and personal ambiguities toward the political and social landscape that contextualizes the inquiry. Taking a self-reflective stance opens the research lens to encompass a broader subjectivity than that of the individual to one that is socially and historically located. An example might be self-reflective feminist inquiry that relates the researcher's life history to the shared experiences of women in a male-dominated social and intellectual tradition. The subject of the research in

this example is the self situated in the context of a virtual, historical reality shaped by social, political, cultural, economic, and gender values that have reified over time.

Yet, transformative research does not rely on the researcher's reflective introspection or personal history as a verification of truth, but instead adopts a relative stance toward truth. Personally held truths are considered in comparison and relation with the personally held truths of other local people. Subjectivist epistemologies denote the collective creation of meanings and understandings by participants and researchers. Thus, truths are not defined in correspondences to individually perceived realities, but are, instead, multiple, ambiguous, paradoxical, contextual, and susceptible to diverse and contradictory interpretations. Meanings are co-created and co-constructed, negotiated dialogically, in part, through the interactions of research participants and researchers. They are simultaneously defined by their ties to history, tradition, mythology, distributions of knowledge, resources, and power; thus, meaning is made relative to context(s). Mystory, herstory, and history become entwined in what are often ambiguous, contradictory, and contextually relevant "truths." Both individual and socially constructed histories and practices influence the research process and its outcomes, but individuals, societies, and their practices are also changed by activations and meanings created while doing research.

Analytical Perspectives

The processes of transformative praxis call for research methods that are compatible with research that is subjective, relational-collaborative, interpretive, and overtly political. Due to the collaborative, interactive processes of transformational research, analyzing data is ongoing and iterative; it requires techniques and attitudes that encourage reflection, dialogue, and imagination. In transformative research models, communities of participants are encouraged to use dialogic approaches to the exchange of perceptions, beliefs, and ideas. The goal for dialogic interplay is not consensus; rather, in most instances, it is the inclusion of multiple, diverse voices of minority participants in the research community. Finally, imaginative thought is a requisite function in answering the question, "Transformation to what?"

Representational Forms

Quality transformative research is evaluated by its diversity of participation, depth of collaboration and other features of community-based inquiry, and by the extent to which it results in transformative praxis that advances equity and social justice. It must move people to reflection and action. It opens the imagination to new possibilities. The results of such research are not always found in traditional research reports and publications in professional journals recognized as being exemplary of “good” work or entrenched in the systems of academic reporting. Its value may be determined by its usefulness to members of participant communities in the research.

Transformative research is contingent to a performance-based social science (e.g., performance ethnography). Its representations show how people experience everyday life and put into practice cultural meanings that shape experiences of injustice, prejudice, and stereotyping. These social performances can take place during the research, through dialogue, community gatherings, and in the creation of cultural artifacts that represent people’s thoughts and feelings toward social systems (e.g., communal artworks that are designed and enacted by research participants). Representations of transformational research lend themselves to multivoiced texts and cultural expressions of thoughts and feelings. As a result, some transformational researchers cross into arts-based research methodologies and utilize drama, dance, stories, poems, and visual art forms in their search for representational forms that are suited to multiple and diverse discourses.

Ethics of Transformational Research Methods

Researchers operating in a transformational mode must ask themselves the following questions: Who chooses the issues of greatest concern is a community? Whose voices are being heard? Are minority voices and diverse factions within a community given space—even when the researcher disagrees with the political and social stance of some groups or individuals? If not, how does one justify excluding some voices while including others? The researcher needs to give great attention to issues like negative freedom and the creation of new forms of oppression that might result because of the research. Basic moral

principles expected in transformative research include intellectual honesty and forthrightness about the researcher’s purposes and assumptions, points of view, and guiding theories; actions taken by the researcher must be responsible and enacted without malice—the researcher must be aware of the impact of research processes and avoid stirring up negative interactions among research participants or other community members. Researchers must take great care in analyzing newly formed power structures; among the many newly formed power structures that researchers are obligated to avoid are paternalistic positionings of the researcher within the community of participants.

Advantages and Challenges of Using Transformational Research Methods

Transformational research demonstrates the unique attribute of being deliberately poised to use inquiry processes to revise both theory and practice. There are immediate results to doing research—it has relevance in communities and to individuals and it does not give way to abstractions that are unconnected to real people and to oppositional social movements. It has potential for emancipation of oppressed individuals and communities and can give rise to positive social change.

In each of its advantages, the researcher might find a potential disadvantage. Because the research is important on a local level, it is rarely easily generalized to larger populations. For many researchers, this means it is difficult to publish and disseminate the results of the research in academic journals and other forums that privilege scientific aggregations of knowledge to the largest possible populations. Because it is moral and political, the research is very demanding for researchers who must give close scrutiny to ethical dilemmas and the political import of the work. Often, the researcher cannot realize the desired results of transformation or emancipation, but he or she may need to settle for cathartic research performances that demonstrate little in the way of policy reformation or changes in social hegemony, and rest with the assurances that many such efforts sustained over time can, indeed, engender social change.

TRANSLATABILITY

All researchers translate concepts from one context to another. However, translatability usually relates to how research findings can be translated across languages. Many researchers do not attempt to question their language base. There is, however, growing interest across a range of disciplines, including anthropology, sociology, sociolinguistics and translation, and interpretation studies, about the extent to which words and concepts can be translated across languages and the best ways of ensuring that meanings are carried across languages in ways that reflects possible differences in views.

Various ways for translating research accounts to ensure validity have been put forward. Some researchers argue for back translation to see if translators agree. Other researchers prefer to use professional translators or argue that community researchers who know the languages involved should be employed as they know the culture. There is controversy about the extent to which these techniques address the issues involved. Many words and concepts have no literal translation. There are many possible words that can be used in a translation. Who is doing the translating has also been shown to be important. For example, a second-generation translator may not use the source language in the same way as someone brought up speaking it. Translating from any language baseline has been shown to involve built-in cultural assumptions as translation constructs boundaries between people like the translator and others who are different. Moreover, there is no one single language community within any language. For example, people may be differentiated according to gender, ethnicity, sexuality, and religion. Both professional interpreters and

community researchers translate from their own perspective and do not represent all language users and all translation positions within a language. Meanings are also not tied to and cannot be attributed to particular languages in any straightforward way. Some degree of interpretation in the wide sense of the term is needed in representing views across languages.

For reasons discussed above, researchers across disciplines are increasingly arguing that there is no one single correct translation possible. They have suggested ways of opening up texts so that the reader can see how the translation has been done and the dilemmas the translator faced in doing them. For example, the original language may be provided, concepts pulled out and the context described, arguments provided for a particular choice of word, or the context of a word that appears to have a straightforward translation discussed to show possibly different uses across languages. The perspective of the translator is important and debated using concepts such as Liz Stanley's intellectual auto/biography, which is used to define research findings as a product of the researcher, the research participant, and the context.

TRANSPARENCY

The notion of transparency is an overarching concern for establishing the quality of qualitative research. At its most basic, transparency is the benchmark for writing up research and the presentation and dissemination of findings; that is, the need to be explicit, clear,

and open about the methods and procedures used. As such, transparency is recognized as a basic requirement of all qualitative research. However, in a broader sense, it is of critical importance for every stage of the research process.

Transparency is often simply taken for granted. It is sometimes referred to in terms of clarity and visibility, or it is implied in discussions of rigor, validity, credibility, confirmability, and so on. However, in qualitative inquiry the need for transparency has become most urgent. The field is rapidly expanding and employs a wide range of quite different methods that in turn are evolving and being refined, sometimes in several different directions at once. Collecting data in naturalistic settings requires compromises and adjustments to procedures. The procedures of data management and data interpretation need to be as explicit as possible. Transparency is the key.

A defining feature of all scientific research, whether qualitative or quantitative, is that the claims of an addition to knowledge are subjected to an exhaustive critical evaluation. This evaluation is a two-stage process: the first involving the reflexivity of the researcher, and the second, involving the dissemination to the target audience. Transparency lays the groundwork for this critical evaluation.

Qualitative inquiry requires a thorough critical self-exploration of the researcher's assumptions, procedures, presuppositions, decisions, self-interests, and so on. Researchers are strongly encouraged to record and explore their self-observations in their research diaries. It is important to stress that reflexivity is applied to the entire research process and is not merely a focus on the potential sources of bias. In planning, designing, and carrying out research, there must be a conscious examination of paradigm assumptions, research strategies, selection of participants, and decisions made in collecting and interpreting the data, pointing to the fact that the researcher has a participatory role in any inquiry. Transparency and reflexivity, therefore, go hand in hand since without transparency, reflexivity is undermined; at the same time, reflexivity obviously promotes transparency.

In addition, transparency is an overriding concern in laying the groundwork for the critical evaluation. Procedures of inquiry, data collection, and data analysis must be clear enough for others to replicate, and therefore must be transparent. Notice that the emphasis here is on the procedures being replicable and not the findings. This difference is an important one between qualitative and quantitative inquiry.

The basic question in writing up research is, "Have I described with sufficient transparency (i.e., clarity and thoroughness) (a) the assumptions and methods used in designing and carrying out my research, (b) the methods used in analyzing my data, and (c) the ways in which my findings and conclusions follow from the data?" This question may seem to be straightforward enough, but the litmus test lies in researchers not only being clear to others about what they have done and what they have found but also being clear to themselves at every step and in every stage about what it is that they are doing and about the assumptions that they are making.

With respect to critical evaluation of the findings and conclusions of a qualitative study, the issues of credibility, confirmability, dependability and transferability, and so on need to be discussed. Again, it is transparency that is the key. The credibility of a qualitative inquiry lies in the transparency of its assumptions, biases, choices, decisions, procedures, and justifications. The confirmability of an inquiry crucially relies on the transparency of the procedures involved. The dependability and transferability of the findings can hardly be considered viable if transparency is not appropriately established.

In terms of good practice, the pioneering development of grounded theory by Barney Glaser and Anselm Strauss, and its subsequent elaborations, could be held up as an excellent example of transparency in action. Other examples might include Jane Ritchie's development of framework, a tool with a high level of transparency used for data management; there is also the situated methodological approach developed by Clive Seale and colleagues in which they recognize, among their list of 23 features of good qualitative research, the researcher's need to be transparent and reflexive about conduct, theoretical perspective, and values.

In addition, critical issues must be raised with respect to how new inquiry methods are to be presented and how existing methods are to be refined and made explicit. For example, recently David Hiles and Ivo Čermák have proposed a model of narrative research called narrative oriented inquiry (NOI). This model explicitly strives toward transparency in both the collection and analysis of narrative data. The critical issue in the development of NOI, and in establishing its rigor, has been in making its underlying assumptions and procedures transparent.

Another issue that should be raised is with respect to the use of computers for qualitative data analysis. There

should be a basic requirement that software is published with the clearest exposition of its data-handling procedures and theoretical assumptions. Joy Bringer, Lynne Halley Johnston, and Celia H. Brackenridge have argued that transparency in the use of software is necessary for accountability and is crucial for establishing congruence between methodology, data analysis, and findings.

Transparency also raises critical issues with respect to how qualitative methods are being taught. Textbooks must be written with an eye for the details in methodology that the novice researcher will need. In addition, transparency can make an important contribution to the ethical considerations of qualitative research; that is, with respect to the role that values play in human inquiry, especially in the examination of the obligations and requirements placed upon participants.

In summary, transparency is a term that is now receiving much more attention within qualitative inquiry. As the field expands, the need for complete transparency of paradigm assumptions, procedures, and data analysis, as well as in research dissemination, becomes ever more pressing.

data analysis. The basic idea underpinning the concept of triangulation is that the phenomena under study can be understood best when approached with a variety or a combination of research methods. Triangulation is most commonly used in data collection and analysis techniques, but it also applies to sources of data. It can also be a rationale for multiple investigators in team research. Questions that commonly arise in discussions of triangulation tend to address one of two concerns: the issues of using triangulation as a test of validity of research findings and the practical difficulties of using more than one method to study the same phenomenon.

The concept of triangulation is borrowed from navigational and land surveying techniques that determine a single point in space with the convergence of measurements taken from two other distinct points. The multimethod approach is seen to be a research strategy that can reduce biases or deficiencies caused by using only method of inquiry. Initially, in the 1950s and 1960s, triangulation was put forward as a way to increase the measures of validity or to strengthen the credibility of research findings by comparing the results of different approaches to a single unit of study. In other words, triangulation could measure what was thought to be the same thing by using different methods of investigation. However, the use of triangulation of methods to minimize measurement biases has been critiqued over the years by qualitative researchers for corresponding too closely to positivistic notions of reliability and validity. It is claimed that different approaches can measure different aspects of a research problem, but they also yield different kinds of data.

In qualitative inquiry, researchers tend to use triangulation as a strategy that allows them to identify, explore, and understand different dimensions of the units of study, thereby strengthening their findings and enriching their interpretations. However, there are differences among researchers and commentators on the nature, degree, and utility of comparison of findings garnered from different approaches.

Norman K. Denzin's widely cited work on the theoretical underpinnings and implications of combined methods in sociological qualitative research has popularized the definition of triangulation as a combination of methods used to study the interrelated phenomena from multiple and different angles or perspectives. His formulation of triangulation is still widely used by qualitative researchers and is comprised of four basic

TRIANGULATION

Triangulation in qualitative research has come to mean a multimethod approach to data collection and

types: triangulation of methods of data collection, investigator triangulation, theory triangulation (including methodological variations that account for between-method and within-method approaches), and triangulation of data sources.

Triangulation of Methods

When designing and conducting research, qualitative investigators frequently combine methods such as interviewing, surveys, and observation across variable times and in different places in order to collect data about their research phenomena from multiple perspectives and in different contexts. Researchers may also vary their methods within each type of approach; for example, in order to gain a more complete picture of a participant perspective, the researcher may use a combination of conversational interviewing and structured interview questions, techniques that would elicit different but complementary data. Another way to provide multiple perspectives is to use a combination of sampling methods to collect data from different kinds of informants or from the same people but at different times and in different places. The findings of quantitative methods of data collection may also be triangulated with the results of qualitative methods. For example, statistical measures may be held against the hermeneutic analysis of conversational interviews in order to provide a more complete picture of the research problem.

Investigator Triangulation

Another way that researchers attempt to increase the validity and trustworthiness of their findings is by deploying more than one investigator in the collection and analysis of data. This technique allows for additional insights in the process of making sense of the data as it brings different perspectives and different epistemological assumptions that may inform the research results. Several commentators on investigator triangulation caution against the use of untrained students and unmotivated research assistants (sometimes called the “hired hands”) who may end up damaging the trustworthiness of any research findings through lack of engagement and accountability. It is generally recommended that co-investigators be full research partners through all stages of the research project, not only to guard against the hired-hand syndrome, but also to allow for the full play of competing

theories and to provide an ongoing opportunity to deal with researcher biases and conflicts.

Respondent or member validation is a related cross-checking strategy that does not usually extend as far as making people co-investigators, but does invite research participants and other stakeholders in the research project to comment on research findings. Respondents may corroborate or refute the conclusions reached by the investigators by providing alternative perspectives.

Theory Triangulation

Examining the research findings using different theoretical lenses can also aid researchers in overcoming their own personal biases or ideological blinders. Different facets of the research problem can be explored by examining research results using analytical frameworks related to different theories. This kind of triangulation does not normally allow for any kind of integration of results and would not be used to make claims of increased validity: this method of triangulation suggests that different theoretical approaches will undermine the credibility of competing research findings. However, exploring research data using a different theoretical lens can be a particularly useful way to examine dissonant or anomalous data. Theory triangulation can enable a deeper understanding of the research as investigators can explore different ways to make sense of the data. Tensions that might arise between theoretical explanations of the same data may yield new insights into the aspects of the research problem. However, many qualitative researchers disagree with the notion that researchers can stand outside of the epistemological perspectives that they bring to any project, claiming that it is not logical to compare analyses of data that are informed by different theoretical concepts.

Triangulation of Data Sources

Qualitative researchers may increase the credibility of their research findings by drawing from evidence taken from a variety of data sources. For example, to name just a few common sources of data, researchers may gather evidence from interviews, participant observation, written documents, archival and historical documents, public records, personal papers, and photographs. Each type of source of data will yield different evidence that in turns provides different insights regarding the phenomena under study.

Issues in Research

Pragmatic issues of research design must be considered when using methods of triangulation. Triangulation can be impractical for some qualitative research projects due to the inflation of research costs related to multiple methods of inquiry and team investigations. Researchers using strategies of triangulation need increased amounts of time to collect and analyze data. The amount of data collected can pose its own problems as triangulation can result in vast amounts of evidence.

Although there is general consensus among qualitative research commentators that triangulation enables researchers to deepen their understanding of either a single phenomena or of a contextual set of interrelated phenomena, there is some disagreement as to the epistemological foundations of such a research strategy. For example, some commentators suggest that one research method comes with its own assumptions about reality, about what is knowable, and about what counts as evidence such that it is incommensurate with another research method that carries its own epistemological concepts and array of ontological evidence.

There also continues to be debate among qualitative researchers regarding the degree to which triangulation strategies allow for comparison and integration of evidence from multiple methods of data collection and multiple analytical perspectives. Furthermore, the tension between notions of verification and the enrichment of understanding is not resolved; qualitative researchers continue to use methods of triangulation to render a fuller picture of research phenomena as well as to verify and validate the consistency and integrity of research findings.

TRUST

Although trust has a commonsense familiarity, defining trust has been a central sociological concern, with different definitions often being intimately tied to authors' wider theoretical projects. Nonetheless, there are some common attributes of trust and several familiar axes in thinking about the dynamics of social trust. Trust is a form of faith in the outcome of another's actions or of institutional responsibilities. It exists in a context of imperfect knowledge and future contingency, and, as such, it is a form of belief despite uncertainty. In modern societies trust has been conceived as a mechanism that helps reduce complexity and enhance communications. It is also seen as a substitute for more formal methods of regulation such as contract. Examined as either the property of individuals or as a social mechanism, trust is typically conceptualized in terms of its positive social consequences, which are often seen as monumental, so much so that a stable foundation of trust has been proposed as a precondition for stable societies.

The first generation of sociologists, including Émile Durkheim and Herbert Spencer, analyzed changes in the nature of trust that they believed were characteristic of the transformation from premodern to modern societies. Today, active sociological research programs examine a series of questions pertaining to trust. These include inquiries into the interpersonal dynamics of trust, the cultural or national differences in trusting relationships, and the kinds of trust that enhance corporate or government performance. Studies of social values and political structures frequently examine the question of whom we trust. Given that individuals cannot independently verify the grounds of most knowledge, trust is also recognized as being a vital epistemological resource that precludes the potentially paralyzing need to personally investigate the veracity of all truth claims.

Other disciplines have also demonstrated a long-standing interest in trust, including political science's focus on the role of trust in democratic governance, psychology's investigations of trust as a personality trait, and economics' focus on trust as an exchange mechanism. Issues of trust are particularly germane to qualitative forms of inquiry as researchers must often establish intimate bonds with research participants, many of whom do not benefit in any immediate way from participating in research. Hence, dynamics of both interpersonal and institutional trust are operational in terms of recruiting and maintaining research participants and also in terms of keeping faith with such individuals. Occasionally, this places a heavy obligation on researchers to understand the expectations of research participants so as to not undermine their trust in the researcher and the research process.

A defining characteristic of trust is that it can be broken. Trust is fragile and is easily undermined through deceit. Considerable sociological research examines structures that arise in a context of reduced trust, including policing, surveillance, and credentialization. The fragility of trust has also led to pronouncements that contemporary societies are experiencing a crisis of trust, attributed to an ostensible decline in the long-standing bases for social cooperation, consensus, and solidarity. Such talk of a crisis can also be seen as symptomatic of a society that is undergoing changes in the dynamics of trust, as individuals are required more than ever before to place their trust in major institutions.

TRUSTWORTHINESS

In qualitative research, trustworthiness has become an important concept because it allows researchers to

describe the virtues of qualitative terms outside of the parameters that are typically applied in quantitative research. Hence, the concepts of generalizability, internal validity, reliability, and objectivity are reconsidered in qualitative terms. These alternative terms include transferability, credibility, dependability, and confirmability. In essence, trustworthiness can be thought of as the ways in which qualitative researchers ensure that transferability, credibility, dependability, and confirmability are evident in their research. Moving away from the quantitatively oriented terms allows qualitative researchers the freedom to describe their research in ways that highlight the overall rigor of qualitative research without trying to force it into the quantitative model.

To understand the differences between these quantitative and qualitative terms, it is helpful to compare the parallel concepts. To start, transferability and generalizability can be compared. Although generalizability refers to situations where research findings can be applied across the widest possible contexts, transferability reflects the need to be aware of and to describe the scope of one's qualitative study so that its applicability to different contexts (broad or narrow) can be readily discerned. In this way, a study is not deemed unworthy if it cannot be applied to broader contexts; instead, a study's worthiness is determined by how well others can determine (i.e., through a paper trail) to which alternative contexts the findings might be applied.

Credibility and internal validity are also considered to be parallel concepts. A study possesses internal validity if the researchers have successfully measured what they sought to measure. In contrast, a credible study is one where the researchers have accurately and richly described the phenomenon in question. Here, instead of ensuring that one has measured what one set out to measure, one is making sure that they have accurately represented the data.

The next pair to be considered is objectivity and confirmability. In an objective study, the data is considered to be unbiased. Confirmability, on the other hand, reflects the need to ensure that the interpretations and findings match the data. That is, no claims are made that cannot be supported by the data.

Finally, reliability-reproducibility and dependability can also be compared. Findings are considered to be reproducible if they can be replicated exactly when using the same context and procedure. Achieving reproducibility or reliability in this way

can be challenging for the qualitative researcher who studies the constantly changing social world. As a result, dependability becomes a more realistic notion in the qualitative context. Here, the researcher lays out his or her procedure and research instruments in such a way that others can attempt to collect data in similar conditions. The idea here is that if these similar conditions are applied, a similar explanation for the phenomenon should be found.

In sum, trustworthiness provides qualitative researchers with a set of tools by which they can illustrate the worth of their project outside the confines of the often ill-fitting quantitative parameters.

TRUTH

Truth may be defined quite simply as undistorted knowledge. Straightforward as that definition may be, there are seemingly endless problems associated with identifying truth in empirical social environments. Positivists maintain that truth must be defined relative to empirically observable criteria. In response, power-elite theorists have asserted that due to the interventions of power brokers, observable reference points must be viewed with suspicion. Indeed, postmodernists have concluded that due to the pervasive influences of cultural power coupled with the inevitable shortcomings of human epistemological systems, the pursuit of universal truth should be aborted altogether. In spite of this pessimistic appraisal, Timothy McGettigan has advanced a definition of truth that, while acknowledging the postmodern critique, reestablishes the importance of empirical observation in the process of redefining reality and thereby constructs an epistemology that is founded upon a universal definition of truth.

Seeing Is (Dis)Believing

Mathematicians have their axioms. However, outside the conceptually precise domain of mathematics it is somewhat more difficult to locate truth. In many scientific fields, empirical observation serves as a means to generate and evaluate knowledge claims. For example, zoologists observe lions and zebras on the African savanna and thereby establish (among other things) the truth of their predator–prey relationship. Although Elton Mayo illustrated long ago in his Hawthorne studies that truth in observation has its limits, nevertheless, the relative truthfulness of various knowledge claims is often equated with the degree to which the phenomena in question are observable. For example, dark matter remained a purely theoretical phenomenon until astronomers identified observable markers of its existence. In the social sciences, however, observation has not been universally endorsed as a valid means of establishing truth.

The insistence upon preserving observation as a basis for articulating truth claims (and as a foundation for “good” science) is closely associated with a school of thought known as *positivism*. Generally speaking, positivism may be understood as a philosophy of science that advocates a reliance on empirical observation to assess the plausibility of theory. Although positivism has been the subject of extensive criticism, it remains an influential, if not the dominant, paradigm in the social sciences.

Relying upon observation as a means to evaluate knowledge claims has a strong intuitive appeal. Human judgment is profoundly influenced by sensory inputs: people tend to invest faith in those things that we can see, smell, hear, taste, or touch, whereas phenomena that defy observation (e.g., the Abominable Snowman) tend to tax credulity. Nevertheless, C. Wright Mills and other elite-power theorists have long maintained that observable social phenomena are not reliable measures of truth. Indeed, elite theorists assert that power brokers often deliberately distort observable social phenomena for the purposes of deceiving casual observers. For example, Enron executives projected an illusion of prosperity that, until 2001, most observers accepted as truthful. Therefore, according to this perspective, regardless of what qualitative researchers may encounter with their senses, observable “truths” should be regarded as potentially cunning fabrications designed by the powerful to deflect attention

from their nefarious undertakings. As a result, elite theorists argue that those who maintain strict faith in the observable world cannot avoid being dupes of the powerful; for example, Enron made a killing as long as investors remained sold on the company's dissimulations. To get beyond elite-generated distortions, Mills argued, observers need to employ a special form of insight—something he referred to as a *sociological imagination*. According to Mills, a sociological imagination is a conceptual framework through which observers can ascertain the impact of invisible social forces on the landscape empirical social reality. Without a sociological imagination, Mills insisted, observers are certain to become lost in a “welter of confusion.”

Rejecting Universality

Further complicating matters, radical power theorists have asserted that while elite power brokers may distort observable reality, an even more insidious form of cultural power tends to subvert observers' cognition. As characterized by Stephen Lukes, the radical face of power creates a dislocation between an individual's real and subjective interests—and induces what Marx referred to as a false consciousness. Essentially, this perspective proposes that a subtle but extremely persuasive form of power cultivates what Pierre Bourdieu refers to as “tastes” in the minds of individual social actors. Such tastes tend to predispose individuals to pursue objectives that appear to be born of individual desire, but that are, in fact, inculcated by prevailing sociocultural influences.

For example, the cultural context of the early 21st-century United States tends to inscribe its citizens with tastes for private homes, automobiles, computers, credit cards, cell phones, and fast food. Generally, Americans do not view their appetite for such cultural products as the work of social coercion. However, if Americans were to be situated in a markedly different cultural context, 16th-century Inuit culture for instance, then their desires would incline in a much different direction; that is, toward a passion for warm fur-lined clothing, well-constructed igloos, dogsleds, kayaks, and raw seafood. In the context of preindustrial Inuit culture, it would be preposterous to lust after Big Macs because the extant cultural system would exert neither the impetus to seek nor include the means to fabricate such delicacies. Thus, the third face of power functions as a remarkably effective

social glue because of the way that it impels individuals to apply themselves tenaciously to the pursuit of those things that existing cultural systems are designed to provide. Conveniently, those selfsame forces facilitate the reproduction of the cultural context within which individuals are embedded: our hunger for automobiles effectively sustains the viability of numerous global industries that are bent on catering to consumer desires; for example, petroleum, steel, shipping, and so on.

Consequently, as a result of the pervasive influences of radical power, many social theorists have argued that individuals are incapable of observing truth. That is, if all observable reference points and every individual's cognitive framework has been manipulated by cultural power, then any truths an observer might identify must be either partly or wholly the product of manipulative social power. For example, Michel Foucault asserted that in every circumstance, knowledge and truth are instruments of power. From this perspective, truth is a mechanism that is employed to achieve the positive goals of political regimes: truth encourages those it influences to “do the right thing”—that is, conform to the will of established authority.

It was for reasons similar to these that postmodernists asserted there was no longer any virtue in championing universal truth. Postmodernists pointed out that all knowledge is constructed within bounded sociocultural systems, and whether touted as truth or not, postmodernists emphasized that no form of knowledge could ever be more universal than the social system in which it was constructed. Indeed, not only does knowledge tote the baggage of the social context in which it was generated, but it also imposes ideological coercion upon those who are exposed to it. Proceeding from those assumptions, postmodernists concluded that the modern, scientific hegemony of truth was nothing more than a duplicitous justification for Western imperialistic abuse. According to this perspective, scientists (being more qualified to assess and represent truths) unduly elide the experience of their subjects by claiming the right to speak on their behalf. The unique concerns of research subjects tend to enter learned dialogues only in the form of parenthetical statements; that is, subjects are generally perceived as being unqualified to register valid truths in sophisticated scientific dialogues.

As an antidote, postmodernists decided to jettison the notion of universal truth in favor of embracing

individual-level truths. This diminution of truth standards remedies what postmodernists identify as a preeminent shortcoming of modernist science: throughout the modern era, disparate voices have been elided from the pantheon of “valid” knowledge due to the fact that modernist truth standards have been excessively coercive and exclusionary. Postmodernists rectified this problem by asserting that all knowledge is equally valid.

Such an inclusive orientation to the philosophy of knowledge accomplishes a number of important goals for postmodernists. First, by elevating the status of common knowledge, postmodernists believed they could offset the destructive influences of Western-model social change. Secondly, postmodernists have argued that, as a consequence of eliminating the pre-eminence of truth standards, learned dialogues could become populated by a greater diversity of voices. In this scenario, research subjects are afforded more opportunities to speak for and thus represent themselves. Consequently, by creating an environment wherein common folk could register their own individual-level truths, one could argue that the rotten core of modernity was more likely to be exposed.

Indeed, Joe Kincheloe and Peter McLaren have proposed that critical or resistance postmodernists, while recognizing the dangers that are inherent in the development of universal knowledge claims, still maintain that the pursuit of some form of truth must remain central to the production of knowledge: both to make nonrelative knowledge claims as well as to effect coherent challenges to existing structures of power that constrain knowledge. Nevertheless, critical postmodernists still find themselves in a problematic philosophical relationship vis-à-vis the concept of truth.

That is, modernist researchers developed objective scientific practices in order to minimize the degree to which researchers’ subjective biases would influence the substance of scientific inquiry. Postmodern researchers have criticized traditional research practices for failing to grapple with invisible ideological influences that are imposed when researchers adopt an objectivist orientation to the research process. Consequently, critical postmodernists have asserted that it is essential to actively challenge the substance of existing structures of power in order to identify, dismantle, and transcend their invisible influences in the research process. However, without being able to rely on a universal definition of truth, it is not possible for postmodernist researchers to be confident that

their efforts to challenge existing structural power relationships are indeed founded in a project that serves better or different purposes than the imperfect modernist strategies they criticize.

Redefining Reality

The crucial flaw in the postmodern strategy has been its rejection of universal truth criteria. Fortunately, the postmodernist disavowal of truth is the product of a remediable misunderstanding. Once again, postmodernists abjure universal truth (in agreement with Foucault) because of their contention that all knowledge is manipulated by power. However, this viewpoint presumes that power can only influence knowledge negatively: distorting and/or corrupting knowledge and deflecting it from an evocation of undistorted truth. Although McGettigan agrees that the effects of power always modify knowledge, he does not believe that power must always corrupt truth. McGettigan’s basis for this claim derives from a theoretical formulation through which he asserts that individuals are capable of generating truth by redefining reality.

To be brief, redefining reality is a process through which individuals can challenge and modify misleading knowledge through a combination of astute observation and a creative capacity for ingenious, innovative cognition (i.e., human agency). As such, via the process of redefining reality, individuals can challenge and negate some of the influences that the third face of power exercises over their consciousness; redefining reality is a means by which individuals can alter the existing landscape of social reality by creating spaces within which they can think and act with a degree of independence from individual, organizational, and cultural social constraints.

Herein lies the crucial distinction between redefining reality and postmodern criticism. Without a nascent, formative definition of truth, innovative critiques of science (postmodern and others) are incapable of coalescing into orderly and constructive epistemologies. On the other hand, redefining reality implies that challenging ideological constraints on knowledge represents only the first step in the process of generating moments of truth. It is only by mastering an understanding of the limitations of established bodies of knowledge that it becomes possible for individuals to develop a platform upon which to fruitfully transcend the shortcomings of established knowledge frameworks.

This process is capably illustrated in the context of a field research project that McGettigan conducted on the Green Tortoise, a neohippie adventure travel company. McGettigan's initial orientation to the Green Tortoise was rooted in an uncritical acceptance of standard research practices. However, an unanticipated emergency altered his perspective profoundly. During a crossing of the Rio Grande, a male Tortoise passenger allegedly pitched a Mexican rowboat operator and a female passenger into the river. Although the boat operator made it to shore, the passenger disappeared downstream. When McGettigan dove into the river to render assistance, he happened to lose his glasses. Thus, McGettigan's optical vision became blurred for the balance of the journey. However, his leap into the river also unexpectedly enhanced his perspective.

In choosing to intervene as a real participant in the field environment, McGettigan transgressed a number of barriers that he had erected for the purposes of doing good science. Ironically, by unintentionally contravening the boundaries that McGettigan had assumed would preserve the validity of his research, his newly uncorrected vision generated redefined insights of utmost lucidity about the irresistible charm of the Green Tortoise.

Thus, the process of redefining reality often begins when agents make unanticipated observations (e.g., as a good scientist maintaining objectivity is a virtue, but it can also be a liability—especially in situations where field subjects encounter an urgent need for help). Individuals may follow up such observations by issuing a challenge to established ideological controls (i.e., if being a good scientist means that I must stand idly by while the people under observation come to harm, then I must transgress the constraints of good science). In the process of attempting to make sense of such difficulties, individuals encounter opportunities to deconstruct the conceptual frameworks that limit their ability to comprehend puzzling phenomena (i.e., as a human being, my foremost responsibility is to render assistance to those who are in need—even if doing so requires intentional, researcher-inspired corruption of the formerly sacrosanct field-site). As individuals reevaluate their beliefs with respect to their inability to comprehend anomalies, the features of their epistemological systems that do not hold up under scrutiny come under substantial erosive pressure. Indeed, if individuals are persistent enough, they may reach a point at which the critical mass of their

contemplations overwhelms the remaining shackles of their former beliefs, and thus they may experience a moment of truth (e.g., privileging subjective human values actually constitutes a basis for better science than the objectivist formula for good science that artificially suppresses such concerns).

A moment of truth is an experience wherein individuals are transported from an inadequate definition of reality to a more satisfactory version. These experiences may be considered relatively truthful moments due to the fact that they are generated through a process that involves the active negation of ideological distortions over a particular definition of reality. This is not to say that the redefined system of beliefs at which one arrives after experiencing a moment of truth is, therefore, truth—far from it. In keeping with the assertions of radical power theorists, McGettigan maintains that all established belief systems exert their own forms of ideological power upon the architecture of knowledge. Thus, to experience a moment of truth does not transport one to an ideal realm wherein truth reigns unchallenged—as opposed to the assertions of Jürgen Habermas in his ideal speech scenario. Instead, McGettigan merely suggests that the process of redefining reality permits individuals to negate some of the influences of radical power and thereby negotiate with the pervasive, consciousness-distorting influences of radical power sufficiently to establish a location for agency in a world of multidimensional social coercion.

Truth and Agency

The fact that agency may be established in a world of social coercion makes it possible to establish and defend a “socially situated” definition of truth. The version of evolutionary truth that McGettigan advocates asserts that no single person will ever produce an unequivocally final representation of truth. Instead, humans can access narrow, momentary glimpses of truth through the process of transitioning from outmoded to improved definitions of reality.

According to the theoretical formulation upon which the redefinition of reality process is based, it remains up to each observer to evaluate the veracity of knowledge claims. For example, even the most widely accepted scientific theories are, and should be, subjected to intense criticism. An environment that invites criticism of even the most popular theories—whether or not people approve of dissenters' viewpoints—is

crucial to the process of progressively and legitimately redefining reality. In other words, dissent is an acid test through which to interrogate good ideas and obliterate bad ones. Once again, no theory produced by humankind either has, or ever will, capture the entire truth. Indeed, precisely because of that limitation, the notion of redefined truth is an essential means through which to emphasize that even relatively truthful ideas often can and should be supplanted by better ideas.

Indeed, given the foregoing discussion about the limitations of culture-bound knowledge systems, McGettigan suggests that it will never be possible for humans to generate absolute truths. Instead, what McGettigan proposes is that eternally provisional, but increasingly proximate paradigms emerge from a negotiation process among

1. ingenious, redefining human minds;
2. observable (and, in particular, anomalous) empirical phenomena; and
3. established epistemological systems.

Redefining Good Science

Thus, the capacity to redefine reality implies that it is possible for social scientists in general, and qualitative researchers in particular, to identify and analyze exercises of the third face of power from within the coercive context of empirical social reality. Indeed, far from dissolving practical reality, as Habermas argues, the capacity for social actors to redefine reality implies that good scientists can only obtain a thorough understanding of sociological subject matter by acting as agents who interrogate the coercive context of social reality from within. One must directly confront the invisible influences of social power in order to effectively grasp the complexities of the simultaneously contradictory and complementary relationships between agents and the social reality they inhabit.

The notion of redefinable reality posits that there is a universe “out there” that exists independent of human cognition. As such, McGettigan argues that universal truth does exist, but such truth is not contained within extant scientific theories. Rather, the truth extends infinitely into the unlocked mysteries of the evolving social and physical universe. Truth is an intrinsic, inseparable feature of phenomena as they exist independent of human perception. Lies and distortions come into existence via the vast human

capacity for ignorance: humans view the empirical world through awed and flawed psyches. Thus, realization of the ultimate, universal truth is only possible through a process of transitioning from inadequate to improved—but never perfect—descriptions of the empirical world. Although admirable in many ways, people’s grasp of infinite mysteries remains woefully limited. Nevertheless, the process of redefining reality supplies the necessary cognitive mechanism—that is, moments of truth—through which to take gradual but confident steps toward a broader understanding of the truths that influence the empirical world—and unless I am mistaken, that has always has been (and always should be) the primary objective of good science.

TYPOLOGICAL ANALYSIS

Typological analysis is a strategy for descriptive qualitative (or quantitative) data analysis whose goal is the development of a set of related but distinct categories within a phenomenon that discriminate across the phenomenon. Typologies are characterized by categorization, but not by hierarchical arrangement; the categories in a typology are related to one another, not subsidiary to one another. Typologies are common in the human sciences and are often used to distinguish among behaviors such as parenting styles or learning styles. In qualitative research, typological analysis requires four steps. First, before data collection

begins, the investigator identifies some organizing framework for typology development. The framework may be structured as a continuum, with endpoints such as doing well or doing poorly. Next, once there are data in hand, the investigator identifies the important sources of commonality and variation that occur in the data set. Third, the investigator looks within those sources of commonality and variation for patterns of similarity and difference. Finally, those patterns of similarity and difference are reconstructed into ideal types or model cases.

Continua used for typology development reflect disciplinary priorities: education researchers may be interested in school success; nurse researchers may be interested in kinds of illness-management behaviors. The continuum and the research question provide criteria for evaluating the importance of sources of commonality and variation. The investigator identifies aspects of a phenomenon that are important across all cases in the sample and are also important to the phenomenon as a whole; for example, in a study of persons with cerebral palsy, all participants may describe getting help with personal care, leading to the development of the theme personal care use. Although major themes may be inductively derived from the data, they are often identified as part of the conceptual model or research question and incorporated into data collection, especially if semi-structured interviews are used. In the example above, participants talking about personal care use may describe differences in the kind of help they receive, in the quality of help they receive, and in their response to the need for help with personal care activities. Each of

these subthemes can be subdivided into categories; for example, quality of help could include good help, inconsistent help, harmful help, or no help at all. Whether the theme derives from the research question, a conceptual model, or a comment from a participant, its legitimacy for use in typological analysis depends on its presence in some form across all cases and on its relevance to the research question.

The development of ideal types or model cases is the last step in typology development. In order to be useful, a typology must identify the confluence of categories that distinguish one type or style from another and present these confluences in ways that are easily recognizable. Typological analysts often present their findings as a series of case examples.

U

UNDERSTANDING

Understanding is comprehending an entity; achieving a grasp of the essence of another or of an experience; empathizing or sympathizing with another individual, group, or culture; or knowing what something is about or what something is like. Understanding is predetermined by a belief that experience is embodied with meaning, significance, and characteristics, that there is something to be understood.

The act of understanding allows us to perceive, distinguish, and make sense of the nature of being-in-world. It also encourages us to know the consequences of things and of actions and reactions to varying entities. The more one understands something, the greater one's awareness becomes of the embeddedness, the implied order, and the interconnectedness of human phenomena and experience. Through understanding, we come to discern patterns of language, sounds, forms, symbols, behavior, action and reactions, themes as characteristics, and the essence intrinsic to individuals and their experience.

Within the realm of qualitative research, unlike the natural science approach, understanding an entity makes no claims of generalizability and instead focuses on the subjective nature of the particular. Understanding from the qualitative perspective is at first paradoxical, as a researcher is asked to suspend his or her prior understanding of behavior or experience, sometimes called bracketing or unknowing. From the perspective of qualitative research the very characteristics of understanding need to be seen for how they might interfere with the research goal, which is in some form to understand. Some of these characteristics that could influence

clarity come from the realization that when one attempts to understand something one already has presuppositions, prejudices, biases, and his or her own experiences and perceptions, existing traditions, history culture, and constructions of reality. Researchers are not blank slates. They are representatives of their own understandings.

Understanding, within the qualitative research paradigm, is a project of discovery with the potential of emancipation from the distorting aspects of prejudices, bias, presuppositions, and traditions. This process of understanding phenomena is very powerful and requires self-knowledge, introspection, and circumspection. Presuppositions, like perceptions, are critical whether one is the researcher or the participant because individuals see these points of view as truth.

Individuals understand the world through constructing it with their own values, beliefs, and attitudes originating from the context and contingencies of their lives. There is a prejudgment to understanding of an entity based on many things, among them the historical, experiential moment in time. So researchers have already presupposed when they seek to understand.

The understanding of individuals, groups, cultures, and experience that originates from contingencies of a different temporal, historical, and cultural context in which individuals no longer reside, nor are a part of, often results in finite boundaries, bereft of meaning, and essentially limited in usefulness. Such acontextual understanding can contribute to poor professional practice, injustice, inequality, oppression, and much misunderstanding in the temporal moment.

Suspending one's understandings of phenomena to the extent possible allows one to engage in an authentic encounter open to discovery and different possibilities

and to engage in the truth of another's understanding. The various interpretations of reality in a very multi-storied world, however, are essential to understand if social and political policies, professional practices, and the emergence of different theories and approaches are to be free of bias and prejudice, appropriate to the individual or group, and effective and successful.

UNOBTRUSIVE RESEARCH

In their book *Unobtrusive Measures*, Eugene Webb, Donald Campbell, Richard Schwartz, and Lee Sechrest noted that each research method has its own weakness or bias. To counterbalance the weakness of one method, they suggested that researchers use multiple methods (referred to in the literature as methods triangulation) to obtain a more accurate or complete picture of the entity under investigation. One of these methods is unobtrusive research, which can be defined as methods that involve no direct or overt contact with the study participants. Although unobtrusive measures also have their own unique weaknesses, Webb et al. suggested their use to complement data collected through other methods.

Types of Unobtrusive Research

Unobtrusive research methods evoke thoughts of historical research or of observations in which the researcher can play the role of a complete observer. However, there is much more to this type of research

than the obvious. In the literature, attempts have been made to categorize unobtrusive research methods. Webb et al. discussed erosion and accretion measures. In the former category are things that demonstrate wear (e.g., worn pages in a book), while the latter category focuses on the build up of things (e.g., the build up of garbage or accumulation of books in a personal library). Another way is to look at these methods through print and nonprint categories. This entry provides a brief description of some of the methods subsumed under this broad categorization of unobtrusive research and the resources used. The method and the resources used by the researcher depend on the purpose of the research project, the availability of the items, and on her or his training, imagination, and creative spirit. Data analysis for unobtrusive research includes content, thematic, or semiotic analysis. For a discussion of these analytic methods, readers are advised to consult other entries in this text, as well as other authoritative sources.

Print Materials

The examination of print material falls under the rubric of unobtrusive research because there is usually no direct contact with the original writer. Researchers, such as historians, use current as well as archival documents, such as diaries, letters, newspapers, historical pamphlets, broadsheets, government documents, and census data, to name a few. Tombstones provide a wealth of information on family histories, wars, immigration, health, and the justice system. Graffiti can be studied from a social or linguistic perspective. Textbooks can be perused to determine how information on a topic has changed over the years. For example, a researcher may examine all the editions of a medical textbook to follow the social, cultural, and medical evolution of a disease. Pharmaceutical advertisements in magazines can shed light on gender issues. In case studies where the emphasis is on gaining a good understanding of phenomena within a particular setting, there is a good marriage between obtrusive (e.g., interviews or overt observation) and unobtrusive methods. Researchers often comb through the emails, memos, minutes of meetings, annual reports, and so on of the case under investigation. Maps or floor plans can also provide unexpected information about activities within and the social milieu of an institution. Other print sources available to researchers are photographs, paintings, and sheet

music. Art historians study paintings to understand the different periods of an artist's career. Photographs can be used to study architecture, automobiles, genealogy, or fashion trends. Dictionaries and thesauri, such as the *Library of Congress Subject Headings* or the American Psychological Association's *Thesaurus of Psychological Index Terms*, can be consulted to trace gender and social changes. There are so many print resources that can be used in unobtrusive research that it is not possible to list them all. Interested researchers can read more about these topics in the list of further readings below.

Nonprint Resources

Included in this category are people, computers, and recordings. Each one will be discussed briefly.

People

In observational studies of people, a researcher can play a number of roles throughout the study. The first role may be as a complete observer, which allows the researcher to become familiar with the people, place, and activities of the community being studied. The researcher's role is restricted to observing, and no attempt is made to engage the participants in conversation. This role can be quite useful in studies of how people use space, such as in airports, subway stations, libraries, or places of worship. For many social science researchers, however, complete observation seems to have lost its appeal because the validity of the data collected may be called into question. Without being able to ask questions, the researcher may misinterpret, misunderstand, or not grasp the full meaning of what she or he sees.

The use of proxies is another unobtrusive research method. People (often students) are recruited and trained to engage in a certain activity, such as asking particular questions of a librarian, teacher, or police officer, to name a few examples. The proxies record their activities, observations, and results and give the report to the researcher for analysis. Although this method has definite advantages (one of which is the detachment of the researcher from the actual interaction), there are some major disadvantages, such as how the proxies play their role, whether they complete the agreed upon assignment, and whether they accurately remember the transactions or write a complete and accurate report.

Computers

The advent of the internet allows researchers to collect data and yet remain completely absent from the scene. Two unobtrusive, nonparticipation methods discussed in the literature are transactional log analysis (TLA) and netnography. TLA allows researchers to observe how people maneuver their way through databases or other online products. TLA is a good way to assess the accessibility and user friendliness of a website or to learn about people's strategies for finding information. Netnography is the ethnographic study of people through their communications in chat rooms, listservs, blogs, and other online forums. Through lurking, researchers can gain an in-depth understanding of people's thoughts, opinions, and beliefs relating to a myriad of issues, such as health, travel, politics, wars, and so on. Two articles, covering many issues in the use of netnography as a research method, have been included in Further Readings.

Recordings

The final category includes musical recordings, audiotapes, films, and videos. The latter two are particularly good resources for researchers interested in understanding the behavior of people within the context of a situation. One example is the use of video cameras to capture both voice and actions of study participants who are testing a new database or website. Audiotapes and musical recordings can be studied for pattern recognition, linguistic trends, social or cultural issues, or other phenomena of interest.

Advantages and Disadvantages

With interviews, questionnaires, and observations, there is the potential for participants to alter their behavior in reaction to the researcher's presence or to the realization that they are being studied. The major advantage of unobtrusive research is that this reactive effect is eliminated. Other advantages are based on the method and resources used. For example, access to print and nonprint resources might be easier. Using netnography, data can be collected in a safe environment, such as in a home, office, or library. Furthermore, because there is no face-to-face contact with participants, researchers may be able to collect more reliable information on sensitive topics. The researcher can work at her or his own convenience because there are no appointments to

schedule with study participants. Finally, some authors suggest that this type of research is less expensive to do; however, they may not be taking into account the cost of traveling to archives or observation sites, obtaining interlibrary loans, or purchasing documents.

However, there are also disadvantages with unobtrusive research. Gaining approval to use nonparticipant or complete observation data collection techniques from an ethics review board (IRB) of a university may be problematic. Some members of the IRB may not see such methods as viable ways to collect data, while others may veto these techniques on ethical grounds. Selectivity is another major problem. People who wrote the original documents may have selectively recorded events, thus incorporating their biases. Their handwriting may be faded or difficult, if not impossible, to read. Furthermore, written material reflects only the stories of literate people. Print and nonprint documents may be missing from collections or, due to budget restraints, curators may have been selective in what they purchased. In the nonparticipant or complete observer role, researchers may not record important events because of lack of knowledge, inattention, bias, boredom, or fatigue. Researchers who decide to use an on-off schedule of observation may miss crucial events during the off period. In addition, the researchers' distance from the people involved in the event may hinder their ability to explain what is really transpiring. Therefore, the representativeness of their observations can be questioned. Thus, although there are some definite advantages, the disadvantages of unobtrusive research methods speak to the need to use them in conjunction with other methods that can offset these inherent weaknesses.

Ethical Considerations

There are ethical issues in both categories of unobtrusive research. In the print category, misrepresentation of information, plagiarism, and violations of copyright are all possibilities. Researchers may also select data that coincide with their opinions or intents and ignore what does not conform. Allan Kellehear mentions that researchers need to be honest with library or archival staff about their intended role. He also addresses the issue of confidentiality (or anonymity) for the people or institutions named in any current documents. They may not want their identities revealed in any published research.

In the nonprint category, ethical issues abound. Studying people without their informed consent is of paramount importance, especially if the researcher intends to publish the results of the study and does not use other methods to corroborate her or his findings. In the literature about the studying of online communities (e.g., netnography), the overarching question seems to concern the ethics of lurking. Discussions center on public versus private domain and the potential invasion of privacy of the people who are posting messages. Are they aware that what they post can be published as part of a research study? Have people had the opportunity to consent or request that their postings not be made public? Do they know that a researcher is lurking on a site where, heretofore, they have felt comfortable discussing issues of interest with other people in the particular community? Some of these questions have been addressed by the IRBs of many universities who have designed specific forms for the use of the internet in research. Items covered may include the typical ones on how the data will be collected and recruitment methods, but may also require a letter of support from the owner of the site. As the use of unobtrusive research methods involving the internet becomes more commonplace, some of these issues may be resolved. Overall, unobtrusive research methods have their place in qualitative research, but researchers have to be aware of the challenges involved so that no harm is done to any individual.

UNSTRUCTURED INTERVIEW

Unstructured interviews in qualitative research involve asking relatively open-ended questions of research participants in order to discover their percepts on the topic of interest. Interviews, in general, are a foundational means of collecting data when using qualitative research methods. They are designed to draw from the interviewee constructs embedded in his or her thinking and rationale for decision making. The researcher uses an inductive method in data gathering, regardless of whether the interview method is open, structured, or semi-structured. That is, the researcher does not wish to superimpose his or her own viewpoints onto the person being interviewed. Rather, inductively, the researcher wishes to understand the participant's perceptions, helping him or her to articulate percepts such that they will be understood clearly by the journal reader.

Qualitative researchers often describe interviews on a continuum. On the one end are structured interviews, which serve purposes similar to those of a verbal questionnaire. Researchers using this method typically begin with a hypothesis, idea, or hunch and then engage participants with demarcated questions about those constructs. Unstructured interviews, often referred to as open interviews, exist at the other end of the interview continuum. Semi-structured interviews typically are combinations of structured and open methods.

When utilizing unstructured interview methods, the researcher frequently begins with vague, general questions. For example, the research might ask, "What is it like being a school nurse?" The research participant has few clues as to the researcher's own opinion of where the researcher would like the conversation to go. Consequently, there are relatively few demand characteristics when using this method. In short, the interviewee determines the direction the interview will take when using an unstructured interview.

Use of Unstructured Interviews

Among others, there are five occasions when a qualitative researcher might wish to employ unstructured interview methods. One is when studying relatively new domains. In such circumstances it is not reasonable to ask a set of preestablished questions of the participant. Rather, researchers approach the interviews

more inductively. Second, unstructured methods may be particularly useful when qualitative researchers utilize research waves. In these waves, an interviewer can begin with unstructured interviews first, then progress to more structured interviews in later periods of data collection. Third, unstructured interviews can be helpful when depth, rather than breadth, is the primary goal of the research project. Often depth and breadth are necessary trade-offs in research, particularly when time limitations apply to the data collection. When researchers are more interested in knowing greater details about a phenomenon, unstructured questions may aptly accomplish those aims.

Fourth, unstructured interviews can be particularly useful for ethnographic research. Living among a group of individuals, learning their culture and perspectives lends itself naturally to having conversations with participants more so than asking them a set of prescribed questions. Lastly, the unstructured research method may be more useful when qualitative researchers work with particularly articulate individuals. Allowing these people freedom to take the interviews where they wish to go may provide insights to the construct being studied that could not be assessed via more structured interview means.

Further Readings

Holstein, J. A., & Gubrium, J. F. (2004). The active interview. In D. Siverstein (Ed.), *Qualitative research: Theory, method, and practice* (pp. 140–161). Thousand Oaks, CA: Sage.

UNSTRUCTURED OBSERVATION

In unstructured observation, the researcher enters the field with some general ideas of what might be salient, but not of what specifically will be observed. Therefore, observation is holistic, unstructured, and unfocused, with the investigator attempting to document as much as possible about the setting and its participants in order to discover themes of interest. Unstructured observation is not constrained by checklists and coding schemes; rather, the researcher

reports in narrative style about observations that are relevant to the research questions. Unstructured observation is most frequently associated with an interpretivist, constructivist paradigm that emphasizes the importance of context, sees knowledge as being co-constructed by both participants and investigators, and asserts it is impossible to completely separate the observer from the observed.

Unstructured observation is characterized by emergent research design, recognizing that what is observed may change as experience is gained in the setting. Data are collected about the physical setting, its history (often through documents), the context, the participants (including their physical characteristics such as age, gender, race and stature, their activities and their interactions with others), and the rhythm of activities. Investigators look and listen, and data collection is very thorough and detailed, especially at the beginning of a project when what is significant is still unknown. Unstructured observation recognizes that important themes can emerge from the mundane. Data are usually recorded as fieldnotes that include jottings, maps, and diagrams. Unstructured observation usually leads to more structured observation as more is learned about the context. This increased structure is better regarded as focused rather than as structured or systematic observation, which uses checklists.

Unstructured observation is particularly useful in the early stages of an observational study. It is more holistic than other forms of observation, capturing more information about the setting of interest. Unlike methods such as interviews, unstructured observation

allows investigation of context and process in an ongoing rather than episodic manner. It is effective for looking at interaction among individuals and between groups. When used with interviews, unstructured observation allows for comparison between participant accounts and actual behavior. Unstructured observation is a flexible method that allows for the collection of comprehensive and rich data.

A major weakness of unstructured observation is that it is susceptible to observer bias as investigators choose what to observe and how to process and analyze that information. In keeping with the concept of researcher as instrument, the quality of data collected and the findings are heavily dependent on the skill and experience of the investigator. Reactivity is also a potential problem, although it is usually overcome through habituation. The very nature of unstructured observation means that it is impossible to predict in advance all that will be of interest. Therefore, for example, obtaining informed consent from all participants (if necessary) requires ongoing effort as individuals move in and out of the research context.

V

VALIDITY

In the field of research, validity refers broadly to the “goodness” or “soundness” of a study. A multitude of approaches to and conceptualizations of validity have emerged, differing significantly depending on the research methodologies and paradigms that guide each particular research project. From positivist to postpositivist perspectives (which guide most quantitative research), validity is often broadly described as being dependent on the degree to which a study actually measures what it purports to measure—whether “the truth” is accurately identified and described. Validity, from this perspective, is increased by researchers’ use of specifically prescribed and well-entrenched procedures and strategies. Along with—and inextricably related to—notions of reliability, objectivity, and generalizability, validity is centered as an essential indicator of research quality in the positivist/postpositivist tradition.

In contrast, numerous conceptualizations of (and values for) validity are described in the field of qualitative research. Because of the multiplicity of paradigms and methodologies that are categorized in the qualitative field, it is overly simplistic—indeed inaccurate—to describe global qualitative criteria for validity. The purposes and methods of each qualitative study dictate, to a considerable degree, the type of validity that is sought. For example, whereas many social constructivists describe the validity of studies as being dependent on the resonance of their findings with participating communities’ common discourses, qualitative researchers from critical and action research perspectives are more likely to describe

studies as being valid to the extent that they are pragmatic (i.e., lead to social change-directed actions). In fact, some qualitative researchers reject attempts to demonstrate validity altogether, suggesting that such efforts counter the very essence of subjective interpretive work. Judging the validity of qualitative research projects is, then, often seen as being done most appropriately in an individualized contextual manner rather than through the application of broadly applicable standards and criteria.

Cognizant of this “validity variance” within the field, there are some validity-related commonalities in qualitative research. One of these is the vernacular that has frequently been used to indicate “goodness” or “soundness” in qualitative research projects. Described by Egon Guba and Yvonna Lincoln (among others) as appropriate qualitative alternatives to the quantitative goals of validity, reliability, objectivity, and generalizability, notions such as trustworthiness, credibility, authenticity, transferability, and plausibility are often cited as parallel criteria for quality research. These concepts suggest that qualitative research can be rigorous in its inquiry into meaning within fluid and continually contested contexts without being held accountable to inappropriate quantitative validity benchmarks. Throughout the course of a study (as opposed to waiting until the completion of data collection and analysis), researchers can increase trustworthiness, credibility, authenticity, transferability, and plausibility by using strategies such as continual verification of findings, member checks, self-reflection, peer debriefing, negative case analysis, sampling sufficiency, theoretical thinking, and audit trails. Ultimately, although the appropriateness of

these parallel criteria and strategies is, as mentioned previously, dependent on each study's guiding paradigm and methodology, most who do qualitative work agree that the validity of all research is heightened by ensuring that research procedures remain coherent and transparent, research results are evident, and research conclusions are convincing.

VALUE-FREE INQUIRY

Value-free inquiry is precisely what the term implies—inquiry (or research) that is thought to be free from the influences of human values. The preceding phrase, “thought to be,” is called to readers’ attention because value-free inquiry is a deeply contested concept. Thus, value-free inquiry is at the center of competing understandings about the nature of knowledge (epistemology) and specifically about how we understand the relationship between what we think of as facts (objective knowledge) and what we think of as values (subjective knowledge). For reasons that are discussed in this entry, qualitative researchers have largely abandoned the claim that any form of research (qualitative or quantitative) is value free or objective, whereas quantitative researchers tend to insist that quantitative research is, to at least some degree, objective and “scientifically neutral.” Thus, researchers from various backgrounds or schools of thought disagree about whether facts can be separated from values. To understand this dispute, it is useful to realize that the very thought of making a distinction between facts and values is, in the larger scope of human history, a relatively new idea. This entry begins with a discussion of the origins of the concept of value-free inquiry that is helpful in understanding why quantitative

researchers came to understand their research as objective, scientifically neutral, and value free.

The Origins of Value-Free Inquiry

The origins of value-free inquiry date roughly back to the scientific revolution of the 17th century. During that time period, a monumental shift took place in our understanding of human knowledge. Influenced by philosophers, physicists, and mathematicians, this shift represented a change in humans’ understanding of the universe (and themselves in it) as a holistic entity to their understanding of the universe as a dualistic relationship between mind and body, fact and value, subjective and objective.

Rene Descartes’s famous dictum, “I think therefore I am,” represented his belief in the necessity for human knowledge to emanate from an essential foundation. There is the mind, and it is distinct from the body, from the external world, and from nature ruled by mechanical laws. Human knowledge, therefore, required bringing the beliefs of the mind into alignment with the world outside of itself. Likewise, Isaac Newton’s metaphor of the universe as a giant clock depicted nature as objective and predictable. Hence, careful and methodical experimentation was requisite to unlocking its mysteries.

As the principal elaborator of empiricism, 17th-century British philosopher John Locke incorporated the concepts of mind/body dualism and reality as mind independent, thereby extending these concepts to an understanding of facts as distinct from human values. During the 19th century, French philosopher Auguste Comte contended that the distinction between facts and values (our subjective, values-imbued opinions) required methods of inquiry restricted to the physically observable. As the leading architect of positivism, Comte held that knowledge could be true only if it corresponded directly with a physically observable fact. Comte’s younger contemporary and correspondent, British empiricist philosopher John Stuart Mill, argued that inductive logic leading to laws of causation is the proper starting place for justifiable knowledge. His development of experimental procedures as a means for eliminating false causes and deriving verifiable causal relationships further instantiated the fact-versus-value distinction. These concepts (e.g., mind/body, fact/value, objective reality as mind independent, correspondence theory of truth, laws of causation) and

attendant experimental procedures were incorporated by early 20th-century French sociologist Emile Durkheim, who favored the scientific method as a superior approach for studying the social world. Social facts, he believed, should be treated as things, and inquiry in the social sciences should be a value-free process.

Max Weber, however, is widely held as being the most influential advocate of value-free inquiry in the social sciences. It is important to note that Weber did not claim that values were not a part of social science research. Rather, he believed that researchers can make objective observations and descriptions of others' values in the absence of making ethical judgments of their own values. Furthermore, he viewed research as making important contributions in helping people to determine the most efficient means to a predetermined and valued goal. Weber invoked a separation between "existential knowledge" (knowledge of what is or exists) and normative knowledge (whether what exists should or ought to exist). The distinction between the terms *is* and *ought to* asserts that researchers can conduct research on political affiliations, for example, without making any judgments about whether people should belong to one affiliation or another. Furthermore, he contended that knowledge about the factual existence of a phenomenon cannot establish its value and vice versa. Within this conceptual framework, social scientists act as neutral brokers, so to speak, confining their inquiry to the factual while leaving normative considerations to others.

Contested Assumptions

Widespread consensus surrounding the assumptions of value-free neutrality has long dominated research in the social sciences, so much so that this consensus has achieved something of a commonsense status among quantitative researchers. This is certainly not the case, however, among qualitative researchers. Because the possibility of value-free inquiry has undergone such a decisive undermining, qualitative researchers realize that it is no longer possible to sustain the assumptions of value-free inquiry. Philosophical critiques centering on the assumptions underlying value-free inquiry point out that value judgments permeate all aspects of research activity. Most obviously, the very choice of a research topic reflects researchers' values about what is important or worthy as opposed to trivial or inconsequential. The

very framing of the research question, the tools selected for the project, and so on pervasively structure the character and form of the results.

Perhaps more fundamentally, however, these critiques have thoroughly undermined two major assumptions underpinning value-free inquiry: the possibility of objective (theory-free) observation and the neutrality of the research methods themselves. First, for inquiry to be value free, researchers must be able to rid their observations of the influences of language, personal experiences, motives, beliefs, and culture. They must, in other words, be able to control their propensities to see some things, not see other things, and generally see things in light of their own interests and prejudices. Yet the possibility of achieving theory-free observations has been discredited both by theoretical physicists and by philosophers of science who have pointed out that it is impossible for humans to achieve such a state of self-transcendence. The objects of human observation do not exist apart from the meanings that observers bring to them, and because this is the case, all observation is inevitably prepossessed by the individual observer's personal dispositions. Stated succinctly, to observe is to interpret.

Second, the empiricist/positivist assumption that research procedures are neutral and, as such, serve as a means for holding researchers' values in check has also been seriously undermined. Research methods, including statistical ones, invariably presuppose the nature of what exists and how it can be understood. They do not supply us with direct access to things as they really are, nor do they provide accurate depiction or neutral access to a mind-independent reality outside of ourselves. Instead, the procedures of research are tools that contribute to the human construction of knowledge. Moreover, research procedures are themselves creations saturated with the intentions, purposes, and worldviews of those who fashioned them.

Although most scholars now acknowledge that all research is manifestly value laden, the implications of such a realization have spurred ongoing debate. In particular, the assertion that value-free inquiry is impossible confronts inquirers with the unavoidable conclusion that all research is a moral undertaking and all knowledge is, at its core, moral. More to the point, it poses the question of how researchers arbitrate differences about competing knowledge claims. If appeals to the supposed authority of methodological

neutrality cannot, and do not, function to adjudicate competing knowledge claims, by what means are these disagreements resolved? Various responses to this apparent quandary can be understood broadly as occupying three main positions: philosophical realism, neorealism, and nonrealists.

Philosophical Realism

The first of these positions can be characterized as an insistence on the foundational tenets of value-free inquiry. Researchers who take this stance (philosophical realism) maintain that distinctions between facts and values not only can be made but also should be made. Despite varying degrees of acknowledgment that absolute methodological objectivity is not possible, adherents of realism argue that the procedures of science (empiricist methods) are the best tools available for distinguishing between objective and subjective knowledge. From a realist perspective, belief in a realm of knowledge that is mind independent, existing outside of our opinions, values, and culture, is a necessity because otherwise all knowledge claims become equal. Finally, realists assume not only that the nature of true knowledge is objective and value free (epistemological realism) but also that the nature of reality (ontological realism) is likewise objective and value free.

Neorealism

The second position is much like the first, although adherents to this position (often termed *neorealists*) recognize that all human knowledge is mind dependent. Even though neorealists agree that researchers cannot obtain objective knowledge in a practical sense given the impossibility of theory-free observation, they maintain that it is possible, at least theoretically, for researchers' knowledge to achieve accurate depictions of an independently existing reality. Stated differently, neorealists have dropped the assumption of epistemological objectivity but still retain the concept of ontological realism. For them, the goal of researchers is to enhance the degree to which their mind-dependent knowledge approaches or achieves closer approximations to that reality. Neorealists hold common ground with realists in that they share the conviction that the assumption of some form of foundational objectivity is indispensable for the purpose of adjudicating disagreements among knowledge claims.

Nonrealists

Those who have relinquished both epistemological and ontological realism, who have fully foreclosed on the possibility of value-free inquiry altogether, comprise the third position. Referred to as nonrealists (or antifoundationalists/nonfoundationalists), researchers holding this perspective point out what they consider to be fundamentally irreconcilable contradictions in both the realist and neorealist positions.

Implications

For nonrealists, the main criticism of the realist position is that its adherents have simply chosen not to engage the issues at hand. Realists, they point out, have not acknowledged, nor can they refute, the conclusion that there is no theory-free observation, no neutral research procedures, and therefore no means for distinguishing between facts and values. Although realists may occasionally concede that absolute objectivity is impossible, they proceed as if this significant concession were of little or no consequence. In asserting and reasserting the possibility of value-free inquiry, realists apparently believe that research procedures can afford them at least partial objectivity. But to claim some form of relative objectivity raises the following question: How might one distinguish between the objective and subjective aspects of the research results? How can any sense be made of cobbling together the opposing concepts of relativism and objectivism? Given that no answers to these vital questions are forthcoming, nonrealists find the realist position to be decidedly unconvincing.

Nonrealists find the neorealist position to be similarly incoherent. Having divested themselves of the concepts of theory-free observation and procedural neutrality, neorealists, like their nonrealist counterparts, embrace the conviction that all knowledge is culturally constructed and value based. They have, in other words, rejected objectivist epistemology. However, like their realist counterparts, neorealists retain objectivist ontology. This effort to carve out an ostensive middle ground strikes nonrealists as deeply problematic. To claim that an objective reality exists outside of ourselves, and that it is a reality about which we can never have objective knowledge, is a moot point for nonrealists. More pointless still is the neorealist contention that the main criterion for judging research is the degree to which researchers'

constructed knowledge approaches or gets closer to that objective reality. This line of reasoning raises a rather obvious question: How would a researcher know if she or he has gotten closer to an objective reality unless the researcher knew ahead of time what that reality is? From the nonrealist perspective, such an undertaking is tantamount to aiming at an unknown target.

The nonrealist understanding that there is no value-free inquiry means that researchers construct, rather than discover, both knowledge and reality. What they know about the social world is not the social world itself but rather what they make of it. Accordingly, researchers cannot appeal to something outside of themselves to evaluate the worthiness of their knowledge claims. This perspective does not mean that research is less important, necessary, or influential. In addition, it does not mean that researchers must consign themselves to perpetual ambiguity or a sense of incapacity and indifference. Instead, they must make careful choices in the absence of complete knowledge and enter into dialogues (with one another) that offer ethical justifications for actions, choices, and practices.

VERIFICATION

Verification is the product of checking one or more aspects of the research process to ensure that they are a true representation of what actually occurred or are clearly derived from the analysis. Within qualitative research, this often occurs once the raw data have been gathered. For example, interview participants might be sent copies of the interview transcripts and asked to confirm that what is represented in the text is a true reflection of what occurred during the interviews. Another strategy to verify findings emerging from the analysis of a focus group might be the presentation of the analysis to the participants of the focus group so as to elicit their responses to the work and to ensure that all participants agree with the direction and focus that have been pursued in the analysis.

Comparable to validation (or the demonstration of validity) within a positivist paradigm, verification is a strategy used most often by qualitative researchers working within a naturalistic tradition to demonstrate the rigor of their work. Yvonna Lincoln and Egon Guba proposed four criteria for ensuring trustworthiness in naturalistic inquiry—credibility, transferability, dependability, and confirmability—with verification of the research findings with research participants (or “member checking”) making up a key strategy for ensuring credibility. However, as John Cutcliffe and Hugh McKenna pointed out, there are potentially a number of different outcomes resulting from this process, and the researcher needs to be clear how this strategy is being used. For example, are all research participants expected to agree with the data as originally noted and to confirm that the emerging theory is reasonable? Or, are participants expected to become actively involved in interpretation, possibly adding their own insights and perspectives? How will the researcher accommodate the views of one dissenting participant within the analysis? Although Cutcliffe

and McKenna supported attempts to verify findings with research participants, they advised care in selecting methods of testing verification and argued for multiple ways of doing this.

Those who espouse a relativist or postmodern approach to research may be critical of the use of strategies to ensure verification, contesting the notion of one single reality and arguing that the “truth” of a phenomenon will be mediated through both the writer and the readers of the research. The critical or postmodern researcher may lay claim to other criteria in demonstrating quality such as reflexivity, which foregrounds the role of the research, rather than laying claim to an authentic or true representation.

VIDEO INTERVENTION/ PREVENTION ASSESSMENT

Video intervention/prevention assessment (VIA) is an audiovisual research method for collecting participant-generated data on human experience. First developed in 1994 as a means of investigating the illness experience of children and adolescents, VIA has proven to be sensitive and versatile, applicable to a wide variety of research questions about the nature of human experience. VIA participants are loaned small, easy-to-use consumer camcorders and asked to “teach the researchers” about their experience by making visual narratives—“video diaries” of their everyday lives. Researchers transcribe the visual narratives into

dual-stream objective and subjective logs of the video data. Researchers import the logs and linked video into qualitative analysis software and parallel code the data. Using grounded theory, researchers from multiple disciplines analyze coded data, triangulate, cross-validate, and synergistically add dimension to findings.

Although the illustrative examples in this entry are from health research, VIA can be used to investigate many aspects of human experience. The purpose of VIA is to investigate human experience from the perspective of the experiencer. A video camera (without a crew) in a study participant’s daily living environment presents a unique opportunity for direct data collection. In the participant’s hands, the camera yields insight on the thoughts, feelings, and beliefs that color and control human experience. These data of direct human experience, when analyzed by a synergistic interdisciplinary team, yield a multidimensional understanding of what it means to be human.

Data Collection

Traditionally, research takes an “etic” perspective of researchers observing participants, but VIA, based on the premise that those who experience are the experts on that experience, takes the “emic” perspective of research participants on themselves. Based predominantly in visual anthropology, the study of humans and their behavior through images of and/or created by the people being studied, VIA incorporates elements of participant observation, narrative and discourse analysis, and ethnography. Photography and motion pictures have long been used by outside observers to document people and their lives. Recent improvement, miniaturization, and simplification of imaging technology have created the opportunity to study human experience “from the inside out” by placing video cameras in the hands of research participants and asking them to show their own experiences. VIA participants produce raw, naive visual narratives of variable production quality but containing firsthand renderings of human experience, perceptions, and behaviors. Objective information about participants’ experiences captured in the visual narratives is enriched by the subjective dimension of their firsthand perspectives.

Participants who meet inclusion criteria for a study give consent and are enrolled, followed by an introduction to the camcorder and study requirements. Informed consent for VIA is a two-stage process.

First, before taping, participants' consent only allows researchers to view the videos. Second, after completion, participants are provided with copies of their videos and asked whether they will release any or all of their visual narratives to the researchers for use in presentations, publications, and/or broadcasts.

To obtain audiovisual data that are the truest possible representation of participants' perspectives on their lives and living environments, researchers teach each participant only the mechanics of operating a camcorder—avoiding filmmaking techniques or conventions of visual style—so as to maintain the direct nature of their visual documentation. Provided with unlimited recording capacity, VIA participants are asked to “teach us about your experience” by carrying the camcorders and documenting their day-to-day lives for 4 to 8 weeks. Their primary mandate is to tell their life stories in their own ways, showing and telling the aspects that best reveal their experiences. Video was chosen because children and adolescents have been brought up with television and may have more ease and fluency in relating personal narratives, particularly sensitive material, in an audiovisual mode rather than a verbal or written mode. However, cultural expectations that photography is reserved for documentation of special events often need to be overcome because the material of interest is everyday behavior. To acquire documentation of common daily activities that can be compared across participants, researchers provide VIA participants with a list of standardized subjects of interest to augment their self-directed visual narratives. Researchers ask participants to record tours of their homes and neighborhoods, where they go and what they do from awakening until bedtime, their schools or jobs, their daily self-care, and their interactions with others. VIA participants interview family members and friends for their perspectives on the participants, their social worlds, and their interpersonal relationships. To reveal elements of their inner lives, participants are encouraged to speak directly to their camcorders each day as if they were writing in diaries, relating their experiences and responses, thoughts, and feelings about those events. When both the participants and the research team believe that the visual narratives are complete, the video equipment and all recordings are returned to the researchers.

Data Analysis

Critical to establishing VIA as a method of inquiry that generates valid and reliable findings has been the

Video Intervention/Prevention Assessment in the Field. A VIA participant videotapes a personal monologue.

Source: Photo by Mark Ostow; used by permission.

development of a rigorous structure for analyzing participants' audiovisual documentation of experience. Because participants direct their own visual narratives, VIA data are often unexpected and best analyzed using qualitative methods. VIA uses a multidisciplinary research team to optimize the analyses of these complex data on human experiences. For health research, this team includes the disciplines of medicine, public health, social work, psychology, and anthropology. Because researchers bring the different perspectives of their disciplines to the analysis, VIA data must be organized so that both the original video and the analyses done by other researchers can be accessed, displayed, and structured. VIA analysis generates a single multidimensional document that evolves through repeated analyses and is enriched by combining observations from different theoretical perspectives.

Because existing qualitative analysis software packages have focused on textual analysis, the VIA visual narratives are logged in a process similar to transcribing verbal data collected through interviews or focus groups, with attention paid to both visual and audio content. Video recorded by participants whose

experiences are being studied is much more complex than audiorecordings of participants responding to a researcher's questions. What participants choose to show on-screen and, perhaps just as important, what they choose not to show on-screen add to and synergize with the verbal content to illustrate the nature of the participants' experiences.

For analysis, the original video is dubbed to tape or downloaded to a digital file, maintaining unique numeric identifiers (video timecode) so that researchers can locate any point in the visual narrative and communicate clearly about specific sections of data. Trained loggers first watch each segment of the visual narrative in "real time" to get a sense of the story it tells and the people who tell it. Oriented by the first-pass viewing, the logger reviews the visual narrative, often requiring several passes to log the audio and visual components in detail. Computerized logs are created, designating objective and subjective content of the scene as well as other relevant details, including the date and time the video was shot, the timecode of the scene, and whether the scene was photographed by the participant, by someone else, or from a fixed camera.

The heart of the log is the objective and subjective content of the visual narrative. Objective notes document audible or visible information that is concrete and emotionally neutral and on which most observers would agree—descriptions of participants' appearance and behaviors, where they are, and with whom they interact. Dialogue is transcribed. Subjective notes record loggers' responsive interpretations of the emotional tone or psychosocial dynamics of the scene. Designed to capture the multifaceted nature of human experience, subjective observations of the visual narratives will necessarily vary. As a means of checking for accurate categorization of objective and subjective data, ensuring reliability, and enriching the subjective assessments, each visual narrative is logged at least twice, ideally by loggers of different genders, ages, ethnicities, and life experiences.

The logs and associated video are imported into qualitative analysis software, linked to the original audiovisual data, and coded inductively using the techniques of grounded theory. As coding proceeds, codes and emerging themes are presented to the multidisciplinary research team for discussion, clarification, consolidation, and refinement. Coding proceeds until saturation occurs and all video is coded by two or more coders in parallel. Once the initial code assignment is complete, codes can be queried across the visual

narrative data for similarities, differences, overlap, and/or proximity. As themes and their interrelationships are developed in research team meetings, codes are structured into groups for conceptual model building. Throughout this process, annotations are attached to the data and an ongoing project log is kept to document the evolution of analysis strategy and communicate it among multiple researchers.

Using the coded logs as a map to the data, researchers evaluate the VIA visual narratives from each of their disciplinary perspectives, meeting to discuss and triangulate their developing analyses. The VIA data are compared with, located, and validated against any other qualitative or quantitative data that may have been collected for a particular study. Overarching themes that cross data and disciplines are identified, and areas of consonance and dissonance are noted.

VIDEORECORDING

Videorecording is a qualitative research method that involves capturing moving images, with or without sound, to study the visual details of interaction and

behavior. Video research is becoming more commonplace, in part because of the availability of easy-to-use, relatively inexpensive technologies that can be readily manipulated by researchers or study participants with a minimum of training. It has the advantage of offering a permanent source of complex data that can be reviewed repeatedly. Despite its advantages, videorecording presents some unique practical, analytical, and ethical challenges to qualitative researchers.

There are two distinct approaches to videorecording in qualitative research: researcher-generated and participant-generated recordings. In researcher-generated recording, the researcher chooses the subject and content of the video. Projects that use researcher-generated recordings are often concerned with capturing situated social activity in a natural setting such as a classroom, health care environment, or community space. In participant-generated recording, research participants either directly control the camera or make the primary choices of what is to be filmed. For example, "video diaries" may be used to illuminate participants' identities or lifeworlds. "Photo-voice" is another technique whereby participants created visual images that outline their stories for the purpose of emancipatory public education. Researcher- and participant-generated video records can also be combined in a single study according to what types of data best address the study purposes.

Videorecording has the ability to capture the complexity and minutiae of social interaction and behavior that would not be possible with observation alone. Video records provide a dense source of data that includes the fine details of conduct, talk, interaction, and comportment as well as the features of place, bodily adornment, and material objects. Permanence provides an advantage over observation by allowing repeated cycles of analysis in which the researcher can attend to different information over time. This allows scrutiny of different aspects of the data at different times and in different ways (e.g., freeze frame, slow motion) and permits repeated analysis by multiple reviewers. Furthermore, videorecordings can be reviewed by study participants to elicit their responses, producing an additional source of data to increase the scope of interpretation of the study phenomenon.

Although videorecording offers a source of rich and complex data, it should be borne in mind that the video record is not a "direct" representation of the object of study. The camera converts and flattens images, and choices are made about what lies in and outside the frame. There is no sense of the social context beyond

what is recorded. If videorecording is the only method used, there is often no opportunity to question participants or test emerging theories as a participant in the activity. To address these issues, a combination of video and other techniques is often fruitful.

The influence of the camera on the phenomenon being researched is a subject of ongoing debate. On the one hand, it is assumed that the method has little impact on what people do or say; on the other hand, it is asserted that the camera has a distorting effect on the social "reality" under investigation. A third position suggests that both viewpoints are problematic and that any attempt to separate the research process from the data comes at the expense of exploring how the process constitutes the data. Thus, as with other forms of data generated within a research project, how persons present themselves for the camera can be viewed as reality-constructing, meaning-making occasions that provide a resource for analysis.

There are numerous technical and practical considerations associated with digital videorecording. Because digital video files are large, a computer with significant storage capacity that can also handle the fast transfer rates for uploading, copying, and transferring files is required. Video editing software is needed to manage, sort, and/or manipulate the data for presentation. If qualitative software is used, it will need to handle video files in a method conducive to the analysis plan. Other technical decisions will affect the quality of picture and sound at the time of taping and will determine how data can be compressed and backed up.

The analysis of video data often involves using transcription and/or logging procedures to convert images into word-based texts. However, the digitization of both audio and video data, along with the increased sophistication of qualitative software programs, has made direct coding of video segments both possible and increasingly practical. Presentation of video data is often challenging because it does not lend itself well to print media such as journals and books. Hypertext and hypermedia increasingly provide alternative methods for presenting findings by allowing readers to view an image, a video clip, an audio clip, or other information linked to the main text of an electronic article or other work. Online journals are increasingly accommodating hypermedia or visual papers, and interactive CDs or DVDs can accompany or replace books and monographs.

Videorecording raises unique ethical issues related to maintaining participant privacy and confidentiality

when video data are included in research presentations. Even without direct representations of participants' images, scenes of settings, homes, or neighborhoods can compromise anonymity. This can be addressed through highly selective use of images or by altering the digital file to obscure identifying information. Alternatively, the researcher may choose not to share the images outside of the research team and limit the presentation of data to anonymized verbal descriptions. The issue of whether or not participants want their video records to remain anonymous must also be considered because this might actually be contrary to the goals of the project. In participatory and emancipatory research, for example, participants may reject the role of anonymous voice and wish to have their contributions acknowledged. These options and their consequences must first be discussed carefully with participants and vetted through institutional research ethics review.

qualitative–quantitative spectrum and are especially valuable in exploring perceptions, attitudes, and behaviors in qualitative research. This entry covers key methodological issues surrounding different types of vignettes and participants' responses to vignette-based questioning.

Types of Vignettes

Vignettes can take a range of written, audio, and visual forms. Written text includes short scenarios and extracts from literature and newspapers. Audio vignettes include spoken narratives, music, songs, and sounds. Photography, painting, and line drawing have been used as visual vignettes. Audiovisual vignettes can include films and live performed acts.

The type of vignette used will be influenced by a combination of the research aims and questions, the nature of the research topics, and the participants involved. In qualitative research, vignettes are commonly embedded within interviews and group discussions.

The content of vignettes can be static or moving. A static vignette represents a one-off unlinked stimulus such as a short descriptive scenario. When a series of static vignettes are used, they risk a carryover effect from one vignette to another. The carryover effect refers to participants drawing from the context of earlier vignettes to aid interpretation of later scenarios. Static vignettes have also been criticized because participants may lose interest and tire of responding, often repetitively, to a number of unlinked scenarios. However, static vignettes are beneficial in their ability to cover a wide topic area and can also act as breakpoints when used alongside other methods.

Moving vignettes typically include extended scenarios such as narratives and film extracts. Longer vignettes can help to keep people interested during research encounters and may also save time in that contextual material need not be supplied for each new scenario. Like static vignettes, moving scenarios also risk careless responses when participants lose interest over time. Moving vignettes usually see the vignette progressing with questioning interspersed between scenarios. There is a risk that participants may become concerned with their answers, for example, if a story takes an unanticipated turn. Therefore, researchers should emphasize that there are no right or wrong answers when responding to vignettes.

It is common practice to use vignettes to be relevant and real to participants' own lives. Such vignettes have been based on previous research findings and

VIGNETTES

Vignettes comprise stimuli that selectively portray elements of reality to which research participants are invited to respond. Vignettes have a role across the

An Example of the Vignette Approach

As an illustration of one application of the vignette approach, consider Rhidian Hughes's research exploring drug injectors' infection risk behavior. Previous research has demonstrated drug injectors' risk behavior to be heavily influenced by situated contexts. Vignettes were used to capture, albeit partially, some of these situations. A short storybook vignette was created, narrating risk behavior scenarios confronting hypothetical drug injectors. The vocabulary and wording in the vignette aimed to be simple and used words familiar to drug injectors in England but avoided those that could cause offense. Drug injectors' overall responses to the vignette were embedded within an in-depth interview guide.

The vignette follows the lives and experiences of fictional characters as they move inside and outside prison. The researcher read the story aloud, with time given afterward to allow participants to digest information, clarify points, and think through their answers.

The storybook shown below (approximately 1,000 words) posed questions in the text for participants, and the questions were asked verbally by the researcher. As a result, a periodic discussion of issues arose.

Ben has been injecting scag (heroin) for three years. His girlfriend Jo hates the thought of Ben injecting, and he is now on a methadone [a prescribed substitute drug] script [prescription]. They are serious about each other and making plans to move in together. Ben has shared works [injecting equipment] in the past.

Ben and Jo don't want children. When they go to bed together and have sex, what protection, if any, do you think they will use?

Jo and Ben used condoms when they first started to sleep together, but now Jo takes the contraceptive pill.

One day Ben bumps into his good friend Paul. They go for a drink, and Paul suggests that they get money together to score some scag. Later they break into a house and sell the stolen stuff to one of Paul's friends.

By the time they find a dealer and get back to Paul's flat, it is past midnight. After all their efforts, they are both dying for a hit [injection of heroin]. Paul tells Ben that he doesn't have any clean works left, and they don't know of anyone nearby who might have some spare works.

What do you think would realistically happen in this situation?

Paul lent Ben his works that time after they had been cleaned with bleach and water.

The next time Ben and Paul get together they go into a department store and steal some clothes to sell, but just as they are leaving Ben gets caught by the security guard. Paul manages to run free.

Ben gets caught for this and other offences, and the judge puts him away for two years. Inside prison he's off his methadone and isn't feeling too good for lack of it. He tells this to one of the men on his floor, who introduces him to a group of men. That night before lights out they offer Ben some scag and a loan of the works that are being shared in the toilets.

What do you think would realistically happen in this situation?

Ben actually borrows the works and gives them a rinse with cold water in the sink before injecting.

Things get pretty desperate for Ben in prison, and he starts to inject whenever he can. He has sorted out a supply of scag. A new lad on the wing called Pete offers him a loan of his works in exchange for a wash out [residue drugs in a filter can be reheated to produce a further weaker injection].

What do you think will happen?

Ben accepts the offer and Pete has a wash out.

As the story progressed, Hughes observed that drug injectors related well to the vignette; some enjoyed the story and felt confident to identify possible outcomes for the vignette characters. Furthermore, participants drew from a range of perspectives in responding, including those of the vignette characters, their peers, and themselves.

constructed in collaboration with professionals and participant target groups. However, vignettes do not always require participants to have in-depth knowledge of the research topic, and some studies have constructed unrealistic vignettes to understand how individuals *might* behave.

Responses to Vignettes

There are a number of perspectives participants can be invited to adopt when responding to vignettes.

Participants may respond from the points of view of the vignette characters, their peers, and people more generally, or they may respond from their own personal viewpoints. A combination of perspectives may also be sought. The perspectives chosen will depend on research requirements. Researchers need to be clear as to what type of response they want to obtain.

Although vignettes do not necessarily require participants to be familiar with the situations depicted, when inviting people to adopt an informant's role (i.e., answering from a third-person perspective), it

becomes necessary to closely match the stimulus to the target participant group so as to minimize response difficulties. Using participants as informants and gathering responses from a third-person perspective provide an immediate distancing effect that can be beneficial when exploring potentially sensitive topics. The approach may also help to minimize socially desirable reporting patterns. Researchers may then wish to build carefully on these third-person responses to probe directly into participants' own lives.

Vignettes may try to uncover how participants themselves would react to the presented scenarios. However, there are important differences between what participants consider should be a response in the vignettes and what they would likely do themselves. Exploring these differences may help to reduce socially desirable patterns of responding.

The difference between the "vignette world" and the "real world" is one of the key criticisms leveled at the approach. Vignette scenarios require selective attention and necessarily omit the wide spectrum of issues that people face and respond to in their everyday lives. Therefore, vignettes are criticized for oversimplifying their presentations of the real world and producing unrealistic results. Vignettes are also criticized because researchers might not be able to distinguish what stimuli and assumptions trigger certain responses.

Different vignette types have also been subject to debate about the level of interpretational demand required of participants. Some researchers favor complex media (e.g., video) over simpler forms (e.g., written text). Arguably, lower interpretational demands may mean that less realistic results are obtained. However, the selectivity of vignettes in terms of both their representation of the real world and interpretation demands on participants can be harnessed as one of the valuable features of the approach. Vignettes cannot contain all of the necessary information that participants may wish to draw on in responding to vignettes because, ultimately, the context vignettes portray is selective. The very selectivity of vignettes can provide a focus for participants and help to clarify principles and concepts under study. Simplified stimuli can help to disentangle the complexities and conflicts present in everyday life.

It is important for researchers to consider the perspectives from which participants respond to vignettes and how vignette-generated data are generalizable, if at all, outside the context of the stimuli material presented. When vignette-generated data are congruent

with data obtained from other sources in the study or the wider literature, boundaries between data obtained from vignette responses and real-life situation responses may tentatively be collapsed.

VIRTUAL COMMUNITY

The term *virtual community* is used in three broad senses: to refer to (1) a group of people who associate themselves over time with a computer-mediated environment, with emphasis on the social behavior of the group; (2) the phenomenon of online group formation, typically in light of the historical and theoretical implications of the terms *virtual* and *community*; and (3) the technological environment (e.g., listserv, chat room, web-based environment) that facilitates and potentially shapes the formation and activity of online groups. The first sense is most common in social science research, the second in humanities research, and the third in technology-focused research and design.

The possibility of virtual communities was first envisioned during the 1960s by J. C. R. Licklider as a natural outgrowth of computer networking. The concept was popularized by Howard Rheingold in writing about his experiences on the WELL bulletin board

system during the early 1990s. Scholarship problematizing the concept soon followed. One concern was that “community” traditionally is based on geographic location, which is often irrelevant in online groups. Another was that traditional notions of community are themselves idealized and that comparisons between online and offline communities create artificial dichotomies (e.g., offline communities are deep-rooted and close-knit, whereas online communities are superficial and fragmented). Moreover, because the word *community* is value laden, having positive connotations of cohesion and reciprocal support, it is often used aspirationally to refer to desired outcomes or properties of online groups regardless of whether community characteristics are objectively present. As a consequence, some researchers avoid using the term *virtual community* and instead refer to (members of) *online forums*, *online groups*, or *online social spaces*. When the intention is to highlight the connections among individuals who make up a group, sometimes the term *social network* is also used.

Other researchers have sought to operationalize the concept of virtual community so as to evaluate empirically the extent to which online groups are community-like. Commonly cited criteria for a virtual community include a shared reason for communicating, the existence of norms or protocols, and regular interaction of some duration that takes places over the internet through a common mechanism. Some researchers add that participants should also feel like they are part of a larger group and develop emotional attachments to others in the group, noting that noninteractive participants (“lurkers”) may also experience this subjective sense of community. Despite these efforts to bring greater precision to the use of the term *virtual community*, it has become conventional in some domains to refer to online groups as communities without further specification.

Virtual communities on the internet (VCs) can be grouped into five types: interest groups (e.g., soap opera fans), support groups (e.g., health related), task-related groups (e.g., communities of practice), geographically based groups (e.g., community networks), and commercial environments (e.g., product websites designed to encourage human–human interaction). Moreover, VCs exhibit variation within each type according to factors such as creation process, age, lifespan stage, size, leadership, geographic dispersion, cultural diversity, and variety of communication technologies available.

In addition to classifying VC types, current research is investigating knowledge sharing in VCs and how VCs develop over time. As yet, little research has addressed cross-cultural communication in VCs or VCs in which communication takes place in languages other than English.

VIRTUAL ETHNOGRAPHY

Virtual ethnography is a research approach for exploring the social interactions that take place in virtual environments. These interactions often take place on the internet in sites such as newsgroups, chat rooms, and web-based discussion forums. The notion of virtual ethnography builds on existing principles for ethnographic research that stress the immersion of the researcher in the setting for extended periods of time and the aspiration to an in-depth holistic understanding of a culture. Whereas an ethnographer would usually expect to observe ongoing social existence within a chosen field site, interacting with its inhabitants and learning about their way of life, the virtual ethnographer becomes immersed in a virtual environment, observing and interacting using media appropriate to those who use that site. In addition to occasional face-to-face meetings with informants, virtual ethnographers may use email or instant messaging for interviews, conduct textual analysis of messages, and carry out social network analysis or hyperlink analysis. This entry describes different ways of defining the field site for a virtual ethnography, and some of the practical challenges that this form of ethnography poses, before concluding with an examination of some applications of this approach.

Field Sites for Virtual Ethnography

The idea of applying ethnographic methods to the understanding of virtual environments became popular in the early days of internet research during the 1990s. Nancy Baym was particularly influential in promoting a view of online environments as potentially rich sites of social interaction. She described a newsgroup used by soap opera fans and formulated an immersive approach that approached the online venue as a cultural site that an ethnographer could set out to describe in its own right. The notion of virtual ethnography became tied quite closely to the idea of online community, with the goal of the researcher being to outline the distinctive qualities of the cultures that prevailed within particular online settings. Questions of shared norms and values, social hierarchies, common languages, and collective goods, as well as the processes through which members identify insiders and deviants, became popular topics within ethnographic approaches to online settings.

In addition to documenting distinctive features of online cultures, a further important dimension of virtual ethnography has been the development of a reflexive understanding of online experience, focusing on how presence in the virtual environment is achieved. Annette Markham wrote of her own experiences of going online and interviewing people that she encountered there, drawing heavily on a reflexive ethnographic tradition to argue that the internet could, under various circumstances, represent either a tool, a place, or a way of being. This style of ethnography focuses particularly on concerns of self, identity, and presence in the virtual environment. Many virtual ethnographers, even where they focus on documenting the culture encountered within a particular online space, draw on the experiences of the researcher as an important means of insight into the prevailing conditions that allow participants to be meaningfully present to one another.

Many virtual ethnographers have chosen particular online spaces as the field sites for their studies. Such field sites are often defined by a particular communication medium such as a Usenet newsgroup, a MUD (multiuser domain) or MOO (MUD, object oriented), a web-based discussion forum, a chat room, or a massively multiplayer online role-playing game. These technologies offer more or less clearly bounded sites of social interaction for ethnographic study. Some, such as the newsgroup, rely on asynchronous interaction, so that the ethnographer can dip in and out periodically,

whereas others consist of real-time interaction and require a more sustained or organized commitment from the ethnographer. In each case, the appropriate form and timing of engagement will be guided largely by the ethnographer's developing sense of the ways in which participants operate in that setting. Some field sites, however, are less clearly bounded, and the ethnographer will need to pay careful attention to the ways in which those sites are defined in an ongoing fashion by participants and the extent to which they draw on diverse media to sustain meaningful interactions. An online game, for example, may involve both in-game communication channels and the use of web forums, external chat rooms, websites, and email. Players may also meet face-to-face periodically or play both across geographic distance and in the closer proximity of LAN (local area network) gaming events. Therefore, it is important for a virtual ethnographer to attend to the constitution of field sites across diverse media.

The issue of online/offline connections has also preoccupied virtual ethnographers. Although early internet studies often celebrated the stand-alone nature of online culture, it has recently become more important to trace the threads that connect online life with offline contexts. Daniel Miller and Don Slater were particularly influential in promoting an approach to ethnography of the internet that focused on its embedding within particular cultural contexts. They described the internet in Trinidad, finding that users there were able to interpret the internet as a means to sustain a distinctively Trinidadian culture. This approach is also linked to the form of virtual ethnography developed by Christine Hine. Here virtual ethnography is conceived as an adaptive and connective approach that takes online sites seriously as places for social interaction but also seeks to follow the threads of meaning-making (both online and offline) through which these interactions make sense to participants. The focus is on the internet as both a cultural context and a cultural artifact that is shaped by various expectations and becomes meaningful to users in particular contexts. Virtual ethnography, in this formulation, becomes more closely allied to the emerging traditions of multisited ethnography found in anthropology. Nicole Constable developed an approach that traversed online mailing lists and web forums, as well as visiting users of these media in their homes in China, the Philippines, Russia, and the United States, in pursuit of an ethnographic understanding of correspondence marriages. Virtual ethnography has become an adaptive approach that does not always confine itself to

online sites but rather tries to take into account the diverse cultural contexts within which online interactions make sense.

Challenges of Virtual Ethnography

Virtual ethnography poses a number of practical and conceptual challenges for the researcher. Although the principles of virtual ethnography have stayed quite close to approaches developed in more conventional face-to-face settings, there have been a number of dilemmas relating to the application of these principles and some specific technical issues that the shift to different media imposes.

Lurking or Participating

The online setting can often be experienced without active participation. Many of the members of a mailing list or web forum will “lurk,” reading messages without actively participating or indeed being visible in any way to other participants. This potential to observe unobtrusively has been attractive to some ethnographers, who find in it the possibility to study a setting that is undisturbed by their own presence and interventions. However, some have questioned how far this form of passive observation can be termed an ethnography given that it lacks the engagement that is often considered necessary for ethnographers to develop in-depth understanding and to expose their developing ideas to input from other participants.

Deception and Identity Play

Some have questioned the ability of virtual ethnographers to make authoritative statements about the users of online settings. A prevailing concern that deception is common online and that many users adopt fabricated identities leads to some caution in taking statements that people make about themselves online at face value. Nonetheless, there are some indications that deception and identity play are not as common as once thought. Also, the question of how far online statements are to be trusted is not always an issue of concern if the goal is to study an online culture in its own right. Many virtual ethnographers will draw on some form of triangulation to confirm the statements of online informants through observation in different forms of interaction.

An Example of Virtual Ethnography: Online Fandom

Nancy Baym's ethnographic study of an online soap opera discussion group, *Tune In, Log On: Soaps, Fandom, and Online Community*, is often cited for its innovative qualities as one of the first efforts to take internet interactions seriously as sites for sociological interest. Baym argued that the newsgroup she studied provided an excellent site for observing practices of audiencehood beyond its significance as an example of online social practice. The study also unpacked the often glibly used notion of virtual community to explore the ways in which a virtual community, a fan community, and a community of practice coexist with and reinforce one another. Baym carried out her ethnographic work as an active member of the group in which she was at first a full participant before adopting it as an ethnographic field site. As an ethnographer, she conducted online interviews and surveys, carried out textual analysis of threads of discussion, and was also informed by in-depth knowledge of the soap opera that participants in the group discussed. Although the study was contained largely within the boundaries of a newsgroup, it needed to attend to the meaning-making that participants performed through their references to the soap opera and to the everyday lives within which their contributions took place.

Source: For more information on this topic, see Baym, N. (2000). *Tune in, log on: Soaps, fandom, and online community*. Thousand Oaks, CA: Sage.

Prerequisites for Immersion in Online Environments

A virtual ethnographer needs to adopt an appropriate persona to be able to interact effectively in an online environment and to present himself or herself to the other participants in these interactions. This can entail consideration of appropriate self-presentation, including choice of signature, adoption of an appropriate avatar, and (sometimes) preparation of a web-site giving details about the researcher and the research project. In some environments, the question of skills becomes particularly significant, most notably in gaming environments where a virtual ethnographer may need to accrue an appropriate skill level or amount of credits so as to maintain interactions with potential informants. Choice of character can also be crucial in shaping the interactions that can be experienced.

Ethics, Informed Consent, and Trust

The question of ethics and informed consent has been particularly troubled in virtual ethnography, largely because of the possibility of lurking unannounced. In any face-to-face setting, there is a danger that participants will forget about the presence and role of an ethnographer over time even where consent has been negotiated. In a virtual environment, however, there appears to be a greater concern that an ethnographer will exploit the opportunity to lurk and observe interactions that participants might otherwise wish to avoid having observed. It might be assumed that internet interactions are public, but this does not always accord with the practices and expectations of participants. The level of concern about this issue varies depending on the sensitivity of the topic, the vulnerability of participants, and participants' expectations about the level of privacy of their interactions. Nonetheless, deliberate deception and covert ethnography are potentially as problematic in online ethnography as in face-to-face settings. Virtual ethnographers may also need to pay particular attention to developing trust with online informants, who may themselves expect to be able to triangulate information on the identity of ethnographers who approach them via websites, guarantees from gatekeepers, or evidence of institutional affiliation.

Applications of Virtual Ethnography

Some modes of virtual ethnography are focused on understanding the online experience in its own right. This approach to virtual ethnography may place particular stress on the relationship between technological affordances and the interpretations users place on them to create distinctive cultures or on the offline cultural contexts that create and sustain particular online formations. Ethnography has been a particularly significant strand of internet research, focusing as it does on the social reality of the online experience and forming a foil to preceding frameworks that stressed the constraints of online interaction. Ethnographers of the virtual environment were able to demonstrate that rich and complex social formations were possible online and that people adapted to and worked around the features of the technology rather than being inherently constrained by them.

In addition to its contribution to understanding online interactions in themselves, virtual ethnography offers a means to explore diverse other important social phenomena as they are manifested in the online environment.

The internet is populated by miscellaneous groups and sets of interests that make visible many issues of concern for social researchers. Virtual ethnography can be used as an approach to explore the ways in which these issues are manifested and undergo transformation on the internet. Fields as diverse as health studies, deviance and social control, ethnicity and gender studies, organizational culture, and media studies find in the internet a potential site to study rich and naturally occurring social interactions related to their concerns. Virtual ethnography offers a means to develop in-depth understanding and detailed descriptions of these cultural domains.

VIRTUAL INTERVIEW

A virtual interview is any form of interview that uses information and communication technologies (ICTs) such as email, discussion board, and real-time chat. It is a specific form of virtual research that enables researchers to use the immediacy of the internet to access participants and gather data for qualitative research investigations. Virtual communication has become one of the main forms of human engagement and is used in the transmission and exchange of ideas, experience, and attitudes. It follows that ICTs provide unique and inventive opportunities for qualitative researchers.

The types of virtual interviews include structured unstructured, and semi-structured interviews, in-depth interviews, focus groups, and group interviews. Each follows the same logic in terms of suitability of method for types of data collected. For example, structured

interviews can be used for large data collection on attitudes; focus group interviews for an in-depth understanding of attitudes, perceptions, and opinions as well as for evaluation purposes; and in-depth interviews for accessing experiential data. To this extent, each technique can be targeted and directed at specific individuals or interest groups, or it can be circulated more broadly to assess attitudinal responses.

One-on-one real-time virtual interviews provide focused and spontaneous responses, as do synchronous virtual focus group interviews. The former aim to closely replicate the discursive nature of face-to-face interviews, whereas the latter can be “fast and furious” so that threads may be difficult to follow with multiple participants responding simultaneously, thereby disrupting the sequential nature of interaction. Asynchronous responses, on the other hand, provide participants with the opportunity to reflect on their own responses and those of others. This enables participants to monitor what information they are prepared to share, and this is ethically

important when discussing sensitive issues. In the virtual setting, participants have a choice of responding to a question or withholding a response, thereby providing a noncoercive discursive environment. With asynchronous virtual interviews, the ongoing discussion is structured by specific questions during a set period of time (usually several days to a week).

One main difference between face-to-face and virtual interviews is the somewhat changed role of the interviewer or moderator. The interviewer must construct the environment for discussion and explicitly set the rules of engagement prior to the interview because the interviewer’s role is less interventionist and less directive than in conventional interviews. Virtual listening cues, the insertion of probes, and additional questions need to be developed both to enhance the steering role of the interviewer and to replace visual nonverbal cues, such as nods and facial expressions, of the face-to-face interviewer.

Lyn Turney

Research Studies Using Virtual Focus Groups

Virtual methods can be considered when designing studies that involve groups or individuals who are, for whatever reason, hesitant or unable to participate in face-to-face interviews. In two separate studies, researchers used virtual focus groups (alongside face-to-face groups) in studies of public attitudes to new biotechnologies. They wanted to include participants who had a stake or special interest in either DNA paternity testing or stem cell research; the participants’ opinions were integral to the studies. Accordingly, for the paternity testing study, a group of fathers’ rights leaders, who advocate unrestricted and direct access to paternity testing, was interviewed online. Men who were involved in fathers’ rights groups were generally unprepared to speak to outsiders but actively participated in a virtual group, providing an in-depth understanding of their attitudes, as well as their constituents’ attitudes, toward paternity testing. The second paternity testing group was mothers whose estranged partners had denied paternity. The mothers and their children were compelled to undergo testing to have the fathers’ names on their children’s birth certificates and/or to meet the requirements for claiming child support payments. All of the women were single mothers with responsibilities for young babies that affected their ability to participate in a face-to-face

focus group. For the stem cell research project, the two interest groups involved were those with a particular interest in, or stance on, stem cell research. The first consisted of a religious group with strongly held views on abortion; the second was a patient group whose members had a medical condition that might be helped or cured by stem cell research. The latter group was interviewed only online. This patient group was people living with either Parkinson’s disease or spinal injury who were young enough to personally benefit from any promising developments in the near future. Their restricted mobility, medication, and need for care rendered it nearly impossible to meet in a face-to-face setting. Anonymity and virtual engagement were enhanced in each group by the absence of physical cues and the use of anonymizing techniques afforded by the technology itself. Virtual identities enabled participants to find commonality beyond the usual social and physical barriers to communication such as socioeconomic status, gender, age, ethnicity, and (importantly) disability status. Overall, the researchers found that virtual interviews fostered democratic participation in research, enabling inclusion of groups whose members’ pertinent views otherwise may have been overlooked.

VIRTUAL RESEARCH

Virtual research can refer to both data collection by means of the internet and research about the internet itself. Because the latter is more about “researching the virtual” than about “virtual research” as method, this entry focuses on the internet as a tool for gathering data from participants and locating data sources for qualitative research projects.

Types of Virtual Research Methods

When the internet is used as a research tool, computer-mediated communication (CMC) drives the data-gathering process (through interviews, observational techniques, document analysis, etc.). CMC refers to a situation in which individuals communicate across a computer network. In an interview, the researcher and participant might interact over email or via real-time chat. In observational studies, the researcher might observe participants’ communication patterns in a virtual community. In document analysis, the researcher might examine the linguistic details of individuals’ web postings.

Interviews

In broad terms, two types of interviews are discussed in the virtual context: standardized (i. e., structured) and nonstandardized (i. e., semi-structured or unstructured)

interviews. In standardized online interviews, participants are asked specific questions and must answer the questions according to predetermined responses. In essence, this process resembles the administration of a questionnaire and typically lends itself to a more quantitative style of analysis and reporting. Email and web-based surveys are commonly seen as possibilities for administering this type of questionnaire. When email is used to administer a structured interview online, the survey can be sent as a text or HTML file, as an attachment, or using a survey design program. Typically, participants complete the appropriate responses and send the files back via email. Web-based surveys, where a researcher can create a survey (i.e., a structured interview) that will look the same to all participants and can be accessed via a website address (URL), are also commonly used. Once participants hit “submit” on the web survey, the data file is sent to a private location on the researcher’s server.

In nonstandardized interviews (individual and group), participants are not limited by predetermined responses. As with all interview methods, the interviews must strike a balance between the participants’ responses and the research goals so that the participants do not stray completely off-topic. With nonstandardized virtual interviews, one must again select the type of tool used to administer the interviews. Typically, this involves choosing between synchronous (e.g., videoconferencing) and asynchronous (e.g., email) modes of communication, with synchronous tools providing more flexibility for negotiating responses and gaining immediate clarification from respondents.

Observational Studies

Observational methods are often used in virtual environments because researchers are less reliant on retrospective accounts from participants and can watch events unfold. Such studies can use participant observation (i.e., researchers engage in the community they are studying) or nonparticipant observation (i.e., researchers observe the community but are not active participants) to examine individuals’ interactions in virtual spaces. As studies of virtual communities become more common, so too do observational studies in virtual environments. Observational studies may examine the linguistic structures present in virtual communities, or they may examine the cultures

that exist in these virtual communities. In all cases, the researcher must select a “space” in which to conduct the research (e.g., a public newsgroup that examines global warming).

Document Analysis

Personal documents (both solicited and unsolicited) are often considered as an optimal means for understanding how individuals experience life events. These documents may take the form of autobiographies, journals, or diaries. Although qualitative researchers have traditionally used hardcopy versions of these texts, online versions are becoming increasingly popular. This shift to online versions of these personal documents may stem in part from the fact that the internet enables researchers to access a wider array of participants from around the globe, enhancing the scope of a study on a particular phenomenon; however, another reason for the shift is the proliferation of personal web postings (e.g., blogs) on a variety of topics. Online data sources offer a built-in archiving structure as the information is collected in electronic form. Furthermore, researchers do not need to be concerned about the legibility of participants’ handwriting. Online sources may include text, video, audio, and a range of other document forms that can extend qualitative analysis of particular phenomena. For participants, writing online can be less time-intensive than writing by hand, and it is easier to send data to researchers. However, a couple of caveats exist. Participants might not write as much in online situations (e.g., due to eye strain), and if they are providing written diaries, the results may be less longitudinal in nature because participants might not link current entries to those posted previously.

Ethics

All three methods for conducting virtual research must be considered in the context of evolving ethical issues as they apply to online information processing, informed consent, confidentiality, and etiquette. As in face-to-face research, participants’ rights are central to the design of research projects in virtual contexts. For example, any data collected should be protected in such a way that they are safeguarded against alteration, unauthorized access, or loss. When conducting

research in private virtual environments, such as members-only discussion groups, researchers may need permission from a list owner and/or list members to gather data. However, researchers may be able to use other data sources (e.g., information posted to publicly available websites) without needing to complete an ethics review. Researchers should consult the guidelines developed by their own institutional review boards, along with other texts, for guidance on the ethical issues relevant to their particular research projects.

When one considers informed consent, the issues will differ slightly depending on the research context (e.g., email, chat). In an email study, consent may be completed *de facto* by participation in the study (e.g., when participants read the consent statement on the top of a questionnaire and submit it via a web form), or the researcher may first need to email the consent form to participants and have them return it via email (or by fax if a signature is required). In the context of a real-time chat environment, participants could be guided to a research website to read the consent form and decide whether they want to participate in discussions. When researchers “lurk” on mailing lists and newsgroups (i.e., read postings without making their presence known), consent may depend on the nature of the group (public vs. private) and other factors particular to the design of the study. As in other qualitative studies, parental consent may be required in projects involving children; however, this may be more complicated in a virtual environment where individuals may pretend to be older (or younger) in age to participate in a study.

Confidentiality also becomes more complex in online environments. Using pseudonyms to maintain anonymity, for example, might not be enough; researchers might need to strip additional data (e.g., email addresses, user login names) or take other steps to ensure that participants’ information remains anonymous. In the context of chat and online communities, researchers must take additional steps to protect the identities of participants—similar to the issues raised with face-to-face focus group methods. In other cases, participants may wish to be identified (rather than anonymized) in research publications. However, in some cases, even researchers might never know participants’ true identities.

Some elements of “netiquette” (the rules of etiquette used on the internet) also have implications

for the ethical treatment of participants in online studies. Maintaining professionalism and being clear about intended meanings may be more difficult in an online research setting than in a face-to-face one. For example, when researchers initially contact participants, it may be inappropriate to use common online conventions such as emoticons. In a real-time chat context, researchers should not be so intrusive as to continually send instant messages to participants if they do not answer initially. When working with mailing lists or newsgroups, researchers should ensure that they provide context for the messages to which they are replying, that they do not “flame” or humiliate participants, and that they do not send private messages to a public list.

Advantages of Using the Internet to Collect Data

There are many advantages to using the internet as a data-gathering tool. First, the online environment allows researchers to contact potential participants around the globe, including areas that are difficult to access in person. The internet can facilitate discussions with hard-to-reach individuals (e.g., shift workers) and provide access to locations that are traditionally closed to researchers or dangerous to access. Participants may also be more willing to discuss sensitive issues because the context can feel more anonymous than in face-to-face communication. CMC also provides access to communities that are entirely web based such as support groups and virtual playgrounds. The financial and time-related costs of conducting research online (e.g., compared with physical travel) can also be quite reasonable. Because the data are already in electronic form, the costs of transcription, recording equipment, and other data collection elements can be reduced significantly.

From participants' points of view, it is often easier to find an internet connection where they can complete the research than to get to a physical location of the researcher's choosing. Moreover, it can also be easier to complete the research tasks in discrete sessions if other responsibilities (e.g., child care) interrupt the research. Some participants may also feel safer completing the research project in an environment that is familiar to them such as their home offices.

Challenges in Using the Internet to Collect Data

Despite these advantages, numerous challenges exist in conducting virtual research. Typically, internet communication is text based, thereby reducing researchers' capacity to interpret nonverbal communication. This can make data analysis and interpretation much more difficult. Researchers may need to consider real-time video or other data collection tools to supplement textual documents obtained via the internet. Also, individuals can easily misrepresent themselves in the virtual context, and this can affect the trustworthiness of the data gathered.

More pragmatically, researchers need appropriate technical expertise to gather data in this way. It can also be challenging to recruit participants without being viewed as a source of spam when requests for participation are sent across newsgroups or in bulk emails. Even locating email addresses for potential participants can be a challenge, especially as individuals and organizations attempt to block spam and other unsolicited messages. Some potential participants might not want to engage in an online study, or they may be unable to participate as a result of limited skills in using computer technology. Clarifying instructions for research participation may be more difficult in a virtual environment than when the researcher and participant are face-to-face. With longitudinal studies, there is a potential loss of participants who simply disappear from the online environment (e.g., when they lose internet access or do not update their contact information). In all projects, it is also important to recognize the impact of the “digital divide”—the fact that geography, socioeconomic status, ethnicity, age, and other factors can leave some individuals without access to computer technology.

As internet tools become more sophisticated, and as the number of internet users continues to increase worldwide, the prevalence of (and potential for) virtual research will continue to grow. Qualitative researchers will need to rise to the challenges that exist in conducting this type of research while capitalizing on the advantages.

VISUAL DATA

A liberal definition of visual data would need to include any empirical material perceivable through the sense of sight. However, such a definition would help little because it would include entities as diverse as social behavior in an experimental laboratory, checkmarks on a questionnaire, interaction in naturalistic settings, and geophysical elements of landscape. Therefore, a stricter definition of visual data that simply includes iconic objects and the symbolic meanings that people attach to these is preferable. To clearly understand the convenience of such a definition, it is important to begin with the concept of “icon.”

American semiotician Charles Sanders Peirce proposed that signs ought to be divided into three main categories: indexes, icons, and symbols. Indexes refer to relationships based on natural causation (e.g., smoke is indexical of fire, lighting is indexical of stormy weather). Symbols are what we commonly use in everyday life to refer to abstract meaning (e.g., words, numbers). Icons are those signs that embody whatever they represent (e.g., a passport picture represents a person’s face, a realist painting of landscape signifies the landscape it portrays, a sketch drawing of a male figure on a public wash-room door refers to a man). Most methods of

visual data analysis deal with iconic signs—still or moving pictures (e.g., advertisements, videos, film), drawings, paintings, maps, and other images. Although for the most part analysis of visual data is conducted on such signs, visual research is also conducted on public behavior (especially nonverbal interaction), material culture, landscape, and the human body and its adornments.

Several qualitative methods are available for the analysis of visual data, including but not limited to the content analysis of visual images, visual ethnography, historical comparative analysis, semiotics, iconography, and social semiotics. The most common examples of visual data in the research literature are those contained in Erving Goffman’s book *Gender Advertisements* and in Roland Barthes’s book *Mythologies*. *Gender Advertisements* featured a collection of advertising images selected from various popular media and accompanied by ethnographic-like reflections on the nature of images as expressions and evidence about complex social realities. Photographs here are studied as statements about social ceremonies—the ceremony of advertising and the iconic ceremony of social portraiture, that is, society’s ways of expressing

Ferry-Boating or Theatre-Going? A visual representation of the gazing aspects of mobility.

Source: Photo by Phillip Vannini; used by permission.

cultural rituals and beliefs visually. Taking a less ethnographic and more critical stance, *Mythologies* instead stands as one of the classics of postmodern visual culture—a culture revolving around the role of ideology or myth. Images tend to be interpreted as natural expressions of the status quo—of taken-for-granted natural realities—because they are seemingly unable to lie. Popular expressions such as “you need to see it to believe it” and “a picture is worth a thousand words” express this belief well. Yet it is precisely because of the alleged “natural” correspondence between an icon and its referent—in other words, between a picture and that which it represents—that visual images are particularly insidious, according to Barthes.

VISUAL DATA DISPLAYS

Visual data displays include tables, figures, and other graphic presentations that assist readers in gaining insights into decisions that were made during the course of a research project. These visual data displays reveal the processes and methods that were used in data collection and analysis, and they contribute significantly to the credibility of the research. This entry addresses some of the strategies that have been employed for assessing the methodological rigor and analytic defensibility of qualitative research. As used here, rigor is defined as the attempt to make data and explanatory schemes as public and replicable as possible.

Background

Criticism from both inside and outside sources, as well as the proliferation of qualitative methods in educational research, has led to considerable controversy about standards for the design and conduct of qualitative research. Discussions regarding these standards

have failed to address one very important dilemma—questions concerning the credibility and status of qualitative inquiry as related to the privatization of this type of analysis. In short, the basic premise involves how researchers account for and disclose their approach to all aspects of the research process. Central to this premise are the core elements of classical science—replicability and refutability.

Three observations form the basis for this call for public disclosure of decisions made during the conduct of research. First, what exactly does it mean when a researcher writes that “themes emerged”? Readers are expected to take the word of the researcher that he or she did a credible job in data analysis—that the themes that were developed and reported actually have some congruence (verisimilitude) with the reality of the phenomenon studied. Typically, little if any evidence is provided for readers to assess the development of the findings that are offered.

Second, although triangulation, member checks, and other qualitative techniques are mentioned frequently in design or methods sections of research articles, rarely is there evidence of exactly how these were achieved. They are invoked as if magical incantations, and readers must simply believe and trust the researcher—a leap of faith that is sometimes hard to accomplish. Many qualitative researchers will note that they used triangulation to increase the reliability of their research findings. Unfortunately, usually little if any evidence of this is found in the data analysis presented. Results of member checks are rarely reported, and where multiple sources of data are used, the data that are presented do not always adequately represent all of the data sources.

Third, rarely are readers privy to the protocols that are used to collect data. For example, many authors do not provide readers with the interview questions or any hint of those questions. Typically, the analysis that is presented actually leads readers to wonder what the data collection protocols included.

These three observations have led to the conclusion that, in all the discussions of validity in qualitative research, there is one major element missing—the public disclosure of processes. One way in which to achieve this public disclosure is through the creation and inclusion of visual data displays either in the body of the research report or in an appendix. Good qualitative research shows the hand and opens the mind of the investigator to his or her readers. The

efforts to do this might not always be successful, but there should be clear paths indicating the attempt has been made.

Documentational Tables

Three dissertation studies that employed visual data displays developed by Vincent Anfara, Jr., are used to illustrate the utility of the tables presented here. These tables document the relationship between a study’s research questions and data sources, the processes of theme development, and triangulation (the example provided deals with triangulation of data sources, but the same technique applies to other types of triangulation).

Conducted in middle schools, the first study (by Kathleen Roney) looked at characteristics of effective middle school teachers, the second study (by Kathleen M. Brown) focused on teaming and advisory programs in middle schools, and the third study (by Beatrice Mickey) investigated the principal as change agent and instructional leader.

Two disclaimers should be kept in mind when considering application of the approach described here. First, no claim is made that this approach ensures validity or trustworthiness. Second, the primary value of this approach rests on its potential to encourage researchers to make analytic events open to public inspection.

Data Collection: Designing Interview Questions That Address Research Questions

Research design can be defined as the logic that links the data to be collected to the initial questions that were asked. Keeping in mind that research questions provide the scaffolding for the investigation and the cornerstone for the analysis of the data, the process of forming interview questions on the basis of what truly needs to be known is a fundamental step. The following matrix (Table 1) presents readers with an excerpt of a study’s three major research questions and two sub-questions that served as the foundation on which the subsequent interview questions were designed. To the right of the two research questions that are presented here are codes (e.g., P3, T5, S4) referring to specific interview questions. P3, for example, indicates the third question from the interview protocol developed for the middle school principals (the “T” refers to teachers and the “S” refers to students). Constantly revisiting the central questions that the researcher hopes to answer is helpful in establishing a base of reference for the exploratory interview questions.

Roney’s multisite qualitative case study was devoted to defining the term *effective* as it relates to characteristics of middle-level teachers. Semi-structured interviews were the primary data-gathering

Table 1 Excerpt From the Table: Research Questions in Relation to Interview Questions

<i>Research Questions</i>	<i>Interview Questions</i>
1. What are the characteristics identified by principals, teachers, and students that middle-level teachers need to possess in order to be effective in teaching young adolescents?	P2, P3, P4, P6 T2, T5, T6, T7, T8, T9, T10 S1, S4, S5, S6, S7, S8, S10, S11
2. How do teacher preparation programs help or hinder the development of middle-level teachers and their feelings of effectiveness?	P4, P5, P6, P7 T2, T3, T4, T5, T6 S4, S5, S7, S8, S9
<i>Excerpt from Interview Questions Designed for Middle School Principals</i>	
P3. How would you describe an effective middle school teacher? Are there characteristics that middle school teachers need to possess or to develop in order to be effective middle school teachers? Is there a priority order to this list?	
P4. What qualities or characteristics are lacking in the middle school teachers that apply for teaching positions? What qualities or characteristics would you like to see in the middle school teachers that you interview?

Note: P = principal; T = teacher; S = student.

source used to help construct the participants' perspectives regarding the research questions. Because of this fact, it was imperative that the interview questions be carefully cross-referenced to the study's research questions. The researcher could not afford to conduct interviews and prepare transcriptions only to discover that the right questions were not asked. It needs to be pointed out that this type of matrix could just as easily show the relationship of other data sources (e.g., documents, observations, surveys) to the study's research questions. Using this type of matrix helps to ensure that the right questions are asked—or at least questions that will help to answer the study's main question(s).

Data Management: Conducting Data Analysis Through Code Mapping

The purpose of analysis is to bring meaning, structure, and order to data. Confronted with a mountain of impressions, documents, transcribed interviews, and fieldnotes, the qualitative researcher faces the difficult task of making sense of what has been learned. The purpose of this process is to present readers with the analytic process and salient themes. Table 2 outlines six themes that were developed as a result of the data analysis of Brown's study investigating how advisory programs either help or hinder the creation of a sense of care and community in middle schools. The following three research questions were used:

1. How do advisory programs help or hinder the creation of a sense of community and care for students and teachers?
2. How do the structural/procedural components of an advisory program hinder or enhance the creation of a sense of community?
3. What do teachers and students say is the most significant effect of advisory programs on school?

The data generated by qualitative methods are voluminous, and this process of sitting down and making sense of interviews and fieldnotes can be overwhelming. The purpose of Table 2 is to present readers with the larger consolidated picture that resulted from the reduction and interpretation of the data collected. As the reams of data were brought into manageable chunks (see first iteration in Table 2), and meanings and insights were brought to the words and acts of the participants involved, several themes

(see second iteration in Table 2) were generated. The third iteration (see Table 2) brings the analysis to a level of hypothesis or theory development. By making all aspects of this analysis process open to public inspection, a chain of evidence and an audit trail were constructed, and strengthened the dependability and reliability of this research.

Findings and Data Triangulation: Methods of Verification

A common criticism directed at qualitative research is that it fails to adhere to canons of reliability and validity. Internal validity is concerned with how trustworthy the conclusions drawn from the data are and the match of these conclusions with reality, whereas external validity refers to how well conclusions can be generalized to a larger population.

The aim of Mickey's research provided in Table 3 was to investigate the principal as change agent and instructional leader. Table 3 (an excerpt from the actual table) shows how multiple sources of data collection as well as multiple voices—the voices of teachers, teacher leaders, and administrators—were used to triangulate the findings of this study. Sources of data collection consisted of individual face-to-face interviews with key informants, observations, a questionnaire that was administered to a select group of teachers, and an examination of a wide variety of documents. Table 3 shows the major findings of this study listed under five categories and the four sources of data collection. Each data source provides corroborative evidence to verify information obtained by other methods. Each finding listed in Table 3 is corroborated by at least one other source of data—in several cases, three or more sources of data. In this particular study the use of multiple sources of data collection as a form of triangulation prevented reliance exclusively on a single data collection method and, thus, aided in neutralizing any bias inherent in a particular data source. In this study, triangulation of the interviews with questionnaires, observations, and document analysis, as well as triangulation of the interviews with one another (teachers ↔ teacher leaders ↔ administrators), rendered a holistic understanding of the situation and generally converging conclusions.

Conclusion

The primary point argued in this entry is that qualitative researchers must be held accountable for their actions

VISUAL ETHNOGRAPHY

Visual ethnography uses photography, motion pictures, hypermedia, the web, interactive CDs, CD-ROMs, and virtual reality as ways of capturing and expressing perceptions and social realities of people. These varied forms of visual representation provide a means for recording, documenting, and explaining the social worlds and understandings of people. It is important, however, to emphasize that visual ethnography is not purely visual. Rather, the visual ethnographer simply pays particular attention to the visual aspects of culture as part of his or her ethnographic efforts.

Until recently, mainstream social scientists have been steadfast in their belief that the written word is a superior form for representing most types of data. Qualitative researchers use narrative accounts, interviews, fieldnotes, and the like, all of which are textually based. Quantitative researchers depend on the written word in their survey instruments to collect their data; although some researchers generate numeric data directly from observations, this approach remains quite rare in the social sciences overall.

The social sciences do, nonetheless, take the verbal self-report as both true and a primary source; after all, such an account can be reduced to text. Ethnographers pay more attention than most to verbal (as opposed to written) information. But

here too the decided preference favors self-reports and words reducible to text. Yet every culture is composed of countless nonverbal images, signs, and symbols; these can be described in words, but one might question whether describing a sunset actually transmits the same aesthetic understandings as when one witnesses a sunset. Approaches to the visual in anthropology and sociology, as each applies itself to questions of culture and meaning, have developed in rather different ways and have evolved using different understandings of the visual.

Ethnography Defined

Ethnography has been around for a very long time, especially as practiced by cultural anthropologists, and although there are a variety of definitions for this term across the social sciences, there are certain elements that remain fairly constant. These include that ethnography is a methodology that involves a researcher immersing himself or herself into natural settings, either covertly or overtly, over some prolonged period of time. During this effort, the researcher will watch, listen, ask questions, and generally collect whatever data are available in an effort to better understand the issues and questions that are the focus of the research endeavor.

The History of Visual Ethnography

Historically, visual ethnography began in the post-positivist tradition where researchers provided photographs to support fairly traditional anthropological accounts in ethnographic studies. Photographs were little more than props used as visual aids in these endeavors; the “true” ethnography was the written narrative accounts of the researchers’ observations. This process grew into what has come to be called *visual anthropology* and was fairly common throughout the 1920s, in studies such as those by Bronislaw Malinowski, and through to the late 1950s.

Concern about the use of visual ethnography began to emerge, however, during the 1960s and through the early 1980s, centering on whether visual images and recordings could be expanded and used to viably support the observational research undertaken in the social sciences beyond anthropology. The concern of many social scientists of the time was that

visual data were too subjective, unrepresentative, and nonsystematic.

Beginning in the mid- to late 1970s, visual anthropologists began to focus their attention on ethnographic film and video, and they also began to question the idea of visual realism that had been the longtime anchor of visual aids in anthropological investigations. Visual sociologists who had also been developing their use of photography from the perspective of a realist paradigm began to react to feminist and postmodern critiques and shifted toward more reflexive and self-identifying orientations in their research, including the use of photography and film.

By the late 1980s and into the 1990s, the social sciences began to hear calls for a redefining of the relationship between researcher, informant, and participant in the form of collaborative and participatory approaches and research frameworks. These notions began to be incorporated into the emerging visual ethnography and to combine with the notion that the meaning of a photograph is constructed by the maker and the viewer—that both possess social understandings and interests in this photographic act. Thus, the photograph was a means by which its maker could express his or her feelings and understandings about something and could inform others both through the image and with further explanation and sharing. This creation, use, and sharing of meaning seemed to approach the same basic tenets of symbolic interaction that words had been associated with previously.

Visual Ethnography and the Social Sciences

Although visual ethnography is certainly used among a growing number of social scientific disciplines, it has flourished most among those disciplines with traditional ethnographic histories, namely, anthropology and sociology. Anthropology, in fact, has been somewhat more open to the use of photography than has sociology. One might speculate that this wider acceptance by anthropology reflects the reality that its traditional focus of research on non-Western cultures can be understood as *visibly* distinguishable from the focus on cultures of the West, where many of the anthropologists themselves originated.

Ethnographically inclined sociologists were also quick to obtain cameras and include photographs in their research efforts. But it is safe to assert that by the 1980s, visual anthropology was somewhat more developed than visual sociology. It was not until the past decade or so that visual sociologists began to innovatively develop the use of visual ethnographic methods and link these to theoretical underpinnings.

Visual Ethnography and Theory

The relationship between theory and methods is always important for understanding any type of research study. Similarly, understanding the theoretical underpinnings of one's method is also important in terms of how well this method will function in investigating a given research problem. Understanding the theoretical underpinnings of the visual ethnographic method, then, is crucial for understanding how images and processes connected with creating images are used to produce ethnographic knowledge. The existing literature on visual ethnography has been criticized for being too centered on "how to" types of descriptions of methods and analysis and being linked to a largely positivist realist framework. This orientation tends to express an image-based research methodology that offers fairly proscriptive frameworks, and that tends to objectify and seeks to make generalizations, but that in effect detracts from the very qualities and potentials that might emerge from the ambiguity and expressiveness of visual images gathered ethnographically. Such criticisms underscore the need for further work in visual ethnography that intentionally departs from the traditional positivist and realist orientations and toward newer more reflexive

and subjectively oriented approaches to making and understanding ethnographic images.

Thus, among the criticisms of visual ethnography found in the literature is that it remains unable to connect with social scientific theory or that visual sociology has only limited connections with sociological theory. However, the collaborative and participatory approaches that have begun to emerge with greater regularity across the social sciences, under the labels of *participatory research* and *action research*, place visual ethnography as a prime methodology for collecting and sharing data and connect visual ethnography with an assortment of social scientific theories associated with this orientation to research. These participatory orientations tend to be highly reflexive and seek to draw meaning and understanding from the various participants. Visual ethnographic techniques provide a means for empowering participants to reflect on their personal concerns and interests as well as to access and share their perceptions on various issues and problems that may exist in their lives. In effect, participants are able to negotiate their visual meanings, thereby expressing their cultural understandings and, to a lesser extent, the production of meaning as attached to aspects of people's social worlds.

The Use of Visual Ethnography

The idea that everything social scientists are interested in studying exists in language or text, or is expressible in those ways, is questionable; the notion that one can explore these interests only by using words or reading texts is simply an inaccurate and rather uncreative viewpoint. To be sure, the use of visual and other methods of data collection may necessarily overlap, but this should not invalidate or diminish visual ethnographic data. Let us consider some of the ways in which visual ethnographic data may be used.

Photo Elicitation

The use of photographs or a film may be undertaken as part of what is sometimes referred to as *photo elicitation*, where the researcher asks the participants to discuss the meaning of photographs or a film specifically created or selected by the researcher with the idea of using the photographs or film to elicit information from the participants. Photographs may also belong to the participants, such as family photographs and home

movies, or may be gathered from other sources, including photo archives, newspapers, television images, and library collections. Typically, the participants' comments and analysis of these visual materials are recorded on either audio- or videotape, providing a means for analysis at a later time.

Rephotography

A slight variation on the photo elicitation technique is rephotography. This technique involves collecting photographs taken at some time in the past and making second images at the current time to reveal how things have (or have not) changed. By asking the participants about these changes, one is granted access into their social understandings about social changes, natural disasters, political causes, war, and the gamut of other social and culturally related elements that may be depicted by various photographs.

Photovoice

The photovoice technique involves a researcher giving the participants cameras and asking them to photograph certain aspects of their lives. After photographs have been taken, the researcher and participants come together to give the latter an opportunity to discuss and explain their photographs—or to literally give voice to their photographs. This technique provides a means for an investigator to gain perceptual access to the world from the viewpoints of individuals who have not traditionally held control over the means of imagining the world. The photovoice technique may involve single photographs of someone or something or a series or sequence of photographs.

Visual Narratives

To expand on the idea of a series or sequence of photographs as data is actually to introduce the concept of the visual narrative. Sociologists use verbal narratives to offer an account, tell a life story, or delineate various aspects of culture. On the microanalysis level, the visual narrative view is wholly consistent with symbolic interaction. Symbolic interaction seeks to orient researchers toward the process of interaction based on interpretations. Visual materials are frequently offered as narrative in form. The most common visual narrative is film (or other media forms of motion pictures) or even single photographs taken sequentially (often many

per second) that, when viewed quickly from left to right, seem to recreate the movements that the eye would see if the images were in motion. When viewed and discussed, these visual narratives can invoke a variety of feelings and represent a number of meanings that reflect an individual's perspective on his or her life, culture, and social reality.

The Future of Visual Ethnography

The use of visual images and visual ethnography is becoming more common, and as this occurs it will gain by being written about more frequently and being theorized more rigorously. Part of the growing acceptance of visual ethnography is likely to stem from the wider acceptance and willingness of various disciplines to embrace reflexivity in their methods and to explore how subjective awareness and experience play a role in the production of knowledge.

There are at least two major tracks that visual ethnography may travel in the future. The first is the fast track, where visual ethnography leads an energized social science forward toward innovatively ethnographic and theoretically interdisciplinary new technologies that promise various ways in which to bring the changing visual experience into the production of social sciences and an understanding of the visual dimensions of society.

If one follows this first possible track, it will involve incorporating visual methods of data gathering and analysis into ethnography to a greater extent across disciplines. As implied, visual ethnographic techniques are not paradigm dependent. Visual methods have been employed extensively, for example, by social scientists examining how women sociologically identify their own roles in the family, by those running social psychological experiments, by researchers trying ethnomethodologically to capture society as it is accomplished, and by Marxists recording accounts of the exploitation of laborers.

The other track is the slower, more plodding one, where the social sciences remain largely unconnected with the rapidly changing technological world around them and become only mildly interested in studying society as a visually interesting and observable phenomenon. The advances in technology, then, have continued, and will continue, to have an influence over which track visual ethnography is likely to travel.

VISUAL NARRATIVE INQUIRY

Visual narrative inquiry is an intentional, reflective, active human process in which researchers and participants explore and make meaning of experience both visually and narratively. Visual narrative inquirers work from a position where experience is an undivided continuous interaction between humans and their environments that includes thoughts, feelings, doings, and perceiving. Visual narrative inquiry builds from a view of narrative inquiry as a study of experience as story and as a way of thinking about experience. Narrative inquiry as a methodology entails a narrative understanding of experiences. Visual narrative inquiry adds the layer of meaning so that photographs and visuals become ways of living and telling one's stories of experience.

The Field of Narrative Inquiry

Relation to Narrative Inquiry

The field of visual narratives has developed over the past 10 years or so as visual narrative inquirers have included images, in particular photographs, to deepen the ways in which researchers can understand experience. Visual narrative inquirers bring photographs into the metaphorical three-dimensional space of narrative inquiry with its dimensions of sociality, temporality, and place. Each discipline and

field of study brings different ways of understanding and different contexts of visual study of experience to the methodology of narrative inquiry.

Philosophical Underpinnings

The origins of visual narrative inquiry are located in John Dewey's views of experience. Thus, for Dewey, humans are not "subjects" or "isolated individuals" who need to "build bridges" to go over to other humans or the things of nature; rather, humans are originally and continually tied to their environment, organically related to it, changing it even as it changes them. Humans are fundamentally attached to what surrounds them. The Deweyan view of experience is further informed by the works of philosophers such as Mark Johnson and David Carr and of literary theorists such as Carolyn Heilbrun and Mary Catherine Bateson. The works of Judy Weiser, Jo Spence, and Robert Ziller also inform explorations of visuality within narrative inquiry.

The Process of Visual Narrative Inquiry

Working within the relational methodology of visual narrative inquiry, researchers become aware of the intentionality and the ethics of listening and seeing the stories that children, youths, and adults share through the process of the inquiry. There is a need for visual narrative researchers to stay engaged with the ongoing ethical negotiations of working visually. This also calls attention to how visual researchers rely on a visual world that is endless and constantly changing: What is missing? What is dismissed? What is not seen? Visual narrative inquiry is a recursive process of engaging with participants in taking photographs and telling stories of those photographs over time. Visual narrative inquirers, as they engage with participants, discuss the possibilities and limitations of composing photographs, collecting photographs, and conversing with/through/about photographs.

Narrative inquiry is always composed around a particular wonder or puzzle, and visual narrative inquiry also begins with a sense of puzzle or uncertainty. As with narrative inquiry in general, visual narrative inquiry begins with the researcher's autobiographical lived experience, and the researcher's own stories of experience shape the relational space with participants. In the visual narrative inquiry process,

the shared photographs and conversations are viewed and re-viewed over time. Visual narrative inquirers listen and re-listen to conversation tapes, and look and re-look at participants' photographs, as they turn both toward the inner and the outer—the personal and the social—of both their own lives and their participants' lives to reflect, meditate, and inquire into the storied experiences that are co-created with participants and researchers. Many visual narrative inquiries work with participants who are active in their subcultures. Visual narrative inquiry has the possibility of deepening insight into what is evaded by inquiring into the stories and photographs of everyday experiences of participants who are typically not seen or heard by those outside of the particular subculture.

In the Field

Like narrative inquiry in general, visual narrative inquiry follows the narrative inquiry process of living in the field, composing field texts, and composing research texts. As a visual narrative inquiry begins, the researcher meets with participants and addresses ethical issues of working with cameras. Informed consent is obtained from adults and, where necessary (or mandated by legislation), from parents of participants under the age of consent, in which case the researcher must also obtain assent agreements allowing the researcher to work with their photographs and taped conversations. As part of the ongoing negotiation with participants, the visual narrative inquirer stays open to further negotiations, realizing that there are shifts and changes, including negotiating relationships, reevaluating purposes, and negotiating transitions before and after narrative inquiries.

Photographic Field Texts

The visual narrative inquiry process often involves working with participants through a series of four “camera works” and numerous research conversations about their camera work. Using camera work techniques in the visual narrative inquiry process means that the researcher's primary position is to listen to and encourage participants' own personal discoveries while exploring and interacting with the ordinary, personal, and family photographs they view, make, collect, remember, or even only imagine; in 1998, Hedy Bach described it as listening and looking for “a recurring rhythm, a story that has been told more than once,

a photograph taken and retaken, a narrative series” (p. 294). The four camera work techniques in visual narrative inquiry are interrelated and interdependent, and they work best when combined synergistically. Analysis of the photographs is based on input that comes from the participants, guided by the researcher's photo-stimulated questions, when the images and stories are discussed during the research conversation. In most visual narrative inquiries, multiple photographs are taken. The four camera works are creating projective photographs, composing self-portraits, collecting culture, and looking at family albums as pictorial communication. Visual narrative inquiry, through the use of these camera works, carries a sense of a search, a “re-search,” a searching again. As part of visual narrative inquiry, the relational aspects are sustained over time and place. Participants' visual narrative field texts (their photographs and stories) have a sense of being full and of coming out of a personal and social history—that which matters to them. A full description of the four camera works can be found in Bach's *A Visual Narrative Concerning Girls, Photography, Curriculum, Etc.*

Visual Narrative Composites: Research Texts

Through multiple conversations with photographs and in writing and rewriting around the photographic field texts, visual narrative inquirers create photographic research texts—the visual narrative composite—by juxtaposing historical, philosophical, and theoretical positions concerned with the reading of participants' photographs and stories within history, memory, culture, geography, language, and identity. One format is a narrative form created in columns with the first column for an image, the second column for the participant's story, and the third column for the researcher's autobiographical story (including the theories that inform the researcher's interpretations).

Ethics

There are pervasive ethical issues in visual narrative research. Images are vulnerable; that is, a photograph holds no steady fixed meaning. The inquiry space, with its attendant ambiguity, highlights the importance of visual narrative inquirers' awareness of where participants and researchers are placed at any particular moment—temporally, socially (in terms of both

the personal and the social), and in place. In any story told, multiple selves speak, and these selves are temporal productions residing in both the present and a reconstructed past. Thus past, present, and future, as contained in stories, can be seen as productions or creations that may intersect and overlap in nonlinear, unfolding, and enfolding ways. Just as living a life is unbounded, visual narrative inquiry is open to possibilities and imaginings.

VISUAL RESEARCH

Qualitative research focuses most readily on spoken and written words. This preoccupation with the complexity of language was evoked by Alan Peshkin, who described the task of the qualitative researcher as “making words fly.” In contrast, visual research focuses on nonlinguistic images. Pictures may be used as a source of data, as a method of data analysis, and as a means of data representation. There are multiple research methodologies for conceptualizing such work. Ultimately, the methods for the analytic use of nonlinguistic visual data can have implications for all qualitative researchers, even those who do not seek to incorporate visual images in their studies.

Philosophical Antecedents

Historically, visual images have been regarded as unreliable. Plato argued that all visual images are essentially lies—pale imitations of a reality they seek to reference. Images were not trustworthy, and the individuals who trafficked in them were dangerous frauds. During the 17th-century scientific revolution,

René Descartes reinforced this classical distrust of the visual by arguing that sight, or any other perceptual sense, is deceptive.

This prejudice in Western thought against the visual began to change during the Enlightenment—first through the work of the British empiricists and then, during the mid-18th century, with the introduction of the new philosophical discipline of aesthetics. Derived from the Greek verb for *perceive* (and the grammatical rules that govern its conjugation), aesthetics suggests a form of mediated understanding with neither viewer nor object controlling the conditions for knowing.

Although this initial concept of aesthetics was soon supplanted by interest in discriminations of preference and judgment, understanding the visual as a form of mediated understanding continued. During the 20th century, this line of inquiry could be seen in Martin Heidegger’s and Maurice Merleau-Ponty’s phenomenological works, which contributed to the interpretive turn in postmodernism that encouraged audiences to derive multiple readings from a single text.

Methodological Approaches Toward the Visual

There is a spectrum of methodological approaches to the use of the visual in qualitative research. At one end of the spectrum, which may be called *objective*, is the use of images as a form of data collection. At this point on the continuum, photographic images, or ethnographic films, are considered to be objective renderings of reality. Analysis of these images, through language, reveals layers of semiotic meanings. At the other end of the spectrum, which may be called *generative*, are images that are created by the researcher through the process of data collection and analysis. These images may be autonomous and require no further explication through language. A midpoint on this spectrum may be called *formative*, which applies strategies for reading latent images to lived experience. This view argues that perception inherently requires framing and focusing. Thus, our experience of objective reality is always constrained by conscious or unconscious schematic filters.

A researcher may incorporate multiple positions from this spectrum and combine aspects of the objective, formative, and generative within a single piece of research. Therefore, it is important that the researcher declare how the visual is used in the process of

inquiry. If differing visual methodological approaches are incorporated, then the researcher must either decide to communicate clearly to the readers when and why these shifts are occurring or decide that the struggle to sift between these changing perspectives is a task that the readers must undergo to experience and mediate the research.

The Objective Approach

Photography and filmmaking emerged relatively simultaneously along with the formal academic fields of anthropology and sociology. Methods for collecting and analyzing visual data are interwoven deeply into both disciplines. Initially, photography was associated with a factual rendering of a given place and time. Initially photographic evidence was assumed to benchmark a “fixed” reality. Later photographic evidence showing how a culture might have changed over time was interpreted as a deterioration of an “authentic” culture.

During the 1970s, this approach to photographic evidence was supplanted by both a more complex view toward the dynamism of cultures and a critical investigation into how the photographic lens selectively frames, omits, and emphasizes information. The camera was no longer regarded as a neutral object that recorded reality. Attention shifted to how an image was constructed. In what ways might a researcher have actively, or passively, manipulated and staged a scene before the photograph was taken—with or without the collusion of the participants? Such manipulations are particularly evident in “documentary” films produced for distribution through popular mass media. To fully understand the visual representation, not only is the visual evidence analyzed, but also the underlying contexts and conditions through which the image was conceived, created, and marketed are analyzed.

Significant ethical and legal issues arose out of the critical examination of photography and filmmaking. The ethical context of how an image was created and how it is presented for viewing is now a major concern in the analysis of any image. This is evident in current institutional review board protocols and publishing contracts. Thus, reflexivity is now essential to visual research. Reflexivity requires self-inquiry by the researcher: Who is taking this image? Why is this image being taken? Who is being framed? Who is telling the story of what is represented in this image? Has the individual pictured consented to, or participated in, this framing?

Example of Objective Visual Research: Fifth Grade, Integrated Visual Art and Literacy Lesson, Chase Street Elementary School, Athens, Georgia. The blackboard records the major ideas of the research along with the visual images that students have studied and to which they have responded. Analysis of the visual image can reveal the curriculum studied and student engagement.

The Formative Approach

Research methodologies are linked to how specific academic disciplines frame inquiry and the production of knowledge. During the 1980s, Elliot Eisner applied methods for the analysis of visual art to the analysis of human interactions within the context of schools. In addition to noting semiotic detail, the critical methods in visual art reveal meaning through attention to subtle qualitative relationships and the felt reactions they generate. For Eisner, both symbol and feeling were critical to understanding the lived experience of a classroom. His methodology of educational criticism cast the researcher in the role of the art or movie critic. To *perceive* (aesthetically understand) the classroom, the critic must be a connoisseur—a person whose insight into mediated reality helps others to perceive what otherwise would have gone unnoticed.

The analysis of visual culture and the meanings that individuals make within their visual environment offer other methodological approaches to formative visual research. Here the researcher is not a critic but rather is cast more in the role of director or producer. For example, the methodology of visual narrative inquiry puts the camera into the hands of the research participants and allows them to frame and interpret the world through the visual signs they see around them. The

participants then select and order these images into forms that represent personal meaning. This shifts the authority of authorship and interpretation to the participants and away from the researcher. With the ubiquity of single-image cameras and digital video in cultures throughout the world, research participants are arguably equally skilled in representing themselves and their lived experiences through images as they are in relating these experiences through language via traditional interviewing methods.

Visual culture research examines the everyday, which includes the visual signs and markers that we create as entertainment or social control. The visual also considers how we present our bodies and how these are read in shifting contexts. Often visual objects, presentations of the body, and actions are created to mask aspects of reality. Sites of such research might include the visual attraction of downtown Las Vegas, a shopping mall, and the staging of an arena rock concert. Research may also focus on what we do not wish to see. For example, Stephanie Springgay has analyzed (through both words and images she has created) the mediated understandings that emerge at the sight of her breast-feeding her child at academic conferences, in family restaurants, or on airplanes.

Visual culture research can aid in the critical analysis of skillful, yet insidious, visual propaganda. An illustration of this is the “Sambo” imagery, which portrays African Americans as childish, slow-witted, and irresponsible, that was widely pervasive throughout the United States during the first half of the 20th century. It manifested itself through product advertising, popular media (including radio, live action movies, and animated cartoons), and collectible figurines. Visual culture research documents and explores the continuing legacy and presence—and even the cultural repurposing—of this stereotype.

The Generative Approach

Photography and film are just two media within the visual arts. Visual research can be conducted through a variety of visual media, including painting, sculpture, performance art, collage, and digital art. The Centre for Arts-Informed Research at the Ontario Institute for Studies in Education of the University of Toronto refers to researchers who choose to represent their data analysis in artistic forms as “scholARTists.” For example, Sara Promislow uses the visual method of collage as a means of organizing and analyzing her

data. Similarly, researchers at the University of British Columbia have developed the methodology of a/t/ography, which also relies heavily on the making of visual art as integral to the process of research, a document of that process, and a form of analysis of the process. Art making may include the researcher and/or research participants maintaining visual journals that record constructed reflective visual images rather than simply reflective words.

Graeme Sullivan argued that the act of creating a work of art can be research by engaging three domains of significance: empiricist, interpretivist, and critical. In the *empiricist* domain, the work of art is assessed by its correspondence to an external reality that can be referenced and compared. In the *interpretivist* domain, work is assessed by its ability to convey personal meaning to both the creator and the viewer. Here, in contrast to the empiricist domain, a multiplicity of meanings may be present—perhaps even desired. The *critical* domain moves individuals to social action. Official religious or political art designed to motivate the viewers toward “best practice” exemplifies such artwork.

A work of visual art might begin in any one of these three domains, but to be considered research it would need to reach out to and interact with at least another domain. The direct or indirect effectiveness of the pathways, or braids, through these domains determines the quality of the artwork as research. This complex web of meaning that lies behind the making of a visual image is necessary to move art from an image to be appreciated to an image that conveys and engages linguistic and nonlinguistic inquiry.

Implications of Qualitative Research

Writing itself is increasingly affected by the visual as it is linked more closely to website design and presented through the internet rather than through the traditional bound book. As never before, the page is both text and visual image (even if the page consists only of letters). Constructing texts as strings of hyperlinked individual pages that the readers can arrange visually challenges the linearity of texts and viscerally reintroduces the concept of aesthetics as mediated knowing.

Visual research inherently explores the implications of creating, documenting, and analyzing data. Visual research reminds us that data are not found; rather, they are constructed. It questions the ethics of

research to frame an issue, the power of participants to give voice to their own narratives, and the role of the readers in creating—rather than receiving—personal meaning from a work of research. These issues have implications for all qualitative researchers. Therefore, the inclusion of structured training in the visual—the objective, the formative, and the generative—is a challenge to the preparation of future qualitative researchers in mediated understanding.

VOICE

Voice in qualitative research refers to the multiple, and often conflicting, interpretive positions that must be engaged in the representation of data. There is a long-standing tradition in deductive research methods of amplifying the voice of the researcher to the limitation, or at times the exclusion, of the voices of those being studied. This approach is grounded in the conviction

that objective perspectives are methodologically feasible and can yield a single univocal truth. In contrast to this position, a range of approaches, including post-structuralism, feminism, and various strands of post-modernism, call attention to the many intrinsic tensions that exist between the voices of researchers and the voices emerging from the data.

Social scientific research necessarily imposes a certain power over those being studied. Accordingly, qualitative investigation demands explicit consideration of the power relationships that exist between researchers and their “subjects.” Given that qualitative research frequently involves the study of marginalized persons, these relationships must be considered throughout the data collection, analysis, and writing processes. Typically, a researcher aims to point out certain features of “original” data. Theories of voice recognize that researchers’ interpretations always differ to some degree or another from the original intended meanings. Furthermore, these theories generally hold that to engage voice is to take into account the varying ways in which reality is constructed and interpreted.

Ensuring that the voices of participants are holistically represented from the data requires paying attention to these constructions and interpretations and also epitomizes our ethical responsibility to our sources. That said, ethically sound research does not necessarily require validation of interpretations from collaborators; such validation might not be possible, particularly when data sources are textual or historical. Acknowledging and understanding participants from their own authentic positions is an integral component of data analysis and interpretation. However, the complexities of voice also necessitate a reconciliation of the reflexive and interpretive dynamics that expose meaning in the data, and that are genuinely and intrinsically present, so that research represents both the scientist and the participants.

Although explanations of the phenomenon of voice vary, they share a common conception that voice is more than a metaphor for individual perspective. As such, these explanations seek to understand voice as part of a reciprocal creation of meaning intrinsic to and inseparable from any kind of social scientific research. The qualitative researcher, therefore, must strive to understand the reality of voice as a process of the lived creation of meaning and not merely as a vague ethical gesture or an attempt to understand the opinion or perspective of one’s sources. Ultimately, the notion of voice encompasses

the interpretive confluence of participant and researcher and all of the reflexive processes following from it.

VULNERABILITY

Vulnerability in qualitative research applies to potential conditions of research participants in which the participants, by virtue of some psychological, cognitive, physical, medical, legal, socioeconomic, or age-related status, are deemed to be more susceptible to lack of full understanding, manipulation, exploitation, or some other possible harm within the research process. Vulnerability often refers to special categories or subpopulations of participants who are regarded, by virtue of their status, as requiring special protections within the research process. Examples of vulnerable subpopulations include pregnant women, inmates, minor children, persons with psychiatric disorders and/or other cognitive impairments, persons with HIV-seropositive status, persons with compromised legal status, and persons with low socioeconomic status. Vulnerability in research participants generally suggests an impaired or reduced capacity to provide true informed consent to participate in a research study. Concern for research ethics with vulnerable populations, however, is not limited to informed consent; it also includes all decision points throughout the entire research process. The ethical principle of care or the duty to care is especially

important when working as a qualitative researcher with vulnerable populations.

Although the term *vulnerability* is generally used to refer to the condition of research participants, researchers themselves are also potentially vulnerable within the context of conducting qualitative research and are subject to susceptibility to various forms of institutional and personal pressure. This entry discusses the potential vulnerability of both research participants and researchers.

Decision Making, Stigma, and Special Protections

Assessment of research participant vulnerability is important because it potentially affects the legitimacy of informed consent. Informed consent is particularly important in qualitative research because of the kinds of data collection techniques that are widely used, including observational techniques, in-depth interviews, oral histories, diaries and journals, conversations and dialogues, and immersion in the field leading to involvement with human participants over sometimes lengthy periods of time. Such data collection techniques in qualitative research are likely to lead to significant personal disclosures, and research participants must be capable of freely consenting to take part in such interactions with the researcher. Because many qualitative research data collection techniques require face-to-face involvement between the researcher and participants, anonymity often is not possible; instead, a relationship of openness, trust, and confidentiality must be developed for the research to proceed. Any psychological, cognitive, physical, or medical condition, or any legal, socioeconomic, or age-related status, that impairs or reduces the ability of a research participant to provide free and fully informed consent compromises or nullifies the trustworthiness of a research project. Qualitative research that goes forward with vulnerable participants who are unable to provide free and fully informed consent violates the rights of human subjects.

Minor Children

Because of the differential in power relationships between adults and children, children are afforded greater protections in qualitative research. Children have less autonomy and self-determination than do

adults because of children's physical, developmental, and psychological levels of maturity relative to adults. Legally, in the United States, they are also not authorized to enter into contracts until 18 years of age in most states and, therefore, must have a parent or legal guardian sign contracts on their behalf. In other countries, where such legislation does not exist, children may be able to do so. In the case of children and research, children may be required to have a parent or legal guardian provide the informed consent to participate in the research study, but this varies by country and by the ethics guidelines used in that country. Increasingly, however, a focus on the rights of children has resulted in growing awareness that children must also be given an opportunity to decide whether they wish to participate in a particular research project and are frequently asked to give or sign an "assent" to participate in research. Simply put, assent is a child's permission to participate after having been given an explanation of the research project, its purpose, and its methods. The assent does not supplant the informed consent signed by the parent or legal guardian, but it is an additional document providing a child's consent that is sought from children who can understand and reason, usually around 7 years of age or older. A qualitative researcher who obtained an informed consent to participate in a study from a parent on behalf of a minor child but who was denied an assent from the prospective child participant would have a difficult time justifying the inclusion of that child in the research project.

Inmates

Special concern for inmates as research participants can be traced to the Nuremberg Code developed by a military tribunal after World War II to prevent the repetition of the inhumane treatment, torture, and death experienced by captive prisoners in Nazi concentration camps who were subjects of medical experimentation. The Nuremberg Code contained a foundation for current ethical guidelines in the conduct of research, especially research with vulnerable groups.

Voluntary consent is the cornerstone of the Nuremberg Code, followed closely by prevention of unnecessary suffering and death or disability, the obligation to terminate the research if it is likely to result in harm to the participants, the requirement that only highly qualified persons conduct research, and the principle that research should advance the welfare of society.

So far as prisoners or inmates are concerned, the question of whether consent can be freely offered within a context of extreme limitation of human freedoms is a serious one. The possibility that inmates might think they will gain benefits in the form of favors from the correctional institution, that inmates might think participating in research will reflect favorably on their prison records in the future at parole hearings, or that inmates might have been pressured or coerced by other inmates into participating in the research makes proceeding with research with inmates particularly complex in terms of the issue of free and informed consent. The prison population is also vulnerable in that inmates' voices about their own experiences are seldom heard "on the outside." Qualitative research provides a singular opportunity to help inmates tell the stories of their experiences and aspirations. Research with the inmate population can go forward, but only with due consideration for the complexities of obtaining informed consent within a context of absence of freedom.

Pregnant Women

The concern about pregnant women in research originated with respect to biomedical research involving pregnant women and fetuses that may result in harm to either or both. The thousands of "thalidomide babies" in North America and Europe resulting from the administration of the experimental drug thalidomide to pregnant women during the 1950s and 1960s only heightened the concerns about biomedical research with pregnant women. These thalidomide babies suffered high rates of limb deformities and premature death. Although pregnant women are classified as a vulnerable subpopulation by the Basic Health and Human Services Policy for Protection of Human Research Subjects, which regulates both biomedical and behavioral research in the United States, they are much less vulnerable as participants in qualitative research than as participants in biomedical research. In fact, qualitative research, with its focus on meaning and everyday life, presents many opportunities for qualitative researchers and pregnant women to explore and describe the experiences of pregnancy and birth within particular cultural and community contexts. However, ethical concerns and vulnerability of pregnant women participants in qualitative research are not eliminated. For example, if qualitative researchers were studying the experiences of pregnant women in the midst of

deciding whether to terminate their pregnancies, they would need to be very mindful of the ethical principle of self-determination in their research practice to avoid influencing pregnant women's decisions. Such concern for a pregnant woman's right to self-determination would be an example of a qualitative researcher acting according to the ethical principles of respect for persons and the duty to care.

Persons With Psychological and/or Cognitive Impairments

In assessing vulnerability to research risk or harm, persons diagnosed with psychological impairments and/or cognitive defects cannot be lumped into a single group with the same risk factors. Persons in this category must be assessed on an individual basis in relation to their current abilities to understand and make decisions. Mental illnesses, for example, tend to run along a continuum of severity; persons with these disorders can be in an acutely ill state with severely impaired reality contact and decision-making ability, they can be in full remission with high functioning, or they can be somewhere in between those ends of the continuum.

The following questions can be vital in assessing the ability to give free and informed consent to participate in research for a person with psychological and/or cognitive impairments:

- Does the person understand the purpose of the research and what is expected of him or her within the research process?
- Has the person demonstrated an ability to make independent decisions by asking questions pertinent to his or her role and participation in the project?
- Does the person appear to be focusing on and attending to the information presented by the researcher?
- Is there any evidence of undue coercion that might influence the person's decision to participate in the research project?
- Does the person understand that he or she is free to discontinue participation in the research study at any time with no penalty?

Psychiatric diagnoses, such as bipolar disorder and schizophrenia, or the diagnosis of neurodegenerative or neurocognitive disorders, such as Lou Gehrig's disease and Alzheimer's disease, should not automatically rule out people's participation in qualitative

research studies. The ethical principle of respect for persons requires that people with psychological and/or cognitive impairments, which represent potential vulnerabilities, not be excluded from research participation; rather, they must be given the opportunity to participate if they wish under conditions of greater protection and consideration for the special needs they may have.

HIV-Seropositive Persons and the Issue of Stigma

Persons who are HIV seropositive are generally regarded as in need of special protections during qualitative research because of the social stigma involved with their diagnosis and the added importance of confidentiality in doing research with any person who has a stigmatizing condition or who is in a stigmatizing situation. Stigma is an important issue in research because those persons who have stigmatizing conditions or who are in stigmatizing situations are already vulnerable to social isolation, ostracism, and shunning. During the early days of AIDS, those who were HIV seropositive were particularly vulnerable to stigma and its associated isolation. Other examples of stigmatizing conditions today include homelessness, especially for those who are newly homeless, and those whose homes have become infested with bedbugs. Such persons tend to hide their status from others because of their vulnerability to social ostracism. Qualitative researchers have historically tended to study persons with stigmatizing conditions and situations because of the unique perspectives they bring to the understanding of ostracism and social isolation. People who have stigmatizing conditions or who are in stigmatizing situations require special protections for confidentiality and respect and care for their sensitive status within the research process.

Guidelines for Protection of Human Research Participants

The infamous Tuskegee Experiment by the U.S. Public Health Service ultimately led to the formation of institutional review boards (IRBs) for the protection of human subjects at universities and other research institutions. The Tuskegee Experiment, which began in 1932 and lasted through 1972, was a longitudinal study of approximately 400 African American sharecroppers with syphilis who were not

told their diagnosis but instead were told they had “bad blood.” Moreover, the men were not given penicillin even after it became widely available during the mid-1940s as an extremely effective treatment for syphilis. The Tuskegee sharecroppers were an example of a vulnerable group based on low socioeconomic status, lack of education, illiteracy, and lack of access to health care information and effective treatment.

Reaction to this Tuskegee Experiment led to the 1979 Belmont Report, *Ethical Principles and Guidelines for the Protection of Human Subjects of Research*. This report outlined the boundaries between practice and research, described basic ethical principles governing biomedical and behavioral research with human subjects, and discussed applications of those ethical principles in relation to informed consent, risk–benefit assessment, and subject or participant selection and recruitment. The Belmont Report was designed to provide a template for making research decisions by applying basic ethical principles of respect for persons, beneficence, and justice so as to protect all human subjects, in particular vulnerable groups.

The principles of the Belmont Report formed the basis for the U.S. Department of Health and Human Services (HHS) regulations governing the protection of human subjects in biomedical and behavioral research. In 1991, the HHS published *Basic HHS Policy for the Protection of Human Research Subjects*, which translated the principles laid down in the Belmont Report into rules and regulations governing the practice of research with human subjects. These rules were most recently revised in 2005. The abusive experiences of a vulnerable group in a research experiment, the Tuskegee sharecroppers, have led directly to the principles and practices established by the U.S. federal government for the protection of human research subjects, and these principles and practices are those that are endorsed by IRBs throughout the nation and in many other countries around the world. In a further development that would prevent any future repetition of an event similar to the Tuskegee Experiment, the World Medical Association in 2000 banned the use of placebos in medical research wherever effective treatment exists. This ban on placebo use is part of the Declaration of Helsinki. Although this ban on placebos states a newly framed ethical principle—not a law—and is specifically related to medical research, it demonstrates the trend toward protection of human subjects in all research and the ethical imperative of the duty to care.

Researcher Vulnerability

Although care for vulnerable research participants must be the central focus of qualitative researchers’ ethical practice, the researchers themselves are not immune from vulnerability as a condition of their work and context. Researcher vulnerability potentially emanates from institutional and/or personal pressures, contextual and legal factors, and issues regarding boundaries between the qualitative researcher and participants and the potential for dual relationships that are harmful to both the researcher and participants.

Institutional pressures on qualitative researchers may increase vulnerability to taking shortcuts in data collection and/or analysis because of pressures to obtain or keep a grant, pressures to report findings prematurely, or related pressures to obtain or keep a job. Qualitative research is not always high on a funding institution’s research agenda and, therefore, may leave qualitative researchers without necessary funding to push forward their own research agendas and conduct their work. Qualitative researchers often work within academic settings where the pressure to “publish or perish” is well known and may leave researchers vulnerable to “quick and dirty” research that is without much significance or benefit to society. These pressures and contextual factors represent potential and not inevitable vulnerabilities that are best addressed by researcher awareness of their presence and implications.

Because no legal privilege guaranteeing confidentiality exists between the researcher and participants, the researcher who has gathered rich detailed information may be challenged to reveal that information in a legal setting. For example, the qualitative researcher working with an inmate population may obtain information about a participant’s criminal history that may then be subpoenaed by an attorney or a court. The possibility of legal demands for a qualitative researcher’s work product is clearly a source of potential vulnerability for qualitative researchers, especially those who work with marginalized populations such as inmates. However, the legal context that surrounds such possibilities remains a contested area in many countries.

Maintaining boundaries in the qualitative researcher–participant relationship may be especially problematic because of the nature of some of the widely used data collection methods. Participant observation, for example, requires that the researcher function not only in the role of data collector and researcher but

also in other roles dictated by the nature of the researcher's participant status. Such shifting roles and positions for the researcher requires careful attention to the nature of the relationship between the researcher and participants and to the complexities of informed consent in such a context. Commitment to ongoing reflexivity throughout the research process is also important to avoid boundary crossings that are harmful to the researcher and/or participants.

Qualitative researchers spend more time more intensely with participants than do other researchers and, therefore, are more vulnerable to the development of relationships that fall outside of the research relationship. Such dual or multiple relationships are particularly harmful when the researcher is not mindful of the differences in power, status, role, and life experiences, and possibly also education and income, between himself or herself and the participants as well as the implications of such differences. For most qualitative researchers, sexual involvement with a research participant represents the most troubling and most complicated dual relationship. Vulnerability to such relationships is a reality for the qualitative researcher because of the intimacy that may be generated throughout the period of fieldwork or intensive interviewing.

Finally, because qualitative researchers study some volatile questions and issues requiring entry into physical spaces that are not part of their everyday worlds, such as drug houses and gang territories, they must consider their vulnerability to physical harm and take steps to protect their own safety. Safety is also an issue when asking participants questions that may generate anger and hostility. Actively thinking through one's work context and making plans to optimize personal safety during data collection and fieldwork in high-risk

environments can reduce a qualitative researcher's vulnerability to personal harm.

For research participants, vulnerability can be identified through differentials in power, status, access to information and knowledge, impaired decision-making abilities, limited or reduced freedom to provide informed consent, pressures generated by stigma and resulting social isolation, and any form of coercion. The effect of an identified vulnerability is to obligate the qualitative researcher to provide special protections relative to the particular needs of the participants and to ensure that the duty to care is exercised. For the researcher, vulnerability can be identified through personal and institutional pressures that might jeopardize judgment and decision making and by the potential for harmful boundary crossings and dual relationships not in the best interests of either the researcher or research participants. Ethical standards in research are evolving continuously, as are the responses by qualitative researchers to address changing standards and to care for vulnerable persons who may become research participants.

WRITING PROCESS

The writing process is the series of sequential steps a writer or researcher follows to record experiences, observations, data, and research. The process of writing, by definition, suggests an ongoing commitment to editing, multiple revisions, self-reflection, and the development of characters, scenes, and findings. While the writing process references the journey between producing and revising a text, it also involves the events leading up to writing and the closing stages that follow. This entry focuses on the writing process as a series of steps leading toward progress in qualitative research projects. The process of writing follows a plan, although not always chronologically or deliberately, that begins with an idea and ends with a final product.

Writing Stages and Strategies

There are innumerable ways to write effectively, but many experts and seasoned professional writers have the same opinion in regard to the procedures they follow. These procedures are consistent with any writing project, including but not limited to academic articles, books, personal narratives, fiction, poems, ethnographies, and other nonfiction text. The step-by-step approach to writing varies, but these different approaches share the same elements. The writing process can be divided into three distinct stages: brainstorming, writing, and editing.

Brainstorming

Brainstorming is the initial stage of writing and includes inventing, thinking, imagining, developing, and organizing the writing project. The process of writing begins with planning. During the brainstorming stage, writers begin to formulate and write down ideas for the writing project. Even though this endeavor is usually done independently, some writers engage in discussions with colleagues during this stage to determine the range of potential topics and research questions and to create a project that responds to established scholarship.

This prewriting stage allows writers to consider a plethora of possibilities that will later be narrowed down significantly. Brainstorming can be in the form of an outline, a list, a set of questions, or free writing that will eventually become the first draft. Free writing allows writers to be spontaneous and unstructured, thinking, feeling, seeing, and experiencing new things as they write. This prewriting occurs during the process of collecting and organizing information so that the writer can consider what the purpose and goal of the writing is. Additionally, researchers must make a commitment to connect their writing to their audience (other scholars, participants, students) and contribute to knowledge through their scholarship.

Writing

Writing about the topic of interest is the second stage in the writing process. The activity of writing allows the writer to engage and teach the audience about the topic and the specific procedures followed. The writing stage

also includes active researching and gathering of information needed to establish and support the main objectives of the assignment. Writers must determine what the goals of the project are, what side they are taking, and what others have said about the subject.

The writing stage involves translating the raw data or fragments collected in fieldnotes and research into accessible and readable passages. Depending on the scope of research, a researcher will write based on his or her research experience or based on the research literature. A writer engages in his or her topic at various stages and builds upon his or her knowledge by writing about it. The writing process reflects and expresses the thoughts of the writer, allowing the writer to discover realizations about the topic and him- or herself simultaneously. The writing involves thinking, predicting, asking or answering questions, and finding answers.

Writing is a way of investigating knowledge and challenging or agreeing with previous interpretations. The writing stage begins once the research has been generated and compiled. Writers must organize their ideas and then position them against other voices. Writing requires practice, commitment, and time. The final step requires editing, revising, rewriting, and time.

Editing

The third and final stage of writing is editing and revision. This step usually occurs several days or weeks after the final draft is written. This step may also include collaborative editing, when one invites a colleague or mentor to review the manuscript. The editing stage includes proofreading, revising, rewriting, redrafting, and reorganizing the text one has already put together. At this stage of writing, the research has been compiled and the main points have been established. The point of revision is to eliminate unnecessary information and words and to construct the best possible final draft of the manuscript. First drafts, which are created during the first two steps of the process, do not necessarily resemble the final version, but they serve as maps that detail and predict how a writer's product will be presented. The editing stage allows the writer the opportunity to reinterpret previous drafts to ensure that the writing meets the goals of the project.

Writing Techniques

Voice and style are opportunities for writers to distinguish themselves and to establish their own unique perspective and creativity. A writer's voice, coupled with his or her experiences, fears, and personality, sets him or her apart and is integrated into the writing process from the beginning. Writing becomes a way of knowing, interpreting, and understanding the world, the subject, and the self. Writers make conscious choices about how (and if) they present themselves in their writing. This judgment determines what voice and style will be used, (first, second, or third person) and how the research is developed and structured.

Several qualitative writing styles privilege the writing process as a legitimate and significant stage of research. Experimental ethnography, also known as creative analytic practices and referred to as CAP ethnography, allows for a creative engagement of data. Writers are able to embed the story of their experience of researching and writing within their research paper, including autoethnography, poetry, performance text, fiction, layered accounts, drama, and ethnography. Participants' voices are typically paramount in written accounts of qualitative research, which may include lengthy quotes or other mechanisms for "giving voice" to participants' experiences and perceptions.
