Reader's Guide

The Reader's Guide is designed to help you find specific entries in general subject areas in the encyclopedia, as well as to identify related entries that may interest you. The main headings (e.g., "Data Analysis") provide quick snapshots of the range of categories covered in this volume, while the individual entries listed under each heading show the range of topics within those categories. Some topics (e.g., "Music in Qualitative Research") are listed only once in the guide; others (e.g., "Diaries and Journals") fall into more than one category. You are encouraged to scan through this list to get a clear sense of the scope of the volume, as well as the labels used for specific topics. As all of the entries are listed in alphabetical order, you can move quite quickly between this listing and the entries themselves in the body of the encyclopedia.

The Reader's Guide classifies entries into 16 general topical categories: Approaches and Methodologies; Arts-Based Research, Ties to; Associations, Centers, and Institutes; Computer-Assisted Data Analysis; Data Analysis; Data Collection; Dissemination and Writing; History of Qualitative Research; Participants; Quantitative Research, Ties to; Research Design and Planning; Research Ethics; Rigor; Textual Analysis, Ties to; and Theoretical and Philosophical Frameworks.

About the Editor

Lisa M. Given, PhD, is the Director of the International Institute for Qualitative Methodology (Faculty of Nursing), an Associate Professor in the School of Library and Information Studies (Faculty of Education), and an Adjunct Associate Professor in Humanities Computing (Faculty of Arts) at the University of Alberta. She received her PhD from the University of Western Ontario (London, Canada) in 2001.

Dr. Given's research interests include individuals' information behaviors, web usability, the design of library and campus spaces, and information use in the context of higher education. She holds a number of grants and awards in support of her qualitative research projects, including the Association for Library and Information Science's 2002 Best Methodology Paper award for an innovative approach to data analysis. Her current Social Sciences and Humanities Research Council (Canada) grant is titled "Participatory Design for a Visually-Based Drug Information Interface: Web Usability in the Context of Consumers' Health Information Behaviors." She

teaches graduate-level courses in research methods and supervises a number of student projects using qualitative methods. She has given guest lectures and served on thesis and dissertation committees in several faculties and departments, such as education, engineering, human ecology, computing science, and nursing. She also regularly conducts workshops on research methods for professional and government organizations.

Dr. Given publishes regularly in the area of qualitative research methods and is the associate editor of the *International Journal of Qualitative Methods*. She is a past president of the Canadian Association for Information Science and currently serves on a number of editorial boards and committees. She is a member of Canada's Interagency Advisory Panel on Research Ethics, Social Sciences & Humanities Research Ethics Special Working Committee, where she is a lead author on a discussion paper titled "Qualitative Research in the Context of the Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans."

Introduction

The Field

Qualitative research is designed to explore the human elements of a given topic, where specific methods are used to examine how individuals see and experience the world. Although qualitative research is often described in opposition to quantitative research, many scholars and practitioners are now using mixed methods and interdisciplinary approaches in their projects. Understanding the goals, intentions, and implications of these different research paradigms is vital to developing and assessing appropriate research designs. Qualitative methods are best for addressing many of the *why* questions that researchers have in mind when they develop their projects. Where quantitative approaches are appropriate for examining *who* has engaged in a behavior or *what* has happened and while experiments can test particular interventions, these techniques are not designed to explain why certain behaviors occur. Qualitative approaches are typically used to explore new phenomena and to capture individuals' thoughts, feelings, or interpretations of meaning and process.

Qualitative methods are central to research conducted in education, nursing, sociology, anthropology, information studies, and other disciplines in the humanities, social sciences, and health sciences. The range of methods available is very broad (e.g., in-person interviews, observation, diaries and journals) and projects are informed by various methodologies (e.g., phenomenology, discourse analysis) and theoretical frameworks (e.g., feminist epistemology). However, students, scholars, and professionals who are new to qualitative research typically need guidance in defining the boundaries of this type of work, including guidance in selecting specific methods, knowing what types of data are appropriate for qualitative studies, identifying theoretical frameworks for particular projects, and so on. It is important that both

novice and established scholars understand the language, culture, and paradigmatic approaches used in qualitative research, especially as interdisciplinary projects increasingly link researchers across varied fields of study. Researchers and practitioners at all levels, and across disciplines, will benefit from this encyclopedia, as it defines and explains core concepts, describes the techniques involved in the implementation of qualitative methods, and presents an overview of qualitative approaches to research.

Rationale for This Encyclopedia

The SAGE Encyclopedia of Qualitative Research Methods presents current and complete information, as well as ready-to-use techniques, facts, and examples from the field of qualitative research in a very accessible style. The volume is designed to appeal to undergraduate and graduate students, practitioners, researchers, consultants, and consumers of information across the social sciences, humanities, and health sciences. The encyclopedia provides a much more comprehensive examination of qualitative methods than is found in other published texts, as it is designed to appeal to readers across disciplines. In taking an interdisciplinary approach, this encyclopedia targets a much broader audience than other texts; it fills a gap in the existing reference literature for a general, interdisciplinary guide to the core concepts that inform qualitative research practices.

The entries cover every major facet of qualitative methods, including gaining access to research participants, data coding, research ethics, the role of theory in qualitative research, and much more—all without overwhelming the informed reader. Although the range of topics is intended to be comprehensive, each individual entry is designed to provide only an introduction to the topic at hand. Each entry is following by a

list of key readings on the topic. In addition, entries may also contain the first and last names of scholars or mention key works that are not included in the Further Readings. These names and resources provide additional starting points for readers who want to identify additional sources on the material discussed in the entry by searching for these people and materials on the internet or in library collections.

To provide quick access to the diversity of topics in the encyclopedia, a “Reader’s Guide” groups the entries into 16 subject categories: Approaches and Methodologies; Arts-Based Research, Ties to; Associations, Centers, and Institutes; Computer-Assisted Data Analysis; Data Analysis; Data Collection; Dissemination and Writing; History of Qualitative Research; Participants; Quantitative Research, Ties to; Research Design and Planning; Research Ethics; Rigor; Textual Analysis, Ties to; and Theoretical and Philosophical Frameworks.

Content and Organization

There was a concerted effort made in the design of the encyclopedia to cover every topic that informs qualitative research methods practice and development. This is easier said than done! Certainly, a volume like this will never be fully complete, as qualitative methods are in constant evolution—being recrafted and reshaped within and between disciplines. New methods and techniques, new journals, and new software packages are created every year. At the same time, existing approaches are often reframed, particularly as new theoretical frameworks inform thinking on qualitative methods design. The richness and vibrancy of the qualitative paradigm is exciting for researchers and often what draws us to this type of work; and yet, this makes the development of a comprehensive encyclopedia a challenging end goal indeed. We have tried our best to be comprehensive and complete while keeping redundancies to a minimum and while respecting disciplinary differences. Indeed, the political landscape surrounding the value of “scientific” research and the place of qualitative methods within that landscape is a recurring theme in many of the entries. Despite the ubiquitous nature of qualitative methods, for decades, across dozens of disciplines, qualitative methods remain a contested and controversial area of work for many scholars and practitioners. Their voices—and those for whom this area of work is well regarded—ring through this volume.

However, it is also important to note that the language of qualitative methods is difficult to formalize. Whether we refer to a study as using a “discourse analysis” approach, a “meta-analysis” approach, or whether we label it as “content analysis” may be a question of interpretation informed by one’s own disciplinary background and training. Indeed, many of the entries point to substantive debates among qualitative researchers regarding how concepts are labeled and the implications for how qualitative research is valued.

In some cases (as with this discourse analysis example), we have included separate entries on related concepts where we felt that a single entry alone could not represent the nuances of these different, yet connected, terms. In other cases, we have included “see also” references to point readers to a single, preferred term to represent a concept. The authors of the entries have also identified see also terms to point readers to additional, related topics. All of these techniques are designed to guide readers through the complex landscape of the language of qualitative inquiry. However, there may well be a few terms where we have inadvertently omitted a linking term or where we have made a difficult decision in choosing one term over another. The “Reader’s Guide” will therefore serve as an invaluable resource for individuals who need some guidance in locating specific topics.

How the Encyclopedia Was Created

The encyclopedia was developed in six steps:

Step 1: Qualitative methods experts from around the world and representing various disciplines were invited to serve on the editorial board. The board includes individuals who have published widely in the area of qualitative methods and who advise students, practitioners, and faculty members on the use and development of qualitative research approaches. Our Managing Editor, Kristie Saumure, was recruited at this stage to oversee the day-to-day progress of our work.

Step 2: We created a list of terms to be included in the volume, which involved two major phases of work. First, an initial list was crafted by the Editor and Managing Editor, based on a review of published qualitative methods texts, journals specializing in

qualitative methods development, qualitative conference proceedings, and other relevant research literature. Then, this list was circulated to the editorial board for their feedback and suggestions. The board's review identified gaps in the list, as well as areas where the terminology should be updated, refined, or altered to reflect disciplinary differences and preferences. For example, although some qualitative researchers use terms for rigor that reflect a quantitative or experimental paradigm (e.g., validity and reliability), others prefer terminology that is specific to qualitative work (e.g., credibility and dependability). Overall, the design of the encyclopedia has taken the latter approach and reflects an inherently qualitative language. In some cases (as with rigor), entries are included that reflect both ends of this language spectrum; in other cases, readers will find appropriate see also references throughout the text to guide them through this complex landscape of terminology.

Step 3: At this stage, we identified and invited contributors to write entries for the nearly 500 terms that are included in this two-volume set. The editorial board was asked to nominate individuals to serve as authors, and we also searched the published literature, consulted with colleagues, and reviewed individuals' personal websites to identify potential contributors. Our goal was to reflect a range of disciplinary and global voices in these contributions. To that end, the authors hail from various countries and disciplines, and the entries reflect a diverse spectrum of research approaches (from more traditional, positivist approaches through postmodern, constructionist ones).

The contributors include junior scholars and senior experts, as well as individuals working outside of academe in qualitative methods training and consulting. Readers will, no doubt, recognize a number of key figures in this volume, who have shaped qualitative methods work for decades, as well as some up-and-coming names in the field. This richness of perspectives may well introduce some areas of conflict and contradiction between the entries; however, such diversity—like qualitative research itself—is vital to energizing our work and moving methods development forward in the future. The contributors share a passion for qualitative research that is reflected in their writing and in their willingness to write for this encyclopedia. Although some individuals we approached could not participate (often due to illness or time commitments), those who did really

took ownership of the text as a whole, in addition to their individual entries. Many of the contributors volunteered to write on more than one topic, suggested new terminology for certain concepts, or asked us to include additional entries, particularly where they were dabbling with new approaches and techniques. This depth of commitment on the part of our contributors has made the encyclopedia far richer and more comprehensive than it would have been without their caring and concern.

Step 4: Contributors were provided with instructions for the creation of their entries, as well as a few samples to guide their writing and research. In particular, we encouraged them to be as descriptive and comprehensive as possible while writing for the educated, yet unknowing reader. Although we have tried to maintain a degree of similarity in the look and feel of the entries, the authors were also encouraged to find their own voice in these texts and write in a way that suited the content of their contributions. For example, although the publisher's style guidelines encourage the use of the third-person voice for encyclopedia entries, the first-person voice is one that resonates strongly in qualitative research and writing. Readers will note that some authors have chosen to write in the first-person voice (including, most appropriately, the entry on the use of first-person voice), while others have chosen to write in the third-person. Such stylistic differences are purposeful in this volume, so should not be read as inconsistent, per se. Rather, these examples speak to the diversity of approaches that define qualitative work and serve as illustrative markers of the various ways that scholars and practitioners approach qualitative work.

Step 5: The Editor and Managing Editor reviewed all of the entries and asked the authors for revisions, as necessary. At times, we also relied on the expertise of members of the editorial board to ensure a high level of quality and comprehensiveness in the entries included.

Step 6: We finalized the entries, compiled the Reader's Guide, and compiled all supplementary materials (such as this introduction).

Acknowledgments

This encyclopedia would not have been possible without the guidance and support of a number of amazing

people. First, I would like to thank our Managing Editor, Kristie Saumure, who enabled this project to unfold since its inception in 2006. I also wish to thank the editorial board for their advice in choosing which terms to include, and the authors, for writing such insightful and comprehensive entries. I would like to thank my colleagues at the School of Library and Information Studies and the International Institute for Qualitative Methodology (University of Alberta), the faculty of Information and Media Studies (University of Western Ontario), and those with whom I serve on Canada's Interagency Advisory Panel on Research Ethics, Social Sciences and Humanities Special Working Committee. I am also very grateful for the support and careful attention given to the project by Sage's publishing team. In

particular, Diana Axelsen has been a wealth of knowledge and support; I've really enjoyed our "cyber-coffee chats" about the nature of qualitative research over the past 2 years. I would also like to thank Neil J. Salkind, my agent at Studio B, who has been a wonderful mentor to me in completing this project.

On a personal note, I would like to thank my husband, Dan Given, for his love, support, and unending ideas for making this project a success. I also wish to thank my parents, Jim and Jean MacArthur, as well as my siblings and friends, for their guidance and support throughout the completion of this project.

Lisa M. Given
University of Alberta

A

ABDUCTION

Abduction is the least familiar mode of reasoning and the mode that was systematized most recently. In conjunction with deduction and induction, abduction is used to make logical inferences about the world. Furthermore, abduction offers great promise as a potential primary mode of reasoning for qualitative research.

The nature of abduction was first systematized during the late 19th century by the American philosopher and logician Charles Peirce. His form of an abductive inference is as follows:

Some event, *X*, is surprising to us.

But if some explanation, *Y*, were in place, then *X* would be ordinary.

Therefore, it is plausible that *X* is actually a case of *Y*.

Another way to look at this inference is to suggest that it is, in fact, reasoning toward meaning. This means that abductive inferences are valid in different ways from the other two modes of reasoning. Whereas deductive inferences are certain (so long as their premises are true) and inductive inferences are probable, abductive inferences are merely plausible. Therefore, abductive inferences are weaker by nature than the other two sorts of inferences.

Even though abductive inferences are weaker, they can be extremely useful. When we reason to meaning, we are expanding the realm of plausible explanations. We are giving ourselves a chance to see things that we

might otherwise miss by staying with tried-and-true explanations. This is what Russell Hanson called the “logic of discovery.”

Although there has been relatively little work done with using abduction, some of it has been quite fruitful. For instance, Gilbert Harman characterized abduction as “reasoning to the best explanation.” This notion of abduction has been incorporated into both expert systems research and artificial intelligence research. In addition, abduction has played an important role in semiotics.

Other work in abductive theory and practice has likened abductive researchers to detectives. In particular, Sherlock Holmes has been identified as an abductive thinker par excellence. That is, his so-called deductions are, in fact, abductions. In a famous case, Holmes infers, from the surprising fact that the watchdog did not bark, the abductive conclusion that the dog knew the kidnapper. Umberto Eco has looked at this aspect of abduction in both his theoretical work and his novels.

Following the work of Peirce, Gary Shank has looked at the application of abductive reasoning directly to qualitative research. In this work, Shank argued that there are actually six modes of abductive inferences that all researchers use. These types of inferences lead to hunches, omens, clues, metaphors, patterns, and explanations. In fact, Shank went on to argue that abduction is actually the ground state, or default mode, of cognition in general. Furthermore, by using the formal structures of abduction per se, these six modes of inferences can be related to each other systematically. In this fashion, the power of abduction as a way to reason to meaning can be employed by

qualitative research, which is the systematic empirical inquiry to meaning.

ACCESS

Consistent with qualitative epistemologies, the researcher needs to view a broad dynamic of the participants as they interact in professional and/or personal environments. It is a close look at the lived experiences of the participants. Because qualitative research typically involves working with human subjects in media such as face-to-face interviews, on-site observations, and written communications, it is essential that the researcher understand how to appropriately gain access to the intended participants. Access can be defined as the appropriate ethical and academic practices used to gain entry to a given community for the purposes of conducting formal research. This entry explores the key issues related to gaining access to participants in qualitative research.

The first and most important consideration in gaining access to research participants in qualitative research is to do no harm. It is essential that any intended qualitative research receive the appropriate formal research ethics clearance from the researcher's home institutional review board or research ethics board. While reviewing the proposal, this board will make sure that access to participants includes a review of considerations such as estimation of risk/harm, sites of data collection, recruitment of participants, benefits to participants, confidentiality, consent process, and procedures for participant withdrawal. In most cases, the consent form (if appropriate for a particular study) that is derived from this review process is the first and most direct line of access to participants, as it is used to request formally their involvement in the study. Following these

formal procedures ensures that access to the participants is ethically sound and protects their psychological, physical, and/or professional welfare.

Another process that may be involved in gaining access to some participants is to go through the proper community or organizational lines of authority. For example, when working with public schools, clearance can come from the district's central administration. In these cases, most districts will allow only a certain number of research studies to be conducted in their area per year. Similar research access models exist in the health care industry as well. Cultural factors also need to be considered. For example, when conducting research on Aboriginal communities, the researcher can consider speaking with tribal elders to gain access to members of the community. When conducting research on religious issues, access to participants may be granted only through leaders, whose attendance may be required during some research, for example, when women are being interviewed. Another consideration for access is related to conducting research in foreign territories. If research is being conducted on participants such as military personnel or government representatives in politically unstable countries, it is essential that the researcher acquire the appropriate government clearance prior to conducting the research. Gaining access through organizational or governmental lines of authority should be a matter of consideration in the research design.

Gatekeepers are another means of access in qualitative research. Gatekeepers are individuals who can be used as an entry point to a specific community. Gatekeepers will have "inside" information that can help the researcher in determining who are the best participants to access in the given community or organization. Gatekeepers can also help the researcher to access the community through introductions and by establishing a relaxed or appropriate environment for the research process. For example, a gatekeeper who chairs a geology department composed of 10 professors can help the researcher to narrow the participant list to 3 people who are most appropriate for the goals of the study. This chair can also introduce the researcher to the participants and then provide access to a comfortable and private room where the interviews can be conducted. Another example is an internet chat room moderator, who will have knowledge about the privacy level of the site and how best to obtain consent from the participants.

A newer dynamic related to access is related to internet participants. There are a whole host of access

issues pertaining to this type of research that both the researcher and ethics review boards need to consider. Participants in this category can be found on the internet in areas such as listservs, chat rooms, course discussion postings, blogs, mailing lists, and newsgroups. Prior to gaining access to the participants, the researcher needs to determine whether the communications on the site are public or private. Public sites do not require consent to access the participants and their communications, whereas private sites typically do. A researcher on a private site, for example, may need to obtain a subscription or registration. In most instances, researchers should avoid hiding on the internet to monitor communications that were intended only for the direct users of the site.

The researcher of an internet community can also gauge privacy by considering the purposes of the site and the number of participants. For example, some chat rooms are only for people suffering from alcoholism, and their guidelines stipulate that professionals should not engage in the communications. Sites that have 5 members are more private than sites that have 1,500 members. If there is any possibility that research conducted in a private internet space could create a potential hazard to the participants or harm the group, it is essential that informed consent be sought.

Once it is determined that formal consent is required, the researcher has two options for gaining consent and access to an internet community. The first is to make a posting or send an email to the internet community describing the research and asking for access to the members' communications. The second approach is to determine the communications (or future communications) needed for the research and then to contact the individuals who made the submissions and ask them whether they would like to be involved in the study. In all cases, the researcher should work closely with the ethics review board to make sure that access to internet communities is handled in ethically sound ways.

By working closely with an institutional review board and one's colleagues, the researcher can make sure that access to participants is academically and ethically sound.

ACCOUNTABILITY

Accountability refers to the obligations the researcher has to the various stakeholders in the research process such as the research participants, the funding body, and the researcher's employing organization. Accountability is an important concept in qualitative research because when it is addressed and made explicit, it can suggest standards of research practice against which the researcher can be judged to determine whether he or she has acted in an appropriate and ethical fashion.

Examples of practices that attempt to address accountability to these different stakeholders include the following:

- *To research participants:* an explanation about how they have been identified and why they have been approached about participating in the research project (usually explained within the participant information sheet); clarification about the nature and extent of participation so that potential participants can provide informed consent (information detailing involvement should be included in the participant information sheet, and potential participants should have an opportunity to ask questions directly of the researcher); assurance that withdrawal from a research study will not adversely affect participants (by including a statement to this effect in the participant information sheet and verbally reinforcing this with participants)

- *To funding bodies:* completion of the research project within the timeframe identified and within budget (the use of project management tools such as computer software and Gantt charts may help to prevent time slippage, and careful planning at the grant submission stage with a regular review of expenditures can help to prevent overspending)

- *To employing organizations:* conduct of research in a manner consistent with governance arrangements (this necessitates familiarity with governance policies and possible liaison with officers of the organizations)

responsible for formalizing and monitoring such arrangements); appropriate costing of overhead such as use of space and resources (discussion with financial officers from the employing organizations and often the inclusion of their signatures as part of a grant application)

The nature of accountability—to whom a researcher is accountable—and the research practices that address this responsibility are matters of some debate. Qualitative researchers, for example, sometimes assume some obligation for involving their participants in the interpretive process. This can often take the form of “member checking,” where the written transcripts of interviews are returned to participants prior to further analysis so that they may check the accuracy of the transcriptions. However, in some instances this is the extent of participant involvement. Within other approaches, such as participatory action research, research participants and researchers may be equally responsible for all aspects of the project, from the original framing of the research question to interpretation of the data.

ACTION RESEARCH

Action research is a flexible research methodology uniquely suited to researching and supporting change. It integrates social research with exploratory action to promote development. In its classic form, action research involves fluid and overlapping cycles of investigation, action planning, piloting of new practices, and

evaluation of outcomes, incorporating at all stages the collection and analysis of data and the generation of knowledge (Figure 1). The outcomes of action research are both practical and theoretical: The knowledge it generates has a direct and ongoing impact on changing practice for participants and on a wider audience through its publications. This entry describes the origins of action research and its use in a variety of fields throughout the world.

Action research is often used in fields such as education, social and health services, and community development, where there is a long history of difficulties in successfully transferring research knowledge into changes in practice. It offers a means of combining the generation of knowledge with professional development of practitioners through their participation as co-researchers. Collaborative action research can also break down the separation between policymakers and practitioners, giving the former richer insights into practice and giving the latter an active role in policy development as well as its implementation.

The first person to use the term *action research* was probably Kurt Lewin, a psychologist who went to the United States from Germany during the 1940s and worked with immigrant groups to promote their better integration into U.S. society. Lewin, like others at the time, was seeking to explain human behavior so as to enable improvement, and his work was closely related to the sociotechnical research tradition developed by

Figure 1 Model of Action Research

Eric Trist and others at the Tavistock Institute in London. The early work at the Tavistock Institute built on a method of group therapy developed in working with shell-shocked military personnel during World War II. In postwar society on both sides of the Atlantic, this innovative new movement in social psychology research pursued a vision of betterment for individuals and increased organizational efficiency through community participation in research and development.

Lewin was familiar with Lev Vygotsky's work in the Soviet Union, and there are a number of similarities between their approaches; for example, Vygotsky was interested in researching the impact of intervention studies, such as the literacy program for peasants in Uzbekistan during the 1920s, on the development of the human mind. It is interesting to note the overlaps between action research and post-Vygotskian activity theory, which sees human activity as mediated by cultural tools and social contexts, particularly as they are regulated by rules governing behavior and divisions of labor according to organizational roles. Lewin believed that human behavior was always a function of the situation at the time it occurred; therefore, he did not believe it was ever possible to make generalizations about human behavior that would apply to all contexts. Action research generates knowledge about the interrelationship between human behavior and sociocultural situations rather than generalizable truths, and it is important that it be reported in a form that includes narrative accounts and rich description as well as analysis and interpretation so that readers can make comparisons with their own situations.

Lewin developed action research as a radical move away from traditional research methodologies, so it was not surprising that, after a brief flowering in the United States during the 1940s and 1950s and in France and Germany during the 1950s and 1960s, action research became discredited as insufficiently "objective" and was marginalized. It enjoyed a resurgence, however, in the United Kingdom during the 1970s through the growth of the teacher-as-researcher movement that sprang from Lawrence Stenhouse's insight that curriculum reform in education depended for its success on the active participation of teachers in researching the purposes and pedagogical practices of reform. This approach was developed by John Elliott, a colleague of Stenhouse at the University of East Anglia, who drew for inspiration on innovative curriculum movements in the United States, such as Jerome Bruner's "Man: A Course of Study" program,

and gained financial support from the Ford Foundation for co-research with teachers into teaching that enabled "discovery learning." With a background in philosophy, Elliott drew on Aristotle's theories of practical wisdom and Hans-Georg Gadamer's reflective hermeneutics to develop a vision of action research grounded in practical reflection akin to the pragmatist philosophy of John Dewey.

This work in the United Kingdom within the field of education was influential in generating new interest in action research both in Austria, through close links with Peter Posch's group at the University of Klagenfurt, and in Spain, where it was used to support educational reform in some of the autonomous regions during the immediate post-Franco era. During the 1980s, Stephen Kemmis (a former colleague of Stenhouse by then working in Australia) and Wilf Carr established a significant new direction for action research by recasting it within Jürgen Habermas's critical theory as a means of empowerment for practitioners and an instrument for promoting social justice in education systems and organizations. Building on the earlier work of Shirley Grundy, they distinguished three types of action research—technical, practical, and critical—and focused on critical action research as a means of emancipating participants by giving them access to knowledge and the power to resist oppressive institutional practices.

By the mid-1980s, a new tradition of action research had been established in the United States, grounded in teacher education rather than curriculum reform. The emphasis was on merging teaching and research and on reconceptualizing the knowledge base of teaching as grounded in teachers' inquiry into their own practice rather than in predetermined decontextualized knowledge developed outside of schools. In the United States, as well as in many other countries, there has been a blurring of the boundaries between action research and practitioner research in which the purpose of inquiry is to deepen understanding and enrich teacher learning rather than to bring about intentional change. Leading figures in establishing a tradition of teacher research and building a corpus of teachers' research studies in the United States have been Marilyn Cochran-Smith, Susan Lytle, and Ken Zeichner.

Action research in other fields, such as health and community care, has been influenced by these developing traditions within education. There has not, however, been a simple development of one action research tradition; rather, there have been several strands of

development drawing, for example, on the civil rights movement in the United States through the work of Miles Horton at the Highlander Center, the liberation pedagogy of Paulo Freire in Latin America, and the tradition of workplace learning originating in the work of Chris Argyris and Donald Schön in the United States. Because action research is grounded in the values and practices of its participant communities, action researchers focus on understanding their own subjectivities and how they affect the research process rather than on trying to eliminate them. Reflexivity, where researchers continuously explore their own assumptions and how these shape their research activities, their interpretations, and the generation of knowledge, is centrally important. The self is understood to be a research instrument bringing the researcher's situational understanding, developed through previous action research, to bear on the analysis of social data. Attempting to be "objective" or to distance the self from the research (e.g., by writing research reports in the third person or using a passive voice) is seen as a futile and, therefore, potentially fraudulent stance. Action research is normally written in the first-person singular as a reflexive account that incorporates a critique of the research process with the generation of knowledge. Action research is often seen as primarily a qualitative methodology, but in fact it is eclectic, using all of the main methods of data collection, including questionnaires and statistical analysis where studies are on a scale, to make these appropriate as a means of enabling interpretation (rather than objective measurement).

Action research is always grounded in the values and culture of the participant researchers who engage in it and, as a result, is a fluid methodology that adapts to fit different social contexts. For example, in developing countries where there is huge social inequality perhaps deriving from a colonial past, or in developed countries among groups concerned with issues of race or gender, action research is focused primarily on promoting social justice, whereas in the context of the British health service it is focused more strongly on improving treatment for patients and ensuring that the underpinning vision behind new policies is fully embedded. Susan Noffke, a historian of action research, developed a useful framework for understanding the variations in approach, dividing them into three broad types that lean more toward "professional," "personal," or "political" orientations. This allows action research to adapt to suit the shifting stances of different communities or professional groups.

An important feature of action research is that it is carried out by a partnership of participants who are "insiders" to the situation under research and external facilitators/researchers/consultants. This makes research ethics extremely important, requiring continuous sensitivity to how power relations may be shaping the partnership and continuous inquiry into the process of collaboration as well. The nature of partnerships varies. Those who work within a tradition of teacher-as-researcher sometimes question the authenticity of action research led by external consultants, but in professions such as nursing, social care, and community care the external consultant often takes on a leadership role. In the tradition of participatory action research, whole community development often starts with an external intervention, and the direction of the research and action is negotiated with participants so that control shifts away from experts toward community members over time. Some of this participatory action research work with strong external facilitation or leadership can be large scale and have a major impact on community development, whereas studies by individual teachers of their own classrooms are necessarily small scale.

One of the most important contributions of action research as a methodology for building understanding of change and development is its unique access to insider knowledge. Through adopting the role of researchers, practitioners are able to reflect on and make explicit the tacit knowledge that guides their practice, and their involvement as co-researchers ensures that the knowledge generated by action research incorporates this unique—and often neglected—component. Thus, action research forms a bridge between practitioner understanding and the generation of theoretical knowledge to inform action. For example, drawing on Aristotle's concept of *phronesis* (knowledge that combines reason and moral understanding as the basis for action), Elliott developed a theory of practitioner knowledge that includes theoretical work as a form of practical activity. Thus, knowledge generation and the development of new practices are integrated and theorized.

ACTIVE LISTENING

Active listening describes a set of techniques designed to focus the attention of the interviewer or observer on the speaker. The goal of active listening is to attend entirely to the speaker, not to oneself or one's own inner dialogue, with the goal of accurately hearing and interpreting the speaker's verbal and nonverbal communication. Active listening skills are useful not

only in research but also in any area where accurate communication and mutual understanding are useful. In addition, active listening skills are often included in curricula for health care providers as a means to facilitate therapeutic interactions. Examples of strategies often recommended in qualitative research, as opposed to therapeutic communication or conflict resolution, are described in this entry.

Active listening strategies use both verbal and nonverbal communication channels. Nonverbal active listening strategies establish and maintain rapport and also serve to focus the attention of the interviewer or observer. Nonverbal strategies that foster rapport include focusing the face and orienting the body toward the speaker, maintaining an attentive demeanor with an open posture, and staying relaxed. Strategies that focus the listener take place within the mind of the researcher. Active listening requires that the researcher attend purposefully to the speaker with attention focused on the communication being sent, not on the researcher's responses to that communication. Active listening demands a neutral open attitude toward the speaker so that even remarks that are shocking or distressing are understood—not judged—by the listener. The goal of the active listener is to receive information—not to give it—and to be a witness—not a critic.

Verbal active listening strategies familiar to qualitative researchers include paraphrasing, reflecting, interpreting, summarizing, and checking perceptions. In paraphrasing, the interviewer restates the content of the communication in slightly different words, for example, "So you are saying that you are not as satisfied with your son's teacher this year as you were last year." Reflecting, in contrast, identifies content perceived through nonverbal channels, for example, "It sounds like you are pretty angry with that teacher." Summarizing provides an opportunity for transitions in interviews between one topic and the next and is a useful way to check perceptions. Both interpreting and checking perceptions can be used to test developing analytic insights. For example, the researcher might ask, "Would you say that you think a good teacher should be able to manage disagreement without confrontation?" All of these strategies demonstrate that the interviewer not only has paid close attention to the speaker but also has been actively processing the speaker's remarks, and these two characteristics are the hallmark of active listening. In addition, neutral probes, such as, "And then what happened?" and "Can you tell me more about that?" and

even neutral encouraging noises, such as “Mmhhh,” all serve to enhance communication.

A final active listening strategy is the use of silence. Although silence is by definition a nonverbal strategy, it is used as a part of the interview. When used carefully, silence can communicate respect, empathy, and interest to the speaker while at the same time demonstrating the interviewer’s own calm and patience.

ADVANCES IN QUALITATIVE METHODS CONFERENCE

The Advances in Qualitative Methods (AQM) conferences are planned to enhance the development of qualitative methods. The first AQM conference was held in Edmonton, Alberta, Canada, in February 1999 to celebrate the first year of operation of the International Institute for Qualitative Methodology (IIQM). Subsequent conferences have been hosted by the University of Alberta IIQM (Banff, Alberta, Canada), the Africa Institute for Qualitative Methodology (Sun City, South Africa), and the Australian IIQM (Surfer’s Paradise, Australia).

These conferences hold the dual mission of dissemination and training. Dissemination focuses largely on the latest developments in qualitative methods and descriptions of how qualitative methods were used in particular research contexts. Scholarly presentations and refereed papers focus mainly on the application of qualitative methods, problems encountered, and adaptations required when conducting research with different populations.

Panel discussions on basic and advanced topics and keynote addresses by international researchers challenge the more advanced participants. For instance, at the second AQM conference, an ethnographic performance by Johnny Saldana—“Finding My Place: The

Brad Trilogy,” a play depicting a case study of Harry Woolcott—produced an additional discussion session on ethics and responsibility. This was later published (in 2003) as a book, *Sneaky Kid and Its Aftermath: Ethics and Intimacy in Fieldwork*, by Woolcott. Other keynote speakers have included leaders in qualitative inquiry such as Norman Denzin (in 2003), Margarete Sandelowski (in 2001), Carolyn Ellis (in 1999), and Elliot Eisner (in 1999).

Training consists of pre- and postconference workshops that are targeted to new researchers and graduate students; these address various aspects of methods and strategies for conducting research. The selection of full-day workshops is broad and may include topics such as qualitative writing, ethnography, grounded theory, use of video, focus groups, various qualitative software packages, arts-based research, narrative inquiry, concept and theory development, and mixed-methods design.

Abstracts are published following the conference in the *International Journal of Qualitative Methods (IJQM)*, providing a permanent record of the event. Full-length articles are developed from the presentation, and session and symposia papers are often published in *IJQM*.

Information regarding the forthcoming AQM conferences may be found on the IIQM website or by searching the internet using the conference name.

ADVOCACY RESEARCH

Advocacy research is intended to assist in advocacy, that is, efforts to assemble and use information and resources to bring about improvements in people’s lives. As such, it shares with some other research approaches (e.g., action research) an allegiance to the values of social responsibility and community empowerment. Common advocacy outcomes to which research may contribute include lobbying, testifying,

pursuing a lawsuit, and seeking media coverage to raise public awareness. Nonadvocacy research may also produce findings useful to advocates, but advocacy research has this goal as its *raison d'être*.

This entry focuses on advocacy at the organizational level and on the role of qualitative research in furthering this effort. Advocacy groups typically address concerns about public health, social welfare, and public safety. Their size and scope of interest can range from a neighborhood group protesting the closure of a local playground to multinational coalitions organized to fight for the rights of the disabled. The goals may be immediate and time focused (e.g., closing a nuclear power plant) or diffuse and ongoing (e.g., monitoring child welfare agencies).

Given the relative scarcity of finances and expertise, few advocacy groups engage in empirical research, instead getting their information through informal interviews, documents and records, legal action, and previous research. The distinction between information gathering and research can be blurry, but the latter refers to the deployment of systematic methods using extant research designs and modes of data collection and analysis. Pursuing formal research can also entail the involvement of research ethics or other institutional committees having jurisdiction over the researcher, the study sites, and/or the study populations.

The following sections provide an overview of advocacy research, including the stakeholders involved and the role of the researcher, useful applications of qualitative methods, strategies to increase trustworthiness and rigor, and ethical issues.

Stakeholders and the Role of Research in Advocacy

The stakeholders in advocacy include three interrelated groups or entities: (1) those being advocated for, (2) those doing the advocating, and (3) those being advocated against. The latter are often represented by entrenched vested interests such as large corporations and governments. Such powerful entities may be the direct target of advocacy, or they may exist as obstacles to achieving desired goals, for example, providing low-cost medications for AIDS patients or saving the earth's environment from the effects of global warming. In instances where the first two stakeholder groups (a and b) overlap, affected communities or groups have organized to advocate for themselves.

At other times, professional advocacy organizations may act on behalf of vulnerable groups such as abused children and the homeless mentally ill.

In this context, advocacy researchers may already be members of stakeholder groups, but they more often come from the "outside" (e.g., academic settings, professional research organizations). Usually part of a team effort, researchers contribute methodological expertise and produce findings that can be used by advocacy groups and their allies, with the latter including attorneys, politicians, scientific experts, and public relations representatives.

Like other forms of applied research, advocacy research is best viewed as a means to an end. Issues of public interest are paramount, including environmental hazards, inadequate services (e.g., health care, social services, sanitation, affordable housing), and corruption or mishandling of public resources.

Qualitative Methods in Advocacy Research

Although the goals of advocacy research may be furthered using a variety of methods, some qualitative approaches are a better fit than are others. With ethnography, the researcher observes organizations and/or communities to understand the behaviors, interactions, and tacit understandings that shed light on the problem being advocated against (or the goal being advocated for) as well as potential solutions. For example, an ethnographer might work with epidemiologists to find patterns of exposure to groundwater contamination among residents in a neighborhood located near a toxic waste dumping ground. Similar to ethnography, qualitative case studies offer in-depth examples of individuals, groups, neighborhoods, organizations, and so on. Qualitative evaluation examines the process and outcomes of a program or an initiative to assess its effectiveness (e.g., a new model of violence prevention for adolescents). When advocacy research is carried out in partnership with the affected community or group, it may overlap with participatory action research and community-based research.

Among types of qualitative data collection, focus groups and individual interviews provide valuable opportunities for individuals to be heard in their own words, and observation and fieldnotes capture events *in vivo*. Documents, whether official records or personal diaries and journals, are also a valuable data resource, as are photographs and videorecordings.

Recent innovations, such as photovoice techniques and use of online web-based technologies, introduce new and often more accessible means of qualitative data collection. Photovoice typically involves community members documenting environmental, public health, or other neighborhood concerns, a low-cost undertaking when using disposable cameras. Although personal computers are not always available in less advantaged populations, online communication can significantly enhance community involvement through email, listservs, and blogs.

Because it is almost always conducted under pressures of time and with limited resources, qualitative advocacy research calls for rapid assessment procedures designed to produce results as soon as possible. These can include targeted sampling of affected stakeholder groups, focused interview questions (including use of some standardized measures), and structured note taking in lieu of verbatim transcription. Similarly, ethnography works best when carried out by someone who already has field experience and familiarity with the setting.

Because the study's results are intended for a nonacademic audience, writing up the findings requires brevity and clarity; for example, an executive summary typically begins the report. Including diagrams, graphs, and photographs helps to explain complex issues in a visually accessible format.

Trustworthiness and Rigor

With its avowed commitment to social, economic, and political change, advocacy research has been accused of placing values ahead of scientific neutrality. However, its defenders argue that research is never truly value free and that advocacy research can also be rigorous. Academic researchers usually have an advantage in this regard because they are less vulnerable to pressure from sponsors or other vested interests outside of the academy.

Ensuring the study's trustworthiness entails many of the strategies used in qualitative research in general. These may include data triangulation (drawing on multiple sources of data), prolonged engagement in the community or study setting, member checking (consulting with study participants on the accuracy and validity of the data and the study findings), and maintaining an audit trail (documenting analytic decisions during the study). Although strategies for rigor are time-consuming

and not always feasible, their deployment enhances the study's credibility.

Ethical Issues

Ethical issues are of vital concern whether or not the study falls under the jurisdiction of a human subjects committee. The involvement of such a committee is typically due to legal requirements governing the researcher's home institution, the sponsoring organizations, and/or the agencies or programs cooperating with the study. When community members are actively involved in data collection and analysis, their training in research ethics is important because they are unlikely to be familiar with the basic premises of human subjects protections.

Recruitment, sampling, and data collection require careful attention to ensuring voluntary informed consent and to protecting the confidentiality and privacy of all parties involved. The use of photographs or video requires signed releases and full disclosure of their purpose. All data must be kept secured under lock and key and preferably retained without identifying information. Given the political sensitivity of most advocacy efforts, honoring protections of privacy and confidentiality is essential for the integrity of the study. Qualitative data and findings carry a particular risk because they include descriptive details that individuals may view as too exposing even when their identities are kept secret.

Ethical issues also arise when producing and disseminating the findings. Advocacy researchers have a vested interest in the study's results as well as how those results are used and by whom. They usually do not embark on such research unless they have anecdotal or other evidence supporting the projected outcome. Yet studies can (and do) produce findings that provide only weak support or even run counter to the advocacy agenda. Although ethical researchers do not distort or alter disappointing findings, they are not obliged to publicize them beyond the required venues.

However, research findings can be valuable for future endeavors and alternative goals even when they are disappointing or unexpected. An example of this comes from Long Island, New York, where concerned citizens organized during the early 1990s to identify environmental causes of the higher rates of breast cancer in the area. The Long Island Breast Cancer Action Coalition pushed for federally funded research on the effects of electromagnetic fields as

well as agricultural pesticides. In a remarkable success story, the coalition was able to lobby and convince the U.S. Congress and the National Institutes of Health to appropriate more than \$26 million in funds for research. Although the subsequent studies did not find that electromagnetic fields or pesticides were linked to breast cancer, the coalition's political clout and organizational effectiveness yielded community benefits in the form of resource centers and support groups for women with breast cancer.

The preceding example points to potential benefits of advocacy research that go beyond the production of study findings. These include increasing group cohesion and cooperation, enhancing the visibility and accessibility of research, and laying the groundwork for future cooperation in advocacy efforts.

The primary purpose of advocacy research is to empirically substantiate the case being made by advocates. Its ultimate success can vary considerably depending on the study's results but also on the power of countervailing forces—whether these forces are large corporations, deadly diseases, or entrenched social problems. Although rigorous advocacy research is more laborious and resource-consuming than are other forms of information gathering, its impact is stronger and longer lasting. In this regard, advocacy research can be a powerful means of advancing a change-oriented agenda.

AESTHETICS

Aesthetics, a term coined in 1735 by Alexander Baumgarten to denote a theoretical and practical discipline aimed at the perfection of sensory cognition, was derived from the Greek *aisthanomai*, meaning perception by means of the senses. Aesthetics has since evolved to refer to two interrelated areas: the philosophy of art and the philosophy of aesthetic experience. The philosophy of art grapples with the question of what constitutes art. Answers from theorists differ widely. Some adhere to the impossibility of defining art given varying focuses on art movements, theoretical foundations, and social contexts, whereas others attend to the creative impulse that undergirds all human activity. The philosophy of aesthetic experience grapples with the nature of encounters with the arts, including artifacts and phenomena (e.g., nature) that possess aspects susceptible to aesthetic appreciation. Some theorists attend to appreciation and enjoyment, whereas others find the aesthetic to be a way of knowing and experiencing the world.

In the context of qualitative inquiry, aesthetics can refer to qualitative studies that attend to the philosophical concepts and considerations of the arts and of aesthetic experiences. Increasingly, aesthetics is understood as attention to the act of creating meaning from within the act of creating itself. Aspects of this fundamental human encounter between subject and other (world) can be traced historically, with a cross section of thinkers addressing varying perspectives. The sensory cognition required and the perceptual reciprocity assumed are at the core of contemporary qualitative research. This entry focuses on the latter.

Qualitative Research on Aesthetics

Margaret Eaton traced research on aesthetic concepts to the 18th-century philosophers Edmund Burke and David Hume, who attempted to explain empirically aesthetic concepts such as beauty by connecting them with physical and psychological responses that typify individuals' experiences of different kinds of objects and events. These philosophers sought an objective

basis for personal reactions. Immanuel Kant argued that aesthetic concepts are essentially rooted in personal feelings of pleasure and pain and, therefore, are subjective, but he suggested that they have a kind of objectivity on the grounds that, at the purely aesthetic level, feelings of pleasure and pain are universal responses. During the 20th century, philosophers sometimes returned to a Humean analysis of aesthetic concepts via the human faculty of taste and extended this psychological account to try to establish an epistemological or logical uniqueness for aesthetic concepts.

As a result of both philosophical writings and extensive empirical work in psychology and biology, we are now wiser and more sophisticated about the cognitive dimensions of aesthetics, dimensions that can be applied to the aesthetic dimensions of scientific inquiry. Age-old questions, raised by scholars from Pythagoras and Aristotle to Hegel and Nietzsche and later to the cognitive revolution of the late 1950s concerning the type of cognition involved in the arts, are now reemerging within the context of the social sciences and the humanities, discussing the contributions of aesthetics to scholarship. Following John Dewey's work during the early 20th century and scholars such as Suzanne Langer, Nelson Goodman, and Harry Broudy, who contributed to the cognitive revolution of the late 1950s and the 1960s, aesthetics pointed to the interconnectedness of perception, thinking, and feeling.

The interconnections of perception, thinking, and feeling entailed within the act of creating draw attention to the role and place of cognitive aesthetic dimensions revealed through inquiry such as assimilation, internalization, and integration. Aesthetic dimensions challenge traditional disciplinary and institutional structures that compartmentalize knowledge, separating content into distinct pieces, knowledge from interests, and theory from practice. Rather, the aesthetic offers a philosophical approach for inquiry of all kinds, striving for connections between and among disciplines, demanding continuous engagement in reflection and deliberation, and honoring all forms of inquiry as complex, creative, and developmental in nature.

An example of the aesthetic dimensions prompted through qualitative methods can be found in the work of Mihaly Csikszentmihalyi and Rick Robinson on viewers' perception in museums. George Willis and William Schubert's *Reflections From the Heart of Educational Inquiry* (in 1991) included essays by prominent scholars, from Ted Aoki to Harry Broudy,

discussing the power of the aesthetic as a way of being in learning, teaching, and living. Recent examples that purposefully transcend disciplinary boundaries include Mieke Bal's *Travelling Concepts in the Humanities: A Rough Guide* (in 2002) and Edith Wyschogrod's *Crossover Queries: Dwelling With Negatives, Embodying Philosophy's Others* (in 2006). Dissertations that examine aesthetic sensibilities include, for example, Boo Euyun Lim's study of aesthetic education for young children in various early childhood settings and Yu-Ting Chen's study of Taiwanese and Aboriginal aesthetics in elementary schools in Taiwan.

Aesthetic-Based Research

Aesthetic-based inquiry, a genre that is based on the contributions that the processes and products of aesthetics can make to research, is grounded within a complex, traditionally antagonistic relationship between the two constructs of aesthetics and research. These relationships go back at least two and a half millennia, long before the coining of the term *aesthetic*. The dichotomous view of knowledge/truth versus perception, a legacy of Plato, was maintained and developed by some of the most important philosophers of the Western world, including René Descartes and Immanuel Kant. According to this dichotomy, aesthetic-based research is an oxymoron, that is, an impossibility.

These traditional dichotomies were eroded by the postmodern worldview of the late 20th and early 21st centuries. The emphasis on crossing intellectual and disciplinary boundaries proved to be a fertile ground for aesthetic-based research. A harbinger of crossing boundaries was the work of John Dewey, relating aesthetic theories to cognition and arguing that art and science share the same features with respect to the process of inquiry.

In the postmodern paradigm of the late 20th century, aesthetic concepts were commonly acknowledged to be context dependent and relationally embedded. The notion of aesthetic universality, along with all other universals, has been deconstructed as contextual and social. Accordingly, research turned to examine the nature of the aesthetic in specific personal and cultural contexts.

Elliot Eisner was pivotal in highlighting attention on the central role of the senses in research. In his conceptualization of research as connoisseurship and educational criticism, and in his notion of the

“enlightened eye,” Eisner expanded the modes and expressions of inquiry from the verbal and numerical to the senses. Maxine Greene’s call for “wide-awakeness” served as a reminder to qualitative researchers of attending to qualities present in situations alongside the capacity to see the potential connections and relations. In so doing, she pointed out the importance of “releasing the imagination” toward cultivating new visions for living and being as the means to change and transformation across all forms of inquiry.

The field of aesthetic-based inquiry has grown tremendously during the past 15 years, and with it has come a proliferation of “genres” reflecting different purposes and commitments. One major area is that of arts-based research. Within the field of education, we note this burgeoning in meetings of the American Education Research Association and its special interest group of arts-based research featuring presentations, performances, and exhibits of research through dance, drama, literature/poetry, and the visual arts; in the popularity of the Winter Institute on Arts-Based Approaches to Educational Research taught annually by Elliot Eisner and Tom Barone; in arts-based inquiry publications in various prominent journals, including *Educational Researcher*, *Curriculum Inquiry*, *Studies in Art Education*, *Qualitative Inquiry*, and *International Journal for Education and the Arts* as well as in publications such as the *Handbook of the Arts in Qualitative Inquiry* and the current *SAGE Encyclopedia of Qualitative Research Methods*.

Within aesthetic-based inquiry, Graeme Sullivan framed arts-based research as the imaginative and intellectual work undertaken by artists as a form of research within areas of individual, social, and cultural inquiry. Here the critical and creative investigations of visual arts practice is regarded as a form of inquiry into the conceptualizations and practices of artists in varied contexts such as studios, galleries, community spaces, and the internet. A related approach, generated by Rita Irwin and her colleagues, highlights seamless connections among art making, research, and teaching—*a/r/tography*. As a form of scholarly inquiry, *a/r/tography* demands that participants invest in the ensuing connections and relations and document these using artistic practices. Arts-based researchers, such as Margaret Macintyre Latta, Melissa Cahnman Taylor, and Liora Bresler, embrace their practices as inquiry-guided methodologies in the making, necessitating artistic ways of knowing and

operating across disciplines and contexts. A complementary tack, held by scholars such as Liora Bresler, places the perceivers at the center (fitting with the distinction between art and aesthetics suggested by Dewey), keeping a (soft) distinction between works of art and qualitative research. The multiple forms and directions that all of these inquiries can (and do) take are integral to the nature of the aesthetic as the capacity to perceive.

The Senses as Central Research Medium

Aesthetic-based research, grounded in perceptual awareness, turns to the significant role of the body as a reciprocal medium for negotiating understandings. The literature on the body as a key research medium and the investigation of ways of knowing through the senses are relatively new areas of scholarship advocated by Liora Bresler, Marjorie O’Loughlin, and Margaret Macintyre Latta. Framing somatic ways of knowing, anthropologist Tom Csordas examined “somatic modes of attention,” which he regarded as culturally elaborated ways of attending to and with one’s body in surroundings that include the embodied presence of others. Extended to research, aesthetic-based inquiry attends to how the body forms and informs the processes of data collecting (e.g., interviewing, observing), interpreting, and analyzing.

Communication to and engagement of audiences is a key concern of aesthetic-based researchers. Positioning audiences to respond in ways that are integral to the reciprocal participation required of aesthetic experience has led to artist/researcher performance inquiries in the works of Donald Blumenfeld-Jones, Melissa Cahnmann Taylor, Norman Denzin, James Sanders, Celeste Snowber, and Susan Stinson, among others. Auditory and gustatory senses—hearing and taste—practiced by individuals contemplating the social meanings attached to creative production, provide ways to reveal and experience aesthetic significances.

All of these different ways of thinking about aesthetic-based inquiry establish and promote innovative ways to conceptualize and understand aesthetics as disciplined, imaginative critical inquiry, privileging imagination and intellect in constructing knowledge that not only is new but also has the capacity to transform human understanding and ways to live with others.

Timely Questions and Concerns

Questions and concerns surface through aesthetic researchers' attention to process, placing value on experimentation, observation, deliberation, dialogue, and interaction. What sensitivities are useful in the training of researchers in general education and the social sciences? What are the conditions and features that must be understood by researchers? How might researchers grow their efforts and articulate the significances given the dominant global concerns for outcomes with little concern for processes? Aesthetic research attends primarily to the given particularities within any situation as the necessary place to begin. Inquiry orients toward an ongoing forming/informing/reforming search. These givens comprise the raw materials of inquiry alive in the situation itself. Recognition of these raw materials and purposeful search for relationships and connections is the work of inquiry. Discerning these relationships is the indispensable condition of attending to the inquiry process.

Inquiry, then, becomes a movement of thinking, a medium in which meaning is not applied or imposed but rather manifested and could never be fully anticipated. In so doing, aesthetic researchers are drawing attention to the role and integral place of aesthetic considerations such as attentiveness to the personal and particular, participatory thinking, emotional commitment, felt freedom, dialogue and interaction, speculation, and greater consciousness within all meaning-making. These significances are often characterized by aesthetic researchers as neglected epistemological assumptions elemental to humans and the human condition. Aesthetic researchers are documenting and addressing the underestimated consequences that these pose to the ethical realm, to the possibility of genuine concerted action, to the growth of self-understanding in relation to others, and to the development of contextually sensitive practices. Thus, aesthetic research and researchers have important educative and leadership roles to assume in making visible and tangible the significances to be found through attunement to process manifesting outcomes not yet imaginable.

AGENCY

The modern notion of democracy is founded on the concept of free will or the idea that individuals are ultimately the arbiters of their own destiny. Human agency is very similar to the notion of free will in that agency may be understood as the capacity to exercise creative control over individual-level thoughts and actions. In keeping with the ideals of Western democracy, there is a widespread assumption that humans are imbued with free will and, as such, routinely exercise agency within the domain of their personal choices as well as in the social and political realm.

Nevertheless, social scientists have demonstrated that unique individual attributes are contingent on extensive social organization of the psyche. In other words, the process of developing basic human potentialities (e.g., walking, talking, learning, loving) is predicated on an elaborate socialization regime: Nurturing healthy, happy humans can be brought about only through a long-term process of intensive social training. This has led numerous social scientists to conclude that, because “individuality” is irretrievably dependent on elaborate social indoctrination regimes, there is in reality no such thing as agency; that is, if every key attribute on which unique human

personalities are based emerges only as a result of social indoctrination, then one can argue that all human creativity and potential are largely (or even wholly) determined by social influences.

Nevertheless, Timothy McGettigan argued that, despite the inescapable impact of societal influences on human psychosocial development, it remains possible to locate agency within the coercive context of social reality. McGettigan argued that actors demonstrate a capacity for agency when, on perceiving evidence that is in discord with their understanding of reality, they refashion their comprehension of reality to facilitate an understanding of that discordant evidence. Acquiring knowledge that might conflict with views that are already present in the minds of agents can be accomplished by participation in communication environments, through solitary reflection, or through various encounters with the empirical world (e.g., having an apple fall on one's head). The impetus (communication, reflection, or encounters with the physical universe) that impels actors to redefine reality is not as critical to the process of generating agency as is the ability of actors to perceive phenomena of which they had no prior conception and then to reconstruct their view of reality to accommodate their newly realized perceptions.

The existence of a capacity for redefining reality establishes that individuals who are situated within rigid contexts of social control can emancipate themselves sufficiently to think and act in a self-determined manner, that is, to exercise agency. Of course, the range of such emancipation is substantially constrained. Once again, just because individuals can conjure novel ideas does not mean that oppressive ideological superstructures will blow away like dust in the wind. However, the capacity for redefining reality implies not only that agents may produce novel ideas but also that agents can translate their groundbreaking ideas into action—and, in so doing, initiate social change at the individual, organizational, and sometimes even societal levels.

ANALYTIC INDUCTION

Rather than beginning with a theory, an explanation, or an interpretation and then seeking evidence to confirm, disconfirm, or otherwise test it in a deductive mode, inductive thinking starts with evidence—the particulars—and builds theories, explanations, and interpretations to reflect or represent those particulars. The close relationship between empirical observation and conceptual formulation guides most inductive approaches.

Analytic induction is the process of developing constructs such as categories, statements of relationship, and generalizations as well as the theory resulting from integrating categories and generalizations by examining incidents, events, and other information relevant to a topic. Abstraction from the concrete to a more inclusive formulation is a key task in analytic induction. Analytic induction asks the following of any event, activity, situation, or attribute: What kind of event, activity, situation, or attribute is this particular one? Classification is another central feature of analytic induction. From a close analysis of an initial case, constructs are generated and are refined through consideration of succeeding instances.

Most important to the developing category system and generalizations are succeeding instances contrary to initial instances, called *negative cases*. Negative cases may delimit a theory, indicating the boundaries of the theory's applicability, or they may compel a revision of a theory so that it will account for the variation. Analytic induction is an iterative process, a kind of recursive thinking from instances to idea to a search for negative cases to be added to the initial instances to refined idea and so forth until a construct is devised to adequately represent all relevant known phenomena.

Arguably one of the first formally named methods for analyzing qualitative data, analytic induction was formulated during the 1930s by Florian Znaniecki to describe how he and W. I. Thomas examined, explained, and interpreted the materials they collected for their magisterial work, *The Polish Peasant in America*. Alfred Lindesmith further developed the method of analytic induction in his study of addiction during the 1940s, and successive generations of

qualitative researchers have adopted and adapted what these scholars explored.

Znaniecki's vision of analytic induction has been criticized by some methodologists as seeking universal certainties, but this interpretation is debatable because Znaniecki disparaged efforts of others to use induction to arrive at absolutely true generalizations. He emphasized that, so long as human life continued, theories would need to change to reflect changing human conditions, changing human experiences, and (especially) changing human knowledge and understanding of the world.

ANONYMITY

Anonymity means that a research participant's identity and responses cannot be identified. Most ethical and professional codes of conduct require that researchers protect participant privacy through strategies that safeguard anonymity and confidentiality. A consequence of such codes is that researchers often assume anonymity must always be protected; they sometimes forget that participants might not share the same privacy concerns and would like to be acknowledged for their contributions.

The anonymity of participants can be full or partial. Full anonymity exists when even a researcher does not know the identity of participants and the participants are unable to identify their own responses. For example, a postal survey with no

identifiers and a questionnaire design that eliminates unique responses is completely anonymous. Such anonymity, however, raises validity concerns because it is also impossible to know whether the survey was completed by the desired participants. Partial anonymity exists when participants' identities are disguised with pseudonyms but their true identities could still be discovered. For example, pseudonymous internet chat room users may be traced to their personal computers. Identities may also be discovered if a researcher discloses unique characteristics about participants that are later recognized by alert readers.

Anonymity is most desirable to protect participants from harms that arise from the disclosure of their identities. For example, participants who are reporting human rights abuses under an oppressive regime benefit from anonymity. When investigating sensitive topics, anonymity can help to increase the likelihood that participants will give more candid information. Moreover, if a researcher does not know the names of interviewees, law enforcement authorities and other interested parties are unlikely to attempt to access confidential research files.

For some participants, a benefit of taking part in a study is the opportunity to publicly express their experiences and beliefs. They may desire acknowledgment of this and seek ownership of their contributions to a study. Indeed, they may even want readers to be able to contact them. Canada's national tri-council policy statement, *Ethical Conduct for Research Involving Humans*, recommends a participant-centered perspective that encourages researchers to collaborate with participants and to ensure consideration of their interests. The participant-centered approach suggests that anonymity should not be imposed on participants who wish to be named.

In qualitative research, anonymity can facilitate candid disclosure of sensitive information while also protecting the privacy and safety interests of participants. At the same time, if a source is completely anonymous, it is also impossible for researchers to account for the authenticity of their data. Finally, many research participants do not seek the privacy often imposed by researchers and ethics boards. Their wish to have ownership of their contributions to research—to be seen—should be given as much consideration as their concerns for privacy.

APPLIED RESEARCH

Applied qualitative research is concerned, first and foremost, with the usefulness and application of knowledge. Its primary focus is on the production of knowledge that is practical and has immediate application to pressing problems of concern to society at large or to specific public or private research clients. It is research that is designed to engage with people, organizations, and interests and is aimed to inform human services, public policy, and other local, national, and international decision makers. This entry reviews the origins of the distinction, describes types and uses of applied research, discusses methodological issues related to applied research, and examines some of the ethical issues that arise in connection with such research.

Historical Context

Prior to World War I, sociology, psychology, and other social sciences were focused primarily on basic research in an attempt to gain status as pure and objective scientific disciplines. However, by the end of World War I in 1918, more opportunities and needs for applied and action-oriented research began to emerge. These served to legitimize this pursuit as multiple examples of social progress and reform established the utility of applied research. At the University of Chicago, where early sociologists focused their attention largely on applied problems and dedicated their efforts to social improvement, community agencies began to partner with sociological researchers in the development of scientifically based human services. In the midst of the Great Depression (1929–1939) and with the onset of

World War II (1939), both the public and scientific communities strengthened their calls for researchers to participate in social and community action. Although the conservative atmosphere that permeated the late 1940s and 1950s shifted the scientific focus away from social reform and back to the pursuit of knowledge for the sake of science and theoretical advancement, the pervasive activism of the 1960s and 1970s led to a resurgence in attention to applied research. This has resulted in a large body of literature on strategies for effective social change. Today numerous researchers in the social sciences remain dedicated to addressing national crises and social concerns, and the National Science Foundation in the United States has prioritized many applied research initiatives.

Over time, the term *applied research* has evolved to include many diverse forms of research. William Whyte proposed the terms *action research* (research that leads to action objectives), *participatory research* (research that involves the participation of organizations or citizens without action objectives), and *participatory action research* (research that fully includes participation of organization members or citizens throughout the entire research process and in the development of action steps) to further delineate various forms of applied research. Kurt Lewin's writings and work are also crucial to applied research. He first proposed the term *action research* to represent a form of applied research in which phenomena are changed so as to observe the subsequent effects of that change. Thus, he called for real-life experiments to be done within natural settings. His famous words, "There is nothing so practical as a good theory," were said in support of applied work in a paper that advocated active cooperation between theoretical and applied research, but these words are often taken out of context and misunderstood as a criticism of applied research. Although Lewin challenged applied researchers to recognize the practicality of theory, he equally challenged basic researchers to remove their aversion to real-life problems and applied research questions. Lewin believed that if active cooperation between basic and applied research could be achieved, it would simultaneously answer theoretical problems and provide rational approaches to practical problems.

Applied Versus Basic Research

Since the inception of applied research, there has been much conversation, across various fields of social science,

about the distinctions, relative strengths, and even relative value of applied versus basic research. These distinctions were historically presented in stark contrast, with basic research being portrayed as pure, highly controlled, bias-free research often done in the lab for the sake of knowledge alone and unchallenged by practical, real social problems. Meanwhile, applied research was described as field based and designed to solve problems, often at the behest of nonscientists; thus, it was viewed as nonacademic, less controlled, less rigorous, potentially biased, and atheoretical in its orientation to outcomes rather than concepts. As various fields in the social sciences sought to distance themselves from their roots in philosophy and align themselves with the so-called hard sciences, whose bailiwick was in lab research, applied social science became undervalued when the fields attempted to emulate the methods and approaches of the flourishing physical sciences.

Many writers, in line with the writings of Lewin, argue against these stark distinctions, viewing the differences between basic and applied social science research as more nuanced and on a continuum rather than dichotomous. Russell Ackoff suggested that it is the researchers' intentions and the audience's use of research data that distinguish the two. Willy Lens showed how B. F. Skinner's basic research had obvious applications, whereas Sigmund Freud's applied work had a clear theoretical basis and outcome. Allan Kimmel further pointed to the dropping of the atomic bombs on Hiroshima and Nagasaki, Japan, as a clear indication that the knowledge developed through basic science is not ethically neutral.

It has been further reasoned that the merits of applied and basic research should depend entirely on the ways in which any particular research study meets the goals of its research question and that both types of research exist along a continuum, building on each other in synergistic fashion. Furthermore, both may be equally crucial to understanding and improving the human experience. Peter Rossi and William Foote Whyte contended, in a 1983 compendium called *Applied Sociology: Roles and Activities of Sociologists in Diverse Settings*, that attempting to apply theory to an applied problem may result in a much better critique than will any peer-reviewed journal. Robert Hoffman and Kenneth Deffenbacher took this one step farther, arguing not only that a bidirectional relationship exists between applied and basic research but also that applied research can contain multiple

elements of the entire continuum, including its ability to invigorate old theory through application, and lead to the creation of new theory. Hoffman and Deffenbacher further conceptualized an alternative way in which to identify research type, rating the research simultaneously on two dimensions: one ecological and focused on external criteria and the other epistemological and focused on internal criteria. The ecological dimensions include validity (are research conditions close to real life?), relevance (are research tasks and materials close to what people actually do?), salience (is the focus of the research important to real people?), and representativeness (do people in the real world often come across the conditions or demands of the research?). The epistemological dimensions are parallel: validity (does the design fit the available theories and accepted research methods?), relevance (are the research hypotheses based on concepts from available theories?), salience (does the research rely on theoretical concepts that are regarded as important?), and representativeness (is the research based on concepts that other scientists use frequently?). Thus, in Hoffman and Deffenbacher's conceptualization, what is often called basic research might be more correctly characterized as research that is high in multiple dimensions of epistemological validity but may or not be high in ecological validity. What is often referred to as applied research would be more properly identified as that which is high in some or all of the four dimensions of ecological validity, whether or not it is high in epistemological relevance.

Types and Uses of Applied Research

An increasing number of academic disciplines and occupational fields use applied research as their primary means of investigating and addressing social problems. Applied foci of some existing fields of study have also emerged to become independent disciplines (e.g., applied physics, applied developmental psychology). Although many would argue that applied research has the most utility when done in consort with decision makers and stakeholders, some applied researchers remain in the more traditional role of academic or professional expert. In this type of approach, sometimes called *action research*, the researcher is largely or entirely responsible for choosing the objective and methods. In contrast, *participant action research* and what the field of public health refers to as *community-based*

participant research both are types of applied research with strong emphases on the full participation of community members at all stages of the research process.

Applied research spans many substantive areas of interdisciplinary research and human services to address a wide range of persistent social problems as well as theoretical questions. Because applied research is so relevant to the general public, it is often used to inform governmental policy and legislation, educational reform, and public health as well as to address pressing social issues such as immigration, environmental planning, and the HIV/AIDS epidemic. It can be used throughout all stages of human services planning—from design and implementation, to needs and resource analysis, to resource allocation and decision making, to the insurance of citizen participation. Applied research is also employed by community-based researchers, such as community psychologists, for community analysis and development, program evaluation and/or planning, prevention research (e.g., substance abuse prevention, violence prevention), and the empowerment of vulnerable populations. The flexibility, versatility, and utility of applied research ensure that it can be conducted within a variety of settings (both domestically and internationally), including social services, educational settings, governmental agencies, business and consumer sites, and rural and urban communities. Other common forms of applied research include demography and survey research, which are often requested and used by marketing or advertising firms, opinion organizations, and government agencies.

Applied Research Methods

Russel Ackoff, in a classic 1962 text, outlined methodological and design issues for optimizing applied research. He delineated six research phases:

1. Formulating the problem
2. Constructing the model
3. Testing the model
4. Deriving a solution from the model
5. Testing and controlling the solution
6. Implementing the solution

Put more simply, Max Elden and Rupert Chisholm suggested the following three stages of applied research:

1. Diagnosing the problem
2. Planning action
3. Implementing and evaluating

In either conceptualization, the first and last phases may be considered the most unique to applied research and the most important to describe in some detail. Recall that applied research is, first and foremost, concerned with the usefulness, practicality, and immediate applicability of knowledge. Thus, the problem formulation is among the most crucial components of applied research and by definition should ideally involve community members, decision makers, stakeholders, and applied experts in addition to the researcher. As Ackoff pointed out, the purpose of applied research is to answer some question, and it is the researcher's job to translate a decision maker's problem into a research question. He suggested that this translation involves identification of four key components of the problem. First, who is (are) the decision maker(s)? Second, what are their related objectives? Third, what are the possible courses of action for the decision maker(s)? Fourth, what is the environmental context that may be out of the control of the decision maker(s)? From a community psychology perspective, it is also crucial to involve not only those with power, such as the decision maker(s) and other direct research clients, but also as many stakeholders and affected community members as possible. Ivan Nye made the point that the utility of a research project may also depend on the choice of problems. He suggested that applied research topics should be selected based on the proportion of the population affected by the problem, the seriousness of the problem, and the suspected amenability of the problem to change.

The translation of community concerns into a research model also involves creating a conceptual context or framework. This framework is essentially a theory that tentatively suggests the problem process and, thus, informs the design of research. Joseph Maxwell wrote about how this conceptual context is "constructed" from four sources: (1) experiential knowledge, which many would argue should include not only researcher knowledge but also that of stakeholders and other native experts in the field; (2) existing

theory and research, what is traditionally considered the literature review; (3) pilot studies; and (4) thought experiments that seek to answer “what if” questions prior to the start of research. Terry Hendrick and colleagues stressed that ethical and accurate research planning involves not only talking to research clients, sponsors, and issue experts but also reviewing reports, statistics, media reports, and position papers from stakeholders on all sides of the problem debate as well as spending time in the settings of interest to gather real-world data and talk with people currently engaged in those settings.

It is also crucial to ensure that, from the very start, one is thinking about the applied audience to whom results will be disseminated. Keeping this in mind will ensure that the research question(s), design, and solution are appropriate, meaningful, and useful to an applied audience.

It is the dissemination of useful knowledge for the purposes of implementation that is the *raison d'être* and hallmark of applied research. Writers such as Nye have argued that one of the basic problems in modern societies is the lack of information necessary to make important and complex decisions. Thus, the dissemination of information gained through applied research is crucial, and Nye argued that it is the researcher's responsibility to make sure that stakeholders receive information and that it is provided in an understandable form. He suggested that researchers should plan for three publications: those aimed at scholarly audiences, those written for practitioners, and those aimed at lay people. Whereas dissemination is the responsibility of the researcher, decision making and implementation are seen by most as the ultimate responsibility of the decision maker and stakeholders in the field. Ackoff pointed out that when implementation is done by nonscientists, changes may occur, and so he compared an applied researcher to an architect—responsible for creating an implementation plan that is detailed, feasible, and understandable to those who will construct what the researcher has designed.

It is also true that the applied researcher not only may make recommendations but also may be involved in implementation. Ackoff wrote of implementation as not only the intended result of applied research but also the best test of the results derived from that research. This recalls the earlier discussion regarding the fact that not only basic research but also applied research can be used for theory building and theory testing.

Shep Kellam's work in the Baltimore City Schools, testing developmental models of preventive interventions, is an excellent example of this. Kellam has maintained throughout his career that the most appropriate test of developmental intervention models is through rigorous, longitudinal, applied field research.

Ethics

Applied research, like any type of research, presents important ethical challenges. In addition, due to the potential and intent of applied research to quickly and directly affect social policy and programming in real-life settings, great care must be taken to protect all who may be affected. Although it is common to conceptualize ethical problems in research as arising mainly from the methodology, Kimmel and others pointed out that the subject matter itself can present ethical challenges. In addition, ethical reverberations can just as easily arise from the study that is *not* done and the questions that are *not* asked as from the study that is conducted. Ackoff suggested that care should be taken to ascertain the motives of the research sponsor(s) and client(s) in requesting research. Issues of status, prestige, control, and the desire to use research to confirm assumptions or obstruct information transfer can damage research and researcher credibility, rigor, and ethics. Ackoff also suggested that sometimes, particularly when enticing but preliminary results arise, researchers have an ethical responsibility to “unsell” findings, that is, to persuade decision makers that further research is necessary before results are acted on in real-world settings. Because most, if not all, ethical guidelines for the social sciences stress researchers' primary responsibility to protect the most vulnerable populations, applied researchers have a serious charge to attend, first and foremost, to the best interests of those who will be affected by the potential and actual knowledge gained and the policy and interventions that may result from their research. Done properly, applied research is a powerful tool with the potential to contribute to both the growth of science and the amelioration of pressing real-life problems.

APPRECIATIVE INQUIRY

Appreciative inquiry (AI) is a deliberate search for the positive core of an individual or collective system. It rests on a belief that there is something that works in every system. This goodness can be identified and drawn out. AI, then, is an inquiry into what is valued and good about the individual or collective system. It generally employs a four-phase process of discovery, dream, design, and destiny. The discovery phase is focused on identifying what already exists in the system that is good. Once that is identified, it is possible to imagine an even better system, which is the dream phase. Creating an infrastructure to support this ideal system is the work that takes place during the design phase. As the new system comes into being, it must be maintained and sustained in such a way that its affirmative capacity is continuously strengthened; this is the destiny phase. As the system lives its destiny, a new cycle begins through another inquiry into what makes it good.

The name most closely associated with AI is that of David Cooperrider, a professor of organizational behavior at Case Western Reserve University. As a doctoral student, Cooperrider questioned the wisdom of the problem-solving mentality with its focus on diagnosing what is wrong. He proposed a different approach, now referred to as appreciative inquiry.

Appreciative Inquiry Described

Foundational to AI is a social construction philosophy. A working assumption of AI is that systems (even individual ones) are socially constructed. They are constructed by and through the influence of people. Thus, they are open to change. What has been constructed can be reconstructed. Regardless of its history, any system can be altered. AI uses the positive past history of the system to direct its future. Images of the future are grounded in the system's past positive history, making the image ideal yet within the realm of possibility.

As an approach to research, AI has been most closely associated with action research, case study, narrative, portraiture, and evaluation methods. In practice, this approach seeks to conduct research that begins with a stance of appreciation yielding useful and provocative data (generating more curiosity) and that is collaborative (recognizing the line between researcher and researched is a fine one). AI relies on collecting data through conducting interviews, making it well suited to qualitative research methods.

Appreciative Inquiry Questions

A hallmark of AI is the positive orientation of the interview questions. The questions asked determine the information received. The information received is used to form conclusions and recommendations. Thus, it could be said that the study is only as good as the questions asked. With its emphasis on the social construction of (individual or collective) systems, the supposition is that the questions asked will effect change in the system. When an inquiry is conducted with a spirit of appreciation, the valued factors and forces in the system are affirmed and illuminated. These factors and forces can be used to guide the future direction of the system.

In AI, a fair amount of time is devoted to crafting “good” questions—those that use positive language,

are posed as an invitation, are phrased in sometimes ambiguous conversational language, and evoke storytelling about peak experiences. There is an assumption that people carry around with them several stories, some of which are positive. Questions are designed to elicit these positive stories. Four primary types of questions are asked: deep story, value, core factors, and future or miracle.

The deep story question is designed to evoke stories about best experiences and to begin to get people thinking appreciatively. People are encouraged to provide rich thick description by talking about who was involved, what made it a peak experience, what they did to make it a peak experience, and what others contributed to make it a peak experience. The value question is crafted to discover what it is that people value about the individual or collective system under inquiry. This begins to personalize the factors mentioned in the deep story response. The third type of question, core factors, is meant to identify what people believe are the core factors that give life—factors that are integral to the system under discussion. This question elicits the specifics about what gives life to the individual or collective and seeks to understand why it gives life. Finally, the future or miracle question is an invitation to dream and imagine the ideal future. What could be is described in detail.

When an AI approach is used for research, the types of questions are adapted to suit the study. For example, in a study about leadership, the interview questions might be as follows:

- Please tell me about a time when you believed you excelled in a leadership capacity. This could be in your personal or professional life. Who was involved, what were they doing, and what were you doing that made it a memorable experience? (deep story question)
- What do you believe you brought to that experience that made it a high point? What specifically do you value about your past experience and knowledge that prepared you to take on the leadership role described? What was it about the context that helped you to excel? (value question)
- Describe what you believe was unique about this experience. In other words, without these factors, the experience would not have been what it was. (core factors question)
- Considering what you know now and what you have experienced, what words of wisdom do you have for

those aspiring to leadership positions? When thinking about the future, what are your wishes for those who would be leaders? (future or miracle question)

Such questions elicit rich narratives about positive experiences.

Interviews are generally conducted face-to-face. It is critical for the interviewer to suspend his or her assumptions about how people will answer the questions and question the obvious. Probing beyond superficial answers yields a rich complex narrative.

Sometimes people have a difficult time focusing on the positive. It is common for people to report that because they are usually asked about what is wrong, they need to purposely reflect on what is right. Yet once they do, they generally find this to be easy to elaborate and frequently grow visibly excited about the topic. For this reason, it is recommended that the questions be asked in the order just presented. As a specific positive situation is identified and expanded on, by the time the “future” question is asked, the interviewee may well propose possible solutions to current problems.

Relationship to Other Research Methods

AI is most closely related to action research, case study, narrative, portraiture, and evaluation methods. Each of these methods has qualitative applications.

Action research commonly uses qualitative methods. Everyday things in life are unpacked by engaging stakeholders in a deeper understanding of their experience. Experiential knowledge is honored in a collaborative process. There is a fine line between the researcher and the researched. The primary aim is to produce knowledge that can be applied directly. When an appreciative approach is used, the questions asked focus on what is working rather than diagnosing what is wrong.

Although quantitative methods can be used, case study is usually considered to be a qualitative research methodology. The case can be the object of study and/or the product of the inquiry. When the case is the object of study, it is bound to be a single or multiple case study. As a product, a case description is reported. The appreciative case study employs a positive stance and studies what is working in the setting. The themes of the case are centered on what is valued.

With its recognition of and reliance on stories as data, AI has a clear connection to narrative. The

purpose of the appreciative interview is to solicit specific kinds of stories. Although the stories shared may be about an individual or collective system, the intent is for the stories to be directed at the positive core. AI encourages the sharing of positive stories in varied ways and forums. The stories shared reflect how people think about the system and provide leverage for making changes.

Portraiture is a qualitative research method that has inherent in it a focus on the good. It seeks to underscore what is healthy and strong. The method concerns itself with discovering the genesis and illustration of what is considered good from the view of the interviewees. With this orientation already built into it, AI is an unmistakable match.

Evaluation research is used to assess the effectiveness of a program or policy. Often qualitative methods are used. The historical focus in evaluation research has been on identifying areas for improvement. An AI approach switches the focus to the strengths of the program or policy and how to build on them.

An appreciative approach and appreciative questions can be designed for a variety of qualitative studies. The possibilities are not limited to those just discussed.

The Appreciative Approach

A major premise behind AI is that the positive core of individual and collective systems has been neglected. This positive core exists in every individual and collective system. It can be used to reconstruct the system.

Although it is changing, research frequently has a focus on problem solving. After all, the first step in designing a research study is to identify the problem being investigated. An AI approach would change the language to describe the issue or topic, rather than the problem, under investigation. An AI approach to research may show up most clearly in the interview questions; however, it can be infused throughout the design of the study. An example of an appreciative case study is a dissertation written by Ron Prindle, *An Appreciative Case Study of Downsizing Effects on a Shore-Based Department of the Navy Reserve Support Organization*. This dissertation, written in 2005 and available from Gonzaga University, illustrates how adopting an AI approach shaped the entire study.

The profound differentiator of AI compared with other research methods is AI's deliberate focus on the creative, generative, and positive aspects of a system

(individual or collective). This focus may be seen throughout the research process—from the construction of the research question, to the design of the interview guide, to the identification of major themes.

ARTIFACT ANALYSIS

Artifacts become data through the questions posed about them and the meanings assigned to them by the researcher. There is no one right way to analyze artifacts. A wide range of disciplines informs the analysis of artifacts, including anthropology, archaeology, art history, history, human geography, ethnography, and sociology. In the process of analysis, we are asking the data to tell us something. An artifact has a story to tell about the person who made it, how it was used, who used it, and the beliefs and values associated with it. For example, a quilt made around the time of the U.S. Civil War may have been used to communicate ideas about abolition, to smuggle messages through enemy lines, to raise funds, or to bury a soldier killed while fighting the war. The materials used can provide a glimpse into what resources were available to the quilt maker. Another example of artifacts that have a story to tell would be archival records such as birth, marriage, and death certificates. These records can be examined for their genealogical value and to understand the patterns of life in a culture or society.

Several kinds of analysis are related to artifact analysis. All are described in more detail in separate entries throughout the encyclopedia. Thus, just a brief overview follows here.

Methods of Analysis

Although there is no one correct way to analyze artifacts, several approaches to analysis may be employed depending on the type of artifact being examined. These include content, discourse, document, historical, and narrative analyses as well as semiotics.

Content analysis is a systematic examination of forms of communication used to objectively document patterns. In general, text is broken down into categories and the presence of these categories is often quantified. Discourse analysis also uses written, spoken, or signed language as its object but is concerned with larger units of analysis such as conversations and the interrelationships between language and society. Document analysis is the study of the written text and takes into account the document's physical condition, the handwriting or printing used, and its idiosyncrasies. Historical analysis concerns itself with understanding the state of the times in which an event occurred or a person lived. Narrative analysis examines the internal coherence of a text and investigates the story being told. Semiotics is the systematic study of symbols or signs and includes the study of how meaning is constructed and understood.

Depending on the specific artifact being analyzed, any one of these or a combination of approaches may be useful. This reflects the wide range of disciplines that can be used to inform the analysis of artifacts.

The Analytic Process

The analytic process is iterative in nature. It involves inferring meaning and making judgments on the part of the researcher. Often the researcher works between the past and the present or between different examples of artifacts looking for relationships. Themes, patterns, and refrains are sought.

It is important to remember that it is common for this type of data to be mute in the sense that member checks often cannot be conducted to verify the interpretation. Thus, the researcher must consider several factors. Questions about the nature of the artifact must be asked. Such questions include the following:

Who made it? What materials were used in constructing it? What was the occasion? What was the purpose of the artifact? How public is it? How structured is it? Who was the intended user (an individual or a group)? Who cannot or did not use it? Did different people use it in different ways? What is shown through the artifact? What is absent? Why was it recorded or saved? Considering the artifact's historical context is critical: What was happening in society or in history at the time the artifact was made? What meaning did the artifact have for the users? Has its meaning or use changed over time? Does the meaning differ for different users? If it was created elsewhere, how did this person or group of people acquire it?

Artifacts were created in a context and, thus, must be studied within that context. Just as it is dangerous to take interview and observational data out of context, it is risky to take artifacts out of context.

In addition, researchers must consider the context of their own study. Questions to pose during this phase of the analysis include the following: What is the focus of the research, and how is this artifact related? What categories of information need to be developed? What perspectives need to be developed in light of the research purpose? How do these data fit in with other data?

Both the context of the artifact and the context of the study must be addressed during the analysis phase. Whereas the artifact must be analyzed within its context, the data provided must be considered within the context of the research. By posing the questions mentioned plus others generated by the researcher, artifacts become rich sources of data. The researcher determines exactly what the data mean as the boundaries of the study are defined.

Artifacts as Data

Artifacts provide a rich source of data. They are a source of information not available from interview or observational data. Artifacts can be used to support or challenge other data sources and literature, to generate or confirm hunches, and to help provide thick description of people and/or settings. The story they can tell is valuable.

ARTIFACTS

Artifacts are things that societies and cultures make for their own use. They provide material evidence of the past by documenting and recording the past. Artifacts can provide historical, demographic, and (sometimes) personal information about a culture, society, or people. Insights into how people lived, what they valued and believed, their ideas and assumptions, and their knowledge and opinions are revealed in artifacts.

Examples of artifacts include photographs, memorabilia, tools, buildings, toys, pottery, jewelry, clothing, weapons, gifts, paintings, graffiti, furniture, and tombstones (Figure 1). They can be religious, artistic, technological, or functional in nature. A common type of artifact is written texts such as documents, diaries, journals, memos, meeting minutes, and letters. Archival records are also sources of artifacts and include public records (e.g., birth, marriage, or death certificates), voting records, and newspapers. Artifacts may also be in the form of film, television, and music.

Besides being items that people have created (e.g., notes, diaries, journals, jewelry, pottery), artifacts can also be things that people have worn away. For example, paths created in grass where people commonly walk and the shine worn away from heavily trafficked areas of a floor would be artifacts that reveal how people navigate a space.

Artifacts can also be researcher generated. For example, the researcher may ask participants in the study to keep a journal. The journal would become an artifact of the study.

The term *material culture* is used in association with artifacts. Material culture covers a broad spectrum and refers to the sum of artifacts found in a

Figure 1 Examples of Artifacts

Notes: Clockwise from top: baseball cap, newspaper, cowgirl boot, kukka (Finnish drinking utensil), oxen shoes, and wooden shoe (from France). Center items: passport and baby spoon. All artifacts are displayed on a beaded and sequined patchwork wall tapestry from the United Arab Emirates.

culture or society. In general, these artifacts are everyday objects that have been left behind or made by people to satisfy needs or wants or to express an idea or belief. They are products of a culture or society.

Artifacts are a frequently overlooked source of data. They serve to enrich a study and often provide information not available from interview or observational data. Although not common, it is possible to build an entire study around artifacts. *Bold Spirit: Helga Estby's Forgotten Walk Across Victorian America* by Linda Lawrence Hunt was based almost entirely on artifacts. Helga Estby and her daughter walked from Spokane, Washington, to New York City in 1896. The little evidence that remains of the journey is in the form of diaries, notes, photographs, letters, and newspaper accounts. Relying primarily on these artifacts, supplemented by interviews with living relatives, Hunt was able to piece together the remarkable cross-country adventure.

Artifacts are a unique source of data that often are right in front of us. They shed light on important aspects of a person, society, or culture, enriching any study.

A/R/TOGRAPHY

A/r/tography is an arts and education practice-based methodology recognizing that the practices of artists and educators are often reflective, reflexive, recursive, and responsive acts of living inquiry. This entry describes these practices in broadly conceptualized forms of inquiry that can be used by scholars, artists, educators, and students.

A/r/tography as a Form of Inquiry

A/r/tography resides in the practices of artists and educators whose forms of inquiry are similar to an understanding of action research that does not follow a prescribed plan or method but rather pursues an ongoing inquiry committed to continuously asking questions, enacting interventions, gathering information, and analyzing that information before asking further questions and enacting more living inquiry. Although these acts might seem to be linear, they are usually intertwined acts of meditative, even contemplative, inquiry. The creative and artistic inquiry practices of poets, dancers, musicians, performers, visual artists, and other artists resonate with these educative acts of inquiry and also inform a/r/tographical practice. A/r/tographers envision artistic and educational practices as enacting dispositions to knowledge creation as they begin to appreciate how inquiry is a commitment to understanding through acts of theorizing. The practices of artists and educators are situated within complex environments. Inquiring in these contexts requires a commitment to an evolution of questions within the living inquiry processes of practitioners. For a/r/tographers, this means an ongoing quest for understanding that is timely, emergent, generative, and responsive for those involved. After all, artists seek challenges that interrupt taken-for-granted ways of knowing so as to see, hear, and experience the world differently. In this way,

a/r/tographical practices are not comfortable habits but rather the challenging practices of learning to question differences and perceive differently in and through time. A/r/tographers understand that who they are is embedded in what they know and do. Theory and practice are no longer divided but rather folded together through lived experiences and lived inquiry.

Methodological Practices of A/r/tography

A/r/tography is different from many other research methodologies that identify specific research problems to be solved through methodological protocols that lead to specific research findings. A/r/tographical inquiry may identify foreshadowed problems, but the intention is to engage in inquiry over time so as to come to deeper understandings of the issues that have been raised. Graeme Sullivan addresses this idea by moving away from the language of probability and plausibility to possibility. A/r/tographers are committed to artistic forms of engagement that help them to create, interpret, and/or represent new forms of knowledge. Knowing (*theoria*), doing (*praxis*), and making (*poiesis*) are folded together in a/r/tography to form rhizomatic ways of experiencing the world and creating the circumstances to produce knowledge and understanding through inquiry-laden processes. Furthermore, knowledge is always in a state of becoming, meaning that there is a need to be continuously committed to inquiry over time.

A/r/tography involves self-inquiry and collective inquiry. Artists and educators recognize that relationality permeates our existence. The work of Maurice Merleau-Ponty and Jean Luc Nancy underscored this concept by maintaining that meaning is constituted between beings. According to Nancy, this betweenness is both unity and uniqueness, the singular plural of being. Each identity is created through encounters with others, and it is the *with* that demonstrates the contiguity and distinctiveness of each entity. The relations between these entities and other entities show how the in-betweenness can metaphorically be conceived as a fold. In a fold, the material is simultaneously exterior and interior with no sides. Gilles Deleuze translated un/folding as dividing endlessly—folds within folds existing side by side. Un/folding performs in the in-between spaces, and in a/r/tography relational inquiring is un/folded between the identities and forms of engagement for the artist/researcher/teacher.

Artists, researchers, and educators do not work in isolation. Their work is related to the work of others. A/r/tographers acknowledge the work of others either by attending performances and exhibitions or by citing artists, educators, and researchers in their written work. Furthermore, a/r/tographers are not limited to academic circles. They can be practicing artists, teachers, learners, and students. Although a/r/tography privileges the identities of artists, researchers, and teachers (a/r/t), it should be noted that these identities are broadly conceptualized. For instance, rather than saying *teacher*; it may be better to say *teacher/learner* so that the teaching and learning enterprise is embraced. Just as a/r/tography challenges habits of knowing, it challenges boundaries that are placed on the identities of artists, researchers, and teachers. In so doing, a/r/tographers also challenge the institutional boundaries often associated with these identities. Artist/researcher/teacher identities exist in a contiguous relationship with one another. In communities of a/r/tographers, one might find separate communities of artists and educators, but it is more likely that hybrid communities of artists, educators, and researchers have been created.

Concepts and Conditions of A/r/tographical Inquiry

A/r/tographers look to Mieke Bal's contention that interdisciplinarity needs to find its basis in concepts rather than methods. Concepts are flexible intersubjective locations for enhanced understanding. The conditions for these concepts are relational forms of inquiry. How does a/r/tography fit within a qualitative methodology? A/r/tographers can use any method commonly used by qualitative researchers such as interviews, observations, and reflective note taking, but what is more important is that a/r/tographers understand that concepts direct inquiry, whereas methods are strategies for gathering information. To emphasize the conceptual nature of a/r/tography, concepts are referred to as *renderings*. Thus, a/r/tographers need to consider the conditions (relational forms of inquiry) and the concepts (renderings) that help them to conduct their living inquiry.

A/r/tographical work may be rendered through the methodological concepts of contiguity, living inquiry, openings, metaphor/metonymy, reverberations, and excess that are enacted when a condition of relational inquiry becomes the site for working with the arts and text while practicing the broadly conceived identities

of artist/researcher/teacher. A/r/tography is necessarily about self. Yet so too can communities of a/r/tographers share inquiries, be critical friends, and work collectively to interpret, create, or represent their evocative/provocative works to others. A/r/tography is certainly about inquiry, yet inquiry also involves the presentation of new understandings (rather than findings) from time to time. Renderings help to conceptualize the processes and products within the inquiry. Moreover, renderings are not procedures but may be conceived as performative concepts of possibility. The first, contiguity, represents the coming together of the arts and graphy (writing) as well as the coming together of the identities and practices of artists/researchers/teachers. Contiguity makes visible the spaces in between these practices and identities as well as the relationships these spaces inspire. The dialectical in/between spaces are dynamic living spaces of inquiry where entities touch and then shift yet lie close together. In this space, inquiry becomes open to challenges, discomfort, and surprise.

Rita L. Irwin's A/r/tography, 2006

In this photograph, I have blurred the environment to see it anew. Metaphorically, this affords me an opportunity to blur other areas of inquiry (e.g., teaching, learning) that lead to new insights and perceptions. In a/r/tography, artists/teachers engage in ongoing inquiry around particular issues or curiosities through their art forms and pedagogies and, as a result, use their ongoing inquiry to pursue change in their practices.

Source: Digital photograph, 2006, by Rita L. Irwin.

Artists, researchers, and teachers engaged in a/r/tography are living lives of inquiry where conclusions are seldom found but searching and researching continue despite the unpredictable. Living inquiry is the second rendering. In a/r/tography, visual, written, and performative processes are enacted as a living practice of art making, researching, and teaching. Living inquiry is an embodied encounter constituted through artistic and textual understandings and experiences that may or may not include representations. Living inquiry lingers in the liminal spaces among *a* (artist), and *r* (researcher), and *t* (teacher) and often arises out of everyday life. As such, the emotional, intuitive, spiritual, bodied, and cognitive ways of knowing are accessed through experiences engaged during living inquiry. Artistic and textual renderings of living inquiry may also expose contradictions and assumptions that lead to evocative or provocative a/r/tographic accounts.

Living inquiry is a fluid orientation finding its rigor through continuous reflexivity and analysis. Some individuals are interested in a/r/tography while believing that they do not need to be skilled as artists. On the contrary, a/r/tographers need to be committed to being the best possible educators and artists they can be. A/r/tography should not be chosen simply as a vehicle for artistic representation through research dissemination; rather, it should be chosen as a way of being in the world. Living inquiry encourages one to experience and question the world from different perspectives and to slow down and notice that which is around one. In a photograph, one can blur the environment to see it anew. Metaphorically, this affords one an opportunity to blur other areas of inquiry (e.g., teaching, learning) that lead to new insights and perceptions.

The third rendering encompasses metaphor/metonymy. Through metaphors and metonymic relationships, we render experiences understandable. Metaphors and metonyms allow insight yet ambiguity of meaning. The forward slash between them allows division and doubling, a reverberation between the two that makes them relational and active. Moreover, meaning un/does itself in that there is often a loss of meaning and deeper insights. The fourth rendering is openings. A/r/tography is both active and responsive—open to what is seen and known and to what is not seen and not known. Cracks, tears, holes, losses, invitations, and encounters can represent openings. Inquiry that opens up conversations creates spaces where relationships can reverberate with meaning. This brings us to the fifth rendering. Reverberations call attention to the

movement that shifts meanings. These movements allow meaning-making to be created at deeper levels, across time, and/or with others. An entanglement of meaning often happens in social networks where we push and pull apart meanings in the company of others. The last rendering is excess where we create to become, where we examine our fears and desires, and where we renegotiate the everyday. Excess can represent waste and the sublime, the awful and the incredible. Excess provides opportunities for complexity by questioning our very being and becoming.

Renderings are dynamic and intersubjective concepts. A/r/tographers engage in conditions of aesthetic inquiry to explore possibilities for creating meaning by performing their living inquiry through the contiguous acts of art making and writing, where ideas metaphorically and/or metonymically reverberate in excess and openings. Renderings are often enacted through rhizomatic assemblages where meanings and understandings are interrogated and ruptured. As a result, a/r/tography transforms the idea of theory as an abstract system distinct and separate from practice to become theory *as* practice, an embodied living space of inquiry.

In closing, a/r/tography allows artistic and educational practices to inform, contradict, and complement one another. As a/r/tography is used more widely, other renderings (concepts) and relational forms of inquiry (conditions) may be interpreted, thereby transforming a/r/tography through practice. Recently, scholars in architecture, health care, and the humanities have been exploring how the a/r/tographic practices of artists and educators can enhance their inquiry. These interdisciplinary spaces concentrate on the conditions and concepts for inquiry rather than on the primary disciplines and are pushing the boundaries of inquiry in the academy. A/r/tography as a creative and educative form of living inquiry will transform over time as the arts and education transform in and through time.

ARTS-BASED RESEARCH

Arts-based research is a form of qualitative research in the human studies that employs the premises, procedures, and principles of the arts. It is defined by the presence of aesthetic qualities (or design elements) within both the inquiry process and the research text. Therefore, arts-based research is quite different in many ways from traditional forms of research that are associated with the social sciences. Arts-based research differs from scientific research both in the process in which the research is conducted and in the modalities used for representing research data. For that reason, social researchers who have been professionally socialized to regard research in the various fields of the human studies as exclusively scientific may dismiss arts-based research as not useful. Over the past couple of decades, however, arts-based research advocates and practitioners have made headway in dispelling the misunderstandings that resulted in earlier

marginalization. This entry reviews the types and purposes of arts-based research, elements of the investigative strategies and communicative approaches it employs, and criteria for evaluating such research.

Kinds of Arts-Based Research Texts

Advocates and practitioners of arts-based research have provided two distinctly different sorts of textual products. The first kind is conceptual insofar as it addresses the nature, characteristics, and purposes of arts-based research. This kind of text is found in articles, books, book chapters, and conference presentations that focus on various dimensions of arts-based research. Of course, as with the formation of any novel approach to researching social phenomena, there is disagreement among scholars regarding these dimensions.

The second kind of text offers actual examples of arts-based research. These examples employ any of a number of art forms in the representation of the social phenomena under study. Various forms of the literary, visual, plastic, and performance arts have been represented, including the following: novel, novella, short story, poetry, found poetry, memoir, autoethnography, readers theater, ethnodrama, verbal portraiture, literary case study, literary essay, educational criticism, autobiography, biography, self-narrative, allegory, mixed genres, photography, film and video documentary and fiction, hypertext, painting, sculpture, museum installation, multimedia, dance, and music.

Purposes of Arts-Based Research

In their increasingly successful efforts to legitimate an approach to social research that is dramatically different from social science, arts-based researchers have identified unique purposes for engaging in their projects. Some scholars have emphasized the capacity of the arts for enabling viewers to perceive qualities within the social world that would have otherwise gone unnoticed. They have suggested, moreover, that different forms of art enable a percipient to see the same phenomena in different ways. This purpose for arts-based research, therefore, may be described as one of enhanced understanding through the communication of subjective realities or personal truths that can occur only through works of art. Elliot Eisner, an educationist scholar who coined the term *arts-based research* during the 1980s, has articulated this aim most forcefully. Eisner, a self-identified cognitive pluralist,

Touching Eternity: The Enduring Outcomes of Teaching

Touching Eternity: The Enduring Outcomes of Teaching, published in 2001, is an example of an arts-based work that attempts to problematize orthodox notions of what constitutes quality in teaching. Using a literary format and writing style, Tom Barone crafted the life stories of several former students of the same high school teacher. The stories were aimed at enabling readers to vicariously experience the student–teacher interactions both inside and outside of the classroom setting. Each student insisted on portraying the teacher as a powerfully influential central character in his or her life. In an ensuing analysis of the life stories, however, Barone raised questions about the possibility of teachers as heroic figures who, operating single-handedly against powerful external forces, can indeed make a significant difference in the quality of their students’ lives. The result is a book that offers no final answers but rather prompts readers from all walks of life to reconsider their own (perhaps deeply held) beliefs about who is a good teacher.

Source: Barone, T. (2001). *Touching eternity: The enduring outcomes of teaching*. New York: Teachers College Press.

advocated a kind of binocular vision that results from investigating educational (and other social) phenomena through both scientific and artistic lenses.

A second purpose identified with arts-based research also entails a shift away from the traditional objectivist epistemology identified with most social science research. Social scientists have tended to strive toward a high degree of certainty in securing and disclosing their findings. The publication of these findings sets forth knowledge claims about the phenomena under study. The higher the validity and reliability of those findings, the more likely they will be deemed useful in predicting, and even controlling, future events. However, arts-based research is not usually aimed toward securing (or even approaching) either “objective” or “subjective” truth. Indeed, most arts-based researchers harbor radically different aspirations for their inquiry projects. This purpose involves the generation of doubts about, the potential for disrupting or transgressing against, and the enhancement of uncertainty regarding presuppositions about the social world that have come to be taken for granted as contributing to a final reality.

Arts-based research texts, therefore, are designed in a manner that will promote profound reconsideration of the commonsensical, the orthodox, the clichéd, and the stereotypical. This disturbance by the arts-based research text of the privilege of the status quo may make possible that toward which many artists strive, according to Maxine Greene and others. This is a work that enables the reader or percipient to reimagine deeply deficient social institutions and practices.

What these articulated goals of arts-based social research—the communication of subjective realities and the vigorous interrogation of a commonsensical way of comprehending the social world—have in common is an enhancement of multiple meanings. Indeed, this possibility of entertaining alternative ways of perceiving the world implies the presence of what Richard Rorty identified as one of two fundamental purposes of human inquiry. If the first purpose has been the discovery of truth through employment of the tools of traditional forms of social science, the second is indeed the revelation of alternative meanings through artistic projects.

Research Design Elements

Research design, of course, involves both investigative strategies and approaches to the communication of research “findings.” Elements pertaining to each of these dimensions must serve the shifting purpose of the arts-based researcher. For example, within social science research that is experimental in nature, elements of design are carefully selected to meet the traditional purpose of moving the reader toward certainty regarding the phenomena under study. An experiment that is carefully designed will theoretically result in the most highly valid and reliable truth claims. Within arts-based research, however, radically different design elements may be selected in accordance with their alternative research goals.

These design elements will, of course, vary to some degree according to art form. For works that are literary in character, the inquiry approach may be less systematic than that employed by social scientists. The research process engaged in by playwrights, poets, and novelists, although often extensive and thorough, might not exhibit the highly structured protocols and procedures found in social scientists’ methodological toolkit. Most social scientists will, after all, perform in accordance with Rorty’s first inquiry aim, a quest for certainty, whereas most arts-based researchers will

honor the process through which interrogative art is created. Similarly, the findings of social science will, on the one hand, quite rightly be revealed within a text that honors the orthodoxies of a scientific report. On the other hand, arts-based researchers will configure their “data” into an aesthetic form that is designed to promote the kind of re-visioning that was described previously. For example, an arts-based manuscript designed to promote an understanding of the world of an adolescent with Asperger’s syndrome may take the form of a novella, a documentary film, or a cluster of poems that enables the reader/viewer to reexperience the world from a previously unavailable vantage point.

The shape and format of this sort of research text will be the result of a reorganization of aesthetic content (“data”) into a form that will entice the reader into a textual engagement where mundane aspects of everyday life are highlighted. Transported into, and repositioned within, an “aesthetic remove,” and thus temporarily bracketed off from the “real world,” the reader can be enticed into reconsidering the meanings underlying the human phenomena being investigated, for the phenomena may now appear strange and unfamiliar and, therefore, in need of reconfiguration within the worldview of the reader. The commonsensical meanings easily attributed to facets of the social and physical world may be challenged, and for the reader the intermediate result may be ambiguity or conflict. However, the ultimate outcome may be increased empathic understanding, that is, a deepened appreciation of alternative outlooks and perspectives—whether those of an emotionally challenged adolescent, members of unfamiliar cultural and/or religious groups, or anyone who dwells outside of what Rorty called the “range of us.”

Qualities of Good Arts-Based Research

Because arts-based research participates in an oft-neglected purpose of human inquiry, the question of what constitutes quality within this approach becomes especially relevant. According to most arts-based researchers, judging their products as if they were indeed works of social science represents a profound category error. They would contend that such assessment malpractice may result in the dismissal of extraordinarily useful research as invalid and even dangerous. Arts-based research projects that serve the purpose of raising profound questions regarding the

value of particular social and cultural practices may be unfairly and irrelevantly critiqued as failing to offer trustworthy knowledge claims.

Advocates of arts-based research contend that an arts-based research text should be judged in terms of the degree to which it possesses the potential for furthering its own inquiry purpose. What, then, are the criteria for making this sort of judgment about the worth of arts-based research texts?

In fact, there is no final set of standards that may be employed to judge the quality of an arts-based work. Indeed, assessing value within arts-based research implies judging not a static quality inherent in the text but rather the degree to which the work possesses a potential for a certain sort of persuasion of members of its audience.

Tom Barone identified three criteria (among additional possibilities) for judging whether an arts-based text evidences the power to raise significant questions regarding commonsensical notions lodged within the prevailing cultural landscape that would otherwise be left undisturbed. First, the research must have reconfigured features of the observed world into a virtual world that is not literally true but plausible, credible, and possible—one that resonates with the experiences of the percipient or reader. Second, the work must be compelling. Does the text have the power to lure the reader into that virtual world so that he or she desires to inhabit it at least temporarily? If the work is not attractive in this sense, it is unlikely to achieve its pragmatic purpose of raising questions in the minds of its audience. Here, most clearly within literary forms of arts-based research, various storytelling devices become important, including (among others) evocative language, strong narrative drive, textured characterizations, and satisfactory sequencing of events. Third, the text must be able to move the reader beyond the constraints of the particular and local, that is, to seduce the reader into seeing the world of the text as analogous to and relevant for situations that reside outside the world of the text and within the more proximate everyday world of the reader/viewer.

The last criterion suggests the importance of a certain sort of “generalizability,” although not in the constricted traditional sense of that term. Instead, the good piece of arts-based research must be able to coax the reader into rethinking the conventionally “real” world around him or her. This text may even provoke groups of audience members into conversation about

the various possible “meanings” of the text and its implications for their perhaps deficient world-at-hand. Profound interrogation of that real world by its audience is indeed viewed by many arts-based researchers as the sign of a successful work of their brand of social research.

ARTS-INFORMED RESEARCH

Arts-informed research is an approach to qualitative research in the social sciences that is situated in sound understandings of qualitative research approaches. Although the focus of the work is not necessarily about the arts, it is grounded in the arts in several ways. First, the researcher is inspired by an art form, an artist, or a body of artistic work to create innovative research processes. Second, these research processes draw from artistic processes characteristic of how an artist works, whether in the fine arts or applied arts broadly conceived. Third, representation of the research (the telling of the research story) relies heavily on art forms characteristic of the arts’ preceding defining qualities. Arts-informed researchers are

explicitly interested in presenting their work to diverse audiences through means that rely on the arts. This entry describes the goals of arts-informed research and the elements that define it. Then, through an examination of the ways in which arts inform the research process and the research representation, the entry identifies the characteristics of good arts-informed research.

Goals of Arts-Informed Research

Arts-informed research is a mode and form of qualitative research in the social sciences that is influenced by, but not based in, the arts broadly conceived. The central purposes of arts-informed research are to enhance understanding of the human condition through alternative (to conventional) processes and representational forms of inquiry and to reach multiple audiences by making scholarship more accessible. The methodology infuses the languages, processes, and forms of literary, visual, and performing arts with the expansive possibilities of scholarly inquiry for purposes of advancing knowledge. Arts-informed research is grounded in creative expressions of qualitative research traditions that are informed by the arts broadly defined. Researchers working in this way can greatly extend and enhance those traditions by placing attention on the development of research processes and representations that are inspired and informed by being situated in one or more of the arts.

Arts-based research and arts-informed research are similar in many ways, including the goal of researching in ways that more fully acknowledge the richness and complexity of human experience. The term *arts-based educational research* is more widely used to describe qualitative research that involves or includes the arts in some capacity to advance knowledge and communicate research understandings. Arts-informed research attends more specifically to the relationship between form and purpose—how an art form can inform both the research process and representation for purposes of making research/knowledge more accessible to diverse audiences, including but beyond the academy. Gary Knowles and Ardra Cole developed this arts-related approach during the mid- to late 1990s for the purposes of enhancing and broadening the communicative possibilities of qualitative researching involving the arts through the process of inquiry as well as the representation of research accounts.

Arts-informed research is a way of redefining research form and representation and creating new understandings of process, spirit, purpose, subjectivities, emotion, responsiveness, and the ethical dimensions of inquiry. This redefinition reflects an explicit challenge to logical positivism and technical rationality as the only acceptable guides to explaining human behavior and understanding. Bringing together the systematic and rigorous qualities of conventional qualitative methodologies with the artistic, disciplined, and imaginative qualities of the arts acknowledges the power of art forms to reach diverse audiences and the importance of diverse languages for gaining insights into the complexities of the human condition. The dominant paradigm of positivism historically has governed the way in which research is defined, conducted, and communicated and has consciously and unconsciously defined what society accepts as knowledge; however, it is not a paradigm that reflects how individuals in society actually experience and process the world. Life is lived and knowledge is made through kitchen table conversations and yarning at the wharf or transit station or coffee shop or tavern, in the imaginative spaces created between the lines of a good book or by an encounter with an evocative photograph, or in an embodied response to a musical composition or an interpretive dance. These moments of meaning-making, however, are not typically thought of as knowledge. Knowledge, as society has learned to define it, dwells beyond the realm of the everyday. It is discovered by intellectuals—researchers and theorists—and held by them until its implications are determined and passed on for consumption. Knowledge is propositional and generalizable, and research is the process by which it is generated. According to this paradigmatic view, knowledge remains the purview of the academy, where it can be carefully defined and controlled.

Arts-informed research, with one of its main goals of accessibility (and breadth of audience), is an attempt to acknowledge individuals in societies as knowledge makers engaged in the act of knowledge advancement. Tied to moral purpose, it is also an explicit attempt to make a difference through research, not only in the lives of ordinary citizens but also in the thinking and decisions of policymakers, politicians, legislators, and other key decision makers.

Arts-informed research is part of a broader commitment to shift the dominant paradigmatic view that keeps the academy and community separated, that is,

to acknowledge the multiple dimensions that constitute and form the human condition—physical, emotional, spiritual, social, and cultural—and the myriad ways of engaging in the world—oral, literal, visual, and embodied. In other words, such research aims to connect the work of the academy with the life and lives of communities through research that is accessible, evocative, embodied, empathic, and provocative.

Defining Elements

- How can the arts (broadly conceived) inform the research process?
- How can the arts inform the representational form of research?

As a framework for inquiry, arts-informed research is sufficiently fluid and flexible to serve either as a methodological enhancement to other research approaches or as a stand-alone qualitative methodology. For example, as a methodological enhancement, one might conduct an arts-informed life history study, an arts-informed phenomenological inquiry, an arts-informed narrative inquiry, or an arts-informed ethnography. As a stand-alone methodology, situated within a qualitative framework, arts-informed research perspectives enhance the possibilities of information gathering and representation.

Broadly grounded in assumptions that define a qualitative paradigm, arts-informed research has several defining elements. First and foremost, arts-informed research involves a *commitment to a particular art form* (or forms in the case of mixed media or multimedia) that is reflected in elements of the creative research process and in the representation of the research “text.” The selected art form(s) serves to frame and define the inquiry process and text.

The *methodological integrity* of the research, a second defining element, is determined in large part by the relationship between the form and substance of the research text and the inquiry process reflected in the text. In other words, the rationale for the use of photography, for example, as the defining art form guiding the inquiry or representation must be readily apparent by how and how well it works to illuminate and achieve the research purposes.

Following the emergent nature of qualitative research in general, the *creative inquiry process* of arts-informed research is defined by an openness to the expansive possibilities of the human imagination.

Rather than adhering to a set of rigid guidelines for gathering and working with research material, a researcher using arts-informed methodology follows a more natural process of engagement relying on commonsense decision making, intuition, and a general responsiveness to the natural flow of events and experiences. Serendipity plays a key role in the inquiry process, much as it does in life. Moreover, we infer that researchers can learn from artists about matters of process. That is, the processes of art making inform the inquiry in ways that are congruent with the artistic sensitivities and technical (artistic) strengths of the researcher in concert with the overall spirit and purpose of the inquiry.

Also, as in most qualitative research, the subjective and reflexive *presence of the researcher* is evident in the research text in varying ways depending on the focus and purpose of the inquiry. In arts-informed research, however, the researcher's artistry is also predominant. By artistry, we include conceptual artistry and creative and aesthetic sensibilities, not just technical skills or an externally sanctioned title of "artist." Extending the idea from qualitative inquiry of "researcher as instrument," in arts-informed research the "instrument" of research is also the researcher-as-artist.

Although we operate on the assumption that all research is inherently autobiographical—a reflection of who we are—arts-informed research is not exclusively about the researcher. In other words, although the focus of an arts-informed inquiry may be the researcher herself or himself, this is not necessarily so. Arts-informed research differs, for example, from autoethnography and autobiography, both of which focus on the researcher as the subject of inquiry. Arts-informed research has *strong reflexive elements* that evidence the presence and signature of the researcher, but the researcher is not necessarily the focus or subject of study.

A sixth defining element of arts-informed research relates to *audience*. Consistent with one of the overarching purposes of arts-informed research, there must be an explicit intention for the research to reach communities and audiences, including but beyond the academy. The choice and articulation of form will reflect this intention.

Related to research relevance and accessibility to audience is the *centrality of audience engagement*. The use of the arts in research is not for art's sake. It is explicitly tied to moral purposes of social responsibility and epistemological equity. Thus, the research text is intended to involve the reader/audience in an

active process of meaning-making that is likely to have transformative potential. Relying on the power of art to both inform and engage, the research text is explicitly intended to evoke and provoke emotion, thought, and action.

Qualities of Good Arts-Informed Research

Arts-informed research, in process and representational form, is neither prescriptive nor codified. It is the creative meshing of scholarly and artistic endeavors. Nevertheless, like all research, studies following arts-informed research methodology must be subjected to scrutiny to assess, and perhaps help to explain, their worth or value as research. A broad assessment is guided by the following two general questions: How do the arts inform the research process? How do the arts inform the research representation? More specifically, a study imbued with the qualities that follow is one that is likely to both exemplify and contribute to the broad agenda of arts-informed research, that of enhancing understanding of the human condition through alternative (to conventional) processes and representational forms of inquiry and of reaching multiple audiences by making scholarship more accessible.

Intentionality. All research has one or more purposes, but not all research is driven by a moral commitment. Consistent with the broad agenda of social science research to improve the human condition, arts-informed research has both a clear intellectual purpose and moral purpose. Ultimately, the research must stand for something. Arts-informed research representations, then, are not intended as titillations but rather are intended as opportunities for transformation, revelation, or some other intellectual and moral shift. They must be more than good stories, images, or performances.

Researcher Presence. A researcher's presence is evident in a number of ways throughout an arts-informed research text (in whatever form it is presented and, by implication, throughout the entire researching process). The researcher is present through an explicit reflexive self-accounting, her or his presence is also implied and felt, and, the research text (the representational form) clearly bears the signature or fingerprint of researcher-as-artist.

Aesthetic Quality. The central purpose of arts-informed research is knowledge advancement through research, not the production of fine art works. Art is a medium through which research purposes are achieved. The quality of the artistic elements of an arts-informed research project is defined by how well the artistic process and form serve research goals. Attention to the aesthetics of a particular genre are, therefore, important; aesthetics of form is integrally tied to communication.

Methodological Commitment. Arts-informed research evidences attention to the defining elements and form of arts-informed research. As such, the work reflects a methodological commitment through evidence of a principled process, procedural harmony, and attention to aesthetic quality.

Holistic Quality. From purpose to method to interpretation and representation, arts-informed research is a holistic process and rendering that runs counter to more conventional research endeavors that tend to be more linear, sequential, compartmentalized, and distanced from researchers and participants. A rigorous arts-informed text is imbued with an internal consistency and coherence that represents a strong and seamless relationship between purpose and method (process and form). The research text also evidences a high level of authenticity that speaks to the truthfulness and sincerity of the research relationship, process of inquiry, interpretation, and representational form.

Communicability. Foremost in arts-informed work are issues related to audience and the transformative potential of the work. Research that maximizes its communicative potential addresses concerns about the accessibility of the research account, usually through the form and language in which it is written, performed, or otherwise presented. Accessibility is related to the potential for audience engagement and response. Such representations of research have the express purpose of connecting, in a holistic way, with the hearts, souls, and minds of the audience. They are intended to have an evocative quality and a high level of resonance for diverse audiences.

Knowledge Advancement. Research is about advancing knowledge however “knowledge” is defined. The knowledge advanced in arts-informed research is generative rather than propositional and is based on

assumptions that reflect the multidimensional, complex, dynamic, intersubjective, and contextual nature of human experience. In so doing, knowledge claims must be made with sufficient ambiguity and humility to allow multiple interpretations and reader response.

Contributions. Tied to the intellectual and moral purposes of arts-informed research are its theoretical and practical contributions. Sound and rigorous arts-informed work has both theoretical potential and transformative potential. The former acknowledges the centrality of the “so what?” question and the power of the inquiry work to provide insights into the human condition, whereas the latter urges researchers to imagine new possibilities for those whom the work is about and for. Researchers are not passive agents of the state, the university, or any other agency of society. Researchers’ responsibilities are toward fellow humans, neighbors, and community members.

ASSOCIATION FOR QUALITATIVE RESEARCH (AQR)

Qualitative research often provides an unparalleled understanding of the motivations behind human behavior, desires, and needs. In the United Kingdom, the principal authority on the qualitative research industry is the Association for Qualitative Research (AQR). Founded in 1981, AQR is a nonprofit organization. Its core objective is to serve the interests of members through the following:

- Developing understanding of the commercial value of qualitative research within the qualitative research community and among market research buyers, marketers, the broader business community, and the media
- Promoting the highest professional industry standards within the qualitative research community and among market research buyers, marketers, the broader business community, and the media
- Providing inspiring, valuable training courses to independents and client- and agency-based qualitative researchers
- Creating forums that facilitate debate and advance qualitative research methodology, analysis, and consultancy
- Promoting qualitative research as a career
- Providing networking opportunities and social events for members

AQR produces two publications: *In Brief*, which comes out every 2 months, and *In Depth*, which appears twice a year. *In Brief* has a news focus, whereas *In Depth* looks at a topic in detail as its name suggests.

Excellence and effectiveness in qualitative research are encouraged through the Prosper Riley-Smith award, which is announced annually. Riley-Smith was a prominent member of AQR until his untimely death, and the award in his memory is judged by a panel of senior industry luminaries. It is a highly coveted award.

As a way of encouraging new graduates to take an interest in qualitative research, AQR undertakes a program of visits to universities every year to talk about a career in qualitative research. In addition, a bursary is offered twice a year for a candidate to have a place on AQR Foundation training courses, which take place in February and November. The bursaries are offered to candidates who wish to embark on a career in qualitative research, and can demonstrate a genuine interest in and commitment to qualitative research, but who have not yet managed to secure a permanent position with a company.

AQR has an international presence and regularly runs conferences jointly with the U.S.-based Qualitative Research Consultants Association (QRCA). Recent events have taken place in Dublin, Lisbon, and Paris.

ATLAS.TI (SOFTWARE)

ATLAS.ti is a qualitative computer software package that assists researchers in their management of textual, graphical, audio, and video data. ATLAS.ti was originally designed for social scientists but is now being used in diverse disciplines such as psychology, literature, medicine, nursing, linguistics, stylistics, history, geography, theology, and law. However, although ATLAS.ti can benefit the qualitative researcher in terms of speed, consistency, rigor, and access to analytic methods not available by hand, it is not a replacement for methodological training.

ATLAS.ti offers two levels of interaction for the qualitative researcher. At the textual level, it allows basic “code and retrieval” of data, and at the

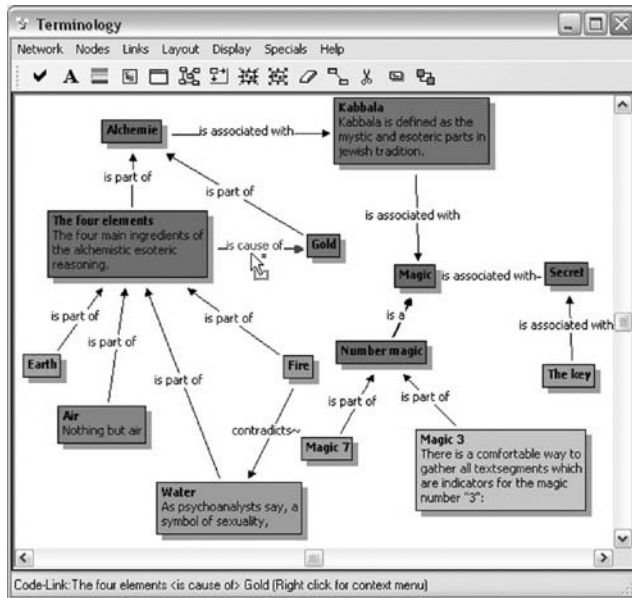

Figure 1 An ATLAS.ti Network Editor Displaying a Network of Codes

Source: Copyright 2007 with ATLAS.ti GmbH; used by permission.

Note: The shadings denote groundedness (amount of data coded) and density (number of links to other codes) of the respective codes.

conceptual level, it allows more sophisticated analysis of model-building activities such as linking codes to form semantic networks and algorithms (Figure 1). Moreover, although ATLAS.ti is intended primarily for supporting qualitative reasoning processes, it is sometimes also useful to analyze the data in a quantitative manner using statistical approaches (especially with large amounts of data). This process is achieved by the Statistical Package for the Social Sciences (SPSS) export function in ATLAS.ti that treats codes as variables and treats data segments (quotations) as “cases.” However, such a function is open to criticism because it may result in the qualitative researcher performing types of analysis more suited to quantitative data.

Another very useful function of ATLAS.ti is its facilitation of co-authoring, where two or more researchers or work groups are involved in the same research project. It allows the transfer and conversion of research data while keeping the respective sources of ideas identifiable at all times.

ATLAS.ti’s main strategic modes of operation are termed *VISE* (visualization, integration, serendipity, and exploration). It allows all aspects of the data and analysis on-screen at once and is able to visually map out relationships between different parts of the data and theoretical ideas—to form links between them and jump back and forth—and this encourages creative processes such as stimulating ideas and recognizing patterns. However, this loose structure of ATLAS.ti may be anxiety provoking for some researchers who may prefer a more structured approach such as that offered by the NVivo software program. Nevertheless, the immediacy of ATLAS.ti is its strength because it is considered easy to understand what it does and how it works, at least at the basic level of operation. Therefore, for simple qualitative projects with limited time available, ATLAS.ti is suitable because it is considered a relatively easy package to learn.

AUDIENCE

Throughout the lengthy history of qualitative research and evaluation, inquiry and writing processes have been engaged in with one primary audience in mind: researchers and academics within particular fields under study. Secondary audiences have occasionally included the participants/informants who are the focus of the research and, for research designed with a cathartic or self-therapeutic end in mind (e.g., some autoethnography), the researchers themselves. Still other audiences (at least within program evaluation research) have included policymakers and administrators overseeing social or training programs in various fields (e.g., social work, nursing, education) and participants involved in those programs.

Although some qualitative researchers are committed to making research results available to readers outside of academia, others (such as program evaluators) have rarely contemplated the possibility of broadening the accessibility of their work. This reluctance has been criticized as perpetuating the insular character of some social science texts. Their tendency to alienate nonacademic audiences is viewed as ironic by some when the text aims at redressing injustices that plague the lives of members of marginalized social groups. This aim may be betrayed by the employment of discursive elements that render the text inaccessible to the very “subjects” whose plight is being documented.

Arts-based researchers—qualitative inquirers who swap the premises, principles, and procedures associated with the social sciences for those of the literary, visual, plastic, performance, vernacular, or digital arts—have also largely inquired and composed for a narrow audience of academic colleagues. Some advocates and practitioners of arts-based research have, however, attempted to look beyond the academy for an audience of members of lay publics. The production of inquiry texts with the potential for influencing both lay audiences and academics (insofar as the latter are both scholars and citizens) is sometimes referred to as “audience blending.” Arts-based works that have been composed for broader “blended” audiences have included novels, short stories, films, and staged ethnodramas.

Some arts-based researchers who also emphasize issues of social justice and equity aspire toward a mass audience by producing works with the potential for becoming significant cultural events. These works thereby move to subvert the prevailing cultural meta-narratives regarding race, ethnicity, gender, sexual preference, and so on by dissemination through mass media outlets.

Of course, many obstacles may impede these efforts toward audience blending. First, the larger culture industry is not easy to penetrate. A second class of impediments arises out of the many hallowed traditions of the academy. Finally, there is the fact that all cultural texts are limited in their ability to reach readers who do not share the cultural background and social values of the researchers/artists.

Some arts-based researchers attempt to surmount these obstacles by identifying with a larger tradition of activist art. The efforts of many activist artists, who

aim toward personal and social transformation, tend to be “local” efforts, participatory and community based, outside of the academy, and bypassing the mass media. Consider, for example, the applied theater projects that attempt to intervene directly in the history of a community. Members of rather circumscribed “publics at large” are both the participants within this work and the audiences of this work.

AUDIENCE ANALYSIS

Audience analysis stems from mass communication studies that seek to explain the impact of various forms of media on social life. In qualitative research, audience analysis refers to inquiry into how a targeted group receives and uses content delivered by an identified sender. Analysis may also focus on groups whose members were unintended receptors of the content and who repurpose the information in ways the sender does not anticipate or condone. Such repurposing can alter the relationship between the audience and the sender. Audience analysis is sometimes referred to as reception analysis and is also associated with focus group research.

Contemporary mass communication studies can trace the theoretical origins of audience analysis to Walter Benjamin’s early 20th-century criticism of cinema, particularly the reproducibility, worldwide accessibility, and devaluation of an authentic original in the then newly emergent art form of film. Benjamin was one of the first theorists to consider the shifting role of the audience from a passive appreciator of a fixed knowable meaning in a work of art to a dynamic interactant in which individuals and groups created their own meanings and responses.

On a practical nontheoretical level, audience analysis evolved from focus group research that emerged during World War II. The first focus group studies pertained to military research. During the postwar era, these skills were applied to commercial marketing as an audience was associated with potential consumers of a given product. Data analysis from these studies was exclusively quantitative.

Qualitative audience analysis became widespread during the 1980s. The change in methodology also reflected a growing critical stance toward mass communication. Qualitative researchers were not concerned with honing a sender's content for acceptance by the largest number of audience members. Instead, they investigated processes for the reception and mediation of information that both duplicated and reconstructed social structures. Through this evolution, the field moved away from empirical survey and focus group research to examination of forms of power. In some cases, power sought and achieved social replication. In other cases, research suggested direct or passive resistance to existing social paradigms. For example, in *Common Culture*, Paul Willis studied the lives of counterculture British youth who had repurposed popular culture to form individual identities that openly challenged social norms.

Mass communication delivers content through a variety of ways. An audience receives and mediates content in a variety of ways as well. For example, audience analysis studies have examined how European and non-Western audiences repurpose U.S. television soap operas. In such research, an audience is not a blank slate; recipients process and reappropriate content into new meanings.

In studies of the repurposing of mass communication, the use of symbols and signs does not tend to be highly dynamic. The variance within usage is usually rather narrow. Such predictable outcomes from repurposing suggest a limited capacity for audiences to create new meanings in response to expanding forms of media. Thus, rather than focusing on construction of meaning, it may be more fruitful to analyze patterns and rhythms of conventional practice.

In this view, information reception is a deeply cultural dynamic process that interprets, reinterprets, and recontextualizes. Socioeconomic factors can define culture—and thereby audiences—as can codes of discourse or physical media that individuals select to receive information. In all cases, audience analysis

research focuses on interpretive communities and anticipates multilayered interpretations between sender and receptor that both synchronistically duplicate and asynchronously reconstruct meaning.

Qualitative research incorporating principles of audience analysis and the examination of multiple levels of conflicting forms of meaning is not limited to mass communication studies. For example, in *Doing School*, Denise Clark Pope examined how an audience (high school students) mediates sent information (instruction in the classroom conveyed through textbooks and lectures). She showed how talented students successfully respond to various forms of institutional assessment by duplicating the culturally normed information and, at the same time, actively resist and reconstruct this information in ways that are antithetical to the professed educational objectives of school.

Critical research into how an audience repurposes information ultimately challenges the very concept of audience. If contemporary audiences are constantly sifting and rebuilding information, the concept of a passive receptive audience is antiquated. Denis McQuail referred to this postmodern view of reception as the end of the audience.

Therefore, continuing to dichotomize the relationship of sender and receptor is problematic. Once again, this theory influences qualitative research beyond mass communication studies, as demonstrated by Patti Lather's *Troubling the Angels*, where she struggled against the dichotomies of researcher/participant and receptor/sender. Lather asked to what purpose her research participants (audience) will productively use her research to construct meaning within their own lives. In turn, if her participants' active construction of meaning is critical to her inquiry, who is "doing" the research? Lather questioned whether her own role in this process is productive or parasitical. In such qualitative research, the audience is a dynamically shifting critical presence. This raises questions of authority and control between researcher and audience.

Audience analysis is also a question of who will read a text. In 2002, a report by the U.S. National Research Council titled *Scientific Research in Education* contended that the vast majority of qualitative research methods were unscientific and, thereby, ineligible for federal funding. In this case, audience analysis would be a helpful tool to critically analyze

the assumptions of the council; for whom is research intended, and how were these research audiences expected to use research?

Tom Barone suggested that qualitative research in general, and arts-based research in particular, has more applicability to broad audiences than does impenetrable quantitative research. Barone argued that a virtue of excellent qualitative research is accessibility by a broad audience. Much like Benjamin's critique of cinema, Barone argued that qualitative arts-based research has the capacity to resonate in the public imagination and, thus, effect serious social and policy change in a way that "scientific" research may never achieve. Instead of viewing the audience as a blank slate that receives and inscribes the researcher's meaning (as conceived in the National Research Council report), Barone envisioned an audience that is an active participant in authoring meaning along with the researcher.

AUDIORECORDING

Audiorecording involves using either analog or digital recording equipment to capture conversations, interactions, and interviews. The most obvious value of audiorecording is that it offers an accurate summary of what was said, and this is especially important for in-depth interviews and focus groups.

Audiorecording in Data Collection

The data captured by audiorecording lie somewhere between the lower level of detail provided by field-notes or simple recall and the higher level of detail provided by videorecording. In addition to the greater

accuracy in comparison with a lack of any recording, audiorecording also provides additional detail by capturing elements of tonality and emphasis. Going beyond audiorecording, videorecording provides even more detail, especially in terms of nonverbal communication.

A common question in qualitative interviewing is whether to use any form of recording at all. The issue here is essentially a trade-off between the advantages of audiorecording and videorecording as tools in data collection and analysis and their potential intrusion in ways that will significantly alter the conversation. Inevitably, the presence of a recording device will have some effect on both the participant and the researcher; thus, the key issue is the degree to which recording will alter the otherwise "naturalistic observation" in a manner that has a substantial effect on either the concept or quality of the data. Qualitative researchers frequently favor audiorecording in this trade-off due to its combination of providing a relatively high level of detail while creating only a minimal intrusion in the interview setting.

The most common way in which audiorecording affects data collection is by inhibiting the research participants from saying things they might reveal if they were not being recorded. For example, audiorecording during interviews with graduate students on the general topic of satisfaction with their program is not likely to have a notable effect on their responses. Alternatively, recording interviews with the same students regarding their satisfaction with the teaching in their graduate program may create concerns that faculty members will learn what specific participants said about them, leading the students to carefully monitor what they do and do not say.

In considering the potentially intrusive effects of how data are captured in qualitative interviewing, it should also be noted that note taking can have its own set of effects. In particular, note taking will almost always reduce eye contact with research participants. In addition, participants may become sensitive to when the researcher takes notes or not—especially when long portions of their conversation do not generate any notes. In contrast, most participants quickly adjust to the presence of audiorecording equipment, leading to the claim that audiorecording can be less intrusive than note taking in terms of its effects on interviewing dynamics.

On a more technical note, the choice of equipment can be an important element of audiorecording. In this regard, the limiting factor is most likely to be the microphone because most audiorecorders (especially digital recorders) are capable of producing high-quality recordings in the range matching the human voice. This is especially important for focus groups because recording devices seldom come with the kind of “omnidirectional” microphone that is best suited to recording groups. How well the built-in microphone in a recording device will work for one-on-one interviews can be determined only by testing the equipment in an appropriate range of settings. That kind of testing is necessary in any event so that the researcher can familiarize himself or herself with the equipment prior to using it. Even when the researcher is quite familiar with the recording equipment, on-site “live testing” of the microphone and recorder prior to the interview is still essential because a blank tape at the end of an interview represents a severe loss of data.

Audiorecording and Data Analysis

The basic point of audiorecording is to capture material for data analysis and reporting. Although this process typically involves transcription of the audiorecording, this is not always necessary—especially when there is no requirement for detailed analysis such as projects that involve either small amounts of data or simple applied goals. Currently, dictation software is not capable of handling recordings that involve more than one person (especially in lively conversations), so researchers face a choice between the relatively lengthy process of doing their own transcribing or the relatively expensive alternative of hiring professional transcription typists. When hiring someone else to do the transcribing, it is prudent to listen to each tape while reviewing the transcript, not only to check for accuracy but also to add notes about tone of voice, emphasis, pauses, laughter, and so on.

After the analysis is done, transcribed audiorecordings are especially valuable as a source for direct quotes to use in presentations of the results. This illustrative material is often an important resource that connects the audience with the original participants. In addition, audiorecordings help to maintain the audit trail, spanning from the steps from data collection,

through analysis, and up to the presentation of the conclusions the researcher draws from the original material.

Finally, it is essential to address the ethical issues raised by audiorecordings that are especially important in research on sensitive topics or any other situation where recordings pose a threat to participants’ confidentiality. Ethics review boards often require that recordings should not be used without the informed consent of the participants. If conversations will be recorded, this should be clearly mentioned in all contacts with potential research participants and the recorded material should be stored in a secure place in accordance with requirements from the ethics review board. Regardless of formal statements of informed consent, researchers should feel an ethical obligation to cease recording any material that clearly makes the participant uncomfortable. In that situation, the researcher and participant can negotiate whether the conversation can continue—possibly with note taking—as well as whether recording can be resumed at a later point. Even if this means a loss in data quality, that concern must be secondary to the protection of the research participants.

AUDITING

The term *auditing* refers to a systematic review of processes involved in decisions or actions. Typically, this is done to ensure conformation with accepted

standards or to validate the accuracy of results. In qualitative research, auditing serves a comparable purpose and can be a valuable means of demonstrating the rigor of an investigation. Such a review offers a strong defense against criticisms that are sometimes posed in regard to qualitative research such as questions regarding the researcher's neutrality. Auditing of the study, therefore, is a useful means of supporting the credibility and trustworthiness of findings and interpretations in qualitative research.

There continues to be debate over the most appropriate ways in which to demonstrate credibility or rigor in a qualitative study. Auditing is not an essential part of the process of qualitative research. It can, however, be a useful mechanism to address quality aspects of a study. Many variations of auditing are available for qualitative researchers to apply in their projects. It is important that plans for an audit be addressed early in the design of a project so that the process can be incorporated in the manner that is most appropriate to each study. This entry describes the ways in which auditing can be conducted in qualitative research, including both internal and external audits and the timing of the auditing process. It also reviews the materials needed for an audit trail.

Methods of Auditing in Qualitative Research

Auditing of a qualitative study involves oversight and, at a minimum, review of the conduct of the study and the conclusions developed by investigators. There are numerous ways in which an audit can be carried out in a qualitative study. Variations include who serves as auditor, when the auditing process is initiated, how often auditing occurs, and the extent of the actual audit.

Internal Auditing

Auditing can be conducted on an internal basis in which members of the research team provide a system of checks and balances for each other. This process can promote consistency in the research process and can serve to identify, and subsequently decrease, the bias of any particular team members involved in the research. An internal audit can involve an exchange of documentation for review by other members of the team who can examine decisions and analytic

processes associated with the research. An internal audit may be very useful in multisite studies where it is important to ensure consistency in the research process across the various settings. These activities enhance the research but might not provide sufficient evidence of rigor as is typically sought through a more formal or external audit.

External Auditing

Auditing conducted on an external basis involves formal and systematic review carried out by people with no vested interest or involvement in the conduct of the research. An external auditor typically is a researcher who is knowledgeable in the processes of qualitative research and who may or may not have expertise in the subject matter involved in the research. In the typical qualitative study, auditing can be accomplished quite easily by enlisting the assistance of an experienced yet objective colleague, with the investigator presenting and defending decision making to that individual. The colleague also can review raw data, notes, logs, journals, and other materials associated with the study. This process is referred to as peer debriefing, although it accomplishes the same goal as an audit.

Timing of an Audit

The actual process of auditing can be initiated at any point in a study. Formative and ongoing auditing occurs while the study is conducted. Auditing also may be carried out on a summative basis at or near the conclusion of the study. Engaging auditors early in the process enables them to provide valuable monitoring throughout various phases of the research. The auditors may even be involved at the initial conceptual stages of the research, providing oversight and reflexive commentary as initial decisions are made regarding the design of the study. Such involvement, however, increases the risk that the auditors might become less neutral themselves due to their engagement with the project and the researcher or research team. Including auditors later in the process may allow greater neutrality on the part of the auditors. Later involvement, however, creates a greater burden on the researcher to familiarize the auditors with the study and its processes because the auditors will not be aware of the various nuances

and twists that have occurred consistent with the emergent design typical of qualitative research. In the initial contracting with auditors, the researcher should be very clear and detailed about the desired level of involvement and the expectations placed on the auditors.

Elements Needed for an Audit

Auditing cannot be accomplished unless there is an appropriate array of materials available for review. The collection of documentation compiled for this purpose during a qualitative study is referred to as an audit trail. Edward Halpern identified the following categories of documentation needed to constitute an audit trail: raw data, data reduction and analysis products, data reconstruction and synthesis products, notes regarding the processes of the study documentation of the intents and prejudgments or inclinations of the researcher, and information about any instruments used in the study. An organized system of note keeping is essential for this process. For ease of maintaining the audit trail, materials can be grouped into, at a minimum, raw data and fieldnotes providing details of actual encounters with participants; methodological notes regarding data collection processes, interview guides, other instrumentation, and changes in an emergent design; and analytic memos or notes to capture ideas generated during the process of data analysis.

AUDIT TRAIL

An audit trail in qualitative research consists of a thorough collection of documentation regarding all aspects of the research. Qualitative inquiry typically involves a design that constantly changes or emerges through the iterative processes of data collection and analysis and requires that the researcher make frequent decisions that can alter the course of the study. As a result, records of study processes can be vital in later providing justification of these actions. The audit trail provides a mechanism for retroactive assessment of the conduct of the inquiry and a means to address issues related to the rigor of the research as well as the trustworthiness of the results.

Typical documentation that constitutes this trail of evidence includes notes about data collection experiences, documentation of changes in design, the researcher's experience in the conduct of the study, and memos generated during data analysis. Fieldnotes are composed of the researcher's observations of a setting during a data collection encounter, including notes about the context of a data collection episode. Methodological notes contain critical information regarding alterations in design or data collection strategies. The audit trail enables the researcher to reconstruct the steps of the study and later provide justification for any changes that took place. Both the strategy and the rationale for the change are needed to provide evidence of the purpose and appropriateness of any modifications.

A reflexive journal provides a means to keep track of the researcher's thought processes during the study. Because the work of data analysis in qualitative research relies heavily on the cognitive processes of the researcher, the ability to document these processes and capture the researcher's own insights, interpretations, and reactions can be beneficial to the analysis process. In practice, there is considerable overlap among all of these aspects to be documented such that the separation of notes into unique bodies of evidence may be detrimental to the process of comprehensive record keeping. Fieldnotes may stand alone as a source of data, whereas the other components generally are closely integrated. Computer software designed for qualitative data analysis can be helpful in the construction of an audit trail through the ability to save copies or printouts of various stages of the analysis

process as well as to record notes within the software while working with data.

The importance of an audit trail may be debatable for some forms of qualitative inquiry. Projects involving a team of researchers or large-scale program evaluation may find the audit trail technique particularly beneficial in demonstrating accountability throughout the research process. However, researchers using highly interpretive processes, such as hermeneutic inquiry, may find that documentation of the cognitive processes of analysis is especially challenging.

AUTHENTICITY

An important issue for qualitative research is that of authenticity. In establishing authenticity, researchers seek reassurance that both the conduct and evaluation of research are genuine and credible not only in terms of participants' lived experiences but also with respect to the wider political and social implications of research. Authenticity involves shifting away from concerns about the reliability and validity of research to concerns about research that is worthwhile and thinking about its impact on members of the culture or community being researched. Authenticity, then, is seen as an important component of establishing trustworthiness in qualitative research so that it may be of some benefit to society.

There are five key criteria for strengthening claims for authenticity as identified by Egon Guba and Yvonna Lincoln. These are linked to the wider context

of research. The first of these is fairness. Qualitative researchers need to ensure that participants have equal access to the research inquiry to avoid bias, for example, by developing research relationships that go beyond stereotypical roles of question asking and question answering from the outset of the research. Adopting this approach means that participants become responsible for the cultural reproduction of the research inquiry in which they have a part and so have a stronger investment in ensuring that the outcomes of the inquiry are authentic. This avoids marginalization during the inquiry process and ensures that all participants' voices—their views, concerns, and perspectives—are represented throughout the research process as well as in any texts, where their stories should be treated fairly.

The second and third criteria are ontological and educative authenticity. Research should help individual participants to develop greater understandings of the social context being studied. This is ontological authenticity—the extent to which participants have a raised level of awareness. Research should also demonstrate that individuals appreciate the viewpoints of people other than themselves through cultural, social, and organizational engagement. This is educative authenticity and requires responsibility on the part of researchers to help participants expand their perspectives so that they not only have a better understanding of themselves but also appreciate the perspectives of other stakeholder groups.

The final two criteria are catalytic and tactical authenticity. Catalytic authenticity refers to the extent to which the research has stimulated some form of action on the part of the research participants, whereas tactical authenticity refers to the degree to which participants (and stakeholders) are empowered to act—to engage in action not only as individuals but also as members of their community—with a view to positively changing their circumstances. Both of these processes need to be supported by researchers. This can be achieved through research practice, such as action research or cooperative inquiry, that creates the capacity to enable participants to have an expanded awareness not only of themselves but also of their social milieu as a consequence of taking part in the research.

AUTHORITY

Authority within qualitative research refers to the claims that actors within the research process, notably the researcher, make so as to speak/write in the way they do about the social process or phenomenon being studied.

The ways in which these claims are made, and whether they are explicit or implicit, vary according to the tradition within which the researcher is working. For example, in positivist research, the voice of the researcher tends to be dominant in identifying the research agenda, determining the research process, and carrying out analysis. However, in qualitative research, the privileged position of the researcher is more often open to challenge and debate. For example, within an ethnography (and particularly with a critical ethnography), the authority of the researcher to interpret and make claims about the group or culture she or he is researching is unlikely to be accepted automatically. In such an example, the researcher will need to be explicit about the basis on which she or he makes such claims (if she or he is intending to do this). The researcher is likely to engage in reflexive practices, such as the keeping of a research journal, that actively enables the researcher to explore her or his own role within the process—previously unacknowledged agendas, preferences, and values.

In postmodern and poststructural research, the unitary voice of the researcher is usually disrupted and fragmented, providing a range of possible interpretations. Examples include the retelling of ostensibly the same research process from the perspectives of different stakeholders or even the researcher herself or himself in the guise of different identities. Another strategy that can be employed to involve the readers more actively in engaging and questioning the written

material being presented is to include alternative lines of argument, or footnotes, that challenge the main thrust of the text. Still other strategies deployed by postmodern researchers are to create partial, confused, and incomplete texts and to include different modes of representation, such as visual (e.g., photographs), auditory (e.g., audiorecordings), and combinations (e.g., a weblog by an imaginary or actual participant), that can facilitate different ways of viewing the research endeavor. Thus, the authority of the researcher is challenged, and the readers are encouraged to actively participate in constructing meanings and reflect on what they additionally bring to the research as research “consumers.”

Some research approaches, such as participatory action research, deliberately seek to enfranchise and give voice to research participants, arguing that the research process often objectifies participants as passive subjects. This is achieved by inviting those being researched to become co-researchers to share in the process of making meaning.

AUTOBIOGRAPHY

Autobiography is among the most important and valuable vehicles for exploring the human realm in all of its depth, complexity, and richness. Although there are numerous ways to define and conceptualize autobiography, for current purposes it may be considered the specific kind of text that results from the first-person interpretive reconstruction of either a life in its

entirety or a significant portion of it, with the aim not merely of recounting “what happened when” but also of understanding, from the vantage point of the current time, the meaning and movement of the past. Located whenever and wherever such interpretive reconstruction occurs—whether in the context of questionnaires, interviews, or those larger literary texts that may be created when an individual takes the time to explore his or her life in its full measure via writing—autobiography is perhaps the primary inroad to the elusive phenomenon of the self, at least as it has emerged in the context of Western history and culture. It is for this reason that during the early part of the 20th century the German philosopher Wilhelm Dilthey, among others, underscored the profound importance of autobiography for the *Geisteswissenschaften* (the human sciences); insofar as the human sciences were to be founded on methods and modes of inquiry suitable for exploring the distinctively human realm, autobiographical understanding would play a leading role in the project.

Autobiography came to play a prominent role in psychoanalysis—in the “personology” of figures such as Gordon Allport and Henry Murray, in certain strands of anthropological and sociological research (including “autoethnography” in which the researcher’s own autobiography serves as the focus of interest), and (most recently) in “narrative inquiry,” a portion of which considers life stories, in their myriad forms, uniquely suited to exploring issues ranging from selfhood and identity to the process of development throughout the life course to the social/cultural “construction” of human lives. With respect to the qualitative research enterprise, autobiography’s virtues are many. Foremost among them are what might be termed its ontological wholeness, temporal wholeness, enculturedness, hermeneutic multivocality, and (perhaps most centrally) embeddedness within the fabric of narrativity.

Autobiography is among the most “unrestricted” sources of qualitative data; rather than being limited to some specific behavior or characteristic or region of meaning, its ontological scope is the whole of a life, that is, anything and everything about that life that is meaningful and significant enough to warrant its being told. Drawing on autobiography in qualitative research, thus, lends itself to an “idiographic” perspective in which the individual, in all of his or her complexity, is the preferred unit of analysis.

Autobiography also embodies temporal wholeness; by depicting either a significant portion of a life or a life in its entirety, its interpretive reach is capacious. Rather than isolating the individual from the flow of life, autobiography is oriented toward the flow of life itself, its continuities and its changes, its identity in time and its possible dispersion. Insofar as the human person cannot be known except in the unfolding of his or her unique and unrepeatable history, autobiography may be seen as the privileged path to such knowledge. It should be emphasized in this context that neither ontological wholeness nor temporal wholeness entails the supposition that autobiographies—and selves—are unified and coherent; autobiographies vary markedly in their degree of coherence, as do selves. Whether unified and coherent or less so, these dual conditions of wholeness remain.

Because autobiography is predicated on understanding the “real lives” of individuals, qualitative work that draws on autobiography is, of necessity, context specific and “encultured.” Much of social science remains decontextualized and continues to seek to understand human behavior and experience through rarefied environs such as laboratories and through experience-distant means such as paper-and-pencil tests. In the case of autobiography, however, context is of the essence. Given that the natural habitat of humans is culture—the life of language, relationships, and communities—it follows that autobiography is not only about the individual but also about the socio-cultural world through which the individual moves. For this reason, qualitative autobiographical research must be vigorously interdisciplinary, cutting across varied disciplines such as psychology, sociology, anthropology, and history.

Another defining feature of autobiography is what is here termed its hermeneutic multivocality. In speaking of the “hermeneutic,” there is an immediate reference to the fact that autobiographical understanding is irrevocably interpretive; it is an effort after meaning, with its aim, again, not being merely to recount dispassionately this or that event, experience, or segment of a life but rather to “make sense” of it. Along these lines, there is also a poetic dimension to autobiographical understanding; insofar as the interpretive process is a constructive one, it is a work of poesis or meaning-making. In view of the fact that the personal past permits of multiple “readings” on the part of both individuals themselves and the researchers who study

them, there is also an inescapable multivocality—a multivoicedness—to the autobiographical text. This does not mean that autobiographical understanding is arbitrary, or that it is merely a function of interpretive prejudices, whether of the individual or the researcher. As the philosopher Paul Ricoeur argued, the hermeneutic process, as applied to the project of self-understanding, is essentially open and, at the same time, delimited by the semantic reality of the text itself.

Finally, autobiography is to be understood in terms of its embeddedness within the fabric of narrativity and, thus, is intimately tied to what might plausibly be considered the literary dimension of human life itself. As suggested earlier, a significant feature of human lives is that the meaning of experience frequently changes over time, thereby necessitating multiple readings. This suggests that a further significant feature of human lives is that they require recollection, “looking backward” again and again, resituating, reinterpreting, and rewriting the past as a function of one’s ever-changing present. Life events, therefore, may be considered “episodes” in an evolving narrative of the self, and just as the past is perpetually rewritten from the standpoint of the present, so too is the self, with the relationship between self and autobiographical narrative being a dialectical one through and through; even as the self is the source of autobiography, autobiography is the source of the self. Central to the literary dimension of both autobiography and selfhood is the idea of plot, which Ricoeur described as the “synthesis of heterogeneous elements” that is entailed in the imaginative act of drawing together the disparate lineaments of the past via memory into a whole constellation. This act, Ricoeur argued, is a function of “narrativity”—the narrative fabric of human life itself.

Its considerable virtues notwithstanding, autobiography is also considered by some to be suspect as a viable source of social scientific knowledge. As critics of autobiography frequently argue, memory not only is “reconstructive” but also is capricious, error filled, and distortive and, thus, cannot help but falsify the past. Precisely because it is not a dispassionate recounting of the past “as it was” but rather an imaginative and perhaps wishfully self-aggrandizing act of poetic self-portraiture, memory of the sort that autobiography relies on simply cannot be trusted. Add to the problem of memory the further problem of

textual inscription—the process of transforming memory into “literature” (even if only the literature of the interview-generated social science text that will inevitably be a function of the specific context in which one’s story is told, to whom, and for what reason)—and the resultant product may be so irreparably tarnished as to disqualify it from the pantheon of bona fide knowledge. As interesting and telling as autobiographies may be, it is their memory-saturated literariness that renders them epistemologically suspect. This, coupled with their notorious unwieldiness as “data” (how, after all, can autobiographies be measured and “contained” and transformed into suitable objects of social science inquiry?), has led to their occupying a questionable place in qualitative research.

Drawing on autobiography in qualitative research nevertheless remains an extraordinarily valuable vehicle not only for exploring the human realm in all of its depth, complexity, and richness but also for casting radically into question what constitutes valid and viable knowledge. Seen from one angle, the literariness of autobiography undermines its truth value and places it too far removed from reality—or at least the reality that objectifying science has seen fit to enshrine. Seen from another angle, however, it is this very literariness that points in the direction of a more open and expansive conception of reality and truth alike, one that is more adequate—and faithful—to the human realm. In this sense, autobiography has the potential to become a pivotal player in the refiguring of knowledge, serving as a much-needed bridge between the sciences and the humanities.

AUTOETHNOGRAPHY

Autoethnography refers to ethnographic research, writing, story, and method that connect the autobiographical and personal to the cultural, social, and political. In autoethnography, the life of the researcher becomes a conscious part of what is studied. During the past two decades, autoethnography has had an important influence on qualitative research. Many qualitative researchers—from realists to impressionist writers—now position themselves in their research and include themselves as participants in their interview and ethnographic studies of others. Likewise, there has been a burgeoning of autoethnographic projects that focus directly on the research and personal experiences of the researcher.

Definition and History

As an autobiographical genre of writing and research, autoethnography displays multiple layers of consciousness. Autoethnographers gaze back and forth. First, they look through an ethnographic wide-angle lens, focusing outward on social and cultural aspects of their personal experience. Next, they look inward, exposing a vulnerable self that is moved by and may move through, refract, and resist cultural interpretations. As they zoom backward and forward, inward and outward, distinctions between the personal and the cultural become blurred, sometimes beyond distinct recognition.

The term *autoethnography* has been in circulation for at least two decades. Anthropologist Karl Heider used autoethnography in 1975 to refer to the descriptions the Dani people of New Guinea gave of their own culture, but David Hayano usually is credited as the originator of the term. Hayano limited the term to cultural-level studies by anthropologists of their “own people” in which the researchers are full insiders by virtue of being “native,” acquiring an intimate familiarity with the group, or achieving full membership in the group being studied.

Autoethnographic studies now take place in many social science and humanities disciplines interested in ethnographic research; they are most prevalent in communication and performance studies, sociology, anthropology, education, social work, and nursing, among others. The turn to autoethnography in qualitative research is connected to a shift from viewing our observations of others as nonproblematic to a concern about power, praxis, and the writing process. This shift was inspired in part by the epistemological doubt associated with the crisis of representation and the changing composition of those who become ethnographers, with more women, lower-class, ethnic and racial groups, and scholars from the developing world now represented.

Approaches and Forms of Expression

The term *autoethnography* has become the broad rubric under which many other similarly situated expressions from multiple disciplines are included, such as personal narratives, first-person accounts, opportunistic research, experimental ethnography, lived experience, radical empiricism, autopathography, life writing, confessional tales, ethnographic memoir, narrative ethnography, and Indigenous ethnography. Likewise, a variety of methodological strategies have been developed in connection with autoethnographic projects, including systematic sociological introspection, biographical method, personal experience methods, feminist methods, narrative inquiry, co-constructed narrative, interactive interviewing, and autoethnographic performance.

Autoethnographic texts appear in a variety of forms such as short stories, poetry, fiction, novels, photographic essays, scripts and performances, personal essays, fragmented and layered writing, and social science prose. They showcase concrete action, emotion, embodiment, introspection, and self-consciousness portrayed in dialogue, scenes, characterization, and plot.

Negotiating Hope, Reality, and Ambivalence in the Face of Death

Visits to Dr. Silverman, Gene's physician, provided occasions for confronting and evaluating Gene's illness. The doctor's office was on Park Avenue in New York City, yet he made us feel we were being visited by a rural doctor in a horse-drawn carriage. Sentimental and grandfatherly, he held Gene's hand and teared when he had to tell us bad news; but his eyes brightened when immediately afterward he informed us of some new medicine to try or of a success story—a mayor who was working while hooked to a breathing machine—or when telling Gene how far he was above the normal curve given the extent of his emphysema.

"Most people in your condition are home in bed, but look at you, you're traveling around the world," he says to Gene, after hearing about our vacation.

"See, I'm not a wimp," Gene tells me when Dr. Silverman leaves the room.

"Don't you know that I know that?"

Gene needed the validation. Otherwise, how could he be certain how well he was doing? The same was true for me, his partner. How else did I know how hard he was trying to cope?

During one visit when there is a dramatic drop, Dr. Silverman tries to be optimistic: "But look at what you can still do. And there are some developments; a new drug is being tested in Canada. Let's see if we can figure out a way to obtain it." Gene listens attentively, hopefully. Then a cloud passes over his face. "But, Doc, it's not a cure, is it?"

"No," the doctor replies, holding eye-to-eye contact with Gene. "There is no cure. Maybe in the future, but not in your lifetime."

Gene's shoulders sag farther into his chair as Dr. Silverman looks away, busying himself with altering Gene's many medications. "I think changing your antibiotic will help. Try taking one four times a day instead of two twice a day."

This isn't real, I say to myself, looking down and holding my breath. Yes, it is. Accept it. Now, you know the score. My mouth is dry, my eyes are wet. How can I feel so numb but like I am exploding at the same time? I suddenly laugh, then cover it with a sigh. "My god," a voice inside my head screams, "he's going to die. There is nothing I can do. Get me out of here." A calmer voice responds, "You can't leave him. You love him. He needs you and he's doing the best he can."

After this visit, we treat ourselves to lunch in an expensive restaurant on the Upper East Side. Settling into Maxwell's Plum, the tension dissolves under the influence

of champagne and gourmet food. Cost does not concern us. Like new lovers, we hold hands. Like old companions, we talk about death and the shortness of time we have left together. We cry softly as we admit the lowered numbers on pulmonary tests have reaffirmed our worst fears.

Then Gene says angrily, "Why does Dr. Silverman pretend there's hope when there isn't any? Why doesn't he just say so?"

"He does, Gene. He said there was no cure in your lifetime." A pall spreads over our conversation.

"But then he says the shuffling of the medicine will help. It won't," replies Gene, still angry.

"That's true. But think of his position. He wants to be honest, yet not totally depress you or make you feel there's no hope for improvement. So he confronts us with the stark reality of your deterioration and then gives us a ray of hope to hang on to. It isn't dishonest. He wants to have hope too."

"I guess," Gene replies, softening with resignation. Then, because nothing reminds us of our love in quite the same way as facing the loss of it, Gene connects with my eyes and mouth, "I love you." As the feeling flashes back and forth between us, my fear subsides.

"At least we have each other," he continues, now changing sides. "And who knows. Maybe I'll live longer than anybody thinks. There's always the possibility of a lung transplant."

Sure, I think ironically, but say sincerely, "Anything is possible. I'm just glad to have this time now. I guess our situation is not really worse than others. Everybody will die."

"This champagne is wonderful," Gene says. "Taste it in the back of your throat. It's so full and dry."

So began a tradition of having lunch at Maxwell's Plum after each doctor's visit. Without fully realizing it at the time, the two of us were being socialized into the roles of dying and grieving. I rehearsed how to show Gene love, yet shut out pain and fear; Gene practiced how to face his illness, yet escape living as a dying person.

The doctor's candid opinion, supported by the declining test results, confronted us with the reality of Gene's impending death. We began to relate to the disease much as the doctor had—facing the inevitable and then looking for some reason to be hopeful. Ambivalence as a coping mechanism offered comfort yet left room for reality. These afternoon lunches provided opportunities to integrate hope and reality, a balance that would tip toward reality as the illness took over.

Personal narrative writing breaks away from the traditional rational/analytic conventions of academic writing in several ways:

1. The author usually writes in the first person.
2. The story often focuses on a single case, drawing attention to what is particular as well as what may be universal.
3. The autoethnographer claims the conventions of literary writing; the mode of storytelling is more akin to the novel or biography, where characters and scenes are developed and action unfolds, than to the traditional research report.
4. The accessibility and readability of the text repositions the reader as a co-participant in dialogue rather than a passive receiver of knowledge.
5. The story highlights private details of emotional and bodily experience.
6. The narrative text resists the impulse to abstract and explain, stressing the journey over the destination; thus, it eclipses the scientific illusion of control and mastery.
7. The story is written in an episodic form that dramatizes the motion of connected lives over the curve of time; thus, it resists the standard social science practice of portraying social life and relationships between people as a snapshot frozen in time.
8. The evocative story activates subjectivity and compels emotional response. It longs to be used rather than analyzed, to be told and retold rather than theorized and settled, to offer lessons for further conversation rather than undebatable conclusions, and to substitute the companionship of intimate detail for the loneliness of abstracted facts.

Deborah Reed-Danahay pointed out that autoethnographers vary in their emphasis on the research process (*graphy*), on culture (*ethnos*), and on self (*auto*). Different exemplars of autoethnography fall at different places along the continuum of each of these three axes. Widely used expressions that provide a sense of the range of approaches associated with autoethnography include those described in the following paragraphs.

Reflexive or narrative ethnographies focus primarily on another culture or subculture, while authors use their own experiences in the culture reflexively to bend back on self and look more deeply at self–other

interactions. The researchers' personal experiences become important primarily in how they illuminate the culture under study. Reflexive ethnographies range from starting research from researchers' own experiences to ethnographies where the researchers' experiences are studied along with those of other participants. *Ethnographic memoirs* or *confessional tales*, personal stories that focus on the backstage of the researchers' experiences of doing studies of others, represent the stories that focus most directly on the researchers.

Michael Jackson used the term *radical empiricism* to refer to a process that includes the ethnographers' experiences and interactions with other participants as vital parts of what is being studied. Reflexive ethnographers ideally use all of their senses, bodies, moments, feelings, and whole being; they use the self to learn about the other. Barbara Tedlock referred to the process of incorporating ethnographers' experiences into the ethnographic descriptions and analyses of others, and emphasizing the ethnographic dialogue between the narrators and members of the groups being studied, as *ethnographic narratives* or *observations of participation*.

Indigenous ethnographies are stories about cultures that have been marginalized or exoticized by others written by Aboriginal researchers who now interpret their own cultures for others. Aboriginal ethnographers share a history of colonialism or economic subordination, including subjugation by ethnographers who have made them subjects of their work. Now as bicultural insiders/outside, these ethnographers construct their own cultural stories (often focusing on their own autobiographies), raise serious questions about the interpretations of others who write about them, and use their dual positionality to problematize the distinction between observer and observed, that is, between insider and outsider.

Complete member texts are in-depth explorations of groups in which researchers already are full members or in which, during the research process, they become full members with complete identification and acceptance. The researchers themselves become part of the phenomena being studied.

Personal narratives are stories in which social scientists take on dual academic and personal identities and focus on some aspects of their personal experiences in daily life. These stories generate the most controversy among scholars given that the emphasis is on the self of the researcher rather than on the

other—the usual purview of ethnographic study. The primary purposes in these stories are to understand a self or some aspect of a particular life lived in a cultural context and to understand a way of life from investigating a particular life. In personal narrative texts, authors become “I,” readers become “you,” and subjects become “us.” Sometimes several authors act as researchers and participants, writing and co-constructing their stories together and sharing authority. Readers also take a more active role as they are invited into the authors’ worlds, evoked to a feeling level about the events being described, and stimulated to use what they learn there to reflect on, understand, and cope with their own lives. The goal is to write meaningfully and evocatively about topics that matter and may make a difference, to include sensory and emotional experience, and to write from an ethic of care and concern.

Autoethnography is a blurred genre that brings together the social sciences and humanities. In many cases, whether a work is called an autoethnography or an ethnography depends on the claims made by those who write and those who write about the work. Whether a study is called an autoethnography or a memoir is connected to writing practices (social science autoethnographies usually contain citations to other academics and use an academic disciplinary vocabulary), publishing practices (who publishes the book, how it is promoted [e.g., the field identified on the outside cover] and labeled [ISBN number]), who is the targeted audience, reviewing practices (who endorses it, who reviews it, and who writes about it), and disciplinary practices (whether those in a particular field are receptive to autoethnographic texts and the crossing of the social sciences and humanities divide).

AXIAL CODING

Axial coding is a procedure advocated by Anselm Strauss and Juliet Corbin in their guidelines for the development of grounded theory (theory derived from data) when analyzing qualitative data. Open coding, where the raw data (e.g., interviews, art, fieldnotes) are broken down so that as many ideas and concepts as possible are identified and labeled, sets the stage for axial coding, where the data are reassembled so that the researcher may identify relationships more readily. To do this, the researcher attempts to flesh out the properties of categories and determine how they vary in terms of their dimensions. Categories are pursued in greater depth on the way to the identification of core categories and ultimately to the explanation of phenomena (selective coding).

Axial coding is the phase where concepts and categories that begin to stand out are refined and relationships among them are pursued systematically. Categories represent phenomena such as events, objects, incidents, and actions. As major categories begin to emerge, the researchers are advised to ask questions of the data that concern them in a focused manner.

The questions that researchers are advised to ask of the data when exploring a given category are referred to as the *paradigm* (a scheme to assist in the organization of data). This features guidelines that urge paying particular attention to conditions or context (structure) (e.g., where, when, why), actions/interactions (process) (e.g., responses, strategies), and consequences (e.g., outcomes) that relate to a given category. The paradigm is a tool recommended to assist researchers in integrating structure and process and in thinking in terms of cause and impact.

Axial coding derives its name from attention during this phase of analysis to the intense coding around the “axis” of one category of interest at a time. The recommendation (especially to new researchers) is to seek answers to a series of questions about this focal category. For example, if one has recognized deviant acts as an important category when analyzing interviews concerning children of offenders, one might ask questions of the data such as how often deviant acts are committed, by whom, at what age, where, what kinds of acts are committed, whether the acts are antinormative or illegal, and what happens to those who commit the acts. As new categories are recognized from the coding prompted by the questions asked, relationships between these categories (referred to as *subcategories*, e.g., types of deviance, amount of deviance) and the focal category are identified. Hypotheses—statements about how the categories relate—are then developed as patterns emerge on the road to explaining phenomena.

There is some debate about the benefits of axial coding. There are those who believe (as does Barney Glaser) that addressing paradigmatic questions prematurely risks imposing schemas that impede the emergence of theory, potentially limiting what analysts ultimately recognize in the data. Even among the many followers who value the procedure of axial coding, a prevalent critique is that confusion can arise from the complicated, not always transparent guidelines and terminology associated with the practice.

AXIOLOGY

Axiology is the recently adopted term used to cover the philosophy of values. It was introduced a century or so ago by the French philosopher Paul Lapie and derives from the Greek *axios*, corresponding to the Latin *valere*, meaning “to be strong” or “to be worthy.” Axiology, or value theory, represents an attempt to bring the disparate discussion of values under a single heading, covering a wide area of critical analysis and debate that includes truth, utility, goodness, beauty, right conduct, and obligation. There is a direct focus on the purported value of matters such as human life, knowledge, wisdom, freedom, love, justice, self-fulfillment, and well-being. Axiology has relevance to the field of qualitative research inasmuch as it has a direct bearing on the ethical context of research, offers an important basis for making explicit the assumptions of different paradigms of research, and provides the foundation for understanding the process of the addition to knowledge involved in scientific inquiry.

Value Theory

Value theory is concerned with the nature of value itself as well as with the various forms that value can take, such as the aesthetic value of beauty, the ethical values of good/bad and right/wrong, and the epistemic values of truth, rationality, and justification.

The central issue of the nature of value is somewhat contentious and has a long history. For example, Plato saw values as essences that are known through intuition, whereas Aristotle saw values as defined simply by human interest. Philosophers in the neo-Kantian tradition have proposed that values are objective and universally valid, whereas existentialists such as Nietzsche and Sartre regard values as constructions, that is, the mere products of human invention. More recently, in the cult novel *Zen and the Art of Motorcycle Maintenance*, Robert Pirsig equated value with “quality,” a sort of meeting point between the human mind and the material world that resists any reduction to either subjectivity or objectivity but represents a subjective–objective reality. Whatever perspective is taken, it would seem that value is clearly not a property of the thing-in-itself, it cannot be perceived by the senses, and it cannot be measured scientifically, but somehow it arises out of our relationship with things.

The study of values often leads to the identification of what amounts to a core value or a hierarchy of values that leads toward a final value. For example, Aristotle proposed “happiness,” the Stoics stressed “tranquility of mind,” Schopenhauer offered “renunciation,” Sartre proposed “authenticity,” and Taoist philosophy positions “flexibility” and “adaptability to context” as the final value. Furthermore, it is useful to distinguish intrinsic values from instrumental values. Something has intrinsic value if it is worthy, or desirable, in and for itself, whereas something is of instrumental value if it offers a means or contributes directly to something else in turn that is intrinsically of value. Nevertheless, the recurrent problem throughout much of the study of value is that although many philosophers offer systematic accounts of what is of value, they do this without offering any proper justification or without any appeal to some claim to validity.

The study of ethics can be seen as closely related to the study of values, and an ethics that is based specifically on value is called axiological ethics. Here the focus is less on what should be done and more on what is worth doing and what should be avoided.

This issue of value, which has so often been taken for granted in the past, has recently been attracting much more attention within the field of qualitative research. Axiology has become recognized as a key dimension in the comparison of competing, or co-occurring, paradigms of research, and this can be helpfully placed within a discussion of the scientific method in general.

Axiology and Scientific Method

The traditional positivist approach to scientific method is based on a sharp distinction between fact and value. Facts are seen as objective truths that are out there waiting to be discovered. In contrast, values are seen as subjective, undermining the pursuit of truth, and a potential source of bias and error in research; therefore, they are to be excluded from all inquiry. Perhaps the kindest description of this position is that it is at the very best naive. The notion of a value-free and ethically neutral science is little better than a myth. Positivist inquiry is run through with value judgments, and to the extent that these go unacknowledged this is a potentially very serious flaw. For example, traditional science is based on an explicit appeal to the values of truth, knowledge, objectivity, rationality, and so on. Although one could argue that these are intrinsic

values, such a claim still needs to be examined thoroughly and repeatedly in the light of the epistemological and axiological issues that are involved.

The point is that even intrinsic values are values. They require clarification and reflection. We engage in inquiry because we care and want to make a difference. The generation of a research hypothesis, the refining of the research question, the judgment of what might be important additions to knowledge in any field of inquiry, and the choices and decisions made in research design, the selection of participants, and the interpretation of data—all of these involve value claims one way or another. Moreover, inquiry leads to knowledge, and knowledge leads to the imposition of some type of order or structure on the world—and this always involves issues of value.

The Human and Social Sciences

The human and social sciences, in their development of a qualitative approach to inquiry, have pointed to the crucial need to deal with the ways in which people relate and give meaning to their social, cultural, and material environments. This points to the acceptance of the role played by human subjectivity, context, and (moreover) human values in the generation of knowledge and in the logic of inquiry.

The growing recognition of the importance of the role that values play in qualitative research is probably best illustrated through the recent work of Egon Guba and Yvonna Lincoln. They published a series of three chapters in the first, second, and third editions of the groundbreaking *Handbook of Qualitative Research* that set out to examine the competing paradigms being used.

In their chapter for the first edition, Guba and Lincoln distinguished among four major alternative paradigms of inquiry: positivism, postpositivism, constructivism, and critical theory. They defined a paradigm as a set of basic beliefs that represent a particular worldview, which in turn leads to particular approaches to inquiry. They also proposed three fundamental interrelated questions with respect to how paradigms might be compared: the ontological, epistemological, and methodological questions. In their discussion, the issue of value was raised briefly with respect to differences in the epistemological posture and practical issues raised. For both the positivist and postpositivist paradigms, values are specifically excluded, whereas for constructivism and critical theory, values take “pride of place” and are seen as

“ineluctable in shaping inquiry outcomes,” according to Guba and Lincoln.

It is important to realize that an inquiry paradigm involves a set of assumptions and that all research—indeed all scientific knowledge and inquiry—necessarily rests on assumptions. Making assumptions is not the problem, but overlooking which assumptions have been made, or taking for granted any assumptions that have been made, will inevitably lead to problems. Because assumptions invariably encode values, the notion of paradigm becomes crucial in the relationship between inquiry and the study of value.

To make the best use of Guba and Lincoln’s ideas, it is perhaps most useful to see paradigms not as competing but rather as pluralistic in approach. This means that, rather than rejecting one worldview or paradigm in favor of another, for any field of inquiry several paradigms might be held as tenable. Indeed, such a preference for a pluralistic approach, rather than a competitive approach, is itself an example of value-in-action.

Guba and Lincoln revised their chapter for the second and third editions of the *Handbook* and specifically highlighted the issue of axiology as a critically important addition. They took up some criticisms of their original chapter that had been raised by John Heron and Peter Reason. One crucial revision involved an expansion of the three fundamental questions by which different paradigms can be compared to include a fourth question—the axiological question. Guba and Lincoln acknowledged that the issue of value had become much larger than they had first conceived. There was clearly the need to recognize the concern with what is of value, and what is worthwhile, as one of the foundational philosophical dimensions of what constitutes a paradigm.

By raising the profile of axiology in this way, Guba and Lincoln acknowledged how values cannot simply be left under the headings of epistemology and methodology, where they become obscured and dealt with through the codes of accepted practice. Instead, they proposed that values need to be explicitly discussed and critically explored in their own right.

Indeed, although axiology has come late into the frame, it could be argued that it might well need to be given some sort of priority, even over ontology and epistemology. Such an idea would be consistent with Martin Heidegger’s contrast between the “readiness-to-hand” and the “present-at-hand.” Those objects and events that are ready-to-hand constitute what is of

value to us, what matters to us, and what is of use to us. Heidegger argued that this type of knowledge has a primacy over our knowledge of the present-at-hand, that is, of the things-in-themselves. Indeed, if qualitative inquiry is to be closely associated with the study of the ready-to-hand, and quantitative inquiry is to be closely associated with the study of the present-at-hand, then it could be argued that it is the qualitative approach to research that should enjoy some sort of priority in scientific endeavor.

Heron and Reason’s Article

The full scope of the article published in 1997 by Heron and Reason that had such an impact on Guba and Lincoln warrants further discussion. It is in proposing an inquiry paradigm that involves a participatory worldview that the need for a more explicit axiology emerges. Heron and Reason explained that none of the inquiry paradigms considered by Guba and Lincoln can account for experiential knowing, which they argued is the ground of our being. For example, Heron and Reason argued that “constructivist views tend to be deficient in any acknowledgement of experiential knowing; that is, knowing by acquaintance, by meeting, and by felt participation in the presence of what is there” (p. 277). Furthermore, “to experience anything is to participate in it, and to participate is both to mould and to encounter; hence, experiential reality is always subjective-objective” (p. 278). In this argument, the inescapable role of values in human experience is being teased out. To know something, to experience something, always implies valuing it in some way or another.

It is precisely these views that led Heron and Reason to propose the fourth fundamental question that is necessary to fully define an inquiry paradigm. Thus, in addition to the ontological, epistemological, and methodological questions, they added the axiological question, which they proposed sets out to ask what it is that is intrinsically worthwhile (i.e., what in the human condition is valuable as an end in itself?). Posed in this way, the axiological emphasis leads to asking questions such as the following: What is the value of knowledge itself? What is the ultimate purpose of human inquiry? How much should inquiry promote human flourishing, individual empowerment, advocacy, activism, relief from oppression and suffering, and so on?

Toward a Transparent Axiology

Clearly much more is at stake here than the simple acknowledgment of the role played by values in human affairs and the explicit role of values in qualitative inquiry. The proposal made by Heron and Reason, and its subsequent inclusion by Guba and Lincoln, amounts to a fundamental change in the characterization of qualitative inquiry, the types of knowing with which it is concerned, and the philosophical underpinnings on which it relies. Moreover, it is a major step toward establishing a more fully articulated transparency of values than has so far been feasible in human inquiry. There is space to consider just two examples here.

The Ethics of Inquiry

One of the most obvious ways in which values play a crucial role in research is in the ethics of inquiry. However, by raising the profile of the axiological question, a more transparent ethics can emerge. First, the positivist claim that there is no place for a consideration of values in scientific inquiry is shown up as something of an oversight. Ethical matters are the concern of all scientific endeavor, and this must apply to all fields of research—whatever their paradigm and whatever their focus. Because ethics always rests on a consideration of values, there is simply no escape. Of course, positivists do not deny the importance of ethical considerations, but there is a basic contradiction, and there are significant dangers, in thinking ethically without any reference to human values.

Second, the axiological perspective offers a more useful perspective on the contrast among the ethical positions adopted by the positivist, constructivist, and participatory approaches to inquiry. The positivist employs a mostly extrinsic approach to ethics, with a reliance on ethical codes, ethics committees, and the accepted standards of good practice. In contrast, the qualitative researcher employs an intrinsic approach to ethics, one that accepts the established codes of ethically sound practice but goes farther by striving toward a transparency of values, toward a transparency of the requests and demands put on participants, and also applies a “process ethics” to the forms of knowing that the specific context of the inquiry requires. Process ethics stresses that codes of practice are only a first step that must be followed up with an open-minded vigilance to ethical matters

that might be raised at any point during the research process.

Research as a Co-Operative Inquiry

Perhaps one of the best examples of an approach to qualitative research that offers a transparency of values is Heron’s own idea of *co-operative inquiry*, which offers an explicitly collaborative approach to research. Co-operative inquiry is critical of the idea of qualitative inquiry as being *about* other people and instead promotes inquiry as being *with* other people. Heron pointed out that in most research methodologies the roles of the researcher and subjects (i.e., participants/co-researchers) are regarded as mutually exclusive. In conventional approaches to inquiry, the researcher contributes the thinking that goes into the project, and the subjects contribute the data for the study. But in the co-operative inquiry model, both the researcher and co-researchers (participants) contribute equally to the design of the research and share equally in the experience. The specific issue that is being explicitly raised here is one of value—the value that is to be placed on the full participation of participants in an inquiry. From this perspective, the key value in research is being with people.

In his final discussion of this approach in 1996, Heron argued that people have a moral right to engage in research decisions that claim to generate knowledge about them. To summarize Heron’s value position with respect to co-researchers, if this right is not respected, then

- co-researchers will be *disenfranchised* in not being able to express their own preferences and values;
- they will be *disempowered* and *oppressed* by decisions and values that are not of their choosing;
- they will be *misrepresented* by research designs from which they have been excluded in their planning;
- they will become *accessories* to the knowledge claims made about them that can be misapplied to others;
- they will be *manipulated* in the acquisition and application of the knowledge about them;
- they will be *denied* the opportunity for increased self- and peer-generated knowledge; and
- they will be subtly *oppressed* and *exploited* by the researcher’s ulterior motives.

If this is an example of the axiological perspective, of value-in-action, then it is to be recommended to all

qualitative inquirers. It offers an example of a profound concern with human values that is crucial to the way in which qualitative research is now being defined and must be considered foundational to all human and social inquiry.

B

BASIC RESEARCH

Some concepts are more easily explained by contrasting them with their opposites, and that is certainly the case with basic research, which is most commonly contrasted with applied research.

Both these terms speak to the immediate motivation of the researcher rather than to any necessary outcome of one's research. Basic research is undertaken for its own sake—to advance knowledge, to develop theory, to solve an interesting theoretical puzzle, or to address a curiosity of the researcher—without any immediate concern for whether doing so will produce anything useful or practical or generalizable. Applied research, in contrast, specifically aims to do something practical about a relatively immediate problem.

One should not be overly rigid in this dichotomization of “basic” and “applied,” however, which is a simplification tied to an older view that basic research comes first and that a separate process of generating applications—done by completely different groups of people who are sometimes even generations removed from the original work—comes later. More recent discussions of the topic, while on the one hand acknowledging the continuing existence of these two pure types, now include a recognition that the time sequence need not be so unidirectional and linear and that the two interests need not be seen as mutually exclusive.

These changing conceptions of basic and applied research and the relations between them reflect broader changes in society and our academic institutions. It once may have been the case that basic research was undertaken in the university by independent academics, while realizing the implications of

these developments was the domain of the private sector. However, more than two decades of government promotion of academic–private sector partnerships have further blurred any lines that might have existed between the two.

Given the pressing nature of many social problems (e.g., crime, abuse, poverty, prejudice and discrimination, injustice), health concerns (e.g., finding causes and cures for everything from the common cold to cancer), and other physical, social, and technological challenges (e.g., how to send people to Mars so that they can survive the trip and return; dealing with global warming), it is perhaps not surprising that some have criticized basic research as an esoteric academic pursuit of ivory tower scholars. In its most extreme form, applied research is considered worthwhile only when its products are in keeping with government-defined priorities and are potentially money-generating through patents, inventions, and commissions. Canada's federal government, for example, would seem to be walking this policy path: the last several decades have seen more and more targeted funding for research deemed in the national interest; most recently, although the Social Sciences and Humanities Research Council (SSHRC) was granted an increase in research funds in the 2007 federal budget, the increased funding was tied to projects dealing with management, business, and finance (see Church, 2007).

Perhaps in response to this policy, the Canadian federal granting councils continue to support basic research in all disciplines, but have actively encouraged applicants for grants to choose project titles that do not sound too esoteric and to address issues of potential applicability even if this involves no more than complete speculation on possible areas of application.

Chad Gaffield, president of Canada's SSHRC, has stressed the importance of clearly identifying the value of funded research projects.

In contrast, James Turk, Executive Director of the Canadian Association of University Teachers—an organization that, like the American Association of University Professors, has for many years extolled the virtues of and vigorously defended academic freedom—warns about the myopia of this view. He questions the wisdom of trying to appease politicians by using language that buys into the view that the only valuable research is research that can promise a payoff:

I have little tolerance for those who respond to these kinds of pressures by trying to dress ourselves up as if we too can pay off commercially. . . . They do a disservice to themselves and lend credibility to the approach that what is really important is that which we can predict can pay off. (Turk, as quoted in Church, 2007, p. A7)

Even if one were to grant that some variant of social value is a desirable criterion, researchers sell their possibilities short if all the emphasis is on the here and now and consider nothing but practical problems. A limitation of applied research is that it is grounded in current (and often very short-term) conceptions, assumptions, and understandings. This limitation confuses *what is* with *what might be*, discourages novel approaches and viewpoints that can put contemporary understandings in broader perspective, and fails to consider new ways of dealing with contemporary issues or even to be open to new issues, products, and considerations. As astrophysicist and Nobel Prize recipient George Smoot of the University of California at Berkeley stated, "People cannot foresee the future well enough to predict what's going to develop from basic research. If we *only* did applied research, we would still be making better spears" (as quoted in Mullane, 2006, p. 5). As this statement suggests, basic research that is undertaken for its own sake is often the foundation upon which future knowledge—and future applied research—rests.

It is, thus, not that basic research does not have social value, but rather that it encourages the pursuit of knowledge for its own sake in the belief that it is only by also encouraging research that is outside the box—even though this innovation involves incurring all the dead ends and false leads that such research inevitably will include—that one also finds jewels of understanding that can open new doors and new

possibilities that applied researchers, operating within a limited frame of reference, are unlikely to have considered. Any comprehensive research strategy will include both.

Examples of research abound where the unique curiosity of individuals later provided the basis for technological marvels and entirely new fields of inquiry. Who would have thought, for example, that Michael Faraday's study of electromagnetic induction in the 1830s would lead to the development of virtually everything electronic we have today? Or that Gregor Mendel's study of the characteristics of pea plants in the 1860s would form the basis of our understanding of the basics of genetics and heredity? Or that Albert Einstein's 1917 theory of stimulated emission would decades later be used to produce the laser, which itself was initially thought to be a technological marvel with no practical use but is now a powerful tool used in communication, industry, physics, chemistry, biology, and medicine and does everything from generating holographic representations to performing eye surgery to playing CDs and DVDs?

But all of these examples are from the natural and physical sciences. What of the relation between basic research and the social sciences and humanities, particularly in the realm of qualitative research? Fascinatingly enough, a review of the literature reveals that virtually nothing has been written about this relationship. One reason one may hear less about basic research in the context of qualitative research is that the fruits of social research—even when they are used as a foundation for the development of new policies or practices—are less direct and more ephemeral. There is something very concrete about a laser or a space station or a drug such as penicillin. In contrast, even when the results of social research on such topics as social cognition, leadership styles, or child development are used to generate improved policies and/or practices with respect to human-computer interfaces, corporate decision making, or educational policies, they are less likely to be written about in the newspaper, result in Nobel Prize awards, or lead to products sold in neighborhood retail markets.

But basic research is conducted within the domain of qualitative research. Indeed, one could even argue that two aspects of qualitative research imply that basic research and qualitative research are made for each other. One that comes to mind is the qualitative dictum expressed by methodologists such as Howard Becker that the first obligation of any piece of qualitative research is to the milieu or people one is studying.

From this perspective, it is essential to ensure that one's research has inductive integrity by taking the research site and its inhabitants on their own ground and understanding them on their own terms for their own sake. Similarly, as Robert Stake notes, the intrinsic case study—a case study undertaken for no other reason than the curiosity of the researcher—also has strong traditions in the qualitative realm. Both these authors affirm that the first priority in qualitative research is to the integrity of the case—analogous to the priority that quantitative-experimentalist researchers attach to internal validity—because it is the foundation without which all else is irrelevant. To thine own case be true; generalizability, if it is a concern at all, comes later and is likely to be more a theoretical than a statistical exercise. In this connection, see Becker's (1998) discussion of the part to whole problem.

Notwithstanding the compatibility of qualitative research and basic research outlined above, qualitative research is also strongly associated with a commitment both to applied research and to mixed-motive research that is designed to contribute to social theory as much as it is intended to improve people's lives. Indeed, strong traditions in qualitative research, such as its emergent character, its commitment to examining and providing voice, and the frequently collaborative processes these principles activate and involve—as described, for example, by Ted Palys and Chris Atchison—have an inherent applied focus in their explicit desire both to contribute to knowledge and theory and to improve the human condition. The same is true of entire methodological traditions such as participatory action research, as characterized, for example, by Peter Reason and Hilary Bradbury, and political activist ethnography, as described by Caelie Frampton, Gary Kinsman, Andrew Thompson, and Kate Tilleczek.

BENEFIT

There are several types of benefit (advantage or profit) in qualitative research. Research may impart benefits to society by fulfilling humans' curiosity and desire for knowledge, fostering further research, and solving problems. Individual research participants may benefit directly through payment, altruism, personal empowerment, or a feeling that they have contributed to science.

The potential benefit of a particular study helps to inform the conditions under which the research may be done. In general, unfunded research does not have to demonstrate any prospective benefit, whereas funded research is generally accountable to government and private agencies. Such organizations engage in a process of scientific peer review to decide which research proposals and applicants merit funding. That is, funded researchers must demonstrate in advance the required methodological expertise, qualifications, and experience to carry out research that may benefit society or the goals of the granting body.

In research involving humans, ethics boards will usually invoke a risk or harm and benefits approach to establish that the potential benefits of a study are not outweighed by potential harms. If proposed research presents no more than minimal risk to human participants,

an ethics board will usually not concern itself with prospective benefits. When research presents greater than minimal risk, an ethics board usually needs to establish that the research has sufficient scientific merit to benefit prospectively the scientific enterprise and society. Scientific merit is normally determined via a process of peer review.

Assessing the prospective benefits of a study is controversial because results cannot be known in advance. For example, Stanley Milgram's psychological experiments on obedience to authority have had far-reaching multidisciplinary application as well as profound contributions to the development of standards for ethical research.

As part of informed consent, research participants should receive information about reasonably foreseeable benefits derived from participation. Immediate benefits to participants include payment, therapy, or new information. Many people participate in research despite no clear benefit, other than to satisfy their curiosity or because they wish to interact with research professionals. It is acceptable to advise participants that not all benefits can be anticipated at the time of the research.

Paying research participants is also controversial. Some scholars argue that payments can coerce participants and undermine the informed consent process. Others argue that payment is not an inducement if an ethics board has ensured participant safety. Finally, some scholars argue that participants are often underpaid and therefore denied proper benefit. This is particularly true in qualitative research.

In summary, the primary benefit derived from research is the contribution to knowledge and ultimately to society. In the case of funded research, the degree of benefit that can be shown in a research proposal will often determine whether or not a study will be done. Research participants may benefit tangibly through payment or intangibly through feelings of altruism.

BIAS

Bias refers to a predisposition or partiality. In qualitative research, bias involves influences that compromise accurate sampling, data collection, data interpretation, and the reporting of findings. Researchers may show bias when they reach conclusions that ignore contradictory data or when the collection and analysis of data are designed to lead to predetermined conclusions. Publication bias occurs when researchers and journals avoid reporting insignificant findings.

The traditional scientific method says that researchers should revise a theory when data fail to fit the theory, or they should abandon the theory and look for new explanations. Nevertheless, Thomas Kuhn has shown that most scientists attempt to make the data fit the theory. Kuhn's work helps to explain that scientists are products of their environments and therefore bring their assumptions and personal standpoints to the research enterprise.

The potential for bias enters the research enterprise the moment a researcher chooses one topic over another, one research question to the exclusion of another, and one particular theory over another. Researchers, like everyone else, are products of the social world and therefore have values that will be more or less apparent in their research.

Decisions around research method, population sampling, and other design issues can introduce bias. In circumstances where researchers repeatedly follow the methodology of previous studies, they run the risk of reproducing similar findings that are method-dependent. In quantitative research, especially, multiple methods are often used to maximize confidence that findings are reliable and valid. Similarly, it is important to recognize whether a particular sample represents the parent population. In qualitative research, however, biases are often assessed in the context of doing the research, to acknowledge and manage the limitations of the research design. Finally, the wording of interview questions merits careful consideration with regard to the wording of questions so that they are not preordained to elicit biased responses. Wherever possible, pretesting should be employed.

Many researchers anguish over the dilemma of doing research that is either impartial and neutral or firmly grounded in a value position. Howard Becker has argued that this dilemma does not exist because researchers are not value-free, and therefore, personal and political views will enter a research agenda. The real imperative is for researchers to be aware of their values and predispositions and to acknowledge them as inseparable from the research process.

Perception of bias can be most apparent when research challenges a status quo. For example, research that opposes the vested interests of public officials is more likely to be criticized for bias than research that does the opposite. Research that challenges longstanding positions such as drug prohibition, gender discrimination, or ageist policy will often be accused of bias.

Researchers manage bias by being self-aware of their values and assumptions, looking for contradictory data, and being open to alternative interpretations of their data. Although many of the social sciences aspire to objectivity, social scientists should acknowledge their own subjectivity in the research process.

BIOGRAPHY

Biography, as a genre, and biographical methods, as distinctive aspects of qualitative research, are influenced by a number of disciplinary strands, including history, literature, anthropology, sociology, psychology, and education. These disciplinary influences have created methodological and conceptual variations of biography, including life story, life history, life writing, narrative, oral history, memoir, fictionalized biography, and forms of autobiography that attend to inter-subjectivity and blurred boundaries between self and other that influence any representation of a life.

Biography, as both genre and research method, involves not only gathering data about a specific individual, either living or deceased, but also interpreting these data in order to create a representation or portrayal of particular aspects of the subject's life and times. As well, biography and biographical methods currently are subject to questions that frame debates in a variety of disciplines regarding the possibility or

impossibility of any one truthful retelling of any individual's life; the influence of the researcher's historically and socially situated autobiographical contexts, discourses, and perspectives on constructions and depictions of the biographical subject; memory and its shifting contextual influences; and the role of the reader. Although this entry focuses on qualitative research methods typically associated with biographical research, it concurrently gestures toward current and contentious issues that characterize this genre of inquiry.

Typical Methods Utilized in Biographic Research

Whether one is interested in researching and representing the biography of a deceased individual or one who is living, qualitative researchers typically first must attend to ways and reasons why they have chosen particular persons as subjects for biographical research. Researchers also must locate and decide on which pertinent archival or repository materials might be further researched and analyzed, whom they might wish to interview in relation to the subject, and in what document analyses, beyond formally archived materials—including, for example, newspapers, letters, diaries, journals, video- and audiorecordings of the subject—they might need to engage further. Also, researchers might wish to involve themselves in some form of participant observation or nonparticipant observation (the researcher observes, but is not an active participant) to research places and contexts in which their subjects live(d) and work(ed).

The Biographer's Relation to the Subject

Biographers traditionally have chosen exemplary or well-known individuals as subjects of their inquiry. However, recent theorizing in the disciplines of history, sociology, anthropology, literature, education, and psychology as well as within women's studies and ethnicity studies, for example, have highlighted a need to attend to historically underrepresented individuals. Such emphases also highlight the necessity of attending to ways in which these potential biographical subjects both have constructed themselves and have been constructed by particular historical and social-cultural circumstances, power relations, and prevailing discourses.

Therefore, qualitative researchers, no matter what their subject choices, must attend to their reasons for

selecting the particular subject of their biographical inquiry. Researchers initially should spend some time examining motivations for their choices, including their degree of attachment or nonattachment to their intended subjects as well as the ways in which their own autobiographic positions and social, historical, or cultural contexts will influence their data interpretations and representations. Such self-reflexive work, further including attention to which details the researcher chooses to discuss or not discuss in the final account, is crucial in order that the contemporary biographer not appear either as omniscient or as absent in the portrayal of an individual's life and work.

Archival Materials

Qualitative researchers may well choose subjects whose work and personal lives are catalogued within special collection repositories or archives, most often housed in public as well as college and university libraries. These repositories or archives hold government, business, or organization materials and records deemed to have permanent historical value. Repositories, in particular, have collection goals that often include documentation of the lives of less well-known individuals as well as famous persons. In the United States, the National Archives and Records Service maintains the archives of the federal government. Other reference tools that will help researchers identify appropriate repositories include the National Union Catalog of Manuscripts Collections, produced by the Library of Congress and available online; the On Line Union Catalog, which is updated daily and chronicles records at member libraries around the world as well as the Library of Congress; and the Research Libraries Information Network, which contains descriptions of nonbook materials held in and outside the United States.

Researchers must familiarize themselves with various institutions' specific requirements for access to archival and repository materials and should establish primary contact with institutions' reference staffs. Qualitative researchers, most often concerned with in-depth examination of all materials and interactions associated with their subjects' lives over time, perhaps will need to make multiple visits to any one site and will want to write ahead to institutions to inform them of their visits, noting date of arrival, major research focus, and length of stay. The Archival Code of Ethics of the Society of American Archivists prevents archivists from describing to others, without permission, any details of a researcher's work.

Interviews

Another method utilized by most biographers is the in-depth interview, either of the living subject as well as associated individuals whose perspectives and interactions can inform the biographer's interpretations or of individuals who, in various ways, have insights about a subject of historical interest.

Again, issues of access are pertinent here. Biographers cast a wide net in terms of identifying appropriate individuals to interview and usually plan on a series of extended and multiple interviews, if possible. One of the primary tasks facing the biographer is contacting and making arrangements for face-to-face interviews; phone interviews are a secondary possibility, but should be avoided if at all possible because of the importance of nonverbal cues and interactions between researcher and participant.

Contemporary qualitative researchers are aware of the interview itself not only as a means of gathering data from another individual, but also as an active, participatory, and often unpredictable event in which both interviewer and participant are constructing versions of what can get told within the contexts of their interactions as well as representations of self and other. Thus, even within the framing provided by structured or semi-structured interviews, in which the researcher constructs a list or series of questions, with appropriate probes, or follow-up questions, qualitative researchers must attend to ways in which their own perspectives, assumptions, expectations, and biases are influencing both the direction and tenor of the interview, *per se*. Researchers also need to attend to ways in which participants are simultaneously guiding and setting the tone of the interview in interaction with the researcher, especially in terms of how much participants may choose to withhold or reveal, how they position themselves in relation to questions posed, and how meanings may shift over time and within various historical and social contexts for both participant and researcher.

Recreating a Life

Data analysis typically is the second stage of the interview process, as in any ethnographically oriented qualitative research method. However, to a biographer, the materials gathered are considered less as data and more as substances that may contribute to the recreation of a life. Although an ethnographer engages in coding data, biographers listen to interview tapes and

focus on overall content, for example, as one means of developing or enlarging their interpretive lenses. Although the mechanics of coding data receive major attention from many qualitative research methods texts, and biographers may want to familiarize themselves with various coding techniques prescribed initially to construct major themes from data, biographers tend to focus on relating those particular themes to larger interpretations about the subject's life and times.

Thus, biographers must attend to questions raised by current debates across the disciplines most closely associated with biographical research to consider in what ways data gained not only from interviews, but also from a variety of ethnographically as well as historically oriented research methods may contain not only facts about the subject at hand, but also evidence of the complexities, uniqueness, ambiguity, and indeterminateness of any lived life.

Biography as Personal Inquiry

Biographers need to decide, in both their interpretive and writing processes, what emphases they will place on their own interpretive influences, which may include but are not limited to their disciplinary preparation, theoretical and epistemological orientations, and social, historical, cultural, and autobiographical positions and situations. Such decisions are imperative within the processes of data gathering from interviews, participant or nonparticipant observations, and document, archival, and repository research as well as within the processes of the writing of the biography, *per se*. One of the most current challenges and simultaneous paradoxes of doing biographical research involves the necessary self-reflexive work of biographers in relation to their constructions of themselves as well as of their biographical subjects. Given the continuing grappling with the crisis of representation in qualitative research, writ large, this challenge and accompanying paradox promise much in terms of researchers working to create new and fresh biographical methods and forms of inquiry.

BRACKETING

Bracketing is a beguilingly simple term grounded in a profoundly complex concept. At its core, bracketing is a scientific process where a researcher suspends or holds in abeyance his or her presuppositions, biases, assumptions, theories, or previous experiences to see and describe the essence of a specific phenomenon. This process allows a focused researcher to observe the unfiltered phenomenon as it is at its essence, without the influence of our natural attitude—individual and societal constructions, presumptions, and assumptions.

Bracketing is conceptually located within the science and philosophy of phenomenology, developed by Edmund Husserl, the founder of the phenomenological movement, at the turn of the 20th century. Initially a mathematician, Husserl set out to develop a scientific theory of philosophy where logical and reasoned inquiry could reveal the inherent essence of things. Similar to a mathematical equation, bracketing suspends specific elements by placing them outside the brackets, thus allowing focus on the phenomenon within the parentheses. For Husserl, bracketing or *epoche* was a process of phenomenological reduction that could philosophically lead to the ideal description and understanding of the universal essences of the investigated phenomenon. Over the years, Husserl continued to develop the concept of bracketing from a purely philosophical ideal to a more descriptive practical conceptualization, where researchers may not discover universal truths of a phenomenon, but could gain local truths or understandings. Although bracketing remained fundamental to Husserl's phenomenology writing, he never provided a clear, concise definition or standard application of the concept.

Over the proceeding century, as bracketing continued to grow within the various schools of phenomenological movement (descriptive, Heideggarian, Utrecht, and existential), each reconceptualized the nature and/or elements of phenomenological reduction. As the various movements within phenomenology emerged, vied with each other, and developed their own theoretical tenets, the concept of bracketing became increasingly disconnected from its traditionally philosophical roots. Although the qualitative application of bracketing in research expanded, the concept behind the term eroded and its meanings and applications fractured, with the result that bracketing became multifaceted. Unfortunately, bracketing can also be seen as a formless technique or black-box term in studies, with a general unspoken assumption that there exists a shared understanding to the term. Despite lack of uniformity and often varied application, bracketing is composed of specific standard elements. Whereas researchers from different philosophical, epistemological, or theoretical traditions may employ bracketing based on their own standpoint and divergent meanings, the elemental components of bracketing are consistent. Bracketing remains an efficacious scientific process across various qualitative approaches based on a researcher's ability to effectively define and apply its elements.

Returning to the core definition, bracketing is a rigorous process that suspends internal and external suppositions, thereby allowing the focusing in on a specific phenomenon to understand or see it as it is. The four core elements of the process are as follows:

1. the actual brackets that the researcher places around the phenomenon;
2. the nature of the internal and external suppositions, experiences, theories, or assumptions being held in abeyance or suspended by the researcher;
3. the temporal structure in which the bracketing is applied; and
4. the reintegration of data generated from the bracketing process.

The methodological concept of bracketing requires researchers to explicitly operationalize and define these four elements. The first element centers on the construction of the actual parenthesis, specifically, on how solid or porous the actual brackets are. For example, does the researcher conceptualize the brackets as

able to hold or suspend all or part of internal (e.g., assumptions, beliefs, theories) and external (e.g., context, culture, time) suppositions that may impact, affect, or distort the phenomenon in its natural state? Some researchers may define these brackets as holding most internal and external elements, whereas others may simply want the brackets to hold only their own experiences and opinions.

The second core component of bracketing is the suppositions, assumptions, hypothesis, and/or experiences that are held aside by the brackets. This element consists of two parts, internal suppositions of the researcher (e.g., personal knowledge, history, culture, values, theories, orientations, etc.) and external suppositions that are centered on the phenomenon (e.g., its history, definition, and larger environmental factors). Researchers need to clearly articulate any internal and/or external suppositions they are bracketing out.

The third central element is the researcher's application of the bracketing process in the temporal structure, that is, the start, duration, and end of bracketing. Although for some researchers, bracketing may begin at conceptualization of the research prior to the literature search, others apply bracketing to data collection (e.g., the interview process). Similarly, the duration and end point of the process may vary. Some researchers close bracketing at the end of data collection. Others open and close bracketing throughout the research process, and some extend bracketing into the early phases of the data analysis.

The fourth element is the unbracketing and reintegration of the data derived from the bracketing process into the larger research. As in mathematical equations, once the data within the brackets have been determined, they are incorporated into the larger equation. This reintegration typically occurs in the analysis section of the research, but it may be incorporated throughout the research process.

Bracketing may not have one universal form, but it retains a core definition that is composed of specific elements. Researchers from diverse qualitative traditions and perspectives recognize and value bracketing as a fundamental methodological concept; however, the rigor of bracketing is determined by researchers' operationalization of the central elements that comprise this scientific concept.

BRICOLAGE AND BRICOLEUR

The French terms *bricolage* and *bricoleur* were given their key academic sense by the anthropologist Claude Lévi-Strauss and were subsequently taken up by others, including some recent writers on qualitative research in the United States.

In contemporary French usage, *bricolage* means, broadly speaking, do it yourself, and a *bricoleur* is an amateur who can turn her or his hand to practical repairs of various kinds. Lévi-Strauss (1962/1966) used these concepts in his structuralist analysis of myths, portraying the production of myths as a form of bricolage. His usage was subsequently applied to new fields and elaborated on by others, including Gérard Genette (1966, p. 145); Jacques Derrida (1970/2007); Gilles Deleuze and Felix Guattari (1972/2004, pp. 7–8); Deena Weinstein and Michael Weinstein (1991); and Cary Nelson, Paula Treichler, and Lawrence Grossberg (1992).

Lévi-Strauss was concerned with the contrast that is often drawn between “primitive” and “civilized” thought, but unlike some earlier views, he did not regard these as inferior and superior ways of thinking, respectively. Rather, he treated them as different modes of orientation toward the world, and he had a distinctive understanding of the value of primitive cultures (see Merquior, 1986, chap. 3).

For him, the character of the bricolage that produces myths is somewhere between that of science and that of modern art. The central feature of myth as

bricolage is that there is a drive to produce a complete picture from whatever intellectual resources are currently available. This drive contrasts with the orientation of the scientist or engineer, who must accept that some things are not currently knowable or doable and who should insist on using only what are judged to be adequate intellectual resources. Furthermore, whereas bricolage focuses on surface features, on things as they appear, and seeks similarities and other relationships among these, science goes beyond surface appearances to find underlying generative structures.

Officially, at least, Lévi-Strauss did not see social science as a form of bricolage; he was explicitly wedded to a scientific version of research modeled on structural linguistics. However, a number of commentators have argued that qualitative research does, or should, follow this model (see Kincheloe, 2001; Kincheloe & Berry, 2004; Lincoln, 2001). In these terms, Norman Denzin and Yvonna Lincoln (2005) portray qualitative research as involving the piecing together of diverse materials so as to produce an emergent construction that they describe as, “A complex, dense, reflexive collage-like creation that represents the researcher’s images, understandings and interpretations of the world or phenomenon under analysis” (p. 6). In qualitative-inquiry-as-bricolage, materials are juxtaposed in open-ended ways designed to provoke readers rather than to convey some closed message. More generally, what is involved is a form of inquiry involving the flexible use of diverse theoretical and methodological resources in a manner that has more in common with art and literature than with natural science, but which claims its own form of rigor. Although the argument that qualitative researchers should become bricoleurs has been influential, it is not without its critics (see Hammersley, 1999).

CAPTIVE POPULATION

In some instances, qualitative research is conducted among a captive population. This term refers to the use of participants who find themselves in a context (often an institution, e.g., a school, a prison, a hospital) where they are constrained and dependent on others for their care and for access to them as research participants.

Researchers may choose to work with these persons because of their physical and organizational proximity. In this case, the respondents form a convenience sample. The best-known example of a captive population may be university students who are asked to participate in a research project of their faculty that aims at providing information about phenomena that are also present among other populations.

In other instances, researchers study captive populations because they are the only ones who can provide relevant in-depth information about (living in) the constraining context itself. Conducting in-depth interviews among prisoners to gain insight into the incarceration experience is an example of this second approach. Compared with quantitative methods (e.g., questionnaires, analyses of official criminal data), this qualitative method has the advantage of producing more detailed information about the perspectives, experiences, and slang of the actors. It also allows researchers to discover illegal or deviant activities and to reach illiterate prisoners who are not able to participate in a written questionnaire.

Working with individuals who are in dependent or restricted relationships with the researcher and/or with the institutional personnel often gives rise to ethical

questions and methodological problems. The most obvious ethical issue is that of voluntary consent because members of captive populations might not dare to refuse participation. When they do participate in a study, these respondents often feel prohibited from talking freely about their experiences. It is the researcher's role to emphasize the confidentiality of research data and to ensure the privacy of the respondents. Methodological issues associated with working with captive populations as a convenience sample and as a purposive sample are nonrepresentativeness and difficulties of gaining access to the research setting (e.g., the institution) and the actors of interest, respectively. The first problem refers to the fact that findings that are based on a study among a specific captive population (e.g., students) cannot be extrapolated to other kinds of audiences in the general population. The second problem refers to the existence of institutional gatekeepers (e.g., prison governors) whose permission is needed to get in touch with the captive population.

It is clear that working with captive populations is sometimes preferable or even inevitable for qualitative researchers, but this also requires special considerations.

CASE STUDY

A case study is a research approach in which one or a few instances of a phenomenon are studied in depth. Case studies were the predominant research approach at the beginning of modern social science. This is reflected, for example, in the work of the Austrian-born anthropologist Bronislaw Malinowski and the Chicago School of sociology, both of which embraced case study research. Nevertheless, after World War II, quantitative methods gained a hegemonic position, at least among methodologists. It is noteworthy that even during this heyday of quantitative research many important studies that provided theoretical breakthroughs and have entered the pantheon of classic works, such as Graham Allison's study on the Cuban missile crisis in 1971, were based on the case study approach. During recent years, we have seen not only a resurgence of case studies in most disciplines but also unprecedented methodological reflection on this approach. This can be seen as an alignment of epistemology/methodology to ontology/theory. The strong emphasis in recent theoretical approaches of aspects such as "ideas" and "timing" is favorable for case study approaches. Social constructivist theories stress the importance of individual perceptions or hegemonic discourses in social processes. Case studies are much better suited than large-*N* studies for tracing these ideas because they can invest heavily in in-depth interviews or discourse analysis. Game theory and theoretical notions such as "path dependency" stress the importance of timing for explaining specific outcomes. Again, producing a detailed historical account is certainly one of the major strengths of case studies.

This entry first discusses the nature of case studies, their advantages and disadvantages, and three perspectives on their use. The final sections of the entry are devoted to the very important steps in doing case study research: case selection and data analysis. Although the praxis of doing case study research is dominated by the challenges of collecting empirical evidence, this stage is not discussed here because useful information for dealing with these challenges can be found in other entries.

What Is a Case Study?

There is no consensus on the basic characteristics of case studies. One reason for this is the fact that the

term is not restricted to social science research but rather is used in many practical contexts. Therefore, the understanding of case studies extends from being a specified tool in a purely positivist scientific research endeavor to being a pedagogical strategy in education and social learning processes. Qualitative case study researchers argue that cases must be seen as configurational context- and/or path-dependent entities. They advocate in-depth strategies such as "thick description" and "process tracing," and they opt for a "case-centered" approach rather than the "variable-centered" one that dominates in quantitative/positivist research.

Case studies focus on one or a few instances, phenomena, or units of analysis, but they are not restricted to one observation. Nevertheless, the boundaries are not fully clear. On the one hand, John Gerring would exclude case studies that lack any spatial or temporal variation. On the other hand, Charles Ragin's qualitative comparative analysis (QCA) methods try to expand the reach of case-centered research approaches beyond the usual limits toward the range of 10 to 60 cases. However, the particular strength of qualitative case study research—the ability to study the case in depth, which is the best-known aspect of research on a captive population—may be lost in this endeavor to bridge the quantitative–qualitative gulf.

Advantages and Disadvantages of Case Studies

To understand the specificities of case study research, it is useful to compare it with the two other main research approaches: experiments and large-*N* surveys. Such comparisons reveal that the main difference between case studies and experiments is that in experiments cases are created by the researcher and factors of influence can be controlled.

The relationship between case studies and large-*N* studies lies in the specific affinities and comparative advantages of these two approaches with respect to specific goals and contexts. First, it is broadly accepted that case studies have been the major source of theoretical innovation, whereas large-*N* studies have their strength in controlling the empirical scope of new theoretical concepts. Second, whereas large-*N* studies tend to focus on causal research goals, case study research has an affinity toward descriptive goals. This does not mean that case study research is not concerned with causal questions, but it usually takes the

descriptive–interpretive elements more seriously. In addition, case studies are often concerned with pinning down the specific mechanisms and pathways between causes and effects rather than revealing the average strength of a factor that causes an effect. Third, even positivist methodologists accept that case studies have a strong comparative advantage with respect to the “depth” of the analysis, where depth can be understood as empirical completeness and natural wholeness or as conceptual richness and theoretical consistency. In contrast, large-*N* studies have advantages in terms of the “breadth” of the propositions, an important argument in contexts where there are many similar cases or where a homogeneous population of cases is assumed. Fourth, large-*N* studies are better equipped for securing external validity by using statistical means of control. In contrast, case studies have advantages with respect to construct and internal validity. The argument for better construct validity is based on the fact that case studies can use more and more diverse indicators for representing a theoretical concept and for securing the internal validity of causal inferences and/or theoretical interpretations for these cases.

Three Different Views on Case Studies

As the methodological reflection on case studies unfolds, it is increasingly obvious that there are quite different understandings of case study research. We can distinguish among three ideal types: naturalism, positivism, and constructivism.

With respect to main goals, naturalists want to generate practical and detailed knowledge, positivists aim at the establishment of conceptually rather narrow but law-like propositions and models that allow predictions, and constructivists see the empirical endeavor of doing case studies as a contribution and check to a theoretical discourse.

Naturalists advocate “natural generalization” through social diffusion and learning processes. Researchers themselves do not try to generalize beyond the case under investigation, but the findings can be taken up by others if they perceive a “fit” to their cases. The generalizations made by positivists can be labeled “statistic generalizations” based on drawing logical inferences from a sample of cases to a specified population. The third approach to generalization was called “analytic generalization” by Robert Yin, but a more distinctive label is “theoretical generalization” because it is characterized by drawing interpretive

inferences from a variety of observable objects to meaningful abstract concepts. For example, Graham Allison and Philip Zelikow used the case study on the Cuban missile crisis to show how an “organizational behavior” model and a “governmental politics” model shed additional light on foreign policy decision making, in contrast to a unified/rational actor model.

Both naturalists and positivists make the ontological assumption that there exists a single objective reality that is independent of human observation. Naturalists try to reveal the authentic nature of a social phenomenon or the detailed elements of a causal process by getting as close as possible. Therefore, strategies such as participatory observation and the use of empathy are fully accepted. The positivists opt for “control” instead of “closeness” to reveal an objective reality. The methodological emphasis is not on bridging the gulf between reality and researcher but rather on revealing the relationship between the particular (the individual case) and the universal (the population). Constructivists, in contrast, do not assume any single reality and believe that empirical reality and theoretical concepts are mutually constitutive. For them, bridging is focused on narrowing the gap between concrete observations and abstract meanings using interpretive techniques. Because interpretation loses much of its associative quality if it is pressed into quantitative methods, constructivists adopt another means of control. They use a plurality of theories to understand and analyze cases.

Choosing Cases

For naturalists, it is the intrinsic interest in a specific case that motivates case study researchers. A case may have an important real-life impact, and therefore it makes sense to concentrate their scholarly efforts on the internal complexity of the case, leaving aside any prior considerations about potential generalizations. Having access is another important criterion for selecting cases from this perspective.

Careful selection of cases is essential for positivists because it enables them to draw statistical generalizations and because they accept only covariation as a basis for causal inference. These two aspects are connected to corresponding selection criteria. First, a case can be selected because it has a specific position within the larger population. Prior quantitative studies are necessary to reveal typical/representative, diverse, extreme, deviant, and (statistically) influential cases. Selecting a

case in such embedded case studies can be used to test or differentiate the causal pathways for a statistically proven causal proposition. Second, a few cases can be selected on the basis of their similarity or difference, making it possible to draw causal inferences through cross-case comparisons. Such attempts to control variance and to select what Arend Lijphart called “comparable cases” either with reference to John Stuart Mill’s “method of agreement” and “method of difference” or with reference to Adam Przeworski and Henry Teune’s “most similar systems design” and “most different systems design” are quite common, although they do not hold up to rigorous logical standards.

Constructivists opt for selecting theoretically “crucial cases.” Harry Eckstein’s notions of “least likely” and “most likely” cases have been taken up as devices for theory-oriented selection of cases. Constructivists do not share the positivists’ covariational interpretation of crucial cases but do share their conviction that the selection of crucial cases makes (theoretical) generalizations possible. Most likely cases are cases where a plurality of diverse indicators of an internally coherent theory would make it very likely that another empirical aspect (e.g., an indicator of a dependent variable but also a causal process) also corresponds to the logic of that theory but does not. The famous studies of Malinowski (in 1926), William Foote Whyte (in 1943), and Lijphart (in 1975) followed this logic, and all of them seriously undermined the hegemony of theories that dominated their fields at the time. The selection of least likely cases is aiming at what has been labeled the “Sinatra inference”: If a theory can make it here, it can make it everywhere. A paradigmatic example is the study by Robert Michels (in 1962) on oligarchies in organizations.

Positivists and constructivists need to invest a lot before strategically selecting useful cases to reach their specific kinds of generalization. Nevertheless, if they have selected their cases on the basis of more practical reasons, they should still reflect on the position of their cases with respect to populations or theories if they wish to reach their goals.

Describing, Analyzing, Interpreting, and Documenting Empirical Evidence

For naturalists, it is especially important to provide a comprehensive and consistent picture of a case. Their inductive approach is associated with thick descriptions, narratives, and process tracing as adequate means to

analyze and document the evidence. Alexander George and Andrew Bennett defined process tracing as a method that attempts to identify the intervening causal processes—the causal chain and causal mechanism—between an independent variable (or variables) and the outcome of the dependent variable. Because they insisted that every element of the causal chain must be empirically documented and stated an affinity to a scientific realist understanding of causal mechanisms, the emphasis is on chronological narratives. In a second step, a detailed narrative might be combined with abstract concepts that provide general assumptions about the functioning of time (e.g., concept of path dependence) to make the conclusion more plausible. The best-known example for path dependency is the explanation of the widespread adoption of the QWERTY keyboard through positive feedback loops based on an initial large market share and on network effects (and not on intrinsic superiority). Nevertheless, the proof of a causal relationship at a specific sequence (e.g., at a “critical juncture”) relies heavily on finding and documenting a “smoking gun,” that is, evidence for a causal connection that common sense would not doubt.

Positivists instead employ quasi-experimental methods to draw conclusions from empirical data. The most important means are cross-case comparisons, splitting the case into multiple entities, temporal sequencing, and counterfactual thought experiments as a means to allow “controlled” spatial, longitudinal, and/or imaginary covariational comparisons and to draw logical conclusions.

The analytic approach that corresponds to a constructivist account is an extended and specified understanding of what George and Bennett called the congruence method. In contrast to naturalistic approaches, it has a strong deductive element because it begins with theories and assesses their comparative strength in understanding and explaining empirical cases. A constructivist would not limit this method to comparing the theoretical expectations with the empirical reality on a variety of indicators for the dependent and independent variables. Instead, searching for (non)congruence is extended to causal processes. In contrast to the naturalist’s inductive understanding of process tracing and the scientific realist’s account of causal mechanisms, the constructivist deduces empirical implications that correspond to a specific theory all along the way from the causal factors to the causal processes to the effects. Only quite general theories that embody a fundamental

causal mechanism, usually some kind of microfoundation, are capable of serving as a basis for this kind of deduction. This ensures that case studies become embedded in the fundamental theoretical debates within the social sciences. The quality of a case study, thus, does not depend on providing detailed evidence for every step of a causal chain; rather, it depends on a skillful use of empirical evidence for making a convincing argument within a scholarly discourse that consists of competing or complementary theories.

The adequate structure for documenting case study findings is chronological for naturalists, linear-analytic for positivists, and comparative for constructivists.

CATEGORIES

Categories are analytic units developed by qualitative researchers to conceptually organize findings related to a phenomenon or human experience that is under investigation. The novice researcher typically makes few distinctions among analyzing for themes, categories, and codes. If one were to think about a micro-, meso-, or macro-level analysis, coding starts at the micro level, the generation of categories moves the investigator to the meso level, and themes that bear out lessons learned or truths that reflect the findings are indicative of a macro-level analysis. Although themes, categories, and codes might build on each other, there are distinct differences.

The qualitative researcher almost always arrives at some point in the research process when developing categories is necessary. Category development can be done either inductively or deductively. To generate categories inductively, the researcher approaches data analysis without a preset list of categories and analyzes the data to identify analytic units that conceptually match the phenomenon portrayed in the data set. When categories are generated deductively, they emerge not from the data but rather from prior studies, relevant literature, research questions, and the researcher's own experience with and knowledge of the phenomenon. Under this approach, there is a chance that the categories generated from other sources will not be relevant or accurately reflect the qualitative data set at hand. Although inductive and deductive approaches work, both novice and senior researchers fluctuate back and forth between inductive and deductive analyses because blending the two methods helps the researcher to fully interrogate the data.

Recalling that both qualitative and quantitative researchers use categories when designing research studies, it is important to remember that there are various data sources that can be used to develop categories for a qualitative study or qualitative component of a mixed-methods study. Sources include formal and informal interview data, focus group interviews, observation notes, emails, journals, newspapers, primary documents (e.g., memos, internal organizational reports, diaries), and open-ended questionnaires. Potentially, a single study may have multiple data sources that must be analyzed before the researcher can reach any plausible conclusions.

Given the potential for diverse data sources that could be critical for a single study, constructing well-defined categories can be overwhelming for the researcher who must wade through what may appear to be mountains of data. The work is tedious and time-consuming but has the potential to yield great insights. Computer software is available to help keep qualitative categorical data analysis manageable. Qualitative software is helpful in managing and organizing categories. Although some programs tend to be more linear and less flexible in their capacity to reflect non-linear findings, overall they are very instrumental in managing large qualitative data sets.

One benefit of using qualitative software (e.g., ATLAS.ti, NVivo) to conduct categorical analysis is that doing so gives multiple research team members the ability to collaborate during this phase of the research

process. As more researchers gain a growing appreciation for qualitative methods, investigators from different institutions, disciplines, countries, and cultures will form more collaborative efforts that require multiple analyses examining concepts at the categorical level.

CATEGORIZATION

Categorization is a major component of qualitative data analysis by which investigators attempt to group patterns observed in the data into meaningful units or categories. Through this process, categories are often created by chunking together groups of previously coded data. This integration or aggregation is based on the similarities of meaning between the individually coded bits as observed by the researcher. Categories in turn may be abstracted or conceptualized further to discern semantic, logical, or theoretical links and connections between and across the categories. The results of this process may lead to the creation of themes, constructs, or domains from the categories.

Categories can also be seen as an intermediary step in an ongoing process of separating and connecting units of meaning based on the qualitative data being collected. Coding is often the first step in the analytic process as researchers attempt to make meaning of the various bits of information collected in the field or generated during interviews. As a second step in the ongoing process, researchers look for connections between or among these separate codes. This coding of the content can produce categories as researchers discern linking patterns between or among the individual codes. The analytic process continues as researchers next look for patterns that run through and across the system of categories. The results of this categorization of the categories can lead to the creation of themes, constructs, or domains.

The categorization process encourages researchers to describe overtly what they have observed and to segment the observed phenomena into units. The characteristics or internal properties of the categories are further developed or discovered as researchers continually and transparently note or memo how all coded units of meaning within a particular category are similar and how the coded units within the category contrast with other coded units perceived as being outside the category in question. Researchers can use a variety of techniques to accomplish this goal, including posing a priori questions from existing theoretical systems (i.e., a deductive approach) and testing the integrity of the categories by constantly judging the credibility of the categories with further observations based on the data (i.e., an inductive approach). Researchers can also use a combination of both inductive and deductive logic in creating and refining categories. The process of categorization continues in a research project until saturation (i.e., no further categories are discovered or constructed based on examination of new generated data) or exhaustion (i.e., the existing system of categories accounts for all meaningful or significant aspects of the phenomenon in question).

In constructing a system of categories, it is important for researchers to evaluate how each category has internal integrity (i.e., is there a high degree of homogeneity across the individual coded units within the category?) and external integrity (i.e., is there a high degree of heterogeneity or differentiation between or among the array of homogeneous categories?). Researchers not only must judge the internal and external coherence across the system of categories but also must be cognizant of the coherence between the categories and the phenomenon in question. Researchers should endeavor to create an exhaustive system of categories so that no meaningful feature of the phenomenon under study falls outside the array of categories. In such a fashion, the process of categorization operates along dual planes of focus: horizontality (i.e., category-to-category relationships) and verticality (i.e., category-to-phenomenon relationships).

Establishing Categorization Integrity

Judging the credibility of the categorization involves posing a number of critical questions. First, how well do the categories capture the richness of data? Second, how

coherent is the internal constitution of the categories? Third, how distinct is each category from the other categories? Fourth, how were the categories created and tested? To address these questions of integrity, researchers have developed a number of strategies to help themselves and external reviewers to render their assessments more readily and effectively.

Researchers should carefully document all analytic decisions that lead to the creation of categories. These documents or memos help to form what is commonly called an audit or a decision trail that provides evidence to support the integrity of the coding, categorization, and interpretive choices made throughout the qualitative data analysis process. Researchers can further improve the content and credibility of their studies by opening up their categorization records for verification from external or third parties in the form of peer review (i.e., to independent referees) or member checking (i.e., to participants who provided the material on which the analysis is being conducted).

Marc Constat developed a comprehensive system for helping researchers to document the category creation process for internal and external review. His system consists of three components: origination (i.e., where does the responsibility reside for the creation of the categories?), verification (i.e., how are the categories justified?), and nomination (i.e., what are the sources of categories' names?). He also asked that researchers share when these decisions were made (i.e., before the data collection began, after the data were collected, or throughout the data collection process).

Another important process in the construction of categories and the establishment of their credibility is to systematically maintain the connections between the codes and categories and the empirical evidence found in the data themselves. Exemplary quotations and excerpts should always remain in contact with their respective codings and categorizations. This contact should also be extended to the publication of the findings so that editors, reviewers, and readers can judge the merits of any categorization based on artifacts from the phenomenon in question (e.g., direct quotations). If done well, the juxtaposition of well-articulated descriptions of categories with rich and vivid exemplary quotations or observations can create a credible account of the findings of a study and a meaningful contextualization of both the categories and the data they are offered to represent.

CENTER FOR INTERPRETIVE AND QUALITATIVE RESEARCH

The Center for Interpretive and Qualitative Research (CIQR, pronounced “seeker”) at Duquesne University is special both for how it began and for what it does. A number of faculty members were aware that a large percentage of the scholars in the liberal arts, health sciences, education, and other schools at Duquesne used interpretive and qualitative methods in their research. Moreover, the university’s psychology department already had an international reputation for its PhD program in phenomenological psychology. Faculty at Duquesne decided that a center devoted to interpretive and qualitative methods would facilitate communication between these faculty members and their students and, in turn, would fulfill a need for intellectual community as well as present information on a variety of interpretive and qualitative research methods. During the summer of 1999, a group of Duquesne scholars wrote a proposal for such a center, including the term *interpretive* in the title to emphasize that qualitative methods used in literature, philosophy, and other humanities departments would be of an importance equal to those undertaken in the social and behavioral sciences. This grassroots effort was aided by the dean of the College and Graduate School of Liberal Arts at the time. After winning approval from the relevant graduate and dean committees, the group was granted “center” status.

The work of the center revolves around several structures. The first of these is a monthly meeting in which faculty and graduate students from Duquesne

and other universities in the area present their work, focusing on their methods as well as the phenomena they are investigating. Typically, a half-hour presentation is followed by an hour of lively discussion in these well-attended meetings. The second structure is an invitation to an internationally known scholar each semester. The scholar gives a public talk and then a smaller symposium that concentrates on methodology. The third structure is a CIQR certificate program, where a certificate is offered to those graduate students who take specified method-oriented courses from the general curriculum at the university and then a special proseminar. The proseminar requires that the students engage in and jointly discuss research projects that they are undertaking. They then present their work to CIQR members at a meeting for that purpose. After only a year, this program had already granted certificates to 10 graduate students and 1 faculty member. The center also plans to engage in community action research.

The CIQR website includes a description of the center, the original proposals for the center and its certificate program, a list of all the CIQR external speakers and their topics, a description of all the monthly presentations, announcements of coming events, a newsletter, and a list of the subcommittees along with their members and functions, and a sign-up procedure for those wishing to become CIQR members.

CHAOS AND COMPLEXITY THEORIES

Chaos and complexity theories, along with fractal geometry, form what came to be called the “new sciences” during the latter part of the 20th century. These sciences, developed in recognition of relativity, quantum theory, and evolution, are based on a general acceptance that “nature”—our environment, planet, universe, and cosmos—is fractaled and turbulent. Here life and death, creativity and stagnation, imbalance and balance dance together in what one observer called an “orderly disorder.” This entry describes the origins of the concepts of chaos and complexity and their application in qualitative research methods

today. Furthermore, the entry encourages readers to look at new possibilities in qualitative research, possibilities inherent in the procedure of layering that bring forth the depth and creation of new meaning.

Traditional research methods, quantitative or qualitative, assume a stable and steady universe, as Isaac Newton and others posited. To use Newton’s own phrasing, “Nature is pleased with simplicity” and “is conformable to Herself.” Adopting this meta-physical assumption, quantitative researchers developed the concepts of norming and the bell curve. Norming, however, assumes a stable and steady population; it does not work on a population undergoing transformative change. To hearken back to Francis Bacon and his (then) new science, a “new method must be found.” Qualitative research, when it has an emphasis on triangulation, also assumes a steadiness for its tripartite viewing. In fact, the notion of research itself focuses on searching for that which is believed (indeed assumed) to be true, good, useful, and valid. There is a sense of definitiveness to (traditional) research, often stated in an authoritative way as in the phrase “research says.”

Complexity theorists proceed from recognition and acceptance of the indefinite and probabilistic; they realize that nature is complex, not simple (albeit encompassing and using simples). Whatever conformity nature displays is dynamic; that is, our planet, universe, cosmos, and selves all maintain an order even as they undergo constant change. Emergence, self-organization, self-similarity, patterns, and relationships all become important concepts in this new orderly disorder. Observing the universe, we now realize that the night skies are filled not only with twinkling stars but also with “dark energy,” pulsars, exploding galaxies, and “black holes” that devour all they ensnare. Amid all of this disorder, creativity abounds; order still exists, but now our concept is not of a simple stable order but rather is one of a complex order—complex enough to merit the term *disorder*.

The mathematics used to show patterns of bringing forth the order in this disorder is that of nonlinear equations. Known but neglected during much of the 20th century, these equations gained significance during the latter part of that century with the advent of powerful supercomputers, able to iterate first hundreds and then thousands of times per minute. These equations are nonlinear in that they do not develop straight lines on a graph or even smoothly curved ones. Rather, how they proceed is unpredictable, known only after the fact (i.e., a posteriori). In a nonlinear x/y functional

relationship, the x s are not prechosen (except for the beginning or “seed” x) but rather evolve from the y (as a function of x) being inserted back into the equation as a new x . Such recursive development can be deterministic as one looks back interpretively, but to predict with any accuracy from Situation 1 to Situation 4 is at best probabilistic—due to intervening Situations 2 and 3—with the attempt of probabilistic predictions for Situation 8 or 9 being near to impossible. This recursive patterning, often labeled “deterministic but not predictable,” accounts for weather predictions being given only in short-term probabilistic frames. In a metaphoric sense, to see Situation 2 emerging from Situation 1 and leading on, and indeed influencing (but not determining) Situation 3, brings forth the need for inquiry-oriented research to be interpretive, open-ended, probabilistic, historically situated, and culturally contextual.

At the turn of the 20th century, Henri Poincaré, mapping the results of measuring the gravitational effects of three moving bodies interacting with one another, saw a “monster” (the nonlinear) appearing and cried out “*prédiction devient impossible.*” Only with supercomputers are humans able to tame and train this monster. Now there are strong advocates for high school classes to teach courses in nonlinear mathematics using the power of computers and graphing the results.

Research methodologies in the human and social sciences informed by chaos and complexity theories are not yet framed. It seems, however, that this type of inquiry, oriented to understanding change over time and involving complex situations, might use a combination of (nonlinear mathematical) pattern analysis and anthropological inquiry (a layering of interpretations). These procedures foreground relationships, with reality being nothing set “out there” for discovery but rather emerging from dynamic relationships viewed over time.

Research of all sorts has always required interpretation—the questioning of the procedures used and the conclusions drawn by the researcher—but such interpretation has been against a (presumed) stable background. When interpretation is understood as a dynamic process, both reiterative and reflexive, influencing the process and direction of inquiry, it still has a historical background of past experiences and patterns to play against, but it also has the possibility of bringing forth the not-yet-seen or yet-to-be imagined. Here in the realms of the not-yet-explored, human intention and creativity come into play as inquiry becomes richer and thicker through the layering of interpretations.

Chaos Theory

Those who study chaos theory accept that the world and universe in which we live are filled with turbulence, fractalness, and difference. Such dynamism is the very nature of our world/universe. Equilibrium, balance, simple harmony and conformity, norming, classification, and even equality and justice are human constructs, abstractions placed by us for what William James called “the blooming, buzzing confusion” in which we find ourselves. Such “conceptual maps” are too often taken as physical realities that make prediction and control overly simple and overly orderly. A dominant assumption in this rationalist way of thinking—patriarchal, modernist, analytic-referential—is that, when all or enough facts are collected, accurate predictions can be made. In his 1812 treatise *Analytic Theory of Probability*, Pierre-Simon, marquis de Laplace posited a superior intelligence—often called Laplace’s “demon”—that, through its enormous intellectual powers, would “embrace in the same formula the movements of the greatest bodies and those of the lightest atoms; for it, nothing would be uncertain and the future, as the past, would be present before its eyes.”

A century later, Poincaré became aware that Laplace’s vision was impossible. As Poincaré said in 1952, even if nature’s laws held no secret for us, we would still not be able to predict perfectly or even well, for in the interactions of phenomena (be they atoms or events), “small differences in the initial conditions produce very great ones in the final phenomena”; hence, Poincaré was aware that Newton’s calculus works on only two interacting phenomena, with the intrusion of a third yielding the mathematical monstrosity of nonlinearity. This monster (nonlinear equations) lay dormant for most of the next 75 years. As is famously known by now, Edward Lorenz, working on weather predictions during the 1960s, substituted data carried to three decimal places for data he already had carried to six decimal places. His assumption, still current at that time, was that small differences would have only small effects; cause and effect would be orderly and proportionate, not disorderly. To his surprise, over time the new prediction data on his printout began to deviate more and more from his past prediction data until the relation between the three-figure and six-figure sets of data—different initially by .001—were eventually incompatible. During the 1970s, with the advent of supercomputers and their tremendous powers of iteration (which pattern analysis of nonlinear equations requires), chaos theory was

born along with its famous metaphor, “A butterfly flapping its wings in Rio can cause a typhoon in Tokyo.” The point here is that accumulated development need not be linear; thus, it is difficult, indeed often impossible, to predict effects from causes. Weather predictions today are given in short-term probabilities. Stock market moves appear to be random. Human development takes many pathways, with too many factors interacting to make developmental predictions (e.g., IQ) useful. Tsunamis, rogue waves, typhoons, tornados, earthquakes, and avalanches appear suddenly and with little (if any) warning. Researchers in these areas, and in human development and actions, need to be aware not only that the map is not the territory but also that the territory is continually shifting, as are the researchers. Future researchers may well need to operate from a nonlinear mathematical frame, including the study of logistic frames.

Logistic frames deal with systems that are inversely interactive such as those of predator/prey, birth/death, and message/noise. For example, as predators increase, prey decrease, but at a certain point—with surviving prey becoming more skillful and faster than predators—an inverse relationship occurs; prey increase because they are caught less, and predators decrease because they are unable to catch the prey due to the development of lazy habits. Equations to describe this relationship are usually written in the form $F(x) = rx(1-x)$, where r is a constant (e.g., food, space, information) and $1-x$ is an inversion of the original x , limiting (but by no means centering) the interactive relationship. The notion of a system being bounded but not centered—one that is dynamically changing—offers challenges and opportunities to any researcher.

An interesting aspect of the logistic equation (above) is that as r increases from 1 to 2, doubling occurs (the output in the equation vacillates between two numbers—a boom/bust, 7 good years/7 bad years bifurcation). Another doubling occurs as r moves to 3, whereas at 3.57 (where doublings are fast and furious) chaos sets in. From this third doubling arises the word *chaos* in a mathematical sense: Period 3 implies chaos. What is even more intriguing here is that in this chaotic realm (≥ 3.57 for r), spaces of regular simple order appear. In a complexivist frame, then, order and chaos are not dichotomous (as modernist and Newton frames posit) but rather entwined. A good/bad, black/white, either/or, right/wrong frame gives way—not to a compromise frame between two

dichotomous poles but rather to a “third space” frame where entirely new possibilities can emerge. The challenge for researchers, then, is to let go of an orientation that looks for and finds cause/effect, either/or simple relationships and to develop research designs that explore the depth, richness, and thickness of the complex relationships that exist in any given situation.

Complexity Theory

It is possible to say that chaoticists study the turbulent aspects of nature with an emphasis on both accelerated development—the dramatic effects of small differences over time—and the intertwining of order/disorder in this development. Regarding complexity theory, it is possible to say that complexivists study nature’s ability to remain “stable” by accommodating and using small differences. Such dynamic stability requires the system to use just the right amount of perturbation for its continued functioning. All living systems are dynamically stable. The human brain is one example; it functions as it is perturbed in “just the right amount.” It is impossible to predict the right amount of perturbation, somewhere between too much and too little disequilibrium. The human body is not so much a smoothly running machine as it is a complex adaptive system.

In complex adaptive systems, concepts such as networks, self-organization (or self-regulation), feedback loops, self-similarity (or nestings), and disequilibrium all are important and have implications for human learning. Learning is a natural activity of the human species, and attention to the concepts inherent in chaos and complexity theories produce an epistemology quite different from the current one based on a Newtonian sense of stability and conformity. An idea from these theories, important to social science researchers, is that of dynamic networks and their feedback loops.

A dynamic network, “alive” due to its constantly adapting to change and new input, may or may not have major nodes. There is not, however, a central dominating node. Rather, there are interconnected pathways, as in a power or communications grid and in the human nervous or immune systems. In such systems, multiple pathways exist. Information flows in, around, and through these pathways. As information flows from one local node or situation to another local node or situation, it is changed as it intersects with other pathways (or experiences). The concept of

there being one and only one major pathway, or royal road, to interpretation, learning, and teaching is quite nonsensical to a complexity theorist. Each local situation has its own uniqueness, and as one local situation connects to another local situation—as happens in a network, even one dominated by major arteries—interpretation/understanding becomes contextualized. Metaphorically, if one wishes to say the phrase “research says,” it is necessary to realize that research speaks with a dual emphasis; each situation is unique, not generalizable, but each situation also is connected to and interacts with other situations. A collection (or nexus) of situations can form a pattern or system made up of interconnected locals. Although each local requires its own contextualized interpretation, relationships among situations, in forming patterns or systems, can show enough similarity to produce a meta-pattern. It is this issue of connecting local situation to local situation, in a meta-pattern frame, that so bothered and consumed anthropological researcher Gregory Bateson. During his 20th-century lifetime, his search was for “the pattern that connects.”

The novel idea of feedback, introduced to systems thinking at the Macy Conferences during the 1950s, provided Bateson not only with insight into the pattern that connects but also with a new way of thinking about research. Drawing a network (visually), with its set of interconnected nodes, one quickly sees that it is nonlinear, with connections going in all sorts of directions. Because of this nonlinearity, information (or a message) flows around various pathways, often cycling back to its origin. Such returning, recursing, and feeding back bring new information gathered along the way, and thus the original is “seen yet again for the first time.” Thus, interpretation of a situation is enriched by being layered with more interpretations.

Interpretive Inquiry

Chaos and complexity theories, the new sciences, are still in their early stages of development and, hence, do not yet have a well-formed research methodology. Being framed by the concept of orderly disorder, however, they potentially offer to researchers a different method of doing research—interpretive inquiry. Inquiry, in its act, requires dialogue (or conversation), and dialogue requires interpretation. Interpretation is a reciprocal act, between text and reader, between situation and researcher. Each influences/directs the other. In this mutually interactive relationship, new

ideas, understandings, and insights emerge. Feedback (or recursive loops) becomes a powerful vehicle. Using such a vehicle, it is possible to conceive of a researcher exploring a situation and then asking others to explore not only the same situation but also the researcher’s own explorations. Recursively, the researcher can then explore the interpretations of those critiquing her or his interpretations. As such a recursive method goes on, spaces open between the interpretations. These spaces, in between boundaries, are often called liminal spaces or third spaces. It is in these spaces that depth of meaning and the creation of new meaning reside. Such a (layering) method, yet to be fully developed, may well be what chaos and complexity theories have to offer researchers.

Research Implications

Research of the 20th century was heavily influenced by analytic quantitative methods. These methods assume a stable base, work from closed system assumptions, and are reductionist and linear in nature. Over a number of recent decades, qualitative methods have come to the fore in a number of disciplines or professions. To the degree that qualitative methods favor triangulation, they mimic quantitative methods and their closed systems frame. To the degree that qualitative methods are narrative, personal, and cultural, they work from an open systems frame and yield the possibility of the newness emerging. The key distinction here is the difference between proving (the essential nature of research) and probing (the essential nature of inquiry). The former is closed in the sense that it is designed to come to a definite conclusion. The latter is open in the sense that it is designed to explore possibilities inherent in a situation. Each has its own methodologies or sets of operation. Research with a quantitative bent follows definite, preset, clearly stated procedures. The frame is one of either/or, as in one procedure/pill being better (more effective) than another, or the frame is one of finding a definite statement or fact, as in historical or legal research. In either case, there is a sense of certainty—of proving—hence the anthropomorphic phrase “research says.” In a proving, certainty-desired model, the logic used is that of domination.

Research with a qualitative—nontriangulated—bent, often labeled as subjective for its emphasis on the personal and narrative, is more open-ended. Here experience, not validity, dominates. Human experience brings in intentionality, conscious reflection, hope, and

angst—all of which one would label under the term *human condition*. It is narrative that highlights this condition, it is narrative that probes this condition, and it is narrative with its interpretive methodology that brings to a situation its “truth.” Such truth is not provable but is felt. The situation is not objectified but is what Jerome Bruner called “subjunctified”—“trafficking in human possibilities.” Research in this mode is far more akin to interpretive inquiry than to usual (and traditional) concepts of research.

CHECKLISTS

Checklists are used to encourage or verify that a number of specific lines of inquiry, steps, or actions are being taken, or have been taken, by a researcher. These surface in a variety of forms throughout data collection and analysis and thereafter as part of either writing or review. For example, checklists might be used by researchers during data collection as a precautionary backup so that they consistently and purposefully take note of a particular phenomenon. These types of checklists might be open-ended (e.g., reminders to take general note of a specific type of behavior) or exhaustive and more structured (e.g., indicating whether a behavior falls into one or more predetermined categories). In the former case, they can make data collection more time-consuming because any number of scenarios might occur and require recording. In the latter case, they can be less demanding on the researcher, either because nothing that falls into the predetermined categories is observed or because only the most basic of note needs to be taken for each (e.g., indicating frequencies or the occurrence). These types of reminder checklists imply specific types of observations that will ultimately affect a study's directions, findings, and conclusions; therefore, if they are used during data collection, it is helpful when researchers articulate why and how and include the details of any categorization system used.

At another level, checklists can be used to either articulate or assess methodological and analytic steps and, hence, indicate the rigor and credibility of a published study. In this sense, they might be developed by researchers and included in their publications or developed by readers/reviewers and applied in their judgment of multiple research reports and articles. Used in both of these ways, checklists have helped those

unfamiliar with qualitative methods (particularly quantitative and clinical researchers) to evaluate them. Recently however, a number of academics have criticized these types of checklists as being oversimplistic, overgeneralized, and formulaic, with their view being that listing technical “fixes” is inadequate for conferring the rigor of each complex and unique qualitative study. Moreover, it has also been suggested that checklists encourage qualitative researchers to use and list well-recognized and standard approaches—such as purposive sampling, grounded theory, and triangulation—as “bumper stickers” to legitimize their approaches regardless of whether they are the best ones to use.

CLINICAL RESEARCH

Clinical research can be defined as research that is related to experiences and descriptions of individual and interpersonal problems, transition, and change. This includes social science and medical science studies of human behavior and interactions, cognition, and somatic experiences from a variety of perspectives. Transition and change can occur as part of one’s life course experiences or as a result of clinical intervention. The purpose of this entry is to provide an overview of choice points for clinical researchers to consider. The entry is not meant to explain how to do qualitative clinical research; rather, it is meant to raise topics and possible issues for researchers to consider as they conceptualize, design, implement, and write up studies. The entry does not differentiate between clients and patients; rather, the word *clients* is used to refer to both patients and clients.

It is important for researchers to position themselves as well as their theoretical and methodological framework, and in doing clinical research this transparency of integrating theory with practice becomes even more relevant. This is due to the multiple

relationships that can occur between researchers and the people participating in their studies as well as the potential for the research itself having an effect on the participants. To help researchers conducting clinical research, this entry contains the following sections: (a) description of the links among epistemology, theory, methodology, and methods; (b) types of research questions; (c) underlying agendas driving questions; (d) consideration of whose perspectives one is considering; (e) researcher/researched relationships; (f) points in time being investigated; (g) presentation of findings; (h) ethical issues in clinical research; and (i) political context of clinical research. As this entry explains, clinical researchers are challenged with a multitude of decision points to consider during the research process. It is important for researchers to consider some of these points at the genesis of conception of a project. Other points of consideration come into play as the projects are designed, implemented, and written up (or performed). In addition, it is recommended that researchers continuously reflect on ethical and political ramifications of their work.

Linking Epistemology, Theory, Methodology, and Methods

This section is based on Michael Crotty’s *The Foundations of Social Science Research*. Crotty made a strong argument for the importance of logical consistency among one’s epistemology, theory, methodology, and methods. Although there is a wide range of methodologies that researchers may draw on to organize their research efforts, how a particular methodology is employed and made sense of will vary according to one’s epistemology. This topic is discussed in the section on theoretical frameworks, and the point here is to advocate that researchers articulate their epistemological orientation and theories they are employing as well as how this framework will influence their methodology, methods, conclusions, and results.

As an example of this point, consider a researcher using videotape playback of sessions with open-ended interviews with clients to find out what they saw as meaningful in marital therapy. From the perspective of a postpositivist (objectivist) epistemology and symbolic interactional theory, the researcher might claim to be discovering the key points that the couple found meaningful in therapy. From the perspective of a postmodern and social constructionist theory, the researcher might suggest that the interviews themselves were shaping the couple’s memories and might have had a therapeutic

impact as well. Although both approaches have research legitimacy, the two studies might come to very different conclusions and implications.

Other aspects of these chains of logical consistency are whether and how researchers bring a critical perspective into their studies. If researchers view human behavior as more than an intrapsychic phenomenon, such that human behavior and personal meaning are shaped by cultural sociopolitical contexts, then researchers will consider more than clients' experiences and descriptions. The research will likely also consider how clients themselves are shaped by cultural discourses as well as how clinical practices are shaped by cultural practices. From this critical perspective, researchers can even consider how their own research practices (and implicit biases) are shaped by cultural values and dominant themes.

Types of Research Questions

Clinical research questions are often viewed as being about either process or outcome; however, it is also useful to conceptualize clinical research as being for the purposes of predicting, understanding, emancipating, or deconstructing. Although these four perspectives are often couched as each corresponding to different epistemological and theoretical frameworks, to some degree a researcher can conceptualize any of these goals in different epistemological grounding. Clinical research seeking to find patterns for prediction is useful for the current evidence-based practice model. Research seeking to understand is helpful for studying the clinical process. Research seeking to emancipate is part of the action research movement and is sensitive to issues of power and social hierarchies while also addressing social justice. Research seeking to deconstruct is examining how clinical practices (and research practices) are not independent of one's societal environment and how practices of power, identity, and meaning are culturally imposed. Depending on the type of question(s) being asked and the purpose of the question(s), the researcher can decide which methodologies and methods may be best suited for the project.

Underlying Agendas That Drive Research Questions

In posing research questions, it is relevant to also consider who or what is organizing the research project

itself: For example, a clinical agency might be seeking a program evaluation. Clinicians might be interested in how their practices are experienced by their clients and in the effectiveness of their clinical work. Funding sources for a program may be behind the research project such that they are requesting data for determining future funding. Government funding sources might be shaping the research questions being posed. Also, the researcher himself or herself might be the one initiating the research project based on his or her own personal experiences or professional constraints or out of personal curiosity. Who or what frames the purpose of the entire research project can influence both the types of research questions being asked and how results are distributed.

From Whose Perspective Do the Data Emerge?

Research data can emerge from many different perspectives. If one conceptualizes clients from a systemic or ecological perspective, the starting place can be (a) the individual (client), and the context can be expanded to include (b) multiple clients (couple, family, or social network), (c) the clinician, (d) the researcher(s), (e) the community, and (f) cultural discourses. Research can focus on any one of these perspectives or consider multiple perspectives.

In terms of framing the individual perspective, such as with a biopsychosocial–spiritual framework, data could include emotional descriptions, behavioral change, current cognitive processes, retrospective descriptions, biological processes (either self-reported or observed by others), and spiritual and religious accounts. Each of these aspects of an individual's experience might involve different methods of data collection.

Multiple clients' perspectives could include a couple, a family, or a broader social network. In considering a multiple-clients perspective, it is important to consider how data are gathered. For example, if a couple is interviewed, are the members interviewed separately, together, or a combination of alone and together? If it is a combination, how are the different accounts woven together? The broader social network might include the client's friends, neighbors, extended family, or fictive kin. The clinician's perspective can include a single clinician or a clinical team working together. With a clinical team, it is important to consider whether the team data are gathered individually,

in a group, or using a combination. The researcher himself or herself can also be a source of data. This is true in autoethnography and heuristic inquiry, but the researcher can include personal reflections and experiences in other methodologies as well. The community perspective could include sources such as officers of the court, social service workers, and school personnel. Finally, one can also consider the cultural perspective on clinical practices, for example, how society's dominant discourses might influence the definitions of health, dysfunction, pathology, diagnoses, practitioner/healer, and responsible treatment.

Relationships Between the Researcher and the Researched

There are various types of relationships that can occur between the researcher and those being researched. In classical experimental research, the people being studied were referred to as subjects. This created a clear separation between the researcher and the "other" in terms of power, personal relationship, voice, and knowledge.

In clinical qualitative research, there are multiple signifiers a researcher can use to define the researcher and "other" relationship. Are the people being researched considered participants, collaborators, co-researchers, or some other concept? The choice of terms has real implications for the research endeavor, with both epistemological and phenomenological impacts. In designing a study, the researcher should have a clear rationale for what descriptors are used in the study and an appreciation for how the language reflects the researcher's relationship with the people being studied. When the people being researched are considered co-researchers, this implies that they have a voice in the research process itself. This voice can include shaping the design before the study is conducted, shaping the analysis, and even having a say in whether or how reports are to be written. When the researcher considers the relationship as collaborative, it is important to consider how power is shared, how decisions are made, and how consensus and nonconsensus are negotiated.

Points in Time Being Investigated

Another consideration for the clinical researcher is what points in time are being studied. Is the researcher interested in the experiences and phenomenon prior to

intervention or prior to the occurrence of the problem(s)? Is the researcher interested in the experiences and phenomenon that occur during the course of treatment? Does the researcher need to have inquiries about the experiences and phenomenon after clinical treatment? Research can look at any of these points in time or at multiple time points. Often when conducting clinical research, one considers multiple time periods. Therefore, it is important for the researcher to be clear as to which anchor points are being studied. For example, if one researcher is looking at the actual talk of therapy through conversation analysis and another researcher is interviewing clients posttreatment through videotape playback, these are two discrete time periods with unique data and interpretation. To consider these two data sets as comparable is problematic. The study of the "talk of therapy" (phenomenon that occurs in treatment moment to moment throughout the process) may be very different from the study of the "talk about the talk of therapy" (discussion by client, researcher, or other about what has happened in therapy or as a result of treatment).

Presenting Findings

There are a number of ways in which findings and reports of a research project can be presented. These include written texts, papers/articles, posters and talks at conferences, web postings, and performances. The type of audience the researcher wants to present to (scholarly, professional, lay, or all three) can also influence how the data are analyzed and written.

Ethics and Clinical Research

Although attention to ethics is important for all researchers, clinical researchers need to be particularly attentive and prepared for issues that may arise. This attention begins with the conceptualization of the project: What risks might participants face from being a part of the project? What information might researchers learn that becomes a legal or moral issue for them (e.g., child abuse, illegal activity, elder abuse, affairs)? Sometimes information gathered is not even relevant to the study but respondents disclose anyway, and then researchers must do something with this knowledge. When is it appropriate to refer a respondent for clinical help? How do researchers know when the boundaries between themselves and respondents have gotten blurred and when the relationship is not

professional? How do researchers take care of themselves as they learn about painful and emotional events that may trigger their own emotions? How do researchers manage multiple roles such as when they are both clinicians and researchers? Which professional lens do they use in conducting interviews and analyzing data? For example, clinical interviews are different from research interviews, and how researchers/clinicians respond can achieve different outcomes.

Addressing these issues is relevant in preparing for human subject approval, but also the researcher needs to be prepared for the unexpected. It is useful to have colleagues to talk with about issues as they arise. Finally, in preparing a report of findings, the researcher needs to consider possible long-range impacts of the study. How might respondents feel when they read the document later? How does the researcher honor the participants' voices but maintain confidentiality? How does the researcher deal with ending research relationships, particularly when the research process has been very collaborative and intimate in the sharing of information? Addressing these questions prior to data gathering may prevent potential ethical dilemmas later for the researcher and participants.

Politics of Research

The last section considers the broader context of the research. Different professional and interpersonal dynamics are at play for research conducted in a university setting, in a hospital setting, at an agency, or for one's private practice. It is important to consider the potential differences among these settings. These might include elements such as who gets (or "owns") the information learned, timelines, relationship dynamics, authorship, data storage, confidentiality, and funding.

In terms of clinical research, it is also important to consider the relationship between one's research and the current culture of privileging evidence-based research. Not all contexts are supportive of qualitative research, especially during the era of evidenced-based health care. Evidence-based medicine is the notion that clinical expertise should be integrated with best research evidence and patient values. Although for many scholars randomized clinical trials and meta-analyses are considered the best external evidence

when researching clinical interventions, there are many questions about "best evidence" that can be answered qualitatively.

Regardless of whether one is doing evidence-based research using a mixed-methods study or a stand-alone qualitative study, the following are questions to consider: How can qualitative research contribute to evidence-based studies? How might qualitative research challenge the findings of evidence-based studies? How might researchers deal with other scholars who may minimize qualitative clinical research and the research findings? These biases could include those of dissertation committee members, fellow faculty or professional colleagues, funding agencies, and other influential people and institutions. What are the implications of funding sources for clinical research? Might a funding source control which results are to be published?

It is important for researchers to be aware of the politics and professional ramifications of conducting qualitative research within their institutions (e.g., medicine, education, government, industry). Finally, it is important for researchers to consider how their findings might be used (or misused) by others, such as for policy change.

CLOSED QUESTION

A closed question is a type of question posed by researchers to participants in research projects that specifies the parameters within which participants can frame their answers. Closed questions typically provide possible responses in the questions, request specific facts or information from interviewees or survey respondents, or may even limit responses to “yes” or “no.” Closed questions are associated with structured interview formats and spoken and written questionnaires, and they assume that people’s experiences may be reduced to facts that can be coded with preestablished researcher-generated categories. In contrast to open-ended questions, which are designed to give participants freedom to initiate topics within research settings, closed questions are worded to eliminate possibilities for participants to introduce their own topics or provide answers that do not fit the researcher’s coding schemes. Such questions are frequently used in a way that formulates the human subject as passive, responding to a neutral researcher working to elicit specific facts concerning research topics.

Closed questions are commonly used in structured interviews and focus groups, and they are especially suited to research projects in which the same information must be obtained from a large number of participants. Given that closed questions are widely used as a means of eliciting data in standardized survey interviews and rely on quantitative methods of data analysis,

close attention has been paid to methodological aspects of question formulation and how questions are sequenced and administered by interviewers.

David Stewart and colleagues identified two forms of closed questions: explicit and implicit. In explicit closed questions, interviewees are provided with possible responses from which they must select an answer. The following are examples:

Do you agree or disagree with the proposal that x should be implemented?

How frequently have you attended meetings about x : never, 1 or 2 times, 3 or 4 times, 5 times or more?

How would you rate the process of information sharing undertaken with respect to the implementation of x on a scale of 1 to 5, where 1 is *very poor* and 5 is *excellent*?

Implicit closed questions include an assumption about the possible range of responses in the questions without providing a specific response. For example, in response to the following questions, interviewees can provide multiple answers that are not included in the questions:

How many weeks do you intend to travel overseas this year?

With what airline will you fly?

Some qualitative researchers have critiqued the use of closed questions as a method of generating information about people’s lived experiences, arguing that such questions limit the ability of research participants to provide rich descriptions and relevant information concerning their lives. Other methodologists argue that a judicious mix of both closed and open-ended questions can be used to generate useful data for social research. How qualitative researchers use closed questions in their work largely depends on the epistemological and theoretical assumptions underlying the research design of a given study.

CO-CONSTRUCTED NARRATIVE

Co-constructed narratives are stories jointly constructed by relational partners about epiphanies in their lives. This approach offers a way for participants to actively construct a version of a relational event that provides insight, understanding, and an in-depth and complex reflection on what occurred. As such, this mode of doing research provides an alternative to traditional interviewing, especially when the topic under consideration is emotionally charged, personal, and sensitive. This entry discusses the goals, concerns, and practices associated with this research approach and the narratives that result.

Co-constructed narratives show dyads engaged in the specific, concrete, and unique details of daily living. They show couples coping and trying to make sense of the untidy ambiguities, ambivalences, and contradictions of relationship life and their local situations. This type of research focuses on the interactional sequences by which interpretations of lived experiences are constructed, coordinated, and solidified into stories. Thus, the local narratives that are jointly produced display couples in the process of “doing” their relationships as they try to turn fragmented, vague, or disjointed events into intelligible coherent accounts.

Co-constructed narratives may be “mediated,” meaning that a researcher may monitor the conversation of two relational partners, or “unmediated,” meaning that a researcher may study his or her own relationship with a partner or two researchers might study their relationship with each other. Mediated co-constructed narrative research is similar to conjoint marital therapy, where couples participate together in therapy after providing their different perspectives on the same events. In mediated co-constructed narratives, a researcher serves as coordinator and moderator as a couple engages in a joint construction of an epiphany in the two members’ relationship. The researcher asks them to reflect on the event and to write, talk into a tape recorder, or be interviewed separately about the experiences. Then, in the presence of the investigator, the participants hold a discussion about the event. Sometimes the participants are asked

to exchange transcripts or stories written independently and to read each other’s constructions before the discussion, although this might not always be feasible. Nevertheless, the goal is to produce or co-construct a version of the event that takes into account each individual’s perspective.

The investigator stays in the role of researcher as she or he takes notes on (and/or records) the interaction. The researcher then writes the participants’ story from the materials they provide as well as from her or his own observations of and participation in their co-construction. While writing their story, the researcher reflects on how she or he views the participants and analyzes their conversational style and their negotiation of the co-construction of their separate stories. The researcher might describe events leading up to the interview, the physical and emotional environment of the interview, and the researcher’s role in the interview (e.g., what she or he asked the participants, how she or he responded to them, and how she or he possibly influenced the conversation). The account of the interview process becomes part of the story told. The researcher also might include her or his views on and experiences with the topic at hand and a discussion of how her or his perceptions and feelings have developed and changed as a result of observation of and interaction with the participants. Including the researcher’s experience helps readers to understand more about the researcher’s interest in the topic and provides background for how she or he interprets what is happening. Although the researcher becomes a character in the story, her or his identity remains that of researcher. The focus stays on the experience of the other research participants rather than on the interviewer.

In unmediated co-constructed narratives, the focus turns directly to the self as researchers examine their own relationships rather than the relationships of others. In such narratives, researchers use the same procedures as just described except that there is no outside researcher mediating the interview process. The two researchers, or a researcher and a partner, write their stories separately, exchange them with each other, read them, and then discuss them. Then they attempt to co-construct a collective version. They might present the result in the form of a script, a short story, or an essay, or they might analyze or even perform their narrative for an audience. Other participants in the event might be asked to add their voices as well. The end result is a collective interpretation, although individual voices might be kept intact.

Co-constructed narratives offer a way to study relationships that closely reflects how we live them in everyday life. The procedures connected with this approach are based on several premises about how relationships are practiced. For example, it is assumed that relationships between people are jointly authored, incomplete, and historically situated. Connections hinge on contingencies of conversation and negotiation that often produce unexpected outcomes. One of the actions we take in relationships is to assign significance and meaning to rather vague experiences and events in an attempt to bring order to the unit. We do this by telling stories about our relationships, stories that are co-constructed continuously and, in that sense, are always unfinished. Each person's views and actions affect the other's, and the joint activity and mutual identification that result (or fail to develop) become part of the relationship.

prior to data collection or may emerge inductively through the coding process. In qualitative research, discussions of coding most often center on the inductive process of searching for concepts, ideas, themes, and categories that help the researcher to organize and interpret data. This entry provides an overview of the coding process, describes strategies for deriving codes, and reviews both the initial stage of open coding and the stage in which more focused coding is carried out.

Coding as Process

The derivation of codes and the coding process tend to differ in quantitative and qualitative research. In quantitative research, codes are commonly created prior to data collection. Concepts and hypotheses are most often developed in advance, and categories and their codes are derived deductively from theory or borrowed from the extant literature. These predetermined categories are used to structure the data that are collected. Many questionnaires, for example, are in fact precoded (the categories and their dimensions are explicitly listed and the respondent is asked to choose among the options provided). For instance, one might be interested in how anger is expressed and ask a respondent to choose among options, such as cursing and throwing things, that provide varying realizations of the concept. The categories, in addition to their definitions and properties, are often clearly laid out in a codebook specific to the study.

In qualitative research coding is the process of generating ideas and concepts from raw data such as interview transcripts, fieldnotes, archival materials, reports, newspaper articles, and art. The coding process refers to the steps the researcher takes to identify, arrange, and systematize the ideas, concepts, and categories uncovered in the data. Coding consists of identifying potentially interesting events, features, phrases, behaviors, or stages of a process and distinguishing them with labels. These are then further differentiated or integrated so that they may be reworked into a smaller number of categories, relationships, and patterns so as to tell a story or communicate conclusions drawn from the data. A coding frame, a scheme that lays out key concepts, their definitions, and criteria for recognition, is evolved over time during the coding and analysis of the data. It is subject to change and refinement as the researcher proceeds with successive passes through the data.

Many researchers keep notes on insights, ideas, patterns, and connections that occur to them as they

CODES AND CODING

Codes and coding are integral to the process of data analysis. Codes refer to concepts and their identification through explicit criteria. Codes may be developed

read and reread the data. This activity, known as mem-
 oiring, occurs throughout the coding process. For many,
 coding starts with attention to very fine details and
 evolves into emergent categories that are applicable at
 much higher degrees of abstraction. Code notes help
 the researcher to keep track of the emergent defini-
 tions of codes and their distinctive criteria. Computer-
 assisted data analysis software is increasingly being
 used to manage qualitative data sets, keeping track of
 notes and comments and where specific codes have
 been assigned to specific data elements, thereby facil-
 itating the sorting and retrieval of data.

Whether one is primarily aiming to provide descrip-
 tive accounts, searching for patterns, or intending to
 develop theory, the goals of code creation are to identify
 categories and themes by making their criteria explicit
 and providing evidence for them—and the conclusions
 based on them—that is drawn from the data. The strate-
 gies and techniques offered for this process vary, but
 there are many commonalities and themes concerning
 procedures for coding that may be abstracted from the
 growing literature on qualitative research methods.

Coding Strategies

A number of methodologists distinguish between two
 main strategies by which codes and categories are
 derived. *In vivo* codes are those obtained directly from
 the data, for example, terms used by interviewees.
 Many respondents will put forward folk typologies;
 for example, prison inmates explicitly speak of types
 of “cons” (convicts). The “snitch” (a con who reports
 the actions of other cons to the authorities) is a vivid
 example of a conceptual category taken from the
 interviewees. Alternatively, social science constructs
 may be created or imposed by the researcher, who
 either derives them from the existing literature or may
 be influenced by the literature in their creation.
 Keeping with the example of an inmate study, the
 social science constructs of stigma or institutionalized
 mentality may be concepts employed by the researcher
 to illuminate aspects of the data and evoke broader
 theoretical issues of interest.

The grounded theory approach to qualitative data,
 associated with Barney Glaser and Anselm Strauss, is
 the most prominent source of an explicit set of tech-
 niques and procedures for coding and processing data.
 In the grounded theory approach, where the develop-
 ment of theory as emergent from the data is more
 heavily emphasized, the dynamism of coding is

stressed. Grounded theory proponents have broken the
 coding process into stages in an attempt to illuminate
 the logic that underlies analysis, although they caution
 that no sharp boundaries exist in actual practice. The
 labeling of concepts and categories during the early
 stages of coding is referred to as open coding. During
 successive stages of coding, the researcher begins to
 hone in on and refine more specific categories and
 their properties, examining in depth one category at a
 time. This is spoken of as axial coding. A still further
 focus on particular links and relationships among a
 few chosen categories (the integration of categories) is
 referred to as selective coding. The grounded theory
 approach tends to emphasize more impersonal, rela-
 tively objective processing and reprocessing of data.
 Although most writers on coding practices acknowl-
 edge their debt to the grounded theory approach,
 many urge relaxing one or another of the recommen-
 dations in hopes of stimulating creativity and insight.

Initial or Open Coding

During this initial stage of bringing order to and mak-
 ing sense of the data, a close line-by-line reading of
 the data is often suggested in a search to identify as
 many ideas and concepts as possible without concern
 for how they relate. A number of researchers suggest
 asking questions of the data to help identify ideas and
 concepts of interest such as the following: What is
 going on? What was done? How is it being done?
 Who did it? What are the goals? What was the mean-
 ing of it? What was the intent? What feelings or
 thoughts are being communicated?

Another place where many begin in coding is to
 look for information as it concerns the original goals
 and interests of the research study. Such advice often
 comes with a warning to keep an open mind for other
 issues that might arise. Controversy exists over what
 stance toward prior knowledge is ideal. Some believe
 that one should begin the coding process without the
 influence of existing ideas and concepts. A more
 prevalent stance, however, is that this is not possible
 given most researchers’ knowledge of their discipline
 and of the particular areas they are researching. Those
 who adopt this stance advise using ideas and cate-
 gories to which one has been sensitized while staying
 alert to other possible concepts, ideas, and themes.

Coding is dynamic. By attaching code labels or
 words to identify occurrences, meanings, activities, or
 phenomena, the researcher begins to group instances

or events that are similar and to distinguish those that differ. For example, when reading interviews of criminal offenders, one might attach the concept of thrill seeker to a remark such as, "I got a rush as I drove off with the car." In talking with spouses of incarcerated individuals, the following event might be coded as an instance of neighbor assistance: "Ed next door helped with snow removal when I couldn't get my car out." The same event, incident, activity, or representation in the data may be coded in multiple ways. For instance, the neighbor's assistance with snow removal might also be coded as spousal help needed or problems encountered. As one continues to comb through the data, many new concepts and ideas may be identified, but similar ones will also be recognized. For example, the code of neighbor assistance might be applied later in the data to instances of a neighbor coming to the rescue when a kitchen pipe broke or when a spouse recounted the story of how Sam, who lives across the street, stopped by with jumper cables to help start a car. The code of thrill seeker may be applied to a remark such as, "I got very excited as I broke into the house, thinking about all the things I might get away with. I like that feeling."

As one proceeds through the stage of open coding, refinements begin to occur to the researcher. Certain concepts may be evidenced repeatedly, whereas others may be viewed as less common or perhaps viewed as variations of a concept or theme already recognized. Many researchers suggest that open coding should continue until nothing new and interesting emerges, some codes begin to stand out as significant or telling, and links between codes begin to cohere. These are signs that more focused and integrated coding should be pursued. In the process of this analytic exercise, broader categories and their properties or dimensions are discovered.

Focused, Integrative, and Selective Coding

The move from open coding to a more focused coding is not a clearly defined step. Many caution that although there are general guidelines that indicate a progression in the coding process from identifying new concepts to refining and integrating existing categories, one should not think of the process of coding as linear. If a new idea is discovered later in the process, or as more data are added, original concepts can arise, and the need to broaden one's outlook or open one's mind to new possibilities again may occur.

As one proceeds through the initial coding of the data, there is usually much potential for pursuing a variety of themes and issues. Nonetheless, as coding progresses, particular categories and themes emerge as more salient, as central to integrating a number of key concepts, and/or as being of interest to a particular topic under study. The data are then more thoroughly and systematically reviewed with fewer specific concepts or categories in mind to determine where and how these are illustrated in the data. The coding process alternatively has both inductive and deductive elements. Codes that emerge from the data, when confronted with further data, are often revised to accommodate the evidence. Newly discovered codes or the refinement of existing codes may prompt the researcher to reread the data or assess newly acquired data.

In the pursuit of a more refined and focused analysis, many concepts are reconceptualized and incorporated into broader, more abstract categories, whereas others are refined by seeking out possible variations in their properties or dimensions. It is through repeated reviewing and coding of the data that links between various codes are made and relationships among categories begin to solidify. The researcher may retrieve all of the data segments associated with a given code and compare them, determining their fit and looking for potential further variation or links. Using the earlier example of neighbor assistance, one might notice different types of assistance from neighbors such as emergency help (e.g., aiding with a car breakdown or a leaking pipe), emotional help (e.g., dropping by for coffee and to chat about troubles), and financial assistance (e.g., lending money for groceries).

With further intense coding, focusing on questions such as what forms of assistance are mentioned by the spouses of incarcerated offenders and who provides it, a number of other types of help might be distinguished. A statement concerning how women at a local church alternated in providing child care could be coded as church support. A remark about how the local food bank helps a family to avoid going hungry at the end of the month might be coded as local charity assistance. Eventually, these various forms of assistance may be combined and incorporated into a broader category of types of community assistance that include neighbors, churches, and local charity organizations.

This higher level category of community assistance may, in turn, be theoretically reworked and incorporated into an even broader conceptual category. In

searching for other types of assistance that spouses of incarcerated offenders received, familial support may be another category discovered with various dimensions that include financial and emotional support. These may be integrated and reduced further, subsumed by a more general abstract category, types of support, that includes subcategories of support such as community, family, and government. Links and ideas about the role that various types of support might play in the lives of the spouses of incarcerated individuals and the impact that various types of support might have on their outcomes may then be pursued. It is through the successive stages of coding in qualitative data that such analytic discoveries are possible.

Some argue that the coding and analysis of qualitative data cannot be systematized or taught. It is an interpretive process that necessarily involves creativity and subjectivity. There are a growing number of researchers who believe that, even if this is the case, laying out procedures and calling for clarity and transparency in the reporting of how researchers proceed in the coding of their data go a long way toward helping to deal with the issue of reliability of qualitative research.

of concepts and categories that mediate the translation of raw data (e.g., interviews, reports, editorials, fieldnotes, open-ended questions) into instances, examples, and illustrations that ultimately make up the storyline summarizing the data (explanation of phenomena). A coding frame or scheme, therefore, supplies the names of concepts and the criteria used to identify and sort them and, thus, the rules used to single out the observations associated with them in raw data. It provides the guidelines for how to label and interpret (code) research observations.

This framework for classifying, organizing, and summarizing raw data may be developed a priori from theory (deductively) or adopted from extant research. In qualitative research, however, a coding frame often emerges inductively from the data. Over the course of data analysis, as categories are uncovered and refined, the coding frame evolves, helping to classify further data segments into already established or new conceptual categories. The terms *codebook* and *code manual* are also used to refer to the written document containing the scheme of concepts and categories used to structure and interpret the data. These terms are often associated with quantitative data sets; however, they are used by qualitative researchers as well.

The approach one takes in developing a coding frame depends on a number of factors, including the issue under study, how well the topic is understood, the complexity of the phenomenon, and even the amount of time one has for analysis.

Coding frames may be more or less formal. For instance, coding schemes for surveys and content analysis (the assessment of all forms of communication that have been recorded, e.g., books, newspapers, paintings) are most often highly formal. Those developed for questionnaires are more often deductively derived, whereas those for content analysis are more often inductively developed. In grounded theory, the ultimate set of codes used may or may not be formally laid out, but the steps taken and the concepts used are often spelled out in memos. More explicit and well-documented coding schemes are particularly needed when research is conducted by teams and coding and analysis are shared tasks. Explicit schemes are essential for achieving intercoder reliability and code consistency checks.

Whether a coding frame for a given study is maintained in the format of a book, kept track of by a computer software program, or contained in memos written throughout the process of data analysis, the common feature of such schemes is to record

CODING FRAME

A coding frame is the guiding conceptual scheme for a research study. As a record of the codes and criteria used to classify observations, it contains the definitions

decisions made in the classification of the raw empirical data into categories for analysis.

There is some disagreement about the value of preset coding schemes versus the development of coding frames from the data. Some argue that preset codes may encourage one to force fit observations into existing categories. Other researchers have expressed concern about possible misclassification of empirical observations in support of newly generated categories that are thought to be key to perceived relationships emerging from the data. However derived, coding frames record the guidelines that governed the analysis of a body of data.

COGNITIVE INTERVIEW

Cognitive interviewing encompasses a variety of approaches for eliciting qualitative data on how participants interpret and respond to a wide variety of situations. Cognitive interviewing increasingly is used in the evaluation of technology interfaces such as websites and tools for informatics. It is used in education to understand how students think about content and respond to test items and in marketing to understand how to evaluate products better. This entry focuses on an especially salient application of cognitive interviewing for researchers in varied disciplines—the development of structured questionnaire and interview items.

Beginning in the late 1970s, cognitive interviewing developed through the interdisciplinary efforts of cognitive psychologists and survey design methodologists. The intent of these interdisciplinary collaborations was to study the cognitive processes that shape participants' responses to questions and to use cognitive theory to improve survey design. Cognitive interviewing increasingly is viewed as an essential aspect of developing valid and reliable standardized measures. Through cognitive interviews with members of the target population for a new measure, researchers are

able to identify problems with question interpretation as well as understand the kinds of information participants use in formulating their responses. Cognitive interviewing also provides insights into participants' decisions to respond to questionnaire items in a particular way. As a distinct form of qualitative interviewing, cognitive interviewing makes important contributions to instrument development and survey design.

Problems Addressed by Cognitive Interviewing

Cognitive interviews are used to identify a variety of potential problems with items of structured instruments. Gordon Willis and colleagues identified key cognitive processes involved in responding to questionnaires that were potentially problematic: comprehension, retrieval, judgment, and response. Problems of *comprehension* are related to respondents' understanding of the item and whether or not that understanding is in keeping with the investigator's intent. Sophisticated or overly technical language and lengthy complex questions can pose a threat to respondents' ability to understand items. In other instances, respondents may understand the item but in an unintended way. For example, the item may ask about respondents' beliefs about health promotion with the intent of eliciting information on what sorts of things are linked to a healthy lifestyle, but respondents may interpret the item as asking how religious beliefs contribute to health. Problems of *retrieval* are related to respondents being able to recall certain information or experiences. For example, respondents may understand the question but have no memories of their experiences or opinions on the issue. Issues of *judgment* relate to respondents' decisions about what information to provide and how to frame their answers. For example, if the question relates to a sensitive topic, participants may respond in a socially desirable way that does not reflect their actual experiences or opinions. *Response* problems have to do with how respondents fit their experiences and opinions into the response format of the questionnaire. As noted by Chris McQuiston and colleagues, members of certain cultural and ethnic groups have considerable difficulty in translating their experiences and opinions into a Likert scale response set. Cognitive interviewing is useful in helping the investigator to uncover the nature and extent of all these measurement problems.

Forms of Cognitive Interviewing

Cognitive interviewing takes multiple forms that address different problematic aspects of standardized measures. Verbal probing and think-aloud techniques are the two main approaches to cognitive interviewing.

Verbal probing usually occurs after respondents have completed the questionnaire, with the researcher asking additional questions about how items were interpreted and the basis for participants' responses. Respondents may be asked to give their interpretations of specific words, their assessments of the accuracy of their responses, or their evaluations of the appropriateness of the questions. Verbal probing can be used to identify problems of comprehension, retrieval, judgment, and response. Respondents may be asked to give their interpretations of specific words or phrases, providing input on the extent to which the items are understandable and being interpreted as intended. For example, using the previous example of the use of the word *belief*, verbal probing would reveal the extent to which respondents had different interpretations of the term. Verbal probing is useful for determining how participants weigh issues of social desirability in responding to a question and for assessing the quality and extent of information that participants consider in formulating responses. Respondents can provide feedback on whether or not they think future respondents will answer a question truthfully. Kathleen Knafl and colleagues used cognitive interviewing in developing a new measure of family management of childhood chronic conditions and found that parents strongly objected to the word *burden* in some of the items and stated that future respondents would not respond truthfully to any items using that word. If the investigator has concerns about the response format of the questionnaire, verbal probing also can be used to judge its appropriateness for certain groups. Verbal probing interviews may be based on a standardized guide, with all participants being asked the same questions about items, or they may be individualized based on each participant's responses. For example, special attention might be given to eliciting data on items that respondents failed to answer or that were answered in the extreme categories of the response set.

Closely related to verbal probing is the technique of paraphrasing, which asks respondents to restate each item in their words. Paraphrasing is especially useful in identifying problems of comprehension and the extent to which items evoke similar interpretations

across respondents. Multiple interpretations of an item provide compelling evidence that the item needs to be either revised or deleted from a measure that is under development. Paraphrasing, when used in conjunction with verbal probing, is useful in identifying respondents' overall understanding of the item as well as pinpointing problematic aspects related to ambiguous or offensive wording.

Think-aloud interviewing is the second major cognitive interviewing approach. In the think-aloud interview, the respondent is asked to say what he or she is thinking while answering an item. Think-aloud interviews provide information on retrieval and judgment issues. Through think-aloud interviews, the investigator gains insight into what the respondent remembers about an event or the memories that inform a particular opinion. This kind of information can be useful for determining an appropriate time frame for a question (e.g., number of times the respondent has attempted to lose weight or stop smoking) and for understanding what the respondent identifies as relevant and irrelevant information when formulating a response to a question. Such information contributes to the revision of questions so that the respondent is retrieving the kind of information the investigator is seeking. Think-aloud interviewing typically takes place simultaneously with instrument completion.

Study Design

Although there are few guidelines for sample size and selection when using cognitive interviews for instrument development, investigators typically report interviewing 20 to 30 respondents who represent the target population. As noted in the description of the different forms of cognitive interviewing, respondents may be asked to recall information retrospectively about their formulation of responses, or they may be asked to think-aloud the basis for their responses at the time when they are answering the questionnaire. Researchers using the verbal probing approach to cognitive interviewing vary in the extent to which they use a structured interview guide or rely on general open-ended questions such as, "How did you arrive at your response to the question?" In either case, cognitive interviews generate qualitative data that are meant to inform further instrument development. The analysis of these data focuses on the item as the unit of analysis, with the investigator reviewing all input on a given item to reach decisions about

retaining, deleting, or revising the item. In some cases the analysis is based on a predetermined list of problematic aspects of items (e.g., lexical, temporal, logical), and in some cases problem identification is based on a content analysis of the cognitive data. Regardless of design or analytic approach, investigators consistently report that cognitive interviewing leads to substantial improvements in instrument quality.

COLLABORATIVE RESEARCH

Collaborative research is research “with” rather than research “on.” It is research that arises out of the expressed needs, interests, and questions of the stakeholders who are most invested in the research and its findings, and it is research conducted in relationship with them. Collaborative research reflects a move in the social sciences away from a hierarchical understanding of research as informing practice to an understanding of the reciprocal and interdependent nature of research and practice. This entry focuses on the epistemological, ideological, and ethical beliefs that underlie collaborative research and the ways in which those beliefs are translated in the design, implementation, and dissemination of such research.

Collaborative research enables the voices of researchers and those in the field—practitioners, policymakers, and other stakeholders—to be positioned alongside one another in a shared inquiry of mutual interest and benefit. Collaborative research can be situated within the specificity of a discipline (e.g., researchers, teachers, administrators, and parents inquiring into ways to enhance parent engagement in schooling), or it can be situated across disciplines where diverse voices and perspectives come together in multidisciplinary or intersectoral teams to pursue a research question in more comprehensive, holistic, or integrated ways (e.g., researchers, practitioners, and policymakers from health, education, justice, and social services, alongside parents and community members, researching reforms to the provision and integration of human services delivery to enhance the well-being and academic success of children and families living in an inner-city neighborhood). Collaborative research can also be situated in a university–community relationship where an issue the community is puzzling over is researched with the support and facility of university academics (e.g., a concern posed to academic researchers in a department of nutrition by a community-based nonprofit food security organization regarding how to work with school lunch providers to enhance the nutritional value of lunches provided in school-administered programs). Although it can involve many types of alliances, common goals and mutuality are integral to collaborative research—a sense that each partner has much to learn from the other and that the results of the

research will be richer through collaboration than any one partner could achieve without the other.

Beliefs From Which Collaborative Research Arises

Collaborative research reflects a belief in experience as education and in all individuals as holders and constructors of knowledge. It steps away from a commonly held notion that theory is generated through research and by researchers and then is transmitted to the field where it is taken up by and acted on by policymakers and practitioners. Rather than perpetuating such a top-down model, it promotes a side-by-side positioning in which the differing experiences and resulting knowledge that each individual brings to the research, whether as researcher, policymaker, practitioner, or stakeholder, is seen as valuable and valued. It reflects a belief that regardless of one's role, all of one's actions in that role are simultaneously acts of theorizing and acts of practice. Collaborative research invites rich dialogue between and among individuals and the multiple perspectives they represent.

Collaborative research is a vehicle for democratic participation in processes of inquiry, problem solving, and social change. It reflects a belief that because social science research can affect the well-being of a social group, members of that group have a place in all aspects of the research. It is based on a shared commitment to furthering both the knowledge of the individual and the knowledge of the collective.

Collaborative research is relational research. It reflects a commitment to a special kind of care and attention in the provision of continuous opportunities for engagement, voice, and response for all research partners (or co-researchers, as they are frequently called). It works to level power differences by creating research structures that do not privilege the researcher's voice over any other (e.g., research team conversation circles, where every voice is equal and heard, rather than research team meetings with set agendas or led by the principal investigator; opportunities for every co-researcher to speak back or write back to field text and research text). Collaborative research reflects an interactivity among team members based on living the research in caring and respectful ways. It calls for a wakefulness to each voice at all stages of the research process and a responsiveness to shaping and reshaping research roles as the research unfolds.

Characteristics of Collaborative Research

Collaborative research is based on a relationship of equity among co-researchers working together to achieve mutually determined and mutually beneficial goals. It reflects a shared belief in both the means and the ends of the research. It reflects the engagement of co-researchers in all aspects of the research, from shaping the research question or puzzle and the parameters in which the research is framed, to designing and engaging in the inquiry process, to discussing field texts, to making and communicating meaning through research texts, papers/articles, presentations, performances, and so on.

It is important to note that the mutuality of the research is based on equity, not equality. Although authentic and genuine participation of all co-researchers is critical to collaborative research, this will not look the same for everyone because of the variations in the individual's role, the time the individual can commit, and/or the skills, interest, or confidence the individual has in different aspects of the research. Some aspects of the research may be done together by co-researchers, whereas other aspects are done as divided labor; some aspects may be done synchronously, whereas other aspects are done asynchronously; and some aspects may be done to a greater extent or more frequently by some co-researchers, whereas other aspects are done to a lesser extent or less frequently by others. There may be a symmetry to the actions of co-researchers or perhaps a complementarity to the roles they play. Returning to the earlier example of an inquiry into parent engagement in schooling, co-researcher participation could unfold as follows: All co-researchers would be involved in regularly scheduled and recorded research team conversations to share stories of their experiences with parent engagement, to respond to each other's stories, to make meaning together of experiences captured in field text, and to monitor and adjust unfolding research plans. Some on-site co-researchers may keep field journals and/or reflective journals of their observations or experiences relating to parent engagement. Other on-site co-researchers may record research moments through photographs or the collection of artifacts. While university co-researchers are engaged in recorded conversations with participants (other parents, educators, community members, and staff members who are not on the research team but who can add to the inquiry),

other co-researchers may also be scheduling and facilitating recorded conversations with other participants to add to the field text. Co-researchers may be reading from a diverse range of literature, from parenting magazines to scholarly books and articles, to infuse new and different ideas into research team conversations. Co-researchers, alone or in small groups, may be visiting other school sites to learn about their beliefs and practices in relation to parent engagement. Co-researchers, together as a team or in small groups, may be sharing research in progress or research findings at the school or community level or within local, regional, or national research communities. Flexibility in individually and collectively determining roles, and in negotiating and renegotiating those roles as the research unfolds, enables each co-researcher to participate in ways that are comfortable yet maintain the inclusivity of multiple perspectives and enhance the richness and outcomes of the research program. What remains important is the sense of interdependence among co-researchers, a sense of shared responsibility for the whole of the research, and a sense of mutual respect for each individual and the contribution each individual makes to the research process and results.

Challenges of Collaborative Research

Although the relational nature of collaborative research is one of its greatest richnesses, it is also one of its challenges. Building trust and establishing rapport among co-researchers is central to all research activities yet takes time, contact, space, and support. Spending time getting to know one another at the outset of the research process is an important investment in the research and needs to be considered when the timeline for the research is being established. Building relationships in social and informal settings, perhaps over food and conversation where bonds can develop between individuals and where individuals can begin to know one another personally as well as in relation to research interests, enables the growing of a sense of trust that is essential to collaborative research. Relationships cannot be assumed or taken for granted; they require nurturing and facilitation.

To get to a place where co-researchers can risk being vulnerable with one another, where they can respectfully challenge one another's thinking or interpretations, and where tension can be viewed as a constructive part of the meaning-making process, there needs to be a move beyond the surface congeniality of

relationships to a deeper collegiality based on a moral and ethical commitment to one another and the research purpose. Explicitly establishing research team norms or strategies for conflict resolution or negotiation early in the research process can make having difficult conversations much easier for any team member later on if that becomes necessary.

Other research team issues that may be beneficial to discuss at the outset of the research include leadership and coordination of the team, workload, division of labor, ownership of data, rights of publication, and career and status issues. Attention paid early on to each individual's agenda and interests can avert any later conflict over issues such as power or knowledge differentials, a sense of appropriation of research data or findings, and recognition or status received from the research.

Advantages of Collaborative Research

In response to the debate about how to bridge the gap between research and practice, collaborative research provides a possibility. Because collaborative research is typically conducted in a field setting with practitioners, the knowledge developed is already integral to practice rather than separated from it. Having co-researchers who are authentically inside the experience—co-researchers who have explored it and understand it from the inside—voids this concern with the research–practice divide.

Creating a collaborative research team, a team that represents multiple viewpoints and voices as well as differing positions in relation to the research puzzle, makes the research richer and more complex and pushes the inquiry deeper. The knowledge of the research context and the particularities, specificities, and subtleties of that research context that on-site co-researchers bring to the research add dimensions to the inquiry that outsiders might not discover, perceive, or understand because of their positioning. Working with co-researchers who are inside the experience invites a different problematizing of practice, a reflection gained from participation in both the practice and the research of the practice that engagement in just one or the other could not produce.

Working as co-researchers rather than in the more typical researcher and participant relationship, researchers reduce the chances that they will “other” the participants. When everyone's viewpoints are laid alongside one another, discussed deeply, searched,

and re-researched, understandings that are shared develop and voices speak together rather than for or about some other. The researchers' backgrounds and biases, their positions and privileges, are not obscured or invisible but rather become part of the inquiry and the co-constructed understandings that emerge from the inquiry. There is no longer an author, an authority, speaking on behalf of someone else.

Collaborative research is a choice a researcher makes based on epistemological, ideological, and ethical beliefs. Although it is research that requires a different thoughtfulness about research design and methods as well as about research relationships, it provides a rich possibility for addressing inequities in the social sciences in researcher-participant relationships and for speaking to the artificiality of the research-practice divide. Collaborative research presents a possibility for impact that more typical forms of research might not.

COLLAGE

Collage is an arts-based research approach to meaning-making through the juxtaposition of a variety of pictures, artifacts, natural objects, words, phrases, textiles, sounds, and stories. It is not meant to provide one-to-one transfer of information; rather, it strives to create metaphoric evocative texts through which readers, audiences, and patrons create their own meanings on a given research topic. Usually, material is taken out of context from a range of sources and used to create a new assemblage from the bricolage collected. What underpins the creation of research collages is the attempt to construct meanings about the research question and/or process, the participants, and emerging themes.

Although collage is traditionally thought of as an artistic product, Donna Davis and Lynn Butler-Kisber focused on its analytic function with the belief that meaning can be mediated through images. Davis, a fine- and commercial artist, found that she projected difficulty she was having with a research participant into a collage she was making for another purpose. On examination, she was able to translate the images into words, further articulating her thoughts on the research. In 2006, Sara Promislow presented a paper about using visual collages as an in-depth analytic tool to assist her in articulating what the research experience meant for her (see Figure 1). She created one on the research process and one for each of the participants: "With the rich information and knowledge gleaned from the collages, I was able to continue the research analysis with a deeper and more complex understanding of their experiences" (p. 5).

Joe Norris, Glenys Berry, and Giacomo Guercio detailed a collage-making process from arts-based courses taught by Norris. Students articulated to one another their research topics/questions and browsed through a large assortment of magazines looking for images and phrases that "called" them. They were encouraged to go to what Lorri Neilsen referred to as the liminal space, a threshold in which new meanings can be found (see sidebar on p. 96). They were asked "not to think, edit, or censor" but to collect everything that intuitively spoke to them. Because this was a

Figure 1 “Methodology” Collage by Sara Promislow

Source: “Methodology” (Promislow, 2004), Collage, mixed media, 11 × 9.6 inches. Used by permission.

group process, they also provided pictures and phrases to classmates when an image or phrase seemed to relate to their peers’ topics.

For Norris, the intuitive is the essential first step. Rather than employing a theme analysis and coding approach that creates categories, he invited researchers to take a leap of faith and enter into an imaginative state where meanings emerge through the interplay among the research question, the collected data, and seemingly disjointed images and words. Using Hans-Georg Gadamer’s theory of translation, Norris believes that new meanings can be found in the space between two languages, in this case the visual and the written. Guercio affirmed this in his description of a collage he made to help him understand his life’s journey:

Creating the collage helped me to find certain meanings that were lost during the process of making a living. . . . In observing my collage I see the cause and effect of leaking and escaping from inner and outer spaces that I created. They are the connections of thought and manifestation.

Both Guercio and Davis claimed that color played a large part in their selection of pictures. Davis claimed that it was for mood setting. Guercio knew this but could not explain why. Davis also noted that space and (implicitly) time play roles in collage construction. For her, the aesthetic dimension was as important as the meaning-making process.

The cutting of pictures and phrases is also an analytic, interpretive, and aesthetic act. An image could be cut into a specific shape, such as a square or circle with contextual or extraneous material remaining or removed, highlighting only what the researcher deems essential. Each cut is a highly interpretive and artistic act that will later influence the entire product. Norris encouraged researchers to keep a meta-cognitive log while making a collage. The interplay between the log and the collage acts recursively, assisting in the articulation of thought in both word and image. Davis and Butler-Kisber promoted the use of both the paradigmatic and syntagmatic approaches in research for deeper meaning-making, and the use of the log is one such means. The act of recording why a picture was cut in such a way further articulates the emergent insights. Such recordings do find themselves in the final research product, with the story of the collage making interwoven with the generated meanings.

Kathleen Vaughan provided her analysis as she documented the research process. Similar to Davis and Butler-Kisber, Vaughan’s stories cannot be separated from the topic. Readers witness the relationship between the researcher and the topic and, like the metaphoric “singer/song,” become one. There can be a recursive relationship between the artist and the collage in that the collage can change the artist, thereby making her or him the product.

The arrangement and ultimate “fixing” of images and words in relation to one another is the final act. A phrase placed over an image has a different significance than the same phrase positioned to the side of the same picture. Some collages may contain three-dimensional elements, some have the entire background full, and others may have blank spaces, strategically placing certain like elements together. Berry chose to photocopy all pictures and used the black and white reproductions to cover an entire poster board so as to explore the construct of identity. Size, location, and juxtaposition along with styles of cutting are part of the collage’s syntax and, like written sentences and paragraphs, have both epistemological and aesthetic dimensions. Although the artistic process can be more emergent than deliberate, the intuitive choices are part of the evocative meaning-making structure.

The preceding examples described how researchers have used collages in analysis and dissemination. Morna McDermott took a different approach, using collage as both a pedagogical and data collection tool. She had her preservice teachers create collages

Textual Collage—An Example

Knowledge, like fiction itself, is liminal space. It never arrives. It is always on the brink.

Source: Neilsen, L. (2002). Learning from the liminal: Fiction as knowledge. *Alberta Journal of Educational Research*, 47, 206–214 (quote from p. 208).

as a reflective process to examine their positions on creativity, social justice, and education. Four students were randomly selected to demonstrate the instructional value of collage to all students, and follow-up interviews were conducted. Students reported that through the process they were learning things about themselves. The implication is that collage making could accompany questionnaires, interviews, and participant observation as another data generation technique. Although Davis and Butler-Kisber referred to collage as an alternative form of representation, it must be noted that the term *alternative* has a political dimension. Arts-based researchers consider these methods as legitimate as traditional methods, albeit novel. The choice of collage is one of many possibilities.

But collages need not be visual. Monika Kostera asked her participants to write fictional stories about her research topics and at times has used an opening sentence as a writing prompt. The stories acted like a collage of issues on the topic, and Kostera used these accounts to understand how the participants perceived their lived worlds. She analyzed the written texts and wrote her own composite response that is a collage of the issues brought forth.

Norris also used the theatrical convention of voice collage to highlight the multidimensional aspects of an issue. In “What’s the Fine Line?” six actors read a list of phrases used by youth and adults that encourage and discourage teenage sexual activity. Collectively, they concisely presented the complexity of sexual pressures facing youth. Like Butler-Kisber’s found poems, an artistic composition pithily provides a synopsis of some of the salient features found in the data.

Copyright is an issue that is still being explored by those creating collages. With most research, the use of a small amount of material from other pieces,

if properly cited, is not only considered legitimate but even encouraged as an essential part of a literature review. Visual collages are different. The appropriation of segments from pictures, phrases, and slogans found in magazines, newspapers, websites, and other media is not as clear. Copyrights rest with publishers, photographers, and commercial corporations that did not intend their property to be used in such a way. In addition, collage creators do not cite their sources, and to do so would be awkward. For those who use collages for data generation and interpretation, this is not an issue because the collage remains private. For those who publicly display their collages in academic journals, questions about the use of others’ works still exist. The common position taken is that these images are taken out of their contexts and reframed in new ones, drastically changing the original pieces. To date, the resources used in collage making have not been legally brought into question.

In summary, although collages are traditionally thought of as products, they can be effectively used in all stages of qualitative research. They need not be strictly visual but also can be written and spoken texts. They are meant to evoke disparate meanings in others and strive to communicate on a metaphoric, rather than a transactional, information-giving level.

COMMUNITY-BASED RESEARCH

Community-based research has emerged as a preference among qualitative researchers who engage in inquiry primarily for its usefulness to the social unit where it originates. Research practices engaged in the interests of community service are evolving and have been shaped by the contexts in which the research occurs. Community-based research methods (i.e., for data collection) have been adopted by researchers using methodologies (i.e., epistemological or theoretical stances) that are participatory and based in an ethics of care that guides human relationships. Community-based research emphasizes relationality and the democratic involvement of participants in research events. Many community-based researchers equate usefulness criteria with empowerment. They seek social justice through the potential for research to strengthen communities by facilitating diverse involvement in research practices and promoting critical reflection about the community by members of the community. An overriding interest is in the power of research events to provoke political action. Community-based research is a form of collective action that a community undertakes as key to its survival, its empowerment, or its continued effectiveness in encouraging social and political change.

Characteristics of Community-Based Research

Community-based research is grounded in Indigenous and ethnic community studies and in feminist epistemologies. Various Aboriginal, Mexican American, and African American communities have also engaged in continuing efforts at decolonizing ways of knowing and

understanding the increasingly globalized world. Black community studies arose in university discourse to criticize domination by Western White epistemologies. From the turn of the 20th century, this work stressed the importance of subjective interpretations of human experience, ethnic diversity in experience as the foundation for learning, and commitment to scholarship that linked research, pedagogical praxis, and community service. From DuBois and contemporary Black writers of his time, there emerged a commitment to research that would improve the daily lives of people of color; the service orientation they envisioned was conceived as an opportunity for reciprocal benefit in collaborations between universities and society. This early vision of community-centered action by university researchers was reinvigorated during the 1960s, and again during the early 1990s, through university and community efforts to establish “Black agenda projects” in the United States. These early scholars in Black studies founded the strong tradition of action-centered, political community discourse about diversity that is central to community-based research.

Similarly, feminist epistemologies have generated community-based research practices in which a relational ontology of self–other defines situated knowledge and partial perspectives. This is, again, overtly political research that privileges the participant's own understanding and processes for meaning-making over those of the researcher. In serving the community, feminist researchers strive to redefine the role of the researcher from one of distant impartiality to structure research through interactions and relationships based in empathy, mutuality, and respect for the expert knowledge of the participant.

Ethnic and feminist epistemologies encouraged a tradition of situated research that is continued today in numerous examples of community-based research.

Community-based research is a feature, characteristic, or (alternatively) a condition on which participatory action research, performance ethnography, critical arts-based inquiry, and other new paradigm approaches are contingent.

These and other strands of community-based research exist simultaneously. There are, however, commonalities in the various theories and approaches to performing research in the community. Community-based research across the disciplines addresses positionality, reflexivity, collaboration, voice, and praxis, and it embraces an ethics based in human caring. All community-based research is grounded in methodologies

that challenge privileged access to truth, impartiality, and scientific objectivity. As such, it draws on the “situated knowledge” of both the researcher and the researched (or research participants); that is, knowing depends on the contexts (space and time marked by borders and interruptions) in which it occurs.

Positionality. Positionality is about the situatedness of knowledge. People experience the world from different embodied, social, intellectual, and spatial locations. How we are situated within social spaces and locations, taken in combination with our personal and shared intellectual histories as well as our lived experiences, shapes each of our understandings of the world, our knowledge, and our actions. Humans perceive “self” and are perceived by others in relation to multiple, diverse, and dynamic social processes, including (but not limited to) gender, class, race/ethnicity, age, and sexuality. These social, geographic, and intellectual spaces that we hold individually and as members of multiple communities serve to position us differently in well-established hierarchies of political power and social privilege. Positionality also refers to the embodied presence of the researcher and the participants’ responses to the dynamic interplay of the presence of the researcher in their social world. Knowledge, facts, truths, and understandings are social constructions marked by the continual processes of life as it has been lived. This concentration on positionality and situated ways of knowing calls for research that plays with the ephemeral, vernacular, and dynamic performances of thought and action.

Reflexivity. In the context of community-based research, reflexivity means the ongoing analysis of relationships, power dynamics, and purposes of researchers. Reflexive researchers acknowledge that it is never possible to fully understand oneself or one’s relationships in the community, nor is it fully possible to understand the motivations, purposes, or hegemonic indicators that pull us toward particular understandings, positionalities, or worldviews. Thus, the research remains open to critical evaluation and reconsideration and is, ultimately, flexible to the ongoing dynamics of individual and group development and change.

Collaboration. In community research, collaboration speaks to the involvement of a social group in the use of inquiry methodologies to promote empowerment and facilitate the emergence of the group as a political

voice. In community-based inquiry events, both the researcher and participants are collaborators in the project of doing research. Often their roles are interchangeable, engaged as they are in a reciprocal exchange of ideas. Research design in this mode is sensitive to how values, power, and politics frame “truths.” Interpretations of information are labeled as constructions and are noted as interpretations of the world marked by the contexts in which they are produced. It is typically a collaborative communal project in which all participants, including both the researcher and the researched, acknowledge that they bring social, historical, familial, and other diverse social constructions into their research interpretations. In practice, this critical reflection about how ideas are formed and traditions are created may take the form of autobiography. Furthermore, among practitioners in the paradigm of community-based inquiry, it is widely acknowledged that research is always political, moral, and steeped in the complexities of power, privilege, oppressions, and representations.

Voice. Voice is an important consideration during data collection when the researcher has the responsibility of including members of the community who might otherwise be silenced or marginalized during the processes of doing research. Voice is also a consideration in analytic and representational processes of doing research; it is expected that the researcher will take care to interpret research data in the context of the community from which they arose (rather than back in the laboratory) and to engage multiple people with differing points of view in interpreting data. Finally, it is the responsibility of the researcher to include the voices of others in the representations of research as a function of demonstrating the dynamic ephemeral qualities of research that exists as community activity. For example, artist-researchers accomplish this by creating open spaces and multiple entrances to their work; they create new ways for people to position themselves in the world. They are the catalysts for new interpretations, understandings, and forces for taking action. Within discursive openings, various and diverse members of the community can form new collaborations that have the potential to revise the hegemonic ravishes of relationship and history.

Praxis. Praxis refers to the interplay between reflection and action that is the purpose of community-based research. In praxis-based research, the purpose is to use

the act of doing research as a means to revise stereotypes, habits of mind, and deeply held meanings that guide people's thinking about social and political issues and to encourage actions that demonstrate these changes in theories or worldviews underscoring the ways in which people live in society. Community-based research involves a group of individuals in the processes of doing research for the purpose of social change that will result in social justice and democratic equity.

Ethics of Community-Based Research

An ethics of care is built on the idea that participants in research are co-equals. As co-equals, interviews are replaced by conversations. Discourse among research collaborators is an exchange of ideas. Power dynamics, hierarchy, and political positions are explicated rather than ignored. Ethics sometimes clashes with reality as the balance of power shifts, as purposes for doing research diverge, and as the very personal dynamics of the collaborative research unfold with all of the tensions and rewards known to occur in human relationships. Retaining reflexivity becomes an important act in preserving the ethics of community-based research. Through ongoing discourse about relationships of individuals, the research can stay on track toward rethinking and reforming social values and practices.

Advantages and Challenges of Doing Research in the Community

Probably the greatest advantage of performing community-based research is the potential for the research participants to exercise control over their own lives, solve their own problems, respond to social situations in their own voices, and promote their own causes.

Among the challenges of collaboration is the possibility of co-opting the research event to larger community goals that do not serve social justice or equity but, instead, reinforce systemic hegemony. Who participates in the collaboration depends on the context, the problem that is being researched, and the inclusiveness of the research participants. The research project may include only individuals who are affected by a particular problem, or it may include representatives of social service agencies or other community actors whose role is to address social issues through systemic functions

(e.g., health care providers who work closely with a community to deliver services while also researching the impact of those services). Thus, community-based research differs greatly depending on membership, and democratic participation does not always serve social justice. For instance, if a group of people living in a shelter become activist-researchers seeking information on how to improve the system of services to unhoused individuals, their efforts could be compromised by an existing system of missionary care or governmental interventions that do not include long-term housing if their research collaborative includes representatives of the existing system.

Researchers need to be attentive to a balance of freedoms such that the positive liberties of one community do not create a powerful hierarchy over another community of individuals. Care must be taken to notice whose interests were not represented in the research. Similarly, researchers need to be caring about the human tendency to know "what's best" for others—based on their own worldviews and experiences—such that community-based research can become colonizing in the same ways as can expert-directed research; the experts are just differently named and larger in number as constituents of a community. Involving all stakeholders in a research project is more easily said than done. Rifts can occur between members of communities and the holders of resources (e.g., university researchers) and can create unintended new power hierarchies. Inclusion carries its own difficulties in that open dialogue can be thwarted in situations where trust is in question. It is always difficult to attend to questions such as "whose truth" is being represented in research, especially when it is a given that different truths exist simultaneously.

COMPARATIVE ANALYSIS

Comparison is at the heart of most social sciences research. Comparison can take place between different entities, such as individuals, interviews, statements, settings, themes, groups, and cases, or at different points in time. These entities or time periods are then analyzed to isolate prominent similarities and differences, a process that is described by the term *comparative analysis*.

A prominent strand of comparative analysis is “constant comparative analysis,” which stems from the grounded theory methodology of Barney Glaser and Anselm Strauss. It involves taking one entity or piece of data, such as a statement, an interview, or a theme, and comparing it with others to identify similarities or differences. By isolating these aspects, it is then possible to develop a conceptual model of the possible relations between various entities. Researchers may, for example, compare the accounts or experiences of two different people who experienced the same event or are in similar contexts to engage in analytic accounts of why there are differences and how these two individuals’ experiences are related to one another.

Comparative analysis is also a primary task within case study research. Case studies are often compiled with the knowledge that comparisons will be made with the description of a particular case. In some instances, researchers will compare a particular case with that of a hypothetical reference group or frame of reference to highlight differences. This focus on comparison is at odds with the approach of “thick description” by Clifford Geertz, where the detailed description of the case itself, as opposed to the comparison, is the focus of the study. A comparative qualitative approach to the examination of cases is often via the examination of a few cases in a very intensive manner.

COMPARATIVE RESEARCH

Comparison in qualitative research is inescapable. The importance and utility of comparative research penetrate virtually all types of qualitative research projects. *Comparative research* is a broad term that refers to the evaluation of the similarities, differences, and associations between entities. Entities may be based on many lines such as statements from an interview or individual, symbols, case studies, social groups, geographical or political configurations, and cross-national comparisons. Comparative research is used within most qualitative approaches, such as comparisons by core emic categories in ethnographic studies, within-case comparisons in phenomenology, case study comparisons, comparative politics, and examination of contrasts in narrative and discourse analysis.

The goal of this entry is to define and outline the goals of comparative research, provide some examples in the field, and then discuss some of the central issues and problems in qualitative research. These include (a) case selection, unit, level, and scale of analysis; (b) construct equivalence; (c) case or characteristic orientation; and (d) issues of causality.

The Goal of Comparative Research

The underlying goal of comparative research is to search for similarity and variation between the entities that are the object of comparison. The examination of similarity often means the application of a more general theory and a search for universals or underlying

general processes across different contexts or categories. The ontology of patterns or categories is assumed to be universal and independent of time and space. In other words, the comparison should be broad enough to allow researchers to compare at a “higher level” of abstraction. However, it remains difficult to determine these general patterns. For this reason, comparative research is often used to separate patterns that are more general and isolate regularities or discrepancies from the context-laden environment. Following Max Weber’s comparative sociology, for example, the search for variance places more emphasis on context and difference so as to understand specificities. Comparisons not only uncover differences between social entities but also reveal unique aspects of a particular entity that would be virtually impossible to detect otherwise.

Examples of Comparative Qualitative Research

The majority of qualitative research relies on some type of comparison either to establish regularities, categorizations, and links or to understand phenomena within the context they are observed and experienced. Because comparison is often a key aspect in studies, there are numerous examples of comparative research across a variety of topics and disciplines. Several examples aid us in understanding how we can use these methods to engage in a comparative study design.

A well-known type of comparative analysis used in qualitative research is Barney Glaser and Anselm Strauss’s technique of “constant comparative analysis” derived from the sociological theory of symbolic interactionism. The central task is to compare one piece of data with all others to compare similarities and differences. Data may be in the form of an interview, a statement, a theme, or another specified unit. These comparisons are used to develop categories and conceptualizations and then to examine potential relationships between these categories. The researcher then compares each new interview, account, or observation until all of them have been compared. This technique is frequently used in narrative research. Using the lens of phenomenological theory, for example, George Butte examined the historical shift in literary subjectivity and intersubjectivity via a comparative analysis of 18th- and 19th-century English novels. Comparative analysis is a useful technique to establish general phenomena such as processes of

marital breakdown, stages of grieving or coping with illness, and other fundamental processes.

Another common comparative application within qualitative research is that of cross-national comparisons. A long-standing practice in ethnography is the use of “controlled comparison” of different societies stemming from the work of Frederick Eggan during the early 1950s. More recent examples include Sneja Gunew’s cross-country comparative study of the meaning of multiculturalism in Canada, Australia, the United States, and the United Kingdom. This research was grounded in comparative studies and Donna Haraway’s prominent concept of situated knowledge or the idea that meanings are often embedded in local, national, and global contexts. Cross-national qualitative case study comparisons are also often used within political science in the research fields of comparative politics and international relations. The use of comparative methods and measurement issues in comparative politics has been the central focus of authors such as David Collier. Researchers can also refer to the widely used book on qualitative data analysis by Matthew Miles and Michael Huberman, who provided a more detailed list of strategies for comparison and advice on how to use these strategies.

Central Problems in Comparative Research

Comparative research poses several key methodological problems that continue to frustrate, captivate, and stimulate researchers. These are the selection of cases (including the unit, level, and scale of analysis), construct equivalence, case versus characteristic orientation, and the debate regarding causality.

Case Selection and Unit, Level, and Scale of Analysis

Bernard Ebbinghaus recently argued that case selection or sampling is one of the most critical problems in comparative research. In cross-national comparative research, cases have been preselected due to historical and political processes. In small-*N* qualitative studies, the selection of cases is often deliberate and theory driven. This is what Charles Ragin categorized as the difference between a “given” population and a “constructed” population. Because the constructed population is more theory driven, it is likewise more driven by the researcher and may be open

to favoring the findings of a particular research question. Conversely, although given or taken-for-granted populations are seemingly objective, they may contain many irrelevant cases that significantly affect the results.

In addition, researchers need to decide on the scale of the analysis. The choice lies between a small sample size and a relatively large sample size (often referred to as the N), each of which poses specific problems. In the case where the choice is to include a large number of units (e.g., countries, cases) with only scant, more general comparative characteristics, the researcher runs the risk of producing superficial results. On the other hand, if the choice is to include only a few units of analysis with a large amount of descriptive depth and characteristics, there is the risk of having too many comparative characteristics and too few cases to effectively examine different explanations or causal models. Some qualitative methods, such as phenomenological approaches, do not aim at finding common patterns but want to find the underlying structure or essence via an intensive descriptive study of individual cases. Other ethnographic approaches also choose to examine detail and depth and to engage in in-depth comparisons within one case.

Yet it is not only the unit but also the level of analysis that is vital for comparative research, and this brings problems on the substantive, theoretical, and methodological levels. This is the difference between studying the effects of macro-structural aspects, such as cultural norms, and studying the effects of micro-level individual characteristics, such as an individual's position in a kinship group or meaning ascribed to certain norms. Another related problem that emerges with case selection is that the unit of analysis or population under study is not always self-evident, for example, the nation-state in cross-national studies or the unit of speech or text in narrative or discourse analysis. Finally, among other issues is the issue of how to deal with large comparative differences across groups such as variation in cultural norms or the value of certain objects or meaning attributed to different aspects across groups and societies.

Construct Equivalence

Because the goal of comparative research is to search for both similarity and variance in cases, research necessitates equivalent instruments or definitions to

measure constructs. Many argue that cross-cultural or cross-national comparisons are valid only when there is construct equivalence. Construct equivalence refers to the instance where the instrument measures the same latent trait across all speech units, groups, nations, or cultures. This includes, for example, efforts to build cross-national and cross-group comparative categorizations of ethnicity, class, or sexuality.

The necessity of equivalent comparison within comparative studies also forces us to debate the utility and meaning not only of standard analytic concepts, such as race and class, but also of seemingly straightforward concepts, such as age and gender. The ethnographer Clarence Gravlee, for instance, demonstrated that the term *race* as used in the North American context is vastly different from what Latin Americans mean for the same term. Cross-national or cross-cultural comparisons of constructs allow researchers to identify which definitions transcend a particular context or which are nation or cultural bound.

Case Versus Characteristic Orientation

Another broader debate within comparative research pertains to the orientation of the approach. The case-oriented approach used in many qualitative methods aims at fully understanding one case, or only a few cases, with "thick description" or rich data, thereby using many comparative characteristics or variables. This is in opposition to a more quantitative variable-oriented approach that stresses the search for parsimony (i.e., the statistical explanation of variance in many cases by means of only a few variables or characteristics). There is a vibrant debate within the literature on this issue, focusing largely on whether researchers should concentrate on characteristics or define comparisons by "sets" of cases.

Causality

Causality is another central methodological issue in comparative research. However, the definition and very relation to the concept of causality differs fundamentally between quantitative and qualitative approaches and has been an area of fierce debate. The more positivist and quantitative nomothetic notions of causality, such as those based on David Hume and

advocated by John Goldthorpe, attempt to draw out regularities and specify the underlying social mechanisms and processes that generate these regularities. Conversely, a wider debate within qualitative research questions the very validity of the concept of causality (e.g., by Yvonna Lincoln and Egon Guba) or challenges the necessity to establish universals with variable-oriented approaches (e.g., by Ragin). Joseph Maxwell provided an excellent summary and discussion of strategies for causal explanation using qualitative methods.

Qualitative researchers are often interested in examining differences, similarities, and associations among a variety of objects such as statements, individual meanings, and political configurations. This makes comparative research virtually inescapable. To accomplish this, researchers need to consider vital aspects such as selecting a particular case or scale of analysis, defining constructs, and deciding whether they will focus on cases or characteristics. Comparisons can then take place on a variety of topics using many different types of qualitative methods.

COMPUTER-ASSISTED DATA ANALYSIS

Qualitative software packages offer a range of functions that serve as resources for analyzing qualitative data. These functions allow users to simulate off-screen approaches used to work with qualitative data. As qualitative software products continue to evolve, they move beyond simple “code and retrieve” tools. Some programs offer specific functionality to imitate simple highlighting of text and writing of margin notes. The ability to diagram ideas and create models that develop over the course of an analysis continues to progress as well.

Qualitative software can be considered as a basic “toolkit” containing specific tools that help users to organize and record thoughts about and reactions to data as well as tools to access and review the material they organize and record.

The Basic Toolkit: Tools to Organize and Record

A three-system foundation forms the core of qualitative software programs. The *document system* allows users to maintain the integrity (the original look and content) of each data document used within a package. The *memo system* provides an opportunity to record notes of different lengths and depths throughout the life of an analysis. The *category system* contains tools to organize data at two different levels. First, entire data documents can be organized according to their attributes. This organization facilitates filtering and comparison according to characteristics of documents, for example, comparing women’s documents

with men's documents or comparing documents in which someone either reveals or does not reveal a personal trauma. Second, individual sections of data documents can be organized into codes. Simple code and retrieve procedures can be used for summary by code topic. More complex procedures can be used to evolve code meanings and definitions, to explore how combinations of codes applied to data influence ideas that emerge during analysis, and to pursue answers to questions that preceded data collection.

Document System

Initially, researchers make decisions about what type of data they will collect and how they will manage those data within software. The document system within qualitative software is the primary tool for storing each data document users work with in a qualitative software package. A document can be in the form of text, graphic, audio, or video file. Several packages allow the use of rich text or Word files, thereby maintaining the original formats (e.g., bold, italic, underline, color) present in documents when they are reviewed within a software package. In software packages where users can engage with multimedia files (e.g., photographs, audio, video), the program either permits full engagement with a file or has a linking system where the users connect an entire multimedia file from within the body of a text document. This procedure works like weblinks placed in the body of an email. Direct work with a multimedia file proceeds in the same way as work with a text document. Users can write notes about all or parts of the file. Sections of the file can be marked and/or coded for later retrieval, and entire files can be organized by major categories that characterize them.

Although users do not engage directly with the document system within a software package, the document system serves to manage and track their data documents. In programs where users can edit files, the document system automatically tracks how any changes caused by editing data documents affect the placement of codes and memos. The codes and memos placed before any edits automatically adjust so that these items remain with the original text where they were first placed.

When users review each segment of text coded to a code or to which they attached a memo, they are able to view that text within the body of the document where it originates. The document system is the core

tool that maintains the integrity of users' original data document so that users are able to view these sections of text in context.

Memo System

Qualitative software offers an opportunity to write memos and locate them in places that are easy to access. These memos vary in size and content. Memos can be simple reactions to a section of a fieldnote, an interview, or a focus group, or they can be reactions to complex theoretical treatises. Users can write a memo about any individual data document, about any section of text, about any code, or about any independent topics that arise in the course of their analysis. In essence, memos about documents, codes, and sections of text are the equivalent of "sticky notes" that users place on those items. Just like working within a word processor or on a notepad, memos in qualitative software are live, editable documents into which users can copy quotes from documents. Any memo that users write can be saved and opened in their word processors. Reminder icons and memo lists help users to access their memos for retrieval, reaction, and adjustment. Memos are easily exported to users' word processors for further editing and integration with other writing on their research topic.

Category System

There are two primary levels of categorization within qualitative software. Researchers can categorize entire data documents into attributes for sorting and filtering larger data sets. In addition, sections of a document can be grouped together to gather examples of topics represented in codes designated by researchers.

Attributes

If a study involves comparisons of groups of data, attribute functions of qualitative software can be helpful. Major variables and points of comparison can be entered into a program, and researchers can identify which documents belonged to specific subcategories of each variable. For example, researchers can add information about participants' background characteristics to compare along lines of gender, age, income, race, ethnicity, and political or religious affiliation. For mixed-methods studies, spreadsheet files that contain

background information and/or responses to key questions can be imported into qualitative software, and specific responses can be associated with corresponding qualitative documents. Points of comparison that arise during review of data documents can be added as well. For example, if researchers discover that some participants experienced financial challenges, this category can be added as well and the sample can be categorized according to who did or did not experience financial problems. Organizing data by attributes of data documents allows researchers to focus reviews of topics represented in code categories. Discussions of religion can be read for all women who live in the northeastern United States and then for all men who live in that same region of the country. These steps help researchers to answer foundation questions that define their analysis.

Codes

Codes are used to organize sections of text into key topics defined by researchers. A review of text by codes is a key component of diagnosing patterns of discussion within qualitative data. Codes can be created, maintained, and adjusted within codebooks, which are inherently flexible. Some researchers start a project by entering deductive codes into their qualitative software program. These codes might arise from research questions, topic literature, and/or interview and data collection protocols. Inductive coding is also possible. New topics that arise via document review can be made and applied to the selections of data where they first appear and throughout an entire data set. Codes can be renamed, deleted, combined, and broken into smaller subcategories.

Codes can also be applied via search facilities within qualitative software. Researchers can search for instances of “health” and code results along with surrounding text to a code category. For more structured data, researchers can use “autocode” functions to sort all responses to each question of an open-ended survey or a structured interview into its own code folder. Use of this feature requires minor data formatting to enable this functionality.

Supplemental Tool: Marking and Labeling Key Sections of Text

As qualitative software evolves, efforts to simulate all tasks that qualitative researchers do off-screen

imitated inside software continue to increase. One area of focus is an early phase of analysis where researchers gain familiarity with text and their reactions to it via a first read. At this time, it is common to simply highlight sections of text and write notes with reaction and reflection in the margin of the document. There are several advantages to this form of computerized text highlighting.

Visual Aid. As with a manual highlight pen, computerized highlighting results in a mark placed over or next to the text that users highlight. This visual aid allows users to easily recognize this section of text on a second review.

Gathering Tool. Sections highlighted within qualitative software are added to a convenient list that allows easy retrieval and examination.

Labels for Sections. The highlighted sections can be named or labeled. To distinguish this process from coding, users are not gathering examples on a topic with this feature. Instead, they are labeling and naming individual sections with what can be considered “nicknames.” All of these labels can be reviewed as a transition into shaping a codebook.

Foundation for Data Profiles. Highlighted sections of text can be imported into diagrams to create pictures and profiles for all or part of a data document or series of documents.

The Basic Toolkit: Tools to Access and Review

Any item created within the systems introduced in the previous section can be reviewed as a means of gaining clarity of its meaning and import to the analysis at hand. Simple memo and code retrieval tools assist in this process. It is important to note that access and review of any memo, code, or combination of these items is not an isolated task. Software packages are built to invite continual evolution of ideas. The names and content of memos, codes, and attributes are easy to adjust as researchers refine their developing understanding of each item. These processes often dictate how researchers take advantage of co-occurrence and diagramming tools found within qualitative software. Researchers use co-occurrence tools to find instances where codes, originally applied by them, occur in

combination (or not in combination) within and across data documents. Changes to these tools now allow researchers to find an anticipated combination of codes (e.g., every time health and finances are coded together) or to assess combinations that they did not predict. This latter function encourages discovery of serendipitous connections. Researchers use diagramming tools as a way to explore potential connections or to design models to portray concrete ideas for presentation.

Simple Retrieval Tools

As users label and organize data into categories and write memos, they begin to reflect on what their efforts are teaching them. Memos, coding, and categorization efforts can be retrieved in isolation or combination to help users assess what they have learned and to help them determine next steps.

Memos

Memos that users write are available for retrieval in two ways. First, lists of memos are available for independent retrieval. As users read any individual memo, they can edit text and/or add sample quotes from their data. Memos can be saved and opened in a word processing program. This facility makes memos portable. They can be attached to or pasted into emails to share with colleagues and research team members.

Memos that were written alongside sections of text can be retrieved as users review codes and co-occurrences. If users coded a section of text to religion and wrote a note about that text, they can opt to display their note along with that text on retrieval. This strategy is common and allows for thinking out loud and linking ideas in data with thoughts and reactions to text with knowledge of material that users bring to their data.

Memos evolve as analysis progresses. They serve as useful transition points in analysis and help to build the foundation for final written material about users' project.

Codes

A core function within qualitative software is the retrieval of all segments of data coded to sections of text. Users can examine complete sets of text coded to any one topic for summary and reflection. Early in a project, this process allows users to determine the importance of a category and the effectiveness of coding efforts. Later in a project, summaries of codes facilitate important conclusions about a data set.

Codes can be reviewed on-screen or in report form. On-screen code review encourages adjustments to

coding. Users can remove or replace codes from text, adjust the amount of text coded to a category, and add memos during this review. They can also review all instances coded to a category in a report for a direct summary of that topic. These reports can be read in users' word processors and/or shared with colleagues. It is common for research teams to share information about key topics using this tool.

Filtering for Comparison

Filters can be applied prior to a review of codes and memos to narrow and focus users' search of these items. For example, users can filter their data set to just the women's documents before they review all instances coded to religion. All coded instances that users review will appear with corresponding memos for just the women's documents. This step should give users a better perspective of women's experiences with and perspectives on religion along with their thoughts on women's discussions of religion. Users can then change their filter to the men's documents to gain a better picture of gender difference. Filtering can be used for single variable comparison or for exploration of how combinations of variables, such as gender and age, affect discussions and experiences within users' projects.

Co-Occurrence Tools

The ability to retrieve co-occurring codes is one of the major features that distinguishes qualitative software from simple code-and-retrieve programs. Rather than just seeing all quotations coded to religion or all quotations coded to health, co-occurrence tools allow users to retrieve all quotations coded to both religion and health, providing better access to the ways in which two codes interact. The existence of co-occurrence tools enables users to monitor single concepts, such as religion and health, and dynamic ways in which topics combine to potentially build thematic discussion.

Co-occurrence tools can be used to find instances where the same two codes are applied to the same text or for more specific questions of how the location of two codes falls across users' entire data set. Users can find instances of one code inside another code, one code overlapping another code, and/or one code preceding a second code. Pursuit of options within co-occurrence tools is determined by users' research questions and goals and their evolving analysis. Recent innovations in these tools allow more flexible engagement with co-occurrence. Previously, these tools required researchers to know code connections,

such as religion coded with health, before they searched for a co-occurrence. New tools monitor co-occurrences throughout a project. At any point in the coding process, users can assess all codes that overlap. They can focus on the religion code and see every code that overlaps at least once and then move to each section that overlaps. Serendipitous connections are now more accessible because of these changes.

Diagramming Tools

Diagramming tools in qualitative software (frequently called maps, models, or networks) can be used for brainstorming about potential or real connections researchers uncover in their analysis or for presenting concrete ideas to an audience. Researchers can link component parts of a project to display connections they are pursuing. Increasingly, researchers have the ability to link any part of their project to any other part of the project. Typically, researchers link codes to codes to show component parts of code groups or how one code might relate to another.

More dynamic connections are available in models of different programs. Users can include icons to represent different sections of text that contribute to an important conversation. Clicking on icons brings users to the text of the data documents. Users can also link data documents to diagram connections between individuals within a data set. Graphic files can be added to maps as well to enhance the messages conveyed by maps. Although currently the functionality presented in this paragraph is uneven across programs, the discussion does represent what is possible and might predict what to expect as functionality converges across programs in the future.

Diagrams created in any program can be exported for work in word processing, presentation, and visual diagramming programs.

Supplemental Tools: Tools for Integrating Qualitative and Quantitative Research and Facilitating Teamwork

Integrating Qualitative and Quantitative Research

If a project requires a combination of qualitative and quantitative data, researchers can use tools to import or export quantitative information to a project. Spreadsheets that provide demographic and survey information for respondents can be imported to a qualitative software program. This information can

be linked to data about these individuals within researchers' qualitative software projects. Importing quantitative information provides the foundation for comparisons outlined earlier in the "Filtering for Comparison" section.

Qualitative software also provides counts of coded instances by code. Counts for individual codes appear next to codes in codebook displays. In addition, tables showing code distribution across documents can be exported to spreadsheets and, in some instances, directly to SPSS software. These outputs can be linked to quantitative databases for further exploration.

Teamwork

Teamwork continues to be an area of focus for qualitative software developers. Research teams can use output reports to share information on key topics. Log-in functions provide basic information about who works on different sections of a data set. Component projects worked on by different members of a team can also be combined via teamwork import and merge functions of qualitative software.

CONCEPT MAPPING

Concept mapping creates a visual representation of the relationships among a set of targeted topics. The goal of concept mapping is to create an actual map where the concepts are represented as nodes and the relationships between them are represented as lines that link those nodes. In addition, the links are often labeled with descriptions of the relationships between the concepts they join. The result of concept mapping, thus, is similar to a network diagram that captures the relationships among a set of topics. In qualitative research, concept mapping can be used in both data collection and analysis processes.

Uses for Concept Mapping in Data Collection

Concept mapping provides a procedure to guide the participants in either individual interviews or focus groups through the generation, classification, and interpretation of the relationships among a set of key concepts. Instead of simply encouraging a dialogue that is later transcribed and coded by researchers, concept mapping allows the participants to be more closely involved with analyzing and interpreting key

topics. In addition, it produces a concrete visual summary of this process.

Concept mapping exercises provide new opportunities to “give voice” to participants and offer insights into the meaning that participants ascribe to their experiences. The original language of participants is preserved as they do the work of sorting and linking the various concepts, providing further understanding of the meaning and significance of not just specific connections but also the overall network of connects that the participants produce. This kind of rich interpretive data is especially likely to occur in concept mapping exercises that are divided into two parts, starting with the creation of the initial map and followed by a more reflective consideration of how this particular map summarizes the overall set of relationships among the concepts.

The initial input for concept mapping consists of a list of concepts that the individual participants arrange and connect in a physical layout. In both individual and group interviews, one of the central issues is whether researchers present a list of predetermined concepts for mapping or whether the participants themselves generate the list of concepts. The main advantage of an externally generated list is the greater ease of making comparisons across the full set of the maps, all of which will share the same set of possible concepts and, thus, differ only in the ways in which participants connect those concepts. Alternatively, letting the participants generate both the list of concepts and the connections among them produces a more emic insight into their thinking but at the expensive of less straightforward comparability across a more diverse set of maps.

Among the range of alternative ways in which to do concept mapping, one of the best-known approaches is a formalized set of procedures developed by William Trochim. His version of concept mapping typically relies on groups that work with a predetermined list of concepts. Each member of a group receives a set of cards with one concept per card, and the participants then sort those cards into piles according to how similar or closely linked the concepts are. The combined pile sorts from a group provide data on how “close” any two concepts are based on how often the group members sorted them together. These data on the closeness of pairs of concepts serve as input to multidimensional scaling and clustering software programs that generate maps describing the overall pattern of closeness across the full set of concepts. Thus, Trochim’s approach creates maps by applying software tools to inputs from the participants rather than

having the participants produce the maps directly, although the resulting maps are often used to generate further discussions in later interviews.

Regardless of how the concept maps themselves are generated, two of the most common research design options are (1) making systematic comparisons of the maps produced by different categories of participants and (2) using repeated interviews where the maps from earlier sessions are presented as “stimulus material” in later interviews. For systematic comparisons, purposive sampling divides the participants into different categories so that researchers can investigate the similarities and differences among these sets of maps. In applications that involve program planning, such comparisons are often used to understand the thinking and preference of different “stakeholder” groups. For repeated interviews, there is typically an intervening process between the rounds of interviews where researchers analyze the various maps from the original participants to create summary maps before showing the results of those analyses to either the same participants or an equivalent set of participants. To continue the previous program planning example, the research team might produce a summary map for each stakeholder group and then use this set of summary maps to find out how each group reacts to the thinking of the other stakeholders.

Uses for Concept Mapping in Data Analysis

This section concentrates on concept mapping as a broad approach to analyzing qualitative data. It is worth noting, however, that concept maps can also be used as a more specific tool for examining interviews and other forms of text data. The most common version of this method, developed by Susan Jones, begins by locating the key concepts used to discuss a topic and then reviewing the text to capture links among those concepts. Thus, in analyzing a set of interviews, researchers would create a concept map for each participant to summarize that person’s thinking on the research topic and then make comparisons across these different conceptual summaries.

The more common use of concept mapping in qualitative analysis, however, is to represent and capture researchers’ own thinking after earlier work on coding and conceptualization. This process usually involves the creation of network diagrams where lower level codes are grouped into a set of more conceptual codes, which are then linked in ways that summarize their relationships. In other words, researchers create a

concept map that represents their own thinking about the key concepts in the data and how those concepts are related. Indeed, the implementation of this process within qualitative software packages such as ATLAS.ti, MAXqda, and NVivo is very similar to that within other software programs that implement this kind of free format concept mapping for a wide variety of purposes such as decision making and educational applications. It is interesting that this increasing use of concept mapping within the overall process of qualitative analysis has not been accompanied by greater attention to concept mapping as a method for data collection. Perhaps either the analysis of concept maps as an explicit form of data or the use of concept maps as an early step in the analysis process will help to create a connection that is currently missing.

CONCEPTUAL ORDERING

Conceptual ordering is a method of organizing data into discrete categories by assessing the data’s properties or underlying meanings and then using these properties to categorize the data into groups. At times it can be helpful to use ratings when organizing the data, for example, rating the level of importance of each of the categories. Conceptual ordering is a first step in developing themes. After conceptual ordering, the data can be grouped into similar categories and then themes can be developed.

There are multiple methods for accomplishing conceptual ordering. Concepts can be the basis for ordering the data, as can other schemas such as time or roles of

the participants. An example of conceptual ordering is an ethnographic account. Ethnographers work to present the actions and beliefs of participants in an ordered fashion. Another example of conceptual ordering is when data are ordered according to time or stages. A final example of conceptual ordering occurring is when data are organized according to actors or actions.

When data have been ordered conceptually, it can be helpful to depict the ordering in a display. There are two common methods of displaying conceptually ordered data: within-case and cross-case. Conceptually ordered within-case displays present information for one case (i.e., a person or a group of people), whereas conceptually ordered cross-case displays present information for comparing two or more cases. The multiple types of within-case and cross-case displays are outlined in what follows.

There are many types of conceptually ordered within-case displays, including conceptually clustered matrices, thematic conceptual matrices, effects matrices, folk taxonomies, and cognitive maps. The first type of conceptually ordered within-case display, conceptually clustered matrices, connects data so that there is conceptual coherence. The matrix is created in table format with multiple research questions included. The responses to these research questions are placed in the body of the table. Ordering the data in this matrix assists the researcher in seeing possible connections among the concepts under investigation.

The second type of conceptually ordered within-case display, thematic conceptual matrices, has a foundation based on themes. Specifically, a thematic conceptual matrix reflects an ordering of themes. To create a thematic conceptual matrix, the researcher starts by clustering those data, in other words, putting similar data together and reading through them to identify underlying issues or problems. These underlying issues then are used as headings in the matrix to assist the researcher in identifying similarities and differences in the data.

The third type of conceptually ordered within-case display is an effect matrix. When researchers have complex data with multiple cases and are interested in relationships, developing an effect matrix can be beneficial. Effect matrices are appropriate when there are “ultimate” outcomes. Effect matrices help the researcher to identify occurrences of change, for example, displaying the “before” and “after” impressions of a new teaching strategy.

The fourth type of conceptually ordered within-case display is a case dynamics matrix. Here the qualitative researcher displays a set of elements for change and attempts to link consequential processes and outcomes for the purpose of initial explanation. As such, case dynamics matrices help the researcher to examine cause and effect.

Not all conceptually ordered displays are in matrix format. Network formats, including hierarchical tree diagrams, can be used. These are commonly referred to as folk taxonomies. Folk taxonomies tend to be idiosyncratic aspects that are not labeled and that can have overlapping categories. More specifically, folk taxonomies typically represent a hierarchical tree diagram that displays how a person classifies important phenomena.

When data are not hierarchical, the fifth type of conceptually ordered within-case display, a cognitive map, can be developed. Frequently cognitive maps contain data for one person—his or her thoughts, perceptions, and/or beliefs. To create a cognitive map, the researcher identifies concepts and nodes and the relationships among each.

When the researcher is interested in comparing across cases, a conceptually ordered cross-case display can be useful. The main type of conceptually ordered cross-case display is a content analytic summary table. The data in a content analytic summary table can be organized by concepts or by demographic information (e.g., job position, gender, level of ability). The foundation of a content analytic summary table is building a matrix that allows the researcher to examine the data without referencing specific cases. Matrices or decision trees commonly are used to represent the table. When generating a matrix, the researcher can use substruction or dimensionalizing, which refers to identifying underlying themes or dimensions systematically. Cross-case content analytic summary tables can illuminate how concepts play out in different cases. Other conceptually ordered cross-case displays include variable-by-variable matrices (i.e., tables that display two major variables in the rows and columns ordered by intensity with the cell entries representing the cases), causal models (i.e., networks of variables with causal connections among them to provide a stable set of propositions or hunches about the complete network of variables and their interrelationships), causal networks (i.e., comparative analyses of all cases using variables deemed to be the most influential in explaining the outcome or

criterion), and antecedent matrices (i.e., displays ordered by the outcome variable that display all of the variables that appear to change the outcome variable). Thus, the qualitative researcher has numerous ways of conceptually ordering data.

CONFIDENTIALITY

Respect for confidentiality is an established principle in research ethics codes and professional codes of conduct. More broadly, in many cultures confidentiality is also considered as fundamental to human dignity. Researchers often give assurances of confidentiality to protect the privacy of research participants. This means that information shared with researchers will not be disclosed in a way that can publicly identify a participant or source.

There are many reasons for respecting confidentiality. It can protect people from embarrassment or save them from harm or stigma. Promises of confidentiality are usually necessary when researchers seek sensitive data such as information about health, sexual behaviors, drug use, tax evasion, and other personal secrets. Without confidentiality, many people either would refuse to take part in sensitive research or would be less forthcoming with the information that they share with researchers. Therefore, confidentiality helps to enhance both the quality and validity of data.

Confidentiality can be protected in various ways. Sometimes participants are truly anonymous and cannot be identified in any way, for example, when people use pseudonyms in secure internet chat rooms. Researchers may also remove identifying information from coding sheets or interview transcripts so that no

particular response can be linked to a specific person. Identifying information is sometimes stored in a secure location separate from the data that will be used for analysis. This allows researchers to keep track of participants without compromising their confidentiality.

A participant's confidential relationship with a researcher can depend heavily on the commitment the researcher makes to guarantee confidentiality. In Canada and the United States, researchers have faced legal threats to compel disclosure of confidential data. In 1993, Rik Scarce, a Washington State University graduate student, was jailed for 159 days for contempt of court when he refused to disclose information to a grand jury about animal rights activists. In 1994, Russel Ogden, a graduate student at Simon Fraser University, was subpoenaed to a coroner's inquest for his research into assisted suicides among persons with HIV and AIDS. He refused to violate a promise to his participants of "absolute confidentiality" and eventually established a common law privilege to protect against disclosure of identifying information. Since then, Ogden has resisted two more subpoenas from Crown prosecutors to a criminal trial on assisted suicide.

Although the experiences of Scarce and Ogden are relatively rare, they highlight the conflict between researchers' ethical responsibility to participants and competing obligations to law. In Canada, there have been calls for the development of law that will allow researchers to promise confidentiality without fearing a legal challenge to such promises.

In the United States, some criminological and health research can receive statute-based protections. Researchers funded by the National Institute of Justice can apply for "privacy certificates." Regardless of the funding body, health researchers can make applications to the National Institutes of Health for "certificates of confidentiality."

CONFIRMABILITY

In qualitative research, the actions and perceptions of participants are analyzed for their expressions of meaning within a given context. Consistent with the practices of the selected qualitative methodology used, the researcher then interprets the participant expressions through a coding or meaning-making process. In this coding process, the researcher is looking for messages that are consistent with, confirm, or expand on current knowledge and theory. From these insights, the researcher is then able to make statements about the context under study. In so doing, additional processes must be incorporated into the research design that verifies the truthfulness or meaning being asserted in the study. This is called confirmability.

Confirmability is often equated with reliability and objectivity in quantitative research. Reliability and objectivity are measures of the accuracy of the truth or meaning being expressed in the study. The epistemological function of this process is to suggest that truth and meaning are reliable only to the point where they can be verified as more than just a singular event peculiar to that specific research endeavor and researcher. This is essential because it is an academic process that moves the research beyond a one-time event into a framework where meaning and truth can be used to build on, expand, or create theory.

Confirmability is an accurate means through which to verify the two basic goals of qualitative research: (1) to understand a phenomenon from the perspective of the research participants and (2) to understand the meanings people give to their experiences. Confirmability is concerned with providing evidence that the researcher's interpretations of participants' constructions are rooted in the participants' constructions and also that data analysis and the resulting findings and conclusions can be verified as reflective of and grounded in the participants' perceptions. In essence, confirmability can be expressed as the degree to which the results of the study are based on the research purpose and not altered due to researcher bias.

Although confirmability does not deny that each researcher will bring a unique perspective to the study, it requires that the researcher account for any

biases by being up front and open about them and use the appropriate qualitative methodological practices to respond to those biases. For example, a researcher using discourse analysis can have multiple coders of the same data to establish a measure of the consistency in the coding of themes. The researcher can also make the research process as transparent as possible by clearly describing how data were collected and analyzed and possibly offering examples of the coding process in the final document. Confirmability can also be expressed through an audit trail where an independent reviewer is allowed to verify the research process and interpretations of the data as consistent on both the literature and methodological levels. Selected participants can also be asked to review some of the coding and meaning-making process to determine whether the researcher's interpretations are consistent with their perceptions.

CONFLICT OF INTEREST

Conflicts of interest occur in research projects when researchers have coexisting personal, financial, political, and academic interests and the potential exists for one interest to be favored over another that has equal or even greater legitimacy in a way that might make other reasonable people feel misled or deceived. Researchers risk appearing to be negligent, incompetent, or deceptive.

Such conflicts have been best explored in the biomedical literature on cases where academics who benefit financially from industry—through research funding, consultancies, or royalties or by holding shares in companies—are more likely to reach conclusions that favor their corporate sponsors. On some occasions, they have conducted research of lower quality and have been less open to peer review.

Although social scientists may be less likely to have a financial stake in their research areas, they

may still need to negotiate financial or contractual relationships with corporations or government agencies. So, should they accept contracts where clients hold a veto over publication? Should they disclose corporate or government affiliations when advising the public or publishing research? Should they assess grant applications from commercial competitors? Many research institutions are developing enterprise cultures that make such conflicts of interest more likely.

Agencies, including professional associations, funding bodies, and university groupings, have developed responses to the threats posed by conflicts of interest. In 2002, the Committee on Assessing Integrity in Research Environments in the United States argued for transparency, urging researchers to disclose conflicts of interest to their institutions as well as in all presentations and publications that arise from their research. Some of these practices were already in place.

Qualitative researchers often use the term *conflict of interest* to describe role conflicts where their relationships with research participants involve multiple roles as researchers as well as (perhaps) teachers, clinicians, activists, colleagues, or friends. This can occur wherever researchers are embedded as insiders in their research sites, notably in action research. In such circumstances, it may be particularly difficult to negotiate informed consent, guard confidentiality, avoid harm, and convince research ethics committees that the research relationship has not been exploitative.

Institutional conflicts of interest may influence the governance and conduct of research. Some ethically acceptable research proposals might be blocked during the ethics review process because of, for example, a desire by the reviewing institution to avoid legal action. Commercial relationships maintained by research institutions can also place individual researchers in invidious positions; even if individual researchers are not directly compromised by their home institutions' corporate relationships, they could be influenced by the knowledge that their own institutions' financial health may be affected by the results of their research or, at least, may be seen as influenced.

CONNOISSEURSHIP

Connoisseurship is the skill the researcher must possess to conduct Elliot Eisner's arts-based methodology of educational criticism. Like an art critic, the educational critic perceives subtle qualitative distinctions. Through carefully crafted language, the critic enables a broad audience to see—and appreciate the educational importance of—these distinctions. Through deep expertise and subjective familiarity with the phenomenon under study, the critic has the ability to bring understanding and appreciation to a subject that might otherwise appear obtuse to the untrained eye.

The educational critic must address four areas of data analysis. First, the critic must provide a full and illuminating description of the phenomenon being studied. Second, the critic must offer an interpretation of how these details form a whole. How do the separate parts come together in a meaningful way? Third, the critic must then provide an evaluation of the goodness or worth of the phenomenon. Fourth, the critic must address thematics. These are overarching and enduring themes raised through the close study. The researcher must address all four areas to demonstrate competency as a connoisseur.

It is important that the critic achieve credibility with readers. The research must be believable. For the study to be worthy of research, the critic must address three dimensions of credibility: structural corroboration, referential adequacy, and consensual validation.

The first condition, structural corroboration, is a question of evidence. Is there sufficient information to sustain a clear argument through the dimensions of description, interpretation, evaluation, and thematics?

The second condition, referential adequacy, relates to the value of the argument for understanding other similar cases. Is our perception of practice sufficiently expanded by the research that we could recognize the features of the phenomenon outside the context of this particular study? Readers must be able to fruitfully apply the insights of the research to different contexts.

The third condition, consensual validation, is concerned with whether the research moves an informed audience to carefully discuss it. The value of the research lies in the broadening dialogue it initiates. A work of educational criticism is not the final word but rather a point of departure for more rewarding conversations.

The concepts of critic and connoisseur have proven to be controversial. In the popular imagination, art critics and connoisseurs are often authoritative intellectuals who render summative, callous, and nondebatable judgments. Eisner explicitly rejected such restrictive connotations of his terms. Nevertheless, feminist researchers found the language to be oppressive. Although deeply sympathetic to Eisner's advocacy for research unabashedly guided by deep subjective knowledge, they called for a more open, and less authoritative, terminology.

Educational criticism is the first fully developed arts-based research methodology. Connoisseurship has been highly influential in the development of other arts-based methodologies, including narrative storytelling and *a/r/tography*.

CONSTANT COMPARISON

Constant comparison is the process used by the researcher in the collection and analysis of data for a grounded theory. It is the term used by Barney Glaser and Anselm Strauss in their 1967 book, *The Discovery of Grounded Theory*. Glaser and Strauss described the research method they called “grounded theory,” so named because the end product, or theory, is grounded in data. The method involves a social psychological examination of a social scene. This entry describes the process of constant comparison and the functions of record keeping, coding, comparison with existing

literature, and sorting as elements in the development of a grounded theory. Constant comparison is vital to every action in the process of developing a grounded theory. It could be said that it is the essence of the method.

The Process

Constant comparison can be thought of as a qualitative approach that resembles the quantitative methods of factor analysis or multiple regression in that every data bit is compared with every other data bit; however, two major differences exist. First, rather than a computer, the analyzing instrument is the researcher's brain. Second, as the theory begins to take shape, the researcher is free to alter her or his study question. For example, a researcher may enter the field looking at the experience of loss associated with home fire victims and find that those emotions are exacerbated by the rituals followed by their social nexus—rituals that can be connected or unconnected to what the victims need.

If the researcher is using interview and observational data, each episode is coded and compared with every other episode for similarities and differences to answer the question, “What is going on here?” In this method, data gathering and analysis go on simultaneously rather than at the end of data collection. The interview schedule and observation site will evolve as the developing theory begins to take shape. When the researcher is able to group analyzed data into categories, those categories are examined for how they are related to one another and then collapsed under a higher level category until the central category that explains most of variation in the data is revealed or “discovered,” as Glaser and Strauss put it. The process holds for other kinds of data, documents, and records as well as the work of other authors.

Memorandums. The mental calisthenics required of the researcher using grounded theory necessitates careful record keeping in the form of memos that represent the researcher's thoughts about the data, how the theory is coming together, and possible next steps. Later in the process these memos, through constant comparison, are sorted into categories and subcategories until it becomes clear that one central category holds the developing theory together and subcategories become properties of the central category. Sorted memos become the basis for the research report.

Theoretical Codes. Theoretical codes are regulators that transform descriptive data into an abstract or

Analysis of Rituals Used in Restructuring Life After Home Loss by Fire

“When fire destroys a home, victims endure feelings of helplessness, sadness, and depletion that are engendered by privation and the problem of restructuring their lives. How do victims process losing their homes to fire, and how does social ritual connect with their needs? With a sample of 113 people from 8 countries we found that, despite the seriousness of the problems victims face, social ritual guides support” (Stern & Kerry, 1996, p. 11).

In the fire study, June Kerry and I realized early on that the rituals in play were unhelpful because people, in general, were unaware of rituals connected to need. Rituals for marriage and death, for example, are firmly in place, but in the case of home fire, we found that the majority of people were at a loss as to what action was appropriate. We asked ourselves under what conditions were connected rituals followed. Constantly comparing our memos, we were able to develop the properties of the main category. For example, it became clear that rural dwellers supplied necessary comfort and material goods because rural citizens need to depend on one another for survival in everyday life, whereas city dwellers, who prefer to maintain separation from their neighbors, have no training or insight regarding what fire victims might need. We named the phenomena *ritual-support connection*; in other words, the most common social ritual that failed to connect to need was hardy assurances of “at least no one was hurt and the insurance will cover everything.” This message belittles the victims’ grief over their losses.

Source: For more information on this topic, see Stern, P. N., & Kerry, J. (1996). Restructuring life after home loss by fire. *Image: The Journal of Nursing Scholarship*, 28, 9–14.

theoretical structure. There are families of codes; for example, Glaser wrote of the “six Cs”: context, condition, cause, consequence, covariance, and contingency.

Comparison With Existing Literature. A grounded theory is verified by its acceptance by the targeted population, but by comparing the new knowledge with existing theory, the researcher can place her or his theory within the context of knowledge development. For example, in a study of home loss by fire, Phyllis Stern and June Kerry looked for other works on loss rituals.

Sorting. Whether using one of the various computer programs available or using the original hand method, sorting involves the constant comparison of memos to determine how the labyrinth of data connects to form an integrated grounded theory. Through sorting, the researcher can literally *see* the conceptual framework build. Using the hand method, memos are distributed into piles of memos that, in turn, are labeled as certain properties. For example in the fire study, under unconnected ritual, Stern and Kerry grouped memos about how friends and acquaintances at first expressed concern but then tried to “make it better” by pointing out the advantage of having “all new things” when what the victims needed was people to help compile the extensive lists of burned items required by their insurance companies and sympathetic ears willing to listen to their tales of grief over the loss of prized possessions, such as “the quilt grandma brought from the old country,” and their places of comfort and safety—their homes.

Writing the Research Report. Judith Wuest advised that students often fail to realize how much analysis goes on while writing the research report. As the researcher struggles to explain her or his theory while comparing the memo groups, the memory of data bits that did not seem important early on come to mind, forcing the researcher to give a new twist to the evolving theory. The write-up of a grounded theory needs to grab readers, help them to understand the theory, and illuminate for them how the theory relates to their work and lives.

CONSTRUCTIVISM

Ontological and epistemological views in the constructivism paradigm disallow the existence of an external objective reality independent of an individual from which knowledge may be collected or gained. Instead, each individual constructs knowledge and his or her experience through social interaction. This research paradigm represents a change from the focus on explaining phenomena (*Erklärung*) typical in the natural sciences to an emphasis on understanding (*Verstehen*), which is deemed more appropriate for investigating phenomena in the human sciences. This change, referred to as the interpretive turn, was initiated during the 19th century through the writings of Wilhelm Dilthey, Edmund Husserl, and Max Weber, among others. These philosophers, especially, articulated how human agency and meaning-making require an approach to the human sciences that is ontologically and epistemologically different from the positivist approach that had been derived from the empiricism of the natural sciences (positivism asserts that causal knowledge of the social world can be obtained objectively through observation and experimentation). During the 20th and 21st centuries, the interpretive paradigm generally labeled as constructivism became more complex with the development of social constructivism, psychological constructivism, and radical constructivism. These approaches to research reflect varying degrees to which knowledge is socially constructed.

Theoretical Antecedents

The antipositivist movement was focused in 19th-century Germany, where scholars sought to describe the inherent differences between the human and natural sciences and, thereby, to develop a paradigm better suited for studying the social world. Essentially, these thinkers saw the need for a science that would investigate the world created by humans—the built environment, social institutions, language, culture, belief systems, and so on—and the meanings humans ascribed to their experience in this social world.

Wilhelm Dilthey (1833–1911)

Dilthey's contribution to the interpretive turn in the human sciences is in his assertion that humans must

be studied within the context of their social and cultural lives. He believed that this investigation should occur systematically and empirically, but not with the aim of developing a mechanistic explanation. Although he thought that there was an underlying order to human experience, this order was developed dialectically through humans' interactions with their social and physical environments and manifested through meaningful constructions such as myths, religions, and works of art (literary, performance, and visual). The aim of the human sciences is to understand the meaning humans give to their experience. This interpretive understanding, *Verstehen*, is a kind of knowledge that is constructed in the exchange between researcher and participant.

Dilthey's ideas were influenced by the hermeneutic tradition that originally referred to the interpretation of texts, especially scripture. Dilthey identified hermeneutics as a method for the human sciences due to the hermeneutic dependence on a knowledge of context for interpretation and the circular process of interpretation. In the hermeneutic circle, interpretation develops out of a constant back-and-forth movement between parts and the whole; one understands the meaning of a sentence based on the relationship between individual words. The meaning of individual words depends on their situation within the context of the entire sentence. This applies similarly to passages of text in relation to the entire work and, analogously, to individual experience in the social world. The process is circular in that there is no obvious starting or end point; meaning is dynamic and developed in the very process of interpretation. Dilthey was concerned, however, with the relativism that this process may engender.

Edmund Husserl (1859–1938)

Husserl's contribution to the interpretive turn in the human sciences was through his development of phenomenology. Phenomenology is the study of experience through reflection. The individual reflects on an experience and describes its essences through imaginative manipulation (an intuitive grasping of what is essential about an instance). It is not a passive process but rather an active sifting through of contingencies and variables to perceive the essential character of an instance or experience. Husserl termed the awareness of the essence of a phenomenon as *Anschauung*—the realization of the insight. The constitution of

phenomena within consciousness—the realization or intuition of the essence of an experience—is historically and socially situated. In this way, intuited meaning may be constructed through researcher–participant interaction. A phenomenological methodology is especially common in interview studies in the constructivism paradigm as the researcher asks participants to reflect on their experience of a phenomenon and describe what was essentially meaningful to them. Through this reflection, both the researcher and participant gain insight, or construct knowledge, about the experience.

Max Weber (1864–1920)

Weber emphasized the agency in human experience. Distinguishing action from behavior, which he described as biological and instinctive, Weber described action as guided by meaning and values. The aim of human science is to interpretively understand (*Verstehen*) the meaning an action has for an individual. This understanding is essential for trying to explain why an action occurs. In this way, Weber was trying to bridge the division between explanation and understanding as aims for social science. Weber, like Dilthey, was concerned with the relativism and subjectivism of the knowledge that may be constructed based on an actor’s description of his or her motivation. Weber’s influence on the constructivism paradigm is evident in social sciences research that focuses on participants’ motivations such as studies of teachers’ instructional decisions and planning for curricula.

The relativism of knowledge is a persistent issue in the constructivism paradigm. Efforts were made during the 20th century to develop methods for establishing the trustworthiness of knowledge warrants in constructivist research. The degree to which practitioners are comfortable with relativism is reflected in the varieties of constructivism as described in what follows.

20th-Century Developments

Moving into the 20th century, John Dewey’s (1859–1952) lifelong investigation of the nature of experience and humans’ interaction with their environment may be considered constructivist in his recognition that knowledge is constructed in social contexts and that students need to be active learners—not

passive recipients—of knowledge. Jean Piaget’s (1896–1980) theory of cognitive development has been considered constructivist in that through activity a child constructs his or her understanding of reality. Most significant is the work of Russian psychologist Lev Vygotsky (1896–1934), whose sociocultural learning theory states that a child develops higher mental functions through interaction with significant adults and peers. Through these interactions, a child learns language and constructs knowledge specific to his or her culture. Therefore, an individual’s understanding is mediated by his or her sociohistorical context.

Constructivism during the latter 20th century included efforts to develop a methodology for understanding the meaning of human experience out of the theoretical foundation laid by German 19th-century thinkers and early to mid-20th-century philosophers and psychologists.

Research and Evaluation Methodology

Egon Guba and Yvonna Lincoln wrote several key works outlining the constructivist paradigm as it relates to social science inquiry, both research and evaluation. They explicitly took up the debate carried on by Dilthey, Weber, and others by articulating how constructivism is different from what they called the conventional paradigm (positivism and postpositivism). Ontologically, reality is relative, multiple, socially constructed, and ungoverned by natural laws. It claims a monistic subjectivist epistemology in which knowledge is constructed between inquirer and participant through the inquiry process itself. Inquiry is carried out through a hermeneutic methodology that is essentially dialectic and iterative and where insights and understanding emerge from the joint construction of inquirer and participant (etic and emic views).

Considering this relativist reality and subjectivist epistemology, there is a need for criteria to judge the merit of knowledge warrants in constructivist research. According to Guba and Lincoln, the positivist/postpositivist strategies for controlling threats to internal and external validity and for assessing the reliability and objectivity of a study are incongruent with the constructivist paradigm. They sought to determine the credibility—not validity—of knowledge warrants in the constructivist paradigm. A knowledge warrant may be deemed as credible if there is consensus among informed and qualified persons. A constructivist inquiry is successful if it presents increasing

understanding of its phenomenon. This relates to the criterion of generalizability as external validity in postpositivist research, but in the constructivist paradigm Guba and Lincoln identified transferability as the more salient criterion. The researcher presents increasing understanding of its phenomenon through thick description as described by the anthropologist Clifford Geertz; it is up to readers to transfer this understanding to other contexts and assess the similarity. In constructivist inquiry, an interpretation is considered to be dependable—not reliable—if the inquiry process is tracked, with changes being documented and made available for public inspection. Constructivism rejects the idea that there is objective knowledge in some external reality for the researcher to retrieve mechanistically. Instead, the researcher's values and dispositions influence the knowledge that is constructed through interaction with the phenomenon and participants in the inquiry. To determine whether the researcher's interpretations are not fictitious, data and their interpretation may be confirmed by tracking the data to their original source and transparently presenting the logic of the interpretive process and analytic strategies in the report or narrative. Finally, because constructivist research is naturalistic—inquiry happens in the settings where a phenomenon naturally occurs (e.g., classroom, medical clinic, community center)—the understanding that results must be authentic. Authenticity refers to the balanced presentation of all perspectives, values, and beliefs related to the inquiry. Criteria for determining the authenticity of an inquiry include fairness, ontological authenticity, and catalytic authenticity. Fairness relates to what extent different constructions and value structures are addressed and respected during the inquiry process and its presentation. Ontological authenticity determines how the participant's understanding of an experience or a phenomenon became more informed or substantial (possibly illustrated through member checks or audit trails) as a result of the study. Catalytic authenticity determines the degree to which action is inspired by the inquiry process.

Lincoln and Guba's discussion of the authenticity criteria came in 2000 in the second edition of the *Handbook of Qualitative Research*. It reflects growing concerns in qualitative research regarding power relations between researcher and participant, the role of the participant in inquiry, and how research may foster social justice.

Variations of Constructivism During the 21st Century

Along with the methodological developments in the constructivist paradigm is an ongoing philosophical exploration of the nature of constructivism. Although categorization is essentially flawed because there are blurred boundaries among various theories, recent scholarship (e.g., D. C. Phillips's writing) aims to provide some clarity regarding the complex landscape of constructivism by offering descriptions of major trends in the paradigm. Phillips delineated the following trends in an edited volume focused on constructivism in education.

Psychological Constructivism

Psychological constructivism addresses the epistemological questions of constructivism and is especially relevant to education as it deals with how people learn and, thereby, how instruction should be carried out. Essentially, knowledge is not acquired but rather is made (or constructed). The learner is an active participant in building knowledge, not a passive recipient of information. The educational theories of Dewey and the psychological theories of Piaget are especially influential in this realm, as is Jerome Bruner's conception of learning as individual meaning-making.

Social Constructivism

Social constructivism addresses the ontological-epistemological questions of constructivism in describing the bodies of knowledge developed over human history as social constructs that do not reflect an objective external world. Everything we know has been determined by the intersection of politics, values, ideologies, religious beliefs, language, and so on. Vygotsky's sociocultural learning theory, especially his work regarding language development and his theory of the zone of proximal development, is influential in this realm, as is the scholarship of the contemporary social psychologist Kenneth Gergen.

Radical Constructivism

Radical constructivism is an extreme form of psychological constructivism. It asserts that any external world is entirely a construction of an individual and

exists in that person's consciousness as his or her subjective experience. Ernst von Glasersfeld's writing reflects and describes this position. For example, in Catherine Twomey Fosnot's edited volume on constructivism, von Glasersfeld related this idea to the concept of environment in educational contexts, both the physical classroom environment and the psychological learning environment. He urged educators to remember that, from a radical constructivism epistemological view, a teacher's perception of the learning environment he or she has created (physical and psychological) is experienced and known differently by each student in that environment. Therefore, according to von Glasersfeld, there is no absolute external learning environment; there is only the perceived learning environment built in each individual student's mind.

Research in the Constructivist Paradigm

In terms of methods, constructivist qualitative research studies typically emphasize participant observation and interviewing for data generation as the researcher aims to understand a phenomenon from the perspective of those experiencing it. The researcher's understanding is co-constructed with that of the participants through their mutual interaction within the research setting and dialogic interaction through researcher-initiated data generation efforts such as interviewing.

Guba and Lincoln's work on developing criteria for determining the trustworthiness of interpretations produced within the constructivist paradigm provides some specificity to how one may conduct and digest research in this paradigm. The preceding historical discussion and delineation of constructivist theories provides possible conceptual frameworks to guide and understand research in this paradigm. For example, Husserl's phenomenology, adapted and developed by contemporary qualitative researchers such as Max von Manen, is a common methodological framework for constructivist research studies. Vygotsky's sociocultural learning theory is an oft-cited theoretical framework in constructivist educational research. For example, Christine Thompson and Sandra Bales described the nature of preschool and kindergarten children's talk surrounding voluntary art activities in an art classroom using a phenomenological methodology in that they observed and recorded students' speech and drawing acts within the specific social context of an art classroom and reflected on what

these acts might mean for the role of speech in early childhood artistic expression. They used the theories of both Vygotsky and Piaget to understand students' use of language in this specific context and area of cognitive development.

Future Directions

The general constructivist paradigm is becoming obscured by the dominating influence of the transformative paradigm in 21st-century qualitative research. The transformative paradigm, which includes feminist critical theory and participatory action research methodologies, grows out of the ontological, epistemological, and methodological foundations of constructivism but has an explicitly social reconstructionist agenda that aims to promote social justice through research and evaluation.

CONTENT ANALYSIS

Content analysis is the intellectual process of categorizing qualitative textual data into clusters of similar entities, or conceptual categories, to identify consistent patterns and relationships between variables or themes. Qualitative content analysis is sometimes referred to as latent content analysis. This analytic method is a way of reducing data and making sense of them—of deriving meaning. It is a commonly used method of analyzing a wide range of textual data, including interview transcripts, recorded observations, narratives, responses to open-ended questionnaire items, speeches, postings to listservs, and media such as drawings, photographs, and video.

Content analysis is a method that is independent of theoretical perspective or framework (e.g., grounded theory, phenomenology) but has its beginnings as a quantitative method. Where quantitative content analysis is helpful in answering "what" questions, qualitative content analysis can be helpful in answering "why" questions and analyzing perceptions. It is commonly associated with mass communications research, but it is widely applied in the social sciences whenever textual data are analyzed. In qualitative research, content analysis is interpretive, involving close reading of text. Qualitative researchers using a content analytic approach recognize that text is open to subjective interpretation, reflects multiple meanings, and is context dependent (e.g., part of a larger discourse). This entry describes how qualitative content analysis is used and how to use it well.

When analyzing qualitative data such as interview transcripts, analyses across the whole set of data typically produce clusters or codes that translate into

"themes." For example, an interview study that explores the experience of new parenthood may produce interview transcripts that are analyzed for content related to themes ranging from stress to social isolation to joy. Those themes may have been identified a priori, so that the researcher seeks evidence for participants' expressions relating to those themes, or may simply emerge from the analysis of the transcripts. Textual data include nonwritten text, such as photographic data, equally open to content analysis. In this case, the researcher may identify content as straightforwardly as identifying objects evident in photographs or may conduct more subtle analyses of symbolic communications that can be unconsciously discerned from a physical space. The level at which content analysis occurs varies widely, from obvious surface-level groups of similar responses to a particular interview question to deeper inductive insights inferred from more sustained, iterative, and recursive interaction with textual data. For example, the varying connotations associated with particular words used by participants, or the degrees of enthusiasm expressed about an issue, are open to content analysis. Regardless of the level at which analysis occurs, the fundamental principle is that content is recognized.

In the case of the written word, that content is often subject related (i.e., analyses refer to the "aboutness" of text). For example, content analysis could be applied to the official reports and policies of an organization; such an analysis may identify the stated priorities of that organization as well as reveal implicit political perspectives. Thus, content analysis is useful for identifying both conscious and unconscious messages communicated by text (i.e., what is stated explicitly as well as what is implied or revealed by the manner in which content is expressed). The results of a content analysis may reveal recurrent instances of "items" or themes, or they may reveal broader discourses. The "categories" or clusters of data identified may represent discrete instances (i.e., something is apparent or not), or they may be represented as degrees of attributes, such as direction and intensity, or qualities (i.e., a quality such as joy is evident to some degree rather than simply present or absent). Identifying themes or categories is usually an iterative process, so the researcher spends time revisiting categories identified previously and combining or dividing them, resolving contradictions, as the text is analyzed over and over. It is also important to note that a single piece of text (e.g., one sentence from an

interview transcript) may be relevant to more than one category or theme. When applying labels to categories, it is good practice to use language consistent with that used in the text under analysis. For example, if new parents in an interview study tend to use the word *joy* to describe one of their experiences, then the researcher should use that word, rather than a synonym such as *happiness*, to label that theme. This practice is related to the need to remain true to the source of the text. As much as possible, the results of a content analysis should make sense and resonate accurately with the producers of that text (e.g., with interview participants).

In quantitative work, content analysis is applied in a deductive manner, producing frequencies of preselected categories or values associated with particular variables. A qualitative approach to content analysis, however, is typically inductive, beginning with deep close reading of text and attempting to uncover the less obvious contextual or latent content therein. For example, a researcher seeking to understand participants' experiences or understandings of a phenomenon of interest is likely to use such an inductive approach to analysis of interview data. The quantitative or qualitative approaches may be combined within a single research study depending on the purpose of the analysis.

Validity and reliability are key to robust content analysis. In qualitative terms, the researcher doing a qualitative content analysis seeks trustworthiness and credibility by conducting iterative analyses, seeking negative or contradictory examples, seeking confirmatory data through methodological triangulation, and providing supporting examples for conclusions drawn. For example, using more than one researcher to analyze the data and seeking agreement between different researchers on the content identified is a common method of improving trustworthiness. In qualitative content analysis, a reliability coefficient of .60 (i.e., 60% agreement between different coders) is considered acceptable. Because meaning is context dependent and subjective, a single piece of text can indeed be open to different qualitative interpretations by different researchers. Reliability of judgment remains important nevertheless, and researchers must always be mindful of the perspectives they bring to their analytic work as well as of the context for the text being analyzed. In addition, once thematic categories are identified, the careful researcher attempts to ensure that the groupings or categories of data are carefully defined in

ways that are comprehensive (i.e., they cover all categories identifiable in the data set and all relevant data are categorized) and mutually exclusive (i.e., their definitions do not overlap). These are important intellectual principles that increase trustworthiness of the analyses and conclusions. The researcher also should consider what is missing or not present in the text being analyzed. For example, if new parents do not mention any positive emotions in interviews, then this absence is also worthy of attention and interpretation.

Content analysis is an intellectual process, but the outcomes of that thinking must be recorded in some way. Practically speaking, content analysis can be accomplished using very low-tech materials such as a pencil and paper, colored sticky notes, or colored felt pens. These tools are likely sufficient for relatively small amounts of text such as a small number of interview transcripts. However, several useful software packages, such as NVivo, are very helpful tools for handling larger quantities of data. These tools can assist the researcher in organizing intellectual work quickly and in bringing identified categories of data together for easy comparison. These programs also offer tools to define categories, annotate text, write memos, and calculate frequencies of categories and codes. Using a computer does not reduce the need for intellectual effort on the part of the researcher, but doing so certainly provides help in recording and organizing the results of that effort.

As an analytic method, content analysis is very flexible, providing a systematic way of synthesizing a wide range of data. It can be a useful way of analyzing longitudinal data to demonstrate change over time and is nonintrusive because it is applied to data already collected or existing text.

CONTEXT AND CONTEXTUALITY

Central to most forms of qualitative inquiry is the idea that human actions, of whatever kind, can be properly understood only *in context*—that by their very nature they are *situated*. In these terms, quantitative methods are often criticized for effectively stripping what people say and do out of their normal contexts. Instead of this, qualitative researchers generally seek to gather data in “natural” settings and in ways that are sensitive to the contexts in which the data were generated.

At the same time, there are some significant differences among qualitative researchers over what taking account of context means. One dimension concerns whether the emphasis is on local or wider contexts—whether the focus is micro or macro. Microethnography emphasizes the role of immediate context in shaping action. In contrast, other kinds of qualitative research insist that we cannot understand what goes on in any local situation without viewing it within the context of the larger national society or, indeed, of global processes.

A second dimension concerns how context is to be identified. Some see social context as socially defined by participants. The researcher’s task, therefore, is to document how people interpret the situation they are in, either by means of in-depth interviews or through close analysis of processes of social interaction. For example, those influenced by conversation analysis argue that contextualization is ongoingly accomplished through actors displaying the context of their actions to one another, with this being essential to communication and the coordination of action. The task of the analyst, then, is to document how contexts are displayed and ratified in and through processes of social interaction.

At the other end of the spectrum are those who see the specification of context as the task of the analyst, drawing on theory. Here the very rationale for research is that people will not be aware of the context

in terms of which their actions can be properly understood. This is because relevant parts of this context will be either below or beyond their awareness—whether in the form of unconscious psychodynamic processes, macrohistorical structures, or both.

A third dimension concerns the ontological status of any definition of context. Is it discovered or constructed? All of the approaches discussed up to now tend to treat context as an objective feature of the world being studied. However, other qualitative researchers treat context as necessarily relative to purpose and perspective. It is argued that, in understanding anything, the analyst cannot avoid relying on inherited background assumptions, and these provide the context for what is observed. Nor does this process need to be interpreted in entirely cognitivist terms; the role of emotional response may also be acknowledged. There is an alternative version of this argument that can be termed postmodernist in broad terms. Here context is essentially arbitrary; there are many incommensurable contexts in which we could locate what we are studying in the sense that a host of stories could be told. There is no notion of validity, in the sense of correspondence with reality, on which we can draw to privilege one definition of context over another. Other selection criteria—political, ethical, or aesthetic—must be used. Moreover, none of these can be treated as being of universal value.

Involved in these various approaches to identifying context are quite fundamental differences in view about the purpose and character of social science. At the same time, much qualitative research mixes these orientations to one degree or another. For example, it generally seeks both to take account of how people define the contexts in which they act and to provide more analytic characterizations of context for the purpose of explaining their actions. Furthermore, although few researchers adopt what we label here as the postmodernist position, many acknowledge the extent to which the analyses they produce reflect who they are.

The concept of context is also implicated in ideas about what qualitative inquiry produces. It is often argued that quantitative methods seek to produce abstract general knowledge about social and psychological processes, whereas qualitative research is idiographic in character, being concerned with providing thick descriptions of particular contexts. Sometimes this amounts to a denial that generalization is possible; instead, readers must use these thick descriptions to make sense of new situations for themselves, engaging in a form of naturalistic generalization.

Of course, many qualitative researchers do seek to develop general theoretical models, but at the same time they seek to give due attention to the particularities of the cases they study. This is true, for example, of those working in the tradition of grounded theorizing. Here, and elsewhere, there is an attempt to blend the idiographic and nomothetic.

One area of qualitative inquiry that throws up issues about context in an especially interesting and difficult way is the study of online communities. Some researchers treat context here as entirely that which is enacted on the relevant websites. Others insist that people's online and offline lives are usually interwoven in complex ways so that a much broader focus must be adopted.

Another area that highlights the issue of context is the reuse of archived qualitative data. Can those data provide access to the original context in which a study was done? Can they be "reconceptualized" in a way that both retains their integrity and provides the basis for a new analysis? Here all of the problems surrounding context outlined above reemerge in various ways.

The notion of context, then, is central to qualitative inquiry. At the same time, it is a complex and contested concept.

CONTEXT-CENTERED KNOWLEDGE

Context-centered knowledge is most generally related to action research. Action research is problem focused, particularly as those problems relate to specific locales or settings. Thus, the knowledge generated from action research is a result of a set of circumstances and occurrences that can also attend to the sociocultural contexts in which the research problem arose. In addition, knowledge generated in these contexts is action oriented and geared toward creating positive change.

Communicating the results, or the knowledge that actors within a setting generate in response to the problem, to an audience whose members are unfamiliar with the setting is often a challenge. This challenge may be more acute given that in many epistemological frameworks the expectation is that the results will be immediately transferable and relevant to all settings. Within particular epistemological frameworks, when the knowledge generated from a specific setting appears to be context specific and unique, it is often dismissed as too subjective and not useful for other settings; however, the specificity of the setting and the results that emerge from within can be informative rather than detracting. Moreover, the specificity, or the uniqueness of the results because of the locale/setting, can provide insights on how to approach an answer to a problem.

Researchers who use ethnographic methods attend to context-centered knowledge similarly to researchers who use action research methods. However, the intent of research might not always be problem centered; instead, it might be to illuminate the beliefs and experiences of a particular group for the sake of illuminating that group.

For example, Black feminist researchers who have examined the pedagogy of Black women teachers situate the teachers' practices within their local settings and focus the analysis on how the teachers make sense of their practices. In addition, these researchers argue that the context—living in the United States and being a woman of color—provides an angle of vision that informs and influences the teachers' pedagogy. In this way, research of this nature also draws on standpoint theory and argues that the knowledge generated from the research provides an understanding of not only teaching but also the specific teaching practices of Black women. Similarly, Indigenous researchers argue that the knowledge generated from their research, which is action oriented but not classified as

action research, is specific to the context and reflects the epistemological framework of the community.

By the same token, researchers who draw on critical race theory as a theoretical framework draw on the context of the project to examine and redress issues related to race, racism, and other forms of marginalization that intersect with race. Although researchers who use critical race theory as a theoretical framework have social justice and social change as the ultimate intent of their research, critical race theory is not related to action research to the extent that it is interventional or offers an intervention. Quite often researchers who use critical race theory draw on context-centered knowledge as a means to illuminate both inequity and responses to inequity.

CONVENIENCE SAMPLE

A convenience sample can be defined as a sample in which research participants are selected based on their ease of availability. Essentially, individuals who are the most ready, willing, and able to participate in the study are the ones who are selected to participate. In qualitative research, it may be helpful to use a convenience sample to test the appropriateness of interview questions in an inexpensive and quick way by approaching an interested group of people first before embarking on a larger, longer, and more expensive study.

One common example of convenience sampling is found in psychology, where introductory psychology

students are frequently recruited to answer psychologically oriented research questions, such as their motivation to exercise, as part of their introductory coursework in psychological research. In essence, these students have been asked to answer questions about their motivation to exercise because they are readily accessible. That is, the researcher could recruit them directly from introductory psychology classes and did not need to venture into the wider community to conduct the research.

Although this type of sampling technique can most assuredly save the researcher time and money at the recruitment stage, it is not without its drawbacks. If the researcher recruits students from a psychology class at a particular academic institution, for example, it is difficult to know whether or not the students' motivation to exercise is reflective of motivation to exercise in other contexts. Similarly, it may be that students are perhaps less motivated to exercise than members of the larger society because they are too busy with their coursework. Hence, it is difficult to assess whether or not the study's findings regarding motivation to exercise can apply to students and the population at large. For this reason, convenience samples can lack transferability (or external validity) in qualitative research. In quantitative projects, it can be difficult to generalize the results beyond the original sample from which the data were collected. However, because qualitative researchers are typically interested in studying specific groups of people rather than generalizing to larger populations, it may be tempting for researchers to view this issue as a less significant problem than it is for quantitative researchers. However, it is still important to be aware that the participants recruited are not necessarily reflective of the population being studied. For example, when recruiting for a study about the views of breast-feeding mothers, it is possible that those who answer the advertisement and come to talk to the researchers are the ones with the strongest opinions. They may be individuals who have the most vested interest in sharing their stories because they want to effect change in society's attitudes toward breast-feeding. With this in mind, qualitative researchers should be aware that the people who are recruited most readily are not necessarily reflective of all viewpoints.

In sum, a convenience sample can be described as a group of participants who have been recruited for a given study because they were readily accessible. Using a convenience sample can be both time- and

cost-effective, but caution about the nature of the results should be considered in their interpretation.

CONVERGENT INTERVIEWING

Convergent interviewing (CI) is a technique developed by Bob Dick from the University of Queensland in Australia. CI aims to collect, analyze, and interpret people's experiences, opinions, attitudes, beliefs, and knowledge that converge around a set of interviews. It was created primarily to address issues in under-researched areas. Although used and documented mainly by Australian researchers in marketing/business disciplines with foci on organizational change and development, it has been extended and adapted to broader social science and health research. This entry describes the CI process and compares and contrasts it with other qualitative techniques and methods. CI provides a mechanism to flexibly structure research projects while using unstructured content to enable greater reflexivity throughout the different phases of research.

CI permits in-depth interviewing by promoting a cyclical research process that requires ongoing analysis as part of the overall strategy. It is most suitably applied when multiple interviewers are being used in a project, and its aim is to document priority issues when these converge over a series of interviews. According to David Carson and colleagues, this process is iterative and, thus, enables continuous refinement. Interviewers engage in a constant comparative reflexive process that permits detailed rich content and theoretical sampling as researchers seek to continuously test emerging interpretations from early interviews in subsequent interviews.

Although designed to accommodate the use of multiple interviewers, a single interviewer can be used

provided that he or she can hold discussions with one or more members of the research team. CI provides a structured process while using unstructured content to enable greater reflexivity throughout the different phases of research.

Several aspects of CI bear mentioning, including use of prior literature, sampling, designing the interview questions, data capture, and comparing and contrasting during the interview process through to the analysis phases.

Prior Literature

Unlike with grounded theory approaches and earlier articulations of CI, Bob Dick encouraged researchers to engage with the literature from the beginning. Prior knowledge is designed to facilitate the development of rapport (interviewers/researchers can make more convincing "sounds" showing their understanding of what participants are expressing), to enable researchers to recognize potential priority issues (arising out of discussions with participants as well as the literature), to aid in the development of a relevantly worded opening question (which can keep participants talking without needing to ask additional questions), to assist in the selection of an appropriate sample, and to increase researchers' confidence when conducting interviews. As Carson and colleagues noted, engaging with the literature throughout the process—both data collection and data analysis—permits an "unfolding" of the literature as priority issues emerge from the interviews.

Sampling and Developing Interview Questions

Sampling is heterogeneous, seeking maximum variation that may be augmented through snowball sampling strategies as deemed appropriate. Participants are sampled as information-rich cases where each subsequent interview is designed to pursue areas of agreement or disagreement on what the priority issues are for the phenomenon under study. To accomplish this, a very general opening question is used to guide the process. This opening question is designed to have the participant speak for a long period of time (up to an hour) without the interviewer needing to ask additional questions beyond gentle follow-ups on what is raised specifically by the respondent; for example, when the

respondent discusses issues of trust, the interviewer might say, “Trust? Please elaborate.” Dick argued that this type of approach helps to ensure that the interviewer does not guide or introduce the content.

The development of the opening interview question requires the participant to comment on, or share a story about, both the strengths and weaknesses, or what was “good” and “bad,” about the phenomenon under study. Although seemingly similar to the critical incident technique, the CI process differs in fundamental ways. Unlike with the critical incident technique, its interviewers do not present participants with a brief statement for their comment on the activity, nor do they query how observed behavior is to be evaluated and classified. Moreover, the CI process does not involve the interview guide being developed prior to data collection (beyond the general opening question), nor are interview questions direct and typically sequential as they tend to be in critical incident interviewing techniques. Rather, the interview guide is developed and built on over time using topics raised during earlier interviews in subsequent interviews as convergence over priority issues is sought through constant comparison.

Data Capture

Dick originally preferred that researchers adopt a self-designed memory system of 20 keywords raised in the interview to reconstruct the key ideas from the interview rather than rely on audiorecordings. However, alternative approaches using CI that have evolved

encourage the use of audiorecordings, and Dick even softened his stance on this point. Like grounded theory approaches, CI encourages the interviewer-researchers to faithfully produce short notes and fieldnotes in addition to making audiorecordings of interviews for later transcription. Fieldnotes also facilitate the discussions of priority issues emerging from the interviews between interviewers.

Comparing and Contrasting

Dick designed CI to accommodate multiple interviewers; although this is not always feasible in academic projects due to limited resources. In many projects, the use of multiple interviewers can introduce substantial variation in quality and reliability that can be minimized if interviewers are given prior training and use a standardized interview guide. However, in CI the ideal circumstance is to have multiple interviewers working in pairs but conducting their own individual interviews. This process involves the interviewers meeting following each pair of interviews to discuss what ideas or issues were raised by participants. They check for early convergence and develop questions to be asked only after the original opening question has been exhausted to verify areas of agreement or disagreement. With each discussion among the interviewers, more prompts are developed over the course of data collection but often are not asked because participants themselves raise these areas unprompted by the researcher. These frequent discussions among the interviewers are designed to ensure that areas of

Table 1 An Example Matrix of Agreements and Disagreements About Issues in Five Convergent Interviews

Respondent	Issue						
	1	2	3	4	5	6	7
A	Yes	Yes	–	–	–	–	–
B	Agree	Disagree	Yes	Yes	–	–	–
C	Agree	Disagree	Agree	Agree	Yes	Yes	–
D	Agree	Disagree	Agree	Agree	Agree	–	Yes
E	Agree	Agree	Agree	Disagree	Agree	Agree	Agree

Notes: This table is for illustrative purposes only. To illustrate, Respondent A raises two issues during the interview. Respondent B agrees with Issue 1 but disagrees with Issue 2. Respondent B also raises Issues 3 and 4. Respondent C agrees with Issues 1, 3, and 4 but disagrees with Issue 2 and raises Issues 5 and 6 and so forth.

agreement and disagreement are consistent across the sample and that no new priority areas or disagreements are being introduced.

Frequent discussions among interviewers also facilitate preliminary and detailed analysis. Unlike with grounded theory, where early analysis can lead researchers in unanticipated directions or necessitate greater sampling, the inherent process of CI forces interviewers to identify differences as the interviews progress. By capitalizing on the use of multiple interviewers, it is possible to reach saturation or convergence on priority issues more quickly because interviewers can gain from the experiences of other participants that they did not personally interview. These iterative discussions between the interviewers may also ensure that the epistemology (theories of knowledge or how knowledge is demonstrated) and ontology (examples of social reality) of the research project are maintained throughout the process of data collection and data analysis. These discussions can also overcome obstacles that may arise when dealing with large multidisciplinary research teams. S. Michelle Driedger and colleagues presented a more detailed discussion of how CI facilitates this by making explicit project epistemologies and ontologies.

Table 1 illustrates the CI process.

CONVERSATIONAL INTERVIEWING

Conversational interviewing is an approach used by research interviewers to generate verbal data through talking about specified topics with research participants in an informal and conversational way. Although all qualitative interviewing relies on speakers' everyday conversational resources, conversational interviewing foregrounds aspects of sociability, reciprocity, and symmetry in turn taking found in mundane conversation.

Whether research interviews are structured, semi-structured, or unstructured, interviewers and interviewees rely on taken-for-granted assumptions about how everyday talk occurs and how speakers make meaning of one another's utterances. In emphasizing features of mundane conversation, conversational interviewers strive to facilitate a research environment in which participants feel free to participate in extended discussions of research topics in a less hierarchical environment than that convened in structured interview settings.

Conversational interviews have long been used by anthropologists and sociologists to talk to people for the purpose of generating data in field studies and ethnographic work. Although this form of interviewing is used by ethnographic researchers undertaking prolonged fieldwork, it is also popular among qualitative researchers who use open-ended, in-depth, or unstructured interview formats and among researchers who advocate feminist and emancipatory approaches to research interviewing.

Methodological discussions of qualitative interviewing have frequently associated conversation with research interviews. Regardless of the theoretical orientation taken by different methodologists, the notion that conversation is synonymous with interview is widespread and the qualitative interview has been

described variously as a “guided conversation,” a “conversation with a purpose,” a “professional conversation,” and a “directed conversation.” Although ordinary conversation is the bedrock on which interview interaction relies, there are distinct differences between conversational talk and interview interaction.

Contrasting Conversation and Research Interviews

Research interviews are frequently conducted with strangers, and researchers must first arrange a time and place for talking with research participants—either in person or via telephone. The scheduling involved in research interviews is unlike the haphazardness inherent in everyday conversation. In making use of conversational interviews in prolonged fieldwork, ethnographic interviewers are better able to emulate the spontaneity of conversation in their interviewing practice when they pose casual questions to participants about what is going on as part of their participant observations. Qualitative researchers must abide by institutional procedures for informed consent, and the requirements for obtaining written or oral consent from participants for their participation in research also deviate from everyday conversation. Thus, conversational interviewers must work against these formal constraints by simultaneously orienting participants to the purpose of upcoming interaction and setting an informal and casual tone for extended conversation.

Conversations routinely take place between people who are known to one another; thus, rapport building is not necessarily facilitated in the talk *prior to* a conversation but might be thought of as being produced *by* good conversation. In everyday life, initiating conversations with strangers is a delicate task, and topics must be introduced judiciously by speakers if the interaction is to be prolonged. Just as initiating conversations with strangers is delicate work, conversational interviews with strangers must be handled with sensitivity, and talk leading up to the discussion of research topics is thought to be important for rapport building. Thus, conversational interviews require that at the outset of interviews, researchers facilitate the kind of small talk familiar to conversationalists who have just met; for example, in Western societies, this could include observations concerning travel, weather, or occupations. Conversational entrées to research interviews are seen to facilitate openness, informality, and rapport between interviewers and interviewees.

Viewed superficially, everyday conversation seems chaotic and unfocused, with speakers collaboratively involved in asking and responding to questions in an interactive sequence that involves new topics and continuous clarification of speakers’ meanings. Conversation analysts have shown mundane conversation to be complex, with routine sequences that speakers deliberately use as resources to accomplish daily activities such as greetings, making excuses, apologizing, complaining, and closing conversations. In research interviews, the central activity is generating data via question-and-answer sequences, and researchers set the scene for subsequent interview talk by providing participants with an outline of the research topic. Interviewers pose questions and follow up speakers’ answers with requests or probes for further explanation. Conversational interviewers strive to create a friendly and informal atmosphere in which participants are respected as equal partners who are free to share their understandings concerning the research topic.

Everyday conversations generally do not have a preset topical agenda for talk; in contrast, researchers use questions drawn from a semi-structured interview protocol or a list of prepared topics to introduce topics of interest into conversational interviews. Whereas in structured interviews there is little opportunity for interviewees to introduce new topics or ask questions, conversational interviewers are open to new directions in the talk provided by participants and are likely to respond in an open and authentic way to questions that interviewees might pose to them.

In everyday conversation, speakers do not necessarily unpack statements made by others in systematic ways. Consider, for example, the following exchange:

Speaker A: How’s work?

Speaker B: It’s going well.

In a conversation with a friend, Speaker A would be unlikely to reply to Speaker B with, “Tell me more about what is going well for you at work,” and without other nonverbal cues from Speaker B, Speaker A would likely move to a new topic of talk. Conversational interviewers, however, unpack the “glosses” provided by interviewees. Thus, in response to the same question in an interview setting, Speaker A’s response to Speaker B’s utterance might not be out of place. Because the utterances made by both speakers in a conversational interview are produced for research purposes, the

interviewer is more likely to take the roles of topic initiator, question poser, and clarification seeker than is the interviewee. The interviewer's ability to pose questions, seek further explanation, and initiate topics as part of his or her research agenda, then, tends to produce a more asymmetrical relationship than one might see in ordinary conversation between equals.

Finally, in everyday conversations, it would be unusual for interaction to be recorded. In conversational interviews, with the prior consent of participants, researchers will make written records of participants' utterances that will become data for analysis and interpretation, and excerpts will be used for research reports. Whereas early qualitative researchers frequently relied on handwritten notes from research interviews that were expanded at a later point in time, qualitative researchers today commonly audio- or videorecord interviews for transcription, analysis, and interpretation.

Issues in Using Conversational Interviews

Although conversational interviewing as a format for eliciting data for research projects has become increasingly favored by qualitative researchers, there are both benefits and limitations to this approach to data generation. A friendly and skilled interviewer facilitates an in-depth exchange with research participants through the use of conversational interaction. Conversational strategies include incorporating informal talk, showing flexibility in allowing topic shifts and questions from interviewees, inviting reciprocity by openly responding to questions and comments from interviewees, and treating conversational partners sociably—with respect, care, and intensive listening. In response to this framing of the interview by the researcher, interviewees may provide confessional and self-revealing details about their lived experiences, beliefs, and perceptions. Although some methodologists have referred to data generated in such exchanges as more authentic than those derived in more structured formats, others have critiqued this view of interviewing as naive and simplistic, instead emphasizing the manipulative potential of conversational interviewing. In generating disclosure from their participants via casual, friendly, and informal interview formats, researchers may be accused of manipulating their participants for personal gain.

Furthermore, data generated via conversation provide much potential for manipulation by researchers

as they code, analyze, interpret, and represent speakers' words. Researchers using conversational interviews in their work must address a range of questions concerning data generation and representation: When is it appropriate for a researcher to contribute personal accounts and views to the interaction? What are the implications of a researcher's contributions to the talk for what participants say next? Given that speakers' talk routinely includes slips and repairs, what features of talk should be transcribed and how should talk be edited for final reports? How much of a researcher's contribution to the generation of the talk should be included in reports? What means of analysis should be used for conversational talk in which both speakers contribute to equal degrees?

Given that interviewing as a method of data generation is complex work, relying on the conversational skills of both interviewer and interviewee, the answers to these questions are likely to be different for each and every researcher in each and every interview encounter.

CONVERSATION ANALYSIS

Conversation analysis (CA) has become the established label for a quite specific approach to the analysis of interaction that emerged during the 1960s in the work

of Harvey Sacks and his coworkers Emanuel Schegloff and Gail Jefferson. Its basic interest was sociological—understanding social order. As such, it was inspired by the sociological perspective of Erving Goffman and the ethnomethodology as developed at the time by Harold Garfinkel. Conversation, or talk-in-interaction as it later came to be called, was chosen as its field of application because the creation and maintenance of social order could be studied in detail by inspecting recordings of actual interactions. As it developed, the method of CA was refined and attracted a still growing number of practitioners, not only from sociology but also from linguistics, anthropology, communication studies, and psychology. Its original impetus and way of working have, however, remained essentially the same. What follows is a sketch of the general properties of CA as a unique approach in the human sciences and then an indication of some of its applications.

To explain what CA is, one can characterize the typical CA research process in terms of a sequence of phases. CA research is essentially a data-driven endeavor, so it starts with the collection of data. Researchers in CA work on audio- or videorecordings of interactions that are “naturally occurring,” meaning that they are not arranged or provoked by the researcher as in experiments or interviews. For CA as such—“pure CA”—there are in principle, and often in practice, no further requirements or limitations, although for specialized forms of “applied CA” it makes sense to collect recordings of specific types of situations.

These recordings are then carefully transcribed using a set of conventions developed by Gail Jefferson. Apart from the words-as-spoken, these conventions allow the researcher to highlight a range of “production detail” concerning timing, intonation, and the like that have been proven to be important for the organization of the interaction.

Listening to the recording and reading the transcript, the analyst tries to understand what the interactants are doing “organizationally” when they speak as they do. They may, for instance, be requesting information, offering to tell a story, or changing the topic. Such understandings will be based, first, on the researcher’s membership knowledge as, one might say, a “cultural colleague” of the speakers. Second, however, the analyst will check the sequential context and especially the uptake of the utterances in question in subsequent talk immediately following (e.g., by granting a request) or later in the conversation.

However, understanding the actions is not the purpose of the research but rather a necessary requirement

for the next step, which is to formulate the procedures used to accomplish the actions-as-understood. CA’s interest is organizational and procedural. The ultimate object of CA research is what Schegloff called the “procedural infrastructure of interaction” and, in particular, the practices of talking in conversation. This means that conversational practices are analyzed not in terms of individual properties or institutional expectations but rather as situated accomplishments.

It is often recommended that the researcher approach data with an open mind, that is, without pre-formulated interests, questions, or hypotheses (except the general organizational and procedural orientation). The idea is that inspecting the data in this way will raise an interest in the researcher’s mind that can be used as a starting point for a more systematic exploration of an emerging analytic theme. The researcher searches the available data for instances that seem to be similar to the “candidate phenomenon” that inspired the first formulation of the theme as well as data that seem to point in a different direction—the so-called deviant case analysis. It may also be useful to collect new data to expand the analysis. In short, the researcher builds a collection of relevant cases in search of patterns that help to elucidate some procedural issues.

Core interests of CA have been the organization of turn taking, sequential organization, and “repair”—how participants deal with problems of understanding. On these and other matters, CA research has produced a range of insights into the organization of talk-in-interaction that can be “applied” to an enormous variety of social situations in which talking together plays an essential role. The following are just a few that have been researched extensively: doctor–patient interaction, news interviews, police interrogations, court sessions, school settings, research interviews, talk of pilots in airline cockpits, and emergency calls. Researchers using video have extended the analysis of talk-in-interaction to include visual aspects such as gaze, gesture, body posture, and the use of various material artifacts. This extension has been most fruitful in the study of work practices in technologically complex environments—so-called workplace studies. CA has also been used to elucidate problems and solutions in the interaction with communicatively impaired persons. Linguists have used CA to throw new light on properties of language-as-spoken, in contrast to language-as-written, as well as on the ways in which properties of various languages have an impact on how talk using such languages gets organized. For some social psychologists, CA has become a major influence in what they call “discursive psychology.”

In all of these branches and applications, the original methods developed by Sacks and his coworkers during the 1960s are still being used fruitfully.

CORE CATEGORY

The concept of core category is most often associated with the grounded theory method developed by Barney Glaser and Anselm Strauss, but it has been used in relation to other qualitative methods such as phenomenology. The terminology varies, and a core category may sometimes be referred to or indexed as a core theme, core meaning, core variable, or central category. A core category is the main theme, storyline, or process that subsumes and integrates all lower level categories in a grounded theory, encapsulates the data efficiently at the most abstract level, and is the category with the strongest explanatory power.

Core categories are identified and developed through the process of coding textual data. Three iterative stages of coding are outlined in grounded theory procedures. First, open coding is the process during which the researcher develops and refines codes through the constant comparison of phenomena in line-by-line scrutiny of the data. Second, during axial coding, relationships between these codes are identified and links between them are articulated. As these two stages progress, core categories develop and

theory appears to cohere around them. Memos and diagrams aid axial coding through helping to identify core categories and show where the gaps are in the developing theory. Third, selective coding is used to saturate weak categories and fill gaps through returning to the original material and/or coding new material gathered specifically for this purpose. A common mistake is to commit to a core category too early in an analysis—before the scheme has been tested and verified against enough data. The general advice is to develop and write up theory around one core category at a time because this should constitute a substantial enough task.

Core categories are always theoretical and abstract, and sometimes they represent basic social (or structural) processes (BSPs). Not all grounded theory studies will identify a BSP, but when they do it is usually the organizing principle of the theory. BSPs are important in accounting for change over time and understanding how phenomena evolve, and often they contain an “-ing.” So, examples of core categories from the published literature include “integrating novelty” (from a study examining the transformational experience of insight) and “holding” (from a study of the use of transitional objects in psychotherapy) but also “relational closeness” (from a study of adult mother–daughter relationships).

There is some debate as to whether categories, including the core category, of a grounded theory analysis should be considered to have “emerged” from, or been “discovered” in, the data or whether categories should be conceptualized as having been constructed by, and hence an interpretation of, the researcher. The language of the original works on grounded theory suggests the former; however, the trend in grounded theory research today is toward constructionist interpretations. This has been clearly explored and articulated in the work of Kathy Charmaz.

COUNTERNARRATIVE

In their broadest formulation, counternarratives are stories/narratives that splinter widely accepted truths about people, cultures, and institutions as well as the value of those institutions and the knowledge produced by and within those cultural institutions. The term *counternarrative* itself clearly highlights its essence in expressing skepticism of narratives that claim the authority of knowledge of human experience or narratives that make grand claims about what is to be taken as truth. This entry describes the nature and potential effects of two types of counternarratives identified by scholars: one that challenges the assumption of the West as superior and one that focuses on the knowledge of those who are marginalized within a society.

The first form of counternarrative challenges modernist grand narratives that position the West at the pinnacle of development and civilization, casting Western ideals and knowledge as irrefutable representations of human knowledge and experience. This first version of counternarratives has dismantled the idea of a universal culture and cultural ideal through the retelling of stories that have revitalized Indigenous cultures, languages, ethics, aesthetics, and epistemologies that are different from Western forms. The expressions of this form of counternarrative, in which non-Western knowledge forms and epistemologies not only are celebrated but also have emerged as a separate and different way of thinking about and narrating experience, are at the heart of decolonizing and postcolonial works found in virtually all disciplines today.

A second form of counternarrative counters unquestioned narratives or “official stories” that are sometimes backed by “scientific” evidence or unquestioned conventional wisdom—that state “truths” about people, situations, or places. An example of a contemporary official narrative is that which conflates Islam with extremism and terrorism and then uses this as a justification for Western intervention in Iraq. This second form of counternarrative highlights the “little stories” of groups and/or individuals that are produced at the margins of the telling of “official stories.” For instance, stories of ordinary peace-loving people in war zones of Iraq living everyday lives counter the official war narrative that equates all Muslims with fundamentalism, extremism, and/or terrorism. Counternarratives that tell those little stories emphasize their social and political dimensions, not merely

the personal ones. Furthermore, those counternarratives highlight the ways in which the marginalization of groups or individuals within a culture are legitimized and used to justify their exclusion, subjugation, and erasure from the official truth telling. Those little stories that constitute the counternarratives of this form engage and deconstruct the official apparatus (e.g., systems of education, justice, and religion) used to create and sustain “otherness” and maintain marginality.

What the two forms of counternarrative have in common is the production of an invisible silent “other” who stands unrecognized at the borders of grand/official narratives that assimilate the other by weaving a narrative of a common culture and shared language. Both formulations of counternarratives hold emancipatory possibilities for groups that are marginalized when stories concerning them are created by other entities. They dismantle the grand/official narratives that sustain hegemony, raise questions about the presumed superiority of one group over another, and take away the power of those entities that characterize, define, and/or claim to speak for all. Furthermore, counternarratives create new spaces and possibilities for the theorizing of a different form of knowledge that is new and non-Western/nonofficial. In this way, counternarratives go beyond merely countering or opposing Western/official knowledge to producing a different way of representation that is distinctly non-Western/nonofficial.

COVERT OBSERVATION

Covert observation is a particular type of participant observation in which the identity of the researcher, the nature of the research project, and the fact that participants are being observed are concealed from those who are being studied. Investigators using covert observation adopt the research role of complete participant.

Covert observation is conducted in three contexts: public and open settings where everyone has a right to be (e.g., grocery stores, airports), closed settings where the researcher is already a member (e.g., a nurse in a hospital), and closed settings where the researcher gains access by adopting a role appropriate for that setting (e.g., pretending to be an antiwar activist at a protest rally).

Covert observation has a number of strengths. It is particularly appropriate for the study of phenomena such as criminal and other deviant behavior of groups and individuals who would not normally allow themselves to be studied. By becoming a member of a group, the researcher directly experiences the activities of the group and so may develop a deeper understanding of the behavior. It has also been argued that this research method increases the trustworthiness of data in that participants are not controlled or manipulated and the reactivity or observer effect is less likely.

Covert observation has a variety of weaknesses. To gain access, the researcher needs to share or adopt characteristics with the group, and this may present a significant barrier. If the real identity of the researcher became known, the investigator could be confronted with a dangerous situation due to either the nature of the setting or the antagonism of unwilling participants. Covert observation restricts data collection. Overt methods, such as interviewing, and data-recording strategies, such as audiorecording and note taking, cannot be used. Fieldnotes must be prepared from memory after the researcher has left the field and, therefore, are subject to errors of omission and faulty recall.

Some researchers regard covert observation as an unethical practice because it represents an invasion of privacy and violates the norm of informed consent. The ethical guidelines for most of the major social science scholarly associations advise against the use of covert methods. However, other researchers, such as Richard Mitchell, claim that nearly all research involves some secrecy. For example, no matter what

method is used, few researchers disclose full information about a study and many adjust how they represent themselves so as to facilitate access. Covert observation conducted in public places, where it may be presumed that individuals know that others will see what they are doing, is less problematic. Finally, ensuring that research protocols involving covert observation undergo rigorous ethics review helps to ensure the safety and support the rights of participants.

COVERT RESEARCH

Covert research is an investigative strategy in which the researcher's professional identity and academic intentions are hidden, either partially or fully, from those involved in the study. Therefore, research is conducted without the knowledge or consent of those being studied. Although the use of covert research is increasingly frowned on, it remains an important qualitative research strategy in studies where opportunities to provide detailed explanations of the research or gain informed consent are limited. This entry outlines the different forms of covert research, discusses the advantages of using it as a research strategy, and considers the limitations of covert research and the challenges its use presents.

Types of Covert Research

It is possible to distinguish between active and passive forms of covert research. Arguably, the distinction between the two forms is meaningless because, in both cases, participants do not contribute willingly to the study. However, active forms of covert research are often more problematic than passive forms because

deceit is such a fundamental part of fieldwork relationships. When conducting active forms of covert research, investigators may purposefully obscure their identities and intentionally misrepresent their motivations for engaging in social interaction. For example, a researcher may participate in the activities of a religious organization as a member of the congregation, or may join a commercial organization as an employee, while actually conducting research on the organization and its members. Most of the prominent and controversial covert research has involved this type of subterfuge. However, researchers may gain access to a group or an individual overtly and still conduct covert research. For example, an investigator can claim to be conducting research on one subject area while secretly using contact time with participants to ask questions, observe activities, and/or gain access to documents that are unrelated to the study to which participants agreed to contribute.

Passive forms of covert research are also conducted without the knowledge or consent of those being studied, but investigators do not attempt to deceive or mislead participants. Traditionally, the most common example of this type of covert research has involved observation of social and physical activity in public places such as shopping malls, parks, restaurants, cafes, and bars. However, with the growth of virtual communities, studies of interaction and communications in internet chat rooms and through electronic message boards are increasing. Investigators may observe and monitor the online interaction of other participants but choose not to contribute or provide a formal explanation of their research. Researchers may also use nonreactive methods to gain information about individuals. For example, an investigator may interview one person as a way to get information about a second individual or group of people, or a researcher may examine records kept on people by organizations without the consent of the individuals concerned.

Passive forms of covert research often emerge because of particular contextual aspects of the fieldwork rather than a need for deception or subterfuge. For example, when conducting observational research in places where interaction between people is minimal, especially in places that people inhabit for short periods, the offer of any detailed explanation or the gaining of formal consent is unfeasible. Furthermore, when a researcher tries to gain access to a group or community without the help of a formal gatekeeper who could introduce the researcher and mediate his or her entry, the researcher's identity and intentions will

inevitably remain hidden from certain members of that group.

Time is also a key factor that determines researchers' ability to provide formal explanations and gain informed consent. The initial stages of research projects concerned with loosely connected individuals, or groups with fluid membership, are often conducted covertly because opportunities for explanation and consent are limited. However, as investigators gain access to individuals and spend increasing amounts of time with participants and informants, details about their professional identities and research intentions become increasingly clear. This is not to say that the research will become completely overt; in these kinds of studies, researchers continue to engage with new individuals who are not acquainted with the studies and for whom they remain covert research.

Advantages of Covert Research

When people are aware that their actions are being observed, recorded, and scrutinized, they often change their behaviors. Individuals may act in socially accepted ways and purposefully abide by social conventions that they usually reject. People may also behave in extraordinary ways and choose to over- or underemphasize certain actions and, thus, project a misleading impression of their identities and the values they hold. Therefore, investigators most often choose to engage in covert research to ensure that participants do not change their behaviors significantly; they may engage in covert research to try to gain a more authentic impression of people and their worlds.

Covert methods are used mostly in studies concerned with individuals who engage in what are conventionally perceived to be morally contentious or illegal activities. Such individuals and the groups or organizations with which they are affiliated often do not wish to draw attention to their activities and, therefore, are unlikely to participate consensually in research that jeopardizes their interests. So, investigators may presume that, to gain access to individuals and obtain information about their activities, it is necessary to conduct the study covertly. If participants are not aware that their actions are being researched, they are less likely to deviate from their normal behaviors. Thus, researchers can gain insights into social practices that are usually hidden from public view.

Beginning a relationship with informants or participants is often difficult. The esoteric nature of qualitative research means that initial encounters with

potential participants can often be made awkward and tense by any attempt to explain the study. Individuals may immediately withdraw from interaction when an investigator mentions that he or she is conducting research. If this happens, there might not be further opportunities to interact with people who decide that they do not want to communicate with the researcher. In covert research, these problems are avoided and, within that social context, social interaction can remain ongoing. By disguising his or her identity, the researcher can gain informants' trust faster and, consequently, get access to information faster. This is likely to be particularly important when researchers do not have extended periods of time in which to conduct fieldwork and there is not enough time to build formal and open relationships slowly between investigators and participants or informants.

Challenges in Using Covert Research

Covert research is, arguably, an abuse of investigators' powerful position. It is certainly true that unwilling participants do not have control over representations of their lives. This problem is likely to emerge in all but the most participative studies; however, in studies involving covert research, the potential powerlessness of participants is even more acute. Therefore, investigators must think carefully about the responsibilities they have to the individuals, groups, and organizations they study and about how social science serves or undermines the interests of particular sections of society. In many cases, covert research is an invasion of privacy, and many people find this objectionable unless there is a reasonable justification for it. Justification is usually based on arguments about the greater social good that such research serves. However, although some individuals and organizations present a clear and immediate risk to society, what social benefits are achieved through covert research and whether they are worth the cost to personal freedom and privacy are often contentious issues. There is certainly a risk that marginal groups and individuals who are studied feel even more stigmatized and, thus, are marginalized even further. In the cases of criminal groups and religious organizations, this will make its members even more suspicious of social science and encourage them to withdraw further from the legal and moral conventions of society.

The deception involved in covert research is problematic for research participants. Unwilling participants may feel deceived, and this may, in turn, taint their relationships with strangers in the future. It may

also make them suspicious of research, thereby fueling a perception that all social scientists are untrustworthy and that social science research is fundamentally exploitative. This may make it difficult for researchers to recruit participants in the future.

There is also a significant risk to investigators who engage in covert research. By adopting alternative identities and roles in the fieldwork, researchers may begin to question their own sense of self. This is especially problematic when conducting research on immoral or illegal activities. Trust between undercover investigators and the individuals who engage in illicit activities is often built through researchers' complicity. These acts may conflict with researchers' own sense of morality, and this may in itself cause psychological harm to researchers. Participation in illegal activities may result in prosecution, and (more seriously) some action may result in harm to researchers or other individuals. For example, those conducting research on fraud, theft, violence, or sex crimes, and who are expected (as part of the study) to participate in these activities in any way, are caught in a very perilous moral, legal, and professional position.

From a methodological point of view, the advantages of gaining access to previously hidden information is offset by the limitation placed on researchers trying to gain access to key pieces of data. When adopting a totally covert role, investigators must act within the boundaries of that role. Asking too many questions or probing questions that are inappropriate in a social context may make individuals suspicious of investigators. Therefore, researchers are limited in what they can find out, when they can find it out, and how they can get to specific pieces of information. Because of this, covert research may be more time-consuming than overt research and may offer only limited information on specific issues that cannot be explored with participants through everyday social interaction.

Finally, academic institutions and the organizations that fund research are increasingly concerned with the ethics of research. Most academic institutions have developed, or are in the process of developing, ethical guidelines that define how research is to be conducted. Most of these institutions also have systems of review that evaluate the ethical dimensions of research conducted by affiliated staff. Support among funding bodies and host institutions for covert research that involves active deception is declining. Fear of legal prosecution, negative publicity, and any subsequent cut in funding has made organizations wary of becoming associated with such research.

Investigators preparing to engage in active forms of covert research must be clear about the risks involved; they need to carefully evaluate the benefits of covert research and must be prepared to justify its use. Investigators working in social or organizational contexts where explanation and informed consent are not possible, or those conducting research in contexts where relationships are built slowly and covertness is unavoidable at certain stages of their studies, must draw on a number of points of reference in deciding how to approach the emerging problems. When deciding on the appropriateness of covert research, investigators must consider the professional and institutional guidelines and the legal implications of their actions, they must draw on the past experiences of other researchers, and they must examine reflexively their own moral and ethical positions before entering the field.

CREATIVE WRITING

Creative writing consists of writing in literary forms such as poetry, fiction, plays, creative nonfiction, and

memoir. Creative writing in qualitative research has several facets. One could consider that all writing is creative whatever the purpose. Indeed, in qualitative research circles, the use of literary forms such as poetry, fiction, plays, creative nonfiction, and memoir has proliferated. Literary writing is usually situated in the humanities, especially literature, theater, and creative writing, where people who use creative writing as a technique usually have some instruction and background. In the social sciences, the increase of literary writing has posed certain problems, especially with regard to the quality of the writing.

Using poetic representation in qualitative research usually takes the form of free verse. Free verse is also called *vers libre*. Qualitative researchers who use the technique of *vers libre* often break up interview transcripts into small (or short) units, or lines, without regard to foot, syllable, or meter. The purpose is to focus and intensify the expression of what the participant said. The poetic technique is usually enjambement, which breaks up the text by clauses or phrases, proceeding through the verse to the period at the end. The use of other verse forms such as blank verse (where there is meter but the ends do not rhyme), the sonnet, the ballad, the villanelle, the rondeau, the epic, and the haiku is rare.

Fiction as a technique in qualitative research is generally frowned on. Rather, qualitative researchers in social science may “fictionalize”; that is, they may be required to change the names—to use pseudonyms—to protect their participants. However, changing the essential facts and findings is not recommended. Audit trails should yield evidence that what researchers purported to find was indeed true.

However, debates have occurred about whether a dissertation can be a novel; for example, the debate among Robert Donmoyer, Elliot Eisner, and Howard Gardner at the 1996 American Educational Research Association annual conference in New York City. Donmoyer and Eisner advocated that, indeed, a dissertation could be a novel, whereas Gardner advocated that writing a novel for a dissertation views fiction as narrative and not as a complex artistic effort requiring familiarity and background with the history of fiction and of writing fiction, a background usually gained when one majors in literature and has studied the tradition, beginning with its inception during the 18th century. The subject is still controversial, and whereas some programs permit fictional qualitative dissertations, others do not.

Those who advocate that one can write a novel for a qualitative research dissertation seem to view the

Fraternity Bar in Athens, Georgia

they were shoulder to shoulder
 drinking beer and playing pool
 the room stunk of smoke from hell
 the light under the bar shone orange
 I sat at the end
 talked to who came by
 of race in Georgia
 inexhaustibly they spewed
 heedless of Mark Fuhrman's ignominy
 that word
 northerners don't dare to use
 and many other words prefaced
 by "they" and "them"
 shaved almost bald
 in fashion in front-faced
 corduroy baseball caps
 ("I'd never wear my hat backwards like them")
 beside their long-haired white-toothed beauties
 they assumed a tribal camaraderie
 from the color of my skin
 told me their scarred inner hearts
 while I smoked their cigarettes
 in words I didn't want to hear
 in words I wish I hadn't asked
 at 2 A.M. they bid me bye
 "y'all come back again, Professor
 when you move to town"
 in a conspiracy of skin and tribe
 I kept my shame.

novel as mere narrative, rather than as art and metaphor rendered more true than the accretion of the facts. They may see fiction in the Aristotelian sense, where the writer is viewed as an imitator of nature. The humanities sees fiction as an art, a creation that is itself, through plot, scene, structure, story, climax, and other elements, a totality that through technique is rendered more than the sum of its parts in the truth that it tells. Often that truth is not consciously intended but is experienced by readers through some

mysterious synthesis that occurs through the process of reading. Again, the question remains whether the qualitative researcher seeking to write a novel (or even a short story) based on the data gathered is being a qualitative researcher or a literary artist and whether the researcher should study fiction so as to write it.

The use of the playwriting genre of creative writing in qualitative research usually takes the form of readers theater, where the participants present the data (from interviews, observations, and documents) in sequence, standing or sitting, dressed in black, on a stage with their script in folders, reading in a dramatic manner. The data are put into the format used in plays. Again, the creativity is in the form of presentation and from the selection of the excerpts that are read by the participants on stage.

Other theatrical forms of creative writing in qualitative research include documentaries and films that are edited in an artistic manner before presentation and publication. These usually have a credits menu that includes the term *writer*.

Creative nonfiction is the most frequent genre of creative writing that is used in the representation of qualitative research. Creative nonfiction uses techniques such as the active voice, rather than the passive voice, in verbs; vivid description using colorful and evocative adjectives, nouns, and adverbs; and recreated dialogue. Creative nonfiction is also called journalistic and takes the form of the essay that is based on researched material. The writing is concrete, with solid examples, and stresses ease of readability, inviting readers to identify with the situation being depicted. In the literary world, the issue of willful falsification has arisen, but in qualitative research circles, the ethics forbid falsification and this is prevented by the necessity to preserve original data.

Memoir, or telling about a part of one's own life in a thematic manner (as opposed to autobiography, which is a chronological account of one's life), is similar to what is called *autoethnography* in qualitative research. Self-observation is the technique, and the attempt to do so again puts forth the questions of whether one can truly observe one's self, whether doing so is social science or literary art, whether or not falsification must occur, whether objectivity is possible, and/or whether objectivity is merely a trope and not possible whether or not one writes in the third person or in the first person. The literary (but not the social science) shelves of bookstores are filled with memoirs by people who have stories to tell, who experienced trauma or addiction or were eyewitnesses to

historical happenings, and who tell their stories using structural techniques such as scene, climax, and even plot and try to write about it in a compelling and interesting manner. Again, the writing is creative, with an intent to amuse and entertain as well as to inform.

In conclusion, creative writing in qualitative research takes several forms, all of which contain their own rules of expression that should be incorporated when the qualitative researcher is writing. The qualitative researcher seeking to write poetry, fiction, plays, creative nonfiction, or memoir should be aware of the literary roots of these genres and even, perhaps, do some study of them.

CREDIBILITY

One of the responsibilities of any qualitative researcher is to create a high level of consistency in the article. For example, the readers and research participants should see why a particular research model was used and why the participants were selected for the study. The data analysis process should also reveal a believable link between what the participants expressed and the themes and codes that emerge. The accuracy of this process for both the readers and participants creates a measure of credibility to the research project. As such, credibility can be defined as the methodological procedures and sources used to establish a high level of harmony between the participants' expressions and the researcher's interpretations of them.

The basic notion with credibility is that both the readers and participants must be able to look at the research design and have it make sense to them. Questions for the researcher to consider in relation to credibility include the following: Were the appropriate participants selected for the topic? Was the appropriate data collection methodology used? Were participant responses open, complete, and truthful?

Here is an example of how these items of credibility could be addressed when putting together a research study on the devaluing of nurses by doctors using a survey instrument and focus groups. The study would lack credibility if nurses were the only participants. It would be more credible by including nurses, registered nurses, and doctors. A closed question survey would lack credibility because the researcher is defining the context through the survey items rather than allowing the participants to define them. A survey instrument with both closed and open-ended items would be more credible. Credibility of the study would be lacking if a focus group of two doctors and two nurses was the only means for the participants to discuss the topic because nurses might not provide open and truthful information in the presence of doctors. In this focus group setting, nurses also would not be able to provide complete information because of the power dynamic that exists between doctors and nurses. Thus, this methodology for collecting the data would have low credibility because it has a very narrow means of illuminating the context under study. The credibility of the study could be enhanced by having a larger focus group, introducing private interviews with the

participants, and then providing opportunities for follow-up interviews as necessary.

The researcher can use the following methodological procedures to increase credibility:

Time: Establish enough contact with the participants and the context to get the information one needs.

Angles: Look at the data from different perspectives and viewpoints to get a holistic picture of the environment.

Colleagues: Use support networks knowledgeable in the area to review and critique the research and data analysis findings.

Triangulation: Seek out multiple sources of data and use multiple data-gathering techniques.

Member checks: Use the participants to make sure that the data analysis is accurate and consistent with their beliefs and perceptions of the context being studied.

CRITICAL ACTION RESEARCH

Critical action research is a validation and extension of action research or participatory action research processes that combines critical theory with the action research paradigm. The critical action research process turns the traditional power hierarchy between “professional” researchers and research “subjects” upside down and invokes a commitment to break down the dominance and privilege of researchers to produce relevant research that is able to be sensitive to the complexities of contextual and relational reality. In this type of research, the stakeholders of the research work with the researchers to define the problem and set the research agenda, find new ways of seeing the situation, and work toward solutions. The process empowers both the researchers and the research participants because the research effort allows discovery and exploration of power differentials in the research

relationship as well as in the community under study. This entry describes action research, critical theory, and their integration to form critical action research. It then presents a number of examples of such research and reviews some of the challenges in using this approach.

Action Research

Kurt Lewin, one of the principal founders of action research, called for a collaboration between organizational members and researchers on all phases of research from planning to analysis. Action research is characterized by three key qualities: (1) a focus on problem solving, (2) an emergent nature, and (3) a collaborative effort between researchers and participants.

The overarching trait of action research is that it involves generation of practical knowledge useful for sustainable organizational or community change. Action research, by definition, always occurs within practice in concrete situations. Action research is change oriented and accomplishes this by involving the people under study as co-researchers, thereby providing them with the tools to effect change themselves.

Action research involves an emergent inquiry process that evolves throughout the research effort and focuses on generation of new knowledge and ways of thinking and seeing the world. In action research, scientific knowledge is combined with organizational knowledge in a collaborative effort designed to solve actual organizational problems. In addition, local knowledge held by the organizational stakeholders is considered to be equally as valid as, or more valid than, that held by the “professional” researchers.

Action research is more concerned with the relational cooperative process between the researcher and the researched, and with the practical nature of the research outcomes, than with following positivist research criteria. In opposition to positivist research, action research deobjectifies research participants by making them co-researchers rather than “subjects” under study and gives participants the opportunity to understand their (and others’) interpretations of the world.

Action research may include qualitative or quantitative research methods and data collection methods such as questionnaires, in-depth interviews, focus groups, informal conversations, journaling, document reviews, and observations. Action research often includes multiple methods and many different ways of knowing as it strives to be inclusive of diverse viewpoints. Regardless of the method used, action research

occurs within natural contexts and often uses interpretive methods of analysis.

Critical Theory

Critical theory looks at, exposes, and questions hegemony—traditional power assumptions held about relationships, groups, communities, societies, and organizations—to promote social change. Combined with action research, critical theory questions the assumed power that researchers typically hold over the people they typically research. Thus, critical action research is based on the assumption that society is essentially discriminatory but is capable of becoming less so through purposeful human action. Critical action research also assumes that the dominant forms of professional research are discriminatory and must be challenged.

Critical action research takes the concept of knowledge-as-power, and equalizes the generation of, access to, and use of that knowledge. Critical action research is an ethical choice that gives voice to, and shares power with, previously marginalized and muted people.

Mission of Critical Action Research

Critical action research, often conducted at the community grassroots level, typically takes as its mission social critique—the study of marginalized, oppressed, disenfranchised, or disadvantaged populations—with the aim to promote social justice among these populations. Critical action researchers do this by questioning the social implications and moral issues of action and by seeking shared understanding of the social action.

Critical action research seeks to empower people by involving them in the study of the social processes that have constructed their submissive positions in society. In the process, critical action research moves people with issues such as illness, disability, and poverty toward equal status with the people who are studying them. Thus, critical action research models a more equal or democratic distribution of power in community. The aim of critical action research is twofold: (1) improved understanding of a social phenomenon and (2) social transformation at a community or organizational level resulting from reflexivity and self-reflection about the hegemony in the research relationship and in the community or organization. Critical action research requires seeing things through

the worldviews of other people and understanding, perhaps challenging, conflicting value systems.

Critical action research follows a collaborative cycle between participants and researchers of reflecting, planning, acting, observing, reflecting, replanning, and so on. Elizabeth DePoy and colleagues in 1999 suggested a model of critical action research that includes the following:

1. Recognizing and articulating a social problem
2. Convening a steering committee from among all stakeholder groups
3. Identifying the scope of the research and the type of social change desired
4. Selecting a collaborative research team
5. Training lay researchers on the research team in research methods
6. Designing the study, including research questions and methods
7. Conducting the study and analysis
8. Reporting the findings in accessible formats to all stakeholder groups
9. Acting on the findings by planning and following through with social change
10. Identifying a steering committee for follow-up inquiry

The cycle of planning, reflecting, and acting between community participants and researchers breaks down the traditional positivist research tradition of certainty and objectivity on the part of the researchers. It requires a willingness for vulnerability on the part of both the researchers and the community participants as they open their own ways of thinking, behaving, and being to scrutiny and question. However, because critical action research allows those being scrutinized to participate in the scrutiny, the level of insight and understanding resulting from the process can be deep and lasting provided that everyone involved is given the autonomy to fully collaborate in every stage of the effort.

Examples of Critical Action Research

Critical action research is frequently conducted in many different fields of study. In education, for example, much critical action research looks at issues of

curriculum or teaching styles by collaborating with students and other educators. Terry Carson's research group, "Collaborative Action Research in Peace Education" or CARPE, initiated a dialogue with other teachers and education professionals on the topic of international peace education. This process used a critically reflective process to develop and implement a practice of peace education in their respective teaching situations. Kathleen Chiswell, also in education, used critical action research to examine her own teaching methods and communication style. Dorothy Lander and Leona English, in adult education, used critical action research to read and respond to each other's research through a dialogic process of reflecting on, analyzing, and synthesizing their writings. Marion Walton and Arlene Archer used a critical action research framework to examine a curriculum on academic literacy. Paul Dufficy used critical action research to investigate the teaching of English as a second language in multilingual classrooms in Australia.

In other fields, Caroline Humphrey studied the personal, professional, and political dilemmas of women, Blacks, people with disabilities, lesbians, and gay men within labor unions in Britain. Jonathan Fox described how Martin Diskin worked with policymakers and development agencies in Latin American studies to conduct what they called "power structure research" in which they exposed injustice as a strategy for building coalitions and motivating movements. Christine Davis's ethnography of a children's mental health treatment team was an interdisciplinary research project involving the fields of communication studies, social work, and mental health. Conducted in partnership with community agencies, this research examined issues of power, marginalization, and control within these teams. It suggested a stance toward children and families that rejects the traditional hierarchical medical model of care and instead treats them as unique valuable humans and as equal partners in treatment.

Challenges to Conducting Critical Action Research

In practice, full democracy in action research is a large and difficult change from traditional research roles. Giving research participants status that is fully equal to that of the researchers is a tall order, and inviting people to participate in research that has already been designed, organized, and set up by professional

researchers will not likely succeed in affecting hegemonic structures. In fact, simply the act of choosing a group or topic to study points out hegemonic power and control issues inherent in a social order. The research act itself, therefore, involves political choices and ramifications. Creating true change in a research relationship requires major shifts in thinking and behaving—inviting participants to formulate the original questions, design the methodology, facilitate the sessions, and lead the analysis efforts. It requires physically moving the research away from the universities and into the community. It requires dissemination of the findings in nontraditional and nonacademic ways. It most certainly requires a different type of engagement on the part of the "professional" researchers to allow "nonprofessional" researchers room to engage.

Effecting true change in a community or an organization from action research is also a challenge. Collaborative knowing requires setting aside assumptions, prejudices, and even experiences brought by all research participants (both professional and lay participants). It requires focusing on the process as much as on the outcomes. It requires being open to different ways of knowing, understanding, and interpreting and having the willingness to take action and risk change.

Summary

Critical action research is an ethical choice that exposes and seeks to change existing power structures and inequalities within the community under study. It does so within a framework of smoothing out inequalities within the research structure. Both of these processes, at the research level and at the community level, are fraught with the challenges expected when rebelling against the status quo. This research-as-activism process leads to social change, but it is neither smooth nor easy. It is, however, worthwhile.

CRITICAL ARTS-BASED INQUIRY

Critical arts-based inquiry is characterized by its integration of multiple disciplines and diverse discourse communities. Similarly, critical arts-based researchers

facilitate community-based performances that reconstruct or blur both physical and abstract boundaries. The first and most dramatic such realignment is the synthesis of beliefs and practices among social scientists with critical revolutionaries among artists. Activism, such as is seen in revolutionary new genre public art and performance art based in a history of resistance, is reflected in critical performance ethnography and other new methodologies used in arts-based inquiry. Social science research that can be described as critical arts-based inquiry is likely to consider social, political, and critical aspects of pedagogy and to enact theoretical stances of dialogic, experiential, transactional, emancipatory class and race theories, and/or feminist critical critique. Indigenous voices and anticolonialist discourse will be features of this work. It will resound with multiple and contradictory worldviews in shared pedagogical spaces. Thus, it will encourage new identity politics that bridge gender, race, and ethnic differences. In so doing, it will embrace radical democratic ideals while performing social criticism. Social science in this ilk uses the processes of critically reflective inquiry to expose the complexities of educational processes, deepens understandings of the power structures inherent in those processes, and creates emancipatory responses to social injustices.

In addition to drawing from the community of radical political artists, revolutionary arts-based inquiry emerges from, among others, qualitative inquiry theories and methods developed in the areas of critical inquiry, arts-based research, and performance ethnography.

Critical Inquiry

Critical inquiry occurs when actors attempt to determine the meaning and value of societal artifacts and actions (e.g., words, work, hegemony). Researchers undertake critical inquiry because they seek to understand the systems of power and oppression at play in society and because they search for ways to disrupt unjust systemic power structures. Inquiry serves as the basis for reenvisioning social interactions, processes, and historically ingrained ideas in efforts to reform society toward democratic practices and values of social equity. Critical inquirers typically either belong to the communities they research or form very strong, caring, emotional, and intellectual attachments with individuals in those communities as part of their methodological praxis. Meanwhile, “inquiry” implies a broader range of questions and modes of interpretation than

does “research,” and it stands in some contrast to “research” in its use in emergent traditions of qualitative research.

Arts-Based Research

Arts-based research draws on emotive and affective responses to experiences, senses, and bodies in exploration of space and place; it arouses imaginative and emotive aspects of intellect; and it opens alternatives for interpretive and creative praxis. Primarily, it addresses the need to explore new options for representing research that are produced within new paradigm methodologies. Arts-based researchers appropriate many different forms of the arts for reporting on research, including dance, film, plastic arts, photography, drama, poetry, and narrative writing.

Types of Critical Arts-Based Inquiry Methods

To do critical arts-based inquiry, researchers-as-artists and artists-as-researchers create spaces for dialogue and facilitate openings for diverse voices. They engage in multiple collaborations of varying types. Although theory provides guidelines for work (both process and product) that is political, pedagogical, moral, and ethical, the purpose of the work is to change accepted theory, create new understandings, and involve a broader community in reflective practice so as to initiate meaningful actions that complete political commitments to social justice, democratic equity, and emancipation of oppressed peoples. It follows, then, that there are no prescribed methods for doing critical arts-based inquiry. The methods will be those that fit the context and priorities of the Indigenous or local community where the research occurs as well as its forms and traditions of art. Modes of performance will fit meanings and be chosen for their “power to inform,” and they are not limited to public murals, films and photographic displays, oral and written poetry and stories, installations, dance, and dramatic and comedic performances. Quality of critical arts-based inquiry hinges on inclusivity, reflectivity, advocacy, and the potential of such inquiry to inspire various types of actions such as the following.

Dialogue/Discursive Action

Within critical pedagogies, the goal of the researcher is educative and includes engaging people

in narrating their own lives to better understand their lived realities. These social narratives reveal problems inherent in social structures that are played out in people’s lives. Voice is itself a social problem. Dialogue reveals problems of voice. Voice ties to relationships, hierarchies and distribution of power, issues over whose knowledge is important, and questions about how we know. Furthermore, it is possible to bridge cultural differences by sharing one’s narratives of lived experience in dialogue with others. Dialogue creates community through empathy for others based in understanding others’ lived realities.

For example, interviews, a common method used in qualitative research, are opportunities for storying individuals’ lives. The interview is an opportunity to give personal voice to a social problem, and it is a forum for critical dialogue. In critical dialogue, meanings are co-constructed but always controlled by the person telling his or her own story, yet the interview presents an occasion for questioning culturally preferred terms of language and interrogating the cultural systems that have deterred or provided opportunities in an individual’s life. In critical arts-based research, dialogue is performative, and it both draws from and challenges the conventions of various literary genres.

Collaborative Action

Collaboration bridges the gap between the researcher and the researched. The task of the critical arts-based researcher is to facilitate inclusion. In principle, the critical arts-based project provides openings for entry of as many affected people as possible in the processes of inquiry. Among the properties of collaborative interaction in critical approaches to research is explicit recognition of difference within communities. Many arts are well suited to demonstrate, represent, and facilitate conflict, tension, difference, processes of change, and juxtaposition of multiple values and points of view.

Reflective Action

Critical arts-based research is produced by critical consciousness, which is achieved through interactions and mutual struggle among people in discourse communities. It is the goal of such research to encourage both participants and audiences of arts-based performances to engage in critical reflection such as is necessarily precedent to meaningful political action. In critical arts-based research, reflective action might be

achieved through poetry, theater, dance, and other performances that are presented to diverse audiences as precursors to dialogue that generates empathy and understanding and also erases the boundaries of “otherness” between people in diverse communities.

Performance/Performative Action

Importantly, for critical arts-based research, use of various art forms is not reserved for reporting research findings; instead, forms of art are adopted from within the community as an already existing form of dialogue that embodies the culture of research participants.

Critical arts-based research is public pedagogy. The telling of life stories can take many art forms. For instance, Indigenous arts often relay stories based in tradition, history, and social realities. Arts can be used to demonstrate the conflict of individuals in a changing world where cultural values are in conflict. They can be used to interrogate stereotypes. Arts-based critical inquiry is action based, process oriented, and situated in real-world problems, events, and communities. Art is used more for its power to emotionally involve audiences and research participants, create dialogue, cause questions, and raise doubts than for representation. Within its limited representational scope, critical arts-based research uses the power of imagination to inspire community efforts to solve social injustices and opens spaces in which to imagine and hope for the creation of circumstances of social equality.

As with other forms of arts-based research, the performative turn in social science research is interdisciplinary, drawing primarily from new paradigm research in sociology, anthropology, communication, and education. Its basic tenet is that cultures are performances (of language, rites, and everyday events) and that, by reproducing the phenomena of everyday events in new reflections of understanding of these performances, researchers can intervene and resist hegemonic traditions in thought, language, and action. Performances of possibility, arrangements that recover meaning from tradition, offer hope and create new ways to see and be in the world.

Ethics of Critical Arts-Based Inquiry

With the new paradigm of community-based research, the values behind reporting conventions have evolved.

Writing and other representations of critical arts-based inquiry deliberately expose the research processes; textual coherence gives way to “messy texts” that expose and even amplify disagreements between researchers and participants, contradictions between beliefs and actions, power relationships in the research community, and conflicts, holes, and gaps in the information used to develop meanings. Transparency is a guiding concept for critical arts-based researchers. Gone are the objective omniscient voices of researchers. The values, worldviews, and assumptions about the research process, the community of participants, and the researcher are exposed and explained in the mediation of meanings brought out during the research process.

Inquiry is a moral act as well as a political act. The primary value exercised in critical arts-based research is the ethic of care. An ethical critical inquirer pays attention to the feelings and emotional investments of participants, is responsive to conflict, and is concerned with analyzing and discussing the political implications of all aspects of the work. Because the arts are conducive to thick descriptions and detailed multivoiced narratives about everyday experiences, they provide useful formats for conducting inquiry that is dialogic and portrays “truths” in flexible dynamic forms. This does not mean that they are impartial; they tell the stories and perform the activities of particular groups and individuals whose lives are improved by reinvigorating an ethics of care at a societal level. Through demonstrations of injustice, there is hope for a dialogue of care to emerge and the possibility for social change to emerge out of dialogue. The arts are uniquely suited to provoking reflection, creating opportunities for dialogue with others about meanings taken from reflection about a work of art, and forming communities of people based in the hope for social change. Such is the function of critical arts-based research. The performative dimension of arts-based research moves the audience to discourse and beyond; it evokes communal expressions of understanding that reveal the engaged imagination, the powers of empathy, and the embodied responses to art.

CRITICAL DISCOURSE ANALYSIS

Critical discourse analysis (CDA) is a theoretical approach to studying the role of language in society that originated within linguistics but has found widespread application across the social sciences. The term is also sometimes used to refer only to the methodological framework of CDA that centers on the qualitative linguistic analysis of spoken or written texts.

Background and Key Tenets

CDA became known through the writings of a group of primarily European linguists during the late 1980s, most prominently Norman Fairclough, Ruth Wodak, and Teun van Dijk. Similar but largely independent developments emerged in the United States around the same time through the work of James Paul Gee. The intellectual origins of CDA reach back to British and Australian critical linguistics of the 1970s that researched the intersection of discourse, ideology, and power. Critical linguists were greatly influenced by

M. A. K. Halliday's systemic functional linguistics, which provides an important foundation for current CDA theory and methodology as well. Although the specific research areas and methods of analysis within CDA are by no means homogeneous, what unites all scholars engaged in CDA is a critical perspective that is geared toward examining the subtle ways in which unequal power relations are maintained and reproduced through language use. Many CDA scholars reject the idea that CDA is an established "school" or "paradigm" and prefer to characterize their work as an explicitly critical and political orientation to studying discourse.

The term *discourse* is generally understood to refer to any instance of signification, or meaning-making, whether through oral or written language or nonverbal means. In this sense, a dinner table conversation and a newspaper article on globalization are instances of discourse, and so is an advertisement in a fishing magazine, although most CDA analyses rely on written texts or transcripts of oral interactions as data. In CDA, discourse is assumed to be a central vehicle in the construction of social reality. Because different ways of using language are thought to produce different social outcomes, close attention to linguistic properties of texts can shed light on how different outcomes may come about. Most CDA research operates within a moderate version of social constructivism that acknowledges the enabling and constraining effects of existing structural arrangements.

CDA scholars also advocate situating linguistic investigations within social analysis. Their emphasis on interdisciplinarity has resulted in an engagement with a variety of theories outside of the linguistic canon, most often in sociology, cultural studies, and political economy. This fusion has entailed a significant expansion in the conceptual toolkit of the CDA analyst because the goal is no longer linguistic description but rather an understanding of how language-in-use (discourse) contributes to and reproduces social inequality. Concepts such as globalization, power, ideology, and hegemony often figure in CDA studies that attempt to capture the interconnections among discourse, power, and social organization.

Areas of Research and Application

Much of the early work within CDA targeted the political domain. This remains a very active line of research

to date, and studies typically scrutinize speeches by key politicians or critique documents published by government agencies, institutions, or international organizations. Many scholars have engaged in researching and critiquing media texts from a CDA perspective, pointing to systematic biases and discriminatory tendencies in news reporting. Examining media images such as advertisements constitutes an important area of visual semiotics, a line of inquiry that has taken CDA tenets beyond the verbal realm. A considerable number of feminist researchers have relied on CDA to produce illuminating analyses of gender-based discriminatory practices in a variety of discourse genres. CDA has been widely applied within research in education, an area not only rife with social problems but also where discursive practices are central and salient. Recently, more CDA studies analyze face-to-face interaction, examining various service encounters or personal narratives produced in research interviews.

Major Theoretical Strands

In addition to methodological and conceptual diversity, CDA as a mode of investigation lacks a unitary theoretical framework, although it is by no means atheoretical. Norman Fairclough was one of the leading developers of CDA's theoretical grounding, and his writings have become standard reference points for many who pursue critical textual analysis. One of the theoretical challenges for CDA as a socially and politically sensitive model of language use has been to explicate the relationship between discourse and social formations while attending to the layered nature of social existence. Fairclough addressed this particular problem by advocating a three-tier organization of social life that is well known within the social sciences: Social events (micro level) are linked to social structures (macro level) by mediating social practices (meso level). Discourse is a part of all three levels; language is seen as a set of structural possibilities from which certain orders of discourse emerge at the level of social practices, which then influence the production and reception of discourse in social events. Importantly, discourse in this sense is not another social practice but rather a part of social practices. As such, it should be analyzed in conjunction with other social elements of events and practices such as material surroundings and participants and their social relationships.

A second theoretical strand within CDA concerns itself with the role of cognition in maintaining oppressive social practices and reproducing ideologies, and the works of Teun van Dijk and Paul Chilton are

relevant in this regard. Cognition within CDA is always socially rooted and encompasses shared group norms, beliefs, attitudes, and ideologies. Researchers studying social cognition emphasize that individual or group discriminatory practices, such as acts of race-related violence or anti-immigrant legislation, need to be studied in conjunction with the social cognitions (attitudes and ideologies) that are necessary to produce and maintain them. Many scholars have studied metaphors as a discursive link that mediates between social cognition and social organization. Discourse constitutes an important arena because beliefs and norms are largely disseminated and reproduced through public means of communication, all of which are controlled by the elite. Through their privileged access to outlets of public discourse, elites play an instrumental role in the shaping of public opinion and the production and maintenance of discriminatory and biased beliefs, attitudes, and ideologies.

In their investigations of discriminatory discourses of various kinds, Ruth Wodak and her colleagues developed the discourse-historical approach as a critical mode of inquiry within the larger framework of CDA. Like most CDA research, discourse-historical studies are concerned with social critique through the in-depth analysis of hegemonic discursive practices within particular social domains, most notably politics. Discourse-historical investigations place special emphasis on studying diachronic changes in discourses as well as tracing intertextual connections among areas of social life as a necessary step to uncover how genres and discourse topics spread across time and social domains. Analyses are complex because researchers rely on multiple data sources (e.g., newspapers, legislative texts, individual narratives) to link text-internal analysis to sociohistorical context and draw on interdisciplinary theoretical frameworks for interpretation and explanation. Researchers working within this strand have identified systematic ways of using language to discursively construct sameness or difference ("us" vs. "them") that are deployed in racist or nationalist discourses across contexts.

Methodological Principles

Given CDA's disciplinary roots in linguistics and the theoretical import attributed to language, linguistic (grammatical) analysis constitutes a core element of most CDA research. However, there is widespread variation among studies in this regard. Analyzing texts for grammatical structures requires some training in

formal linguistics. Scholars who have taken up CDA vary greatly with regard to disciplinary orientation and background in linguistics, resulting in analyses that differ widely in their scope and detail to attention to linguistic properties of texts. Second, in every text, there is a multitude of potentially relevant discourse structures that could be examined so that a full analysis of any piece of discourse is impossible. Third, the type of data used will, to some extent, determine the type of linguistic properties that can be examined. For instance, although a politician's speech may be studied for the intonation patterns and phonetic features he or she employs, such analysis is clearly impossible when one is dealing with newspaper articles.

In line with CDA's explicit commitment to furthering social justice, most investigations start by identifying a social problem that has a discursive aspect. Often the social problem under scrutiny involves some form of systematic oppression or marginalization of particular groups by a dominant group such as racism or nationalism. Studies focus on the discursive manifestations of (hegemonic) oppression within a particular network of practices such as education or the media. The specific social domain will also partly determine what kinds of data are to be analyzed. Studies looking at media representations of minority groups may examine newspaper articles, transcripts of television debates, and/or radio interviews. If the locus of interest lies in the discursive exclusion of immigrant children in mainstream classrooms, the researcher may record class interaction and conduct interviews with teachers. There are no rules for how much data are enough; that decision will depend on the scope of the research project. Analysts can choose to look at how a particular event is reported in several newspapers, compare two textbooks for ideological content, or critically examine a single political debate. Ideally, CDA research is conducted within an ethnographic framework or involves a thorough description of the institutional framework in which the given social practice is embedded. The ultimate goal of analysis is to identify ways of resisting or changing oppressive discursive practices, although this objective often receives only modest attention.

Regarding the analytic procedures of CDA, texts can be examined for a number of properties that are thought to contribute to their ideological shaping. When researching how certain people or events are discursively represented, for instance, one can examine how agentive or salient they appear in a text. One way of doing that is to analyze the grammatical role in which a person is placed (e.g., actor, affected) or whether a

person appears as a named individual (e.g., Mr. Brown), as a member of a group (e.g., a policeman), or as a collective (e.g., the police). One can also look at the types of processes that are associated with particular people and look for any patterned differences. In a newspaper article, for example, who typically appears as agents of activities that have negative connotations? A researcher may choose to concentrate on analyzing the argumentation structure of a text and its rhetorical effects. This may entail looking at how clauses and sentences are linked through causal, contrastive, or other relations. The text may also be analyzed with regard to the source of legitimation the author uses to support points and claims (e.g., personal narrative, reference to authority), and an examination of modality (e.g., modal verbs, hedges) can shed light on whether the information is conveyed as a fact, a possibility, or an opinion. Studies that look at conversational interaction will have additional analytic dimensions such as turn taking, interruptions, and the role of nonverbal cues.

Critical Assessments

Critical discourse analysis has gained currency and legitimacy across many disciplines in the social sciences and, due partly to its popularity, has also become the target of substantial scholarly critique. Probably the most serious critique has questioned the assumptions of CDA research regarding the relationship between linguistic form and social function. It is a problem of circularity; CDA claims that no linguistic form has intrinsic ideological function, yet analysts are able to "read off" the manipulative intent of texts. Many critics have also raised the point that, given the analyst's a priori critical and political stance, the analyst is likely to find what he or she is looking for in a text. This also relates to charges against a lack of methodological rigor in data selection/elicitation and analysis that leaves too much room for researcher bias to guide the research process. Finally, a preference for structural and ideological critique within CDA has precluded analyses that highlight the creative power of language that enables people to resist or subvert powerful discourses. Clearly, CDA scholars will need to continue engaging with these critical issues, especially if CDA is to maintain its appeal as a cross-disciplinary framework and advance both theoretically and methodologically.

CRITICAL ETHNOGRAPHY

Critical ethnography is a relatively new mode of qualitative investigation and one in need of further elaboration, discussion, and debate. Critical ethnography shares the methods of traditional ethnography, such as by seeking the emic perspective gained through intense fieldwork, but it adds an explicit political focus. This focus places critical ethnography in a unique position to examine power-laden social and cultural processes within particular social sites. More specifically, critical ethnography can be defined as a research methodology through which social, cultural, political, and economic issues can be interpreted and represented to illustrate the processes of oppression and engage people in addressing them.

History

Critical ethnography is a relatively new research methodology. However, critical ethnography has its roots in the well-established tradition of anthropological ethnography. Critical ethnography grew out of dissatisfaction with both the atheoretical stance of traditional ethnography, which ignored social structures such as class, patriarchy, and racism, and what some regarded as the overly deterministic and theoretical approaches of critical theory, which ignored the lived experience and agency of human actors.

In the Chicago School, traditional ethnographers were beginning to examine critical issues by researching subordinate populations and shifting the focus from individual experience to cultural dominance and marginalization. In Britain, a “new” sociology produced prototypes for a dialectical representation of structure and agency.

In parallel with sociology and cultural studies, critical ethnography was being taken up in education. Here critical ethnography was positioned as the

convergence of traditional ethnography and composition pedagogy, providing a new sociology of education that highlighted both neo-Marxist and interactionist perspectives. These shifts occurred from the 1970s onward in both North America and Europe, producing differing accounts of what constituted qualitative methodology—and, within this, ethnography and critical ethnography—and how they should be practiced. During the past decade, however, advances in the description and application of critical ethnography have produced a more coherent account.

The most notable publications influencing the uptake and development of critical ethnography have been Jim Thomas’s *Doing Critical Ethnography*, which outlined the theoretical underpinnings of critical ethnography, and Phil Carspecken’s *Critical Ethnography in Educational Research*, which provided a methodological theory of critical ethnography accompanied by empirical techniques, data, and findings.

Carspecken’s work has been most influential. In his text, Carspecken drew on the work of Joe Kinchloe and Peter McLaren, who outlined the assumptions shared by critical researchers. These include assumptions that inequality exists in society, mainstream practices often reproduce inequalities, oppression occurs in many forms and is most forceful when it involves hegemonic learning, and critical research should engage in social criticism to support efforts for change. These assumptions mirror the tenets of critical ethnography regarding both the nature of reality and the ethics or purpose of such research.

The philosophical approach that underpins critical ethnography stems from the historical debates regarding the role and function of qualitative research. There has been a shift away from positivism toward methods that accommodate negotiated meanings and the power differentials inherent in research relationships. To this end, critical ethnography is openly ideological and is often at odds with both the objective positivists and relativist constructivists. To outline a research stance that can accommodate both negotiated meaning and the existence of larger social structures, great attention must be paid to the philosophical issues of ontology, epistemology, and the validity of critical ethnographic research.

Philosophical Positions in Critical Research

Carspecken contributed most to the description of a philosophical critical ethnographic approach; however, he regarded this position as more in line

with critical qualitative research in general rather than ethnography more specifically. This mirrors other researchers' assertions that ethnography has not been able to sufficiently separate itself from positivist assumptions as it seeks to describe the social "reality" of a particular group. Carspecken's description of a critical qualitative epistemology, however, provides a pathway between the purported neutrality of positivism and the multiple realities of constructivism that do not lend themselves to an analysis of the social production of oppression.

Carspecken pointed to what he referred to as a social ontology tied tightly to critical epistemology. He described the social site of research as composed of social interactions between actors and the social practices that reproduce systemic relationships. These interactions and relations occur within the context of economic, political, and cultural structures that integrate the particular social site, and the actors within it, within a society. These interactions, Carspecken noted, can be evidenced through objective, subjective, and normative truth claims inherent in all human interaction. Disaggregating these truth claims can provide powerful data on the legitimacy, organization, and structure of cultural relations. It is by documenting, understanding, and interpreting the interactions between actors within the site and their references and representations to broader societal structures that critical ethnographers can begin to examine cultural forms of oppression and engage people to address them.

The values and assumptions of critical ethnography point toward criteria of validity that extend beyond those of positivist research. Although Carspecken dismissed the relativity of some constructivist research standards, many researchers have suggested that trustworthiness, catalytic validity, and reflexivity, as informed by the work of Yvonna Lincoln and Egon Guba, are essential criteria that have been endorsed by numerous critical ethnographers. Critical ethnographic researchers have suggested that reflexivity is required to reflect on the social positioning of research, action and structure, theory and practice, and so on. They suggest that critical ethnographic research necessarily involves dialectic among the researcher, the research process, and the research product and regards reflexivity as providing rigor and member checking as ensuring validity.

Methodology

Critical ethnographic approaches necessarily rely on reflexivity of method and, as such, must recognize the

interplay between the researcher and the participant, between data and theory, and between research and action. Critical ethnographic projects need to move beyond the interview-only study not only to engage participants in naturalistic dialogue but also to involve them as co-researchers with a stake in interpreting results and suggesting avenues for action. Once again, the most notable source of information comes from Carspecken, who outlined a comprehensive five-step approach to conducting a critical ethnographic project. These steps involve building and analyzing a record of observations, fieldnotes, and natural interactions between participants in the social site; using interviews and videotaped observations or interactions with participants; and examining broader social structures and systems that interact with and influence the social site.

D. Soyini Madison also provided a useful description of critical ethnographic methods. Her description, in contrast with Carspecken's philosophically grounded account, centered on the practicalities of conducting the project. Taken together, these works provide useful starting points for those venturing into critical ethnography. Madison's work focused on the ethnographic interview as the primary source of data, yet it must be stressed that interviews alone will not provide the detail required to make connections between the social interactions of actors and the social routines that reproduce system relations. To this end, some researchers have called for an expansion of critical ethnography to include a greater analysis of discourse. However, this may be inherent in the methodology of Carspecken when he called for an examination of policies, documents, and cultural commodities such as books, television shows, and music to consider their possible symbolic and cultural meanings. Others, such as Norman Fairclough, have suggested that a combination of critical discourse analysis and ethnographic analysis in fact constitutes what is regarded as critical ethnography.

In terms of analysis, Carspecken suggested a micro-analysis of interpersonal interactions, breaking them into objective, subjective, and normative-evaluative truth claims and locating these within broader system relations. This type of analysis extends beyond thematic coding to examine what Michael Agar termed "rich points," which are disjunctures between the source (participant's) perspective and the target (researcher's) perspective or problems in translation between the world of the participant and the world of the researcher. These rich points, when broken into objective, subjective, and normative truth claims, can reveal underlying assumptions regarding power hierarchies, inequities, and

Using Critical Ethnography in Work With Welfare Recipients and Agencies

By engaging people in monologic and dialogic data collection, sharing the results of critical analysis, and supporting participant action on these findings, critical ethnographic processes and results can assist individuals, groups, and communities in addressing their own situations or lobbying to change oppressive social structures. For example, engaging sole parent welfare recipients and welfare agencies in a critical ethnographic analysis of return-to-work efforts may provide impetus for single parents and welfare agencies to lobby for increased benefit levels and support services.

cultural knowledge. This process relies on abductive logic that involves the formulation and subsequent testing of plausible hypotheses or premises. When applied to critical ethnographic analysis, this process involves seeking out new premises to explain what happened in the rich point and why. For critical ethnographic projects, as in many qualitative projects, building theory requires a reciprocal relationship among the data, analysis, and emerging theory. The researcher must be allowed to generate propositions to be tested in the data. These propositions should be derived from two sources, with attention paid to the dialectical relationship between them. Critical ethnography permits the use of a priori theoretical frameworks but safeguards against their rigid and unquestioned use. At the same time, new conceptual frameworks emerging from the data are the primary source of insight, yet these frameworks must be compared with existing theoretical knowledge to develop a robust and useful theory to be applied to the particular social site.

Communication of Results

When it comes to documenting the results of critical ethnographic research, researchers early in the period of the proliferation of critical ethnographic methodologies suggested the need to move away from descriptive “storytelling” to engage in a synthesis of description and theory as just described. It was suggested that openly ideological research raises issues beyond those encountered in naturalistic research as it seeks to place individuals’ experiences within

larger structural systems. As such, the interplay between participants’ experiences and the researcher’s interpretation of them needs to be carefully documented and justified.

The action imperative implicit in critical ethnography requires dissemination in a variety of formats to reach research participants, influential members in the social site (e.g., politicians, community leaders), and (to a lesser extent) academics. Disseminating critical ethnographic work requires researchers to examine the power differentials between researchers and participants and to question who is speaking for whom and how they can be represented. Often the need to conduct research with catalytic authenticity, or an action impetus, is at odds with the need to publish in high-impact, peer-reviewed academic journals. How this tension is reconciled within a university context remains a challenge for critical ethnographers and participatory researchers more broadly.

On this note, although researchers have suggested that the methodology of critical ethnography could be used by practice-focused disciplines, such as health promotion and social work, to instigate action around research findings, writers on the development of critical ethnography have criticized the lack of action resulting from such studies. To this end, it has been suggested that the focus in critical ethnographic projects be placed on developing the skills of participants to enable them to continue researching their own lives and settings long after the researchers have departed. Some have also recommended moving critical ethnography farther into the realm of action research where the power differentials that exist between the researcher and the researched dissolve. Again, how these practices are carried out within the hierarchical and outcome-focused setting of the university remains a contest.

Challenges

With respect to theoretical aspects of critical ethnography, several challenges have been identified. First, it has been suggested that critical ethnography is ahistorical because it does not take into consideration changes in social and cultural trends. The challenge for researchers is to bridge the divide between the micro-level interactions of participants and macro social and cultural systems rooted in historical traditions. Second, many critical ethnographic projects have been criticized as being too site specific; that is, they have focused on a local setting, such as a school,

rather than on a broader social or cultural setting, such as the education system. In many of the research studies using critical ethnographic methodologies, this appears to be the case. Again, how researchers are able to link site-specific interactions with broader social and cultural systems is a challenge.

In summary, the methodology of critical ethnography has emerged as a useful approach to explore many of the issues confronting contemporary society. Although there are a range of possibilities in terms of method, these need to be located within a robust ontology and epistemology to counter challenges posed by critics of openly ideological research. Although a single study might not achieve the structural change desired by either researchers or participants, adhering to the principles of critical research methodologies will enable both parties to identify and explore oppression and inequality and to move closer to emancipatory action.

CRITICAL HERMENEUTICS

Critical hermeneutics is the umbrella term for the shared theoretical and methodological projects

undertaken by a variety of philosophical and social-theoretical thinkers since the 1960s. It is “hermeneutics” because the core of the shared orientation consists in reconstructing the general grounds for the understanding and interpretation of symbolic expressions, including texts, actions, images, and practices. Yet it is “critical” because it takes the grounds of interpretation to be essentially linked to social power and domination and, thus, to require a systematic analysis of the nature, structure, and impact of power on the constitution and understanding of meaning. In the same vein, the focus on power gives this theoretical project a critical dimension inasmuch as its cognitive interest aims at a normatively motivated transformation of social practices toward more freedom, self-realization, and equality. The basic idea is that acts of interpretation are internally related to forms of power, whereas this reflexive insight can foster practices of critical interpretation within which power practices are unmasked. Those existing power practices thereby become challengeable, enabling an improved ethical practice.

Critical Social Theory as Critical Hermeneutics

We can distinguish two phases in the articulation of a critical hermeneutic paradigm. By “paradigm” here, we mean a coherent vision and perspective vis-à-vis the understanding of social agency as well as its symbolic and cultural expressions. Such a perspective emerges first in the debate between philosophical hermeneutics and critical social theory. Jürgen Habermas articulated, initially on the basis of neo-Marxist assumptions, a forceful criticism of Hans-Georg Gadamer's philosophical hermeneutics. Gadamer's lasting achievement was to bring Martin Heidegger's insight on the universal significance of interpretation for human existence to bear on the methodological self-understanding of the human and social sciences. Humans are, in Charles Taylor's words, interpreting animals; human agency is intrinsically defined by linguistic concepts grounded in social and historical practices. Gadamer showed how this entails that all explicit understanding remains bound to an implicit pre-understanding that encompasses all interpretation. Given that pre-understanding makes interpretation possible because it provides a horizon of significance and relevance, the positivist illusion of objective understanding and neutral assessment of meaning must be abandoned. In its place moves the concept of a dialogic encounter of other meaning that

is oriented at truthfully explicating the other's beliefs and assumptions while knowing that any such process will entail a fusion of horizons based on the involved background concepts.

Habermas understood the force of these insights but challenged the claim to universality that Gadamer raised on its basis. He rejected conceiving social-scientific understanding solely on the basis of a linguistic dialogue because of the fact that language itself is shaped and determined by social factors. Modern bureaucratic power and capitalistic economy present us with objective shaping forces that a comprehensive (and critical) social science must take into account. Taking such factors into account means methodologically developing theoretical tools that transcend the internal first- and second-person orientation to dialogic meaning and introduce third-person explanatory models. For example, reading a religious text cannot focus solely on its intended meaning regarding the truthfulness of the message concerning God but also must recognize and analyze how this discourse might express and legitimize social power and hierarchy. Habermas set out in a first step to conceive a theory of communicative competence that entails the normative resources to understand critical interpretation, meaning that the orientation to validity is seen as essentially built into language use. Yet he eventually fulfilled the promise of a comprehensive social theory in his opus magnum theory of communicative action where he combined the internal communicative approach to meaning and truth with a functionalist perspective developed in terms of social systems theory. This made it possible to analyze how value orientations might be systematically affected by structural social power relations.

The critical exchange between Habermas and Gadamer gave rise to a larger debate about the foundations of critical theory. In this context, the term *critical hermeneutics* was first raised to capture the communicative transformation of critical theory (which was initially conceived as a fusion of Karl Marx and Sigmund Freud). Habermas's paradigm of critical theory makes linguistic communication (not labor as with Marx) central, and it is oriented at communicative action as a means to engage in dialogic rationality so as to solve social conflicts. However, many believed that the hermeneutic insights into the contextual nature of interpretation and the moment of productive historical dialogue here are given up for a universalist neo-Kantian conception of communication because in the end the validity claims of communication are seen as the most important structuring force of language. The

main emphasis of Habermas's work and influence led to a discourse ethics and a normative theory of the law and democratic state. Attempts to relate communicative theory to issues relating directly to the intertwining of discursive meaning and social power are already inspired by the second and mature paradigm of critical interpretation.

Critical Hermeneutics as Articulated Paradigm

The emergence of French poststructuralism (in particular Michel Foucault but also Jacques Derrida) on the international scene set the stage for a new paradigm of critical interpretation. A fusion of hermeneutics and poststructuralism suggests itself because both perspectives argue for the general significance of language for mediating human experience, both take such a mediation to be essentially contextually defined and articulated, and both agree that linguistic practices or discourses are to be understood as expressions of social practices and contexts. Thus, the stage is set for a methodological connection of discourse and dialogue with social power.

To be sure, the two paradigms exemplify radical differences in methodology: Philosophical hermeneutics continues and transforms a romantic first-person theory of understanding that it turns into a general form of dialogic interpretation, according to which interpreters are engaged in coming to an agreement concerning the subject matter at stake. Poststructuralist discourse analysis, however, tries to objectify and distance the existing communicative practices to discern the underlying rules, norms, or power structures that remain hidden for the intentional understanding of agents. Yet the hermeneutic approach is itself essentially premised on the assumption of an implicit and linguistically mediated background understanding on which all dialogue necessarily draws. And one can show that any discourse analytic approach must approach the meaning of the communicative practices by reconstructing what the discourse is talking about, that is, its subject matter. Thus, it turns out that a comprehensive conception of situated intentional understanding can integrate the insights of hermeneutics and poststructuralism by reconstructing how the implicit and linguistically mediated background relates to the intentional and conscious interpretation of discourse.

Indeed, the methodological coalition of hermeneutic and poststructuralist ideas can strengthen interpretation

by addressing blind spots in both positions. Hermeneutics' obvious weakness—the failure to take social power sufficiently seriously—was exposed by Habermas. But one can integrate into the conception of the hermeneutic background the layer of social power relations as a structuring force. This keeps power intrinsically connected and integrated to understanding. Yet the poststructuralist tendency of giving power relations an overwhelming and excessive significance, such that intentional meaning and dialogic reflexivity are reduced to nothing but an expression of power, can now be avoided as well; because power relations are one dimension of a symbolically mediated background, they structure meaning without defining it in its entirety. Thus, dialogic interpretation can in good conscience attempt to achieve an adequate understanding of the subject matters and their contexts and in this process can itself thematize the role of power for interpretation. Thus, we have arrived at a genuine mode of critical interpretation that avoids the Scylla of hermeneutic idealism, where all meaning finally fuses into a harmonious consensus of truth, and the Charybdis of power reductionism, where the epistemic gain of power analysis is paid for by the abandonment of any truth-based or normative meaning.

The Methodological Core of Critical Interpretation

The theoretical core of critical hermeneutics claims that all explicit or conscious acts of interpretation are essentially grounded in an implicit and unthematic background understanding. Because this background is linguistically mediated and culturally and socially situated (and, as such, always contextually anchored and defined), the internal orientation of one's focus in interpretive understanding is unavoidably impregnated by social power practices. Accordingly, the horizon from within which all understanding initially takes off entails power because the linguistic background is, as such, shaped by social practices entailing power relations. Yet it is also true that the interpretive process can thematize, challenge, and partially transcend those power structures through its internal dialogic dynamic that allows interpreters to transcend their previously taken-for-granted horizons and look critically from the outside at their own assumptions and practices. The practical core of critical hermeneutics, thus, is that although understanding is structured by power, human agency is nevertheless not doomed to remain power defined. The linguistically grounded capacity to interpret one's

existence is seen as a critical source of self-definition and resistance capable of challenging and transforming existing social practices and, thus, of unleashing a potential of autonomy and self-realization the masking and control of which is precisely an effect of existing power. But how exactly is this process to be understood? How can the potential of critical self-reflexivity be unleashed through the process of dialogic interpretation? And how are interpreters to approach their object such that the beliefs and assumptions of the other can develop their critical force?

The guiding idea for this methodological attitude is to reconstruct in a particular way the insight into the mutual dependence of linguistic meaning and intentional thought. To understand a symbolic expression, we need to understand the belief it expresses, that is, what it is about. Understanding something as meaningful entails that we take it to express a belief. But to understand a belief means that we need to have beliefs ourselves; accordingly, this requires that we correlate the other thought or belief to our own thoughts. Similarly, whenever we encounter symbolic expressions or practices, interpreting them means that we articulate the beliefs they express. Thus, interpreting symbolic expressions means relating them to our own beliefs. Now because beliefs are thoughts that we take to be true, philosophical theories of interpretation tend to emphasize the necessity of attributing true beliefs to the meaning of another belief. Interpretation can succeed only if we can reach a truth-based fusion of horizons (Hans-Georg Gadamer) or maximize shared true beliefs (Donald Davidson). This assumption also guides Habermas's conception of implicit yet foundational validity claims as grounding intersubjective understanding. Yet although it is true that all interpretation must begin at home, because we need to invest our own belief-based pre-understanding to reconstruct the meaning of symbolic expressions, the orientation at shared truth as an explicit methodological objective does not follow.

The critical hermeneutic approach grounds all interpretation in the interpreter's background but reconstructs the process of dialogic interpretation as one within which the different symbolic, cultural-social, and individual presuppositions can become reflexive. Based on a phenomenology that captures all interpretive encounters—not just those that end in shared substantive consensus—the projection of one's own taken-to-be-true background beliefs is taken to be subjected to an ongoing check that often results in the articulation of differences concerning a

subject matter. The process of reflexive dialogic understanding that can be unleashed from here has three ideal typical phases.

First, the different symbolic background assumptions are articulated in mutual contrast and an understanding of the different ontological, value-based, or normative premises is reached. To profile the different symbolic ontological assumptions, the interpreter makes use of his or her epistemic outsider position vis-à-vis the other expressions and practices. The interpreter necessarily starts from his or her own conceptions to connect with the other context but at the same time brackets the normative value judgments that would suggest themselves given the interpreter's background. Thus, it becomes possible to focus on the internal connections and assumptions that would make the other's expressions valid according to the other's respective contextual standards.

Second, the different symbolic premises are then looked at in the context of social practices and institutions, where the linguistic concepts and beliefs will show how their conceptualization of reality involves the constraining and predefining of experiences based on social power. Beliefs and assumptions here are seen as discursively structured because they are necessarily embedded in networks of discursive practices. Those practices are always part of larger contexts of social networks that are organized in social fields. Because their internal organization tends to be hierarchical and constrained, the discourses themselves are internally influenced and structured by power. Here power works as a structuring force that shapes the background understanding of intentional agents and their self-understanding. The critical hermeneutic attitude is in particular interested in thematizing both the power relation between theorist and agent as well as the power relations that exist in the respective social background contexts of the agents and the theorists.

Third, this insight into the connections of discourse–power relations can now be incorporated into the reflexive self-understanding of the agent as an interpreting subject. The process of critical interpretive reflexivity comes into its own when the agent qua self-interpreter learns to see hitherto taken-for-granted beliefs and assumptions as implicated in hierarchical and discriminating practices and, thus, is put in a position to react to them. Similarly, the theorist may come to see himself or herself as the agent with particular background assumptions that deserve further scrutiny.

Accordingly, although critical hermeneutics conceives social understanding to be an interpretive and

embedded process, it does not rest content with the given intentional orientation at meaning and truth in which either agents or theorists may be engaged. Instead, this approach intends to restore meaning in its social (power) contexts and to challenge theorist and agent alike to reflexively thematize their hidden power dimensions, but without reducing this process itself to nothing but an expression of power. The goal is a state of critical reflexivity that should inform a complex conception of situated autonomous agency. In this respect, critical hermeneutic insights, sometimes under this explicit label and sometimes not, have been explored in a variety of fields, including cultural anthropology (James Clifford in 1988; Brita Renee Heimark in 2003), religious studies (Fiorenza Schüssler in 2000), reflexive sociology (Pierre Bourdieu and Loic Wacquant in 1992; Hans-Herbert Kögler et al. in 1997), multiculturalism and intercultural understanding (Cosimo Zene and Arvind Mair in 2005 and 2006), and social psychology (Jack Martin et al. in 2003; Frank Richardson in 2002). At stake are the understanding of other cultures, different religious traditions, intercultural relations, the agency/structure relation, and a new conception of agency and autonomy. A methodological approach can be defined as critical hermeneutic when the situated reconstruction of another's (and in turn one's own) meaning premises is undertaken with the explicit consciousness of the power relations involved and with the declared goal to enhance the critical reflexivity and ethical self-determination of the social agents in light of this.

In sum, critical hermeneutics is a philosophically grounded approach that aims at reconstructing the basic implications of all understanding and interpretation such that this critical process can become a viable option for human agents. Its aim is to foster a methodological practice of critical interpretation that defines a normative practical attitude of analysis in social and cultural studies.

CRITICAL HUMANISM

Critical humanism refers to a set of research practices that focus on the difficult task of understanding human cultural differences as the expressions of an underlying human nature. The difficulty with this approach lies in providing a nonreductionist and nonexclusionary account of human identity. There is no definitive history of critical humanism, but as its

name suggests, its origins must be related to the emergence of humanism during the Italian Renaissance. This broader movement drew together thinkers from a number of distinct philosophical and scientific traditions. Uniting these distinct thinkers was an interpretation of the Greek and Roman classics as defining expressions of the virtuous development of human capabilities. The humanists sought to develop and extend the Greco-Roman idealization of the human form. Implicit in this movement was the principle that the proper governance of human life must be determined by reflection on the nature of human being itself. Of course, this approach did not rule out appeal to transcendent standards, but these standards themselves were interpreted in light of the specific context and problems of human life.

Historical Roots

It was within this broad movement that perhaps the key principle of what one can call “critical” humanism emerged. This principle was best expressed in the work of the neo-Platonic thinker Giovanni Pico della Mirandola. He espoused a doctrine of syncretism—the belief that the truth is a transcendent unified order that manifests itself in different concrete forms in different historical and cultural contexts. Hence, although essentially a neo-Platonist, Pico was well read in Persian, Egyptian, Islamic, and Jewish thought. His arguments exemplify the contribution critical humanism can make to the qualitative study of society. Instead of simply accepting different cultural interpretations of the truth as given facts, Pico tried to explain them as different responses to the same problems. He neither denied the reality of differences (as a reductionist approach would) nor accepted them as ultimate (as a relativist might). The principle that he asserted is essential for the development of a critical humanism is that the distinctiveness of humans lies in their self-creative nature. In a retelling of the Judeo-Christian creation myth that commences his most important work, *Oration on the Dignity of Man*, Pico argued that what distinguishes humans from other living species is that the human form or essence is not a determinate predicate, such as rationality or bipedalism, but rather a general capability to create and change the essence of humans. This principle is implicitly critical because it enables philosophy to think about human identity without needing to rely on falsely universalized cultural assumptions. The standard of “truly human life” is identified not with any

particular culture but rather with the practices of cultural world creation found at the basis of all human societies. That which makes humanism critical is precisely the historical focus on the different practices by which different possibilities encoded in human organic social nature are repressed or developed in different institutional forms.

Hegel and Marx

Of course, Pico did not develop this insight with any sophistication. Its subsequent development traces a line through Giambattista Vico and Georg Friedrich Wilhelm Hegel to Karl Marx, arguably the most important contributor to the development of critical humanism (although he never used the term). Marx took up and developed the core insight of Hegelian philosophy that human self-consciousness is the realization of universal rationality. Hegel meant that human history is a complex and contradictory series of struggles for self-understanding. He did not reduce human nature to a single exclusive property but rather claimed that it is variously expressed in the general practices of world building and world transformation. Each shape of human social life is a real expression of one aspect of human being. The whole truth of humanity is found not in some particular set of institutions but rather in the understanding of the general truth made manifest in human history—that humans are not the object of external determining forces but rather the collective subject, the active creators, of their own reality.

Hegel, it is true, did not always remain true to this core principle, especially when discussing the contributions of non-European peoples to the expression of essential human capabilities. The same objection could be leveled at Marx. However, the failure of Marx's political project (communism) does not negate the insights of his understanding of human being. His early philosophical work can be read as a systematic elaboration on the critical humanist principle that human nature or human identity is self-creation. The value of this principle for research is that it concentrates attention on the general capabilities that enable people to build and rebuild their social worlds. Thus, critical humanism not only can aid in generating cross-cultural understanding (by explicating cultural differences as the result of shared needs and capabilities) but also can aid in effecting social change by revealing that societies are not given and unalterable

facts but rather the results of collective human action subject to change through changed actions. If human being is essentially self-creating being, then it follows that every human, no matter what culture, class, gender, or ethnicity he or she belongs to, is considered an individual member of this species who is essentially capable, as Marx said in *Economic and Philosophic Manuscripts of 1844*, of free and conscious creative activity. A society that systematically impedes the full and free development of this capability for conscious activity is, according to this reasoning, coercive (i.e., in contradiction to the essential value of human life).

Critical Humanism and Contemporary Social Critique

The critical impetus of this form of humanism need not be read in strictly Marxist terms. The essential value of the critical humanist perspective is that it enables philosophy and social science to avoid the opposed dead ends of cultural imperialism and cultural relativism. Because the conception of human identity is derived from a contrasting reflection between human world-building activity in general and the more limited forms of activity of other species, it cannot be accused of falsely generalizing its conception of human nature from some particular historical or cultural tradition. Although some forms of social life permit wider or narrower expressions of human being, all depend on this world-making power. Thus, the essential human capability is neither absent nor fully realized in any particular cultural form. Despite this truth, critical humanism does not remain agnostic about the social implications of conceiving human identity in terms of free self-creation. Precisely because it is critical, it must refuse a merely empirical attitude toward history that is incapable of judging or evaluating different social forms. Its aim, as its name suggests, is to criticize any and all social, cultural, political, and economic impediments to the full and free development in each individual of his or her creative capabilities. For example, a critical humanist researcher investigating race in a given society would look to see how racialized minorities are “constructed” by that society so that they appear to lack the “essential” capabilities according to which that society defines humanity. The critical humanist would then demonstrate the way in which that society essentially tries to block the realization of the subaltern's self-creative power. In other words, the critical

humanist would assert the humanity of the subaltern (their capability to express and realize their concrete differences) against the oppressive structures that impede the realization of the capability.

Critical humanism does not judge values as good or bad relative to their coherence with some particular assumption about human being (e.g., that the good for humans is the maximal accumulation of wealth, altruism, love of Jesus, or ascetic self-denial). Rather, values and modes of activity are judged according to whether they are coerced by others/coercive to others or whether they are freely determined by the individual and enabling of the free activity of others. In principle, this approach leaves open the question of what sorts of societies are consistent with human nature. If the realization of the essence of human being can be impeded in different ways (by class structure, sexism, racism, etc.), then it follows that it can be realized in different ways as well. Properly understood critical humanism does not impose some definite form of historical development on different peoples, although it does argue against any sort of institution that relies on preventing the full and free development of human potentiality for everyone. Its essential aim, however, is not to demonize this or that culture but rather to uncover the different forms of institutional blockage standing in the way of all-around development of individually meaningful and socially valuable modes of activity. In keeping with its principle about the self-creative nature of humans, critical humanism must leave the solutions to definite social problems in the hands of those most concretely affected by them.

At the same time, critical humanism does have something to say in general terms about what a human society, as opposed to an inhuman society, must look like. First, critical humanism maintains that a free or human society must satisfy the life interests of all humans equally. Critical humanism, regardless of its different forms of development, must demonstrate that humans share a general organic nature as well as certain fundamental social needs linked to the development of their conscious creative capabilities. If it cannot or does not demonstrate these shared needs, then its claims about human identity are mere assertions lacking any objective grounds. In line with this contention, it follows that no society that systematically denies basic life resources to designated groups of humans on the basis of their supposed "inferiority" can be legitimate. Indeed, the essential value of critical humanist modes of research lies in their ability to

expose and diagnose these pathological forms of ideological and institutional exclusion. Second, it also follows from a critical humanist perspective that human life is essentially social and interdependent. What this principle means is that because every human relies on the work of many other humans for the satisfaction of his or her basic life interests, the realization of everyone's capabilities, in a truly human way, must be socially valuable as well as individually meaningful. That is, a purely egoistic focus on self is incompatible with the principles of critical humanism. This claim does not entail the necessity of self-denying altruism; rather, it entails a principle of social reciprocity according to which the full value of individual activity is determined by the degree to which the activity one finds individually meaningful at the same time contributes to the satisfaction of other people's life interests and, therefore, is socially valuable as well.

Critical humanist approaches to the problem of human identity can play a vitally important role in the contemporary period. Regardless of how globalization is evaluated, one undeniable result is that it has brought different human cultures into more extensive and intensive interaction than ever before. These new forms of interaction have generated a great deal of anxiety about the incompatibility of different value systems. Alarmists from all quarters have been quick to warn of impending clashes of civilizations generated by contradictory value systems struggling against each other. Because a critical humanist approach focuses on the dynamic nature of human cultures and, therefore, accepts the fact that cultures are products of human activity that are always changing, it does not immediately draw alarmist conclusions from the fact that intensifying global dynamics are causing people to reshape their cultures. The key question from the critical humanist perspective is not "Is change as such good or bad" but rather "What values are shaping the changes?" From this perspective, the important conflict is not necessarily between culturally specific value sets but rather between more basic socioeconomic and political interests. If change is being coerced by social and economic dynamics that do not affirm human self-creative freedom as the most basic value, then globalization appears to be problematic. By refocusing attention on the underlying clash between prevailing socioeconomic interests and the common life interests in institutions that satisfy fundamental needs and, thus, enable people to realize their self-creative potential, a basis of solidarity

between cultures is established. In that way, critical humanism can engender dialogue about new institutions and practices that gradually transcend exclusionary forms of power to make way for a different world in which the expression of different cultural practices is not threatening to nonmembers because it takes place in a global context of solidarity and the equal satisfaction of shared life interests. Such a world would be based neither on indifference toward the practices of others nor on the imperialist imposition of the same practices on everyone by a group powerful enough to do so. It would be a new constellation of different practices equally committed to the principle of equal satisfaction of life interests for the sake of equal freedom in the active expression of human capabilities.

determining the job requirements critical for success in a variety of occupations across many industries, relied on expert observations in the field, and was used as a tool to create a functional description of an activity. The CIT was defined by Flanagan as a set of procedures to collect direct observations of human behaviors in a way that facilitates their use in solving practical problems and developing broad psychological principles. Since its introduction more than 50 years ago, it has evolved into a robust research method whose influence has expanded into many disciplines, including counseling, nursing, psychology, education, job analysis, marketing, social work, and organizational learning.

Since its inception, the CIT has advanced in two major ways as chronicled by Lee Butterfield and colleagues. First, whereas initially it was very behaviorally based, now it is also applied to studying psychological states or experiences. Second, emphasis has shifted from direct observation by experts to retrospective self-report. These changes have proven to be fruitful in a number of research studies, but there also have been some challenges. Due to the increased subjectivity of the data gathering, there is a greater need for establishing credibility or trustworthiness checks. What follows is an overview of the current steps involved in conducting a CIT study and the credibility checks that need to be incorporated.

A number of researchers have suggested that the CIT have the following five major steps.

Step 1: Ascertain the general aims of the activity to be studied. In essence, this becomes the research question—the activity or psychological construct that one wants to observe or have participants self-report.

Step 2: Make plans and set specifications. Flanagan described four specifications to be decided on: (1) defining the types of situations to be observed or reported, (2) determining the situation's/experience's relevance to the general aim, (3) understanding the extent of the situation's/experience's effect on the general aim, and (4) deciding who will make the observations or whether participants will self-report.

Step 3: Collect the data. Data collection can be done by direct observation of people performing a task by supervisors or experts in the field or through participants recalling past incidents or experiences and

CRITICAL INCIDENT TECHNIQUE

The critical incident technique (CIT) is a qualitative research method with roots in industrial and organizational psychology. Early use of the CIT was developed by John Flanagan and focused primarily on

describing them in face-to-face or telephone interviews or by questionnaire. When data collection involves an interview, it is important for the interviewer to start by establishing rapport. The interviewer then proceeds to gather the critical incidents that helped or hindered participants, their importance or meaning to participants, the outcome of having employed the critical incidents, and an example (if possible). In a CIT study, the size of the sample is determined by the number of critical incidents gathered, not the number of participants. Demographic information is usually collected at the end of the interview.

Step 4: Analyze the data. This involves (a) determining the frame of reference that arises from the use to be made of the data, (b) formulating the categories through an inductive process, and (c) determining the level of specificity or generality to be used in reporting the data. The narrative form of a CIT study is that of categories with operational definitions and self-descriptive titles.

Step 5: Interpret the data and report the results. To determine the trustworthiness of a CIT study's results, a series of nine credibility checks have evolved: (1) audio- or videotaping the interviews, a check that ensures accuracy and provides descriptive validity; (2) interview fidelity, where a CIT expert listens to a sample of interview tapes to ensure that the method is being followed; (3) independent extraction of critical incidents, where someone independently extracts critical incidents from 25% of the interviews; (4) exhaustiveness, that is, tracking when new categories stop emerging from the developing category scheme; (5) participation rate, that is, the percentage of participants who cited incidents in a particular category (a participation rate of at least 25% is required for a category to be considered viable); (6) independent placement of incidents into categories, where an independent judge places 25% of critical incidents into the category scheme and calculates the match rate (a match rate between 75% and 85% is needed for the categories to be considered credible); (7) participant cross-checking, that is, a second interview with participants to review the accuracy of the critical incidents and categories developed from their first interviews; (8) expert opinions, that is, inviting experts in the field to review the categories and comment on their utility, what is surprising, and what is missing; and

(9) theoretical agreement, that is, making explicit the assumptions underlying the project and comparing the category scheme with appropriate literature. Using these credibility checks makes the method more robust by helping to ensure that the results more accurately reflect the situation that has been studied and by situating them in the broader research and professional community.

The CIT continues to evolve and now routinely uncovers context, captures meaning, explores incidents of personal significance, and focuses on eliciting the beliefs, opinions, and suggestions that formed part of the critical incident itself. The flexibility of the CIT that allows it to be used in these new ways is one of its strengths. When the method is followed as just described, it strengthens researchers' claims that the findings are credible or sound. The credibility procedures as described here are in keeping with Flanagan's philosophy that establishing the credibility of the findings in a CIT study is an important responsibility of the researcher.

CRITICAL PRAGMATISM

Several critical versions of pragmatism have emerged throughout the 20th and 21st centuries. These perspectives have done much to rediscover the radical political spirit of classical pragmatism and to present an updated progressive version of pragmatism capable of critically assessing the shortcomings of liberal democracy and the global consumer capitalist spirit typical of the current times. Although there are no clear boundaries between pragmatism and critical pragmatism, and although critical pragmatists share with pragmatists at large key presuppositions about human nature and social processes, it is fair to say that critical pragmatists strongly emphasize the emancipatory, polemical, and transformative potential of pragmatist philosophy and social theory and research as well as the polemical and even activist role of the citizen-scholar.

Classical pragmatism, embodied by the likes of John Dewey, Charles Sanders Peirce, William James, W. I. Thomas, Charles Herbert Cooley, and George Herbert Mead, has often been criticized for positing a view of human nature as excessively voluntarist and optimistic, complacent toward the status quo of U.S. democracy, and largely biased by a classless, raceless, and genderless ideology. Such criticisms of classical pragmatism have also often been mounted against the social theory of symbolic interactionism—pragmatism's main intellectual offshoot in the social sciences.

Although these criticisms have taken a strong hold in a handful of sociological circles, in actuality early pragmatism constituted a sharply critical perspective, even a radical one for the times. Pragmatism's views on social reality as being constantly in flux, on knowledge as relative and shaped by multiple and instrumentalist goals, on society as a form of discursive interaction, on the self as a biographical project free of metaphysical baggage, on science as will to meaning and power, and on methodology as a form of situated inquiry largely predate the onset of most postmodern and poststructural social and cultural criticism. Indeed, philosophers such as Michel Foucault, Jacques Derrida, Jürgen Habermas, Donna Haraway, and Jean-Francois Lyotard all have been clearly influenced by classical pragmatism, and to their credit some of them have explicitly recognized their debt. Therefore, rather than an entity living on its own, critical pragmatism stands in close rapport not only with the history and past intellectual development of

classical pragmatism but also with current social and cultural theory. Furthermore, its boundaries are extremely difficult to draw, and the identity and status of its figureheads are contested and uncertain. Nevertheless, critical pragmatism is enjoying a remarkable renaissance across the social sciences, and its followers are multiplying exponentially. Rather than describing central figures or currents, this entry outlines four critical characteristics of classical pragmatism. These four characteristics represent strong theoretical threads in the ongoing growth of critical pragmatism.

The Socially Constructed Nature of Reality

Whereas for many theoretical perspectives the world is either ready-made or hardly malleable, for pragmatists reality is constantly open to change, becoming, and flux. Pragmatism's indeterminate view of reality is now shared by many researchers who put a premium on the constructed nature of social reality. On the one hand, this has opened up pragmatism to the criticism of those who believe its indeterminacy easily dismisses obdurate sources of social inequality; on the other hand, this makes pragmatism particularly amenable to progressive political philosophies aiming for cultural criticism, social reform, and political transformation.

Pragmatists view social action as the site where multiple realities are created. Contemporary critical pragmatists supplement this view with an emphasis on the construction of reality as a struggle between conflicting discourses and competing definitions of the situation. Viewing reality construction as a site of contention opens up the space for deconstructive and polemical approaches to the making and remaking of reality as a political act. Because pragmatism privileges the doing and the performing over the done and the performed, critical pragmatists emphasize the openness of culture to critical change, to knowing as a critical form of inquiry, to reflexive understanding as emancipation and radical pedagogy, to concerted action as orchestrated resistance, and to power as knowledge.

Influenced by the quasi-pragmatism of Foucault, many contemporary critical pragmatists emphasize the polyvocality of power, pluralism, inclusiveness, the value of subaltern cultural beliefs and practices, and the incomplete, partial, and contingent nature of

reality. Critical pragmatists value involvement and participation and, therefore, embrace an understanding of multiple realities as the tool for a participatory orientation toward praxis and change. As Norman Denzin discussed, such a critical pragmatist view of cultural realities becomes a politics of resistance and possibility and a moral call for everyone to intervene in public life and interrupt the uncontested flow of inequality.

The Emergent Nature of Social Structure and Organization

Pragmatists have repeatedly been criticized for their supposed astructural bias. The story goes that pragmatism and related theoretical perspectives neglect to consider the pervasiveness of structural powers and the deep-rootedness of ascriptive traits, such as race, sex, and (in part) class, and instead privilege an overly voluntarist view of life. Yet both classical pragmatists and contemporary critical pragmatists argue that the very nature of interaction constitutes a form of social organization that limits (as well as enables) individual and group action. In other words, pragmatists are well aware of the constraining potential of group life, yet they refuse to believe that individuals have no choice but to succumb to the power of the structures they have created.

Contemporary critical followers of the pragmatist tradition such as Peter Hall have capitalized on the pragmatists' rich arsenal of concepts for the study of social structure and built their theoretical approaches around a negotiated and historical view of social organizations and institutions. These approaches emphasize organization as recurring patterns of collective activity, interlinked contexts of action, intersecting intentions, conflicting goals, and the emergent formation of conventions and practices. Researchers influenced by critical pragmatism have outlined the differential consequences of forms of inequality, the interactive constitution of injustice, and the contingent nature of the creation and reproduction of social problems and their definitions.

Inspired by the emancipatory political consciousness of C. Wright Mills, current studies informed by critical pragmatism pay close attention to the components of generic social processes of inequality reproduction within institutions such as stigmatization, "othering," marginalization, alienating emotional labor, subordination, the formation of symbolic boundaries,

the selective transmission of cultural and social capital, the regulation of discourse, the scripting of mass events, and more. These inequality orders function neither at the macro level nor at the micro level of sociological analysis alone; rather they function within a meso domain that mediates distant contexts and local situations of interaction through forms of meta power—processes that influence local conditions of interaction from afar.

The Situated Nature of Knowledge

Classical pragmatists' stance toward objectivist epistemology is without doubt one of its most critically progressive aspects. Knowledge cannot be generated from the outside; it can be understood only through sympathetic introspection by taking the role of the other. Understanding the world from a culture member's perspective constitutes a uniquely radical position in a world still dominated by universalist and absolutist pretensions toward the objects of knowledge. Participant observation and life history research—the methods privileged by most social researchers influenced by pragmatism—require that research-driven knowing not be guided by overly rationalist, pretentiously unbiased, deterministic, and atomistic models. By blurring the boundaries between common sense and scientific knowledge, by privileging depth and diversity over superficial uniformity, and by viewing the verification of truth as a contingent process based on negotiation, pragmatism features one of the most critical and radically democratic views on knowledge.

Contemporary critical pragmatists such as Dorothy Smith have embraced a view of knowledge based on embodied situated forms of experience of the world. Recent growing interest in institutional ethnography, critical ethnography, reflexive and postmodern ethnography, and narrative and performance studies has blended traditional pragmatist approaches to knowledge with contemporary poststructural concerns with the power of discourse, the social construction of knowledge, and representation. For example, institutional ethnographers study how everyday experiences are shaped by relations of power generated within social institutions and typically transmitted through texts and discourses. Performance scholars such as Norman Denzin have instead been instrumental in shaping and diffusing awareness of postcolonial research strategies that center around emotions,

polemics, situated narratives, bodily presence, cultural diversity, and multiple versions of truth.

Contemporary critical pragmatist approaches to knowledge continue to show the relevance of earlier pragmatist concerns with the changing character of scientific truths, the sensitizing nature of research concepts, the role of science in constituting knowledge (and thus in reproducing or eradicating inequalities), the obtuse instrumental rationality of quantifying research procedures, the anthropocentric character of science and technology, the alienating character of nonintimate methods such as mass scale survey research, the cognitive bias of positivism, ethnocentric faith in formal rationality and linear logic, and the elitist and exclusionary character of scientific writing and representation.

The Progressive Nature of Pragmatism's Democratic Ideology

As the influential contemporary pragmatist scholar Hans Joas noted repeatedly, classical pragmatism has been wrongly accused of being an overly naive, optimistic, and accommodating philosophy. The creativity of human action that pragmatism posits, coupled with its adaptive spirit and accompanied by healthy skepticism toward essential views of human nature and teleological perspectives of social history, constitutes the very backbone of a truly democratic philosophy. When compared with the elitism of polemical critical theories, the inevitability of destiny embraced by historical materialism, the various forms of reductionism typical of much social theory, and the deindividualizing spirit of structuralism and functionalism, pragmatism's egalitarianism appears to be most congenial with the ideology of authentic democracy. Indeed, pragmatism's view of social reality as malleable could very well be the philosophical foundation for programs oriented toward social reform.

Within critical pragmatism, no principles of truth are absolute; no realities transcend the local conditions under which they emerge. Experience and interaction are the sites where knowledge takes shape, and dialogue is the process through which consensus is achieved. Pragmatism is critical of liberal democracies founded on technocratic principles. Science is meant not to rule but rather to help in concrete circumstances. Ethics is to be guided not by universal codes but rather by context-driven action focused on how

goals-at-hand serve the public good. Cultural policy is to follow not objective aesthetic criteria of elites but rather a universe of diversity. State organization is not to supersede the spirit of individuals freely collaborating and creating local institutions built to protect civil liberties. Meanings can be shaped and shared in communicative action. The public sphere can be reformed through mutual understanding and relationality. Communication can be free from domination and occupy the most central role in the formation of inclusive social welfare structures. Citizens' ability to form associations and movements can impede further colonization of the lifeworld by the hands of a consumerist corporate hegemony.

Yet this is no carefree rosy optimism. Contemporary critical pragmatists share a deep concern for the conciliatory nature of bourgeois liberalism. Nancy Fraser's socialist-democratic feminist pragmatism, for example, challenges the essentialism of male-centric views of power and politics and opens the door for a historical and hermeneutic criticism of institutions as the site of gender-biased discursive political practice. Her perspective is critical of hegemonies in the structures of knowledge and the economy that lead to unequal gender divisions of labor, the racial segmentation of markets, and a global economy insensitive to need. Other contemporary critical pragmatists have empirically outlined systems of disjuncture and difference in global cultures and identities, the blurring of national and ethnic identities, the power of the technological imperative to shape media ecologies, the pervasiveness of diasporic populations, the transnational formation of identity-based and interest-driven social movements, the demagogic impression management of ruling politicians, and the resilience of old conservative meta-narratives and the reactionary party structures that support them.

Much like classical pragmatism, contemporary critical pragmatism's power resides in its potential to generate useful knowledge through concrete empirical observation. The future of critical pragmatism, therefore, resides not in its internal coherence or its resilience from external criticism but rather in its potential to remain useful for the critical goals its followers set out to achieve.

CRITICAL RACE THEORY

Critical race theory (CRT) is a theoretical perspective that purposely centers race and racism in its analysis. It considers racism to be the central reason for racial inequality in the United States. In CRT, racism is defined as a structure embedded in society that systematically advantages Whites and disadvantages people of color. Rather than aberrant or random acts, racism is considered a normal condition of U.S. society, relating directly to and resulting from the racialized history of the country. Originating in the United States, CRT is just now beginning to be explored by scholars around the world seeking a new way to analyze systematic racial inequality in law, education, and other dimensions of society.

The goal of CRT is to dismantle systematic inequity by calling attention to it. CRT does this by intentionally focusing attention on race, problematizing the neutrality associated with dominant ideologies, and highlighting the situatedness of one's perspective. It also centers the stories of those who have personally experienced racial inequality and enables these stories to be told in compelling ways so

that a wide audience can learn from their perspectives. This entry first describes the history of CRT, beginning in the mid-1970s. It then explores the characteristics of CRT, including its description of racism as embedded, normal, and permanent; its critique of liberalism; the concept of interest convergence; and the view that Whiteness constitutes a property right. It also discusses the role of storytelling in CRT. Finally, it describes some of the current “outside-centered” theories that are outgrowths of CRT.

History

CRT originated in the United States in the field of law during the mid-1970s, growing out of and responding to critical legal studies (CLS), which at the time was an emerging movement of legal scholarship that rejected the notion that legal matters were neutral and could be interpreted objectively. Influenced by postmodernism, CLS advocates argue that politics and social situations influence U.S. jurisprudence. Legal scholars Derrick Bell, Alan Freeman, Kimberlé Crenshaw, Richard Delgado, and Mari Matsuda, among others, responded that race and racism also play significant roles in U.S. law, influencing laws as well as those who interpret them. The U.S. civil rights movement and the nationalist movements advanced by Malcolm X and the Black Panthers also influenced the creation of CRT. Bell, Crenshaw, and Freeman (considered the founders of CRT), among others, believed that the progress made during the 1960s toward civil rights was already stalling by the mid-1970s. Thus, CRT was created to focus specifically on racial inequality in all aspects of U.S. jurisprudence and to actively work toward dismantling racism in the law.

In 1995, Gloria Ladson-Billings and William Tate introduced education scholars to CRT in their article in *Teachers College Record*, “Toward a Critical Race Theory of Education.” In this article, they argued that CRT can explain racial inequity in school achievement by focusing on race and racism as influential entities in all aspects of U.S. society and schooling. Some scholars in education now frequently address the influence of racism on the historical constructions and purposes of school and schooling as well as on teachers, administrators, and student achievement. Like CRT scholars in the area of law, Ladson-Billings and Tate suggested that the “business as usual” of racial inequality in education will not be resolved

until it is addressed pointedly. CRT has also been adopted into the social sciences literature and can be found as a theoretical and analytical tool in very diverse fields of study.

Characteristics

Whereas CRT is a multifaceted theoretical perspective, it has several key characteristics, including the embedded normal nature of racism, the permanence of racism, the critique of liberalism, interest convergence, property rights in Whiteness, storytelling, and the goal of dismantling racism.

Embedded Normal Nature of Racism

A foundational aspect of CRT is the belief that racism is embedded in society. In 1995, Richard Delgado, one of the major contributors to CRT, emphasized, “Because racism is an ingrained feature of our landscape, it looks ordinary and natural to persons in the culture” (p. xiv). Racism, in this perspective, is seen not only in the rantings of the Ku Klux Klan but also in the racial makeup of those in power and those who are disempowered as well as in the frequent absence of people of color in everything from political leadership to school curriculum to popular media. CRT theorists (or criticalists) argue that because racism is so deeply ingrained in society, it is necessarily ingrained in jurisprudence, education, and all other institutions and aspects of society.

Permanence of Racism

A second foundational aspect of CRT is the notion that racism is persistent, enduring, or even permanent. The progress of race relations is not considered linear, moving toward equality as time passes. Rather, the structural embedded nature of racism prevents it from being removed from the fabric of society. Progress toward future equality is questioned, and much criticism is given to the exceedingly slow and unpredictable nature of societal change. Recognizing racism as a permanent embedded condition in society is what Bell termed “racial realism.” Racial realism is in the tradition of legal realism, which was a precursor to CLS. Its main tenet was that because humans create law, their own imperfections are mirrored in the law. The term *racial realism* implies that racism is a

problem influencing law and society because it is a problem influencing humans.

Critique of Liberalism

Directly related to the preceding understanding of racism is the CRT critique of liberalism. Because racism is considered to be embedded and persistent, many tenets of liberalism are rejected by criticalists as actually standing in the way of racial equity. These tenets include the belief that jurisprudence is neutral and outside or above the influence of humans. This is the central tenet of U.S. law which CLS and legal realism also reject. In addition, criticalists reject the notion that jurisprudence is color-blind. They argue that color-blindness masks the influence of race and racism in everyday forms of inequity and prevents them from being recognized as entrenched aspects of the justice system. Criticalists also disapprove of the liberal tenet of incremental change through the system of legal precedence. They assert that this system ensures that the dominating social group in society, Whites in the United States, controls change. As a result, change is slow and comes about only when the dominant group benefits from such change.

Interest Convergence

The notion that the dominant group permits legal change toward racial equity only when its own best interests are served is termed *interest convergence*. This concept was developed by Bell, who used it in 1980 in reference to the landmark 1954 Supreme Court decision in *Brown v. Board of Education*. Bell called attention to the ways in which the Supreme Court’s decision in *Brown* reflected the recognition by Whites that desegregation had economic and political values for Whites unrelated to the immorality of racial inequality. For example, in anticipation of this case, the U.S. Department of Justice filed an amicus curiae (“friend of the court”) brief stating that racial integration in the United States was important because it was considered as highly beneficial for the image of the United States abroad. Affirmative action can also be examined through the interpretive lens of interest convergence by examining its impact on White women compared with its effect on men and women of color. A third example of interest convergence can be found in the history of the Martin Luther King Jr. holiday.

Although federal legislation creating the holiday had been passed in 1983 and Arizona Governor Bruce Babbitt had signed an executive order designating it as a state holiday in 1986, Governor Evan Meacham rescinded this executive order when he took office in 1987. This action set off a tourist boycott that in 1991 prompted the National Football League to move the 1993 Super Bowl from Arizona to California. In 1992, Arizona voters passed a proposition establishing the holiday, and the 1993 Super Bowl was held in Tempe, Arizona.

Property Rights in Whiteness

The notion that being White confers valuable rights as inalienable as they are unearned is another central tenet of CRT. During the time of slavery, African Americans were recognized under the law as property, whereas Whites had no such status and could not be enslaved. African American slaves could be bought, sold, and substituted for cash for purposes of paying debts or making purchases. Legal scholar Cheryl Harris argued that Whiteness, initially a concept of racial identity, was so closely attached to the right to be free and to own property that Whiteness itself became a kind of property right. Harris suggested that such a property right can be seen in legal precedents that give individuals the right to sue for defamation for being erroneously called Black but not for being erroneously called White. *Black* was considered to be a slanderous label affording harm to an individual, but *White* was not.

Another property right put forth by Harris was the “absolute right to exclude.” Because Whiteness is constructed as the absence of African heritage, it is inherently exclusionary. The privileging of Whiteness is also evidenced in the “one-drop rule” written into law in most U.S. states, beginning with Tennessee in 1910. This rule contended that any amount of African heritage deprived an individual of the rights attached to Whiteness. The last one-drop rule was repealed by the state of Louisiana as recently as 1983. In contemporary times, Whiteness is still recognized as valuable property that affords certain rights such as the right to be trusted, the right to be given the benefit of the doubt, the right to be perceived as a professional, and the right to attend schools and school programs where one’s race does not prevent one from accessing excellent materials, curricula, and teachers. These issues

have been examined by Harris and the education scholars Ladson-Billings and Tate, among others.

Storytelling

A central characteristic of CRT that readily lends itself to qualitative methodology is the importance of narrative in general and of storytelling in particular. Because voices of color have so often been ignored and dismissed by the dominant group in society, first-person narratives are considered to be particularly powerful. They often tell the stories that have not been heard. Being influenced by postmodernism and critical legal studies, CRT maintains that one reality and/or truth does not exist. Instead, reality is considered to be socially constructed and, as such, individuals are believed to have their own realities and truths that are shared through storytelling. In addition, the stories people tell are often engaging and easy to understand, enabling stories to make strong impressions on audiences from a variety of backgrounds. This emphasis on accessibility aligns with the activist nature of CRT. If a wide variety of people are able to comprehend complex and often esoteric legal issues through first-person narratives told in absorbing ways, many people can then actively respond to these issues.

Because of the emphasis on multiple truths and realities, criticalists often use nontraditional forms of writing to make their points. Harris and Ladson-Billings, for example, weaved in stories from their own lives to make their points more vivid. Harris wrote about her grandmother’s experience in “passing” for White during the 1930s. Ladson-Billings wrote of being mistaken for a waitress while passing time in a VIP lounge after giving an invited lecture. Bell used science fiction to tell the story of “space traders” who come to the earth offering gold and energy in exchange for just one thing: all African Americans. He followed this short story with a critique of liberalism in U.S. jurisprudence. Delgado took on an “alter ego” in his *Rodrigo Chronicles*, where he shared the fictionalized stories of law student Rodrigo and his professor mentor. Through this writing style, legal and social issues are examined in dialogic fashion with questions, answers, ambiguities, and hesitations par for the course. These scholars are recognized for their more traditional styles of writing as well, but all saw great potential in the creativity and related accessibility of these more engaging writing forms.

In addition to narrative and storytelling, two other strategic forms of stories are used in CRT: stock stories and counterstories. Stock stories are akin to grand narratives in postmodern language. They explain “why things are” in ways that satisfy the dominant culture. The following are two typical examples of stock stories. First, there are so few people of color in leadership positions in business and academia because there are few qualified people of color. Second, only people who prove to be untrustworthy or dangerous are followed by security in department stores or pulled over while driving by the police. Counterstories purposely disrupt stock stories by telling personal accounts that contradict the stock stories. For example, a counterstory to the first story could be a first-person account of being the most objectively qualified person who was not hired because of subjective concerns about “fit” as a person of color. A counterstory to the second story could be a first-person account of being exceedingly trustworthy and not dangerous (e.g., a teacher, a medical doctor, a church pastor) and nevertheless being followed in department stores and pulled over by police for appearing to be suspicious. These are stories that people of color of all economic backgrounds, and of all educational and professional attainments, tell. The first-person voice, absent in this encyclopedia entry, brings the sincerity, passion, and gravitas to the counterstory.

Goal of Dismantling Racism

It is important to emphasize that the overarching goal of CRT is to dismantle racism. Although critical theories, including CRT, are sometimes criticized for being too idealistic, changing and improving lived realities is a central tenet in all of them. By naming racism, criticizing “liberal” approaches to addressing racism, and highlighting and legitimizing the personal stories of those who experience racism, CRT endeavors to dismantle the systematic nature of racism. Thus, CRT necessarily has a social justice agenda. It is not a component of research conducted for its own sake.

Related Outsider-Centered Areas of Study

Although CRT has not focused only on African Americans, African American perspectives and concerns have shaped much of CRT. Its focus on the lived

experiences and perspectives of those who are subordinated in society, its critique of dominance, its main tenets, and its creative use of form and substance have inspired other outsider-centered theoretical perspectives that have emerged—and continue to emerge—out of CRT. Recently emerging (1990s–2000s) race-centered areas of scholarship include LatCrit, which focuses specifically on Latina/o perspectives and experiences in law and society; AsianCrit, which focuses similarly on Asians; and TribalCrit, which focuses similarly on Native Americans. Well-known scholars in these three fields include Richard Delgado, Robert Chang, and Brian Brayboy, respectively.

Critical studies in Whiteness is also an emerging area of study in the social sciences. Inspired by CRT legal scholars and other scholars of color who look at the ways in which Whiteness dominates society and other racial groups through its idealism and apparent neutrality, academics in a variety of areas have been critically examining Whiteness since around the late 1980s. Ian Haney López (in law), Peggy McIntosh (in women’s studies and education), David Roediger (in history), Ruth Frankenberg (in sociology), and Alice McIntyre and James Scheurich (in education) are some of the best-known Whiteness scholars.

Another compelling outgrowth of CRT is critical race feminism, which centers both race and gender in its theoretical framework. An example of a unique term in critical race feminism is “Blackwoman,” which emphasizes the inimitable experiences of Black women and the importance of situating one’s perspective in race and gender. The goal of critical race feminism, like other dimensions of CRT, is to dismantle racism and sexism as well as to highlight the lived experiences and perspectives of those living within and without the borders of what society deems to be neutral. Jennifer Russell and Adrien Katherine Wing are two well-known critical race feminists.

Although not specifically race centered, queer theory is also connected to CRT, emerging from some of the same social theories and forces that continue to shape CRT and the other race- and gender-centered theories already described. Just as CRT seeks to disrupt Whiteness and the neutrality that masks its power, queer theory strives to disrupt the neutrality associated with heterosexuality and to situate it as an often idealized exclusive construct. In contrast to the neutrality of heterosexuality, other sexual and gender orientations are often demonized, essentialized, or omitted in public and private discourses. Queer theory

draws attention to this inequity with the goal of eliminating it. The works of Annamarie Jagose and Francisco Valdez are examples of this theoretical perspective.

Recently, outsider-centered theorists have also begun troubling the binaries that emerge when constructs such as queer and heterosexual, and of color and White, are compared and contrasted with one another. Many of these criticalists argue that, rather than having sharp borders, race, gender, and sexual orientation (among other aspects of identity) have frayed edges that lend themselves to complex, rather than essentializing, analyses. As these concerns indicate, theories that challenge dominant ideologies are emergent and dynamic, influencing each other and a variety of fields of study as they continue to evolve.

CRITICAL REALISM

Critical realism offers an ontology that can conceptualize reality, support theorizing, and guide empirical work in the natural and human sciences. It views reality as complex and recognizes the role of both agency and structural factors in influencing human behavior. It can be used with qualitative and/or quantitative research methods. There are strong links between critical realism and other theoretical approaches, such as complexity theory, social emergence, and systems theory, variations of which can be underpinned by a critical realist ontology.

Background

Critical realism (alternatively termed *transcendental* or *complex realism*) is most closely associated with the early works of the philosopher Roy Bhaskar. It has been developed mostly in the social and health sciences, evaluation, and economics.

Critical realism is one of a range of postpositivist approaches positioned between positivism/objectivism and constructivism/relativism. Critical realism simultaneously recognizes the existence of knowledge independent of humans but also the socially embedded and fallible nature of scientific inquiry. Among other criticisms, positivism is viewed as failing to acknowledge the inherent social nature of knowledge development, the influence of underlying unobservable factors/powers, and the meaning-centered nature of humans. However, constructivist philosophies are also criticized for overprivileging these human perspectives and attendant problematic variations of relativism that cannot adequately resolve competing claims to knowledge or account for knowledge development.

To resolve these epistemological issues, the early work of Bhaskar conceived the existence of three realms of reality: the actual, the real, and the empirical. The *actual* domain refers to events and outcomes that occur in the world. The *real* domain refers to underlying relations, structures, and tendencies that have the power to cause changes in the actual realm. Most often these causal influences remain latent; however, under the right circumstances, factors in the real domain can act together to generate causal changes in the actual domain. These causal changes are neither uniform nor chaotic but are somewhat patterned. The *empirical* dimension refers to human perspectives on the world (i.e., of the actual and real domains). This could be perspectives of an individual or, in a wider sense, of scientific inquiry. The real and actual domains can be perceived only fallibly. Hence, this ontology advocates the existence of an objective reality formed of both events and underlying causes, and although these dimensions of reality have objective existence, they are not knowable with certainty.

Other tenets of critical realism tend to emerge from this ontological basis. A strong focus in theorizing and research informed by critical realism is placed on understanding causality and explaining events in the actual domain. This movement from events to their causes, known as abduction, is contrasted with other

common goals of research to describe, predict, correlate, and intervene.

Critical realism attempts to respond to and understand reality as it exists in the actual and real domains. Hence, being led by the nature of that reality is of overriding importance and takes precedence over disciplinary, methodological, or ideological predisposition because each of these could distort perceptions of reality. This results in a postdisciplinary vent that seeks to be led by reality in all its complexity and to avoid simplification, narrowness, and distortion.

In the realm of the real, critical realism views behavior as being influenced by both agency and structural factors. Although humans have a degree of agency, this is always constrained by wider structural factors that are viewed as surrounding the individual. Although culture can be conceived as being dependent on and created only through the existence of humans, critical realism argues that culture exists independent of individuals. Likewise, social phenomena are made possible by the presence of humans but are deemed to be external to individuals and have existence and the power to constrain whether this is recognized by individuals or not.

Suitability of Critical Realism for Qualitative Research

The strengths of critical realism for qualitative research lie in its desire to render complexity intelligible, its explanatory focus, its reconciliation of agency and structural factors, and its ability to recognize the existence of wider knowledge while respecting the importance of social meaning to humans.

Critical realism is particularly well suited to exploring research questions that relate to understanding complexity. Rather than controlling for or simplifying complexity artificially, the approach advocates that complexity must be embraced and explored. Although other research methods, such as the randomized trial, have control and artificiality as defining characteristics, critical realism advocates that phenomena must be understood in the real world. Understanding phenomena in this natural realm means that findings do not need to endure problematic generalizations from unnatural to natural settings.

Critical realism is also well suited to questions that seek to explain outcomes. A huge volume of research (mostly quantitative) describes outcomes in the

natural world. The demographics of death and disease, educational achievement, and health care are monitored systematically in many countries. Moreover, researchers often use trial interventions or programs in an effort to find out what approaches work best so as to improve outcomes in different populations. However, in both instances, little work is carried out to explain the patterns identified or understand the underlying phenomena. As a result, there is often difficulty in accounting for why trends exist or why programs perform as they do. There is nothing inherent in critical realism that directs researchers to theoretical, qualitative, or quantitative methods. The tenets of critical realism place overriding importance on understanding reality. Methodological decisions are secondary to this aim. Some critical realists advocate greater reliance on qualitative work; however, these arguments are based mostly on the assumption that qualitative methods are better suited to understanding complexity in the real domain.

Critical realism is also compatible with critical social science because it views individuals as having the potential for emancipation. Critical realism recognizes that humans can actively shape and change wider social phenomena through channels such as collective action, the arts, and research.

Applications of Critical Realism in Qualitative Research

Critical realism has been applied in qualitative research in a variety of ways. Its ontology may underpin empirical work irrespective of whether this is overtly recognized or acknowledged. Much qualitative research seeks to understand the causes of social phenomena through recourse to both individual and contextual factors. How closely authors of such research ascribe to or identify with the tenets of critical realism is open to debate. Arguably, a wealth of research that has come to be labeled as interpretive descriptive is underpinned with principles that are not dissimilar to critical realism. However, investigators are often reticent or unable to draw comment on the philosophies underlying their work.

In terms of method, critical realism can be used to guide empirical work as part of recognized approaches. For example, interpretations of critical realism can underpin variations of ethnography and grounded theory. Alternatively, approaches that are presented as

critical realist have been developed. Although there is no single critical realist method, these various approaches have some commonalities.

In common with many methodological approaches to qualitative research, critical realism places a strong importance on adequate conceptualization, rigorous description, and convincing explanation.

Given that reality is seen as independent of individuals, attaining an adequate conceptualization of phenomena being explored is very important. If researchers have an impoverished or incomplete conception of phenomena, the quality of the understanding likely to accrue from the research is compromised. Research must seek an accurate understanding of reality in all its complexities but also must avoid the imposition of the researchers' preconceptions or ideology on reality. This rationale informs the argument for postdisciplinary research. From a strong conceptualization, rigorous description and adequate explanation should follow. Again, both of these aims stem from the assumption that reality is complex and external to the individual.

Explanation should be rich and deep, invoking both agency and structural factors in a complex way to account for patterns in data. In this way, results are not descriptive but should provide an explanation of patterns identified in data. Interactions between factors should be described, and a sense of complexity should be to the fore. Different types of data can be relied on to provide a case for explanation, including lay accounts from different key groups or document analysis. These qualitative data can also be linked to quantitative data for corroboration or further explanation. The rationale for this multiplicity is that each method or perspective can provide evidence of what is occurring in the world.

There is a place within this for research exclusively into lay accounts. This follows from the recognition that knowledge of the world exists and that social structures influence human behaviors in the recognition of hermeneutical dimensions. The beliefs, understandings, and meanings of humans do matter—not because they determine what objective reality is but rather because they are likely to influence behavior. Although it is understandable that a patient with a fatal form of cancer might not believe he or she has cancer despite a range of biological indicators and symptoms that point to the contrary, the patient's beliefs do not determine objective reality; that is, they do not cause the cancer to disappear. It remains important to understand the cancer patient's perspective because this will have implications for his or her

self-care, but the patient's views should always be framed as an account of reality rather than being taken to determine reality. Hence, critical realism can be used to guide research into lay beliefs, accounts, and discourse with the broad caveat that data produced in these inquiries relate to accounts of reality that may or may not be accurate but do not determine reality. This is compatible with many forms of qualitative research, including phenomenology/lived experience research.

Sampling in qualitative research informed by critical realism retains the same concerns as do other methods, including saturation, typicality of sample, and purposive case selection. However, sampling should also be focused on using key groups to assist in the explanatory project. Careful selection of similar individuals with different outcomes can provide case-based comparisons that can illuminate factors in the real domain of prime importance. Sample sizes should be sufficiently large to allow meaningful comparisons to be made.

The Future of Critical Realism in Qualitative Research

In the rush to do research as a basis for intervention in policy and practice in health, education, and social services, solutions to well-established problems remain surprisingly and consistently illusive. Inequalities remain, performance is weak, and problematic patterns persist. All too often, the promising results of randomized trials or demonstration initiatives fail to be replicated in the real world or across different settings. Disturbingly consistent adverse patterns in health, education, and social well-being continue to be found internationally. After the initial faith that evidence-based practice could eradicate all such ills, more sophisticated and less reductionist approaches such as critical realism are increasingly seen as being needed by governments and organizations.

Critical realism retains the axioms that knowledge of the underlying complexities of the world can be not only accrued but also applied for human benefit. However, it views having a deep understanding of why patterns exist as a prerequisite to effective action. As such, its future in guiding work to address intransigent real-world problems may be a particularly fruitful area for its continued application.

CRITICAL RESEARCH

Critical research is a loosely defined genre of social inquiry whose central theme involves the problematization of knowledge. Knowledge is not simply a matter of representing and explaining reality but rather a social phenomenon itself, having substantive–constitutive relations to personal identities, social practices, institutions, and power structures. This includes knowledge produced by social researchers; therefore, critical research must profoundly include a self-reflexive or reflective component.

The list of contemporary forms of research that self-identify as critical includes most prominently critical ethnography, critical discourse analysis, feminist research, critical race studies, cultural studies, postcolonial studies, gender studies, social constructivist research, queer theory, critical hermeneutics, and critical psychology. The problematization of knowledge found in each of these research communities can be attributed to two broadly conceived perspectives: the critical theory tradition and poststructuralism/postmodernism. Both perspectives take issue with modernity, specifically with Enlightenment and post-Enlightenment concepts of knowledge, truth, and rationality. Critical theory bases its notion of critique on a paradigmatic shift in the concepts of universal reason, reflection, emancipation, and the human subject. In contrast, poststructuralism/postmodernism bases its notion of critique on the rejection of any universal features of these same concepts. Thus, although both perspectives are “critical,” they are fundamentally opposed when it comes to explaining the ultimate basis of critique.

Most critical research practiced at this time draws from both critical theory and poststructuralism/postmodernism despite the differences between them. This is possible because there are intersections

between critical theory and poststructuralism/postmodernism at the level of methodology and at many levels of sociocultural criticism.

Origins:

The Self-Contradictory Human Subject

Michel Foucault made the argument that by the end of the European Enlightenment, an epistemological thematization of subjectivity occurred for the first time in Western history, resulting in a contradictory notion of the human subject. The subject was taken to be both an object of knowledge and a condition for all possible knowledge. Critical research can be understood by looking carefully at this development.

The Human Subject as Object

As the 18th century drew to a close, empiricism was well on the way toward becoming the dominant epistemological framework for science. This framework became hegemonic for concepts of knowledge-in-general during the 19th century and remains so to this day. Empiricist reason, related to instrumental action, also became embedded within industrial and postindustrial social practices to produce what critical theorists have called “the dialectic of reason.” Instrumental reason resulted in technologies on which to base factory modes of production and, treating people like other objects of nature, organized work into fragmented menial activities. Greater poverty and less meaning and freedom were the result, as revealed in critiques by Karl Marx and Max Weber. Hence, Enlightenment reason appeared to lead to a society that was in contradiction with Enlightenment ideals. With human phenomena objectified and studied within a framework that makes predictions of measurable outcomes from measurable manipulable initial conditions, there is little room for concepts of freedom, choice, morality, and other notions dear to the Enlightenment.

The Human Subject as a Condition for Knowledge

On the other hand, Immanuel Kant developed what he called “critical philosophy” during the final decades of the 18th century to reveal limits to empirical knowledge. The human subject cannot fully be an object of study, according to Kant, because aspects of

it are a precondition for all other kinds of knowledge. To understand these preconditions, we cannot use empirical methods because these already presuppose the conditions. Instead, we must use reflection—transcendental argumentation. In particular, according to Kant, the “I” part of the human subject is presupposed by the unity of experience, by the fact that all experience internally contains the sense of being “my” experience, and by the fact that experience is always an experience *of* something, meaning that it involves something other than its objects. The “I” is not an entity, not an object, yet it is presupposed in all forms of experience. Thus, Kant showed limits to empirical knowledge and was able to defend morality as a rational activity by distinguishing between subject–object and subject–subject relations. Knowledge in general is then divisible into types, including empirical, reflective, and moral.

The relation of knowledge to power can be understood, therefore, in two broadly conceived ways. It can be understood as the result of mistakenly considering the human subject to be either an object of or a condition for knowledge. Then research as critique may proceed with the removal of this belief. Or the relation of knowledge to power can be understood in terms of an internal tension in the self between objectivity and subjectivity. Then research as critique will examine processes that systematically block full self-expression, self-recognition, and needs for self-development.

Poststructuralism and Its Critical Methods

Foucault argued that by his own time in history the philosophies and theories of modernity had exhausted all of the possibilities entailed by a contradictory notion of the human subject. Thus, the argument goes, a new era—a *postmodern* era—that features the “death of the subject” in its understanding of knowledge is under way. As in structuralism before it, poststructuralism rejects the idea of an intentional subject. In addition, any notion of universal reason is rejected. “Structures” internally construct forms of reason and subjectivity, and structures are not grounded in anything (hence *post*structuralism) but rather rise and fall, mutate and disseminate, intersect and network in simply accidental nondirected ways. Belief in universal reason and the human subject make it possible for knowledge and culture in general to be forms of oppressive power.

Critical Methods Informed by Poststructuralism/Postmodernism

Foucault’s research methods are called archaeology and genealogy. Both are ways to study knowledge in the human sciences as discourse practices that construct specific forms of the human subject internally (e.g., “the insane,” “the criminal,” “the sexual deviant”), mask the arbitrary form of these constructions, and then subjugate the constructed subjects to punishment, discipline, examination, and surveillance. People also apply such power and discipline over themselves when interpellated within a discourse practice. Concepts of reason and truth are similarly regarded as constructions internal to discourse practices, which themselves are viewed as objective forces. It is the false belief in essentialism that such constructed subjects are real and transcend the discourses about them that make discourse practices forms of power. Archaeology is a form of reconstructive analysis claimed to be nonhermeneutic because knowledge practices are treated like objective forces rather than like meanings.

Historically, discourse practices change dramatically and not as the result of learning processes, as when we say that a field of knowledge has improved and progressed, but simply through accidental splits, convergences, and intersections with other discourses. The study of these contingent and nonintentional historical relations is called genealogy of knowledge.

In other poststructuralist/postmodernist work, deconstruction as introduced by Jacques Derrida has been very influential. Deconstruction is used to implode theories and discourses from within. The commonsense notion of knowledge is that it consists of signs that systematically represent objective and subjective states of affairs. Accurate representation is then believed to ground the meaning of signs (e.g., words, symbols, languages). This ensures that repeated use of signs will mean the same thing to the extent that what they represent will be more or less stable. But deconstruction reverses this commonsense perspective, showing that it is the repetition of signs that generates belief in objectivity and subjectivity (as categories that transcend sign systems). Nothing is really outside of a text. And texts iterate, mutate, and shift without direction, intention, or purpose.

Deconstruction is an artful strategy rather than a method per se, for if it were formulated explicitly enough to be called a method, it would be deconstructable itself. It has been used to deconstruct highly

influential theories and philosophies that subtly privilege masculinity over femininity, science over art, mind over body, and other binaries that have supported/constituted power relations in modernity.

There are many examples of social research conducted along poststructuralist lines. *Troubling the Angels* by Patti Lather and Chris Smithies is exemplary. A collection of studies can be found in *Working the Ruins: Feminist Poststructural Theory and Methods in Education*, edited by Elizabeth St. Pierre and Wanda Pillow.

The Critical Theory Tradition

Contradictions in the notion of the human subject as it emerged at the end of the 18th century are regarded as insightful—not condemning—by critical theory. Philosophies based on dialectical reason modified Kantian insights to argue that existence itself is contradictory. Freedom is a state of knowing one's self to not be anything objective, but self-knowledge requires objectivations from which to reflect. Hence, in different ways, Johann Gottlieb Fichte, Georg Wilhelm Friedrich Hegel, and Karl Marx developed theories in which the epistemic subject–object relation has an ontological status; knowledge is part of an existential spiral in which subjectivity acts to objectivate (“posit”) itself and then reflects from the objectivations to know itself and know itself as free. In Hegel and Marx, the subject is transindividual—a cosmic subject for Hegel and a species subject for Marx—and develops itself through history with the staged overcoming of alienated forms of self-understanding.

Most contemporary critical theory, however, rejects the subject–object framework of dialectics and relocates the essential tension in the self within the subject–subject relations of intersubjectivity. This shift in paradigm draws on insights from Wilhelm Dilthey (who modified Kantian theory to argue for the primacy of hermeneutics in the human sciences), George Herbert Mead (who distinguished between the “I” and the “me” components of self), and Ludwig Wittgenstein (who understood “meaning” as knowing how to respond to the acts of others rather than as having an object present to consciousness). Dilthey argued that humans have identity through being able to produce self-narratives yet are motivated to be recognized as the authors and critics of these self-narratives and, thus, be not fully absorbed by them. Mead argued that self-knowledge is mediated by

taking other social positions in relation to one's own acts, and these positions are culturally contingent. Hence, one can find one's subject status and needs for self-expression, self-development, and self-validation constrained, denied, and/or distorted if the identity categories supplied by cultural milieu are hierarchical with respect to things such as gender, race, sexual orientation, and class. The critical researcher further relates distortions in the milieu through which people must construct themselves to noncultural features of a social system such as the economy.

Accordingly, an ethical and moral principle embraced by many poststructuralists and critical theorists is to not fully represent another human subject in objectifying ways because to do so not only is epistemologically in error but also blocks needs for dignity and self-development. Essential tensions in the ontology of the subject—the “I” and “me” distinction—make sense of this moral principle that simultaneously implicates a standard for sociocultural critique.

Critical Methods Informed by Critical Theory

Critical theory has had a first generation, which emphasized dialectical reason but sought to combine it with Weberian social theory and the psychoanalytic tradition, and a second generation, which shifted from dialectics to intersubjectivity. The theory of communicative action developed by Jürgen Habermas has been most influential for contemporary forms of research informed by critical theory. Such research makes use of virtually all research methods available to the social sciences at this time, including empiricist methods, interpretive hermeneutic methods, critical hermeneutics, and systems theory. What makes research critical are not the methods employed but rather the theory of knowledge and society used in designing a study and interpreting results. A typical critical research project will artfully combine several methods.

Social research is generally interested in (a) patterned coordinated social action, (b) the conditions responsible for action coordination, and (c) people's experiences of life within or in relation to such patterns. Critical research adds an interest in evaluations of a form of life as made by participants in conversations with the researcher.

Unlike the patterns we find exhibited in nature, patterns in social life are not the result of causal relations but rather the result of contingent and criticizable

conditions within which action takes place. Conditions of action can be divided roughly into two types: those that are in principle under communicative negotiation and control (cultural conditions) and those that are not.

Cultural Conditions of Action and Power

The distinction between “I” and “me” is related to the concept of illocutionary force, which in turn is related to the fact that we hold other people and ourselves accountable—responsible—for what we say and do. The freedom of people to act otherwise, and thus to be able to separate themselves from their actions and statements so as to take responsibility for them and engage in self-criticism when appropriate, is a presupposition of social life. Thus, common situations of blatant power, when to act in certain ways would result in coercive sanctions, are ascertained to involve power by the constraint put on this sort of freedom. In contexts where coercive power is not obvious, action is coordinated in relation to illocutionary force. When people interact in any manner to communicate meaning, part of the meaning consists of claims or bids for a certain type of social relationship based on norms—presuppositions or explicit claims about what is appropriate, good, and right. The person to whom a meaningful act is addressed is in principle free to accept or reject the bid, and acceptance or rejection will be based on reasons a responsible human subject can and will articulate if appropriate. The normative claims that inform illocutionary force are, therefore, in principle criticizable.

But consent to illocutionary claims in daily life usually occurs for reasons other than a fully conscious assessment of reasons. We are socialized into cultural traditions that carry many implicit assumptions, beliefs, and values we simply take for granted. Moreover, norms are deeply linked to identity structures. Every meaningful act contains an identity claim at levels of foregrounding and backgrounding that vary. The unity of a self is also a claim brought about through an integration of routine identity claims within a self-narrative. Components to identity claims are drawn from the cultural milieu where they abide very often in hierarchical structures of mutually implicating terms such as male–female, white–colored, and heterosexual–gay. This means that it is often difficult to claim a self either as part of a meaningful act or in a self-narrative that is not dependent on there being other

kinds of selves of greater or lesser cultural value. It also means that it is sometimes difficult to claim a self that is fully embraced and recognized by the one who claims it. Consent to norms or criticism of norms both entail consequences for the identity of the actor—in many cases because culturally valid identities are tied to positions taken on norms. It is possible for cultures to separate identity from specific positions on norms and beliefs—an emancipating condition—but this is an exception rather than a commonality in most contexts. Hence, cultural power frequently works through identity structures to fix normative positions and make their criticism difficult and unlikely. Where this is the case, human needs for self-expression, validation, and development will be adversely affected, and this will manifest within the experiences of actors, albeit often at tacit levels that are hard to bring into articulation. In addition, possible criticisms of social institutions characterized by the second set of action conditions—those outside of communicative controls but still socially structured—are blocked. Sources of identity milieu include cultural traditions, the entertainment and news media, and educational institutions in contemporary societies.

A characteristic critical research project will begin with a study of culture using hermeneutic reconstructive methodology. The researcher must seek to attain an insider’s position as much as possible using ethnographic methods and/or maieutic interviewing with individuals and focus groups. Maieutic interviewing employs active listening, paraphrasing, and/or direct questioning to facilitate the articulation, by the participants themselves, of latent concepts, conceptual relations, and identity components in structured relations. The implicit intersubjective structures that participants make use of in their daily interactions with others and their self-monitoring activities are acquired by the researcher, such that he or she becomes more or less able to take positions with others as his or her participants do. This results in the acquisition of implicit forms of knowledge that the researcher then articulates into explicit discourse with his or her participants’ help. Validity is determined by the recognition by participants of their own and the researcher’s explications of the implicit cultural milieu. Resulting data are in the form of articulated norms, values, identity structures, stories, and self-narratives, all of which are themselves embedded within larger cultural structures such as discourses and narrative genres.

Simultaneously, the researcher will learn from participants not only how they live within their social and cultural contexts of life but also what it feels like to live this way. This sets the groundwork for critical analysis. To bring critique into the picture, participants must be engaged in conversations (e.g., interviews, focus groups) about their lives and experiences so that tensions between identity investments and expressive self-developing needs may become conscious to both participants and the researcher.

Relating Culture and Power to Noncultural Features of Society

The second set of conditions coordinating social action confront the actor from the outside such as market situations, economic resources and constraints, laws, formal organizational rules, and aspects of the physical environment. People in such situations find their freedom limited to instrumental forms in which essentially individuated choices are made in relation to a system of resources and constraints largely beyond their control. Examples include income distributions, the effects of laws on diverse groups of people, the formal rules of organizations, housing conditions, formal means of access to health care, and education. Where communicative processes do make a difference in social contexts like these, it is as mediated by political institutions—the amount of influence that public opinion can have on the formation of laws and policies. Critical researchers are most definitely interested in these features of social life that can be accessed through an objectivating, empiricist-like framework augmented with systems theory.

Critical research also seeks to access the legitimacy of social institutions like these. Many social groups are faced with unequal opportunities, unequal distributions of resources, poor housing, poor medical care, and meaningless work. A basic research question will always be whether or not such groups explicitly criticize these objectified features of social life and what means are at their disposal to try to change them. By comparing critical hermeneutic reconstructions developed through qualitative research with features of society that confront actors externally, the functions served by cultural formations for legitimating and/or reproducing other aspects of a social system can be revealed.

There are many examples of research informed by critical theory. *Learning to Labor* by Paul Willis is a classic text of this kind. *We Are All Equal* by Bradley

Levinson is an exemplary study. And “Reforming Educational Practice Against the Boundaries of (Re)iteration: A Critical Ethnography of the Hidden Curriculum of a Constructivist Charter School,” a book chapter by Barbara Korth Dennis, is particularly illuminating.

CRITICAL THEORY

Critical theory is a foundational perspective from which analysis of social action, politics, science,

and other human endeavors can proceed. Research drawing from critical theory has critique (assessment of the current state and the requirements to reach a desired state) at its center. Critique entails examination of both action and motivation; that is, it includes both what is done and why it is done. In application, it is the use of dialectic, reason, and ethics as means to study the conditions under which people live. This entry describes the development of critical theory and its applications to a variety of research questions.

Background

Critical theory has a considerable history; from its beginnings with the Frankfurt School to the current time, it has undergone some changes. That said, its usefulness as a means of inquiring into questions of social structure and action is undeniable. Critical theory retains its fundamental postpositivist character even in its transformed state.

Origins

Approximately seven decades ago, Max Horkheimer articulated the foundations of the social-theoretic school of thought that would be called critical theory. Horkheimer, along with Theodor Adorno, Herbert Marcuse, and others affiliated primarily with the Institute for Social Research at the University of Frankfurt am Main, began to revisit Karl Marx's critique of capitalism and apply it to contemporary society.

The Frankfurt School founders drew to some extent from the idealism of George Wilhelm Friedrich Hegel as well in their development of dialectical means of analysis. The Hegelian source was far less important, however, than were Karl Marx and Max Weber. The difference of their approach was to situate it in immanent (knowledge within the realm of possible experience) terms rather than transcendent (the condition of the possibility of knowledge) terms. The role of history was central to Horkheimer, Adorno, and Marcuse. For that reason, historical examination was, for them, an important element of analytical method. The historical was not merely artifactual; it was essential to understanding of the social situatedness of contemporary social life.

Second Phase

Critical theory is usually separated into three stages. Following the work of the Frankfurt School

members, some transformation of underlying principles, and so methods, was begun. Jürgen Habermas studied with founders of the Frankfurt School; his early work demonstrated his intellectual and practical debts to them. His analysis of the public sphere was firmly historical in that he drew his analysis from the manifestation of public political and social behavior. Habermas then began to turn to communication and language as the analytical and normative bases for inquiring into social action. The normative aspect is important as a distinguishing mark between his work and that of others who are linked to a movement sometimes called the "linguistic turn." One element of consistency between the first and second stages of critical theory is the denial of relativism that can characterize other theoretical and methodological approaches.

Third Phase

Some students of Habermas further transformed some of the conceptual and analytical bases of critical theory. The third stage of work built on Habermas's critique of instrumental reason—something that he continued, but altered, from the Frankfurt School founders. During the third stage, the force of ideology and its influence on social action became more particularized. Analysis became, if anything, more immanent. The situatedness of specific human actors—and their historical development—was a methodological centerpiece. Also, the connection of ideology and the ethical analysis was strengthened.

Critical Theory and Method

Although there are three identified stages of critical theory, all three conceptions have methodological value. There are some conceptual and foundational differences among the three stages, but there are questions as to which methodological specifics of each stage can be applied. The realm of social theory generally is extremely broad; any historical, political, economic, and technological elements can be studied in depth. Furthermore, conceptions of ideology can be applied to analysis in numerous ways. Therefore, the changes to critical theory do not represent supersesive variables. Because of the breadth of critical theory's brush, many kinds of questions may be amenable to its application.

Historical Analysis

Because all of critical theory relies on a particular kind of historicism (the starting point that people are historical agents who are participants in action as well as being subject to action), the analysis of historical situatedness is an important methodological component. The historical analysis of critical theory is of a specific sort. Rather than being explanations of events, it is intended to be indicative of current states. Because much of critical theory owes a debt to Marx, the political and economic investigation that it supports depends on examination of the genealogy of capitalism. The historical analysis generally focuses on societal action and the impact of large-scale policies and decisions on the behavior of individuals in society. If a particular Marxian starting point is adopted, for example, the analysis might examine class differences and the distinctions of the ways in which people of different classes live. The Marxian approach is emblematic of the first stage of critical theory, but it is a bit less pronounced during the latter two stages. Although that emphasis is less pronounced, it still informs analysis to some extent. The historical examination could seek evidence for the loci of decisions that affect the study of society. A single decision could have varying effects on different segments of society; what benefits one group may be detrimental to another group. The kinds of differences, and their sources, are of interest to researchers.

Historical evidence comes substantially from documentation. Official documents are usually the most authoritative sources for the decision-making activities of the state. This sort of documentation can record policies relating to zoning, transportation, infrastructure, taxation, education, and other areas that have direct impacts on people's lives. The locations of schools and the paths of public transportation, for instance, are largely matters of public record and are open to examination. Other documentation, however, might be necessary materials for researchers to gain a purchase on deliberation and debates and on responses to the policies. Newspapers are among the sources that a researcher could consult. In the cases of more recent events, there might be archives of community access broadcasts that record public meetings and community-led discussions. The entirety of the documentary record might need to be consulted in an effort to understand the critical events and discourse that affect society.

Historical evidence is one building block of critique. That is, the critical theorist will interpret evidence in terms of effects on those individuals and segments of society that can be least likely to be positioned to influence policymaking. A tenet of critical theory follows from Kant's dictum that people should always be treated as ends—never as means—that guides interpretation. An implication of the tenet is that historical analysis is particular, not universal. Individuals' lives are affected by turns of events; the events themselves are brought about by humans. The particularistic historicism requires that, so far as possible, people's interpretations of their own states should be taken into account.

Observation

Methodologically, the understanding needed by the researcher can be achieved in part through observation. Daily lives of, say, the working poor can be followed. The observation consists of the living conditions of individuals, the kinds of work being done and the places where the work is done, and spatial limitations that effectively limit movement, living space, and other kinds of existence. The observation is informed (shaped) by critical theory. That is, the theory identifies restricting factors as well as potentialities for emancipation. The Marxian aspect of the theory is especially important in shaping observation. Living conditions (including, but not limited to, housing) are economically determined, but they may also be affected by several other social and other components. Race, as well as economic class, may also be a factor involved with circumstances affecting people's lived lives. The observation follows from the numerous instruments that influence much of life. Reason, underlying observation, enables the researcher to understand the "other." So, the individuals who are observed are not objects of study but rather people whose conditions are genuine.

Opportunities for observation in the critical theoretic framework exist in the normal course of events. For example, a city may plan to rejuvenate a downtown area that has fallen into a state of deterioration. The plan could involve housing, retail business, office space, and other elements. Initially, the plan will likely be subject to review at several levels, including community response. Hearings and meetings could help and could be observed as they occur. In keeping

with critical theory, the researcher could trace who speaks—where the individuals live, what their interests are, and so on—and what they say. Speakers may indicate what their interests are and how the plan will serve or disrupt those interests. Enactment of the plan probably entails dislocation of some people; the disposition of the people can be followed. The economic states of all involved in the plan can be observed as well, and the observation can be extended over time. There are numerous other conceivable examples that necessitate observation.

Interviewing

Observation, in the application of critical theory, is not sufficient even if it is necessary. Individuals, who are other selves, apprehend their lived lives in some particular ways. For instance, spatial limitations might be perceived not merely as geographic boundaries but also as social and cultural boundaries. The meaning of perceptions can be comprehended by researchers only by inquiring of the individuals. Asking people what they believe is open to them and what is closed is the practical application of reason by the researcher. The interviewing process also opens the potential practice of reason on the part of the interviewees. At this point, the act and product of critique is vital. Interviewees may be constrained in their perceptions and their interpretations of their own perceptions by instrumental reasoning. Their reasoning may be guided by the expression of interests other than their own. Once again, the Marxian character of critical theory provides the interpretive impetus for the researcher. Questioning may elicit responses indicating that interviewees do not perceive their labor as their own, that people's perceptions are influenced by capitalist culture, and/or that senses of value and belonging do not exist. The interviewing process must be open (as in not directed by the interviewer) so that forthright responses are given.

Public Participation

The second and third stages of critical theory, in particular, pay attention to people's lived lives. The second stage is especially influenced by Habermas's work in communicative action and discourse ethics. During this stage, a more pragmatic focus to inquiry is evident. Examination of what people say and how

they say it (especially in public) is frequently foremost. In terms of theory, the pragmatism of communication and discourse constitute norms. There are ideal ways in which to communicate, discourse is bound by reason, and there is an ethical imperative that guides people's discursive interactions. According to this normative theory, there is a gauge against which human action can be assessed. With regard to public discourse, human agents are bound to apply practical reason and ensure that ethical responses are given to others' speech. Such normative standards influence research practice.

Reason

One factor that pervades all three stages of critical theory is the recognition that reason is possible and necessary for human action. The practice of critique depends both on reason as a tool for the practice and on observation of practical reason. Reason as applied by the researcher entails the avoidance of engaging in human behavior and action as instrumentalities. From the inquirer's standpoint, this necessitates developing an understanding, informed by practices described subsequently, of difference. For example, the lives lived by the poor are materially and qualitatively different from the lives lived by others. The difference is likely to affect all aspects of existence. Reason is applied in defining not just the material differences but also the qualitative and other differences. What people do is important to critical theory, but why people do what they do—and also what they cannot do—is also important.

Reason also is intended to supply a link between the immanent and the transcendent. That is, throughout the entirety of critical theory, the actions of people should be guided by truth that is provided by the exercise of reason. Application of critical theory, in light of reason, is also intended to connect theory to the interests that people have. Critical theory, then, is not an abstraction; it is a way of examining normative elements of human action in terms of the many and varied material interests that lead to action. Critical theory is also a mechanism by which a researcher can assess honesty as well as truth, for example, can evaluate what people say they believe in and what they do. This form of evaluation permits the analysis of differences between practical reason and instrumental reason and the outcomes of the use of the one as opposed

to the other. A researcher's inquiry into the use of reason necessitates employing historical analysis, observations, and interviews as well as examination of some underlying social and communicative dynamics.

Ideology

Analysis grounded in critical theory includes examination of ideological forces and statements that influence human action. Once again, this aspect of critical theory signals its Marxian basis; capitalism is a major ideology that has been, and continues to be, the focus of much attention. During the first stage, capitalism was the dominant perceived ideology. During the latter two stages, the study of ideology was broadened to include many aspects of race, gender, class, and other things. The purpose of including ideology in analysis is, as always, critique. The existing conditions of people are the focus of analysis, as is the possibility for emancipation from current conditions. Study of the communicative actions of people can unveil some of the ideological presumptions that underlie what people say and do. For instance, the communication and discourse may reveal processes of inclusion and exclusion. Study can investigate who is given voice and who is not as well as the agency of the speakers (the extent to which their voices are heard and acted on).

The researcher is challenged by the study of ideology. The sources of belief might not be readily apparent because the ideological origin can be deeply rooted through history and situation. Analysis of ideology requires examining the discourse that is used in a variety of settings, perhaps especially official settings, and the definitions and applications of discursive terms. For example, in critical theory, "Enlightenment" carries ideological import that may shadow particular kinds of control. Other emblematic terms may also serve similar purposes. It is important to note that critical theory embraces much more than just the economic elements of life. All aspects of lived lives, including association, mobility, and schooling, fall under the purview of critical theory.

Challenges for the Research

Because critical theory has been developed and reshaped over several decades, the researcher must be aware of all the nuances and influences of the key figures. In fact, the researcher must apply historical analysis to critical theory itself so as to form the

clearest understanding of the framework it supplies. The most pressing challenge for the researcher rests with ideology. Any commitment to investigation of ideological underpinnings of human action necessitates initial inquiry into any potential ideological baggage that the researcher may carry. Ideology tends to be suffused throughout society; successful ideological forces are those that are less than conscious in their influence over action. The researcher may be required to engage in some self-critique—investigation into beliefs that are held and internal situatedness—prior to conducting analysis. Only then can the effects of ideological policies, discourses, and the like be fully comprehended.

The warnings that customarily apply to observational study, interviewing, and phenomenological research in general also apply with regard to critical theory. Errors or insufficiencies in those areas could have deleterious effects on the process and product of critique. Because critique is the intended outcome of investigation, it is essential that the researcher apply the theory with care and vigilance. This application of critical theory involves a substantive difference from grounded theory, which is inductive. There is a perspective that informs critical theory; the assumptions that reason can yield truth, that instrumental reason can subvert practical reason, and that ideology shapes the relations between people and between groups of people all provide epistemological and ontological starting points for inquiry. When it comes to methodology, there is an onus on the researcher to make the assumptions very clear. There is also an onus on readers of critical theory-based research to be aware of the point of view that the theory adopts. These challenges do not render critical theory irrelevant or impossible; rather, they position research rooted in critical theory within a particular political, social, economic, and dialectical framework.

CROSS-CULTURAL RESEARCH

Cross-cultural researchers examine differences and similarities between different groups in society. A concern with culture and cross-cultural research permeates a range of disciplines, including anthropology, sociology, sociolinguistics, cultural studies, and social work. However, within and across disciplines, there is controversy over the meaning of the term *culture*. Some researchers have interpreted it as referring to the set of values, beliefs, and concepts that a group shares. Others believe that this approach is essentialist; that is, it assumes that cultures determine how people behave and leaves them no agency in their own lives. They prefer to see the term *culture* as a heuristic device that allows researchers to interpret and understand behavior and to situate it in context. This allows researchers to investigate social life in practice in a way that does not assume that belonging to any group is unchanging or means the same thing to everyone.

Part of the difficulty in defining and separating cultures is that what they consist of can be based on a variety of characteristics, including race, gender, and age. There has been interesting research, for example, on youth culture, lesbian culture, and drug and gang culture. Cross-cultural research in these examples would refer to behavior and beliefs characterized by age, sexuality, and lifestyle. However, cross-cultural research is often seen as being about race, ethnicity, and (more recently) religious differences.

Even when a particular characteristic is the focus of research, there is no one set of perspectives within that culture that can be used to define what belonging to the group would involve. For example, what it means to belong to Indian culture may vary according to time of migration, age, where someone was born, gender, religious beliefs, and sexuality. What it means to belong may also depend on context in that characteristics such as gender, ethnicity, and age used to define culture

might not always be relevant to how we think or behave. For example, being Catholic or Greek sometimes may influence what we say or do, whereas at other times it might not. Part of the context in which decisions about the nature of belonging to a group, or the group's significance, is informed by who is listening (i.e., the audience) and by the context of discussion.

Cross-Cultural Research: Doing It Yourself

Researchers have studied cultures using a variety of methods, including interviews and ethnographies. Interviews are usually loosely structured to allow participants to put forward their concerns and perspectives. Interviewers can use a variety of theoretical approaches to inform their interviewing, including the increasing use of biographical narrative theories to situate lives within the context of the culture they are examining. This involves asking people to talk about their life histories as well as their everyday lives and experiences. There is also an interest in reflecting on the role of researchers and participants in research findings and how people from other cultures are presented by researchers. For example, the influences of ethnicity, gender, and religion during the interview process are put under scrutiny.

Some of the issues addressed by cross-cultural interviewers are also of concern to ethnographers, and ethnographers may use interviews to collect some of their data. Ethnography is a method by which researchers participate, in varying degrees, in the lives of people they are studying to collect data. They immerse themselves in the culture of others to try to see it from the "inside." There are differing views about the period of time needed to study a culture in this way as well as the status of the findings. Some researchers believe that it is a way of finding "the truth" about a culture, whereas others suggest that it provides valuable data but is still dependent on the perspectives of those involved. Increasingly, ethnographers are situating their perspectives, values, and beliefs within their ethnographies to seek to understand how they define people as belonging to other cultures. The debates on the status of ethnography include the difficulties (already discussed) in dividing cultures and insiders from outsiders, the time needed to learn about differences within cultures, and concerns about the ethics of this kind of research. Due to the constant involvement of researchers in the lives of

others, there are concerns about participants becoming vulnerable as a result, for example, of not being constantly aware that they are talking to a researcher who is not necessarily a member of their culture.

Doing Cross-Cultural Research With Help: Community Researchers

This is an attempt to harness the knowledge of people who straddle different cultures, however defined. Someone defined as belonging to a culture, and thus with knowledge of it, may be employed to act as a “cultural broker.” When different languages are involved, these “community researchers/interpreters” will also help in communicating with participants. Community researchers may carry out the research themselves and then pass it on to the researcher or assist the researcher, for example, by acting as an interpreter. Therefore, their input and the impact on the research vary. They may be used solely to pass on what the researcher wants and have little input in the actual research. Alternatively, they may be actively engaged in debating concepts and formulating the questions that are asked, as is often the case in participatory approaches to research. There are a variety of ways of widening the baseline of analysis to actively involve community researchers. They include making certain that they have meaningful input in the research proposal at the outset rather than after the research questions and topics have been decided, are involved in debating the meanings of concepts used throughout the research process, and are included in report writing. Also, the influence of all the perspectives of everyone involved on the research should be examined.

There are many advantages to working with people who are insiders, particularly when access would otherwise be impossible due to language differences. Some researchers go farther and argue that, wherever possible, there should be “matching” of researchers and participants, usually along gender lines, when ethnicity is concerned. The argument is that matching helps to achieve some understanding and trust between people. However, no one person is ever an insider in terms of all social characteristics, and just because people share gender, for example, does not mean that they see their lives in the same way and will understand each other’s perspectives. There is also the question of which characteristics, and how many, to match on. For example, does one need to be a disabled Black woman to interview a disabled Black woman, or is being Black enough of a match? Asking the

participants themselves, rather than making assumptions about what people want, may be a more appropriate way of addressing the issue. Participants may prefer someone like them in some ways (e.g., for religious reasons), they may want someone who is not part of their community, or it might not matter to them.

Community researchers/interpreters may act as “gatekeepers” for populations and limit access to only those people whose views they approve of as suitable to define their culture. For example, community leaders may help gain access to people for the researchers, particularly because they are likely to know who is active within the community, but they might not put forward anyone who challenges their status or views. There is some evidence that restricting research to participants chosen solely via gatekeepers may result in limited engagement with the range of views possible within any community and that such a sampling strategy has consequences for the research findings. It has also been pointed out already that no one person can be expected to represent a culture. This has implications for research that limits itself to community leaders and people who are active in formal organizations. There may be many people who consider themselves to be part of a culture but who do not participate in the activities of formal organizations and/or are not known to community leaders. When working with community researchers and community leaders, therefore, it is important to investigate their position within cultures.

Moreover, no one person is completely an insider or outsider to a culture. For example, a female community researcher who knows the language and is active in the community may help to access the views of other women who are similarly active. Some women may, however, prefer to speak to an outsider due to issues of confidentiality. Therefore, insider status is not always an advantage. What we say, how we say it, and to whom we say it vary, but this does not mean that one account of belonging is more accurate than another; it may just be different. There are also differences between language users, with people who speak the same language living differently and people sharing values and lifestyle but speaking different languages. There is no simple relationship between language and culture.

When researchers are not able to speak the languages involved in research, techniques such as back-translation have also been put forward as a way of ensuring “correct” translations and interpretations from community researchers. Those who believe that

there are many possible translations and interpretations, depending on perspective and context, have questioned the status of these techniques. There are also concerns here about how people are represented. The researcher brings to the research a set of beliefs that others speaking another language might not hold. There is a danger here of ethnocentric assumptions being built into the research and of “linguistic imperialism” or “domestication” taking hold, that is, how concepts are defined in the researcher’s main language are used throughout the research without an analysis of possible differences in meaning. Various means have been suggested for addressing these issues, including an analysis of the processes of interpretation and translation to situate possible sources of differences in meaning that includes an analysis of who is doing the research and from what perspective.

the researcher and participants but also their interactions with each other. Understanding both participants’ cultural context and the researcher’s place within it can be essential for successfully recruiting participants, conducting the research itself, and analyzing the data.

Concerns related to cultural context should not be isolated for exclusive use in cross-cultural research; instead, they should be viewed as “best practices” for qualitative research in general. These issues do, however, require particular care when working with participants from foreign countries as well as when conducting research with minority groups or subcultures in the researcher’s own country. Although issues of cultural context are obvious when dealing with language differences, it is just as important to recognize the distinction between being “bilingual” and “bicultural.” For example, members of subcultures may share the researcher’s language and many of the same broad cultural assumptions at the same time that they use jargon and engage in practices that are completely “foreign” to the researcher.

When there is a substantial difference between the researcher’s and participants’ cultural backgrounds, there may well be a need to develop trust within the community of potential participants. This often begins during the process of gaining access to the participants, either by building rapport with already trusted community groups or by relying on a liaison person from outside of the community. When participant observation is the primary method for data collection, key informants often play an essential role in helping the researcher to recognize and deal with cultural differences. The same advantages can also apply when interviewing is the primary method by using informants to learn about sensitive topics, appropriate language, and proper behavior during the interviews. In addition, key informants can assist interviewers with issues of cultural context by reviewing the content of the questions and by recommending initial interviewees who will be relatively tolerant of the researcher’s “outsider” status.

Cultural context is also important in analyzing and reporting data. In most cases, the issues encountered during data collection will already have sensitized the researcher to the importance of the participants’ cultural context when interpreting the meanings of their words and behavior. Even so, it is crucial to recognize that the researcher’s own background and the implicit assumptions that go with it also create a cultural context that can affect the interpretation of the data. Many of these same issues carry over into writing up the results, where there is a need to recognize and deal with the difference between readers’ and participants’

CULTURAL CONTEXT

Cultural context consists of the broad background of beliefs and practices that guide the behaviors of both the researcher and research participants. Cultural context is an essential element of any research project because it affects not only the individual behavior of

cultural contexts so as to present the results in ways that facilitate an appropriate understanding of what was learned through the research.

D

DANCE IN QUALITATIVE RESEARCH

Dance can be content and/or form, process and/or product, in relation to qualitative inquiry. It may serve one or more of a variety of roles such as the subject matter for research, an aspect of methodology, and the format for presentation of findings.

Dance, dancing, and dancers have been examined as subjects of research during the past century and even before. Although dance scientists and some dance education researchers use primarily quantitative methods, a variety of qualitative, usually interdisciplinary, approaches have dominated dance research, with researchers invested in exploring dance and dancing as bodily experience, aesthetic object, and social and cultural process. Although different approaches and orientations are described in this entry, in practice the lines between them are often not easy to draw.

Although current dance research emphasizes interdisciplinarity, there is debate within the field regarding the need to develop research methodology intrinsic to dance rather than borrow from other traditions, and movement analysis has been put forward as a candidate for this role. Movement analysis is used to study human and animal movement as well as dance. The best-known system, based on the work of Rudolf von Laban, derives from perception of movement according to defined characteristics such as body action (*what*), space (*where*), and effort (*how*). As with all analysis systems, these parameters cannot be applied across cultures and reveal only certain kinds of information; researchers create new ways of attending to bodily sensations and the rhythmic and visual

organization of movement to meet the needs of individual research projects.

In the tradition of anthropologists, early 20th-century Western dance ethnographers, such as Beryl de Zoete and Franziska Boas, studied dance practices within cultures other than their own. Dance historians, such as Lincoln Kirstein and Walter Terry, wrote chronologies of Western dance and biographies of great artists. During more recent years, these once separate practices have fused, with dance scholars pursuing a hybrid, interdisciplinary “dance studies” approach. Joanne Kealiinohomoku’s classic essay, “An Anthropologist Looks at Ballet as a Form of Ethnic Dance” (originally published in 1969–1970), helped to change this landscape. Dance culture in theaters, classrooms, studios, clubs, competitions, and other community settings is now studied through participant observation, interviews, and analysis of texts, images, and dance works as well as through a variety of theoretical lenses. The writings of the late Cynthia Jean Cohen Bull (Cynthia Novack), Susan Foster, and Susan Manning, among many others, exemplify this approach.

Like anthropologists and historians, researchers grounded in dance education may use an ethnographic approach, including participant observation, interviews, and (sometimes) movement analysis; Susan Stinson initiated such work during the 1980s. Data may also include visual images (both moving and still) and other kinds of original materials found in the setting; Karen Bond pioneered the use of children’s drawings as data for dance education research. Interpretation of the source material is heavily dependent on the research tradition of the principal investigator. Action research, or research on one’s own

Dancer With a White Rope. This photographer describes his process as creating an environment in which dancers feel comfortable to experiment and the camera has appropriate lighting. In this photo of Carrie Denyer, the improvisation began with her desire to do something with a white rope. The movement depicted was being performed for the first time.

professional practice, has more recently become popular among practitioners, especially dance education researchers seeking to better understand and transform their practice. Qualitative approaches may also be used for research focused on evaluation and advocacy in dance education, although quantitative procedures may be demanded by external funding agencies.

Qualitative researchers with a personal dance history, such as Valerie Janesick, have used their understanding of dance processes such as warm-up, stretching, and improvisation to enhance their understanding of similar research processes and have recognized the variety of aesthetic decisions that get made in research. Other aspects of dance and dance making, or related bodily experiences, may also be used as metaphors for aspects of the research process.

Scholars seeking to integrate their “dancer-self” with their “researcher-self” often recognize the significance of the researcher’s body as an “instrument”

even when discarding instrumental language. Qualitative dancer-researchers may be acutely aware of their own bodies in the perception of data, using the kinesthetic sense to perceive other bodies. In the tradition of phenomenology, researchers such as Sondra Fraleigh emphasize their own bodily experience; some researchers ask participants to recollect bodily sensations in descriptions of their “lived experiences” that are then used as data. Use of one’s own body in movement and stillness in the process of analysis/interpretation and theory building may also occur as researchers seek ways to understand the concepts and relationships in the data; scholars may perceive a concept somatically before having the words to express it.

Although technological advances have made it easier to record and preserve this ephemeral art form, all dance researchers struggle to some extent with how to adequately present their findings in a way that is accurate and also as engaging as the practices they study.

Donald Blumenfeld-Jones, Mary Beth Cancienne, and Celeste Snowber are among the scholars in dance education who have pioneered alternative forms of presentation. Dance artists in higher education have long argued in forums at professional meetings and in appeals to their own institutions that choreography, performance, reconstruction, and other forms of artistic production should be accepted as the equivalent of scholarly research. After many years of advocacy, this is now the case at most universities. Although choreography and performance are widely accepted as valid research within dance departments in higher education, such ventures by those in other disciplines are still typically regarded as unusual by their colleagues, even when spoken text is included in a performance, and may become trivialized or romanticized. Because a dance performance as a research outcome is so rare in other disciplines, one dilemma faced by dance researcher-artists is that the audience may focus only on the performance itself and not on the content. Another dilemma is that print is still the primary mode of publication, and publication is viewed as essential in many disciplines. With the increasing popularity of electronic journals, moving images may become more integrated into print in the future, offering new possibilities for resolving this issue. This will also introduce new challenges with the new medium of presentation.

A vision of researcher as artist and research as an art form often rests on a vision of art as personally constructed. However, academic and aesthetic expectations of the culture/subculture of which the dance is a part are equally as important as the vision of the dancer-researcher who has created a performance to represent research findings. The body itself, as well as the performance, is a sociocultural construction, one that is in the foreground in dance art and research. Dance studies scholar Ann Daly has examined how the dancing body acquires meaning based on the expectations of audiences and on period understandings of nature, gender, sexuality, race, and nation. Ann Cooper Albright is known for her work in investigating social and cultural expectations of variously abled bodies. Again, interdisciplinary approaches offer the richest possibility for continued understanding.

DATA

The term *data* refers to a collection of information. A more detailed definition includes types of data that combine to be the collected information such as numbers, words, pictures, video, audio, and concepts. Many definitions of data include the word *fact*, or *facts*, but this implies an inference about the data and not the data themselves. This occurs more often in the physical sciences. One may also see the word *raw* as a descriptor of the data. This description is used to separate data such as the number 42 from information such as at 42 one is 5 years older than one’s sibling. Once data are gathered, they are typically put into a format that can be analyzed by machine or human. The format can be a spreadsheet, notecards, or literary analysis software and serves to increase the ease of data analysis.

In the generic split of quantitative versus qualitative research, quantitative research gathers data that are in numerical form. The original data can be in nonnumerical form such as statements that are recoded on some specific numerical scale. Quantitative data separate into categories based on their measurement type—nominal (e.g., gender), ordinal (e.g., law school class rank), interval (e.g., degrees Fahrenheit), and ratio (e.g., degrees Kelvin).

Qualitative data are generally nonnumerical but have a greater variety of sources. Those data sources are generally categorized as verbal and nonverbal.

Data are verbal if the majority of what is being analyzed is words. Verbal data sources include items such as personal diaries, letters, media reports, surveys/interviews, and fieldnotes. Within the group of interviews the data can come from in-depth/unstructured interviews, semi-structured interviews, structured interviews, questionnaires containing substantial open-ended comments, focus groups, and so on.

Nonverbal data sources include items such as student concept maps, kinship diagrams, pictures, video, film, art, and print advertisements. Each type of data and how it was collected has different strengths and weaknesses in relation to the research questions and analysis techniques. For example, nonparticipant observations from video collected through surveillance cameras potentially allow the researcher to collect data without influence in the field, but there are issues with the ethics of these observations.

DATA ANALYSIS

Data analysis is an integral part of qualitative research and constitutes an essential stepping-stone toward both

gathering data and linking one's findings with higher order concepts. There are many variants of qualitative research involving many forms of data analysis, including interview transcripts, fieldnotes, conversational analysis, and visual data, whether photographs, film, or observations of internet occurrences (for the purpose of brevity, this entry calls all of these forms of data *text*).

For novice researchers, data analysis may seem like the most enigmatic and daunting aspect of qualitative research. On the one hand, there are so many pages of fieldnotes, interview transcripts, and/or images that the task seems overwhelming. On the other hand, no matter how much data one has, there is always the fear that there might not be anything of importance. The following features of data analysis affirm the dictum of "trusting the process."

Regardless of the perspective or paradigm one uses, the analysis of qualitative data involves a number of common features. These include simultaneous data collection and analysis, the practice of writing memos during and after data collection, the use of some sort of coding, the use of writing as a tool for analysis, and the development of concepts and connection of one's analysis to the literature in one's field. This entry discusses each of these features of data analysis.

First, the gathering of data and the analysis of those data are iterative processes. In its ideal form, early data analysis provides sufficient insight to shape the gathering of further data. Grounded theory, for example, features the constant comparative method, the conceptual interaction between analysis and data, as its chief strength. Researchers who conduct interviews may use early analysis to revise interview guides or to focus future interviews. Some field-workers do not settle on a research question until they have spent some time in the field and have observed and begun to analyze what is of theoretical interest in a particular social setting.

Second, both during and after collecting data, researchers engage in memoing. Memoing occurs when researchers take note of personal, conceptual, or theoretical ideas or reflections that come to mind as they collect and analyze the data. Early memoing may occur while researchers are writing up fieldnotes or transcribing interviews. In this situation, researchers embed memos within the text itself (usually marked off by special characters such as square brackets).

These memos may involve researchers' guesses about what is going on, questions raised by the data, or links to literature that may be useful in helping researchers to interpret the data and relate them to

other substantive areas that might involve similar generic social processes. For example, Deborah van den Hoonaard found that widows' descriptions of the work they did to maintain a good front when they were with their friends were comparable to the processes of emotion work and feeling rules that Arlie R. Hochschild described in her study of airline stewardesses, *The Managed Heart: The Commercialization of Human Feeling*. Thus, a wider acquaintance with a body of literature can invoke insights that, in the end, might prove to be helpful in the analysis of the data.

Some researchers find it useful to embed memos into their actual fieldnotes or interview transcripts, whereas others find it more profitable to set up the memos separately. No doubt there are researchers who combine the two methods. Some researchers use memos themselves as material for coding, as described next.

Third, any analysis of data involves some form of coding. Coding reflects both the personal analytic habits of researchers and the general principles that flow from particular qualitative research methodologies and theoretical perspectives. In its most stringent form, the analysis of data can entail line-by-line coding of text whereby researchers capture every empirical and conceptual occurrence in each line. In conversational analysis, even the duration of pauses is measured and used as data. At the other end of the continuum, some researchers adopt a more flexible approach, perhaps coding whole paragraphs or groups of sentences at a time.

Researchers inextricably come to the question as to what ought to be coded. They may well conclude that coding at successive levels achieves the best analysis. In this case, researchers first indicate all empirical instances that seem to be related to the research question. This scanning of the text by researchers constitutes the first and second process of familiarizing themselves with empirical instances. The analysis, however, would remain a mundane exercise if researchers, searching for higher order concepts, stopped at the level of mere description rather than conducting subsequent scans.

At first glance, the data often seem opaque. However, through the process of multiple readings of the text, researchers gain confidence that it contains enough material to warrant discovery and analysis, moving first from empirical observations and finally to conceptual insights. It is often during early readings of the material that researchers develop a list of preliminary codes to try out. As coding continues, researchers may refine the codes to include more relevant categories.

Fourth, qualitative researchers arrive at a more profound analysis of the data when they engage in writing up the data as soon as possible. These short or lengthy writing bouts often yield insights that were not readily apparent even after the coding had been completed. Indeed, researchers may find that they need to go back to the data to recode for concepts that became apparent during the initial writing up of the data.

Fifth, all data analysis must move toward developing concepts or relating to already existing concepts. This final stage of data analysis is analogous to having a conversation with the literature of the discipline or what was found in other social settings.

Researchers, since the earliest days of qualitative research, have offered insights into the specific ways in which they have extracted findings and ideas from their text. Here, too, there have been many variants. Some used colored pencils, others used a numerical system, and still others used a given word to indicate the code. In these cases, the researchers made ample use of a wider right-hand or left-hand margin for this purpose. Some researchers found it more convenient to use single-spaced written text so that the context of items was more clearly visible and categorizable. It is helpful to remind oneself that in the more distant origins of qualitative research—at least when typewriters were still in use—researchers needed to make as many copies of the fieldnotes (or interview transcripts) as typewriters would allow and, in addition to keeping a “master file” of the text, copies would be cut up and sorted according to topic or concept.

These seemingly archaic approaches to analyzing data have had a pervasive effect on today's approaches. Many researchers still abide by some of these techniques of coding, whereas others have adapted them to computer-generated texts. Computers are powerful allies in the analysis of data. With the advent of word-processing programs, it became possible to use cut-and-paste methods along with maintaining separate files for data related to a particular code or concept. This technique maintained the philosophical underpinnings of the color coding or index card approach to data analysis.

More recently, researchers have seen the introduction of software, such as Ethnograph and NVivo, developed for the express purpose of managing and coding qualitative data. These programs, however, remain controversial and have influenced, and continue to influence, data analysis in unforeseen ways. They allow researchers to code large amounts of data

and have arguably led to researchers' conducting studies involving far greater numbers of participants than in the past. There is, however, no guarantee that the analysis is any better, because it may foreclose on the interplay among creative insights, memoing, and continuing development of codes that results from an ongoing connection with the raw data. Some argue that the software imposes a structure that may imperceptibly constrain the analysis. Some researchers who use qualitative programs have removed themselves from the coding process, handing it over to research assistants, and from the hands-on approach typical of earlier styles of qualitative analysis.

DATA ARCHIVE

A data archive is a resource center that acquires, stores, and disseminates data for secondary analysis for research, learning, and teaching. The prime function of such archives is to ensure long-term preservation and future usability of the data they hold. Data archiving is a method of conserving expensive resources and ensuring that their research potential is fully exploited. Unless preserved and documented for further research, data that have often been collected at significant expense may later exist in only a small

number of reports that analyze only a fraction of the research potential of the data. In the case of digital archives, within a short space of time the data files are likely to be lost or become obsolete as technology evolves. This entry focuses on digital archives for qualitative data.

History

The social science data archiving movement began in the United States during the 1960s within a number of key social science departments that stored original data of survey interviews. The Inter-University Consortium for Political and Social Research (ICPSR) is the U.S. national archive. The movement spread across Europe, and in 1967 a data archive in the United Kingdom (UKDA) was established by the U.K. Social Science Research Council. During the late 1970s, many national archives joined wider professional organizations such as the International Association of Social Science Information Service and Technology (IASSIST), established to promote networks of data services for the social sciences and foster cooperation on key archival strategies, procedures, and technologies.

The first data archives of the 1960s collected data of specific interest to quantitative researchers in the social sciences such as opinion poll and election data, but as the trend for large-scale surveys grew, by the late 1970s the UKDA began to acquire major government surveys and censuses. Key British government series include the General Household Survey and the Labour Force Survey. In the United States, key government survey series include the Current Population Survey and the National Health Interview Survey.

By the 1990s, collections had grown to thousands of data sets spanning a wide range of data sources and including large national longitudinal studies, major cross-national series such as the World Values and European Values Surveys and the International Social Survey Program Series, historical data, and (in the United Kingdom) qualitative data. It was not until the early 1990s that the U.K. research community recognized the needs of qualitative researchers by funding the Qualidata service at the University of Essex. In 1995, a history data service was also established and devoted to the archiving and dissemination of a broad range of historical data. In 2003 in the United Kingdom, the Economic and Social Data Service (ESDS) was established to provide a long-term and

integrated strategy for preserving, processing, and disseminating all types of social science data with an enhanced focus on supporting and training users.

Qualitative Data Holdings

Typically, social science data archives acquire a significant range of data relating to society, both historical and contemporary, from empirically derived sources. Whereas most data archives typically collect numerical coded data that can then be analyzed with the use of statistical software, the UKDA also holds in-depth interviews, fieldnotes, audiorecordings, and digitized open-ended survey questions. Other data archives that hold collections of qualitative data include the Murray Research Center at Harvard University and the Finnish Social Science Data Archive (FSD). Data sets from across the world are available through national data archives' reciprocal arrangements with other national data archives, although qualitative data are still in short supply.

Data Acquisition

A key concern for a data archive is to ensure that the materials it acquires are suitable for informed use and meet demand. All materials deposited are selected and evaluated and must meet certain criteria such as being documented to a minimum standard and, of critical importance, meeting any promises negotiated under informed consent (e.g., nondisclosure, preservation of anonymity). Copyright of interviewees' words or company information and third-party defamation or slander in research materials should also be taken into consideration before data can be assumed to be shareable. Acquisitions policies should be flexible and responsive to changes in both data and information needs of the research communities and in the rapidly changing climate of technology.

Long-Term Preservation

It is the responsibility of data archives to keep up with technological advances by monitoring hardware and software developments and migrating their collections accordingly. When technology changes, the data in their holdings are technically transformed to remain readable in the new environment. Computer programs are maintained to allow data to be easily transformed from an in-house standard to the various formats required by users.

Preparing Data for Archiving

Data-processing activities include first sorting and checking, for example, examining texts for the risk of identifying individuals. Data may be anonymized. Second, meta-data (data about data) are produced with the aim of producing high-quality finding aids and providing good user documentation. Meta-data cover information describing the study and the data, and a systematic catalog record is usually created, detailing an overview of the study, the size and content of the data set, its availability, and its terms and conditions of access. User guides contain further information on how the data were collected, the original topic guides, and how to use the data.

Providing Access to Data

Data supplied by data archives can be used for many purposes. Secondary analysis strengthens scientific inquiry, avoids duplication of data collection, and opens up methods of data collection and measurement. Reusing archived data enables new users to revisit rich descriptions; ask new questions of old data; undertake comparative research, replication, or restudy; inform research design; and promote methodological advancement. Finally, data can provide significant resources for training in research and substantive learning.

Users typically request data in a particular format such as a word-processing package or a computer-readable audio format. These days, data can be accessed via instant web download facilities and increasingly via sophisticated online analysis tools, where users can search and analyze data via a web browser such as ESDS Qualidata Online. Users are typically required to be registered and sign an agreement to the effect that they will not attempt to identify individuals when carrying out analyses.

DATA COLLECTION

The term *data* often is misunderstood by quantitative researchers when engaging qualitative colleagues about their studies. To quantitatively oriented individuals, the term usually refers to numbers. They are numerical values used to apply statistics, showing significant differences between independent variables. Often quantitative researchers are surprised when listening to qualitative researchers describe their findings, based on “data,” given that frequently there are few numbers discussed in the study (“Where are the data?”).

For qualitative researchers, the term *data* most often is associated with words. Consequently, when qualitative researchers speak of “analyzing data,” they mean that participants’ words or other empirical evidence were assessed. As such, qualitative research is a means of empirical investigation—in the purest sense. Sometimes that phrase is used to indicate that a study was quantitative in design. Qualitative research examines evidence—sometimes visual and sometimes verbal—but the findings are not purely theoretical; they are grounded in empirical data. In short, it is the data collection process that separates qualitative research from speculative, philosophical, or archival research. There are many means that qualitative researchers use for collecting data. Four are highlighted in this entry.

What Are Data?

Interviews

Qualitative researchers typically ask questions of those participating in a study. While not denying the

potential for subliminal or subconscious processes, qualitative researchers use directive means of finding what people are thinking, feeling, and doing. In other words, if researchers want to know what is occurring with people, they ask them.

Words are of utmost importance to qualitative researchers. Not only are the general ideas salient, but also the richness in word choices, metaphors, and even slang is salient. Consequently, simply taking notes most often does not suffice for rigorous qualitative data collection. Rather, researchers audiorecord (or videorecord) their participants. Following this practice has multiple benefits.

First, researchers are free to think creatively while the interviews are taking place. Taking copious notes while participants are speaking makes it difficult to steer concentration and give appropriate focus to the intent behind what the speakers are communicating. In addition, tape-recording the interviews allows researchers to conduct later in-depth analysis of participants’ statements—comparing them with previous or future statements as well as with the interviews given by others. Third, recording participants’ words ensures integrity of the data. Social psychologists indicate that they tend to fill in gaps when information is missing. By audiorecording participants’ interviews, researchers are more assured that they are capturing the true essence of interviewees’ intents.

Fieldnotes and Memos

During the data collection phase in qualitative research, apt researchers are aware of the surroundings where information exists. Depending on the nature of the study, such data may include smells, sounds, graffiti, garb, tastes, and the like. For example, if a qualitative researcher is studying crack cocaine addicts, he or she may spend a period of time living in a “crack house” or hotel. Ethnographically, this would enable the researcher to better understand the milieu of the research participants as they experience their own worlds. The researcher, for example, potentially would become aware of mold smells, dripping faucets, crying, broken appliances, and unrepaired damage in the crack house. Each of these components would be “data” for later consideration by the researcher.

Memories are finite; we all forget. Consequently, qualitative researchers write down notes of what they encounter. When experiencing a foul smell repeatedly, for example, one may forget the impression rendered

the first time it was encountered. Consequently, recording these experiences, either with pencil and paper or with an audiorecorder, ensures that the data are not later overlooked or forgotten.

Memos are similar to fieldnotes in that they are generated throughout the data collection process. In general, however, fieldnotes involve recording information gathered by the senses. Memos, on the other hand, involve recording impressions, ideas, hunches, and potential codes or themes. Due to sensory overload, researchers later may forget these key insights, so they are recorded on the spot for future analysis in the form of personal memos to themselves.

Triangulated Information

Qualitative researchers generally believe their participants and take what they say at face value. Otherwise, there would be an unclear rationale for conducting interviews. Nonetheless, for the sake of integrity and enhancing the findings' internal validity, interview data are compared with information obtained from other sources. For example, a researcher studying a parochial school may listen to administrators and faculty members speak of how theological beliefs drive the daily activities of the school. Qualitative researchers would want to observe the school to see whether the pictures, statues, and other art forms substantiate that claim. Likewise, checking publicity brochures, websites, advertisements, meeting minutes, disciplinary records, bulletins, mailings, and other sources sheds light on the degree to which the interviews aptly reflect the reality that religion is portrayed in daily life. Participants can say anything to deliberately or unintentionally mislead a researcher. Ideally, interview data should be consistent with what the researcher observes from other sources related to the persons interviewed.

Member Checks

After qualitative researchers have drawn tentative conclusions about their findings, often they return to the study's participants and check their findings, garnering feedback. This does not imply that participants exercise veto power over the findings. Rather, they may illuminate them or give researchers reason to analyze the findings from multiple perspectives. But data collection in this context involves asking individuals to participate in the analysis process.

How Data Are Collected in Qualitative Research

Transcribed Interviews

Audiorecording is the most common method of capturing the words and experiences of the qualitative setting. Videotaping also is used in some situations. Qualitative researchers typically obtain prior permission from participants before recording them. This is important for both ethical and legal reasons. A transcription machine or transcription software typically is used by researchers to type up the words from the audio- or videorecording.

Chaining

In situations where researchers are new to a milieu or have no firsthand experience in it, they often do not know where to obtain all the needed information to complete the study. In the example cited earlier, for example, a researcher might never have been a crack addict or never previously lived in a crack-infested setting. Consequently, he or she likely would not know where the key data components exist at the outset of the study.

Data often lead to further data when conducting qualitative research. In other words, participants typically know who the key persons are for finding what the researchers need to know. Researchers explicitly ask for such references, and those individuals often provide names of additional key individuals. In this manner, the process of chaining occurs, whereby researchers advance from person to person, each time gaining new insights into the phenomenon under investigation.

The principle is true not only of key people but also of key data pieces. For example, even though an organization's secretary might not be on the list of persons to be interviewed, he or she may be able to provide astute observations of human dynamics in the organization. Secondary sources such as this also can be invaluable in discovering how to obtain key documents needed for triangulation and other purposes.

The point is that qualitative researchers often do not know at the outset of a study where they will find their most salient information. They depend on individuals in the research setting to provide assistance in making them aware of these key data sources. Most often one source leads to other sources, and over time researchers possess a collected patchwork of rich data.

Capturing the Phenomenon

As mentioned earlier, not all qualitative research data are obtained through interviews. Researchers audiorecord sounds and sometimes can videorecord surroundings depending on ethics, rules, laws, and other considerations. Researchers typically carry with them a small tape recorder and/or pencil and paper to write down important observations. Drawing schematics of room arrangements or locations of key items can later prove to be insightful when combined with other collected data.

An apt adage for qualitative researchers' data collection is "When in doubt, collect too much." Researchers can always discard or discount data after they are collected. However, many researchers end up wishing they had obtained more or different information when writing up their journal articles. Often the problem is that the desired data at the time of writing did not seem important when collection occurred in the field. Sometimes synthesis occurs (in a subjective manner) as components of a study are integrated. The whole truly is greater than the sum of its data-collected parts in qualitative research. As researchers gain experience, they typically grow more astute in the types of data pieces that most likely will be useful to them at the point of writing about their findings.

DATA GENERATION

Data generation refers to the theory and methods used by researchers to create data from a sampled data source in a qualitative study. Data sources include

human participants, documents, organizations, electronic media, and events (to name just a few examples). Qualitative data are products of the data sources and so include quotations, transcripts, observations, fieldnotes, and excerpts from documents such as images and newspaper articles. To generate data from a sampled data source, researchers interact with the data source using qualitative research methods within an overall strategy of inquiry. Many qualitative researchers recognize that by interacting with the data source, they cannot remain external to what is being studied and will have an effect on the data generated. The effect that researchers have on the data generated extends from the decisions that they make regarding the theoretical influences and design of the study as well as the beliefs, attitudes, values, and orientations of the researchers.

The term *data generation* is used in preference to *data collection* by researchers whose theoretical views about the nature of the social world and the production of knowledge extend to viewing data as a product of the interaction between the researchers and the data source during fieldwork. The term *generation* is intended to encapsulate the variety of ways in which the researcher, social world, and data interact in qualitative inquiry. Data are not considered to be "out there" just waiting to be collected; rather, data are produced from their sources using qualitative research methods. Researchers who hold such theoretical views reject the notion that the role of the researcher is simply that of a neutral detached observer of an objective reality. Rather, what is understood as "reality" is viewed as being socially constructed, and the role of the researcher is to actively construct knowledge of the social world using research methods and techniques that engage him or her with the data source(s).

Interviews are an example of a data generation method. An interview involves some degree of reflection by the participant in response to the questions posed by the interviewer. When reflecting on the questions during the interview, the participant may realize that he or she had not previously considered a question posed by the interviewer. Rather, the ideas generated in response to the question posed may have arisen only during the interview, or the ideas expressed may have been shaped in response to what had been said earlier in the interview, the manner of the researcher, or the tone or wording of the question. In some instances, it is possible that ideas would never have been formulated or expressed without the research interview. In light of points such as these,

data may be considered to have been created using intellectual, analytic, and interpretive activities during the interview rather than to have been collected.

Because it is not possible to select or observe everything that relates to a research topic, researchers must make decisions about what is to make up the sample of data for their study and how these data can be generated. Decisions regarding the method of generating data from a data source, and thus the resultant form of the data obtained, are shaped by the theoretical framework informing the study and the aim(s) or question(s) that the research is intended to address. For example, if the data source is human participants purposefully sampled to meet the aims of the study, data could be generated using any number of qualitative methods and strategies, including different forms of interviewing, focus groups, observation, drawing, photography, writing, and performance.

It may be that different forms of data are required to explore different aspects of the phenomenon being studied, so some studies include multiple data generation methods within a single research design. Examples include studies that use focus groups to generate issues to be probed in interviews and those that combine interviews with document analysis for discourse analysis. Because there are no set rules for combining multiple data generation methods, many creative possibilities are open to qualitative researchers. However, it is important that the data generated be integrated to meet the aim(s) of the study as opposed to an ad hoc unsystematic combination. Decisions about the processes and techniques used to generate data in a qualitative study are made as part of the construction of the research design. Therefore, it is important that researchers document how data were generated and justify the decisions that were made. This information can then be included in the research report, thereby allowing readers to make judgments about the quality and rigor of the research undertaken.

The judgments a researcher makes about the theoretical influences and design of a study, as well as the beliefs, attitudes, values, and orientations of the researcher, shape what is looked for or observed in the data source and how the data source is looked at or read. Consequently, the researcher also shapes what is *not* looked for or observed, and the way in which the data source is read or viewed will exclude alternative ways of reading or viewing. Given the same data source, different researchers (or the same researcher operating in a different way) could generate different

data for analysis depending on what they attend to and how that is interpreted given the aim or theoretical influences of the study. Because the researcher interacts with the data source and, thus, influences the data generated for a study, it is important that the researcher reflect on his or her position, including the values, assumptions, and theoretical views that he or she brings to the study. Such reflexivity adds depth and rigor to the research undertaken by clearly exposing the influences that have shaped the design and conduct of the research.

DATA MANAGEMENT

Data management, as it relates to data created during the research process, comprises “what to manage” and “how to manage it.” It is not only data per se that need to be managed; accompanying information, such as documentation and other contextual and methodological information, also needs to be managed.

Data management is important because it ensures safekeeping or future proofing of data during the research process. Good data management reduces the risk of data loss, increases accuracy and verifiability, and reduces the loss of productivity if core staff members leave before the end of the project. It also offers greater potential for longer term data preservation and increases the ability to reanalyze older data sets.

This entry considers general principles of managing data that are pertinent to a wide range of qualitative

research projects creating data. It focuses on digital data but also briefly addresses nondigital formats.

What Materials Should Be Managed?

Data

Qualitative data usually include transcribed interview or focus group transcripts, fieldnotes, observations, and so on, and they may also include audiorecordings and videorecordings or photos. These data are increasingly being created in digital format.

Documentation and Meta-Data

Comprehensive and accurate documentation is essential for informed use of data. Key documentation describes how the data were created (e.g., sampling, fieldwork), prepared for analysis (e.g., transcribed, digitized), and subsequently collated and processed. The content of each file, such as an interview, should be clearly documented and should include information about who was being interviewed, when, where, and so on. Meta-data are information that describes the data set and its creation and are typically structured to common international standards such as the Data Documentation Initiative (DDI).

The Importance of Data Quality

Optimal data management relates to a combination of best practice procedures applied to high-quality data. Quality of interview data might include appropriate research question and sampling formulation, good interview technique, careful attention to audiorecording, and high-quality or systematic transcription.

Data Management Strategies

Data management encompasses five basic procedures: (1) data storage, (2) format conversion, (3) backup copies, (4) authenticity and version control, and (5) control of access and security. This section describes each of these procedures in more detail.

Storing Data

Digital data should be stored on secure computers or servers and on selected archival media. Magnetic media include cartridges and disks and provide a versatile and inexpensive storage medium with high storage capacity. Optical storage media, including CD-R and DVD-R,

are an increasingly popular method of storage. All media should be refreshed on a regular cycle within the lifetime for archival storage.

Converting Formats

Data should be stored as master copies in formats that are suitable for long-term digital preservation, typically meaning “open” formats as opposed to “proprietary” formats. For example, textual data should ideally be marked up using XML according to an appropriate document type definition (DTD) or schema, but rich text format (.rtf) is a format that is commonly used. Audio files are currently stored as Microsoft waveform (.wav) or audio interchange file format (.aiff). Qualitative data held in a computer-assisted, data-analysis software package are tied to that particular software, which might not be readable in years to come. While progress is made on developing export facilities, data should be exported out of these packages to enable longer term access.

Making Backups

The media used to store digital data are fragile. To reduce the risk of damage to or loss of data, they should be backed up at appropriate intervals and older backups should be stored. Although most institutions do have backup policies, it is prudent to maintain independent backups of critical files, with at least one copy being stored off-site. A backup should be validated with “checksums” (a count of the number of bits in the original and copy of a file), using robust and reliable backup media (e.g., tape, CD-R) and refreshing backup media regularly.

Ensuring Authenticity and Version Control

Digital data can be copied, altered, or deleted very easily. Therefore, it is important to demonstrate the authenticity of files. Files should have limited write access and a master file, and a checked master copy of the data should be kept. Copies may be preserved at certain stages of development, and changes to master files should be recorded, with old master files being retained. Different copies of files, materials held in different formats, and information that is cross-referenced between files should be version controlled. Files should be uniquely identified, and the version, status (e.g., draft, interim, final), and relationships between items should be recorded.

Controlling Access and Security

Computer systems holding data require adequate security, and unauthorized access to data should be prohibited for ethical and legal reasons. Confidential data, such as names and addresses, should not be stored on servers or computers connected to a network. Restricted access to rooms holding computers with data or media should be considered, and removal of media or hardcopy materials from storerooms should be recorded. Relevant security-related upgrades and patches to operating systems and applications should be carried out regularly, and all project computers should have up-to-date virus detection software.

Nondigital Material

Research projects still commonly generate important nondigital material, be it data, documentation, or meta-data. The most common nondigital media are paper (e.g., photographs, reports, questionnaires, transcriptions) and analogue audiovisual material. Such materials need to be properly managed and, where possible, digitized. Nondigital media should also be clearly labeled with meaningful identifiers. All materials that form part of the project, such as signed consent forms and handwritten fieldwork notes, should not be routinely disposed of when the project ends.

High-quality media should be used for paper-based materials from the outset or for copies of originals, for example, using acid-free paper, folders, and boxes as well as nonrust paperclips (rather than staples).

Data Management and the Project Lifecycle

A data set typically has a longer lifespan than the research project that creates it. Data management by the research team occurs within the lifecycle of the project, but follow-up projects may subsequently be funded to continue to analyze or add to the data set. Professional data archives can take on the primary management role of preservation and dissemination of data after the originating project has finished and can provide advice on the most up-to-date recommended standards.

DATA SATURATION

Researchers commonly seek to collect data to explain a phenomenon of interest and then construct theories from the collected data. Theory construction takes place as the data are being collected. Saturation is the point in data collection when no new or relevant information emerges with respect to the newly constructed theory. Hence, a researcher looks at this as the point at which no more data need to be collected. When the theory appears to be robust, with no gaps or unexplained phenomena, saturation has been achieved and the resulting theory is more easily constructed. If the researcher does not attain data saturation, any resulting theory may be unbalanced, incomplete, and essentially untrustworthy. As a result, the data collection process is considered to be complete only when saturation has been achieved.

However, reaching saturation is considered to be somewhat relative in that if researchers perpetually collect new data and look for new information, eventually something novel and pertinent may emerge. Nonetheless, researchers do need to decide when collecting new data will result in diminishing returns, with new details adding little to the emerging theory. Some researchers consider a sample size of 15 to 20 as appropriate for saturation of themes during analysis; however, the sample size will vary depending on the context and content under study. Researchers also note that saturation cannot be achieved through frequency counts but instead must be achieved through an examination of the variations within the data and how these variations might be explained in the context

of the emerging theory. Therefore, it is essential at the early stages of analysis to consider each piece of data equally because this allows researchers to locate, understand, and explain variations within the sample.

Although there is some confusion and controversy about what it means to achieve saturation, a variety of strategies for reaching saturation have been established. First, saturation may be achieved more quickly if the sample is cohesive (e.g., if all participants are members of a particular demographic group). In this case, one is not trying to make the theory transferable to the general population, where great variability is likely to exist and more sustained data collection may be needed. Second, theoretical sampling is key to achieving saturation quickly. Here research participants are selected so that the resulting data help to build and validate the emerging theory. Researchers are cautioned against using a random sample because it is possible to randomly select individuals who simply repeat what everyone else has said or who simply have no relationship to the emerging theory (e.g., if one is building a theory about nurses, one does not necessarily want data from nursing assistants). Third, engaging in sustained field research can help to achieve theoretical saturation. Researchers who have been in the field for some time will better understand the nuances of the research setting, so it is more likely that they will develop a thorough understanding of the themes and their interrelationships. Finally, negative cases provide salient evidence of where gaps may exist in the developing theory, illustrating whether saturation has or has not been achieved.

DATA SECURITY

Data security is concerned with ensuring that valuable qualitative data resources are kept safe during the research process and beyond if data are to be formally

archived. Both digital and nondigital aspects of security should be considered by those creating, storing, and curating data. Security is a multifaceted consideration, spanning physical security related to access to buildings and disasters such as fire and flood as well as issues such as information technology security relating to access prevention of viruses and malicious code and the security of having multiple copies of preserved materials. Confidentiality is a particularly critical aspect of security for qualitative research data. This entry reviews a number of considerations relating to security of research data concerning the actual content of data to access, physical storage of data, industry standards for data security, security of data stored on computers, and destruction of data.

Confidentiality, Anonymization, and Data Linkage

Storage of qualitative data raises issues of confidentiality. Risks of identifying information that was agreed to be kept confidential at the time of consent negotiation are typically maintained through anonymization of data and provision of access through a robust rights management framework. Data archives, such as the United Kingdom Data Archive and the Murray Research Archive in the United States, run national social science data preservation and dissemination services that make use of depositor licenses, end user agreements, and authentication/authorization systems to ensure that access is controlled to suit the needs of each particular piece of data.

Data linkage to other sources of data brings greater risks of breaches of confidentiality and anonymity, but linkage can be successfully achieved while retaining anonymity. The most sensitive examples lie in the context of clinical patient records, biological samples, and genetic data, all of which could be potentially linked to qualitative data.

Physical Storage Security

Restricted access to rooms holding data (digital or nondigital) should be considered. Rooms should be locked when staff members are absent, and doors should be equipped with key entry or a code-protected keypad, preferably linked to an on-site alarm system and security office. A record should be kept of who has access or who holds keys/keycodes. Computer media or hardcopy materials should always be logged if they are removed from storerooms to avoid materials going missing.

Areas and rooms designated for storage of electronic and any physical materials should also be structurally sound and free from the risk of flood and, so far as possible, from the risk of fire. For obvious reasons, smoking should not be allowed in buildings storing data, and fire action notices should be displayed throughout the building. Machine rooms holding a preservation system should be protected by an argon or argonite gas-based fire-extinguishing system.

Other environmental considerations include temperature and humidity control. Both paper archives and machines require consistent temperature through cooling systems. Ideally, electronic logging of both these variables should be carried out to allow real-time monitoring of data and to trigger an alarm if out-of-range conditions arise.

Industry Standards

Ideally, a data preservation system should be based on industry standard operating systems and configured so as not to leave any known security holes. There is an international standard describing information security in an organization, namely ISO/IEC 17799:2005. This standard is intended as a common basis and practical guideline that can be implemented to meet the requirements identified by risk assessment such as asset management, human resources security, physical and environmental security, access control, and so on.

Computer Systems

Computer systems holding data require adequate security. Researchers will hold electronic data throughout the lifecycles of their projects, and data that are offered for sharing will typically reside on a preservation system in a data archive.

In instances where identifying information should remain confidential, restricted access to files should be ensured. A good example is the storage of consent forms and interview cover sheets from an interviewing project that will typically contain names, addresses, and signatures.

There is much ongoing research into computer techniques that aim to ensure that communication and applications meet reliable standards of security and confidentiality. A number of types of computer security should be borne in mind, including the following:

Restricting Computer Access. All computer systems holding data should be lockable by a log-on password

system to prevent unauthorized access in the case of a security breach of the room.

Firewall. All computer systems holding data should be protected by a firewall system.

Power Surge Protection. All computers and servers should be protected by power surge protection systems through a line interactive uninterruptible power supply (UPS) system.

Upgrades and Patches. Relevant security-related upgrades and patches to operating systems and applications should be carried out regularly, particularly in the case of virus detection software.

Network Security. Confidential data, such as those containing names and addresses, should not be stored on servers or computers connected to a network, particularly servers that host internet services (web or email). Where data archives disseminate qualitative data to users via internet means, a range of software solutions and procedures are employed, including protection, authentication, and authorization. The risks of intrusion and tampering, through ever-increasing efforts by hackers, provide a constant challenge. Increasingly, systems are offering early detection, correction, and damage limitation to deal with hacking.

Intruder Detection. Ideally, a preservation system should be equipped with a software detection system (e.g., TripWire) that ensures the security and integrity of files on the main preservation server (including operation system files) by reporting if, when, and how files have changed.

Data Synchronization Checking. When saving files to a preservation system, all copies should be compared for completeness. Preservation systems check the MD5 sum values, file size, and date to ensure the integrity of the files. Any off-site servers should be synchronized by secure File Transfer Protocol (FTP) mirroring software.

Backups. All data should be backed up to avoid loss.

Destruction of Data

In rare cases, the kind of informed consent negotiated at the time of fieldwork necessitates destruction of data at the end of a project. This should be done in a consistent manner, with paper being shredded and computer files being permanently deleted from all systems.

DATA STORAGE

Storage of data relating to research projects should be taken seriously from the outset to ensure that valuable qualitative data resources are kept safe during the research process and beyond if data are to be formally archived. Both digital and nondigital aspects of storage must be considered by those who create, store, and curate data. There are a number of considerations relating to data storage, including data preparation procedures, confidentiality of data, physical conditions, and security.

Data Preparation

Qualitative data usually include transcribed interview or focus group transcripts, fieldnotes, and observations, and they may also include audiorecordings and videorecordings or photos. These data are increasingly being created in digital format and should be prepared for longer term storage using best practice procedures such as those provided by the United Kingdom Data Archive (UKDA) and the Murray Research Archive in the United States. Where possible, data should be archived in future-proofed formats that meet long-term readability requirements. XML and ASCII text are two such examples, although rich text format (.rtf) and

Microsoft Excel (.xls) are widely used formats that are likely to be around for a long time.

Comprehensive and accurate documentation is essential for informed and accurate use of the data; thus, data should be accompanied by file and contextual documentation that describes how the data were created (including sampling and fieldwork practices), prepared for analysis (e.g., transcribed, digitized), and subsequently collated. The content of each data file, such as an interview, should be recorded, and the record should include information about who was being interviewed, when, where, and so on.

Nondigital materials include paper (e.g., photographs, reports, transcriptions) and analogue audio or audiovisual material. Such materials need to be sorted and properly labeled with respondent identifiers recorded on interview folders and on audiovisual recordings. Other materials that form part of the project, such as handwritten fieldwork notes, should be kept.

Confidentiality of Data

Storage of qualitative data raises issues of confidentiality. Risks of identifying information that was agreed to be kept confidential at the time of consent negotiation are typically maintained through anonymization of data and provision of access through a dedicated rights management framework. Data archives, such as the UKDA, which runs a national service for archiving and disseminating qualitative data, use licenses, user agreements, and authorization systems to ensure that only those who are allowed to view materials are able to do so. Signed consent forms that usually contain identifying information should be stored separately from the data, although an anonymous ID system that can help to link the two sets of materials together is required (e.g., for recontact purposes).

Physical Conditions

Areas and rooms designated for storage of digital or nondigital data should be suitable for that purpose. The conditions under which data are stored will significantly affect their longevity, and a good storage environment should be built into plans for longer term data storage.

Printed materials and photographs are subject to degradation from sunlight and acid (e.g., from skin and some kinds of paper). High-quality media should

be used for preparing paper-based materials from the outset or for copies of originals, for example, using acid-free paper, folders, and boxes as well as nonrust paperclips (rather than staples).

Physical materials should be well organized, easily located, physically accessible, and, ideally, placed on purpose-built shelving. Storage rooms should be structurally sound and free from the risk of flood and, so far as possible, from the risk of fire. Fire-extinguishing systems should be in place. Other key environmental considerations include low lighting levels, sealing against pollutants, and adequate control of temperature and humidity. Both paper-based archives and machines holding data require consistent temperature through cooling systems. Ideally, electronic logging of both these variables should be carried out to allow real-time monitoring of data and to trigger an alarm if out-of-range conditions arise.

Digital media are as fragile as, if not more fragile than, paper. They can be overwritten by mistake, and the media are prone to decay. Data formats and the computer platforms on which the data are stored might well become obsolete in a short space of time. Researchers or groups who wish to store data for their own needs should pay attention to backing up data, meaning keeping backup copies on-site and, ideally, also at an off-site location.

Formal data storage or preservation systems, such as those used by data archives, should be industry standard operating systems and adhere to international information security standards. It is the responsibility of data archives to keep up with technological advances by monitoring hardware and software developments and migrating their collections accordingly. When technology changes, the data in their holdings are technically transformed to remain readable in the new environment. Computer programs are also maintained to allow data to be easily transformed from an in-house standard to the various formats required by users.

Restricted access to rooms holding data (digital or nondigital) should also be considered, and computer media or hardcopy materials should always be logged if they are removed from storerooms to avoid materials going missing.

Security

Security concerns are an important part of storage requirements. Controlled access to buildings and rooms holding data may be necessary, and disasters such as

fire and flood must be anticipated when planning storage space. Theft or vandalism by staff members or unwelcome intruders should never be ruled out as a possibility.

Information technology security relates to backing up data, preventing unauthorized access, and preventing viruses. User access to data banks held on servers can be restricted using technical methods of access control.

In rare cases, the kind of informed consent negotiated at the time of fieldwork necessitates destruction of data at the end of a project. This should be done in a consistent manner, with paper being shredded and computer files being permanently deleted from all systems.

DEBRIEFING

There are six major types of debriefing in qualitative research: peer debriefing, debriefing the participants on completion of the study, debriefing the gatekeeper, debriefing among multiple researchers involved in the same study, debriefing focus group moderators, and a new type of debriefing involving debriefing the researcher. Each type is discussed in this entry.

Peer debriefing, the first type of debriefing, is a method for establishing credibility. This is undertaken

by the researcher discussing the study with a trusted and knowledgeable peer who can give informed feedback to assist the researcher in exploring aspects of the study that have, until that point, remained hidden. Through peer debriefing, the researcher attempts to keep her or his bias out of the study. Furthermore, peer debriefing can motivate the researcher to delve deeper into the data so as to understand more fully the participants' perspectives. Another purpose of peer debriefing is to resolve methodological issues. Analysis and interpretation of data can be discussed through peer debriefing either after the data analysis and interpretations have been made or as the data analysis and/or interpretations evolve. This can help the researcher to obtain trustworthy findings by ensuring that the findings are confirmable by the peer debriefer. Using peer debriefing in this way motivates the researcher to keep an audit trail, which represents a systematically maintained documentation system that includes a statement of the theoretical/conceptual framework underlying the study, a description of procedures used to collect and analyze the data, emergent themes, extracted data, interpretations of data, and memos. Peer debriefing can be conducted to enable the researcher to discuss political or ethical issues, to have a sounding board for confusing or uncomfortable issues, and to clear her or his mind.

A second type of debriefing involves the researcher debriefing the participants on completion of the study so as to explain the goals, purposes, and outcomes of the study. Typically, debriefing is conducted with the participants when there has been any undisclosed information about the study, but debriefing could be conducted to inform participants of the results. If the researcher senses any uncomfortable feelings or thoughts from the participants, debriefing at the end of the study can help to clear the air. Sharing the results at the culmination of a study shows respect for the time and energy that the participants gave to the study. The qualitative researcher could use debriefing sessions to reassure the participants that confidentiality will be maintained. Debriefing sessions also could be used to negotiate elements of the participants' stories that will appear in the final report.

In the third type of debriefing, the qualitative researcher should debrief (e.g., delineate findings to) the gatekeeper, who is the person from whom the researcher must obtain approval to gain access to a group or cultural site. Such debriefing should motivate the

gatekeeper to provide the researcher with future access to the participants.

A fourth type of debriefing is when more than one researcher is involved in a study. In this situation, the researchers should debrief each other regularly. Debriefing among researchers should occur in a comfortable private location where they can discuss issues that include thoughts about interactions with participants, the research focus, data collected, unexpected findings, ethical dilemmas that emerged, and/or whether a change in the research study's direction is warranted. Being able to discuss thoughts and perceptions with another researcher can create a "shared space" of investigation that can help researchers to move beyond the surface of the investigated phenomenon and delve deeper into the study, thereby enhancing understanding (i.e., increasing *Verstehen*) of the underlying phenomenon. Sharing memos with each other during debriefing also can be beneficial. Debriefing discussions should be audiorecorded because the information from these discussions can be considered as data that can help the researchers to understand the phenomenon under study.

A fifth type of debriefing involves moderators of focus groups. When there is a moderator and an assistant moderator, these two people should debrief one another immediately after the focus group interviews in a private location. Issues to discuss include initial perceptions of the focus group participants (e.g., whether one focus group participant dominated the group), noteworthy quotes, unexpected findings, and whether data saturation occurred (i.e., no new or relevant information emerged relative to previous focus groups). Furthermore, changes for future focus groups, including alternative techniques for creating a more open atmosphere, would be useful to discuss. Most important, debriefing between moderators gives researchers an opportunity to clear their heads so that they can start afresh with the next focus group. The debriefing session should be audiorecorded and used as data to help understand the topic under investigation.

A final type of debriefing involves debriefing, or interviewing, the researcher. Throughout the study, the researcher has a plethora of information, thoughts, and perceptions regarding the research. Unfortunately, the qualitative researcher often is alone in analyzing the data and in trying to understand the phenomenon under investigation and so might not take fully into account the information that has been stored in her or

his own head. Debriefing can help the researcher to promote reflexivity, that is, to reflect on her or his historical, sociocultural, and geographical situatedness as well as the biases the researcher brings to the study, her or his personal investment in and commitment to the study, and so on. To debrief the researcher, a person who is not involved in the study interviews the researcher. Possible topics for the questions that the interviewer might ask the researcher include the researcher's perceptions of the participants, the richness of the data, ethical/political issues that might have arisen during the study, and issues or dilemmas that emerged during the study. Most important, the interviewer should seek to help the researcher to reflect on and identify how the research study has had an impact on her or him, including how the researcher's self-perceptions have changed. The interview should be audiorecorded so that the information extracted can be used as data in the study. This process of interviewing the researcher can provide richer data that can add more meaning to the overall interpretation of the results.

DECEPTION

Perhaps no other research paradigm with human participants has such extreme variations in the use of deception as does qualitative research. The spectrum includes projects in which people are who they say they are and do what they say they will do; it also includes research in which people assume false identities and do not disclose the true purpose of their activities. This entry discusses common qualitative techniques such as naturalistic observation, interviewing, and participant observation, and it identifies some principles that mark out the ethical terrain of deception in research.

Naturalistic Observation and Interviews

Qualitative research projects vary in the degree to which they intrude into the lives of those they study. Deceiving participants about the nature of the research becomes a more serious issue as the research becomes more intrusive. Naturalistic observation is relatively nonintrusive. Standing at an intersection and watching whether people roll through stop signs is an example. Presumably, the behavior would occur whether the researcher is present or not. If the researcher dresses in a police uniform and stands on the corner watching, there is mild intrusion and mild deception.

Celia Kitzinger discussed “structured eavesdropping” as a method of data collection. Such research might be considered as deceptive if the researcher arranged to be invited to an event with the express purpose of listening to conversations.

Interviews may or may not involve deception. A researcher who cannot gain access to an executive may have a revealing “conversation” with the boss's secretary that yields the desired information. Other secondary informants may include court clerks discussing how judges behave and dental assistants talking about the billing practices of dentists.

Participant Observation

Participant observation always involves some intrusion into the lives of participants whether it is deceptive or not. Many projects are nondeceptive; for example, a researcher may ride in police cars to write about police work with no deception involved. But a researcher may also ask a police officer to describe a shift without telling his or her colleagues that they are being observed for research purposes.

A researcher may need to become immersed in the setting to understand it fully. William Whyte spent years in a working-class section of Boston interacting with a broad spectrum of people to understand their lives. The result was documented in his classic *Street Corner Society*. To the extent that not everyone he met, talked to, bowled with, and so on knew that he would write about his experiences, deception was involved.

Deception obviously compromises informed consent. In some situations, people would not participate if they knew that a researcher was involved. Medical

anthropologist Ralph Boulton tested the Belgian government's claim that it had been successful in persuading gay men to use condoms for casual sex. He went to places where such encounters took place and kept track of whether gay men suggested using a condom before they engaged in oral sex. The findings dramatically contradicted the government's claim.

The usual argument for deception is that the data cannot be gathered in any other way. The anthropologist studying sexual practices in Belgium argued that deception was essential; if he had told participants he was doing research, it would have changed behavior and reduced participation rates.

Participant observation permits the researcher to travel in someone else's shoes or even in their skin. John Griffith used chemical means to darken his skin and then traveled across the southern United States as an African American, reporting his experiences in the

famous *Black Like Me*. Recently, Nora Vincent used a similar technique to study gendered experience. She entered some situations as a woman and then used clothing and other techniques to experience the same situations when people perceived her as a man.

A researcher may feel the need to play a role to get a deeper understanding of a lifestyle that one could get from surveys or interviews. Barbara Ehrenreich worked at low-paying jobs to get data for her best-selling book *Nickel and Dimed* and then followed up with a similar method to study white-collar unemployment in *Bait and Switch*.

Researchers may believe that surreptitious role-play is necessary for an adequate test of their theories. Social psychologist Leon Festinger developed his theory of cognitive dissonance in controlled experiments. The theory predicts, among other things, that people who pay a high price for something will inflate its

Deception and the Study of Psychiatric Diagnoses

Many researchers argue that some topics cannot be investigated properly without the use of some deception. An example is David Rosenhan's work on the reliability of psychiatric diagnoses. Rosenhan hypothesized that what is considered sane in one culture may be considered insane in another culture. Even within a culture, the labels people are given will depend on the setting in which we see them. Furthermore, the same behavior will be labeled differently in different settings. For example, people who take a lot of written notes during the day will be viewed differently if we think they are journalists than if we see them as mental patients.

Rosenhan tested his hypothesis by having eight sane people gain secret admission to 12 different mental hospitals. He and his colleagues told staff members in admissions that they heard voices that said "empty," "hollow," and "thud." All of the other information they provided about their lives (except for disguising their professions) was factual. Once they were admitted, the pseudopatients ceased simulating any symptoms of abnormality.

It took an average of 3 weeks in a hospital before the pseudopatients were released. Nursing reports, which were obtained later, routinely described them as friendly, cooperative, and showing no abnormal reactions. Despite their normal behavior and failure to exhibit symptoms, they were still presumed to be mentally ill because of the setting in which they were observed. For

instance, all pseudopatients took notes. This behavior was coded as symptomatic by staff members who observed it, although actual patients tended to think that the pseudopatients were journalists or "checking up on the hospital."

None of the pseudopatients was detected. Even when the pseudopatients were released, it was because their conditions (usually identified as schizophrenia) were said to be "in remission."

The second phase of the study, also involving deception, came when the administrators and staff members of a research and teaching hospital who had heard of the earlier results said that such an error could not occur at their institution. Rosenhan told them that at some time during the following 3 months, one or more pseudopatients would try to be admitted. Each staff member was asked to rate each patient who came for admission or was admitted and on a ward.

Judgments were obtained on nearly 200 patients. Of these, 41 were identified as pseudopatients with high confidence by at least one staff member, with 19 being identified as pseudopatients by one psychiatrist and one other staff member. In fact, Rosenhan had not sent any pseudopatients to that hospital at all. This was a clever way to reconfirm the unreliability of psychiatric diagnoses and the importance of our belief sets in determining how we judge the behavior of others.

Source: For more information on this topic, see Rosenhan, D. L. (1973). On being sane in insane places. *Science*, 179, 250–258.

value to justify the cost to themselves. Students who have a hard time getting into a university, for example, will value the institution and the experience more than will those who get easy entry.

Festinger was interested in a real-world test of his theory. He read about a group that was preparing for the imminent end of the world. He had assistants join the group and keep notes on the reaction of various members when the world failed to end as prophesied. He was able to establish, as cognitive dissonance theory would predict, that significant sacrifice (selling all of one's possessions) was related to continued fervent belief in the prophesy even after it had failed.

Is Deception Harmless?

Deception violates the right to informed consent, but many researchers argue that it is both necessary and harmless. Sometimes, however, participants may be put in harm's way. Laud Humphreys studied impersonal sex in public places. His participants were family men who frequented public lavatories to engage in homosexual activity with strangers. His first deception was to set himself up as a "watchqueen"—someone who keeps an eye out for the police—in a public lavatory. After each assignation, Humphreys left the lavatory in time to note the car license of the participant(s). He represented himself as a market researcher to obtain the names and addresses of the car owners from the Department of Motor Vehicles. He waited a year and changed his appearance and then entered participants' homes as a member of a public health research team and interviewed them. Clearly, there was no informed consent, but was there risk of harm? So long as the information remained private, no harm was done. But the participants had no control over the security of the information. They were at the mercy of the researcher without knowing it.

In light of concerns about deception in the social sciences, several rules of thumb have developed to guide researchers who are considering the use of deception in research. The research question must be worth investigating, there must be no alternative nondeceptive way to answer the research question (or the deceptive procedure must add substantially to the answer), and there should be no risk of harm to the participants. If there is risk of harm, it must be weighed against the potential value of the research.

DECONSTRUCTION

When asked by *The New York Times* reporter Dinitia Smith to define *deconstruction*, the late Jacques Derrida (1930–2004) replied, "It is impossible to respond. . . . I can only do something which will leave me unsatisfied." I feel much the same way about writing this entry. An encyclopedia is designed to enclose, encapsulate, reduce, and simplify its subject matters, whereas deconstruction is oriented toward opening, expanding, amplifying, and complexifying them. To conform to the generic conventions of an encyclopedia entry, I must put deconstruction in a nutshell. But as John Caputo wrote in the ironically titled *Deconstruction in a Nutshell: A Conversation With Jacques Derrida* in 1997, "whenever deconstruction finds a nutshell—a secure axiom or a pithy maxim—the very idea is to crack it open and disturb this tranquility" (p. 32). But Caputo also noted that when Derrida was called on to briefly characterize deconstruction, he often had recourse to the expression "experience of the impossible" and even suggested that this might be the "least bad" way to define deconstruction.

My approach to providing a least bad nutshell is first to provide a brief history of the term *deconstruction* in Derrida's work (and its travel into contemporary social science via literary theory) and then to offer an example of deconstructive reading from my own practice as a curriculum scholar. I trust that by *performing* deconstruction, rather than simply *representing* it, I may be able to share with readers something of the pleasure and generativity of experiencing the impossible.

Deconstruction: A Short History

In a letter to Toshihiko Isutsu, a Japanese scholar seeking assistance with translating *déconstruction* into Japanese, Derrida explained how he came to use the term, a word rarely used in French at the time, in *De La Grammatologie* (published in France in 1967 and later in English as *Of Grammatology*). Among other things, Derrida wanted to translate (and adapt to his own purposes) the German terms *Destruktion* and *Abbau*, as used by Martin Heidegger in a 1927 lecture series (later published as *Basic Problems of Phenomenology*). In these lectures, Heidegger asserted that phenomenology is a method of doing philosophy that has three steps: reduction, construction, and destruction. Although Heidegger argued that construction in philosophy is necessarily *Destruktion* (destruction), he elaborated his understanding of philosophical destruction by using another German word, *Abbau* (literally “unbuild”).

In his letter to Isutsu in 1985, Derrida explained that in Heidegger’s work both *Destruktion* and *Abbau* signified “an operation bearing on the structure or traditional architecture of the fundamental concepts of ontology or of Western metaphysics” (p. 2). But the French word *destruction* too obviously implied “an annihilation or a negative reduction much closer perhaps to Nietzschean ‘demolition’ than to the Heideggerian interpretation or to the type of reading that I proposed” (p. 2). Derrida recalled that the word *déconstruction* came to him somewhat spontaneously and that he checked to see whether it was “good French” by consulting “the Littré” (the common name for the four-volume *Dictionnaire de la Langue Française* by Émile Littré first published in 1877). Derrida was pleased to find that the grammatical, linguistic, and rhetorical associations of the term—for which there were several entries—were “fortunately adapted to what I wanted at least to suggest”:

At that time structuralism was dominant. “Deconstruction” seemed to be going in the same direction since the word signified a certain attention to structures (which themselves were neither simply ideas, nor forms, nor syntheses, nor systems). To deconstruct was also a structuralist gesture or in any case a gesture that assumed a certain need for the structuralist problematic. But it was also an antistructuralist gesture, and its fortune rests in part on this ambiguity. Structures were to be undone, decomposed, desedimented (all types of

structures, linguistic, “logocentric,” “phonocentric”—structuralism being especially at that time dominated by linguistic models . . .). (p. 2)

In Derrida’s work, deconstruction is a complex response to a number of theoretical and philosophical movements, especially phenomenology, structuralism, and psychoanalysis. But in the English-speaking world, deconstruction has had a major impact on literary theory and criticism, with flow-on effects in the social sciences resulting from the narrative and textual turns in those disciplines. In these contexts, deconstruction can be understood as a theory and method of reading and analytic inquiry that aims to undermine the logic of opposition within texts. For example, in an interview with ImrÉ Salusinsky in 1987, the literary critic Barbara Johnson responded to an invitation to define deconstruction as follows:

One thing I could say is that the training most people get from the beginning, in school and through all the cultural pressures on us, is to answer the question: “What’s the bottom line?” What deconstruction does is to teach you to ask: “What does the construction of the bottom line leave out? What does it repress? What does it disregard? What does it consider unimportant? What does it put in the margins?” So that it’s a double process. You have to have some sense of what someone’s conception of what the bottom line would be, is, in order to organize the “noise” that is being disregarded. (p. 81)

Thus, for Johnson, deconstruction is less an argument about the nature of signs than a vocabulary and a set of practices oriented toward uncovering what she called “noise”—that which our usual cultural and cognitive schemas disregard or marginalize. It is a disposition toward reading for subtexts, for textual contradictions, for textual blockages, for that which is textually suppressed or textually excluded. As Raman Selden wrote in 1989, deconstruction begins when we locate the point at which “a text transgresses the laws it appears to set up for itself. At this point texts go to pieces, so to speak” (p. 87). In other words, the structural distinctions that authors deploy subvert themselves.

In 1993, Cleo Cherryholmes offered a clear example of how one particular text, Fred Kerlinger’s

Deconstructive Reading: A Demonstration

What follows is a lightly edited version of the introductory sections of my essay review of William Pinar and William Reynolds's edited book, *Understanding Curriculum as Phenomenological and Deconstructed Text*.

Imagining an Erroneous Order

"I behaved stubbornly, pursuing a semblance of order, when I should have known well that there is no order in the universe."

"But in imagining an erroneous order you still found something."

(Umberto Eco, *The Name of the Rose*, p. 599)

My first impression of the text under review was that the editors were "pursuing a semblance of order" by juxtaposing phenomenology and deconstruction in a curriculum text. (Whether or not they "found something" by "imagining an erroneous order" is a question I defer for the moment.) The following passages, which encapsulate the meanings Pinar and Reynolds ascribe to understanding curriculum as phenomenological and deconstructed text, exemplify some of the discontinuities and tensions between these two orientations (and incidentally provide examples of some of the narrative strategies through which their semblance of order is maintained):

Curriculum understood as a phenomenological text communicates a story in which quantitative social science is an evil character whose effort to quantify the immeasurable is unethical and epistemologically unsound. Those elements of experience that are observable and measurable tend to be rather small and specific. The firmament in the positivist sky twinkles with precision and rigor. However, spaces between stars and those hidden by clouds recede and disappear. Phenomenology seeks to name those spaces, their relation to the stars and to us. (pp. 1–2)

Curriculum as deconstructed text acknowledges knowledge as preeminently historical. Here, however, history is not understood as ideologically constructed, rather as a series of narratives superimposed upon each other, interlaced among each other, layers of story merged and separated like the colors in Jackson Pollock's paintings. . . . To understand curriculum as a deconstructed (or deconstructing) text is to tell stories that never end, stories in which the listener, the "narratee," may become a character or indeed the narrator, in which all structure is provisional, momentary, a collection of twinkling stars in a firmament of flux. (p. 7)

Despite the continuity of the concept of story and the sky/star metaphors in these paragraphs, the comparison of curriculum as phenomenological and deconstructed text reveals a number of contradictions and tensions. (It also seems misleading to assert that "history is not understood as ideologically constructed" in deconstructive readings; one chapter in the text under review demonstrates that feminist poststructural analysis not only recognizes the constitutive force of ideological discourses but also problematizes the agency of the individual in taking up specific ideologies as her or his own.) For example, phenomenology's project seems pointless in deconstruction's "firmament of flux" insofar as it seems futile to attempt to "name" the "spaces between stars" in a universe where "all structure is provisional, momentary." Furthermore, the phenomenological aspiration "to name those spaces [and] their relation to the stars and to us" entertains the possibility of ultimate and essential truths—finite stories that will relieve us of the deconstructionist desire "to tell stories that never end."

Thus, although phenomenology and deconstruction share conceptual tools that allow them to accommodate a view of curriculum as text, this does not necessarily mean that they are commensurable; that would be like saying that we can accommodate Jackson Pollock and, say, Vincent van Gogh within the same critical framework simply because they both used paint to make pictures. I would argue that van Gogh's and Pollock's worlds (and worldviews) are incommensurable to the extent that we are unlikely ever to "see" van Gogh's starry, starry night in the universe Pollock (re)presents. Yet I can *imagine* Pollock's white cockatoo taking flight in van Gogh's sky. In a similar way, Pinar and Reynolds might have "found something" by "imagining an erroneous order" in the interrelationships of phenomenology and deconstruction.

This essay review tells something of what I "found" by reading the text under review, and it rehearses some of the possibilities for other readers' interpretations of it. My review assumes that *Understanding Curriculum as Phenomenological and Deconstructed Text* should be read as a deconstructed (or deconstructing) text and, therefore, that readers should go beyond a single interpretive act "to tell stories that never end." As Kenneth Knoespel wrote in 1991, "rather than reading a single text a single time, [deconstruction] promotes the reading of many texts many times for an ongoing confessional comprehension of how meaning is generated" (p. 116). This essay, then, is a series of incomplete stories featuring the text under review.

(Continued)

(Continued)

Positioning This Essay Intertextually

One of the understandings I take from deconstruction is that the meaning of a text is impossible to recover unambiguously. Thus, as William Paulson wrote in 1988, the “very impossibility of doing so becomes the only ‘meaning’ literally recoverable” (p. 93). This position presents considerable difficulties for a book reviewer. For example, to demonstrate that I have understood *Understanding Curriculum as Phenomenological and Deconstructed Text* deconstructively, I need to demonstrate that it is “incomprehensible” in the sense that a text is “irreducible to any schema other than itself” (p. 184). As Morris Zapp (quoted in David Lodge’s 1984 novel, *Small World*) said, “every decoding is another encoding” (p. 25), and what I am constructing here is not so much a decoding of the text under review as an encoding of the meanings, significances, ambiguities, and complexities that my reading of it has produced.

After reading this text, I am confident that it would have been easier (simpler and less complicated) to review it (generate meaning) from a phenomenological perspective than to attempt a deconstructive critique. However, my reading of the text has amplified my understanding of poststructuralism and multiplied the reasons for my belief that deconstruction irreversibly destabilizes phenomenology. Indeed, the more I understand curriculum as deconstructed text, the less I am able to understand it phenomenologically. Thus, although Pinar and Reynolds provide a number of logical reasons for linking phenomenology and deconstruction intellectually, and some genealogical notes that chart collegial interrelationships among phenomenological and poststructuralist curriculum scholars, the juxtaposition of these two orientations to curriculum inquiry in this particular text may very well facilitate their further disjunction. Perhaps the editors of *Understanding Curriculum as Phenomenological and Deconstructed Text* intended the title to be interpreted in poststructuralist jest, for although it appears to name unambiguously a proposition that readers might well

expect to be “literally recoverable” from the text, it also names a proposition that deconstruction reveals to be absurd, namely, that curriculum can be understood as both phenomenological and deconstructed text. In other words, a meaning that I have “recovered” from understanding *Understanding Curriculum as Phenomenological and Deconstructed Text* deconstructively is the very impossibility of understanding curriculum as both phenomenological and deconstructed text.

The two preceding paragraphs are a modest attempt to demonstrate some of the qualities of a deconstructive reading that many scholars find generative and illuminating but that others find infuriating and confusing. In deconstruction, iterative techniques and recursive looping are seen as ways to destabilize texts and make them yield unexpected conclusions—in this case, the conclusion that the text under review generates meanings that are antithetical to the proposition insinuated by its title—although the proposition that these meanings are antithetical to other meanings is itself not unambiguous. Deconstruction continually defers positive meaning, savoring complexity and favoring the positive value of making no positive interpretations.

The preceding comments deliberately position this essay as an artifact of the meaning production processes initiated by my reading of the text under review. They also signal my empathy for an approach to deconstruction that owes less to Derrida than to Henri Mensonge, who in Malcolm Bradbury’s 1987 faux biography embodies poststructuralist concepts such as “the disappearance of the subject” and “erasure” so effectively that we do not have any unambiguous evidence of his existence. Via Bradbury, Mensonge provides a sense of what might remain after deconstruction has led us to dismantle our preconceived frameworks of consciousness and perception, to demythologize our ideas of the transcendent and the everlasting, and to demystify our senses of truth, essence, and reality. As Bradbury wrote, deconstruction “discloses to us a world of parody and pastiche, query and quotation; and having shown us all this, it teaches us how to enjoy it” (p. 5).

Source: Gough, N. (1994). Imagining an erroneous order: Understanding curriculum as phenomenological and deconstructed text. *Journal of Curriculum Studies*, 26, 553–568.

once widely used textbook *Foundations of Behavioral Research*, subverts itself. In his introduction, Kerlinger wrote that the book “is a treatise on scientific research; it is limited to what is generally

accepted as the scientific approach. It does not discuss historical research, legal research, library research, cultural research, philosophical inquiry, and so on. It emphasizes, in short, understanding

scientific research problem solution” (p. viii). But as Cherryholmes pointed out, by asserting a structural distinction between what is scientific and what is nonscientific, Kerlinger introduced a problem that he failed to recognize, address, or resolve—namely, that research procedures, practices, and results must be interpreted (e.g., judgments must be made about validity, generalizability, and applicability), but the scientific status of interpretation remains unclear because interpretation may involve historical, linguistic, library, literary, or philosophical research. All research occurs in historical context, and theoretical constructs, hypotheses to be tested, and theories to be evaluated are objects of history. Moreover, the norms of scientific research require that theories of empirical phenomena be internally consistent and not contradictory. But decisions about consistency and contradictoriness are made by appealing to logic, and logic is a branch of philosophy. The scientific–nonscientific distinction deconstructs. Cherryholmes’s deconstructive reading of Kerlinger’s statement attended to the rhetorical play of meanings that the author concealed by imposing distinctions, categories, and taxonomies.

Concluding Note

To illustrate the intent of deconstruction, see the piece titled “Deconstructive Reading: A Demonstration” that accompanies this entry. Here, I model deconstruction with regard to specific texts to show how deconstruction “works” in this context. I will emphasize here that I intend my references to novels by Bradbury, Eco, and Lodge—all of which have parodic elements—to be instructive, because we can learn a great deal about deconstruction by studying parody. Indeed, Robert Phiddian (among others) argues that Derrida’s work might be the first fully developed theory to be couched in the parodic mode. Phiddian’s argument is not only that Derridean deconstruction is a serious theory couched in parody (that it constitutes a parodic theory of language) but also that it treats questions of language, truth, and referentiality as if they were already in a play of parody—that Derridean deconstruction is a theory of parodic language.

DEDUCTION

Deduction is one of the three primary modes of reasoning, with the other two being abduction and induction. Of the three modes, deduction is the oldest and most venerable. Using the notation of Charles Peirce, and taking an illustration from a

famous example by Aristotle, deduction in syllogistic form has the following structure:

Rule (also known as the major premise): All men are mortal.

Case (also known as the minor premise): Socrates is a man.

Result: Socrates is mortal.

In its earliest formulation, in Greek philosophy, deduction was the mode of valid inference that drew implications from true premises. The power of deduction was this: If the premises were true, then the implications derived from the process of deductive reasoning were guaranteed to be certainly true as well. In fact, for centuries deduction was considered to be the only valid mode of inference. It was not until the work of medieval logicians that induction first began to be accepted as a mode of reasoning, and abduction did not make its appearance formally until the work of Peirce during the early 20th century.

With the advent of modern science, the scope and use of deduction began to expand. Deduction was no longer confined to inferences based on premises that were absolutely true. Instead, researchers began to use deduction to make implications from premises that were only empirically (and therefore probably) true. These resulting implications were themselves used as the basis for making further empirical tests and were called hypotheses. This overall process, known as the hypothetico-deductive method, is an important tool in scientific theorizing. When applied properly, the method works as follows. First, via the process of observation and data gathering, researchers inductively establish the likelihood that certain claims about nature are most likely true. These claims are used as premises, and implications are deduced from those premises. These implications then serve as hypotheses, which are tested to see whether they are most likely true as well. Once the hypotheses have been tested, they themselves can now serve as premises, and the cyclical process continues. This leads to the solid creation of hypotheses that are worth pursuing and an increasingly informed and subtle set of further hypotheses.

The method just described is at the heart of many quantitative research programs. The role of hypotheses, and hypothesis testing, has always been more problematic in qualitative research. Some qualitative researchers, especially those inclined to support

mixed methods approaches, argue that hypotheses can and should play key roles in qualitative research efforts. Others believe that the fundamental logic of qualitative research is different from that of quantitative research and that hypotheses play little or no role in qualitative inquiry.

The other side of deduction deals with the issue of argumentation. Starting with Aristotle, philosophers have used deduction as a tool for valid reasoning in developing valid arguments and for determining whether or not existing arguments are valid. Needless to say, the role of deduction as a means for determining whether or not arguments are valid is important for all forms of research writing, qualitative and quantitative alike.

DEPENDABILITY

One of the challenges of working within a qualitative context is the variability of the environment. Through extensive literature reviews and experience in the context, a researcher can create a pretty good theoretical understanding of what the environment will be like and then design appropriate methodologies for studying it. Once the researcher is out in the field, he or she may find it to be quite different from what was expected. This could affect research procedures such as what types of interview questions are asked and how many interviews are conducted. Dependability in a qualitative study recognizes that the research context is evolving and that it cannot be completely understood a priori as a singular moment in time. Dependability accounts for these issues through relevant methodologies.

A catalyst for research is the desire to have the study affect theory and/or practice on a broad scale.

This means that the results should be consistently linked to revealed data and that the findings should be an accurate expression of the meanings intended by the participants. For this to happen, there must be a research infrastructure to support a repetition or replication of the study that will have similar results. This condition, which is equivalent to reliability in quantitative research, requires that the researcher supply adequate and relevant methodological information to enable others to replicate the study. If a study design is so unique and specific that it cannot be replicated, the research will have limited impact beyond the context of the study and the dependability of the study design will be affected. An example of this would be interviewing the last two clients of a social services program that is ending. It would be very hard to repeat this study because there are no more clients and the program is completed.

Dependability also addresses the fact that the research context is open to change and variation. The researcher must be conscious of change and must track all of the nuances that differ from the design in the proposal. As part of this, the researcher should track the alterations to the research design made necessary by the changing context. This could include changes in methodology such as increasing the number of interviews required, tracking nonverbal cues as well as spoken text, including document analysis, increasing intercoder reliability by having more coders, and/or increasing contact time in the environment from 1 week to 2 weeks. Tracking this process is called an inquiry audit. An external agent will review the researcher's fieldnotes and log book to ensure that the various changes in the research design have both methodological and theoretical foundations and are linked to the revealed data. The transparency and relevancy of this process will increase the dependability of the study.

DESCRIPTION

See RICH DESCRIPTION

DESCRIPTIVE STATISTICS

Description of the data collected in research is an important component for both the researcher and the reader. In both quantitative and qualitative analysis, the reduction of a large amount of data to an easily digestible summary is an important function. In qualitative research, descriptive statistics are typically observed in mixed method, action research, or other qualitative designs. More important, description lays the foundation for later analyses and interpretation of collected data.

When numerical data are collected, the description of these data is termed *descriptive statistics*. Descriptive statistics constitute a mathematical summarization of the data where a large number of observed values are mathematically converted to a few numbers. This is a variable-oriented approach where typically a large number of cases are involved versus a case-oriented approach where typically a few cases are involved. In qualitative research, descriptive statistics allow researchers to provide another context, a richer picture or enhanced representation, in which to examine the phenomenon of interest. The inclusion of quantitative data can also enhance legitimacy (e.g., validity, credibility, trustworthiness, transferability), although this might not be appropriate for many qualitative projects.

The simplest ways to categorize descriptive statistics are (a) numerical, such as measures of central tendency and variability; and (b) graphical, such as histograms, bar charts, and scatter plots. Descriptive statistics are different from inferential statistics, where the purpose is to infer from the sample to the population of interest.

To make meaningful inferences, descriptive statistics must be used properly, and that begins with understanding when to use each quantitative descriptive technique. Common descriptive statistics in multi-method studies are the three measures of central tendency: mean (\bar{x} , M), median, and mode. The three measures of central tendency provide a set of values that describe the typical score in a distribution of scores. The measures of central tendency are calculated from

Figure 1 Histogram of Reading Achievement Scores

continuous data (e.g., test scores) and not categorical scores (e.g., gender identification). For example, in educational research a common variable is an achievement score such as reading comprehension, and in gambling research a common variable is the speed of play on a slot machine.

The mean, or average value, for the reading comprehension example is the summation of all scores divided by the number of test scores. The median is the middle score of all the ordered achievement scores. The mode is the most common, or highest frequency, achievement score. There can be more than one mode in a data set.

Measures of variability (i.e., score dispersion) are typically reported for continuous data and include the range, variance, and standard deviation of the scores. The range for a set of scores, or the distribution data, is calculated by subtracting the largest score from the smallest score. From the example of students' reading comprehension scores, this is the highest test score minus the lowest test score. The standard deviation (*SD*) is the average distance that scores are from the mean. The more dispersed the values, the larger the standard deviation. In a normally distributed data set (i.e., looks like

a bell curve), 68% of the values will be within 1 standard deviation above or below the mean. The standard deviation is more commonly provided because it is easily interpreted, whereas the variance simply indicates that variability in the observed scores exists. If the variance, and therefore the standard deviation, is zero, then all of the scores are the same. A fourth, albeit less commonly provided, dispersion descriptor is the interquartile range. The interquartile range is the distance between the 25th and 75th percentiles and indicates where the middle 50% of the values are located.

Many times during observations, researchers will note the number or frequency of behaviors of students or teachers. These frequency count data are considered as categorical in quantitative terms and are traditionally displayed using frequencies, proportions, or percentages (e.g., 5 of 20 students, 20% of the class, the gambler's pace at the slot machine is 120 "pulls" per hour).

Other common numerical descriptors in educational research are percentile rank, stanine, grade equivalent, and other converted or transformed scores. A percentile rank occurs when a single student is compared with a reference group and a rank is assigned to the particular student's score. For example, a rank at the 84th percentile indicates that the student's test score is equal to or greater than 84% of all other reference group members who took that test. A stanine score, which can range from 1 to 9, provides a rough approximation of performance that takes into account measurement error. Grade equivalent scores are commonly reported but are the most misinterpreted scores. For example, a fourth-grade student

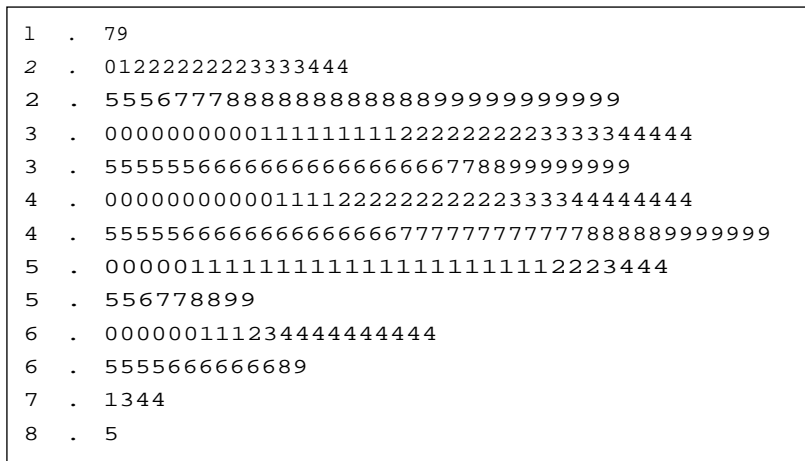

Figure 2 Stem-and-Leaf Plot of Reading Comprehension Scores

Table 1 Faculty Gender by Race

	<i>Black Non- Hispanic</i>	<i>American Indian/Alaskan Native</i>	<i>Asian/Pacific Islander</i>	<i>Hispanic</i>	<i>White Non- Hispanic</i>	<i>Unknown</i>	<i>Total</i>
Female	8	2	10	2	227	7	256
Male	5	1	4	1	160	2	173
Total	13	3	14	3	387	9	429

who has a grade equivalent score of 7.3 does not indicate the student can do seventh-grade work; rather, it indicates that the student performed as well as a seventh-grade student in the third month of seventh grade would perform on the fourth-grade test.

In addition to the many numerical descriptors, there are numerous forms of graphic descriptions. A few common ones are discussed in what follows. As with the mathematical summarization, the type of data affects the type of visual description needed. A bar chart provides a visual description with ordinal data values such as frequency counts of books being read and numbers of teachers with bachelor's, master's, and doctoral degrees. The bars in this type of chart are not connected because there is no implied relationship among the categories.

Histograms (Figure 1), which are visually similar to bar charts, are used with data that are continuous or have an implied continuity to them and the bars are connected. Quantitative researchers commonly use histograms to examine data before conducting statistical analyses such as inferential tests.

Other graphic representations of data include frequency polygons, box plots, and stem-and-leaf plots. A frequency polygon is similar to a histogram but connects the data by points and lines instead of bars. A box plot marks the lowest value and then the lower whisker (the bottom 25% of values), the box (the middle 50% of values), and the upper whisker (the top 25% of values or 75th percentile and above). Scores that fall out of the whisker range are typically denoted by a star and are considered extreme values. A stem-and-leaf plot (Figure 2) takes part of the data values and uses them as a stem and uses the remainder part as the leaf.

The preceding numerical and graphical descriptions all concern looking at one variable. A correlation describes the linear relationship between two variables, that is, a bivariate relationship. The correlation coefficient describes the magnitude and direction of that relationship. The magnitude ranges from 0 to 1, where 0 implies no linear relationship and 1 implies a perfect linear relationship. The direction describes whether it is a positive or negative relationship. A positive linear relationship implies that as the values of one variable increase, the values of the second variable increase. The correlation and correlation coefficient are simply descriptions. Once tested against the hypothesis that the correlation coefficient is 0 (i.e., null hypothesis), this figure becomes an inferential statistic.

In addition to univariate graphs, there are two common bivariate descriptive statistic displays. The first, cross-tabulation, creates a table where two variables

**Figure 3** Scatterplot of Gambling Times

can be crossed and, for example, the frequencies can be examined. Table 1 provides an example of a 2 (gender) by 7 (race/ethnicity) frequency table that is commonly reported in university and college reports. There are 10 female faculty members with an Asian/Pacific Islander designation.

A second bivariate description is a scatterplot or scattergram. A scatterplot is used with continuous data and displays the linear relationship between two variables. The scatterplot is a graphic representation of a correlation. Figure 3 displays a scatterplot of a slot machine gambler's times between pulls by pull number.

Descriptive statistics allow the researcher to provide a succinct picture of the numerical data. This efficiency can add to the narrative by providing another line of evidence without overwhelming the reader.

DIALOGUE

Dialogue is a mode of communication characterized by an open exchange of ideas and meanings. In qualitative research, dialogue has been conceived both as a data collection method and as an ethical means of conducting research regarding researcher-participant relationships and the construction of knowledge and understanding. Learning that occurs through dialogue is conceptualized as potentially transformative and empowering with, in some cases, a social reconstructionist intention. Within the qualitative research paradigm, there has been particular attention paid to the theoretical and practical implications of dialogue for evaluation as a participatory democratic process. These conceptions of dialogue in qualitative research and evaluation are informed by the writings of the European philosophers Martin Buber, Hans-Georg Gadamer, and Jürgen Habermas;

the ancient Greek philosopher Socrates; the Russian literary theorist M. M. Bakhtin; and the quantum physicist David Bohm.

Theoretical Influences

The writings of the scholars just listed inform the more technical conception of dialogue in research as well as dialogue as an ethical practice and way of being. Each emphasizes the communicative role of dialogue as a relational learning process.

Dialogue as a Learning Process

The Socratic dialogue, which uses a questioning strategy to make the speaker aware of implicit knowledge or ways of thinking, is relevant to the interview in which the researcher asks a series of questions intended to draw forth a participant's knowledge or insight, or insight may be constructed during the dialogic exchange of the interview. Habermas's conception of dialogue recognized the role of speech in conveying knowledge but emphasized the moral importance of uncoerced, and thereby equitable, communication. Bohm also focused on dialogue as a form of learning through a nonjudgmental open exchange of ideas. Habermas's and Bohm's emphases on equity and open-mindedness (or the resistance to judgment) inform the researcher-participant relationship as collaborative instead of power-laden.

Dialogue as Relational

Buber defined a genuine dialogue as a reciprocal relationship between "I" and "thou" in which a mutual exchange of ideas promotes reconciliation. Bakhtin's theories are especially relevant to the researcher-participant relationship in that dialogue is integral to one's self-development; each person is inevitably influenced by engagement with another person.

Dialogue as Transformative

Gadamer also discussed the transformative quality of dialogue. Through dialogue, the researcher and participant exchange ideas and insights in a reciprocal process that may be mutually transformative through constructing understanding about the research topic as well as fostering each person's self-understanding. This relational and transformative quality of dialogue underscores the ethical practice of research and evaluation

both in terms of the research process as a beneficial (albeit possibly emotionally or psychologically painful) learning experience and in terms of the research process as one that may instigate change on the part of the participant, researcher, or reader.

DIARIES AND JOURNALS

As narrative methods gain popularity in the social sciences and other disciplines, so does the use of diaries and journals as valuable qualitative tools. The word *diary* is derived from the Latin *diarium* (daily allowance), and the word *journal* is derived from the Old French *jour* (day). Although both terms relate to first-person chronological records, each yields distinctive types of data. Diaries are generally used to track participants' daily activities and objective experiences, whereas journals capture writing that includes emotion, introspection, and self-reflection. This entry explores ways in which both diaries and journals can be used effectively in qualitative research projects.

Overview

Although written self-stories existed before the 10th century, it was at this time in history that personal diaries were popularized by Japanese women of royalty who secretly recorded their fantasies and fears in “pillow books.” These clandestine tomes heralded a new genre of writing that highlighted self-expression and feelings rather than mere historical or factual events.

During later centuries, the practice of diary keeping exploded as literacy and self-reflective practices increased across the globe. During the early 1900s, two influential figures advocated the benefits of reflective writing: Swiss psychoanalyst Carl Jung extolled the diary as a unique tool for recording dreams and exploring the unconscious, and Anais Nin's published

diaries encouraged women to pursue self-fulfillment and creativity through habitual writing.

The mass publication of Anne Frank's diary was followed by widespread marketing of pastel-colored books with tiny locks and keys during the 1950s. Although diaries were promoted as an adolescent female hobby, within two decades this trivialization of diaries would abate with the publication of Tristine Rainer's book, *The New Diary*, in 1978. Rainer emphasized that internal probing and consequent awareness of one's feelings, thoughts, and actions is inarguably beneficial and can increase lifelong happiness. Likewise, Ira Progoff's book, *At a Journal Workshop*, became immensely popular during the late 1970s and solidified the place of self-writing as a tool for transformation. From their rich historical beginnings to the current day, diaries and journals have been kept by both men and women across the globe for personal, professional, and academic purposes.

Diaries

In academic research, diary writing is beneficial in eliciting personal yet structured responses. Diaries have been used in the academic realm to study a large spectrum of human activities, including but not limited to sexual and dating practices, sleep habits, exercise routines, television viewing, social activities, food consumption, educational pursuits, eating behaviors, work interactions, internet habits, leisure activities, cell phone use, travel routines, menstrual and fertility cycles, and a wide range of physical and mental health events. Diaries are particularly appropriate in recording routine or everyday processes that are otherwise unnoticed if not documented. Researchers may want to employ diaries as a method when extant research data are useful but there is a gap in the literature pointing to a need for nuanced information that is best captured by hourly or daily responses over time.

Many qualitative studies use diary analysis to observe, improve, or enhance people's practices by tracking their patterns and cycles. Checklists are often used with formats resembling survey and questionnaire techniques. Such diaries can assist health care professionals in diagnosing patients' symptoms, adjusting medication type or dosage, and ensuring compliance with prescribed medical protocols. Regardless of the discipline in which they are used, diaries can provide researchers with enlarged and detailed “snapshots” of what people have experienced.

Although diary formats vary, usually they do not offer open-ended questions but rather supply participants with a specific set of fixed responses. These optional answers can be in a dichotomous (yes/no), scaled, or multiple-choice format. Likewise, diaries can be constituted in the form of logs, ledgers, or calendars.

When analyzing diaries, researchers have a variety of options. Diaries lend themselves to mixed methods while also offering rich subjective data. If researchers include open-ended questions in diaries, participant responses are usually coded thematically with an eye toward emerging themes and subthemes.

Journals

Using journals is one of the most effective research tools to mine the rich personal experiences and emotions of participants' inner lives. When sensitive or taboo topics are studied, journals often allow participants to feel comfortable with their degrees of self-disclosure. Likewise, introverts or those who have been marginalized may feel particularly comfortable when voicing their ideas in private writing. Research studies using journals as a method include but are not limited to topics related to sexual frequency and activity, child abuse, trauma, chronic and terminal illnesses, divorce, posttraumatic stress syndrome, unemployment, infertility, spousal death, eating disorders, depression, and hospice experiences. Journal use is also particularly valuable when little attention has been devoted to a topic and the study seeks to elicit fresh data from first-person experiences.

When analyzing journal entries, a system of thematic or content analysis is usually applied. This form of coding allows for categories and themes to emerge from the journal entries. Qualitative researchers read the journals looking for causal connections, patterns, recurring issues, and reactions; sub- or by-themes may also be noted and categorized. Although journal entries are often completely unstructured, researchers may also ask guided questions to encourage participants to write more specifically about a discrete experience or event.

Cyber Writing

Although a detailed account of cyber writing is beyond the scope of this entry, researchers should be aware of the burgeoning popularity of "blogs" (web logs) as a potential tool for rich data. One of the distinct advantages of studying online writing is the

ability to access more participants than is possible in traditional face-to-face studies. Furthermore, it is easier to pinpoint online communities that share common interests or serve as cyber support groups. Unlike traditional diaries and journals, blogs defy several aspects of time and space. They are written and read in reverse chronological order and also extend beyond the computer page to include hyperlinks, photos, videos, and responses by others.

Researchers' Writing

Whereas many qualitative researchers analyze others' diaries and journals, there is an increasing practice of researchers themselves keeping detailed journals. Traditionally, social scientists record fieldnotes to document their observations. However, Carolyn Ellis, a pioneer in the field of autoethnography, promotes using first-person and introspective journal keeping as a tool for capturing researchers' lived experiences. Kim Etherington, another advocate of reflexivity (ongoing self-awareness), keeps a researcher diary that records her personal feelings, insights, and experiences that are later incorporated into her academic findings. Researchers can use detailed journals or diaries to record and reflect their own behaviors, attitudes, feelings, and thought processes to provide a multilayered facet to their academic studies.

Ethics

Diary or journal writing often evokes introspection, and precautionary measures should be considered. One concern is that participants may recall painful memories or become overwhelmed by emotions while writing in their diaries or journals. Making sure that participants have access to mental health professionals will assist in the event that participants need help in processing their emotions.

Researchers should always ensure that participants give signed informed consent and that minors have their parents or guardians approve of participation in the study. In studies involving the use of private diaries, and particularly in studies involving a "vulnerable population," formal approval must be granted through the appropriate ethics review board.

Another concern in using diaries and journals as data sources is the issue of confidentiality. Although participants initially may have agreed to have their writing published, they may have written with the understanding that a researcher or only a select few

would be the “audience” for their responses. In this regard, it is important to be mindful of what is divulged about participants and others involved before publishing the study.

Several techniques are useful in protecting the anonymity of participants. Diaries or journals may be submitted in person, mailed in, or gathered from a drop-off location, giving participants options for safeguarding their writing. Researchers may also use pseudonyms or assign numbers to respondents. When publishing, researchers may further protect participants’ identities by combining data into composite responses or discussing general themes rather than particular entries. Diaries and journals are unique and valuable tools for qualitative researchers, yet regard should always be given to the ethics of participants’ well-being and care.

DICTION (SOFTWARE)

DICTION is a dictionary-based language analysis program that analyzes the implied meaning of a text

Figure 1 DICTION 6.0: Project View

Note: DICTION 6.0 operates on Windows XP, Vista, Macintosh, and Linux platforms.

by searching it with the assistance of some 40 dictionaries or word lists. DICTION's corpus consists of 10,000 search words, none of which is duplicated in its search routines. DICTION provides an unusually comprehensive examination of a given passage by comparing it with a 25,000-item sample of contemporary discourse. Although the dictionary scores are individually interpretable, the program also creates five master variables: *optimism* (language endorsing some person, group, concept, or event or highlighting its positive entailments), *activity* (language featuring movement, change, the implementation of ideas, and the avoidance of inertia), *realism* (language describing tangible, immediate, and recognizable matters that affect people's everyday lives), *commonality* (language highlighting the agreed-on values of a group and rejecting idiosyncratic modes of engagement), and *certainty* (language indicating resoluteness, inflexibility, and completeness as well as a tendency to speak *ex cathedra*). Correlations among these master variables are largely nonexistent, thereby affording five independent examinations of each passage analyzed.

The current version of the program, DICTION 6.0, was developed in Eclipse using Java 5.0 and operates on Windows XP and Vista, Linux, and Macintosh platforms. It processes 2,500 text files within 1 minute and produces both project output and alphanumerical files for subsequent statistical analysis (Figure 1). The program accepts PDF, RTF, Microsoft Word, and HTML input files for processing. Users can also supplement the program's built-in search features with up to 30 customized dictionaries of their own creation. DICTION 6.0 comes with a file management system so that users can group texts based on semantic commonalities, highlight specific textual regions for inclusion or exclusion, and identify (via color coding) different speakers or passage segments.

DICTION has been used to study political messages, media reportage, corporate annual reports, historical and literary documents, religious sermonizing, economic forecasting, medical documents, crisis communications, and (increasingly) websites and internet traffic. Unlike other programs, DICTION is largely "deductive" in that its dictionary structure has been conceptually derived and it compares all output with a normative data bank, thereby highlighting a given text's rhetorical distinctions and permitting immediate cross-comparisons with other DICTION-processed texts.

DISCOURSE

Discourse, in the most general sense, is the study of language as it is used in society expressed either through conversations or in documents. However, the term *discourse* also carries with it various historical traditions influencing the definition employed and the type of research conducted. The major disciplines that have contributed to the development of these traditions include diverse fields such as psychology, sociology, philosophy, and linguistics.

The two major approaches to discourse analysis are influenced by either ethnomethodological or Foucauldian traditions. Regardless of the approach, discourse analysis can be distinguished from strict conversation analysis and other forms of linguistic analysis by its focus primarily on the meaning of talk (or text) rather than on the linguistic organization of the components of talk (e.g., grammar, sentence structure, word choice).

Ethnomethodological discourse analysis has its roots in the ethnomethodological approach of Harold Garfinkel that seeks to understand the implicit rules governing human conduct. An ethnomethodological approach to discourse assumes the same aim. Often referred to as non-Foucauldian discourse analysis, ethnomethodological discourse analysis is concerned primarily with the structures of interaction that produce meaning. Assumptions that underpin this approach include expectations that communication is structured, stable, contextual, organized, and sequential. Researchers aim to uncover the rules of language in a particular context to determine both the structure

of conversation and the resultant meaning of what is said. An example research question could focus on how language is used by teenagers to create shared meanings about the social acceptability of alcohol, tobacco, and drug use.

Foucauldian discourse analysis shares a focus on the meaning of talk or text with ethnomethodological discourse analysis. In contrast, however, a Foucauldian approach to discourse, rather than exploring the rules that govern meaning-making, focuses on the power inherent in language and seeks to understand how historically and socially instituted sources of power construct the wider social world through language. For example, researchers employing a Foucauldian approach to discourse analysis would be more interested in how language is used by doctors, parents, the media, and governments to subordinate and marginalize the views of teenagers with respect to substance use. They would also be interested in the discourse of teenagers as a form of resistance to the hegemonic discourses of the cultural mainstream. As such, Foucauldian discourse analysis assumes a more critical approach and focuses on how power is operationalized through language.

DISCOURSE ANALYSIS

Discourse analysis (DA) is best seen as a cluster of related methods for studying language use and its role in social life. Some of these methods study language use with a particular interest in its coherence over sentences or turns, its role in constructing the world, and its relationship to context. Others take discourses to be objects in their own right that can be described and counted. This entry identifies a range of terminological confusions, discusses some of the origins of DA, and describes the main contemporary approaches.

Terminological Issues

Different forms of DA have emerged in different disciplinary environments—linguistics and sociolinguistics, sociology and social psychology, philosophy, education, and so on. This can lead to confusion that can be compounded by the different senses in which the term *discourse* is used. At its most general, the term is used to refer to virtually any language use or even to related semiotic systems; however, other work uses the term specifically to refer to a linguistic object that can be described and counted.

Using the specific definition, a study might, for example, attempt to identify a discourse of medicine and a discourse of counseling operating side by side in a medical consultation. Under the broader definition, discourse analysis covers large areas of sociolinguistics and linguistics, much cognitive science concerned with language use, social semiotics, and work on educational interaction as well as areas of work such as discursive psychology, critical discourse analysis, Foucauldian discourse analysis, and simply discourse analysis.

There is also a strand of work associated with post-structuralist thinking, particularly the work of Michel Foucault, that is often referred to as continental discourse analysis (sometimes Roland Barthes and Jacques Derrida are included in this definition). Confusingly, this work is rather different from Foucauldian discourse analysis. DA has developed as a contested terrain where different books with “discourse” in their titles can exist with no overlap in content.

Historical Developments

The earliest use of the term *discourse analysis* is probably in Zelig Harris’s linguistic research during the

early 1950s that focused on the attempt to explicate sentence meaning in texts by relating the sentence to surrounding sentences. Since that time, the first sustained approach to explicitly use the term was developed by linguists John Sinclair and Malcolm Coulthard in studies of classroom interaction. Their aim was to build a systematic model of how interaction is organized in the classroom. The prototypical pattern they identified was the “initiation–response–feedback” sequence. This has the following form:

Teacher: What are five fours? (initiation)

Pupil: Twenty-four miss. (response)

Teacher: Close, Julie. Have another go. (feedback)

Sinclair and Coulthard had the ambitious aim of explicating the interaction structures of different settings by comparative work. In this aim, it prefigured more recent work on institutional interaction by conversation analysts. Although the analytic materials are simplified and the analytic categories are relatively undeveloped, this work was a departure from a linguistic approach that worked with invented materials or written sentences.

A separate linguistic tradition focused on the way in which sentences are linked together in coherent discourse. One strand in this work involved studying the way in which terms such as *however* and *but* work to generate coherent discourse. This work has merged with a tradition of research called discourse processes that attempts to join linguistic and psychological concerns. This tradition considers questions about how psychological experiences become transformed when they are reconstructed into verbal narratives and, conversely, how mental scripts are used in the understanding of narrative. In its research practice, the work on linguistic coherence typically used standard linguistic methods, drawing on invented examples and considering whether they were “well formed” or “anomalous.” The more psychological work has drawn on a range of approaches; sometimes records of interaction are coded for statistical regularities and contrasts, and sometimes experimental manipulations are used. Work in this tradition is often published in the journal *Discourse Processes*.

Foucault and Discourse Analysis

A very different tradition is associated with the cultural historian and poststructuralist Michel Foucault. He

treated discourse as “a set of statements.” Although this might seem to be a linguistic definition, his account owes much more to philosophy and sociology. For him, statements have a constructive role; they come to constitute objects and subjects. For example, the discourse of medicine may produce objects, such as “bile” and “HIV,” as distinct and countable things. At the same time, that discourse works to produce the identities of doctors and patients, each with their own distinct knowledge and authority. In analytic terms, Foucault’s work aimed to identify discursive practices. In the example of medicine, this would include the historically evolving discourses that help to shape the development of medical practices, the procedures of investigation and diagnosis, the practices for dividing the ill from the healthy, the procedures of medical record keeping and surveillance, and the very architecture of wards, consulting rooms, and so on. Although Foucault’s work has been enormously influential, it does not offer a method as such. His work tends to involve theoretically guided historical (or “genealogical”) interpretations of institutions.

Sociology of Science and Discourse Analysis

A further influential tradition of DA emerged within sociology, specifically sociology of scientific knowledge. The focus here was neither linguistic nor genealogical. Rather, the key focus was epistemic, and the analytic focus was on the role of talk and texts in constructing the social world. In an intensive study, Michael Mulkay and Nigel Gilbert suggested that scientists’ discourse is put together using two contrasting interpretive repertoires (interrelated vocabularies of terms and linguistic constructions, often organized around a central trope or metaphor). The *empiricist* repertoire was dominant in research papers/articles and was used to warrant scientists’ own claims in the manner of textbook science. The *contingent* repertoire was a much more fragmentary set of ideas used in interviews and other informal settings to explain away claims that were inconsistent with scientists’ own claims by making reference to a wide range of social, political, and psychological influences. The key point here was that scientists drew on both of these repertoires to produce an orderly picture of the world; neither was sufficient on its own.

This style of DA was developed and applied to a range of social science topics by Jonathan Potter and Margaret Wetherell. For example, they provided an

alternative way of understanding racist discourse and a respecification of the notion of attitudes. They developed the methodological approach for dealing with interview transcripts and documents by drawing more explicitly on ideas from poststructuralism, ethnomethodology, and conversation analysis. This work offered a distinct perspective on social constructionism focused on the way in which talk and texts are used to produce versions of events that can sustain particular practices. This influenced discourse analytic research in a wide range of disciplines, including psychology, sociology, organizational studies, medicine, and communication.

The emphasis on people producing versions out of contrasting interpretive repertoires was used in Michael Billig and colleagues' notion of ideological dilemmas. These authors suggested that the emphasis on ideologies being effective because of their consistency was flawed. Instead, in practical settings, it is the tensions and contradictions between the different repertoires that make them so powerful for constructing versions of the world. Thus, in the case of scientists, it is not the familiar textbook image of science embodied in the empiricist repertoire that sustains their claims; rather, it is the *combination* of this repertoire with the alternative contingent repertoire that sustains their claims.

The notion of interpretive repertoires has been analytically fertile, offering an account of complex, historically developed organizations of ideas that could be identified through a systematic analysis of interviews, records, and texts. The notion builds an appreciation of the flexibility needed if a repertoire is to be fitted into a range of different practices in formal and informal settings. Thus, it has some advantages over some neo-Foucauldian uses of the notion of discourse. Nevertheless, it has been criticized as failing to fully accommodate the complex and locally organized nature of human conduct.

Contemporary Developments in Discourse Analysis

DA has become a lively and contested field since the mid-1990s. It is common to distinguish the subfields of critical discourse analysis (CDA), Foucauldian discourse analysis (FDA), and discursive psychology (DP). CDA is a collection of approaches to discourse that are given coherence by an emphasis on social critique and the use of analytic concepts from linguistics,

in particular Michael Halliday's functional grammar. This style of work often aims to reveal the ideologies and discourses that underpin different forms of talk and text and, importantly, sustain relations of inequality.

Some CDA work draws on Foucauldian ideas. However, a distinct tradition of Foucauldian discourse analysis has emerged recently. Like CDA, it focuses on issues of social critique; however, unlike CDA, it tends to work with interview material rather than with texts. This work is best treated as being inspired by Foucault's notions rather than as strictly applying them. Foucault himself did not analyze interviews, and it is not clear whether he would have seen such analyses as profitable. Moreover, in his break with hermeneutics, Foucault specifically rejected the kind of focus on meanings that is common in FDA. In addition, he was concerned about decomposing the idea of individual subjectivity by considering the institutional practices through which individuality and subjectivity are produced. This does not sit easily with FDA's common focus on subjectivity itself. Much FDA appears to build more on the tradition of analyzing interpretive repertoires than on Foucault's concepts or genealogical style of research.

DP developed out of the constructionist tradition of DA associated with Mulkay, Gilbert, Potter, and Wetherell. Its focus is on the way in which psychological issues become live in human practices. It typically starts with records of interaction in everyday and institutional settings rather than with interviews or texts, and it has generated a very different vision of what psychology is to mainstream social and cognitive psychology. DP has put practices, rather than individual cognition, at the center of its analysis, and it has increasingly drawn on the analytic rigor of conversation analysis to ground its claims.

There have been some important debates over the relative merits of poststructuralist and conversation analytic approaches to discourse and the value of the neo-Foucauldian notion of subject positions. There are live issues regarding the extent to which discursive structure reflects conceptual organizations or is a by-product of the patterning of situated practices, and there are particular sharp differences between CDA and DP. Although its critical potential is not signaled in its name as it is in critical discourse analysis and Foucauldian discourse analysis, discursive psychology has generated a sustained critique (at the level of method and theory) of traditional approaches to psychology while also contributing to studies of gender,

race, and ideology. Work in these traditions is often found in the journals *Discourse & Society* and *Discourse Studies*.

Despite the challenging and complex weave of different, and sometimes contradictory, perspectives that make it up, DA is a vibrant and fast-changing field of endeavor that has stimulated methodological and theoretical innovation.

DISCOVERY

From the standpoint of social science, discovery is both process and result. As process, it refers to the several ways in which social scientists attempt, employing certain procedures, to find new ideas about the social world. As a result, it is what these attempts or procedures produce or lead to—the ideas they generate.

Bridging process and product in discovery is the creative or innovative moment during which the scientist intuitively and imaginatively comes up with a novel idea. C. Wright Mills's *The Sociological Imagination*, an influential essay on discovery, revolves around such intuition.

Discovery can be either intentional or unintentional. It can also be either deductive or inductive. Unintentional discovery, exemplified in this entry as serendipity, is inductive. Although scientists intending to discover something, whether working deductively or inductively, consciously employ certain procedures in their quest, they have at most only a general idea of what their efforts may produce. In general, the novel ideas intentionally sought or accidentally found during social scientific discovery bear on phenomena such as actions, activities, groups, processes, and cultural items regarded as important to the people whose actions, activities, and the like they are.

Deduction

There are at least three types of deductive discovery. For each type, deduction is the principal logical process framing the scientist's attempt to find new phenomena. Moreover, because deduction is ideational, no direct contact with people or their material culture is required. Deductive discovery is a conscious, intentional, and systematic process. The classic type, referred to here as *theoretical deduction*, proceeds according to standard deductive logic. In this type, the scientist strives to discover something new by deducing one or more corollaries from basic premises or propositions (e.g., boredom is a coerced condition; leisure is an uncoerced activity; therefore, boredom is not leisure).

The *metaphor* constitutes another type of discovery. A metaphor is not intended to represent the phenomenon under study in the same way as resulting theory will (or at least should); rather, its purpose is preliminary—to suggest, by deducing from premises of the metaphor, fruitful paths leading to discovery of the nature of that phenomenon. This process eventuates in new data, concepts, and propositions related to the phenomenon. With a metaphor, this is accomplished by orienting thought and research using one or more of the concepts comprising the metaphor, in effect converting them into what Herbert Blumer labeled as sensitizing concepts. Such concepts are heuristic; they guide open-ended discovery research

on new groups, activities, and so on. In brief, applying metaphors is a fruitful and distinctive way of generating grounded theory.

The *dialectic*, fashioned by Friedrich Hegel and Karl Marx, is a third type of deductive discovery. In rudimentary form, it states that Social Condition A (thesis) leads to an opposite Social Condition B (antithesis), thereby creating a tension leading to its resolution in Social Condition C (synthesis). Thus, Marx theorized that capitalist exploitation of workers (A) would lead to revolution and a classless society (B) followed by dictatorship of the proletariat (C).

Induction

Discoveries can also be made by way of inductive argument, whose ambit is substantially broader and more open-ended than the closed circle of logic found at the heart of deductive argument. Inductive logic rests on comparatively free-ranging direct observations of the empirical world (e.g., people's activities, situations, groups, material culture) and the conclusions (sometimes called generalizations) inferred from these observations. There are at least four types of inductive discovery.

Andrew Abbott discussed *trial and error* and how later trials are mounted when errors prove earlier ones to be ineffective. Trial and error is, at bottom, a type of intentional inductive discovery in that it proceeds by trying to discover, through direct observation of people or their material culture or both, a feasible alternative that comes to the discoverer's attention and that offers an effective solution to the problem at hand. Abbott's approach to discovery is an active one, unlike the passive approach of its cousin, serendipity.

Serendipity is unintentional discovery. Robert Stebbins defined it as the quintessential form of informal experimentation, accidental discovery, and spontaneous invention. Serendipity, like other inductive procedures, springs from direct contact with the empirical world. Robert K. Merton and Elinor Barber observed that serendipity can refer either to finding something of value while searching for something else or to finding something sought after in an unexpected place or manner.

Exploration is broad-ranging intentional discovery. Stebbins defined it as systematic data collection designed to maximize discovery of generalizations based on description and direct observation of an area of social or psychological life. Most commonly,

researchers who explore generalize from the shared ground they find in sets of observations usually made over several instances of the object of investigation. This meaning of exploration differs from that of exploring to become familiar with something by testing it or experimenting with it. A second sort of exploration is that conducted by artists, inventors, and innovators. In still another sense, exploring means traveling over or through a particular space for purposes of discovery and adventure. A final sense of the concept is to examine a thing or an idea for diagnostic reasons—to search it systematically for something. This meaning suggests that because explorers here already know what to look for (e.g., oil, cancer, toxins), they need only hunt for it methodically.

Construction of the *ideal type*, a fourth kind of inductive discovery, works in ways similar to exploration in that both rest on direct observations about an aspect of life. But ideal-typical observations are unsystematic even if they are generalized and integrated into a single hypothetical concept. Ideal types have guided a range of exploratory and verificational inquiry, including Max Weber's idea of power, defined as one person in a relationship being able to realize his or her own will despite the other person's resistance.

Today the most common types of discovery appear to be theoretical deduction and inductive exploration. Use of metaphors and the dialectic is also reasonably common. Trial-and-error research, serendipitous research, and ideal-typical research are infrequent. These are estimates, however, for no one has surveyed the literature on the matter. Scientifically, all types of discovery must be seen as antecedent to verification of the newly found ideas. Discovery contributes empirically grounded valid concepts and propositions with which verificational scientists then work.

DISCURSIVE PRACTICE

Discursive practice has at least three important and distinct senses in current qualitative research. It appears as a major technical term in the work of social theorist and analyst Michel Foucault. It is used more loosely in a wide range of analytic work that is often described as Foucauldian discourse analysis. It also has a technical sense in conversation analysis.

In Foucault's "archaeological" study of psychiatry, for example, the term *discursive practice* is used to refer to the broad constellation of statements that embody the founding of psychiatry as an institution and its subsequent history, the "dividing practices" through which the sane are separated from the insane, the procedures of psychiatric testing, and the very buildings in which the insane are incarcerated. All of these things are treated as elements that come together to constitute psychiatric knowledge. A discursive practice can also encompass the rules for the formation and transformation of these things and, in particular, the procedures through which particular subjects (e.g., the sane) and forms of subjectivity (e.g., delusional) are constituted. Foucault's studies are more influential in their visionary linking together of issues of knowledge, psychology, power, and institutions than through the details of their analytic apparatus. Few other analysts, in their studies, have sustained the full and challenging complexity of Foucault's notion of discursive practice.

More commonly, the notion of discursive practices has been used in a restricted sense in Foucauldian discourse analysis. Such work tends to use a broadly linguistic focused treatment of discourse and often starts with materials generated in a set of open-ended interviews. Foucault's own studies were historical and did not use interviews. Moreover, Foucault specifically contrasted his analysis with studies of a linguistic nature that foreground participants' meanings. Such studies often draw on the form of discourse analysis developed by Jonathan Potter and Margaret Wetherell that attempts to show how a weave of discourses or "interpretive repertoires" is drawn on to legitimate

particular social arrangements or undermine the claims of minority groups.

In the subdiscipline of conversation analysis, discourse (the coherent production of talk-in-interaction) is studied as something interactionally achieved. Conversational actions can be produced by different discursive practices. For example, Emanuel Schegloff considered the way in which certain kinds of repeating practice (e.g., repeating some of the prior speaker's words) can be used to accomplish the action of initiating repair to something that has been said by a prior speaker. The term *practice* here is used to emphasize that there is not a simple speech act category for what was done, nor is it easily seen as the product of an individual's strategic understanding.

These three different styles of research draw on very different senses of discursive practice. Even experienced researchers can become confused over these differences, particularly over what is involved in doing Foucauldian analysis.

DISCURSIVE PSYCHOLOGY

Discursive psychology (DP) starts with psychological phenomena as things that are constructed, attended to, and understood in interaction. It is not just psychology as it appears *in* interaction; rather, it understands psychological language, and broader "mental practices," as organized *for* action and interaction. It is a specifically *discursive* psychology because discourse—talk and texts—is the primary medium for social action. Part of its focus is on the organized resources used to build actions.

DP works with three fundamental principles in its approach to discourse:

1. *Action orientation.* DP analyzes discourse as the primary means through which actions are done and interaction is coordinated. Actions are seen as typically embedded in broader practices. This focus on action rather than cognition differentiates it theoretically from cognitive psychology and underpins the analytic focus on discourse rather than experimental comparisons of input and output.

2. *Situation.* DP treats discourse as situated in three complementary senses. First, it is organized *sequentially*, such that the primary environment for any utterance is the immediately prior utterance and the new utterance provides the context for what comes next. Second, discourse is situated *institutionally*, highlighting the potential relevance of institutional identities (e.g., counselor, client) and tasks (e.g., assessing trauma, offering advice). Third, discourse is situated *rhetorically*, such that any description can be inspected for how it counters relevant alternative descriptions (often from the immediately prior talk).

3. *Construction.* In DP, discourse is understood as both constructed and constructive. Discourse is constructed from resources (e.g., words, membership categories, rhetorical commonplaces, interpretive repertoires). Discourse is constructive of versions of the world, including versions of events and actions, settings and structures, psychological entities and experiences. DP studies both the actions done with these constructions and the way in which these constructions are built to be stable, objective, and independent of the speaker.

Methodologically, DP performs intensive qualitative studies of audio or video records of interaction in everyday and institutional settings. Research will typically study a corpus of examples of some phenomenon and will work simultaneously with the digitized video or audio and a full Jeffersonian transcription (named after its developer, Gail Jefferson). Increasingly, DP has drawn on the analytic power of conversation analysis. Notable research areas have included counseling and therapy talk, helpline interaction, mediation, police interrogation, food, and interaction. At the same time, DP has offered new approaches to familiar social science topics, such as race and gender, attitudes and scripts, social representations and emotion, and also

has formulated new topics, such as the role of descriptions in the formation of actions, the management of stake and interest in delicate circumstances, and the way in which talk is organized to display psychological states.

DP can be illustrated through Derek Edwards's research on script formulations. Traditional social psychology treats scripts as mentally encoded templates that guide action. DP focuses on the prior issue of how descriptions are produced to present actions as following standardized routines. Consider the following fragment from a couples' counseling session:

Counselor: Whe:n: (.) before you
 moved over here how was
 the marriage.

(0.4)

Connie: O↑ ↓. (0h2) I- (.) meo
 all alo:ng, (. right up
 to now, (0.2) my marriage
 was rock sold.

(0.8)

Connie: Rock solid.= Wehad argu
 ments likeeverybody else
 had arguments, (0.4) buth
 (0.2) tome there wasno
 major problems.

Jefferson's transcription system has been used here. It marks features of the delivery of talk that have been found to be relevant to interaction in a large body of conversation analytic work. In this extract, underlining is used for emphasis; colons mark extensions of the preceding sounds; arrows show marked upward or downward pitch shifts; dashes mark cutoff sounds; numbers in parentheses show delay timed in seconds; and equals signs mark hearably fast transitions or rush-throughs.

Note the way in which Connie depicts the arguments that she and her partner have as the routine sort that everybody has. Although arguments might be viewed as a problem with a marriage, Connie "script formulates" them as actually characteristic of a rock solid marriage. The orderliness of action and interaction is accomplished as such in interactions of this kind. DP here focuses on the locally organized practices for constructing the world to serve relevant activities (in this case managing the live question of who is to blame

Conversation Analysis: An Example of Transcription in Discursive Psychology

In discourse analysis, a detailed transcription is often used to record features of speech such as volume change, pauses, and overlaps. The point of this transcript is to enable the researcher to see on the page features of the delivery of talk that are often crucial for how the participants understand it. Failure to transcribe can lead to highly misleading representations of interaction.

The Jeffersonian scheme is most widespread in discourse and is named after its developer, Gail Jefferson. In the following fragment from a couples' counseling session, for example,

- underlining is used for emphasis;
- colons mark extensions of the preceding sounds;
- arrows show marked upward or downward pitch shifts;
- dashes mark cutoff sounds;
- numbers in brackets show delay timed in seconds; and
- equals signs mark hearably fast transitions or rush-throughs.

Counselor: Whe:n: (.) before you
moved over here hbw was
the marriage.
(0.4)

Note: For the best exposition of the Jeffersonian system, see Jefferson, G. (2004). Glossary of transcript symbols with an introduction. In G. H. Lerner (Ed.), *Conversation analysis: Studies from the first generation* (pp. 13–31). Amsterdam: John Benjamins.

Connie: 0↑ ↓. 0.2) I- (.) tme: all
alo:ng, (.) right up tnow,
(0.2) my marriage wasrock
solid.
(0.8)

Connie: Rock solid.= We hadarguments
like everybody else had
arguments, (0.4) buthh (02)
to me there wasno major
problems

For example, the 0.8-second delay after “rock solid” is an occasion where the counselor might have come in. The transcription allows us to see something that is not there but might have been. However, the equals sign after the second “rock solid” is a “latching” that holds off other speakers. The counselor would need to compete in overlap to take a turn at this point. We can also note that the emphasis that Connie puts on “me” (in two places) is hearably suggesting a potential contrast to her co-present partner.

Other systems of transcription exist, but Jefferson's has increasingly come to be seen as the “gold standard.”

Blake D. Poland

and who needs to change in the counseling). In the DP vision, scripts are an inseparable part of the practical and moral world of accountability.

DP is a vibrant research program now being conducted in a number of centers worldwide. It aims to offer a postcognitive psychology that is grounded in a direct study of people's practices rather than the more common indirect approach via open-ended interviews or experimental studies.

DISENGAGEMENT

Qualitative researchers are encouraged to become fully engaged and invested in their research site by immersing into the day-to-day routines of the group members being investigated and becoming familiar with their rituals and experiences. Ethnographers begin their

research as investigators of a social phenomenon or query with the objective of developing and answering research questions once they gain entry to the field. In the same way as relationships must be initiated and developed to begin a research project, researchers must also negotiate the closure or end of the research project. Disengagement refers to the process and experience of leaving the field after a research project is completed. Disengagement marks the end of the research project and refers specifically to the closure that occurs once a research project has ended.

David Snow, a sociologist, was one of the first scholars to mark disengagement as an under-investigated process of participant observation research and a phenomenon of researcher–participant relationships. Researchers are often unprepared and untrained for the process of disengagement, which can sometimes be problematic when researchers experience anxiety about leaving the field or leaving the participants with whom they have developed relationships. It is also problematic when researchers question whether or not they have collected enough information during the duration of their research period.

The level of disengagement researchers will experience depends largely on the details and obligations of the study. The more time invested and spent in a community and with a group of research participants, the greater the intensity of personal relationships. The greater the intensity of personal relationships, the more difficult it is to leave the field and return to separate lives.

Research or field relationships are understood to be temporary relationships that will last only as long as the research project. Disengagement becomes necessary to mark the end of the researcher–participant relationship even if the researcher maintains a relationship that is established during research. Disengagement allows a transition from the researcher–participant relationship whereby the researcher is no longer investigating the “other.”

Disengagement refers specifically to the process of the researcher leaving the field but does not consider the process of being left in the field. Further research could determine how the process of disengagement affects the participants and community members who have been actively involved in the research project. Participants are equally likely to develop attachments and investments in the research project and researchers and, thus, to be affected when the relationship ends or changes.

The process of disengaging from the field, however, should not be abrupt. Researchers should take the time to confirm their information by conducting final analyses and should settle moral obligations with their participants.

DISINTERESTEDNESS

The concept of disinterestedness comes from the discipline of aesthetics. It refers to a necessary detachment from subjective feeling that permits an accurate appraisal of beauty. Thus, the concept of disinterestedness, as commonly used in aesthetics, is closely linked to objectivity.

The philosopher Immanuel Kant first used the term *disinterestedness* in 1790 in the *Critique of Judgment*. Kant argued that the problem of rendering a judgment of beauty is the powerful presence of subjective desire. Kant claimed that this is different from a cognitive problem of reason, where objectivity alone rules. Therefore, to make a judgment of taste, it is necessary to overcome one’s own attraction or repulsion toward the object under consideration and to strive for an indifferent stance. Only through such a position of disinterestedness could one render a judgment that was more than personal preference. In fact, through disinterestedness, a judgment of taste could become a rule to which others should rightly adhere. For Kant, disinterestedness is a mental stance that recognizes the necessary presence of subjectivity and strives to keep it in check. This is different from objectivity, which rejects subjectivity completely.

Postmodern philosophers such as Pierre Bourdieu have challenged Kant’s framework for aesthetic

analysis. Bourdieu suggested that disinterestedness produces only cultural capital—objects that have no intrinsic worth to individuals but are useful in the advancement of social status. It also provides a framework for excluding the working class, whose members are unsophisticated enough to genuinely value those objects that they find attractive or beautiful. Furthermore, postmodern semiotic theory suggests that there is no essential quality or character to be grasped through disinterested analysis. Therefore, disinterestedness is best regarded as an oppressive tool that facilitates totalizing and colonizing theories.

Hannah Arendt and Clifford Geertz offered a different postmodern interpretation of disinterestedness as guiding moral action within liberal democracy. In this view, disinterestedness allows reflective analytic action to come out of felt response. Rather than attempting to force their feelings to conform to an external moral guide, individuals respond to their own feelings in a dispassionate and authentically moral manner.

Geertz sees disinterestedness as an exquisite balance between the tensions of subjective aesthetics and mechanical objective scientism. He maintained that real science can occur only in the space between these two tensions. Research that swerves too far into either rudderless subjectivity or narrow scientism is ultimately flawed and potentially morally irresponsible.

Interpreting Kant's concept of subjectivity as a valuable presence that must be rigorously disciplined, and seeing the tension of the presence of subjectivity as essential to the ethical conduct of science, has influenced the late 20th-century qualitative methodologies of educational criticism, narrative storytelling, portraiture, and *a/r/tography*.

DIVERSITY ISSUES

The issue of diversity has surfaced in the qualitative literature as a major topic area during the past decade and has been discussed largely in terms of race, gender, and class. The appropriateness of giving such attention to diversity in qualitative research rests on two points. First, qualitative research is foremost a research design, method, and tool that involves uncovering and discovering meaning about a particular phenomenon as it occurs in its natural setting. Second, the researcher is the primary instrument as the one who designs and conducts the research and presents the data. Given these two critical factors and the role of race, class, and gender in Western society, it is important to thoroughly examine the phenomenon of diversity and how it could affect a research process involving human instruments and human participants. Although race, class, and gender are social constructs, they are real in terms of the social power and privilege attached to them even though the ways in which they determine how Western society functions and influence lived experience may be invisible.

Qualitative research and its methods are conducive to understanding and validating the lives and experiences of women, minorities, and other disenfranchised groups in that within the qualitative paradigm there is a departure from positivist research traditions that emphasize objectivity and rationality as well as separating the researcher and participant from the social context. This line of thought parallels the underlying beliefs and values of researchers who engage in feminist research, who move away from male-dominated research paradigms and create space for relationships between the researcher and the participants, thereby attempting to address the inherent hierarchical power disparities in the research relationship.

Insider/Outsider Perspective

The insider/outsider relationship is one of the primary discourses or perspectives in qualitative research where power and matters of diversity are considered. The term *insider/outsider* refers to the relationship or position of the researcher to the researched and takes into account whether the researcher stands as an outsider or as an insider relative to the group being studied. The location of the researcher to the researched

has been characterized in the anthropological literature in several ways—endogenous and exogenous, the native and the colonizer, the observer and the observed, the participant observer and the participant. But the stance of the researcher is not easily defined despite obvious oppositional pairings of terminology. The experience of the researcher as an insider or outsider cannot be a fixed one given that one's position and identity are not static and are context specific. In addition, the perspectives of the researcher can be multifaceted and susceptible to shifts influenced by interactions with others, the changing research context, time, and other variables.

Feminist researchers made a significant contribution to the insider/outsider discussion by adding an analysis of power relations between the researcher and the participants. Although researchers ultimately hold the power in terms of analyzing and interpreting the data, feminist research posits that researchers should make it a point to attempt to equalize equal power relations. James Banks, in his 1988 article "The Lives and Values of Researchers: Implications for Educating Citizens in a Multicultural Society," contributed a fixed four-part typology that recognizes the complexity of the researchers' position: the Indigenous insider, the Indigenous outsider, the external insider, and the external outsider. The first part of his binary pairings refers to the circumstance of researchers as being Indigenous or external members in relationship to those being studied. The second component references the political and cultural position of the researchers. Do they share the values, beliefs, and views of the people they are studying? Banks's sociologically based definitions are extensions of Robert Merton's insider/outsider concept, which was first introduced in his 1972 essay, "Insiders and Outsiders: A Chapter in the Sociology of Knowledge." Patricia Hill Collins's outsider within concepts were contained in her 1990 article, "Learning From the Outsider Within: The Sociological Significance of Black Feminist Thought," and were introduced in her text, *Black Feminist Thought*. Using the earlier research on the insider/outsider perspective as a base, more recent qualitative literature acknowledges that research conditions are dynamic, standpoints can shift, and power can intervene to complicate data collection and postfield analysis.

One position set forth within the insider/outsider perspective is that the common bonds of gender, race, and class provide groundwork on which to construct trust and dialogue. Therefore, this perspective provides

the researcher with an assumed empathetic base within these boundaries. There are three types of the outsider/insider statuses widely recognized and discussed in the qualitative literature: people of color discussing how they research within their own groups, Whites reflecting on their research on people of color, and women discussing how they research within their gender given the various intersections of race, ethnicity, class, and sexual orientation.

Each position has its own set of strengths and weaknesses. Common issues affecting the researcher's perspective are ethnocentrism, assumed understanding, an ahistorical viewpoint, lack of knowledge about the researched, bias, assumed objectivity, and assumed subjectivity. There are no definitive answers to whether researching within the culture is less intrusive, less harmful, more politically correct, or more politically astute. The major areas of discussion are certainly that the groups on the boundaries of research are there because of existing societal power disparities. In the final analysis, reconciling power and positional statuses seems impossible to accomplish with any degree of finality and is dependent on the researcher's skills. A synthesis of the qualitative literature sets forth that the following are essential tools: respect for the research participants, an ethic of care, humility, power sharing, and an appreciation of lived experience.

Issues of Representation

A second major component of the discussion of diversity in qualitative research is the issue of representation. Overwhelmingly, the literature suggests that the researcher has an obligation to be ethical and empathetic regarding representation, considering questions such as whether the participants will recognize how they are portrayed, whether the participants have a say in how the data are presented or interpreted, and whether the participants' voices or stories are the central focus of the research or are subjugated to the researcher's voice or analysis.

An equal concern regarding matters of representation is whether the researcher provides a politically aware and responsible representation. For example, does the researcher reinforce stereotypes regarding the participants, or does the research provide a portrait of the researched set in a multifaceted context that would explain an unflattering depiction? The key inquiry posed by the qualitative literature on representation of the diverse "other" research remains:

How can researchers present their data in a way that honors the subjective experiences of the participants while ensuring that the audience is aware of their personal subjectivities and relation to the research?

Using the Theoretical Frame to Inform Research

A diverse array of theoretical perspectives informs qualitative research methods. Any type of research, whether qualitative or quantitative, is guided by the researcher's beliefs about what constitutes knowledge of and within a particular subject area or the researcher's epistemological positioning. Epistemology, which informs the theoretical perspective, concerns the ways of knowing and creating knowledge. The researcher's epistemological stance also emphasizes the relationship of the researcher to the research population or participants. A variety of epistemological foundations inform the work of qualitative researchers. Major goals of many qualitative researchers include the movement from more positivist research positions to those that emphasize relativism and the socially constructed nature of reality.

Qualitative researchers who employ positivist research methods believe that there is an objective reality that can be discovered or ascertained, that there is one essential measurable "truth," and that this truth is available to researchers if the appropriate research tools are used. In contrast to positivist perspectives, social constructionist views place emphasis on the socially constructed nature of reality. This social constructionist perspective is often employed by qualitative researchers who represent and research issues surrounding race, gender, class, and sexual orientation. Specifically, this perspective also suggests that there is not one reality but rather multiple realities and truths that are constructed by researchers throughout the entire research process.

In addressing the myriad ways of knowing and constructing knowledge in qualitative research, qualitative researchers employ a variety of theoretical perspectives. The major perspectives used include critical, feminist, and postmodern perspectives. These theories emphasize relativity, the shifting and changing nature of reality and identities, and employ methods that address power, language, and social change. Qualitative researchers informed by critical and feminist theory often engage in projects that highlight inequity, critiques of power structures, and individual

and collective agency among individuals and groups in addition to the study of social institutions such as the family. The methods used by critical qualitative researchers reflect the foregrounding of critique of social systems with an end goal being a type of change or transformation.

Also concerned with issues of diversity and equity, feminist research is more than a method; it is a perspective that lends itself to addressing the significance of gender in shaping women's realities. Qualitative methods informed by feminist perspectives can also provide a way of establishing a sense of connection between the participants and the researcher while leaving room for the participants to guide the interview process. There are several other issues involved in the process of feminist research, particularly concerning interviewing, that include issues of language, friendship, relationship building and reciprocity, managing power dynamics, and attending to the researcher's feelings about the process.

In addition to critical and feminist theory, women and qualitative researchers of color have developed and use perspectives informed by their experiences with race, gender, and class oppression. These include, but are not limited to, critical race theory, Black feminism, and other feminist theories developed by women of color. Regarding issues of diversity, critical race theory has also evolved as a perspective developed within the study of race and law. Critical race theorists present the centrality of race in the lives of people of color and suggest that using a race-based lens is integral to studying racial and ethnic minorities. Qualitative researchers informed by critical race theory privilege narratives and highlight the significance of storytelling from racial and ethnic minorities. Critical race theory then can be used to examine how the research participants engage race to resist oppression and become empowered in their everyday lives.

Relating to racial and ethnic diversity in qualitative research, feminists of color often engage feminism from their perspective of being on the margins of society. Theories such as Black feminism, Indigenous feminism, and Chicana feminism, for example, highlight women of color's experiences with and responses to oppressive situations. To illustrate, qualitative research from a Black feminist perspective emphasizes the intersecting forces of race, gender, and class in the research situation and in the research participants' lives. Black feminism also highlights the

significance of Black women's diverse cultures and defining the self in an oppressive society.

Postmodern methods differ somewhat from critical and feminist research methods in that the former involve critiquing the ways of thinking about the topic at hand as opposed to having a goal of social change or transformation. Postmodernists critique essentialism and other aspects of modernist Enlightenment ideals such as the search for any sort of "grand truth." Postmodern qualitative researchers emphasize subjectivity or the beliefs, experiences, and values the researcher brings to the research setting. Postmodern researchers also address the power of language to shape reality and the significance of the various contexts of the research situation. The beliefs, values, and assumptions of the qualitative researcher guide the entire research process, from initial design and preparation to the final write-up of the data. In qualitative research, the researcher's epistemological stance and accompanying theoretical frameworks are significant in that they inform and provide a lens through which to view and guide the research process. In addition, these theories reflect the shifting and ever-changing researcher perspectives to the qualitative research project.

Data Representation in Diversity Research

Qualitative researchers are currently expanding their modes of data representation in an effort to be more inclusive and representative of diverse populations. This is especially important when women, racial and ethnic minorities, and the socially and economically disenfranchised are studied because in research conducted prior to the 1990s their experiences and voices were often misrepresented, misappropriated, and devalued. Qualitative researchers can represent their data in a variety of ways such as thematically and as narrative text. With qualitative research, written text is the most widely used method of representing and presenting data. Thematic presentation of data, for example, continues to be the most common form of representing qualitative research findings. However, there is a growing concern and questioning of these more traditional methods of data presentation.

The concern about representation in addressing diverse populations has centered on introducing methods that place the participants as the center of consideration, that give voice to the participants, and that incorporate reciprocity or exchange into the research

process. This important growth area in qualitative research includes alternative ways of representing data that often include narratives, poems, and dialogically driven methods. Narratives, particularly constructed narratives, are often used in the study of marginalized populations such as women and minorities. The use of narratives can present women's stories in a nonlinear and holistic manner so that their stories are brought to the center of the inquiry. For instance, constructed narratives, where the data are organized and presented as a long, cohesive, and coherent story without the researcher's questions, is used by feminist and postmodern researchers. As a mode of representation, narratives not only are examined for story content but also move away from the traditional, fragmented thematic representation to a more holistic portrayal of the participants' words. The use of narratives privileges and centers the voices of the research participants.

Many qualitative researchers are also using drama, fiction, and performance-based formats to illustrate the potential for diverse representation formats. Performance, for instance, is becoming a commonly used form of creative expression to represent qualitative data. Those engaged in feminist and critical research often present their text as performances through plays, skits, poetry, music, and dance. The use of representational formats permits qualitative researchers to stretch and challenge the boundaries of more customary formats. Although these forms of representation are becoming more acceptable in academic research, issues of rigor and substance continue to be brought into question. The literature on representation makes explicit the personal subjectivities of the researcher and the researcher's relation to the research and the research participants.

Diversity and Qualitative Researcher Subjectivities

Addressing diversity in qualitative research methods also includes the discussion of researcher subjectivities. Subjectivity or bias, as a commonly used term in quantitative research, is typically described as something that poses a threat to the validity and reliability of the research. However, many qualitative researchers posit that researcher subjectivities are to be continuously scrutinized throughout the process so as to highlight how they inform and guide the study.

According to many qualitative researchers with postmodern, critical, and feminist perspectives, the

researchers' individual lives and subjectivities are never isolated from the text, which is produced from the qualitative interviews and/or observations. It is suggested in the qualitative research literature on subjectivities that research topics are quite often extensions of researchers' subjective experiences with or surrounding their particular topics. Addressing researcher subjectivities is a central aspect of the qualitative research process and must be taken into account when discussing diversity issues in qualitative research.

The values, belief systems, and worldviews of qualitative researchers inform the entire research process and will inevitably affect the methods and tools researchers use to collect, interpret, and present the data. For example, data collection in qualitative research frequently involves the use of interviews and observations. Feminist researchers often develop questions that incorporate the individuals' life experiences but also account for how the experiences are situated within various contexts as well as what their stories reveal about larger social processes surrounding gender, race, and/or class. The researchers' goals for the study and their epistemological stances, whether positivist or constructionist, affect and shape the types of questions the researchers will ask participants. Interpreting research findings also requires qualitative researchers to address their subject positions given that the lenses through which they interpret are also shaped by their subjectivities.

DOCUMENT ANALYSIS

Although documents often serve as key sources of social scientific data, their role in social research is rarely highlighted. Indeed, consideration of their use is sometimes subsumed under the amorphous heading of “unobtrusive” methods. In contrast, there are many well-defined approaches to the analysis of speech. Although there is no obvious way to account for the differing fortunes of speech and writing in research practice, it is worth noting that Barney Glaser and Anselm Strauss, in their renowned description of grounded theory, considered documents as on a par with an anthropologist's informant or a sociologist's interviewee.

The standard approach to the analysis of documents focuses primarily on what is contained within them. In this frame, documents are viewed as conduits of communication between, say, a writer and a reader—conduits that contain meaningful messages. Such messages are usually in the form of writing but can engage other formats such as maps, architectural plans, films, and photographs.

Although documents invariably contain information, it is also quite clear that each and every document enters into human activity in a dual relation. First, documents enter the social field as receptacles (of instructions, obligations, contracts, wishes, reports, etc.). Second, they enter the field as agents in their own right, and as agents documents have effects long after their human creators are dead and buried (e.g., wills, testaments). In addition, documents as agents are always open to manipulation by others—as allies, as resources for further action, as opponents to be destroyed or suppressed. (We should not forget that people burn, ban, censor, and forge documents as well as read and write them.) Given these multiple facets of documentation, it is not surprising that multiple methods are appropriate for their analysis.

The most straightforward approach to document content involves the adoption of some form of content analysis. At its simplest, content analysis concentrates on word and phrase counts as well as numerical measures of textual expression. More sophisticated approaches to document analysis using strategies derived from the analysis of speech transcripts—involving, for example, notions of grounded theory and thematic coding schemes—can also be applied to the written word. At another level, discourse analysis is feasible.

The concept of discourse is a complicated one. Perhaps the best intellectual starting point for a qualitative researcher is in the work of Michel Foucault (1926–1984). Although not an adherent of discourse analysis in the methodological sense, Foucault was essentially interested in the ways in which sets of ideas and concepts in science, medicine, and everyday culture tended to cohere into determinate ways of seeing the world. More important, such “discursive formations,” as he called them, were crucially linked to specific forms of social practice. In short, Foucault argued that what is written is inextricably locked into what is done. So, there is assumed to be an essential connection among documents (and their contents), practical action, and sites of action—all of which express aspects of a discursive formation. With this in mind, we can consider three specific moments of documentation in social action: moments of production, consumption (or use), and circulation.

The production of documents, such as statistical and other reports on crime, health, poverty, and the environment, has figured as an object of study in numerous areas of social science research. The standard research stance is to use such reports as a resource for further study—as, say, a source of data on crime or health. Following the work of ethnomethodologists, however, it is quite clear that documents as reports can also be usefully studied as a “topic.” In the latter frame, the key questions revolve around how reports and accounts of the world are actually assembled by social actors. What kinds of conceptual and technical operations become involved in their production, and what range of assumptions is deployed so as to achieve the end result of a “report”?

Issues concerning the consumption of documents often turn on matters of use and function. In this frame, what is important is a study of the manner in which people use written (and nonwritten) traces to facilitate or manage features of social organization—whether they be transitory episodes of interaction or the ongoing functioning of a hospital, a business, or a school. For example, in the field of medical sociology, there have been numerous studies directed at showing the ways in which patient identities and diagnoses are often shored up through the use of written traces in medical “charts” and patient files. The creation of identity through documentation is also something that has figured prominently in the wider history of qualitative social science.

Figure 1 Email Contacts Among General Practitioners in South Wales in 1999

Note: The trace of the documents outlines a network.

In the circulation or exchange of documents, whether they be greeting cards, memos, or business files, it is possible to see the development of social networks and the emergence of identifiable human groupings. For example, studies of citations in scientific papers have been used to identify patterns of interaction (at least at the intellectual level) between groups of scientists. Similar work using web-crawlers has been used by information scientists to identify emergent research networks in specific scientific fields. By implication, it is conceivable that a sociological study of e-mail contacts and text messaging contacts among the ordinary public may also demonstrate how the exchange of text and documentation functions to both define and to cement social groupings (Figure 1). It is, above all, in this context—and in the light of actor–network theory—that documents may be conceptualized as actors in their own right, shaping and channeling forms of interaction every bit as much as do humans. Indeed, actor–network theory, commonly associated with the work of sociologists such as Michel Callon and John Law, essentially argues that the networks of action that arise in everyday life cannot be reduced to purely social relations, for “things” (e.g., documents, machines, chemical compounds, currency) invariably function as intermediaries between humans. As such, the task of the sociologist is to understand and determine how things, as well as people, “act” through the network.

DOCUMENTS

A document is a text-based file that may include primary data (collected by the researcher) or secondary data (collected and archived or published by others) as well as photographs, charts, and other visual materials. Documents constitute the basis for most qualitative research. Primary data documents (PDDs) include transcriptions of interviews; participant observation fieldnotes; photographs of field situations taken by the researcher as records of specific activities, rituals, and personas (with associated locational and descriptive data); and maps and diagrams drawn by the researcher or by field assistants or participants in a study (with accompanying explanations). These documents are filed systematically so that they can be readily recovered for classification, coding, and analysis. Most PDD archiving systems are computerized, although hard copies of materials also are kept. Researchers should choose data management programs that allow for inclusion and coding of most types of PDDs.

Secondary data documents (SDDs) are materials that are important in describing the historical background and current situation in a community or country where the research is being conducted. They include maps, demographic data, measures of disparity in health or educational status (records of differences in types of surgery, disease distribution, graduation rates, etc.), and de-identified quantitative databases that include variables of interest to the researcher. Some forms of research, such as studies based on spatial data, rely primarily on SDDs or secondary databases, which must then be integrated and overlaid in geographic information system (GIS) software to display hypothesized differences in the distribution of

variables in space. Historical research also depends heavily or entirely on SDDs. Other types of qualitative studies, however, do not depend solely on SDDs.

Certain types of SDDs can be very helpful at the start of a study. For example, obtaining well-drawn or digitized maps of a study community early in a study can assist in the development of study samples and can provide the basis for orienting the researcher in space. Censuses, other national surveys, and/or local educational or health databases can be used to explore hypothetical linkages among study domains prior to the collection of additional qualitative data and can provide guidance in formulating in-depth interview questions. Archived photographs can be important in illustrating changes in built environment or life conditions.

Acquiring and preparing SDDs for use in a study requires considerable time, patience, and communication/negotiation skills. Although national or other secondary data sets are easily obtained, they may be large and need considerable manipulation, including the formation of new variables relevant to the study. Obtaining medical or educational records is subject to local and national regulations and may also require participant permission. Historical documents and photographs may be properly archived in libraries or museums or may be stored in basements or other “unofficial” places, and both personal and professional relationships may be required to access them. Unlike other types of SDDs, these materials may be considered as important cultural capital, and care must be taken in negotiating how they are represented to the public.

DRAMATURGY

Dramaturgy refers to a specific approach to the understanding of social interaction put forward by Erving Goffman. This approach, rooted within the traditions

of symbolic interactionism, focuses on actors' performance of everyday social activities. A dramaturgical approach to understanding social interaction embraces the Shakespearian notion that "all the world's a stage, and all the men and women merely players." From this standpoint, people can be seen to actively manage their social performances to construct impressions and evoke desired responses in their audience.

Continuing the theatrical analogy, performances are given on the frontstage, whereas rehearsals, costume choice, and scripts are managed backstage away from the audience's view. As such, rather than presenting the unproblematic view of social interaction put forward by traditional symbolic interactionists, dramaturgists propose that social interactions can be calculated, manipulative, and open to audience skepticism. When an unconvincing performance is given (e.g., by not looking the part, by using inappropriate language), an actor's frontstage character is betrayed and embarrassment or exposure as a fraud ensues. Thus, the actor's desired audience response is also in jeopardy.

An example of an unconvincing performance may be a clean-shaven man in a business suit begging for money on the street. His costume, script, and performance do not make sense to the audience; therefore, he may be unsuccessful in eliciting the desired audience response. However, dramaturgists would argue that social behaviors that appear to be unconvincing from one social position may be entirely convincing when viewed from an alternate position. The businessman may be begging for money because his wallet was stolen and he needs change to make a phone call. When the audience has access to the social context in which to view the performance, the subtext of the performance can be better understood. As such, it is often the actor's job, as part of his or her performance, to make this social context explicit, for example, by the businessman stating to each passerby, "I've been robbed—can you give me change for a phone call?" Of critical importance are the social norms that underpin the context in which the actor's performance occurs. It is most relevant to examine why the businessman must note that he has been robbed and to document the social norms governing why this tactic will enhance the success of his performance.

Although Goffman's dramaturgical approach provides a useful approach with which to understand social interaction, it falls short of providing an explicit method for documenting and appraising social performance. Dramaturgical analysis relies on actual social

interaction, and observation, interviews, and naturally occurring talk are the most useful kinds. Dramaturgy can be applied to a wide variety of social interactions—from micro-level encounters, to group interaction, to roles within institutions. Each level of interaction remains underpinned by social norms and conventions that outline which types of performances will be successful within a particular social context.

DUOETHNOGRAPHY

Duoethnography is a relatively new research genre that has its genealogy embedded in two narrative research traditions: storytelling and William Pinar's concept of "currere." Its approach is to study how two or more individuals give similar and different meanings to a common phenomenon as it was experienced throughout their lives. Created by Rick Sawyer and Joe Norris, duoethnography avoids the hegemonic style of the meta-narrative found in autoethnography by critically juxtaposing the stories of two or more disparate individuals who experience a similar phenomenon. Like *currere*, which conceptualizes one's history as a composite of learning experiences and thus makes it an informal curriculum, duoethnography examines how individuals have acquired beliefs that influence their actions and the meanings they give them. Norris uses *currere* to assist graduate students in examining their life histories to determine how their curriculum of a concept, such as beauty, size, what to fear, quality, or life/death, influences their beliefs and behaviors. Andrew Foran used the framework in his dissertation, *Teaching Outside the School: A Phenomenological Inquiry*, to examine how attitudes toward the outdoors are taught and learned. Whereas

Differences in Researchers/Writers in Duoethnography

Whereas most of duoethnography is written as dialogue, this excerpt demonstrates how differences in researchers/writers broaden the landscape of the research.

For Joe, a heterosexual male, it is a present absence perspective. He was initially taught that homosexuality was a shame, a disease, a sin. Slowly, through experience, he came to see beyond his initial curriculum as he met those who identify with the orientation. He began to know them as individuals as lost and found in life as he and believed that their choice of sexual partner(s) was as legitimate as his.

For Rick, his *currere*, or curriculum of life, was occasionally an absent presence in the formal curriculum in the classroom but always close and personal in the hidden curriculum. As with many marginalized groups, this aspect of his identity played out on different levels in school. A hidden minority member, Rick learned early to use a dual lens when confronted with dissonance between perceptions of self and school. This lens included both an insider's and an outsider's view.

Source: Sawyer, R., & Norris, J. (2004). Null and hidden curricula of sexual orientation: A dialogue on the *curreres* of the absent presence and the present absence. In L. Coia, M. Birch, N. J. Brooks, E. Heilman, S. Mayer, A. Mountain, & P. Pritchard (Eds.), *Democratic responses in an era of standardization* (pp. 139–159). Troy, NY: Educators International Press.

currere examines an individual's perspective on a concept, duoethnography extends *currere* by employing multiple voices in dialogue. Its purpose is to explore how the life histories of different individuals affect the meanings they give to experiences.

The investigation is loosely based on Maurice Merleau-Ponty's belief that consciousness and culture influence experience and that experiences are always mediated by the meanings given to past experiences. Duoethnography is an examination of the process through which individuals make meaning out of a particular phenomenon. Pinar claimed that *currere* is a regressive, progressive, analytical, and syncretical process with the aim of reconceptualizing oneself and the world in which one lives and that duoethnography employs these elements. Duoethnography not only reports the participants' stories but also interrogates them in a collegial conversation.

Each author of a duoethnographic piece is both the researcher and the researched. The team employs storytelling to simultaneously generate, interpret, and articulate data. Stories beget stories and—like interview questions—the stories enable the research-writing partners to recall other past events that they might not have remembered on their own. Their stories weave back and forth in juxtaposition to one another, creating a third space between the two into which readers may insert their own stories. Tom Barone claimed that a story acts as an evoker of the meanings of others, enabling readers to both recall and reexamine their own experiences of the phenomenon in the light of the written discussion. Duoethnography, as Norman Denzin suggested about all qualitative research, has a pedagogic element. Readers witness the authors in conversation with one another as the writers analyze both their own meanings and their partners' meanings. This dialogic element models analytic reflection to readers, inviting them to engage in the conversation and teaching them the act of self-interrogation. Unlike Clifford Geertz's concept of "bracketing out," Norris and Sawyer considered the personal to be essential and called for a "bracketing in."

But this does not mean that duoethnography is egocentric. Antoinette Oberg encourages autoethnographers to situate themselves within their research as the sites—not the topics—of their research. Following Oberg's suggestion, duoethnography explores the informal and formal curriculum of a topic focusing not on the individuals themselves but rather on their experiences of a phenomenon. For example, the phenomenon of beauty is examined through the individuals' experiences. The participants are the sites, but the concept of beauty and how it is made manifest in society and within individuals is the topic. Its aim is to provide multiple stories that intersect and, at times, contradict one another. The monologue in autoethnography becomes dialogue in duoethnography, extending the text beyond one individual's perspective.

Examples of Duoethnography

Sawyer and Norris, a gay male and a straight male, examined their own personal curricula of sexual orientation. They discussed how their views toward homosexuality changed through life experiences and conversed over how their upbringings influenced their behaviors. It is a sociological study as well as an

autobiographical study. Darren Lund and Rachel Evans, a straight male and a queer female, also examined sexual orientation through their political involvement in a small town. They weaved in aspects of their personal lives as they explored their own curricula of sexual orientation. Jim Greenlaw and Joe Norris, one an avid reader and one not, examined their encounters with creative writing. One found reading and writing to be a painful and lonely experience, whereas the other thoroughly enjoyed it. They showed multiple pathways to finding the creative spirit that elicits voice for themselves and their students. Donna Krammer and Rosemarie Mangiardi interrogated the process of schooling through the concept of the "hidden curriculum" of meritocracy, relating how the system teaches alienation and shame. Others also have shown interest in the methodology. Rick Berault has examined the currere of male elementary teachers, and Nancy Rankie Shelton and Morna McDermott have explored their learned concepts of beauty.

Basic Tenets of Duoethnography

As duoethnography develops, basic tenets and approaches that frame the method have emerged. The first is that the methodology must remain open to avoid becoming prescriptive. As John Dewey stated in 1934, "If the artist does not perfect a new vision in his process of doing, he acts mechanically and repeats some old model fixed like a blueprint in his mind" (p. 54). Although Sawyer and Norris initiated this methodology, they laid no claim of proprietorship. Each group of researchers can and will adapt the method to their unique circumstances using the basic tenets as a guide. The aim of duoethnography is to promote and articulate research conversations in dialogue. Making it overly prescriptive is antithetical to its dialogic nature.

The second tenet is that each individual voice is made explicit. Most of the text is written as a conversation and like a play script, so readers can distinguish who is writing what. Readers witness the two or more individuals in a quest for understanding self and others as they compare their experiences with one another. The aim is not to reduce a concept to universal statements gleaned from the conversation; rather, the conversations present both thesis and antithesis, enabling readers to form their own synthesis. The format of distinguishing individual voices makes this possible.

Building on this, a third tenet is that a change of perspective is central to the methodology. Emphasis is on the quest or questioning; it is not on uncovering meanings but rather on creating and transforming them. Once trust is established between the researchers/writers, this becomes possible. Throughout the conversation, one or more of the researchers/writers may change their opinions and add to or discount parts of their original stories; the researchers/writers are open to (re)storying their own lives. These emergent changes are not edited out to create a conclusive text; rather, they are made explicit to readers who witness these emergent changes in the individuals as they converse with one another. Emmanuel Levinas claimed that we need the other so as to understand the self. Self, then, is defined not as a fixed entity but rather as a fluid one. Readers will witness an emergent and organic progression of meaning-making. Such writing invites readers into the conversation.

Caution is taken by the researchers/writers not to situate themselves as either the hero or the victim. These positions tend to polarize and fix the storyteller. Placing self in one of these roles reaffirms a preestablished meaning. In conversation with one's research partner(s), these meanings can be challenged and transformed. Readers should witness the researchers/writers searching for meanings rather than preaching preestablished ones. The methodology is underpinned with the belief that individual perspectives are socially constructed. Hero or victim sagas tend to be positivist and not receptive to change.

The fourth tenet purports that differences between the researchers'/writers' points of view are a strength. Because duoethnography is not looking for universals but rather examines how different individuals give both similar and different meanings to a shared phenomenon, it looks to the margins to create a range of meanings. The gay/straight difference between Sawyer and Norris and the different attitudes of reading and writing between Norris and Greenlaw increased the range of perspectives, making such differences a strength. The quest for reporting differences between researchers/writers is encouraged; however, similarities are not excluded.

In summary, duoethnography is a literary style that provides stories of insights containing theses and antitheses of two or more individuals between which readers can form their own synthesis. It is a dialogic approach to meaning construction.

Methodological Approaches

To date, two methodological approaches have assisted in the development of duoethnography. One approach is the integration of data collection and analysis processes within the writing itself. The storytelling (collection) and discussion (analysis) are part of the writing process, not discrete phases. The rigor rests with the many revisions during which each partner contributes to the analysis of the other's thoughts and adds additional stories.

The second approach is a review of scrapbooks, photo albums, report cards, saved letters, and/or other memorabilia that can be strong memory prompts. Writers are encouraged to reexamine their entire life histories as evoked by such artifacts. Sawyer and Norris included pictures of friends, schools, work, and historical sites in their telling of the curriculum of sexual orientation. These assisted in both memory recall and the style of narrative presentation.

E

ECOLOGICAL RESEARCH

Researchers who describe their research as “ecological” generally share two interests. One is a concern for the environment, the relation of the environment to humans, and the impact humans have on environmental health and sustainability. A second commonality stems from the belief that the phenomenon of interest needs to be understood in context; that is, in relation to other actors, events, practices, and policies within the local and global settings where it occurs. In this way, the methodology claims to be nonreductionist and founded on the theories and philosophies of ecosystems, cybernetics, chaos, and complexity. For many researchers, ecological research is inherently critical of the dominant Western materialistic ethos. Its critical perspective derives from concerns for the well-being of future generations, a stance of stewardship for the earth, and the relationship of humans with all living things.

The past few decades have reflected considerable interest in ecological research by natural and social scientists, philosophers, and educators, especially those wishing to understand environmental problems, human learning, and societal change through interdisciplinary and transdisciplinary approaches. However, not all researchers are referring to the same thing. As a methodology, ecological research can vary depending on the intents and purposes of the research and the theoretical and conceptual frameworks used. This entry reviews four different types of ecological research and also describes research methods used in this field.

Types of Ecological Research

Ecological research can refer to several types of research, including research that is done from a worldview emphasizing the interrelatedness of all forms of life, research that integrates ecology with the social sciences, research that focuses on a philosophical understanding, and research that focuses on an understanding human knowing, learning, and action as they occur in particular settings.

The Ecological Worldview

One type of ecological research embodies a particular worldview, also described as research from an ecological perspective. The worldview is nonreductionist, refusing to separate the focus of inquiry from its context, and is concerned with the way in which the object or event is embedded in and reciprocally related with natural and social environments. Researchers value all living things and consider humans to be only one part of the large integrated web of life.

This type of ecological research seeks to understand complexity and the emergent nature of knowledge and how this relates to the well-being of future generations. The research is driven by the belief that humans can learn from the study of ecosystems that are sustainable communities of plants, animals, and small organisms. The promise is that by understanding the principles of organization of ecological communities, humans can revitalize their social and cultural communities based on ecological principles. The basic principles of ecology are both descriptive and normative. First, interdependence suggests the mutual reliance of all living things on

each other through nonlinear networks of feedback and cycles. Second, cycles are the essential nature of ecological processes. Third, interdependencies are marked by cooperation, partnership, and co-evolution—processes of change and learning. Fourth, flexibility enables a system to adapt to change and maintain itself. Fifth, diversity within a system enables resilience through a complex network that adapts to change more easily.

The main concepts in this type of ecological research are chaotic attractors, fractals, dissipative structures, self-organization, and autopoietic networks. Chaotic attractors enable patterns or shapes to form, representing seemingly random data or repeating patterns that are never identical. Fractals refer to shapes that occur in nature when the whole is constituted by repetitions of the part. Dissipative structures demonstrate characteristics of nonequilibrium, nonlinearity, instability, and indeterminacy—characteristics of all living systems. Self-organization refers to the emergence of new structures and modes of behavior in open systems characterized by nonequilibrium and nonlinear patterns. Autopoiesis refers to the life of living systems and the processes through which they make themselves from their different components and at the same time produce those components.

Interdisciplinary and Transdisciplinary Research

A second type of ecological research is inter- and transdisciplinary; for example, involving both ecology and social science researchers. This research seeks to understand the interrelationship between natural ecological systems and society so as to create solutions to current sustainability problems. This research can be identified in the community of researchers whose writing appears in the journal *Ecology and Society*. Their work applies ecological perspectives to research projects and seeks to formulate long-term socioecological research strategies essential to building a new sustainability science. Although they borrow and adapt concepts from the ecological perspective outlined in the previous section, their interest is in producing knowledge to solve current sustainability problems. Their interests are in investigating the state of the environment and changes in natural ecosystems as well as the effects of ecological change on society. Furthermore, they are interested in creating solutions to the problems investigated.

Within this research approach, four themes (metabolism, land use, governance, and communication) and

three meta-principles (design, socioecological transitions, and research process and participants) are considered as essential to an operational model of society–nature interaction. Metabolism recognizes processes of production, reproduction, and consumption and is measured through stocks and flows of materials and energy. Land use encompasses the social and economic histories of a region, the changes in biophysical conditions, and the consideration of drivers affecting these changes over time. Inquiry into governance focuses on discrepancies between policies and actual practices through a focus on local actors. Communication encompasses the investigation of discourses, knowledge formation, and communication through critical analysis and through the participation and communication of stakeholder groups. The latter recognizes that research has a responsibility to inform those who will be affected by an environmental problem and to participate with them in bridging gaps between stakeholder perspectives and influencing the future.

The meta-principle of design calls for inquiry that focuses on the interaction of processes in social and natural systems, a process of co-evolution of two structurally coupled systems. The meta-principle of socioecological transitions locates inquiry in the present and past, particularly in the intertwined changes in the relationships of society and nature. The meta-principle of research process and participants calls for research that is a transdisciplinary endeavor; that is, an endeavor that involves researchers trained in different disciplines and a self-reflective process that considers the perspectives and dominant narratives of researchers, citizens, and managers.

This socioecological research is not to be confused with the social ecology of Murray Bookchin that is considered to be a radical view of ecology and social/political systems. It explores the contradiction between competitive society and the natural world so as to change both economic relations and the cultural, ethical, aesthetic, personal, and psychological areas of inquiry—an anticapitalist standpoint. Bookchin did elaborate the notion of thinking ecologically, and this is further developed in a third type of ecological research current today.

The Search for Philosophical Understanding

The third type of ecological research is constituted by the search for philosophical understanding. This research critiques the preceding types of research and

conceptual work and seeks a more defensible conceptualization of ecology on which to ground research, learning, practices, and policies. These writers critique the worldview type of research described earlier for modeling humans and human social systems on mechanistic reductionist theories borrowed from the natural sciences and mathematical modeling. In addition, they accuse the worldview researchers of ignoring axiology that they claim needs to be restored to ecological thought. The philosophical writers develop the concept of ecological thinking to construct a foundation for an ecological worldview. They use dialectical logic to capture the tension and dynamic between the human and nonhuman natures. They argue that humans are not equal to all other living creatures because of humans' ability to conceptualize, reason morally, and empathize deeply with all living forms. Different ways of knowing are considered to be different modes of attuning to the world. Humans are regarded as loci of valuing activity, with an obligation to respect and protect the conatus (conditions of freedom in nonhuman nature) and a responsibility toward nonhuman nature. Research in this perspective is a kind of eclectic art employing multiple perspectives, insights, and analyses to arrive at a coherent grasping of the world.

Understanding Human Knowing, Learning, and Action

A fourth type of ecological research is focused on the search for understanding human knowing, learning, and action in particular settings; for example, in education, health, economics, and psychology. These researchers, whose work appears frequently in the *Journal of Learning Sciences* and *Educational Researcher*, draw on concepts from theories of complexity, situated learning, and ecology with the purpose of creating an ecological theory of knowing. Concepts central to this effort include affordance networks, lifeworlds, and effectivity sets. Affordance networks designate the possibility for action and may encompass information, material, or people that can be activated in reaching a particular goal. Lifeworld refers to an individual's environment that contains current intentions and goals. Effectivity set refers to actions an individual takes in creating and activating an affordance network. Knowing is conceptualized as an activity, achieved in a context or setting by engaging in meaningful actions or practices in that environment.

Other Perspectives

These four types of ecological research represent the dominant arenas of the current burgeoning interest in ecological research. Beyond these, other uses can be found in many disciplines and practice fields. Researchers who identify with disciplines of community sociology or environmental sociology are also working from ecological perspectives to understand the relationship between humans in social communities and between humans and the biophysical environment. Researchers of social work practice have conceptualized a human development–ecological framework to study the ways in which people shape and are shaped within historical and cultural systems that are complex and dynamic and that involve sociological, psychological, and biological personal systems. Anthropologists are employing ecological perspectives in inquiry into current and past cultures. Human ecology is a diverse field with the primary interest of understanding the interrelationships between people and their environments. It employs ecological perspectives and draws the foci for inquiry from fields ranging from home economics, to landscape architecture, to geography.

Research Methods

The methods used by ecological researchers are eclectic, drawn from a range of qualitative and quantitative approaches. Methods of data collection can include interviews, participant observation, and surveys. Data may include archival documents, statistical records, historical artifacts, visual records, and material traces. They may be generated through a range of participatory methods such as dramatizations, focus groups, conversations, group dialogue and decision making, search conferences, journals, and public performances. Strategies of analysis and representation may include comparative case studies, visual representations, public performances, narrative constructions, and event/action modeling.

EDUCATION, QUALITATIVE RESEARCH IN

This entry provides an overview of key topics and methods in education research. The nature of inquiry concerning the use of qualitative research methods continues to evolve over time; for example, from positive to critical theory research paradigms. However, the role of qualitative methods comes in the wider discussion of where methods reside within the educational research process. Methods are used to collect data that have been shaped by literature reviews that ultimately address a research problem. Although the primary focus here is on education, many of these points also apply to other social science disciplines; the entry is written in general terms to apply to these broader contexts as well. First, key topics concerning research process, peer support, and research improving practice are described. Then the qualitative methods of the questionnaire, interviews, and participant observation (three of the most commonly used methods in education research) are examined. Strategy is as important as method within education research because the researcher needs to decide how productively methods can be used within practitioner methodology. The strategies and use of methods discussed in this entry are designed to appeal to a general social science audience and are not geared specifically toward education.

The Importance of Education Policy

Before we examine key topics and qualitative methods, it is important to analyze how the literature in the subject area of education policy connects with qualitative methods and other subject areas. The literature on

education policy is vast, so this entry provides readers with only a taste of what is “out there” within the international literature. Martyn Hammersley examined research and evidence-based practice and drew on the similarities and differences between education and medical research that could shape policy. Peter Baldock and colleagues examined the reflective method when examining “early years” education policy. Marilyn Cochran-Smith called for cross-disciplinary, multiple methods research that can be cross-institutional and longitudinal within policy shaping teacher education. Finally, Les Bell and Howard Stevenson highlighted the importance of case studies and interviews in their policy analysis concerning citizenship and social justice. All of these examples use qualitative methods concerning education policy but can also be applied to other subject areas. All education-related subject areas are vast, but this entry highlights the importance of key elements in the choice of methods (both qualitative and quantitative) and also reviews qualitative methods that can produce data for analysis across many education-related subject boundaries.

The Research Process

The research proposal for students of both university- and outside-funded research is the stage when the education researcher needs to choose what subject category within education is going to be researched. The proposal covers research design and an idea of the research question to be addressed during the research process. Qualitative methods also need to be chosen, and an early idea of an evolving methodology is useful at this stage. Subject category choices (e.g., education, health studies) that concern funded research may be limited due to the demands of a sponsor; however, this discussion focuses on strategic considerations relating to proposals to undergraduate and postgraduate students. A good place for a junior undergraduate researcher to start a piece of education-related research is with a contents page that allows thinking and reflection on the research focus. The aim here is to develop structure and coherence. A research question is important within education research, but a researcher must consider how this will shape the construction of a literature review on the subject in question and the methods that the researcher will use in the field. Qualitative methods need to be chosen at this stage when considering what empirical data to collect, and researchers need to engage with the methods

literature to decide which methods to use in collecting data for analysis. The development of the literature review helps with these decisions. Education studies (e.g., sociology, criminology) is a vast area that encapsulates many different and varied themes. A researcher must decide which specific theme—history, philosophy, policy, sociology, special needs, inclusion, gender, (under)achievement, and so on—to choose. Literature reviews help to make this choice and also assist in the choice of qualitative methods (e.g., can an education researcher use participant observation, interviews, questionnaires, or a combination of all three? Which data presentation and analysis techniques will be used within the research project?).

Making the Right Research Choices: Peer Support

All researchers can benefit from setting up a peer support network because such a network can enhance and develop research processes and also lead to constructive debates when choosing methods and discussing evolving research methodology. Researchers who organize collaboratively and use critical friends when designing research proposals and frameworks, choosing which qualitative methods to use, and collecting, presenting, and analyzing data nearly always produce more coherent research projects and findings. Tutors or supervisors need not be replaced or have their roles redefined; however, a more informal approach of peer networks can increase the understanding of concepts, theories, and qualitative method techniques within the research process at both the undergraduate and postgraduate levels. Although formal support may come from different countries and tutors, groups of education researchers who have come together at times during their master's studies may also gain from that interaction and collaboration. When team and group work are encouraged at the undergraduate level, students can develop and refine skills and techniques that can be useful in qualitative education studies.

Research Improves Practice

Teachers at all levels who conduct research should be encouraged to address issues that they encounter not only in the classroom but also in the school staff room and within senior management teams. Practitioner researchers, not only in educational contexts but also in areas such as health and social work, have a

responsibility to carry out research that uses research methods that focus on elements of practice and make constructive changes that produce positive outcomes. Of course, there are practical restraints that hinder research opportunities (e.g., do practitioners have enough time in the day to carry out action research?). An interesting debate concerns whether findings from action research projects produce “action” that modifies existing practice or “research” that produces practical recommendations but that also adds to existing debates within education research. What needs to be highlighted again is that either practitioner or action research (however the latter concept is defined) can improve classroom, school, and institutional practice. Indeed, if we are to apply the notion of “lifelong learning” to education, this is one way of not only allowing more practitioner research but also retaining colleagues in universities and schools for longer periods. Practitioner research is becoming more visible within many social research areas. However, it is important to consider what opportunities are actually being given to practitioners within the global profession to carry out research on social issues such as gender, class, and social inequality within qualitative education studies.

Choosing a Qualitative Method: The Questionnaire

Many education researchers, especially students and other junior scholars, choose to use a questionnaire because it is believed to be easier to compile and carry out than are many qualitative research methods. This has shaped, and continues to shape, university and funded research projects at all levels. Researchers may prefer a questionnaire because they perceive it as a more efficient and less time-consuming way in which to gather data. All methods are technical in the sense that the more preparation that is put into the design of a research instrument, the more data that can be obtained. But a questionnaire is limited by the number of questions that can be asked, and the questionnaire may fail to provide the researcher with the amount of relevant detail that can be obtained through qualitative methods such as participant observation in the field of education.

The researcher's choice of a questionnaire may indicate a lack of time but also may reflect the reluctance of many researchers to develop relationships in schools or social care units. The choice of a questionnaire may also result from the reluctance of a school

or hospital to provide teachers, doctors, and nurses with sufficient time for research given the demands of their workloads. However, contacting the school and getting permission from senior management, teachers, and parents to distribute a questionnaire are time-consuming for everyone involved. Because access to school and medical environments can be difficult, some researchers use a gatekeeper to gain access to a school. Interestingly, the gatekeeper can be as simple as a family member or friend. But what strategies do practitioner researchers use if they do not have this form of access?

Using time strategically is a crucial issue for all researchers, and more time makes it possible to develop a more coherent approach to the topic of investigation. Therefore, it is important for researchers to use the questionnaire to gather relevant data that test the research question. Students tend to focus on a general topic within questionnaire design, but some neglect the focal question. Questionnaire layout, question ordering, sampling, pilot study, and distribution and return are the main issues in questionnaire design. Creating a pilot questionnaire for a health care worker or criminologist, for example, and giving it to a small sample is a good research strategy. Distributing the questionnaire is perhaps the most interesting issue, with the use of electronic communication to get a questionnaire to a larger sample. This can partly solve the issue of time, or the lack of time, but preparation is still important here. If a student does get access into any institution whereby permission is granted to contact respondents electronically, there is still no guarantee that health care workers, teachers, or administrators will respond because they might not have the time to do so. The questionnaire is still one of the most economical means of obtaining data, and it can be used in conjunction with qualitative methods (e.g., interviews).

Choosing a Qualitative Method: Interviews

Interviews are perhaps the most fashionable and common method of data collection in qualitative methods within education. Time periods are problematic for undergraduate researchers because they not only must organize and carry out interviews but also must transcribe them. Will researchers in social work or health transcribe only the data that will be used for analysis? Typically, the opportunity for one-on-one discussions

with a supervisor arises only after students reach the level of doctoral studies; until that point, they may lack supervisory guidance on methodology, data presentation, and analysis of an interview script. Time constraints hinder, rather than encourage, junior researchers throughout the social sciences to fully transcribe and use all of the data available to them. If they have more time, there are more methodological and data analysis possibilities.

Choosing a Qualitative Method: Participant Observation

A very useful qualitative method within the social sciences (including education) is participant observation. This is perhaps the most productive method practitioner researchers can employ within a number of different environments (e.g., health, social work). Researchers can adopt an observing role in which they take part in activities that they examine. Participation by researchers enables them to record their own perceptions of events, feelings, and thoughts as processes expressed verbally and through actions. This information is a useful complement to the other records of participant perceptions.

Ethical Issues in Qualitative Research

Interesting ethical considerations arise for all practitioner researchers. Anonymity of patients or children can be guaranteed, but permission needs to be obtained from both parents and the institution to carry out the qualitative research. Practitioner preparation begins in the workplace, with the teacher deciding which colleagues can be approached for consultation. Informing senior management within the institution is also an important step not only because institutional or (inter)national ethical guidelines (if any) will need to be followed but also because many researchers will be reporting their findings to these very people, so it is very strategic to get these people involved at the start of the research project for constructive and institutional advice. Senior management can also advise on how to approach parents in asking permission for children to be used within a qualitative project.

Anonymity is not the only ethical issue a qualitative researcher must consider. The sensitive nature of some questions needs to be reflected on and possibly changed during the research process, depending on

the respondent and the nature of the question. The data obtained from the interview need to be analyzed and presented in a professional, agreed-on way. The recommendations taken from the data might be presented to colleagues in oral and written presentations. Practitioner research is about changing practice, but the strategies researchers need to devise outside of the research process can be as complex, and perhaps as important, as changing practice in different social and cultural environments. Effective research employing qualitative methods should produce practical recommendations that build on existing school policies. Researchers technically look for an original angle, and it is important to remember that coherent research findings build on existing practice and that this applies to all practitioner and research environments.

One personal example of participant observation research that comes to mind was how a postgraduate student, in examining special education needs, used participant observation and photographs of a playground not only to gather data but also to show what was going on with children at play as well as playground interactions between children and members of the staff. The student researcher raised an interesting ethical consideration. Would the student be visually showing her respondents' images, and could they be identified? My response was that so long as the student had permission from the school and parents to use the images, it should be fine. One has a moral obligation to those being studied—a responsibility to the participants—and showing the pictures was ethically justified. To justify showing the pictures, the researcher needed to take into account ethical responsibility to the participants in the study. In such cases, it may also be appropriate to ask the children themselves for consent to use the images. In this case, the student moved the images into a data analysis chapter within the dissertation, and I believed this increased understandings of playground interactions in a project concerning special needs. Observations in this case were used to triangulate data obtained from qualitative methods from several schools.

Conclusions

This final section summarizes the most important topics, strategies, and issues in relation to using qualitative methods in education. Research preparation and the constructive and effective choice of qualitative methods are crucial and have shaped what issues and

subjects have been researched in many subject areas. Although time constraints often do not allow researchers the opportunity, having sufficient time can help to cement research design, the research question, the introduction chapter of a thesis, and the choice of which qualitative methods to use in a research project. The research proposal should be completed before the final dissertation begins, and many education undergraduate programs have research modules that focus on qualitative methods and process. Using time strategically means that qualitative research can be more coherent, structured, and even fun. How qualitative methods are used to obtain data to test the research question is also crucial. Choosing methods and creating a methodology are very strategic and are up to the social science researcher. The objective is to use qualitative methods productively. This can produce practical recommendations that not only improve practice but also contribute to ongoing debates within the social sciences and other subject areas (e.g., education, human rights, sociology, citizenship).

EMAIL INTERVIEW

Email interviews emerged during the late 1990s as one of a number of online qualitative methods. Such interviews differ from face-to-face (FTF) interviews because of the features of asynchronicity, reduced cues, and anonymity.

Asynchronous communication allows both the researcher and participants to respond at a time of their choosing rather than in “real time.” They can also respond in a setting of their choice. These factors may suit participants who are marginalized because they cannot attend FTF interviews due to distance, chronic health issues, impairments, work or personal commitments, and/or discomfort with discussing sensitive topics. Asynchronicity allows more time for reflection, and this may produce a richer quality of data. Prolonged engagement is also possible; however the spontaneity of FTF interviews is sacrificed.

The lack of FTF contact in email interviews is referred to as “reduced cues” because the interviewer and participants cannot see or hear each other and the primary mode of communication is text. This feature has been criticized as a threat to rapport, although recent studies have disputed this claim. Nevertheless there is a heavier reliance on the sensitivity and skills of the “researcher as instrument” than there is in FTF interviewing, particularly in relation to vulnerable participants who may need support when discussing sensitive issues. Therefore, ethics review board applications may need to address support options for online participants given that the interviewer is not physically present to respond in the case of participant distress.

In email interviews, lack of FTF contact can provide a sense of anonymity even though recruitment forms, individuals’ email addresses, and/or signatures can provide identifying details. Anonymity may encourage participants to feel more comfortable about self-disclosure and provide a leveling ground for people who may feel stigmatized or inhibited in FTF settings (e.g., people with disabilities). However, anonymity

may encourage false representation, and recruitment procedures may need to address the authenticity of participants.

Technological failure is a common problem with online methods, which may disrupt rapport and affect participant confidence and commitment. Therefore, it is essential that the email interviewer have a level of technical competence to solve potential difficulties.

Email interviews can include persons who may be marginalized from FTF interviews; however, this method has also been criticized as undemocratic due to “digital divide” factors. For example, the cost of internet technology, service provision, and computer maintenance, as well as discomfort with technology due to illiteracy and/or lack of appropriate training, may exclude some individuals from participation. Recruitment procedures need to consider these barriers.

Email interviews can be both economical and time-efficient by reducing travel costs and transcription time (i.e., as email transcripts are copied directly into data files). However, the method can be time-consuming because the frequency of participants’ responses is unpredictable. In addition, data richness may be affected by individuals’ email communication styles (i.e., lengthy prose vs. question-and-answer form). Finally, although some participants may feel more reassured by FTF contact, email interviews are an important adjunct to the range of qualitative interviewing methods.

EMBODIED KNOWLEDGE

Embodied knowledge situates intellectual and theoretical insights within the realm of the material world.

Embodied knowledge is sensory; it highlights smell, touch, and taste as well as more commonly noted sights and sounds. Knowledge grounded in bodily experience encompasses uncertainty, ambiguity, and messiness in everyday life, eschewing sanitized detached measurement of discrete variables. Such an epistemology, or way of knowing, resists the Cartesian mind–body split that underlies Enlightenment philosophy and its persistent remnants, including the scientific method and the glorification of objectivity. Embodied knowledge is inherently and unapologetically subjective, celebrating—rather than glossing over—the complexities of knowledge production. Fieldwork, interviewing, writing, and other qualitative methods involve embodied practices performed by actors occupying specific standpoints or positions within cultures. The researcher’s body—where it is positioned, what it looks like, what social groups or classifications it is perceived as belonging to—matters deeply in knowledge formation.

The normative erasure of researchers’ and participants’ bodies from conventional disembodied accounts of qualitative research yields deceptively tidy accounts of data gathering and analysis. Research reports typically follow strictly scientific conventions that obscure the author’s agency via passive voice (e.g., “data were collected . . .”) or represent a sanitized “I” that reports completed actions without any thick description of the bodies involved. The resulting invisibility of bodies in accounts of qualitative research shapes our understanding of interaction and meaning-making in real-world contexts. Feminist researchers contend that such writing conventions reaffirm the mind–body split and the association of males and masculinity with mind and the association of females and femininity with body. Western cultures deeply privilege the mind over the body, positing a sharp distinction between mind, equated with self, and body, the (potentially unruly) property of the (higher) mind. An alternative perspective blurs the boundary between the mind and body. For Trinh Min-ha, the body is not a possession of higher mind to be manipulated and controlled; rather, the body and self are one, and that one generates inherently embodied knowledge. With the “narrative turn” in social sciences, health, and education, positivist assumptions about objectivity have been decentered in favor of realistic positioning of scholars as imperfect, embodied social actors. Edited collections and journals that focus on interpretive methodology, such as *Qualitative Inquiry* and *Journal of Contemporary*

Ethnography, publish embodied knowledge in narrative and interpretive research, reflecting what sociologist Laurel Richardson called “creative analytic practices.” Rather than apologizing for subjectivity or simply stating one’s “biases,” qualitative researchers can generate rich accounts of embodied knowledge both through using creative forms of representation, such as narratives, poetry, and autoethnography, and by including thick description of bodily experience in mainstream research reports.

EMERGENT DESIGN

Emergent design involves data collection and analysis procedures that can evolve over the course of a research project in response to what is learned in the earlier parts of the study. In particular, if the research questions and goals change in response to new information and insights, then the research design may need to change accordingly. This flexible approach to data collection and analysis allows for ongoing changes in the research design as a function of both what has been learned so far and the further goals of the study. Within the broader framework of qualitative research, emergent design procedures are closely associated with the broad goal of induction because success in generating theories and hypotheses often depends on a flexible use of research methods.

An emphasis on emergent design marks an important difference between most approaches to qualitative research and those to quantitative research. In particular, quantitative research is typically based on a fixed set of stages, starting with research design decisions that specify a set of predetermined data collection procedures that must be completed before data analysis can begin. Thus, survey research cannot redefine its

sample or change its questionnaires midstream, and experimental interventions are equivalently locked into a set of design decisions that cannot be altered during data collection or analysis. In contrast to this “linear” set of well-defined stages, the emergent design approach in qualitative research is often summarized as a circular process. This means that new data are continually being analyzed as they are collected, so that both the research procedures and questions can be adjusted in an iterative fashion in response to what is being learned in the field. Ethnography is a useful illustration of this process because the ongoing analysis of fieldnotes leads to a shifting interpretation of both which issues are relatively well understood and which issues require further observations, so that ethnographers make design decisions—on an almost daily basis—about how to pursue their emerging interpretations.

Despite the importance of emergence in qualitative research, it would not be prudent to overstate the dominance of emergent design. Even the most flexible qualitative study begins with some ideas about what to observe, where to find sources for those data, and how to collect the relevant information. The prior ideas and beliefs that researchers bring to the field are sometimes known as “sensitizing concepts.” Hence, no research design can be fully or completely emergent; instead, emergent design allows for an ongoing reassessment of how to conduct the research based on what has been learned from prior data collection and analysis.

Emergent Aspects of Data Analysis

In comparison with the role of emergent design in data collection, issues related to the emergent aspects of data analysis typically receive more attention due to the heavy reliance on emergent procedures in nearly every form of qualitative analysis (with the notable exception of forms of content analysis that are based on predefined codebooks). In particular, many forms of qualitative analysis move from an initial stage of relatively descriptive or open coding to the creation of a broader set of emergent themes and concepts that then become the basic elements in the process of theory creation. This process of abstraction by moving from raw data to theorized conclusions is a central aspect of the link between emergent procedures and induction. Because the connection between emergence and induction is widely discussed within the literature on qualitative analysis, most of this entry concentrates on issues

related to data collection, where emergence receives less explicit attention. There is, however, at least one aspect of analysis and emergence that deserves more attention.

Although some qualitative studies appear to segregate data analysis as a separate task from data collection (e.g., by not starting the formal analysis until “all the data are entered in the computer”), most of those designs still involve an informal process of emergent interpretation that occurs throughout data collection. One way to grasp how deeply qualitative analysis is embedded in the data collection process is to ask the following question: When does the analysis process begin in qualitative research? The most basic answer is that researchers begin their analysis as soon as they learn something that affects their interpretation of the data. For example, the first discussion that a moderator hears in a focus group may either reinforce or challenge existing preconceptions, and the first few days of observing a field site can have the same effect. The emerging interpretations from this “informal analysis” process can affect the data collection itself (e.g., by producing subtle changes in which topics are probed or pursued in which ways). Even more important, the emergent interpretations from informal analysis will inevitably influence what happens during subsequent, more formal analysis activities.

Emergent Aspects of Data Collection

Emergent aspects of data collection focus on two decisions: choices about which data sources to include in the study and about which techniques to use for gathering data from those sources. With regard to the emergent selection of data sources, the best-known approach is the use of theoretical sampling. In this process, the tentative conclusions from ongoing analyses serve as the basis for selecting a new set of data sources according to what would be most useful for either building on or challenging those emerging conclusions. For example, a tentative theory about the experiences of dying patients based primarily on observations from a surgical ward in a hospital might lead to a new set of observations investigating whether the same processes occur during terminal care in a nursing home. Although the term theoretical sampling arose within grounded theory, it is actually a highly general procedure that can be applied to most forms of qualitative research. The broad value of this approach reflects a general connection between theoretical sampling and induction,

whereby new observations are sought as a basis for building on earlier observations and interpretations.

Moving from the evolving selection of data sources to flexible aspects of collecting the data, one key aspect of emergence involves shifts in the topics that the study pursues. This process can move in one of two classic directions: either expanding the research focus to bring newly discovered topics into the study or narrowing the research focus to gain a deeper and more detailed understanding of things that are already part of the study. In the case of discovery, emergent designs become more open and less structured so as to include things that were not anticipated when the study was originally designed, especially in the case of exploratory research. Alternatively, narrowing the focus requires shifting to a more structured pursuit of topics that require more attention than the original design anticipated. Indeed, when qualitative researchers propose an emergent approach to their research design, they often mean that they cannot predict in advance either what new things they might discover or which existing topics might require more thorough attention.

The actual data collection techniques, as well as the topics covered, can also shift and evolve as part of an emergent design. As the previous discussion suggested, this could involve a change toward either a more structured or a less structured approach to data collection depending on the needs arising from the earlier observations and analyses. One common timeline for this kind of emergence begins with a more open-ended approach to data collection that emphasizes the discovery of relevant concepts and experiences. During the next phase, the data collection procedures would be altered to examine those previously discovered issues in more depth and detail. Finally, in an idealized form of this style of research, a highly focused round of data collection would target any topics that were less well understood while also pursuing theoretical insights that emerged from previous analyses.

Designing for Emergence

The importance of emergence as a principle in qualitative research can lead to a questionable claim that it is impossible to design qualitative research because there is no way to know in advance either what will be important or which methods will be most appropriate for studying those emergent topics. One immediate problem with such a claim is that it ignores the researcher's prior ideas and implicit theories about the

subject of the research—a fallacy that is referred to as treating the researcher as a blank slate or *tabula rasa*. One way to avoid this problem is to design for emergence. In particular, the initial research design can make the researcher's assumptions explicit—in the form of tentative statements about what to observe, where to find it, how to elicit it, and so on.

Thesis proposals from graduate students are one common situation where questions about how to design for emergence arise. In this case, there is a tension between a student's desire to pursue an emergent design and faculty members' need to know what the study will be about before they approve it. One solution is a format where the proposal begins with a description of the initial research activities that the student anticipates on entering the field accompanied by descriptions of likely scenarios that might emerge from that initial work as well as statements about how the student would pursue the emergent design in each of those scenarios. This format allows faculty members to approve undertaking independent research that relies on emergence when students demonstrate both a realistic knowledge of the field to be studied and a mastery of the skills that are necessary for research in that setting. In many cases, students will encounter a situation that is close to one of their anticipated scenarios and can proceed as planned; however, there will always be some situations that are well outside the original plans, and the best policy in those cases is to submit a revised proposal based on the newly emergent design.

A different issue in designing for emergence is the possibility of creating research designs that are built around the goal of emergence itself. One such design could be based on the three-part data collection timeline described in the previous section—beginning with an exploratory phase, followed by pursuing a more in-depth understanding of the results from the earlier phase, and concluding with targeted data collection that moves the project toward completion. For example, in a project using focus groups, the first round of groups could be a relatively open-ended and unstructured set of discussions that were aimed at learning the participants' perspectives on the research topic. Analysis of those groups would lead to decisions about which participants and topics should be the basis for a second set of groups that would pursue the issues raised earlier. The last set of groups would again consider which data sources and which topics would be most useful, where the goals in this case

would typically be to expand coverage of material that was poorly understood and to enrich the understanding of emergent conclusions from the previous groups. As this example illustrates, it is quite possible to propose a research design that specifies the activities of the research team in some detail while still allowing for a broad process of emergence in selecting both the topics to be investigated and the most appropriate ways to collect data on those topics.

As a final note, it is also important to recognize that the degree of emergence will vary from one qualitative study to another. In particular, for cases where the goals are relatively predetermined, it may well make sense to use a relatively fixed set of procedures to collect the data and then emphasize emergence during data analysis. Because qualitative researchers have a range of options with regard to emergent design, it is important to provide explicit justifications for how any given design meets the needs of a specific project. Ultimately, questions about both the extent of and the nature of emergence in qualitative research designs need to be addressed in terms of the purposes that the research is pursuing.

EMERGENT THEMES

Emergent themes are a basic building block of inductive approaches to qualitative social science research and are derived from the lifeworlds of research participants through the process of coding. Inductive approaches exist within positivist, postpositivist, and

social constructionist paradigms. Some qualitative researchers believe that emergent themes are part of the process that leads to generalizable theories of human society, whereas others use emergent themes to provide rich and detailed insight into the micro and meso levels of intersubjective experience. Themes emerge from the close analysis of any data source, including fieldnotes, ethnographic and reflective memos, interview transcripts, and various print, visual, and digital media.

To prepare to develop themes from research data, researchers often start by engaging with the data through interactive reading, which facilitates the analysts' connection with the data. An accompanying practice is memo writing, which may range from personal notes, to methodological observations, to analytic formulations, with their main purpose being to enrich subsequent analysis. Another practice involves a process of abstraction—creating categories from the complexity of the data. Researchers should avoid the temptation of forcing preestablished distinctions onto the data. Emergent themes must be grounded both empirically (in the data) and conceptually (linked to the wider analytic context).

The actual process of theming entails a bit-by-bit or line-by-line coding. As analysts group bits of data, they need to be “attentive” enough to allow redefinition, reduction, subdivision, or expansion of themes as the analysis proceeds. Emergent theming formalizes analytic connections among pieces of data but does not constitute the end of analysis. Having identified themes, analysts then must assemble them to establish substantive connections. Looking for patterns in the data, identifying regularities or irregularities, constitutes an important activity in making substantial connections.

Grounded theory, in both its positivist formulations (e.g., work by Barney Glaser and Anselm Strauss) and its constructivist reframing (e.g., work by Kathy Charmaz), is strongly committed to inductive analysis and emergent themes. Grounded theory encompasses a core set of analytic strategies beginning with open coding and followed by an iterative process between theoretical sampling and constant comparison of data among and within emergent categories. The goal is to reach saturation, a point at which no further insight can be gained through additional data analysis. Researchers engage in writing memos to explore emerging theoretical ideas that will facilitate the development of themes (also called conceptual models). There is disagreement as to the role of theoretical influence prior to the research process. In the strictest sense, themes may

emerge from data regardless of researchers' theoretical biases so long as a grounded theory methodology is adhered to rigidly. This position has been critiqued by constructivist scholars who argue that theoretical bias is inevitable and, therefore, must be considered as themes are developed.

EMIC/ETIC DISTINCTION

An emic perspective is the insider's view of reality. It is one of the principal concepts guiding qualitative research. An emic perspective is fundamental to understanding how people perceive the world around them. Qualitative researchers often begin by asking people open-ended questions about how things work from their perspective. This allows an individual to frame the concept, idea, or situation and then elaborate on it. This provides a more accurate depiction of the individual's "mental map" or cultural understanding. This can be followed up with more fine-grained questions for additional depth and questionnaires to help determine how representative the viewpoint is in the culture. An emic perspective is grounded in a phenomenological view of the universe in comparison with an a priori set of assumptions about what people think and why they act the way they do. Adopting an emic perspective allows for "multiple" realities depending on the role and/or perspective of the individual in the community. An individual's view of the world might not conform with "objective" reality. However, there are real-world consequences for people's perceptions of reality, shaping how they behave in social situations ranging from their families to communities-at-large. Moreover, the validity of an emic construct is based on the native

informant's or community member's views, not on the external social scientist's views. Emic perceptions are shared views of cultural knowledge from the insider's "normative" perspective.

An etic perspective is the external social scientific perspective on reality. The validity of etic descriptions or analyses is based on logical scientific analysis. Etic descriptions or analyses conform with rules of science, including falsifiability, logical consistency, and replicability (when possible and appropriate). Most qualitative researchers start collecting data from the emic or insider's perspective and then try to make sense of what they have collected in terms of both the native's view and their own scientific analysis. An external view without an emic or external foundation is unusual and is uncharacteristic of qualitative work. The etic perspective is typically adopted after multiple, and often conflicting, emic or insider views are collected. The etic view involves stepping back from the insider's views in an attempt to explain how groups are communicating or miscommunicating. Etic knowledge is the foundation of most cross-cultural work, often referred to as ethnology.

EMOTIONS IN QUALITATIVE RESEARCH

Contemporary researchers have transformed the place of emotions in qualitative research. Emotions no longer receive short shrift as subjects of research, and many qualitative researchers now recognize that emotions

provide critical resources for data collection and analysis. In the past, positivist researchers eschewed emotions, considering them to be emblematic of the irrational volatility of humans and, therefore, inappropriate for social scientific research. In addition, most researchers attempted to set aside or ignore their own emotional responses so as to emulate the professional ideal of affective neutrality.

Qualitative researchers have historically contended with the criticism that their ongoing and frequently close involvements with research participants render their studies unscientific and subjectively biased, as if the lack of social contact with participants—common in quantitative research—automatically yields objectivity. Due largely to the efforts of qualitative researchers who examined participants' situated emotions and realized their significance for understanding interaction, emotions gradually drew attention as research-worthy phenomena. And with this shift, some field researchers realized, by extension, that rather than strive to erase evidence of their emotional involvement in their work, they could turn their emotional responses into a source of data that would help them to gain a greater understanding of their research participants and the research process itself. Paying greater attention to their emotions by incorporating them into their data ultimately permits qualitative researchers to analyze their subjective responses and unpack the assumptions they carry rather than ignore emotions and pretend that they have no impact on researchers' findings.

Qualitative Studies of Emotions

Qualitative researchers have contributed greatly to our understanding of emotions. The concept of “emotion management,” which captures how people try to change, suppress, or evince feelings or expressions in themselves or others, applies to a wide variety of populations and research settings, no matter the size of the group or its levels of interaction. Perhaps most well known is Arlie Russell Hochschild's study of flight attendants and their required—but unpaid—emotional labor. Hochschild's findings inspired a proliferation of studies that track what happens to workers who attempt to manage their emotions under challenging working conditions (often in professional and service occupations).

Through a variety of techniques, qualitative researchers have provided valuable information on

emotions such as fear, anger, shame, sadness, grief, love, desire, sympathy, excitement, suspicion, aggression, frustration, and boredom. Qualitative researchers have contributed greatly to our understanding of how emotions are socially constructed by examining how emotional experiences and the meanings attached to them may vary widely across different cultures and subcultures. They have clarified how the expression, or display, of emotions carries different meanings based on individuals' social statuses and the definitions of the situations in which they interact. For example, qualitative researchers have observed that when someone with high social status (e.g., privileged by sex, class, or race) expresses anger, others may respond as if that anger has a greater intensity and impact than when someone with lower status expresses anger. Someone with high social status may also enjoy immunity from the emotional demands of subordinates. Consequently, emotional privileges accompany the invisible privileges and unearned social rewards that benefit members of high-status groups.

Another important way in which qualitative researchers have learned more about emotions in the course of their investigations comes from their focus on how people learn to be members of social groups. Not only do new members learn what groups define as normative behavior, but they also must learn to feel and express themselves emotionally in ways that other group members expect, understand, and respect. Studies of “emotional socialization”—how people of all ages are taught and learn the “emotion norms” that help them to perform roles and take on new identities and social statuses—add greatly to our understanding of emotions in social life. Qualitative research efforts to track how participants' emotions change over time, and with what consequences, have yielded a greater appreciation for how people come to join, sustain, and leave intimate relationships, therapeutic settings, self-help groups, jobs, subcultures, and social movements.

Emotions as Tools for Qualitative Research

Through their innovative efforts to understand the emotional worlds of others, researchers gained a vocabulary of emotions that could be applied to their feelings about their research and those they researched. Because qualitative methods are predominantly interactive, some researchers realized that their emotional responses to participants—and to

themselves—offered valuable data on the social conditions that help to shape emotions and social life more generally. Analyzing those emotional responses yields both methodological and theoretical benefits.

Treating researchers' emotions as data takes several forms. In some cases, when researchers wonder how a situation or procedure actually makes people feel, they can put themselves in that situation and record the results by taking reflexive notes about what they experience. Sue Estroff famously ingested psychotropic drugs to understand how such medications made psychiatric clients diagnosed with schizophrenia feel and why taking medicine to treat mental illness seemed to be a more powerful stigma than mental illness itself.

In Candace Clark's study of sympathy, rather than limiting her data collection to observing and interviewing other people about their experiences with sympathy, she also carefully recorded her own emotional reactions to ongoing events, interactions, and personal experiences that might or might not trigger sympathy. She studied cultural and material products, such as fiction, commercial "get well" and condolence cards, and published ethnographies, and she recorded introspective fieldnotes after paying attention to when feelings of sympathy arose, to what degree, under what conditions, and with what characters as well as to when sympathy was withheld.

The greatest potential for collecting in-depth data on researchers' emotions is present in autoethnographic research. Carolyn Ellis demonstrated how researchers who engage in "systematic sociological introspection" could improve their understanding of how people experience and process emotions subjectively in the course of their daily lives. Systematic introspection yields valuable insights into how people experience and interpret their emotions physiologically as a part of their everyday meaning-making. Moreover, it is instrumental for investigating how individuals may experience emotions multiply and sequentially as an intertwined process.

The connection between emotions and qualitative research goes much further than researchers' efforts to introspectively collect information on emotions. Emotions have also proved to be vital to qualitative researchers' attempts to gain approval and entry, maintain rapport and access, and exit research settings when their studies approach completion. For example, the abundant literature on obtaining and maintaining research rapport chronicles the critical importance of role-taking emotions, such as trust and empathy, and the

social conditions that enhance or threaten these feelings. Establishing trust and feeling empathy are not ends in themselves; they serve as tools for discovering how and why participants feel and act toward researchers as they do, how participants regulate group membership, and how participants socialize new members. Empathy, in addition, offers a rich opportunity for researchers to understand how participants feel about a range of shared experiences, from commonplace to extraordinary. However, rather than assuming that they have gained insiders' perspectives by striving to feel exactly what participants feel or by attempting to feel deeply for them, researchers fare better if they make an active effort to gather participants' self-reports, compare them with their own observations and reactions, and then consider what those findings mean.

Emotions also offer clues when researchers' efforts stumble; for example, when potential participants refuse to allow access by acting evasively or even forcefully or, after researchers gain entry, when participants suddenly "clam up," respond angrily, or cancel interviews. Some researchers have been expelled from productive research settings and have seen their requests for further contact be rejected. In such cases, the sources and meanings behind participants' distrust and suspicion deserve careful examination and review, as does these researchers' own sense of disappointment and frustration.

But even if participants gradually warm up to the idea of being studied or if they enthusiastically accept an invitation to be studied, qualitative researchers benefit from cultivating a feeling of skepticism. Deciding whether or not to conduct projects, ask particular questions, explore leads, contact interviewees, uncover contradictions, and check out working hypotheses all are places where skepticism may provide a payoff. A small measure of skepticism may serve researchers well by helping them to avoid jumping to conclusions or forging blindly ahead without considering the consequences.

However, sometimes researchers go beyond cautious skepticism and instead feel deep distrust or dislike toward participants and regard their actions and belief systems as mistaken or harmful. Occasionally field researchers expect at the outset to feel distancing emotions such as disgust and anger, particularly if they study groups whose goals differ radically from their own such as members of right-wing racist or sexist social movements. But other times researchers' dislike of some participants catches researchers by surprise, leading them to worry that they are deficient

researchers because they lack empathy that they think is required for “good” field research. Rather than interpreting a lack of empathy as a research failing (and trying to fake it), qualitative researchers can instead use this absence of emotion as an analytic prod and explore the assumptions that unintentionally guide their research. Likewise, unpleasant emotions such as anger can serve as clues about inequalities that deserve further attention. If researchers’ sense of injustice is provoked while conducting research, that feeling may signal more than empathy for certain participants and antipathy for others. Analyzing the conditions that provoke feelings of injustice and considering alternative conditions that would not trigger the same reaction can help researchers to understand the beliefs, assumptions, and interactions that shape inequalities in participants’ social worlds.

Ultimately, researchers’ emotions can be critical for analyzing data—made easier if researchers record their emotions while collecting data in the first place. Noting how, when, what, for whom, and under what conditions researchers feel particular emotions during their studies can open multiple opportunities for research discovery and sharper analyses. To interpret their emotional responses, researchers should examine the background identities, roles, and political ideologies they bring to their studies. By analyzing how their worldviews may differ from or resemble those of participants and by trying to put those differences or similarities into context—topics that some investigators discuss openly with participants—researchers gain analytic insights relevant to their projects that extend far beyond simple self-awareness.

A final source of emotions data that bears relevance for analysis can be found in how other people react emotionally to the topics and populations researchers study (and how researchers feel as a result). These reactions may mirror how influential outsiders view and constrain participants’ lives—especially when those participants belong to subordinate groups—and so may provide additional clues and questions for researchers to pursue.

By treating participants’, outsiders’, and their own emotions as valuable data from the beginning of a project to its close, qualitative researchers can enrich their research processes and deepen their analytic insights.

EMPATHY

Research with human subjects can often involve conflicting emotional responses on the part of the person conducting research. The researcher, for example, may feel a sense of aversion to what she or he sees and hears. More commonly, however, the researcher may develop a sense of empathy with the research participants that involves feelings of identification with participants’ life problems. When research techniques such as participant observation and other similar qualitative methods are employed, the researcher often attempts to see the world from the participants’ perspective and tries to develop an ability to take the role of the “other.” Such empathetic role-taking between humans suggests that most people have a desire to understand what life is like for those who are different from themselves. Qualitative researchers who employ such methodologies involving interviewing, observation, and ethnography do so to better understand how participants interpret and give meaning to their own experiences. Developing empathy for the social and

personal lives of research participants facilitates a deeper understanding of social life in general.

One of the possible difficulties of developing empathy with the subjects of qualitative research is that one's objectivity may diminish. Rapport with research participants helps to understand their attitudes, feelings, and lived experiences, but it also may lead to overidentification. In anthropology, for example, some researchers have crossed the line of objectivity to the extent that they have chosen to live permanently in their research settings and not return to academic life. Under these sorts of circumstances, the scientific value of their ethnographic research could be lost altogether, especially if they chose not to publish the results of their study. In sum, developing rapport and showing empathy for the subjects of research, usually called "informants" in anthropology, can lead to useful insights into the lived experiences of local peoples, but it can also lead to a diminished objective viewpoint that may hinder placing the results of one's research in a wider context. In fieldwork settings that can be far removed from universities and other centers of scholarly activity, and may involve long periods of isolation for the social scientist, it is important to remember the initial goals and reasons underlying one's research activity so as to maintain a proper perspective.

EMPIRICAL RESEARCH

Empirical research, following the tenets of empiricism, is grounded in the belief that direct observation of phenomena is an appropriate way to measure reality and generate truth about the world. Within the realm of qualitative research, then, empirical research has been redefined to challenge traditional notions of

"truth" and "evidence" while still maintaining the basic premises of acknowledging the materials under study as "empirical." This entry reviews the development of empirical research in the social sciences, describes the role of qualitative methods in the field, and considers ways in which qualitative researchers have sought to redefine rigor and find new criteria for evaluating research.

Empirical Research and Logical Positivism

Empirical research in the social sciences has been shaped by logical positivism, an ontological framework that assumes social phenomena can be studied scientifically when modeled along the objective, experimental, verifiable, and generalizable methods of the natural sciences. The philosophical assumption in positivist research is that of foundationalism—that all knowledge has a secure foundation and that following the right procedures leads us to "truth." From its origins, social science has been enmeshed with the Enlightenment ideas about human reason. From Francis Bacon to David Hume, to Auguste Comte, to Émile Durkheim and several others after that, the focus has been on facts (defined as an observable reality "out there" that is independent of the researcher and that the researcher can capture by being objective and following certain methods) and the causal explanation of facts. Logical positivism insists that value is not a part of science, primarily because it cannot be observed and is not part of an "objective" philosophy. Human subjectivity in knowledge creation is typically sealed off. Only observations are important, and methods are designed to control biases and prejudices. The main goal of this kind of research is to generate universal explanations and predictions of social phenomena. It is assumed that there is always a causal explanation for phenomena. In traditional empirical research, human action is constrained and shaped by factors and forces (including external stimuli) that must be observed correctly and objectively if knowledge is to be created. Positivist and much post-positivist practice defines knowledge as a product of something we use (techne/method).

However, contemporary naturalism accepts that no unequivocal procedures/criteria for choosing among different competing knowledge claims is possible. Also, facts and values are no longer entirely separated, and it is now accepted that observation is theory laden, thereby creating more similarities with the anti-naturalist stand.

Empirical Research Within Qualitative Research

Qualitative methods texts outline various approaches to conducting empirical research within this paradigm. For example, John Creswell outlined five methodological approaches to qualitative empirical research: narrative research, phenomenological research, grounded theory research, ethnographic research, and case study research. Similarly, Norman K. Denzin and Yvonna Lincoln discussed several sources of, and techniques for, gathering empirical data: observation, interviews, analysis of cultural and archival records, visual methods, autoethnography, data management and analysis techniques, computer-assisted analysis, focus groups, applied ethnography, and conversation and cultural analyses. All of these approaches address the central goal of empirical research—to observe phenomena in the social world so as to generate knowledge about these phenomena.

Rigor in Empirical Qualitative Research

Empirical research is based on ideals of credibility, confirmability, and other core tenets of rigor, all of which are interconnected and engaged with the researcher's own objective or subjective stance. In qualitative research, traditional notions of objectivity, reliability, generalizability, and validity (central to rigor in quantitative projects) have been challenged and redefined. Unfortunately, many scholars in the quantitative realm misunderstand the nature of rigor in qualitative research, and this has led several empiricists to question whether qualitative research and qualitative methods can be truly considered “empirical” and, therefore, adequately scientific. What warrants subjectively mediated meanings? This issue is discussed greatly by qualitative empirical researchers, both in defense of their underlying philosophy and in improving their practice of research, by making clear that an “anything goes” approach to knowledge is not acceptable.

Qualitative researchers have proposed several approaches that offer alternative ways of achieving validity. These include contextualized (“thick”) description, catalytic (validity) criteria, and triangulation.

In contextualized thick description (formulated mainly along Clifford Geertz's ideas and in ethnographic research), the goal is to understand what

“goes into” the phenomena in question by “searching out” and analyzing symbolic forms, such as words, images, institutions, and behaviors, in terms of how people actually represent themselves publicly. The main issue here is how the context is described and taken into account through the research. Thus, descriptive validity can be achieved by keeping the data linked to issues of interpretive validity.

Catalytic validity directs us to the possibility of the research moving to help those researched so as to transform their world and experiences. Therefore, as has been argued by many, the criterion for this kind of validity will focus primarily on the effect of the inquiry process in changing reality. Triangulation refers mainly to the multimethod focus of qualitative research. The use of multiple methods helps in gaining greater rigor and more in-depth understanding of the issues or phenomena in question. It adds to the overall richness of the research and provides a much more varied set of data as compared with the use of one single method.

Challenges to Positivism

Thomas Schwandt described the “crisis of legitimation” that has emerged through the challenges to claims that a text is an authoritative account of experience. From a positivist empirical perspective, the knower and the known are separate and distinct, and knowledge claims are warranted by the appeal to the use of proper methods. Proper methods ensure that claims depict the world accurately and objectively without the biases of the observer/knower. In contrast, a constructionist empirical stance is grounded in the belief that observations are theory, value, and perspective laden and that the knower and the known are inextricably intertwined. No particular set of methods is epistemically privileged.

Critical theory, feminist stances, and some social constructionist stances would state largely that issues of epistemological criteria must be considered within a larger political framework where power relations, in particular, are addressed. In postmodern qualitative work, for example, rhetorical and aesthetic persuasion and coherence may play a key role in shaping the work, leading to a shift in dissemination toward literature and performance as representational forms.

A strong postmodern stance and radical skepticism/nihilism would state that understanding and meaning-making are relative constructions, rendering definitive notions of “validity” obsolete. According to Ian

Stronach, for example, one can only engage in the endless play of difference rather than locating and reflecting common experiences. Some qualitative researchers would say that we need to bring open-ended, constantly evolving lists to the project of judgment—lists of characteristics relevant to that text—and that we must be intentionally polyvocal. Criteria, then, must be context specific.

According to a Gadamerian hermeneutic position, research is not about epistemic criteria but rather about dialogically engaging in open, morally relevant conversations about understandings of appropriate practice. We need to offer our reasons for analyzing and making research determinations based on our knowledge claims and engage in conversations about them, for judgment is inherently social and shared.

The Politics of Empirical Research

Scholars working in areas such as feminist research, Indigenous research, African American studies, South Asian studies, queer studies, cultural studies, and a number of other disciplines have tried to redefine traditional understandings of what constitutes “valid evidence” by questioning what and how knowledge is re-produced and re-presented and for whose benefit. Empirical research in this context, then, is politicized by these critical qualitative groups of scholars across the globe and by other “scientific” scholars who continue to claim to be proponents of truth and the ways of achieving it through empirical research.

Indeed, traditional patterns of exclusion (e.g., of lived experiences of marginalized communities) can be further supported by the state through funding, supporting, and setting standards for research. The concept of empiricism is often politicized in this manner when the state defines standards by which to determine what scientific interventions are “working.” In the United States, the United Kingdom, Canada, Australia, and New Zealand, as well as in parts of Europe, a global movement toward an audit accountability culture shaped by state funding of scientific research tends to emphasize evidence-based social science research projects modeled along the biomedical sciences. This approach raises new questions for qualitative scholars in the debate around what constitutes “valid,” and therefore “fundable,” research.

EMPIRICISM

The central claim of empiricism is that experience is the foundation of knowledge and that the project of gaining access to a reality other than experience is problematic. However, like *positivism*, a term with which it is closely associated, *empiricism* has been used to designate different claims and tendencies during its

long history, and the concept has evolved to such an extent that those who are now regarded as copybook empiricists—for example, the British empiricist trio of John Locke, Bishop George Berkeley, and David Hume—were strongly inclined to reject that description of themselves. Both terms suffer from radical ambiguity, for just as positivism cannot be identified with a single view uniquely defining a distinctive position, so too is empiricism extremely difficult to pin down precisely, especially as many of the ideas routinely labeled *positivist* could, with as much or as little justification, be equally described as *empiricist*. It might, therefore, be sensible to read this entry alongside the corresponding one on positivism.

The entry begins with a review of empiricist ideas in philosophy and then considers the impact of these ideas on the social sciences, specifically the way in which they are reflected in qualitative methods.

Empiricist Claims in Philosophy

Historically, there are a number of beliefs and attitudes that have been attributed to empiricist authors. Most frequently cited, perhaps, is the claim that the only source of knowledge is experience. However, there are ambiguities in this sort of formulation, and it gains in precision only as alternative views are specified and rejected. For example, granted that experience is the only source of knowledge, does an empiricist permit operations to be performed on experience—and, if so, what kind of operations? Some empiricists think that the only permissible type of operation is simple numerical induction; others, such as John Stuart Mill, reject this stringent limitation and argue for more sophisticated inductive methods (including, in Mill's case, the methods of agreement and difference) capable of identifying causes and effects. In Mill's terminology, it is empiricism that he was repudiating, although he took himself to belong to the "school of experience" rather than to the "school of intuition." The irony is that, according to modern typologies, he would be classed as an empiricist par excellence.

Bacon's Insects

Mill's use was inherited from Francis Bacon, who compared empiricists to ants, "merely collecting and using," and contrasted them with dogmatists or "spiders" who "spin webs out of themselves." But according to *The Philosophical Works of Francis Bacon*,

published in 1905, Bacon's preferred insect was the bee, which gathers "flowers from the garden" and then "by her own powers transforms and digests them; and the real work of . . . [science] is similar" (p. 288). The empiricist tendency to which Bacon metaphorically objected, then, was the mere aggregation of "findings" as opposed to the kind of intellectual work that does something creative with them—although it is equally opposed to dispensing with empirical data in favor of philosophy, dogma, and religion.

Innate Ideas

Next is a claim that differentiated the 17th- and 18th-century British empiricists from the continental rationalists. Locke, for example, argued that the mind is originally a *tabula rasa* and that all ideas are the result of experience literally imprinting itself on this blank sheet. This is in contrast to Gottfried Leibniz, for example, who believed that the mind is more like a block of marble, with innate ideas already threaded into it and ready to be sculpted by whatever experience brings. This distinction is clearly very different from the one between spiders, ants, and bees. It refers not to any methodological alternatives but rather to a view about the nature of the mind. Moreover, it is clear that the two distinctions are independent of each other; it would not be any more inconsistent for Bacon's ant to believe in innate ideas than for the spider to believe in *tabula rasa*. This observation anticipates a problem (which is typical of positivism as well as empiricism); the views associated with the label do not necessarily need to belong together. The ant, for example, is an empiricist in Bacon's sense, but not necessarily in Locke's sense.

Nominalism

Another aspect of Locke's doctrine is his nominalism. This is the view that general descriptive terms refer not to real structures or qualities in the world but rather to ideas derived purely from sense experience. Locke's claim was that we can form abstract ideas on the basis of the particular things we experience but that the words associated with these ideas do not refer to anything beyond experience itself. There is an "external" fundamental reality that underlies our experience, but it is not something to which we can have access, and the general terms we use do not apply to it. In other words, concepts reflect only the

organization of experience; they do not reflect the way in which reality is “carved at the joints.” Locke, then, rejected the view that it is possible to know the “real essences” of things (although in fact there are real essences) and argued that the objects of knowledge are “nominal essences”—the various combinations of experience to which we give names. In Locke’s form of empiricism, there is an unknowable reality as well as experience. In other forms (e.g., Berkeley’s), there is no unknowable reality because the only reality is experience itself.

Against Certainty

A significant corollary of nominalism is the view that experience is always specific, never general. We apprehend particular things, not universal properties, and still less universal truths. It follows from this that any general claims we do make must, by definition, go beyond the particularity of experience and, therefore, are less than certain. So not only is it true that we can never know about an underlying reality, but also generalizations about experience cannot be guaranteed either, although they may be assessed in terms of probability or, in Locke’s terms, “likeliness to be true.” To this extent, therefore, empiricism represents a principled resistance to speculation about the real world, appeals to entities and forces that cannot be observed directly, and the assumption that some things can be known with certainty.

Because empiricism takes all legitimate beliefs to be derived from experience, it is normally regarded as a foundationalist position. Even here, however, there is something of an ambiguity. Empiricism is quite clearly foundationalist in the sense that all knowledge must ultimately be referable to experience, but that is only one rather weak criterion. A stronger criterion is that, for a belief to count as knowledge, it must be possible to demonstrate its correctness, starting with particular experiences and deriving the belief from them according to some rule of inference. This is obviously a more ambitious project, and not all empiricists have aspired to it. Locke, for example, could not be classified as a foundationalist in the second sense because his rejection of the claim that generalizations can be known with certainty shows that he did not believe that demonstration of this kind was possible (at least for that type of belief). So the idea that empiricism is intrinsically foundationalist should be treated with caution.

Observation and Theory

Still, empiricism does require a distinctive account of theory and theoretical ideas. Scientific theories, especially in physics, seem to refer to entities that do not occur in experience (e.g., subatomic particles). So, if the empiricist believes that all knowledge is derivable from experience, she or he must explain how this is possible. A number of solutions to this problem have been proposed. The classic solution involves claiming that all theoretical concepts are reducible to (i.e., definable in terms of) observational language. Wherever a theoretical term is used, it can in principle be translated into claims about what has been, or might be, observed—even if such a translation is unlikely to be forthcoming in practice. If this solution can be made to work, theoretical concepts simply become convenient forms of shorthand, ultimately equivalent to sets of actual and possible observations.

One of the main reasons this does not work, however, is that it implies a certain type of distinction between observation and theory. Specifically, it implies that there must be experiences that can be identified and described independent of theory (because all theory is reducible to the language of observation). But the overwhelming consensus in philosophy of science during the past 40 years or so is that observational terms are “theory laden”—that it is impossible, in other words, to describe even the simplest observation without making reference to some theory. So, the classic solution, it is now universally agreed, fails.

The idea that all observation is theory laden has another apparent implication—that “plain observation” is unable to adjudicate between competing theories simply because observation statements have theory built into them and so cannot (after all) be “plain.” But if that is correct, then it would seem to follow that it is futile to attempt to determine the truth of any matter because there is no neutral, theory-independent way of adjudicating between theories. This view seems to lead to some form of relativism and has had a significant impact on methodological writing in the social sciences.

Summary

On this account, then, the claims most commonly attributed to empiricism are that experience is the only source of knowledge (although there are different views about what sorts of operation on experience are permitted, ranging from mere ant-like aggregation to

intellectual procedures of varying degrees of sophistication); experience is the foundation of all knowledge (opinions differ on how strong a claim this is); there are no innate structures in the mind; we experience particular things, not universal truths; we have no access to reality (unless we take experience to be the only reality) and cannot know things with certainty; theoretical statements are ultimately a form of shorthand, translatable into accounts of what has been, or might be, observed; and observation can hope to adjudicate between competing theories and determine which of them is more likely to be true.

Empiricism and Social Research

It is presumably true to say that the majority of social scientists are empiricists in the weakest sense of the term, which involves the claim that experience, in the form of observation, is the ultimate source of knowledge without any specific implications about what forms that observation should take or about the nature of the relation between observation and theory. But this is only to say that most social scientists are committed to empirical inquiry and that very few of them believe that significant conclusions can be drawn on the basis of pure speculation, theology, philosophy, or unsupported intuition. In a similar way, the existence (or not) of innate ideas plays virtually no part in methodological thinking (although many cognitive scientists believe that the mind has innate, or innately channeled, processing systems). So, for the purposes of this discussion, these characteristic tenets of rationalism can be left to one side.

Dust Bowl Empiricism

However, other elements of empiricist philosophy do surface in writing about sociological method. For example, Bacon's complaint about empiricist "ants" is reflected in rather similar objections to the "mere collection" of social facts, an approach to inquiry that is likewise dismissed as empiricist. It is argued that arid accumulation of this kind is atheoretical; it offers no explanations, tests no hypotheses, solves no intellectual puzzles, suggests no interpretations, and therefore provides no real understanding of the social world. This is sometimes called "dust bowl empiricism," a metaphor derived from the term used to describe the dry, dust storm-ridden plains of Texas, Kansas, Colorado, and Oklahoma during the 1930s. The idea

is that, in the absence of theory, a heap of unconnected facts is as barren as the American Dust Bowl. (On the other hand, it could be argued equally well that in some areas of social research, such as market research and public sector statistics, empiricist fact collection is justifiable.) Although this "abstracted empiricism" is most commonly associated with quantitative methods, it can also take a qualitative form. Indeed, some phenomenological researchers make a point of being purely descriptive, collecting accounts of respondents' experiences in a manner that is self-consciously uninformed by theoretical considerations. Arguably, this is no less "dust bowl empiricism" than the stacking up of bare statistics.

Empiricism and Qualitative Methods

Fact gathering is the form of empiricism that both Bacon and Mill rejected. But if empiricism, taken less narrowly, begins with experience and derives theories and explanations inductively from data (as in Mill's own account), then commonly adopted methods in qualitative social research can evidently be classified as empiricist. Grounded theory is an obvious example. The whole point of grounded theory is to build theory out of data, with theoretical terms defined in terms of codes emerging from the analysis of data and, therefore, semantically bound to evidence. In this respect, grounded theory is a qualitative version of operationalism, the empiricist strategy more frequently associated with quantitative methods, in which theoretical concepts are defined by how they are measured. In qualitative work, measurement is not in question; however, if the meaning of a theoretical concept is tied strictly to the procedures for analyzing data as in grounded theory, then the link between observation and theory is comparable. In a similar way, the analytic induction tradition, extending from Mill to Charles Ragin, generates explanations on the basis of purely logical relations between qualitatively defined variables without any reference to external theoretical constructs.

The contrast here is with independently defined theoretical terms and inference to the best explanation (sometimes called "abduction"). The recent interest in social mechanisms provides an excellent example of an approach—largely qualitative—that is certainly not empiricist because it postulates mechanisms (conceivably unobservable themselves) underlying observable phenomena and finds evidence for their existence, and the nature of their operation, by testing corresponding

hypotheses during data collection. Although there are several variations on this theme, they all are rooted in an explicit critique of empiricism and positivism. By the same token, they are realist in orientation, taking as a premise that there is a knowable reality behind appearances (in opposition to Locke), a reality that cannot be identified just with our experience of it (in opposition to Berkeley). Qualitative methods suited to this approach have been discussed, particularly in the context of evaluation research and case studies.

Observation as Theory Laden

The view that all observation is theory laden complicates matters and has encouraged many writers to reject both empiricism and realism. Because observation, according to this view, is not neutral and cannot be described independent of prior theoretical commitments, the operationalist strategy of grounded theory is blocked (the antiempiricist argument). At the same time, however, it is impossible to adjudicate between competing realist theories given that observation cannot provide an independent court of appeal (the antirealism argument). This line of thought leads to constructivism, interpretivism, and hermeneutics because the only strategy left open is the exploration of various accounts of experience, each of which will embody different theories, different interpretations, and different preconceptions. These positions imply that the researcher's own account is just one interpretation among others, one that cannot be shown to be more "accurate" or more "true" than any other, for this would require neutral, non-theory-laden observations to test competing accounts—and that, according to the premise, is impossible.

Or so the argument goes. But one familiar counterargument should be mentioned. This recognizes that observation is theory laden but points out that the theory being tested is not necessarily the same as the theory that is built into the observation (in fact, this is highly unlikely). The project of adjudicating between theories need not be abandoned, therefore, because there is no circularity involved.

Parallels Between Empiricism and Constructivism

Despite their rejection of some empiricist claims, constructivists and interpretivists are very close to empiricism in other respects. They share with the classical empiricists a skepticism about "universal truths" and

generalizations, preferring to focus on the particularities of unique situations and experiences. Like Locke, they are hostile to the idea of reality, the aspiration to certainty, and the assumption that it is ever possible to check for a "correspondence" between reality and theory. Like Berkeley, they believe that (interpreted) experience is all there is, although their idealism is more extravagant than Berkeley's because they favor multiple realities instead of just one reality. The concepts they develop cannot be identified with Locke's real essences but instead are nominal essences, as "constructed" as the concepts used by their research participants. Only in studies allegedly based on the phenomenology of Edmund Husserl (especially in nursing research) is there any ambiguity about whether the "essential structure" of a phenomenon is essential to somebody's experience or is essential to something (the phenomenon) that is independent of that experience.

Conclusion

Empiricism, then, is a family of claims, with not all of them compatible with one another, and to that extent it makes little sense to either reject or embrace empiricism *tout court*. As with positivism, however, the assumption that it represents a single, coherent unified paradigm has taken hold over the past 40 years or so, making it more difficult to evaluate individual claims on their own merits. The unexamined view that all of these claims stand or fall together has tended to polarize methodological and epistemological discussion and creates the impression that the empiricist "package" can only be rejected in its entirety. Still, perhaps the recent reexaminations of the history of both empiricism and positivism in philosophy will loosen some of the more rigid beliefs, and prompt qualitative researchers into recognizing that they do not necessarily need to abandon every empiricist idea just because they have rejected one.

EMPOWERMENT

An ethical stance in qualitative research is to create an empowering space in which research participants share power with researchers. Empowering methodologies have the ability to promote social transformation by turning upside down the traditional hegemonic relationship between the researcher and the researched.

Researchers can move toward equalizing the inherent power differential in their relationship with research participants by paying attention to issues of voice, interpretation, interactions, dialogue, and reflexivity; by making a conscious effort to include the voice and feedback of all system of care participants; and by seeking to understand participants' own meanings and interpretations and using these interpretations of reality rather than their own. Empowering methodologies have the ability to represent multiple voices in a collaborative co-constructed manner. However, there is a difference between voice and empowerment. It is certainly possible to include participants' voices in a research project but to still not empower participants.

Empowering research takes place in collaborative dialogic processes that examine the research relationship

itself and seek to understand the role of the researcher and the researched as co-participants in the research process. In addition, methodologies that let research participants have a say in how the research is conducted by exerting or influencing control over the conversations have the potential to tilt the balance of power in the research relationship from the researcher to the participants. Participatory action research is an example of one methodology that attempts to break down power relationships between the researcher and the researched by letting the stakeholders define the problem and work toward solutions. True participant empowerment would imply giving research participants status that is fully equal to that of researchers. Creating full empowerment in a research relationship requires major shifts in thinking and behaving—inviting participants to formulate the original questions, design the methodology, facilitate the data collection, and lead the analysis efforts. It might require moving the research into the community. It most certainly requires disengagement on the part of “professional” researchers to allow “nonprofessional” researchers room to engage. This is not an easy task. Professional researchers must be willing to let go—to step away from the process—so as to open a space for the other participants to have power.

Therefore, although participant empowerment is certainly a worthy and ethical goal of qualitative research, full empowerment of participants is almost impossible. Inviting people to participate in research that has already been designed, organized, and set up by professional researchers will not likely succeed in truly affecting the power relationship inherent in a research project. Research findings written for the academy marginalize and subordinate voices that are not academic. Thus, experience has shown that, despite attempts to empower participants as co-researchers, participants seem to experience critical homeostasis—the return to traditional power dynamics in the researcher–researched role.

EMPOWERMENT EVALUATION

Empowerment evaluation is the use of evaluation concepts, techniques, and findings to foster improvement and self-determination. Empowerment evaluation is designed to help people help themselves and improve their programs using a form of self-evaluation and reflection. Program participants—including clients, consumers, and staff members—conduct their own evaluations, with an outside evaluator often serving as a coach or an additional facilitator depending on internal program capabilities. By internalizing and institutionalizing self-evaluation processes and practices, a dynamic and responsive approach to evaluation can be developed.

The roots of empowerment evaluation are in action anthropology and community psychology. This evaluation approach is shaped by traditional ethnographic concepts and techniques, including adopting an emic or insider's perspective, remaining nonjudgmental, contextualizing the data, and applying a cultural interpretation. In addition, it relies on qualitative and quantitative data.

There are three steps involved in helping others learn to evaluate their own programs: (1) developing a mission, vision, or unifying purpose; (2) taking stock or determining where the program stands, including strengths and weaknesses; and (3) planning for the future by establishing goals and helping participants to determine their own strategies to accomplish program goals and objectives. In addition, empowerment evaluators help program staff members and participants to determine the type of evidence required to document and monitor progress credibly toward their goals.

Baseline Comparison and a Culture of Evidence

The “taking stock” step creates a baseline self-assessment of the program. The “plans for the future” step represents the intervention or “treatment.” Conventional evaluation tools, such as interviews, questionnaires, focus groups, and observations, are used to

determine whether the strategies are working or accomplishing the group goals. These mini-tests represent an ongoing feedback mechanism, providing corrective feedback for decision making. Program staff members and participants can make midcourse corrections before “it is too late.” If the strategies are not working based on the evaluative feedback, then it is time to change the strategies. Approximately 3 to 6 months later, another formal “taking stock” session is conducted. The first “taking stock” findings are compared with the follow-up or second “taking stock” findings to document change over time. Once again this is used for corrective feedback, confirming the effectiveness of certain strategies that should be maintained or enhanced and the ineffectiveness of other strategies that need to be revisited and changed. The cyclical process helps to internalize the logic of evaluation and builds an evaluative folk culture as well as a culture of evidence.

Principles

Empowerment evaluation is secondarily about methods and specific activities. Communities may adopt a 3-step approach, as discussed earlier, or a 10-step approach, such as the Getting to Outcomes model. In addition, there are many specific tools and methods that can be used to conduct empowerment evaluations, ranging from online survey software to video storytelling. However, these are tools to accomplish only specific objectives. Empowerment evaluation practice is a reflection or manifestation of empowerment evaluation principles and values.

The 10 principles of empowerment evaluation are the following:

1. Improvement
2. Community ownership
3. Inclusion
4. Democratic participation
5. Social justice
6. Community knowledge
7. Evidence-based strategies
8. Capacity building
9. Organizational learning
10. Accountability

These principles guide every part of empowerment evaluation, from conceptualization to implementation. The principles of empowerment evaluation serve as a lens to focus an evaluation. For example, the principle of inclusion recommends erring on the side of including rather than excluding members of the community, even though fiscal and scheduling constraints might suggest otherwise. The capacity-building principle reminds the evaluator to provide community members with an opportunity to collect their own data, even though it might initially be faster and easier for the evaluator to collect the same information. The accountability principle guides community members to hold each other accountable and also situates the evaluation within the context of external requirements. The community is accountable for reaching specific standards or delivering specific results, products, and/or outcomes.

Process Use

In an empowerment evaluation, members of the community, organization, and/or program conduct their own evaluation. Moreover, they are engaged in various aspects of the evaluation, ranging from the conceptual direction to specific data collection, analysis, and reporting responsibilities. This is at the heart of process use and knowledge use. The more community members participate in and control the evaluation, the more likely they are to embrace the findings and recommendations because they own them. However, not every community member engaged in the evaluation needs to conduct a survey or write a report. The group

may elect or appoint representatives. They (the individuals, groups, or representatives) must be involved in a substantive component of the evaluation and take control of the direction of the effort, but there are no absolute mandates concerning specific rules of engagement or the percentage of time on task.

Theories of Action and Use

One of the primary tasks in an empowerment evaluation is the reduction in the gap between what people say they want to do and what they are actually doing in practice. The aim is to reduce the gap between what is intended and what actually happens. To accomplish this objective, empowerment evaluation relies on the reciprocal relationship between theories of action and use. A *theory of action* is usually the espoused operating theory about how a program or an organization works. It is a useful tool that is generally based on program personnel views. The theory of action is often compared with a *theory of use*, which is the actual program reality or the observable behavior of stakeholders. People engaged in empowerment evaluations create a theory of action at one stage and test it against the existing theory of use at a later stage. Similarly, they create a new theory of action as they plan for the future. Because empowerment evaluation is an ongoing and iterative process, stakeholders test their theories of action against theories of use during various microcycles to determine whether their strategies are being implemented as recommended or designed. The theories go hand in hand in empowerment evaluation.

Figure 1 Contrasting Patterns of Alignment

Source: Fetterman, D. M. (2005). A window into the heart and soul of empowerment evaluation: Looking through the lens of empowerment evaluation principles. In D. M. Fetterman & A. Wandersman (Eds.), *Empowerment evaluation principles in practice* (p. 14). New York: Guilford. Reprinted with permission of Guilford Press.

These theories are used to identify gross differences between the ideal and the real. For example, communities of empowerment evaluation practice compare their theory of action with their theory of use to determine whether the two theories are even pointing in the same direction. Three common patterns that emerge from this comparison are in alignment, out of alignment, and alignment in conflict (Figure 1). *In alignment* is when the two theories are parallel or pointed in the same direction. They may be distant or close levels of alignment, but they are on the same general track. *Out of alignment* occurs when actual practice is divergent from the espoused theory of how things are supposed to work. The theory of use is not simply distant or closely aligned but actually off target or at least pointed in another direction. *Alignment in conflict* occurs when the two theories of action and use are pointed in diametrically opposite directions. This signals a group or an organization in serious trouble or self-denial.

After making the first-level comparison, a gross indicator, to determine whether the theories of action and use are even remotely related to each other, communities of empowerment evaluation practice compare their theory of action with their theory of use in an effort to reduce the gap between them. This assumes that the two theories are at least pointed in the same direction. The ideal progression is from distant alignment to close alignment between the two theories. This is the conceptual space where most communities of empowerment evaluation strive to accomplish their goals as they close the gap between

the theories (Figure 2). The process of empowerment embraces the tension between the two types of theories and offers a means for reconciling incongruities. This dialectic, in which theories of action and use are routinely juxtaposed in daily practice, creates a culture of learning and evaluation.

Conclusion

Empowerment evaluation is similar to many forms of evaluation. Many of the same tools are used, including interviews, questionnaires, focus groups, and observations. The only difference is that it places conventional evaluation and wisdom on its head. The group is in charge of its own evaluation instead of the evaluator being in charge. The evaluation is a collaboration instead of an individual or external enterprise. The evaluator is a coach or critical friend rather than an external expert. The focus is on self-determination, capacity building, internal accountability, and program improvement. At every step, the evaluation process becomes more responsive to the context and culture of the group. Diversity is a valued contribution, adding to the effort instead of subtracting from the effort.

Empowerment evaluation adheres to evaluation standards. It does not operate in a vacuum. It is conducted within the context of existing external standards and requirements. In addition, internal or empowerment evaluation and external evaluation are not mutually exclusive. They work together very well. They strengthen each other. The difference between

empowerment and many forms of conventional evaluation, however, is that program staff members and participants take charge of their own lives. They act as self-motivated and actualized individuals with intermediate objectives associated with larger group or organizational goals. They internalize and institutionalize evaluation. They create a dynamic and creative learning organization that can be sustained in one format or another for a lifetime.

EPISTEMOLOGY

Epistemology, according to the *Oxford English Dictionary*, is the theory or science of the method and ground of knowledge. It is a core area of philosophical study that includes the sources and limits, rationality and justification of knowledge. Its etymological roots are Greek from *episteme* (knowledge) and *logos* (explanation). Although it is an ancient concept, the term *epistemology* first appeared in English use during the mid-19th century; this gives it modern meaning. The following three questions are basic to epistemology. What is knowing? What is the known? What is knowledge? These questions have wide interest

for fields of inquiry but are central to the sciences broadly defined, including qualitative research. Because of its disciplinary base, this discussion deals only with matters that have concerned philosophers. Because of its modern importance, it deals primarily with relatively recent philosophy and concentrates on the 20th century and today. Following overview discussions, a central section on exemplary epistemologies suggests the underlying position of this entry—that the meaning and application of “knowledge,” as a history of philosophy suggests, has always been (and still is) dynamic, diverse, and “at bottom” diffuse. Another purpose of the entry is to introduce readers to the language of philosophy.

Foundations

A history of Western epistemology reveals that the principal philosophical occupation has been what American philosopher John Dewey called “the quest for certainty.” A first aspect of this quest, or the search for foundation, has been to align philosophy with other organized bodies of inquiry that were thought to be “certain.” Across millennia, these have included religion, mathematics, logic, and science. During the 20th century, the foundations of knowledge were sought in mathematics, in the natural sciences (especially mathematical physics), and in the structures and uses of language.

A second dimension of the search for foundation has been in posing philosophical systems. Historically, many philosophical systems were posited—with each apparently thought to be *the* answer to the quest. The idea of a system is that a set of “founding premises” serves as a basis for asking subsequent epistemological questions. Modern but traditional examples include rationalism and empiricism, idealism and realism. Not discussed elsewhere in this encyclopedia, the rationalism of René Descartes serves as an illustration. For him, philosophy is a process in which the mind turns inward seeking foundation through reason. Employing a method of doubting all that he knew, Descartes came to a clear and distinct idea—a truth. Two were revealed: the cogito or consciousness and God. Descartes’s framework is the dualistic separate relationship of self and object. With the writings principally of Descartes, David Hume, John Locke, and Immanuel Kant, epistemology rather than metaphysics became central to modern philosophy. In general, questions arising across foundational systems focus on

the relationship of person to world and to other persons, of inner immaterial mind or minds and outer material world. Additional questions include source, authority and form of knowledge, process of making a claim, and domain of application.

Perhaps the important philosophical contribution of the past century was to “give up” the quest; that is, to generally acknowledge that there is no one and only one system that founds knowledge. “-isms” or traditions within philosophy are still posited but with a nonfoundational status. This shift basically occurred through discussions of the related roles of language and truth. A contemporary position known as “foundationalism” still holds that there are basic propositions from which nonbasic propositions can be inferred. Its contrasting position is “coherentism,” the denial of any such base.

A final point about epistemological foundations is that across Western thought and culture there have always been “other,” nonfoundational formulations. Consideration of them begins with a note about history and its contingency. It is often said that the development of philosophy, and within it epistemology, began with and has since been a footnote to Plato. It is well recognized that Plato’s views were a response to his own historical situation—to one of societal and personal political crisis. Plato’s system, thus, was an exclusionary system in which domains and processes of knowing and knowledge were theoretically possible above a “dividing line” and were not possible below the dividing line. Philosophy and absolutism were “in,” and rhetoric and sophism were “out.” And arts and poetics were “way out.” The division has continued to this day. Interestingly, there have been times when Plato’s hierarchy was reversed, or at least when the line was blurred, as in the Renaissance and the era of the Romantics and as the focus of C. P. Snow’s debate between the “two cultures” indicates.

Units, Kinds, and Processes

From Plato’s time onward, philosophers have described knowing and knowledge through a series of synonyms; that is, of what constitutes knowledge. Today, in common sense, knowledge is facts and information; today, in philosophy, knowledge is the purview of propositions or discourse. Historically, many other “inputs” and “outputs” have comprised knowledge. Philosophical questions concerned input source and output manifestation and much later concerned integrative

processes of consciousness. Recognizing both external sensations and internal initiations, knowledge was perfection with units prior to modernity that included ideal forms and God’s words. These were available to “man” as imperfect appearances or ideas. Input units across time have included external perceptions and “sensa” as in Locke’s view during the 18th century. Reason has always been central to knowing and became an end in itself, for instance, in Georg Wilhelm Friedrich Hegel’s view during the 19th century. In more recent times, process units of experience and belief have resulted in product units of being, meaning, judgment, and even inference and interpretation. In contemporary traditions, belief and experience remain mediated or accessible through language. Today, language units comprise discourses that themselves are defined as knowledge; still other units related to language are game and practice.

Distinctions among kinds of knowledge have also interested philosophers. An early distinction was that between perfection and imperfection. Others include distinctions between explicit and tacit, direct and indirect, and private and public formulations. The first two pairs concern justification of knowledge, especially in the presence or absence of self-consciousness. The last pair is significant in that early modern philosophers such as Thomas Hobbes posited that external inputs placed ideas in a mind but then did not account for how private ideas became public. The key insight of Ludwig Wittgenstein during the 20th century was to deny the existence of private knowledge. A second distinction, between a priori and a posteriori knowledge, was proposed by Kant as an attempt to resolve debates between rationalism and empiricism. Related to this is that different combinations of the operation of mental faculties result in truth, goodness, and beauty. In these formulations, the latter two are derivative of the first one—intellectual formulation. Today, a priori knowledge is still defined as independent of sensory experience that defines a posteriori. Related is another distinction arising once knowledge is conceived as propositional; this is of analytic and synthetic propositions. The former are true by meaning as opposed to true based on fact. Much debate has ensued over relationships of these two paired forms of knowledge. Emerging as “setting the standard” is knowledge as propositional and tested by experience. A final example of distinctive kinds of knowledge is between “knowing that” and “knowing how.” Credited to Gilbert Ryle and for him related to consciousness,

the first describes states of affairs and the second describes procedures. A recent formulation subsumes many different statements of knowledge under “knowing that.” These include facts and persons as well as states such as which, whether, and when. Qualifications also name “acquaintance knowledge,” that which is indirect by inference, and knowing how as “ability knowledge.”

Continuing from knowledge kinds, modern philosophers have attended to two basic processes of knowing. One involves the exercise of “mind” alone, and the other involves the mind’s operation on perceptual stimuli. Evolving from rationalism and empiricism, various idealisms and realisms are much stronger than Kant’s knowledge kinds because each was determined to be the source for all knowing, both of internal consciousness and of external materiality. During the past century, various philosophers also have attended to mental processes that today are thought of as intuition and cognition. Of note, except for a contemporary critical realism in social science, within philosophy these systemic processes have been supplanted by influence of the linguistic turn (discussed in the next section).

Contemporary Traditions

Twentieth-century philosophy saw a blurring, somewhat and for some theorists, of Western traditions, often named as Anglo-American and continental. It is arguably more instructive to identify two approaches to knowledge. First, the analytic approach has focused on, and continues to focus on, the rationality of knowledge; philosophers of this approach have largely explored logical and linguistic conditions of knowledge claims. Second, those from the “social” approach instead have focused on conditions of the societal function of knowledge. In common, both approaches acknowledge and work variously from what has been called the linguistic turn. Historically, two phases can be identified. A first phase sought foundation in language function and use. Developing out of a modern realism, Bertrand Russell’s analytic foundational move from mathematics to language structures is illustrative, and Ferdinand de Saussure’s continental structuralist theory of the basic linguistic sign is another example. Related to various “postmodernisms,” a second phase turned to the openness of language. Two contributors are the neopragmatist Richard Rorty, for whom knowledge and philosophy itself are conversation, and the poststructuralist

Jacques Derrida, for whom a deconstruction of language, knowledge, and philosophy always operates. Across traditions today, knowledge is envisioned to a lesser or greater degree as language and as ambiguous, tentative, and fallible.

The first approach is analytic philosophy, initially identified with Russell, G. E. Moore, and Wittgenstein. It has been the dominant philosophical tradition in Anglo-American thought since the mid-20th century. Analytic philosophers posit the “standard view” of epistemology and define knowledge as justified true belief. Once the debate about truth was generally informed by Alfred Traski’s semantic theory, philosophical considerations within this approach have concentrated largely on issues of justification. The second approach, the social approach, understands knowledge as historically and discursively contextualized and, thus, as influencing its use. Here “-isms” continue to be identified, but this practice is largely inaccurate because individual philosophers are so different from each other. One subtradition is the classical pragmatism of C. S. Peirce, William James, and Dewey related today to a strong neopragmatism. For Dewey, pragmatist knowledge is “warranted” through persons’ enactments in environments where both are changed as a result. A second subtradition receiving much intellectual attention today is that of French poststructuralism. Like pragmatism, it is composed of philosophers sharing “family resemblances.” Key figures include Jean-François Lyotard, Michel Foucault, and Derrida. Too simply put and with a nod to Foucault, for them knowledge is a societal construction that often is imbricated with inequitable illusive manifestations of power.

A long-standing “nonepistemological tradition” also deserves mention. Descended from Plato’s adversaries, this is rhetoric. Historically, it is the art of fine speaking, of persuasion, grounded not in abstract truth or goodness but rather in its own form. Rhetoric also is fundamentally social. Enjoying a renewal of interest today, knowledge can be described via rhetoric—perspectival, partial, incomplete, infected by partisan desires, interests, and projects, and in recent times relative to discourses. Those for whom a rhetorical tradition has relevance believe that, indeed, all knowledge is “uncertain” in just these ways.

Epistemologies

Working from the two broad approaches to epistemology presented in the previous section, a principal purpose of this entry—to indicate both variety and evolution—is

served through illustration. Out of the analytic approach, four examples are from Russell, Wittgenstein, Willard Quine, and Edmund Gettier. During the past decades, other important writings on epistemology include those by Karl Popper, Donald Davidson, and Alvin Goldman.

British logician Bertrand Russell (1872–1920) was generally named a realist for whom all knowledge is based in experience. He posited two processes: knowledge by acquaintance (in which there is direct inference of sense data) and knowledge by description (in which there is indirect inference of sense data). Positing logical atomism, he searched for an ideal isomorphic language with which to map the world but came to see his own search as unsuccessful. His foundational analyses of mathematics and language structure initiated the modern analytic tradition.

Countering Russell in his work, Viennese-born Ludwig Wittgenstein (1889–1951) was the founder of the movement in ordinary language philosophy within the analytic tradition. Two ideas are especially important from him. One is that a word may well refer to multiple entities, and the other is that words relate to each other in family resemblances. Wittgenstein's idiom of "language game," that language use occurs in particular social and linguistic contexts, has had a huge influence across Anglo-American and continental philosophical traditions.

Central to analytic philosophy, Willard Van Orman Quine (1908–2000) was influenced by Wittgenstein and contributed these two ideas: a denial of the analytic–synthetic distinction in propositional content and an underdetermination and holistic interconnection of theories. Quine's perspective came to be known as "naturalistic epistemology," in which he argued that the empirical science of psychology ought to replace philosophy as the basis for knowledge. His view that all that can be known is the sensory cause of belief has been discredited, but a contemporary modification of his naturalism remains well respected.

Also influenced by the later Wittgenstein, the last contributor is little known outside of analytic philosophy. Edmund Gettier's (1927–) name is attached to the "Gettier problem" from a brief article published in 1963. Its impact was to call into question knowledge as justified true belief. In a series of examples, he argued that beliefs can be both true and justified yet still not be knowledge. Much work, as indicated earlier on the issue of justification, has been written since Gettier's argument was published.

Out of the social approach, four examples are from Dewey, Martin Heidegger, Hans-Georg Gadamer, and

Foucault. During recent decades, other important contributors include U.S. philosophers Donald Davidson, Rorty, and Hilary Putnam; French philosophers Lyotard and Derrida; and the important German critical theorist Jürgen Habermas. In what follows, Dewey is a classical pragmatist, Heidegger's philosophy is best named a phenomenology, and Gadamer offers a present-day hermeneutics. Foucault then stands in for the diverse tradition called poststructuralism.

With influences from British empiricism and idealism, American John Dewey's (1859–1952) epistemology cannot be divorced from his political philosophy. Knowledge, or "warranted assertability," is a process of continual inquiry in which utility is posed and justified in consequences, in action. His "reconstruction" process has traces of a Hegelian dialectic in which a particular problem, temporary solution, and new problem form the epistemological situation. Ideally, inquiry takes place within a democratic society, one that Dewey posited as the interconnecting advances of science and society.

German Martin Heidegger's (1889–1976) philosophy of hermeneutic phenomenology has had a significant impact on much of continental social theory. Influenced greatly by Edmund Husserl, his major contribution concerns the meaning of "being" as "in itself" misunderstood across the history of Western thought. Being, always already temporally situated, points to the prefigured existence of all knowledge. His writings also attend to "technology," a basic but potentially dangerous mode of human existence. Heidegger's reattention to classical thought also is a model for subsequent philosophers.

German Hans-Georg Gadamer (1900–2002), a student of Heidegger's, offers a significant project via the linguistic turn in updating classical hermeneutics, biblical/textual interpretation that sought true meaning. He posits that history, culture, and tradition fuse as "horizons" to bound any interpretation. With a method that is discursive, dialogic, and conversational, Gadamer has written across many topics for which knowledge matters; these include poetry, literature, art, politics, and ethics.

French philosopher-historian Michel Foucault (1926–1984) is identified by an English-speaking audience, arguably inappropriately, as a poststructuralist. Like all European theorists, his writings relate in some ways to humanist, phenomenological, and critical traditions—but his are a unique alternative. Foucault's studies of social institutions reveal epistemological interconnections of discursive and nondiscursive

formations in his idiom of “power knowledge.” In effect, “regimes of truth” come to be constituted and stabilized; of them, different historic eras produce different underlying rationalities. It is these that matter as knowledge use.

Conclusion

In this encyclopedia, entries related to the results of research are primary for qualitative researchers; knowledge and what philosophers have had to say about it are indeed central. This entry has introduced a complex topic of which other aspects are similarly interesting and important. Extensions include a study of the meaning of truth and recent movements in “alternative epistemologies.” Among these are contributions from feminist and minority scholars. Readers and researchers are encouraged to read further as they consider epistemological implications for and from their own work.

ESSENCE

Essence in general means the reality of things as disclosed to rational thought. The idea of science as an organized body of knowledge depends on the presupposition of a distinction between a world of appearance and an underlying universal reality of basic elements and forces.

The philosophical development of the idea in Plato and Aristotle added an irreducible normative dimension. For Aristotle, the essence of things was not simply the universal definition that stated the intrinsic nature of things; it equally expressed the unique set of possibilities that those things ought to realize. Hence, essence combines “is” (that which grounds the division of reality into classes of things) and “ought” (the content of the “good” for each class of things). The concept of essence is distinguished from all of the other categories of Western philosophy and science by this synthesis of the normative and the descriptive.

The revolution in physics in the work of Galileo, René Descartes, and Sir Isaac Newton eliminated this idea of essence from natural science. The concept of essence was subsequently reserved for judgments of human life. Georg Wilhelm Friedrich Hegel and Karl Marx were crucial to keeping the concept of essence alive in social and historical philosophy. They rejected the static conception of a set of essential possibilities for all humans for a conception of the human essence as necessarily historical. Instead of the idea of a timeless universal form lying behind the apparent diversity of human cultural practices, the idea of the human essence that emerges from Hegel and Marx focuses on the ever-developing self-creative capabilities of humans.

The use of the concept of essence as an objective basis of social criticism itself became the object of criticism during the 1960s. Philosophers such as Michel Foucault and Jacques Derrida, drawing on the arguments of Friedrich Nietzsche, argued that the idea of essence is always linked to definite strategies of exclusion. In their account, the critical function of the concept of essence was charged with being another form of power whose aim was to legitimate itself by

delegitimizing other forms of understanding. There could be no essence, whether historical or not, lying behind appearances because everything, including what counts as appearance and what counts as essence, must be stated in language. The concept of essence tries to free theory from the plurality of meaning typical of language, but because it too is meaningful only in language, it must itself succumb to the pluralism it tries to control.

This so-called postmodern critique of the concept of essence has proven to be powerful into the contemporary period, so much so that “essentialism” is now almost universally regarded as a theoretical strategy that must be avoided. The concept remains an important methodological tool, however, whenever qualitative research needs to ask foundational questions, especially regarding different social interests. Unless the concept of essence (in some form) is employed, it is not clear how the legitimacy and relative value of competing social interests are to be established.

maintain, first, that all objects and concepts can be defined by reference to certain core properties that make them what they are and, second, that it is instructive and useful to inquire into the nature of these essential features. The view that there are certain properties essential to humans, such as a “core self” that defines us as people, is often referred to as “humanism.” Essentialist philosophy has exerted a significant, if sometimes covert, influence over many of the widely accepted and sometimes taken-for-granted tenets of qualitative research, including key issues such as validity, reliability, sample selection, and generalization.

The Origins of Essentialism

The belief that certain properties of things (where “things” include objects, concepts, experiences, etc.) are essential to our understanding and definition of them can be traced back at least as far as Plato, for whom every object or quality in the physical world was derived from a divine, invisible, changeless transcendental “form.” Platonic forms are “ideal types” or essences that exist outside of time and space and of which objects and concepts in the world are merely pale imitations. Let us take as an example the form of the “good.” Some aspects of this transcendental “goodness” can be said to lie at the heart of all good people, and it is this goodness that we perceive when we describe someone as good, although no good person could ever display the good in its essential form because the forms transcend the temperophysical world.

The relevance of this transcendental type of essentialism to research becomes apparent when we consider that, for Plato, all people have had a prior acquaintance with the eternal and divine forms before their births. We can all recognize worldly goodness when we see it because we have all previously had experience of the form of the good. Thus, knowledge of the essence or true nature of things in the world comes not from our senses, which merely show to us the many imperfect manifestations of the form as they exist in the world, but rather from our memories of the forms themselves. Knowledge of the essential nature of everything in the physical world is a priori (prior to experience), and thus research is a process of reacquainting ourselves with what we already know but have forgotten. This gives rise to the so-called Socratic dialogue method of discovery (or perhaps of “recovery” or “research,” the search for something

ESSENTIALISM

Essentialism is the philosophical doctrine that certain properties of an object or a concept are necessary or essential rather than contingent or accidental. Thus, we might say of a person that being good is accidental because it is possible not to be good and yet still be a person, whereas occupying space is essential because it is impossible to be a person and yet not occupy a physical space in the world. Essentialists

that has been lost) in which the teacher does not attempt to impart knowledge but rather asks a series of questions to draw out the knowledge that the pupil already possesses. As Socrates said to Meno, “The soul has learned all things. . . . Enquiry and learning are entirely recollection.” If we accept this radical form of essentialism, then research is merely uncovering what is already known and does not rely to any extent on empirical observation of the physical world; indeed, such observation is more likely to confuse and confound than to enlighten.

A similar essentialist philosophy can be seen in early Judeo-Christian culture right up to the Renaissance. In this version of essentialism, all knowledge is related back to God and in particular to the idea of *logos* as both the word of God and the principle of rationality. This dual meaning can be seen in the opening verse of John’s Gospel, “In the beginning was the Word, and the Word was with God and the Word was God,” and at various junctures in the Old Testament such as Adam’s naming of the animals in the Book of Genesis. The word (*logos*) brings order out of chaos; to name something is to impose order on it, and to know the name of something is to know the thing itself. The French philosopher Michel Foucault observed that, according to the Old Testament, language was a gift to humankind by God himself, and as such it was an absolutely certain and transparent sign for things in the world, so that the name of a thing and the thing itself were indivisible. Foucault argued that, right up until the 16th century, there was an underlying belief or episteme that words retained a resonance of God’s original language to the extent that it was possible to know something of the essence of a thing simply by knowing its name. Thus, the word *lion* somehow summoned up the essence of *lionness* and the word *good* articulated *goodness*.

Essentialism and the Scientific Method

However, by the 17th century, a distinct move away from this reliance on innate knowledge could be detected. The philosopher John Locke laid the foundations of scientific empiricism by distinguishing between the “nominal” essence of an object and its “real” essence. Although the real essence or fundamental truth of an object could be investigated only through inner contemplation, Locke held that it was nevertheless possible to determine facts and laws concerning

its nominal essence or surface properties solely through the senses. This turn to the senses as a primary source of knowledge ushered in the so-called Age of Reason or Enlightenment and with it a splitting of the sign from what it signified. Language was no longer seen to be intrinsically linked to the world; rather, it was merely a representation of it. Thus, the essence of a thing could no longer be discerned simply by knowing its name or even by rational contemplation; to determine its essential nature, it became necessary to examine the thing itself.

David Hume pushed Locke’s empiricism to the extreme, arguing that all attempts to discern the real essence of an object (apart from the abstract objects of mathematics) through inner contemplation or pure reason were doomed to failure. What is believed to be “innate” knowledge about the essence of things is, in fact, derived in subtle ways from the senses. Thus, Hume famously argued that any book that was not concerned with empirical experimentation should be committed to the flames because it could contain “nothing but sophistry and illusion.” We can see, then, that the rise of empirical science during the 17th century ushered in a new approach to essentialism at centered on discovery of the true nature or essence of things in the world through observation and experimentation.

Scientific research, therefore, continued the search for the essential properties that constitute the core of a physical object or an abstract concept but shifted the focus of this search in a significant way. This shift can be seen, for example, in the contrast between the pre-scientific study of astrology and the science of astronomy. Astrologers were concerned with the search for the distinct and unique essence of each individual planet; for example, to distinguish between the warlike influence of Mars and the peaceful influence of Venus. Furthermore, these essences could be discerned through contemplation of the inner “nature” of the planets. In contrast, astronomers and other early scientists turned their gaze outward to the planets themselves and employed inductive or cumulative research methods to categorize objects into groups based on similarities. Astronomers wished to formulate general laws that explained the behavior of all planets because this enabled them to make predictions about the existence and movements of other as yet unknown planets. The search for essential properties continued but shifted from inner contemplation to outside observation and from the individual to the universal.

Nevertheless, the notion of logos, the confluence of naming, organizing, and knowing, continued to be a major feature of the work of many early scientists, for whom the practice of science was largely a program of labeling and ordering the natural world.

Essentialism and the Human Sciences

The search to understand, predict, and control the essential properties of the world continued throughout the 18th and 19th centuries and played a major role in driving the industrial revolution in Europe. However, a different focus of essentialism emerged toward the end of the 19th century when the scientific gaze turned back inward toward people themselves as subjects of study rather than as the dispassionate and disinterested objects that conducted the study. Prior to this reflexive turn, the scientist as the observer and experimenter stood largely outside of that which was being observed and experimented on. As Foucault noted, classical rationalism accorded humans a privileged objective position in ordering and making sense of the world, but the person was not recognized as a potential subject of this scientific study. The shift in focus to conduct research into the essence of what it is to be human ushered in the “human sciences,” such as sociology and psychology, during the latter part of the 19th century.

This particular focus of essentialism is known as “humanism,” which argues that humans in general can be defined in terms of a core “human nature” that is common to all. By conducting research into human nature, the behavior of people could be understood, predicted, and controlled. The method of the early human scientists, such as Émile Durkheim and John Stuart Mill, was to imitate the scientific rationale and methods of physics and chemistry in the hope of reproducing their successes. Thus, the person became both the subject of study and the object that studied, resulting in a form of “objective subjectivity,” an attempt at a quantitative study of self and others from an objective and impartial perspective. However, a number of philosophers and sociologists, such as Wilhelm Dilthey and Max Weber, argued that such an objective “scientific” approach was untenable and pressed for a qualitative approach that went beyond a scientific explanation (*Erklären*) to accomplish something that Weber argued is never attainable in the natural sciences, namely, the subjective understanding (*Verstehen*) of the action of the component individuals.

This call for an “insider” subjective understanding of the essential nature of the person to counter the “outsider” objective explanations derived from the methodologies of the physical sciences was taken up by, among others, Edmund Husserl, who proposed a phenomenological philosophy as a “viewing of essences.” Although Husserl’s approach to phenomenology began as a descriptive subjective psychology, he later developed it as a form of transcendental idealism where all meanings and essences are already embedded somehow in what he referred to as the “transcendental ego.” Idealists hold that reality “takes place” within individual consciousness; therefore, the project of transcendental phenomenology, as devised by Husserl, was to suspend all empirically derived assumptions about things in the world so as to arrive at an inner understanding of their essential nature. The suspension of experiential knowledge (*epoché*), therefore, results in a reduction down to the “pure phenomenon” or “absolute data” of an experience that somehow contains the “intrinsic character” or essence of the thing in question. What remains is “pure subjectivity” or the essence of our sense data stripped of all prior assumptions and beliefs.

In many ways, the aim of Husserl’s subjectivity is an extension of Hume’s empiricism and has parallels with the scientific ideal of objectivity—to see things as they really are, to uncover their essential nature. Furthermore, although Husserl’s position is intensely subjective, it is not solipsistic. Whatever it is possible for one person to intuit through this phenomenological reduction is also open to everyone else. This point is of utmost importance to qualitative researchers because it suggests the possibility of a scientific method for the subjective study of essence. There are clear similarities here with Plato’s forms (although Husserl rejected this comparison); each posits a transcendental “world” of pure phenomena, each suggests a method by which individuals can gain access to these essences, and each recasts epistemology as a branch of ontology. The difference is that whereas Plato located the essential forms outside of the person (indeed, outside of the physical and temporal world), Husserl regarded essences as buried deep in the individual’s psyche. Ultimately, then, phenomenology is a way of “essential seeing” (*Wesenserschauung*); it is an empirical science rather than an a priori recollection.

Although transcendental phenomenology has its roots in philosophy and descriptive psychology, it was enthusiastically adopted and adapted by qualitative social researchers during the last quarter of the

20th century. The various attempts to employ what was originally an intensely subjective and introspective method of empirical reduction to the study of other people cannot help but undermine Husserl's original project. First, the object of study inevitably shifted from the "inner" experiences of the investigator to those of the subjects (or, more accurately, the objects) of investigation. Second, when phenomenology is employed as a social research method, reduction or bracketing operates on the verbal accounts of those experiences as told by the objects of the study rather than directly on the experiences themselves. This has prompted a number of critics to point out that phenomenological reduction has been misunderstood and misapplied by most qualitative researchers. Whereas Husserl wished to reduce sense data themselves to their pure and uncontaminated essential form, most phenomenological researchers accept without question the experiences of the objects of their research and instead apply reduction to their own perceptions of the research objects' reported accounts of their experiences. This, claim the critics, is not phenomenological reduction as Husserl advocated; rather, it is merely a form of positivist objectivity disguised as subjective social science.

An Essentialist Paradigm of Qualitative Research

Although phenomenology might be regarded as the foundation, or even as the essence, of essentialist research, its influence has spread from simply a method for doing research to encompass a broad and mainstream paradigm of qualitative research. This general essentialist influence is particularly apparent in the way many qualitative researchers think and write about issues such as validity, generalizability, and reliability.

If validity is taken broadly to be a concern with the truth claims of research findings, then essentialist researchers will begin from the assumption that the essential nature or truth is somehow and somewhere lodged in every single example of the object of their inquiry. This belief in a common essence is held not only for external objects and internal concepts but also for the experiences of individuals. For example, the transcendental phenomenologist might elicit the "lived experiences" of a number of individual respondents, but the aim will be to arrive at common themes and categories to answer the question posed by Denise Polit and Cheryl Tatano Beck in 2005, "What is the

essence of this phenomenon as experienced by these people?" (p. 219).

Research (in keeping with the Platonic view), therefore, is a process of uncovering that truth or essence, of *recovery* or *discovery*, of what is already there. The aim of the researcher is to reveal the essence of the object of inquiry (whether an external object, an internal concept, or a personal experience) without contaminating the truth by imposing his or her own preconceptions, which are put in "brackets" for the duration of the study. This objective subjectivity is usually achieved by the research community agreeing on an appropriate method and following it rigidly with a minimum of deviation. For essentialist researchers, therefore, validity is closely connected with rigor because rigorous adherence to a predetermined method offers the best hope of producing research findings that are uncontaminated by the views or influence of the researcher. Rigor is monitored in essentialist research by the careful documentation of the procedures followed by the researcher (sometimes referred to as an "audit trail"), often in conjunction with a research diary in which any indiscretions and deviations are presented and accounted for.

The essentialist paradigm also influences decisions about the selection of research informants or respondents. Unlike most quantitative researchers, for whom sample selection is an issue of statistical generalization, and nonessentialist qualitative researchers, for whom generalizations can be made only on a case-by-case basis, essentialist researchers argue that all cases of a particular phenomenon will contain the essence or truth of the object of inquiry. The researcher, therefore, is free to make a purposive selection of respondents based on criteria such as the breadth and depth of their experience of the relevant phenomenon and their ability to articulate this experience. For the essentialist researcher, therefore, sample size is determined by the number of respondents required to fully uncover the essence of the object of inquiry rather than by considerations of representation of some wider population. The essentialist researcher is able to make an analytic generalization from one or more discrete cases to a theory or other universal statement, much as a natural scientist can test and confirm a theory from a single observation. In an ideal situation, one very experienced and articulate respondent will suffice, but in practice data collection continues until no new information is forthcoming, at which point saturation is said to have occurred.

Multiple respondents are also necessary to satisfy the criterion of reliability or trustworthiness. Essentialist researchers in search of the stable essence of their object of inquiry would expect to uncover very similar facets of the same unchanging truth of the matter regardless of when and by whom the study was conducted. Therefore, reliability (the degree of trust placed in the accuracy and consistency of the findings) can be tested and confirmed by repeating the data collection method at varying times and with different researchers and respondents. Similarly, essentialists would claim to be able to confirm the accuracy with which they had collected their data by returning the raw data for checking by the respondents and returning the analyzed data to the respondents or to another researcher for confirmation of the themes and categories. The assumption behind these checking techniques is that the essence of the object of inquiry remains unchanged over time and fluctuating circumstances and that this essence, in the form of themes and categories, will be perceived in much the same way by whoever analyzes the data.

Although essentialist philosophy has exerted a significant influence over the development of many of the key concepts and practices of qualitative research, it should be noted that some researchers adopt a nonessentialist approach founded on a substantially different set of assumptions.

ETHICS

Ethics is the part of human philosophy concerned with appropriate conduct and virtuous living. This entry considers ethics and its related constructs, kinds of ethics, and ethical issues in qualitative research. Research in general and qualitative research in particular are viewed by most qualitative scholars as moral ethical endeavors because they are human endeavors.

Ethics and Related Constructs

The formal study of ethics is associated with the ancient Greeks. Ethics in this tradition is both the study of the frameworks underlying judgments of what is appropriate conduct and the substance of the judgments themselves. Some scholars, however, prefer to use the term *ethics* for the study of frameworks for judgment (e.g., consequentialism) and to use the terms *morals* and *morality* for specific injunctions (e.g., “do no harm”). Europeans conventionally view ethics and morality in binary terms such as right and wrong, good and bad, and doing the right thing and avoiding wrong action. Other cultures have formulated appropriate conduct differently. Some view it as balancing complementary or competing forces such as the Chinese yin and yang. However ethics is defined, human societies everywhere have ideas about what is appropriate conduct and how to live an exemplary or virtuous life. When these are codified into rules enforced by authority, they are considered to be laws.

Values, the study of which was called *axiology* by the Greek philosophers, is a broader category of what is considered to be important and significant. Values include ethics and morality but also other kinds of standards such as aesthetics or what is considered to be beautiful, manners and mores or what is considered to be socially acceptable, and taste or what individuals prefer in the choices they make. These categories are not mutually exclusive. Principles for aesthetic judgments may also have implications for ethical judgments. Ethics and values are attributes of all human

societies. However, what differs from one group to the next, as well as among individuals within any group, is the nature of those values and how they are conceptualized. Furthermore, because virtue and appropriate conduct are central to religious and spiritual ideologies, some people view ethics as tied inextricably to religion. The development of scholarship on ethics in the West since the Enlightenment reflects, in some respects, an effort to detach supernatural arguments from moral theories and ethical decision making and to focus ethical thought on the conduct of human relationships and on individual well-being.

Kinds of Ethics

The study of ethics can be divided into two areas. First, the common area most influential in research practice is called normative ethics or moral theories. These are frameworks used to decide what is preferable to do among the choices available. The second area is called meta-ethics. These are the assumptions and values underlying normative ethics and moral theories. Meta-ethics, as discussed later, is often associated with research epistemologies and ontologies or the assumptions about what constitutes knowledge and reality and how knowledge is best developed.

Normative Ethics and Moral Theories

Normative ethics and moral theories are frameworks organized around either principles to guide decision making or relationship dynamics to guide human conduct. However, the more traditional influence on the Western practice of the social, human, and professional sciences has been the ethics of principle, centered on some guiding doctrine. Arguably the most commonly used in research ethics have been justice-based ethics, duty-based or deontological ethics, consequence-based or utilitarian ethics, and virtue-based ethics.

The guiding principle of virtue-based ethics, explored by Aristotle more than two millennia ago, requires that people act virtuously toward one another, typically with ideals of character such as honesty and integrity, respectfulness, wisdom, justice, and compassion. In some respects, virtue-based ethics was the guiding assumption of 19th- and early 20th-century scholars. Their education was assumed to foster virtues that would make them competent and trustworthy investigators of the human condition in their public

lives. In devoting themselves to the pursuit of knowledge and undergoing the intensive training required for admission to the academy, these researchers were thought to be wiser and more dispassionate than ordinary folks and to be able to project the consequences and implications of decisions better than others. However, by the middle of the 20th century, enough egregious acts had been committed in the name of research by the highly educated in Germany, the United States, and elsewhere that philosophers, policymakers, and researchers themselves questioned whether the reliance on character development in scholarly training was sufficient to ensure the ethical practice of research.

The codes of ethics for research practice that have been developed by government bodies and professional scholarly associations during the past 60 years or so are based on a mix of elements from justice-based ethics, duty-based ethics, and consequence-based ethics. Justice-based ethics, as used here, is an amalgam of the principle of individual human rights and the principle of fairness. Because they are human, individuals are entitled to certain basic expectations of treatment by others. The justification for these rights can be supernatural or ensured by a deity, natural or assumed integral to human nature, or social and ensured by contractual agreements. Two typical statements of human rights are the presumption of life, liberty, and pursuit of happiness from the U.S. Declaration of Independence and the various rights endorsed by the 1948 United Nations Universal Declaration of Human Rights. Rights must be protected, however, and justice or fairness in the treatment of others is the imperative that everyone's rights must be equitably observed. The right to liberty assures people that they have the right not to be studied if they elect to decline an invitation to participate in research. The right to privacy assumed in many 21st-century societies assures people control over their personal information and the authority to decide when information may be made public, which information they are willing to share confidentially, which information they are willing to share anonymously, and which information is not to be shared at all. The right to justice means that individuals can expect a fair distribution across human groups of the risks and benefits of research.

Duty-based or deontological ethics is based on the principle that humans have obligations or duties to their fellow humans, their communities, and themselves. Deontology can be viewed as the human responsibility

balance to human rights. It requires that humans act toward others in such a way as to meet obligations and avoid wrongdoing. Kant, the most influential deontologist in Western thinking, developed the categorical imperative that specifies human duty in two ways. First, individuals must treat others always as ends and never merely as means. Acknowledging humans as autonomous decision makers means, among other things, respecting their refusal to participate in research and informing those who do participate of what is involved. Second, individuals are enjoined to always act as though each action were the universal template for all such actions. This aspect of the categorical imperative requires scholars to define their obligations as researchers and to carry out these obligations consistently.

The third principle-oriented category of normative ethics influential in research ethics is consequence-based or utilitarian ethics. Consequential ethics is decision making based on the anticipated outcomes of a choice. Utilitarianism, a kind of consequential ethics developed by British philosophers during the late 18th to mid-19th centuries, specifies the greatest good for the greatest number as the best ethical choice. Like the directive to “do no harm,” cautioning researchers to consider and avoid negative effects of their research activity, the concern to balance benefits and risks in research activity is grounded in utilitarian ethics. Consequences matter. Researchers might not be fortune-tellers, but they are expected to anticipate the results of what they do and inform their participants of these expectations.

A normative ethic organized around relationship dynamics rather than principle was developed by the psychologist Carol Gilligan and the philosopher Nel Noddings during the last quarter of the 20th century. The ethics of care is grounded in the supportive relationships among people. Caring requires a balance of attention to the best interests of all involved in the relationship—self and others. The ethics of care directs qualitative researchers to conduct themselves toward others naturally and directly and to support relationships based on positive feelings and concern for each other. The ethics of care has been especially influential in recent qualitative scholarship conducted by feminists and other researchers using critical frameworks who have also addressed how ethics and morality are affected by power imbalances in human relationships and the inherently political nature of human interactions.

Meta-Ethics

These relational and principled bases for ethical choices, as influential as they have been, are incomplete sources for ethical decision making if researchers lack awareness of the meta-ethics that underlie how normative ethics is applied. Meta-ethics and its epistemological linkages have become particularly relevant to postmodern, poststructural, and postcolonial challenges to conventional Western thinking about ethics.

Meta-ethics is the assumptions individuals make about their moral theories and their ethical decision making. Epistemological positions, such as objectivism, subjectivism, intersubjectivism, and constructivism, and ontological positions, such as materialism, realism, and idealism, are as relevant in the ethics of research as they are in other conceptual and methodological areas, and readers are referred to those entries elsewhere in the encyclopedia. However, three facets of meta-ethics bear discussion here.

One dimension of meta-ethics is how firmly frameworks apply to decisions. Some view ethical frameworks as absolute; others view such frameworks as relative—either as relative to the cultural setting or as situation dependent even within the same cultural milieu. Consequently, cultural relativism, the recognition that cultures vary in ideologies, is not always the same as moral relativism, the position that moral choices cannot be assessed by a unitary standard. Some cultural patterns are either universal or so common as to be nearly universal such as incest taboos, prohibitions on lying, and some restrictions on killing other humans. The source of universally absolute positions may be supernatural (a deity wills it), natural (conforming to a presumed human nature), or even social (convention requires it). Furthermore, people vary in when they assume situational, relative, and absolute positions; some norms may be taken as absolutes, whereas others are viewed as relative or situational. For example, how absolutely researchers should respect people’s right not to be studied becomes relevant when societies’ needs for knowledge conflict with this individual right. This is likely most pressing for qualitative researchers in the health professions when the need to prevent or manage threats to community health urges coercive measures for research participation.

A second facet of meta-ethics is the assumptions made about the locus of decision making. Since the European Enlightenment, most Westerners view decision

making as an autonomous individual's choice, although elsewhere in time and space, important decisions have been considered to be a community prerogative. The continuum of individual-to-communal decision making maps, to some extent, over a similar rights-to-responsibility continuum. All human groups are composed of individuals who interact as some kind of community, so all ethical decision making involves both individuals and their communal associations. Individuals have rights but also responsibilities to others. Where the lines are drawn varies considerably across groups. In the United States, for example, individuals whose autonomy is considered to be limited by youth, incapacity, and/or incarceration are considered to be vulnerable; responsible others must consent before the vulnerable can assent. In contrast, prior to approaching even adults for consent, researchers must first seek tribal or group approval for their research studies on many Native American reservations.

A third facet of meta-ethical thinking is represented by assumptions about how ethical decisions ought to be justified. Some ethicists believe that decisions ought to be made on the basis of rational argument alone, whereas others permit various degrees of affect, intuition, and emotion in the decision-making process. The principled versus relational normative ethics discussed previously differs partly over the admission of emotional concerns into ethical decisions. However, in the day-to-day ethical decisions that researchers report, some combination of reason, emotion, and intuition comes into play.

Ethical Issues in Qualitative Research

Research ethics and ethical decision making in research draw, then, from both normative and meta-ethical frameworks. Although early social, professional, and human scientists were expected to rely on the character development and virtues assumed to be emphasized in their educations as scholars, these communities of researchers were very small and members did exert moral influence over one another even though disagreements occurred. A case in point is the censorship by the majority members of the Executive Council of the Anthropological Society of Washington in 1919 of Franz Boas, later acknowledged as the "father of U.S. anthropology," for his public objection to intelligence gathering by some members of the anthropological community. This is

one of the earliest instances in which scholars publicly disagreed about the moral purposes of research.

Ethics in qualitative research, currently often associated only with the relationship of researchers to those they study, is an integral aspect of all decision making in research, from problem formulation to presentation of results. Policymakers, journalists, and members of the public sometimes appear to believe that scientific research and scholarship generally is supposed to be value neutral, disinterested, and free of moral or ethical positions. However, few researchers share this view. Research purposes serve some moral intent, research designs are expected to have integrity, research conduct is required (in some cases by law) to observe certain principles of humane consideration of participants, and research presentations (the representation of results) must observe the ethical conventions common to the venue of the reports.

Qualitative researchers produce studies intended to contribute to knowledge, improve practice, and transform the lives of participants. Although this emphasis on consequences predominates, other normative moral theories are also relevant to reflections on purpose. Participatory action theorists and critical theorists, including many feminist qualitative scholars, sometimes appeal to the ethics of care in formulating their goals. Others in the same traditions stress the ethics of justice, and they seek to uncover social ills and inequities in their research.

The censure of Boas was due partly to a difference of opinion about the purposes to which scholarship should be directed.

However, research ethics also addresses the integrity of the research activity. Honesty, openness, and candid revelation of a study's strengths and limitations according to commonly held standards of practice are typical indicators of the integrity of the scholarship. Some consider any covert work conducted in secrecy, for whatever purposes, to lack integrity because it is not amenable to the checks of peer review. More recently, the challenge to better protect participants in research has led to withholding or limiting public access to fieldnotes, transcripts, and other information collected in communities despite pressures from the media, the courts, and policymakers for full disclosure. Research integrity is most influenced by the ethics of virtue and the ethics of duty. Both, however, depend on standards for virtuous and dutiful research conduct, and these are contested in qualitative research practice.

Nevertheless, the ethical concern in qualitative research reported and discussed most frequently is the issues that arise because qualitative researchers work with participants face to face, over lengthy times, and (sometimes) in very intimate situations. Unlike most survey and experimental researchers, qualitative scholars learn what they seek to know by developing relationships with their participants. The extent to which these relationships can be caring and just while not exploiting participants is debated. Reporting the research then presents new issues for a world where many, if not most, research participants have access to whatever is published or presented about them. Here the ethics of consequences becomes the most common principle applied, although researchers also consider the justice of their presentations. In addition to how participants view themselves as represented, scholars consider how these representations of people in various walks of life convey morally legitimate images to the public. Thus, qualitative researchers must address the moral implications of their representations to those they study, to their scholarly colleagues, to policymakers, and to the media and the public. These competing interests and the varying moral priorities of researchers themselves mean that the ethical conduct of qualitative research is complex, evolving, and contingent across the course of a study and is a matter of continuing debate in the qualitative research community of practice.

ETHICS, RELATIONAL

See RELATIONAL ETHICS

ETHICS AND NEW MEDIA

New media of communication, such as computer networks, portable digital technologies, and email, offer qualitative researchers numerous possibilities for implementing traditional methods with novel adaptations and for shaping new research strategies. This entry reviews ethical concerns raised by the use of these media with respect to the impact on participants, the role of informed consent, expectations of privacy, and the need for security of data.

Alongside interest growth over the past decade, there has arisen much uncertainty, debate, and disagreement over ethical considerations surrounding research and new media. Whereas a handful of organizations

have adopted standardized ethical regulations, other scholars find that research ought to be informed by existing codes of ethics written before the advent of the new communication technologies. A third group continues to oppose codes altogether, preferring to make case-by-case decisions informed by the value of avoiding harm to research participants. The latter party finds that standardized procedures and regulations impede judgment rather than aid it and also impose uniform norms that are blind to the diversity of contexts, the dynamics of groups under study, the nature of the topic, the research approach, and the will of participants.

Impact on Participants

Notwithstanding their attitudes toward the institutionalization of codes, qualitative researchers who use new media of communication to conduct their research should, regardless of the research site, design, and objective, carefully examine the potential impact of their research on the experiences of the participants. Researchers should minimize or avoid altogether disruptions of existing social worlds or individuals' lives and should provide participants with informed consent whenever possible. There are three main types of research conducted through new media: textual analysis, interview research, and participant or nonparticipant observation. Most ethical issues around informed consent, privacy, and security are common to all of these research methods, yet some differences exist.

Informed Consent

Qualitative researchers doing work on new media need to be careful to avoid narrative appropriation—the stealing of personal stories. The procedure of informed consent is designed in part to avoid such a problem. For example, informed consent is not needed (although permission to reproduce copyright material might be) for the content analysis of publicly accessible websites. Research projects whose design is limited to the analysis of such easily available information are also typically exempt from institutional ethical reviews. Nevertheless, problems may arise when the intent of writers is not clear and when websites are password protected but still easily accessible. In both cases, information may be relatively easily available, but the intended audience may exclude researchers. On the other hand, individual or group interviews conducted through new media, as well as

electronic ethnographies (of both the participant and nonparticipant observation variety), should always be preceded by the granting of informed consent. To be sure, exceptions to the need to receive informed consent do exist. First, as previously noted, informed consent is generally not needed for analysis of the content of websites to be available to anyone. Second, informed consent is not always needed, or even desirable, in those cases where the mere request of consent could constitute a significant disruption of naturally occurring interaction on the research site unless that research site is owned or moderated by an access-granting group or individual. Third, informed consent is generally not needed when the type of information collected is not sensitive (i.e., does concern “intimate” or “private” information) and there is no possibility of indirectly identifying its author(s).

Privacy

Because participant observation studies generally require a high degree of interaction between researchers and informants, ethical issues surrounding privacy often arise. Therefore, researchers typically should clearly disclose their identities, roles, and objectives from the very beginning of their research. “Lurking” uninvited on a group's activity may be possible due to the nature of the medium, but it is clearly not always appropriate to do so. Researchers should remain open to receiving feedback from participants and should periodically inform the group of their identity and role so as to notify new members who may have only recently joined the group under study. Creating a website that explains the nature of the research, and making the website address known in a public profile, is also a particularly good idea. Even though consent might not be needed, some researchers also generally make every possible effort to disguise the identities of the people under study. This can be done by assigning fictitious names instead of using actual screen names, by never mentioning the name or URL of internet websites, and by paraphrasing instead of quoting (given that exact quotes can easily be retrieved with the help of search engines). Nonparticipant observation studies, conducted through lurking as it were, are ethically feasible only when the group is meant to be easily accessible, when the researcher's presence would be disruptive if publicized to the group, when the information collected is not sensitive, and when the group's location and

confidentiality can be safely preserved. Ethnographic researchers conducting participant or nonparticipant observation should finally consider the degree of “popularity” of certain groups. Several studies have shown that members of groups whose activities traditionally attract the interest of scholars and students (e.g., self-help groups) are beginning to openly reject researchers’ presence, having grown tired of continuous requests for participation.

Security of Data Ownership and Exchange

Finally, research studies may cause concern regarding issues of security of data ownership and exchange. For example, email communication is amenable to interception and is easily copied and forwarded. Researchers must give careful consideration to strategies of preventing data loss, unauthorized access, inadvertent disclosure, and modification. These concerns may require advanced technical expertise for their solution, and it behooves researchers to seek the help of experts whenever needed. Issues of copyright may also complicate data collection. For example, who owns a message posted on a bulletin board or exchanged in a chat room or via a listserv? What should one do when message authors cannot be traced and contacted? Answers vary from case to case, and researchers should investigate these issues carefully before data collection.

ETHICS CODES

Ethics codes are directives specifying what is right and good, as well as what is wrong and bad, in research. Nations such as Canada and the United States have developed policies for the ethical conduct of research, administered as codes of research conduct. More detailed ethics codes have been adopted by professional societies to guide members in their research activities. Because many of these codes were designed to cover the range of research designs from biomedical to social-behavioral, and from quantitative to qualitative, researchers attempting to apply them have reported some difficulties and challenges.

Prescriptions and proscriptions, injunctions to engage in or refrain from specified behaviors, are as old as human records. What is recent is the codification of injunctions for researchers. Ethics codes for researchers originated during the post-World War II era with the 1949 Nuremberg Code and the 1964 Declaration of Helsinki, developed in reaction to Nazi medical experimentation on concentration camp inmates and to questionable research conduct in Western democracies such as the U.S. Public Health Service syphilis studies among African Americans in Tuskegee, Alabama.

Ethical conduct of federally sponsored research in the United States is guided by the Belmont Report of 1979 and in Canada is guided by the Tri-Council Policy Statement (TCPS) of 1998. Other countries have developed comparable guidelines administered by a variety of agencies, but all national research codes of ethics focus on protecting the public. The Belmont Report, for example, mandates three principles for ethical conduct of research: respect for persons, beneficence, and justice. These are commonly translated into procedures ensuring informed consent and protection of vulnerable populations, balancing of risks and benefits, and equity in the distribution of risks and benefits.

Concurrent with the development of national ethics codes have been the various codes of research ethics developed by professional associations. In addition to protection of human subjects, these codes address the quality or integrity of the research, intellectual property rights and scholarly relationships, and the moral conduct of researchers as means to maintain the discipline’s public standing. Unlike national ethics codes, usually enforced by peer review of research plans

before studies may begin, professional codes are often considered to be educative rather than disciplinary. Professional organizations rarely take on review and resolution of ethical disputes, leaving these actions to other institutions such as the universities or agencies employing those charged with violations.

ETHICS REVIEW BOARDS

See INSTITUTIONAL REVIEW BOARDS

ETHICS REVIEW PROCESS

Many countries are experiencing continuing growth in qualitative research, especially since the early 1990s, involving numerous disciplines and fields. At the same time, the ethics review process has gained prominence in these same countries. The ensuing engagement between qualitative research and the ethics review process has not been easy. This entry presents the sources of these difficulties and their impact, identifies key ethical issues, and presents current debates and actions.

Sources of Difficulties

Some of the difficulties reside in the fact that policies related to research ethics—national in scope—are premised on biomedical research and inadvertently promote an epistemology that is in conflict with paradigms associated with qualitative research. Moreover, membership on (local/university) ethics committees is represented by disciplines that do not naturally gravitate toward qualitative research. These two distinct facets of the ethics review process present qualitative researchers with an abundance of obstacles in receiving approval for their work.

The other set of difficulties arises from the diversity of disciplines and the variety of methods employed by qualitative researchers. As a consequence, it is difficult to formulate a coherent, one-format approach to ethics review for qualitative research proposals. Some disciplines, such as nursing, stand far closer to the medical model of research, whereas other fields, such as adult education (which might use autobiographical narratives), are far removed from the biomedical model.

A third source of the problem involves communication and can be traced to power differentials between those who promulgate ethics codes inspired primarily by concerns in biomedicine and those who practice qualitative research. Qualitative researchers are required to articulate their distinctive approaches, strategies, and paradigms in a language familiar to the dominant positivist model of research. This articulation is made more problematic by the fact that qualitative research is diverse. There is no one voice. By way of analogy, it is comparable to the many diverse Indigenous tribes who must express their wishes with one voice.

Impact of Difficulties

No doubt, the diversity of approaches within qualitative research has meant that the impact of the ethics review process has been felt unequally by those disciplines. There is very little empirical research on this impact, although there are a number of published, usually personal, accounts of qualitative researchers. The Qualitative Analysis Conferences in Canada, for example, have seen a decline of subcultural research that is a natural home for qualitative research. Research ethics boards issue many cautions about doing research on vulnerable or marginal groups or on groups engaged in questionable illegal activities. Researchers perceive such cautions as obstacles. Also in Canada, field research has suffered a significant decline over the past

10 years or so. In sociology alone, the proportion of master's theses using research participants dropped from 57% in 1995 to close to 42% in 2004. When one considers that the proportion of master's theses using fieldwork through 2002 averaged 21% per year, one notices an immense drop of such theses after the introduction of the national research ethics codes, with an annual average of 5.5%. In anthropology, Will van den Hoonaard and Anita Connolly also discovered that Canadian master's theses have increasingly come to rely on interviews, rather than fieldwork, as the sole data-gathering technique (47.9% in 2004). Disciplines relatively new to qualitative research do not see anything unusual in this trend. In conventional fieldwork, however, formal interviews were not a main component of research, although conversations, chats, and the like

were more common at that time than they are now. No doubt, other pressures on students, such as time limitations on completing their degrees, have exacerbated this trend toward more simplified models of research, pushing field research to the back.

These findings underscore the process of the homogenization of methods—a research situation where several disciplines have adopted one data-gathering technique; namely, the interview method. The decline of field research would lead one to conclude that we are also witnessing a pauperization of the disciplines; history, society, and culture are pushed to the background, and although the “voices” of the participants are privileged (and no one can deny their importance), without placing them in a historical and social context, the voices carry less power.

Two Contrasting Examples of Ethics

Mitch Duneier's *Sidewalk* (published in 1999) does not follow ethics guidelines advocating anonymity. The book features photos of all 28 people Duneier interviewed or observed. Except for a very few minor instances, there is no attempt to cover the identity of the people featured in this ethnography. It is a study of the social structure of sidewalk life in New York City—an area of three city blocks. Duneier asserts that the lack of anonymity allows readers and researchers to verify his findings. It is striking that his research covers a “vulnerable” group. It is also notable that participants were particularly enthusiastic about and interested in Duneier's research. Some interviewed each other when Duneier was absent at times; others expressed their gratitude that their names and photos would appear in the book so that they would have something to show their families as having accomplished something in life. Two research participants became part of a university course as presenters.

Whereas *Sidewalk* represents a form of scholarship and research liberated from the shackles of anonymity and confidentiality, Timothy Diamond's book, *Making Gray Gold: Narratives of Nursing Home Care* (published in 1992), involves covert research and intricate relationships with all those with whom Diamond came into contact when he worked as a nursing assistant in three different nursing homes in Chicago for 3 to 4 months each. Several chance encounters with exhausted and complaining nursing assistants in a local coffee shop had aroused his curiosity about life and work in nursing homes. As his research moved along, the circumstances

of the nursing homes forced him to conduct undercover research. However, he was the only White person on staff and, as such, his presence would evoke questions. He confesses, “In this atmosphere [of poorly paid work and tension], since the workers had viewed me with some suspicion in the first place, it became increasingly impossible for me to reveal to management that I hoped to write about my experiences.” The suspiciousness of the climate and the divisions of power between management and staff prevented him from disclosing his work. “Eventually,” Diamond confesses, “I disclosed to some residents that I hoped to write about nursing-home life,” and then they proceeded to give him advice. A number of nursing assistants asked him whether he was writing a book, and he truthfully said that he was. His scribbles during his work as a nursing assistant led to the question: “What are you doing, Tim, writing a book?” He came up with a reply, fearing a rejection, but his disclosure resulted in people saying, “Hey, good luck.” The nursing assistants even said that he should not forget to put this or that item in his fieldnotes.

Both Duneier's and Diamond's accounts are significant in the annals of social research. Their research is demonstrably highly ethical, as is evident from the profound respect toward research participants and from the researchers' attempts to bring injustice and the plight of the human condition (homeless street vendors, the indignities suffered by nursing home residents, and the abysmal working conditions of nursing assistants) to the attention of the broader public.

Sources: For more information on this topic, see Diamond, T. (1992), *Making Gray Gold: Narratives of Nursing Home Care*. Chicago: University of Chicago Press; Duneier, M. (1999). *Sidewalk*. New York: Farrar Straus & Giroux.

It is tempting to attribute (wholesale) these changes in qualitative research to the ethics review process. However, disciplines (both individually and collectively) are also undergoing changes as a result of developments in the larger context of culture, society, and the economy. A heightened sense of individualism and pressures on professional advancement through grants, for example, also play a significant role in shaping qualitative research.

Key Ethical Issues

Among the more serious distinctions that qualitative researchers might find troubling in ethics policies is the emphasis on individualism. Policies emphasize the importance of humans as organic entities—a legacy of their biomedical origins—rather than as social and cultural beings. How can consent of the group be predicated on such a model? Does the use of written (and signed) consent forms vitiate the relationships and personal trust on which field researchers rely? Is confidentiality a nonnegotiable item in ethics review of research? Qualitative researchers recognize a number of settings where research participants insist that their voices be heard and that their names and contributions be recognized. Similarly, requiring research participants to sign forms has a coercive element. Qualitative researchers might find the use of an “information sheet” more appropriate for their research settings; while containing basic information about the research, the information sheet puts the ethical onus on the researchers and is less likely to engender distrust because it is only the researchers who sign the sheet, not the research participants. In participant observation research, consent forms (and even information sheets) are impossible to use given the large number of people involved in everyday settings. Another fundamental issue concerns the open-ended nature of qualitative research that qualitative researchers see as its strength. The notion of “hanging out,” or of having just exploratory questions guiding the interviews or research, does not fit into the ethics review process mold. Yet these issues drive at the heart of qualitative research.

Among the more minute distinctions includes the coinage of terms that are unfamiliar to qualitative researchers. The use of the term *human subject* was a hotly debated issue that seems to have resolved itself because biomedical researchers themselves are now using the term *research participant* as a matter of course. The term *protocol* constitutes another distinction between dominant research and qualitative research paradigms. In this case, the switch has gone

in the reverse direction. Qualitative researchers use the word *protocol* more frequently to describe their plans for research, although in a strict sense the term refers to a measurement that is not subject to interpretation. The qualitative research approach is more iterative than what the term *protocol* suggests.

Publications constitute another significant area not directly covered by the ethics review process. Whereas in biomedical research data have already been anonymized by the time they reach the publication stage, in qualitative research it is unlikely that data are anonymized to the same extent. This condition forces qualitative researchers to consider more carefully the nature of identifiable data and persons in the publication of research findings. National research ethics codes do not offer guidance in this respect, leaving qualitative researchers to educate themselves and each other.

Current Debates and Actions

A number of countries are undertaking the task of bringing qualitative research more visibly into national research ethics codes by an explicit recognition of its methods, epistemology, and approaches that are at variance with the medical model of research. This task is receiving obliging support from those responsible for developing national research ethics codes, especially in Canada and Australia.

Still, obstacles to fully integrating the models of qualitative research into research ethics policies remain. The discourse on interdisciplinarity, for example, insists that the language of qualitative research needs to conform to the dominant one. This discourse makes it more difficult to focus on the distinctive characteristics of qualitative research because it takes the thrust away from the particular needs of qualitative research. The challenge, then, is to admit the importance of interdisciplinarity without letting go of the distinctive problematique of ethics vis-à-vis qualitative research.

What the future of qualitative research and the ethics review process will bring is hard to predict. The ethics review process is an inexorable one, and new researchers see it as normative. If the paradigms of qualitative research find a voice in research ethics policies, one must surmise that other fields will stand to gain given that they too must acknowledge that some of their work is more inductive than they formally advocate. The key to change, then, is to acknowledge that when the ethics review process takes qualitative research seriously, the whole research enterprise will stand to benefit.

members. His studio exercises in “ethnodramatics” preceded more formally staged ethnotheatrical productions by scholars and artists. Various academic disciplines have explored ethnodramatic approaches to research and include fields such as education, anthropology, sociology, and health care. The professional commercial theater has also developed a few successful works that are ethnodramatic in nature such as interviews of a New York City fire captain’s grief and healing after the September 11, 2001 terrorist attacks in Anne Nelson’s drama *The Guys*, a musical adaptation of Studs Terkel’s book *Working*, and Eve Ensler’s raucous one-person show *The Vagina Monologues*.

Purposes and Goals of Ethnodrama

Ethnodrama, as a form of arts-based research, is a representational and presentational mode of ethnographic reporting chosen by the researcher or artist when the dramatic genre and theatrical medium will create the most credible, vivid, and persuasive portrait of the participants’ culture and lived experiences and, hence, an informative, emotion-generating, and aesthetic experience for its readers and/or viewers (assuming a well-developed script, sound production values, and a receptive audience). Producers of ethnotheater may have varied goals for their work, ranging from basic education of its audiences about a particular culture, to social change agendas for motivating discussion and action toward the unjust, to artistic yet for-profit ventures produced by the commercial theater industry.

ETHNODRAMA

An ethnodrama is the written transformation and adaptation of ethnographic research data (e.g., interview transcripts, participant observation fieldnotes, journals, documents, statistics) into a dramatic playscript staged as a live, public theatrical performance.

More than 50 terms synonymous with or related to ethnodrama have been coined and include variants such as ethnographic performance text, performance ethnography, documentary theater, docudrama, nonfiction playwriting, theater of reenactment, and reality theater. For purposes of this entry, *ethnodrama* refers to the written playscript, whereas *ethnotheater* refers to the production and live performance of the playscript.

Anthropologist Victor Turner experimented with traditional ethnographies that were dramatized and performed improvisationally by students in classrooms to gain a deeper understanding of a culture and its

Ethnodramatic Playwriting

Ethnodramas are as varied in style as the historic and contemporary canons of dramatic literature. Some ethnodramas may be scripted as verbatim, slice-of-life naturalism to replicate authentic social interaction on-stage. Others may be scripted and produced as direct address presentations, incorporating theatrical devices such as abstract movement, poetic choral speech, projected media, and evocative background music.

Ethnodrama, like traditional dramatic literature, is most often composed as monologue and/or dialogue and is usually accompanied with stage directions. The primary sources of an ethnodramatic text are the participants’ lived experiences, which can emerge from the researcher himself or herself as autoethnographer, to qualitative or ethnographic fieldwork with everyday citizens whose lives and perspectives have been documented and then adapted into dramatic narrative form.

Playwrights of ethnodramas must consider the balance between naturalistic authenticity and the creative interpretation of reality—each a legitimate style for the staged performance of social life, but artistic choices that may affect the production’s and research project’s credibility and aesthetic impact on its audiences.

As a brief example of naturalistic reconstruction of dialogue, refer to the sidebar with an excerpt from the ethnodrama *Street Rat*. This conversational exchange among three teenage girls orients the audience to the culture of runaway youth. (Their references to “Roach” and “Tigger” are about teenage boys who also live with them.) *Street Rat*’s primary data sources were interviews with homeless youth in New Orleans conducted by Susan Finley during the late 1990s coupled with her son Macklin Finley’s personal observations, lived experiences, and evocative poetry of street life in the city. Johnny Saldaña, as primary adapter and director of the ethnotheatrical production, reassembled the Finleys’ body of nondramatic creative work into playscript form and, after conducting participant observation fieldwork in New Orleans, staged the play

with authentic regional artifacts, music, and costuming to represent the cultures depicted in the drama.

Examples of Ethnodrama

Although some members of the academic community question ethnodrama’s legitimacy as a form of research representation and presentation, the commercial theater has successfully produced ethnodramatic work since the 1980s. Selected examples of ethnodramas from the commercial canon include (a) Anna Deavere Smith’s *Twilight: Los Angeles, 1992*, a series of monologues adapted from interviews with Los Angeles residents about the April 1992 riots prompted by the Rodney King verdict; (b) Moisés Kaufman and members of the Tectonic Theater Project’s *The Laramie Project*, a collage of monologues and small group scenes of citizens from Laramie, Wyoming, reflecting on the 1998 murder of Matthew Shepard; (c) Jessica Blank and Erik Jensen’s *The Exonerated*, the stories of six innocent people on death row who were falsely accused and convicted for crimes and then exonerated; (d) Doug

Excerpt From an Ethnodrama

An excerpt from Scene 2 of the ethnodrama *Street Rat* by Johnny Saldaña, Susan Finley, and Macklin Finley:

(lights rise and music fades as JEWEL and QUIZ enter, escorting GENIE, about seven months pregnant and a worn tote bag strapped on her shoulder; they are orienting her to the life of a street rat at The Fortress, their squat)

JEWEL: Sometimes it takes a while before you find a squat.

QUIZ: You’ll look around and find a place, and then find out that somebody’s already squatting there.

JEWEL: Either that, or a place will be really dirty and you have to clean an area, pull all the trash.

QUIZ: Try to find a squat where there are already other squatters and then stay, because it’s safer, as long as there aren’t too many people.

GENIE: (sitting and looking at the property) The first place I stayed was this cool old house. It was abandoned. We slept in the attic.

JEWEL: This complex is condemned. The city is supposed to tear it down eventually.

QUIZ: Roach decides who can live here.

JEWEL: That means he can decide what’ll happen to you. He kicked his girlfriend out during a raid, and she was afraid she would run out there and get arrested.

QUIZ: Most people don’t give a fuck what Roach does. For one thing, he won’t even hit girls. If he just dislikes you, he doesn’t care if you stay here, but if you do something to piss him off, you don’t even want to stay here. Roach and Tigger had to chase three people out last week. They beat Scooby up a couple of days before that. (showing GENIE) All these holes in the wall? They put his head through it.

JEWEL: Roach owns The Fortress. But you want some protection, some kind of squat boss. Every single room is open—take your pick. We call the courtyard the pit. If you’re going to fight, you take it to the pit.

Source: Saldaña, J., Finley, S., & Finley, M. (2005). Street rat. In J. Saldaña (Ed.), *Ethnodrama: An anthology of reality theatre* (pp. 139–179). Walnut Creek, CA: AltaMira. Used by permission of AltaMira Press.

Wright's Pulitzer Prize-winning *I Am My Own Wife*, a one-man show based on interviews with gay German transvestite Charlotte von Mahlsdorf; and (e) Emily Mann's *Still Life*, monologues of a veteran marine, his wife, and his friend's struggles to cope with the traumatic aftermath of the war in Vietnam.

Selected examples of ethnodramas from the scholarly literature include (a) Joni L. Jones's *sista docta*, an African American woman's complexities as a professor in European American academia; (b) Gail Campbell and Diane Conrad's *Arresting Change*, observations of incarcerated 12- to 18-year-old male offenders in Alberta, Canada; (c) Johnny Saldaña's *Finding My Place: The Brad Trilogy*, an adaptation of Harry F. Wolcott's anthropological case study of a paranoid schizophrenic; (d) Brad Vincent's *The Silence at School*, a readers theater collage of boys' stories about growing up gay in Texas elementary and secondary schools; and (e) Ross Gray and Christina Sinding's *Handle With Care?*, a profile of women's experiences with metastatic breast cancer.

In addition to the work of Victor Turner, scholars such as Dwight Conquergood, Norman K. Denzin, D. Soyini Madison, Jim Mieniczakowski, Johnny Saldaña, and Richard Schechner are generally viewed as principal writers of ethnodramatic theory and practice.

ETHNOGRAPH (SOFTWARE)

Developed by U.S. sociologist John Seidel and first launched in 1985 by Qualis Research Associates, Ethnograph was among the first wave of computer software packages that facilitated the electronic management of qualitative data (transcribed words). Like the majority of these types of packages, it can be used for storing, searching, retrieving, reorganizing, and selectively viewing qualitative data input into text files. Ethnograph frees researchers from the time and effort involved with needing to manually perform these tasks—often formerly done by physical cutting and pasting of hard copy—and consequently gives them more time to focus on understanding their data and theory development. Other potential strengths include making data more accessible, more secure, and less likely to be lost or confused. Ethnograph has a good reputation as being reliable and user friendly, with a good network for assistance and training. It can be obtained through individual private purchase or accessed through institutions that hold an appropriate license. The latest version of Ethnograph introduced in 2007 (Version 6) includes a range of improvements related to functioning and ease of use (Figure 1).

Beyond performance comparisons with rival packages, no serious criticisms have been leveled specifically at Ethnograph. All software management packages, however, have been collectively subject to the same general criticisms. Some academics have noted that they are based on, and thus are far more suited to, the analytic process used in grounded theory. Others have noted that they reduce traditional manual approaches to inferior status—when in fact there is no evidence to suggest that they are inferior. In turn, it is thought that their use can be motivated by the perceived need to legitimize the analytic process within publications. Other critics have claimed that they make qualitative data analysis far too procedural and routinized, which can have two negative outcomes. One is

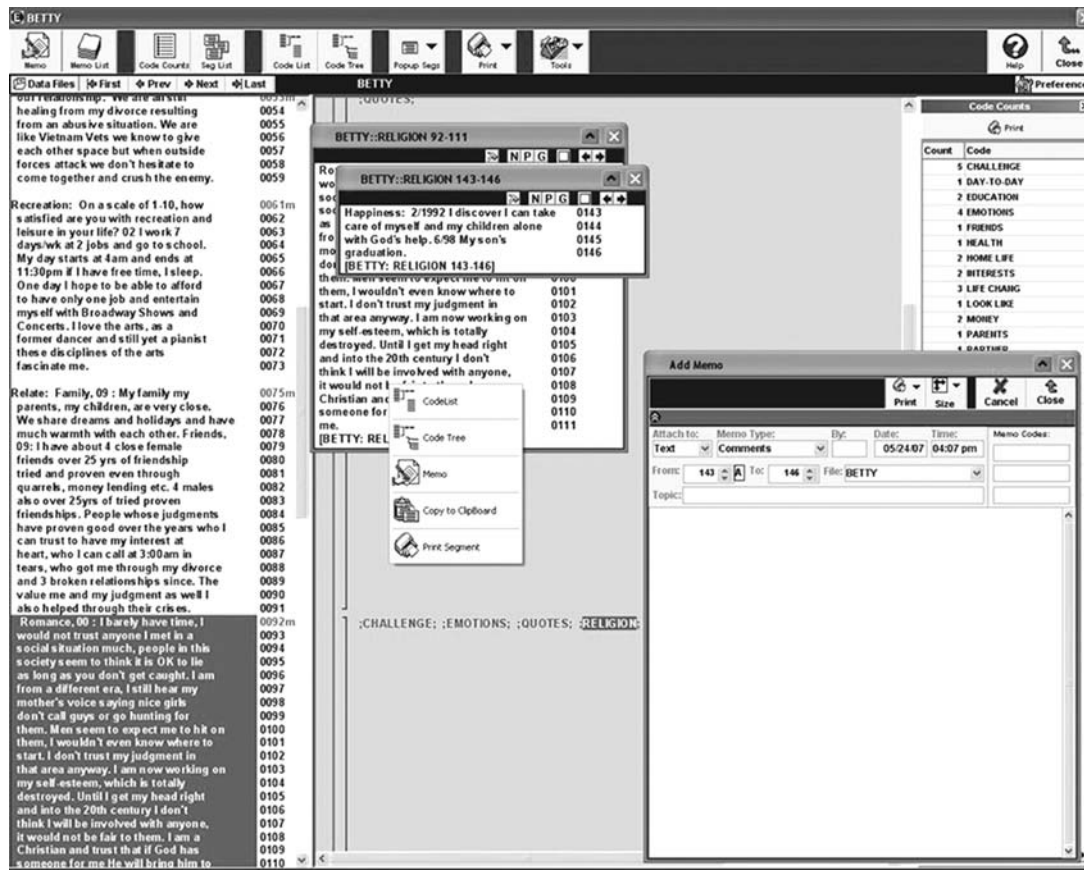

Figure 1 Ethnograph: The Coding Module in Ethnograph (Version 6)

Source: Used by permission of Qualis Research.

“coding fetishism,” whereby a software management package’s structural emphasis on coding makes coding become an obsessive end unto itself. A second negative outcome is that this encourages researchers to look for patterns in their data, rather than their meaning, potentially distancing researchers from “understanding” their data well. Overall, however, strong sales of Ethnograph and similar packages over two decades suggest that researchers find them to be of great use.

ETHNOGRAPHIC AND QUALITATIVE RESEARCH CONFERENCE

The Ethnographic and Qualitative Research Conference (EQRC), formerly known as the Ethnographic and Qualitative Research in Education Conference, originated in 1988 at the University of Massachusetts at Amherst. The conference was created to provide a forum for the dissemination of qualitative research studies. It subsequently moved to Teachers College at Columbia University in New York City. Thereafter, the conference was hosted at Duquesne University in Pittsburgh. EQRC moved to the State University of New York at Albany in 2004. In 2005 and 2006, the conference moved to

Cedarville University in Cedarville, Ohio, and plans are to continue hosting it there for several more years. Information regarding the past and present conferences, including electronic proceedings, remains posted on the respective university websites.

Moving EQRC to Ohio helped make the conference more accessible to potential participants from midwestern U.S. institutions. Located just outside of Dayton, the current location also is within driving distance of Cincinnati and Columbus airports. Consequently, accessibility is optimal with respect to both driving and air transportation.

The conference historically has been held around the first or second weekend in June. This allows professors to finish their semesters—and also to complete write-ups of papers they have developed over the course of the academic year. The conference has been hosted on university campuses, rather than in hotels, to make the experience feasible for graduate students and other researchers with limited travel funds.

EQRC draws more than 100 presenters annually. Papers are presented both in oral formats and via poster presentations. Presenters are drawn from a wide spectrum of institutions, ranging from Ivy League faculty members to graduate students. Results from doctoral dissertations and master's theses are presented regularly. Research projects are shared from all traditions of qualitative inquiry as well as conceptual and methodological papers.

Following the 2005 and 2006 conferences, selected peer-reviewed papers were published in a book by Cambridge Scholars Press under the title *Ethnographic and Qualitative Research in Education* (Vols. 1 and 2). A new peer-reviewed (print) journal has been established for publishing future selected EQRC papers. It is titled the *Journal of Ethnographic and Qualitative Research*.

In sum, EQRC has a distinguished history and has become a place both to hear paper presentations of cutting-edge research and to network with other qualitative researchers. The 2-day conference now provides a publication forum for scholars to place their research articles into print. The call for papers typically is issued in February on the EQRC website (<http://www.cedarville.edu/eqre>).

ETHNOGRAPHIC CONTENT ANALYSIS

Ethnographic content analysis (ECA) refers to an integrated method, procedure, and technique for locating, identifying, retrieving, and analyzing documents for their relevance, significance, and meaning. The emphasis is on discovery and description of contexts, underlying meanings, patterns, and processes rather than on mere quantity or numerical relationships between two or more variables.

A document is defined as any symbolic representation and meaning that can be recorded and/or retrieved for analysis. Document analysis will expand as recording technologies improve and become more accessible, including print and electronic media, audiotapes, visuals (e.g., photos, home videos), clothing/fashion, internet materials, information bases (e.g., Lexis/Nexis), and fieldnotes.

ECA involves emergent and theoretical sampling of documents from information bases (including those developed by researchers, e.g., fieldnotes), development of a protocol for systematic analysis, and constant comparisons to clarify themes, frames, and discourse. For example, if one is interested in studying television violence, it is not an act of violence per se that is socially significant but rather how that act is linked to a course of action or scenario as part of an entertainment emphasis (e.g., bad guys get shot by good guys to achieve justice) or how the use of violence is somehow linked to bravery, cunning, skill, and (of course) sex. The latter are themes or general messages that are reiterated in specific scenarios. The aim, then, is to query how behavior and events are placed in context and what themes, frames, and discourses are being presented. Steps include the following:

- Pursue a specific problem to be investigated.
- Become familiar with the process and context of the information source (e.g., ethnographic studies of newspapers and/or television stations). Explore possible sources (perhaps documents) of information.
- Become familiar with several (6–10) examples of relevant documents, noting particularly the format.

Select a unit of analysis such as each article (this may change).

- List several items or categories (variables) to guide data collection and draft a protocol (data collection sheet).
- Test the protocol by collecting data from several documents.
- Revise the protocol and select several additional cases to further refine the protocol.

A dynamic use of ECA is that of “tracking discourse” or following certain issues, words, themes, and frames over a period of time, across different issues, and across different news media. Initial manifest coding incorporates emergent coding and theoretical sampling to monitor changes in coverage and emphasis over time and across topics. For example, in a study of fear, a protocol could obtain data about date, location, author, format, topic, sources, theme, emphasis, and grammatical use of *fear* (as a noun, a verb, an adverb, etc.). The contexts for using the word *fear* are clarified through theoretical sampling and constant comparison with delineate patterns and thematic emphases. Materials are enumerated, charted, and analyzed qualitatively, using a word processor and a qualitative data analysis program (e.g., NVivo), as well as quantitatively.

ETHNOGRAPHY

Ethnography is the art and science of describing a group or culture. The ethnographer enters the field with an open mind, not with an empty head. Before asking the first question in the field, the ethnographer begins with a problem, a theory or model, a research design, specific data collection techniques, tools

for analysis, and a specific writing style. A series of quality controls, such as triangulation, contextualization, and a nonjudgmental orientation, place a check on the negative influence of bias.

The ethnographer is interested in understanding and describing a social and cultural scene from the emic or insider’s perspective. The ethnographer is both storyteller and scientist; the closer the readers of an ethnography come to understanding the native’s point of view, the better the story and the better the science.

Fieldwork is the heart of the ethnographic research design. In the field, basic anthropological concepts, data collection methods and techniques, and analysis are the fundamental elements of “doing ethnography.” Selection and use of various pieces of equipment—including the human instrument—facilitate the work. This process becomes product through analysis at various stages in ethnographic work—in fieldnotes, memoranda, and interim reports but most dramatically in the published report, article, or book.

Concepts

The most important concepts that guide ethnographers in their fieldwork include culture, a holistic perspective, contextualization, an emic perspective and multiple realities, an etic perspective, nonjudgmental orientation, inter- and intracultural diversity, and symbol and ritual.

Culture

Culture is the broadest ethnographic concept. The classic materialist interpretation of culture is the sum of a social group’s observable patterns of behavior, customs, and way of life. According to the cognitive approach, culture includes the ideas, beliefs, and knowledge that characterize a particular group of people. Ethnographers need to know about both cultural behavior and cultural knowledge to describe a culture or subculture adequately.

Many anthropologists consider cultural interpretation to be ethnography’s primary contribution. Cultural interpretation involves the researcher’s ability to describe what he or she has heard and seen within the framework of the social group’s view of reality. A classic example of the interpretive contribution involves the wink and the blink. A mechanical difference between the two behaviors might not be evident. However, the cultural context of each movement, the relationship between individuals that each behavior suggests, and the contexts surrounding the

two behaviors help to define and differentiate these two significantly different behaviors. Anyone who has ever mistaken a blink for a wink is fully aware of the significance of cultural interpretation.

Holistic Perspective and Contextualization

Ethnographers assume a holistic outlook in research to gain a comprehensive and complete picture of a social group. Ethnographers attempt to describe as much as possible about a culture or social group. This description might include the group's history, religion, politics, economy, and environment. No study can capture an entire culture or group. The holistic orientation forces fieldworkers to see beyond an immediate cultural scene or event in a classroom, hospital room, city street, or plush offices in Washington, D.C.

In a study about programs for dropouts, it was important to describe the inner-city environment in which the schools were located—an impoverished neighborhood in which pimping, prostitution, arson for hire, rape, and murder were commonplace. This helped policymakers to understand the lure of certain elements in the community that competed with the school for students' attention.

Emic and Etic Perspectives

The emic perspective—the insider's or native's perspective of reality—is at the heart of most ethnographic research. Native perceptions might not conform to an "objective" reality, but they help the fieldworker to understand why members of the social group do what they do. In contrast to a priori assumptions about how systems work from a simple, linear logical perspective—which might be completely off target—ethnography typically takes a phenomenologically oriented research approach.

An etic perspective is an external social scientific perspective on reality. Most ethnographers simply see emic and etic orientations as markers along a continuum of styles or different levels of analysis. Most ethnographers start collecting data from the emic perspective and then try to make sense of what they have collected in terms of both the natives' views and their own scientific analysis. Just as thorough fieldwork requires an insightful and sensitive cultural interpretation combined with rigorous data collection techniques, so too does good ethnography require both emic and etic perspectives.

Nonjudgmental Orientation and Inter- and Intracultural Diversity

A nonjudgmental orientation requires the ethnographer to suspend personal valuation of any given cultural practice. Maintaining a nonjudgmental orientation is similar to suspending disbelief while watching a movie or play or reading a book; one accepts what may be an obviously illogical or unbelievable set of circumstances to allow the author to unravel a riveting story.

Intercultural diversity refers to the differences between two cultures, whereas *intracultural diversity* refers to the differences between subcultures within a culture. Intercultural differences are reasonably easy to see. Compare the descriptions of two different cultures on a point-by-point basis—their political, religious, economic, kinship, and ecological systems as well as other pertinent dimensions. Intracultural differences, however, are more likely to go unnoticed.

Most of the houses in the inner-city neighborhood in the study of dropouts were in disrepair, many were marked by graffiti by local gangs, and entire blocks were in rubble. This was the "norm" concerning quality of housing in the neighborhood. However, there was intracultural diversity. There were families who were attempting to improve the quality of the neighborhood, and they "put their money where their mouths were" by painting and repairing their homes. They represented a special group with a symbolic message of hope in the community (Figure 1).

Symbols

Ethnographers look for symbols that help them to understand and describe a culture. Symbols are

Figure 1 Example of Intracultural Diversity in Terms of Housing in the Neighborhood

Source: Photo by David M. Fetterman.

Figure 2 Yeshiva in the Inner City With Graffiti

Source: Photo by David M. Fetterman.

condensed expressions of meaning that evoke powerful feelings and thoughts. A cross or menorah represents an entire religion. A swastika represents a movement, whether the original Nazi movement or one of the many neo-Nazi movements. A flag represents an entire country, evoking both patriotic fervor and epithets.

Symbols may signify historical influences in a community. For example, a Jewish star or Star of David on a building marred by graffiti and broken glass marks the historical presence of an orthodox Jewish community (Figure 2). This symbol of the past provides some insight into the roots of current tensions between young African Americans in the community and older Orthodox Jews.

Rituals are repeated patterns of symbolic behavior that play a part in both religious and secular lives. Ethnographers see symbols and rituals as forms of cultural shorthand. The next section details the ethnographic methods and techniques that grow out of these concepts and allow the researcher to carry out the work of ethnography.

Methods and Techniques

Fieldwork is the hallmark of research for both sociologists and anthropologists—working with people for

long periods of time in their natural setting. The ethnographer conducts research in the native environment to see people and their behavior given all the real-world incentives and constraints. This naturalist approach avoids the artificial response typical of controlled or laboratory conditions.

One of the benefits of fieldwork is that it provides a commonsense perspective to data. For example, in a study of schools in the rural South, David Fetterman received boxes of records indicating very low academic performance and high school attendance. This was counterintuitive and contrary to his experience in working with schools in urban areas where students who received poor grades dropped out of school. However, traveling to the school while watching cotton, rice, and soy fields pass by, mile after mile, it became clear to him that the data made sense. There was nothing else to do but show up at school.

Participant Observation

Participant observation characterizes most ethnographic research. Participant observation is immersion in a culture. Ideally, the ethnographer lives and works in the community for 6 months to a year or longer, learning the language and seeing patterns of behavior over time. Long-term residence helps the researcher to internalize the basic beliefs, fears, hopes, and expectations of the people under study.

In applied settings, participant observation is often noncontinuous, spread out over an extended time. In these situations, the researcher can apply ethnographic techniques to the study but cannot conduct an ethnography.

Interviewing

The interview is the ethnographer's most important data-gathering technique. General interview types include structured, semi-structured, informal, and retrospective interviews.

Formally structured and semi-structured interviews are verbal approximations of a questionnaire with explicit research goals. These interviews generally serve comparative and representative purposes—comparing responses and putting them in the context of common group beliefs and themes. A structured or semi-structured interview is most valuable when the fieldworker comprehends the fundamentals of a community from the insider's perspective.

Informal interviews are the most common in ethnographic work. They seem to be casual conversations,

but where structured interviews have an explicit agenda, informal interviews have a specific but implicit research agenda. The researcher uses informal approaches to discover how the people conceptualize their culture and organize it into meaningful categories.

Retrospective interviews can be structured, semi-structured, or informal. The ethnographer uses retrospective interviews to reconstruct the past, asking informants to recall personal historical information. All interviews share some generic kinds of questions. The most common types are survey or grand tour, detail or specific, and open-ended or closed questions.

Key Actor or Informant Interviewing

Some people are more articulate and culturally sensitive than others. These individuals make excellent key actors or informants. Key actors become performers in the theater of ethnographic research. Key actors can provide detailed historical data, knowledge about contemporary interpersonal relationships (including conflicts), and a wealth of information about the nuances of everyday life. Anthropologists have traditionally relied most heavily on one or two individuals in a given group. Ethnographers establish long-term relationships with key actors who continually provide reliable and insightful information.

Questionnaires

Structured interviews are close approximations of questionnaires. Questionnaires represent perhaps the most formal and rigid form of exchange in the interviewing spectrum—the logical extension of an increasingly structured interview.

Online surveys and questionnaires provide an efficient way in which to document the views of large groups during a short period of time. The questions are posted on the web and include yes/no, all that apply, open-ended, and 5-point Likert-type scale questions. Respondents are notified about the location of the survey on the web (with a specific URL), enter their responses, and submit their surveys online. The results are calculated automatically. The responses are often visually represented in a bar chart or similar graphic display as soon as the data are entered.

Unobtrusive Measures

The ethnographer attempts to be as unobtrusive as possible to minimize effects on the participants' behavior. A variety of measures, however, do not

require human interaction and can supplement interactive methods of data collection and analysis such as outcropping, and these unobtrusive measures allow the ethnographer to draw social and cultural inferences from physical evidence.

Outcropping is a geological term referring to a portion of the bedrock that is visible on the surface—in other words, something that sticks out. Outcroppings in inner-city ethnographic research include skyscrapers, burned-out buildings, graffiti, and syringes in the schoolyard. The researcher can quickly estimate the relative wealth or poverty of an area from these outcroppings.

Equipment

Notebooks, computers, tape recorders, cameras—all the tools of ethnography—are merely extensions of the human instrument; that is, aids to memory and vision. Yet these useful devices can facilitate the ethnographic mission by capturing the rich detail and flavor of the ethnographic experience and then helping to organize and analyze these data. Ethnographic equipment ranges from simple paper and pen to high-tech laptop and mainframe computers, from tape recorders and cameras to digital camcorders. The proper equipment can make the ethnographer's sojourn in an alien culture more pleasant, safe, productive, and rewarding.

Analysis

Analysis is one of the most engaging features of ethnography. It begins the moment a fieldworker selects a problem to study and ends with the last word in the report or ethnography. Ethnography involves many levels of analysis. Some are simple and informal; others require some statistical sophistication. Ethnographic analysis is iterative, building on ideas throughout the study.

Triangulation is basic in ethnographic research. It is at the heart of ethnographic validity, testing one source of information against another to strip away alternative explanations and prove a hypothesis.

Ethnographers look for patterns of thought and behavior. Patterns are a form of ethnographic reliability. Ethnographers are more confident about the accuracy of their descriptions when they see patterns of thought and action repeat in various situations and among various players.

Writing

Ethnography requires good writing skills at every stage of the enterprise. Research proposals, fieldnotes,

memoranda, interim reports, final reports, articles, and books are the tangible products of ethnographic work. The ethnographer can share these written works with participants to verify their accuracy and with colleagues to review and consider them.

Performance writing often drives good ethnographic writing. It involves writing for an audience, caring about audience members, and hoping that one's work will make a difference to them. It is relational in that it treats the readers like a gyroscope or a compass whereby the writer's words revolve around them.

Writing is part of the analysis process as well as a means of communication. Writing clarifies thinking. In sitting down to put thoughts on paper, an individual must organize those thoughts and sort out specific ideas and relationships. Writing often reveals gaps in knowledge.

Ethics

Ethnographers subscribe to a code of ethics that preserves participants' rights, facilitates communication in the field, and leaves the door open for further research. This code specifies, first and foremost, that the ethnographer do no harm to the people or the community under study. In seeking a logical path through the cultural wilds, the ethnographer is careful not to trample the feelings of insiders or desecrate what the culture calls sacred. This respect for social environment ensures not only the rights of the people but also the integrity of the data and a productive enduring relationship between the people and the researcher. Professionalism and a delicate step demonstrate the ethnographer's deep respect, admiration, and appreciation for the people's way of life. Noninvasive ethnography not only is good ethics but also is good science.

Ethnographers must formally or informally seek informed consent to conduct their work. Ethnographers must be candid about their task, explaining what they plan to study and how they plan to study it.

Ethnographers need the trust of the people they work with to complete their task. Ethnographers who establish a bond of trust will learn about the many layers of meaning in any community or program under study.

ETHNOGRAPHY (JOURNAL)

Ethnography, published by Sage, was launched in 2000. The current editors are Loïc Wacquant (University of California, USA) and Paul Willis (University of Keele, UK). *Ethnography* has an international editorial board with representatives from the United States and the United Kingdom but also Brazil, Denmark, France, India, Korea, the Netherlands, and Sweden. The journal's website outlines its scope. However, this was also set out in the "Manifesto for *Ethnography*" published in the journal's first edition. Four distinguishing features of *Ethnography* are articulated. First, the journal seeks to promote "theoretical informed-ness" rather than the pursuit of increasingly self-referential "grand narratives" of the social sciences or, on the other hand, merely descriptive research. Second, *Ethnography* seeks to recognize the centrality of culture in the broadest sense rather than narrowly discursive sense. Third, the journal seeks a critical focus on research and writing. Fourth, *Ethnography* promotes an interest in cultural policy and politics.

Consistent with its interdisciplinary focus, *Ethnography* has produced several special issues focusing on topics of scholarly interest that invite participation from disparate disciplines: "Global Ethnography" (2001, Vol. 2, Issue 2), "Dissecting the Prison" (2002, Vols. 3 and 4), "Pierre Bourdieu in the Field" (2004,

Vol. 5, Issue 4), “Phenomenology in Ethnography” (2003, Vol. 4, Issue 3), “Grounds for a Spatial Ethnography of Labor” (2005, Vol. 6, Issue 3), and “Worlds of Journalism” (2006, Vol. 7, Issue 1).

In 2003, *Ethnography* and the Center for Urban Ethnography at the University of California, Berkeley, held a conference on “Ethnography for a New Century: Practice, Predicament, Promise.” This brought together academics from anthropology and sociology, with one aim being to clarify the standards of the journal.

Ethnography does not appear in the *Journal Citation Reports* and, hence, has no impact factor. Its website does, however, usefully provide a monthly updated list of the 50 most frequently read articles (based on hits received by articles archived on the site) and a list of the 50 most frequently cited articles (based on citations from articles in HighWire-hosted journals). For example, for the month beginning November 1, 2006, the two most frequently cited articles were Michael Burawoy, Pavel Krotov, and Tatyana Lytkina’s “Involution and Destitution in Capitalist Russia” and Burawoy’s introduction to the special issue on global ethnography, “Manufacturing the Global.”

Ethnography: <http://eth.sagepub.com>

the taken-for-granted “methods” used by members of collectivities to maintain a local sense of social order. It can be seen as a respecification of sociology as conceived by Talcott Parsons and as inspired by the phenomenology of Edmund Husserl, Aron Gurwitsch, and Alfred Schutz. Ethnomethodological studies require a deep immersion into the details of members’ practices in their local specifics through close observation ethnographically and/or by using audio- or video-recordings. At the same time, the researcher should “bracket” pre-given conceptions and evaluations of the character of the activities to be studied. Such studies cover an enormous variety of practical activities, ranging from ordinary conversation to highly specialized professional investigations. Ethnomethodology has been a major influence in the emergence of conversation analysis, whereas another offshoot, membership categorization analysis, is gaining more prominence. Because of its principled difference from other kinds of sociology, it offers a major challenge to social theory and sociological research practices.

Ethnomethodology’s Interest

To understand ethnomethodological studies, one must realize their specific interest. This differs so much from the taken-for-granted interests in the other human sciences that reading such studies without understanding what drives them only leads to confusion. What is basically at stake is the local achievement of accountability. The general idea is that in anything they do, people (as members of society) design their actions in ways such that their meanings are made available to other members. The empirical interest, then, is to explicate how this is achieved—how the sense of actions, their accountability, is made observable in situ.

Consider a simple action such as greeting. There is an enormous range of activities, such as gestures and sayings, that can be done to “do a greeting.” The way it is concretely done can be taken by recipients or others as somehow significant, say as warm or routine or reluctant. Timing in relation to other events and the fit in the situation will be essential. Any deviation from “greeting as usual” can be consequential for the relationship in which it occurs. For instance, a slow greeter can be held accountable: “Are you angry?” When less simple actions are studied, such as in the work of airline pilots to be considered later in this entry, similar interests will be pursued—the selection

ETHNOMETHODOLOGY

Ethnomethodology is the somewhat confusing label for a specific “alternate” sociology developed during the 1960s by Harold Garfinkel. Its mission is to study

of concrete modes of doing things, their fit in the local situation, their routine character or deviations from routines, timing, previous actions, later uptake, and so on.

For ethnomethodologists, specifying a culture's repertoire for doing particular actions is not enough. They want to know more about the circumstances and the concrete details of the local application of a culture's possibilities. Furthermore, they are not particularly interested in some of the aspects that many others in the social sciences want to know about, such as frequency distributions in terms of external variables, or various mental attributes, such as cognitions or attitudes that are often proposed to "underlie" specific actions.

In short, ethnomethodology asks "how" questions rather than "why" questions; its interest is procedural rather than explanatory.

Ethnomethodology's Methods

Ethnomethodology cannot be said to have one specific method. Instead, the methods that ethnomethodologists would use in a particular case should be adapted specifically to the character and circumstances of that case in the light of ethnomethodology's interest. Following from that interest, however, they do have certain (dis)preferences. The core data for ethnomethodological studies tend to be observations, either directly as ethnographic observations or indirectly by studying audio- or videorecordings. A major difference with most other qualitative researchers is that ethnomethodologists tend to avoid using interviews as their major data. In other research traditions, interviews are often used to gather self-reports, expressions of opinions and attitudes, and/or descriptions of scenes that the researcher has not observed directly. For an ethnomethodologist, these are "accounts" that for them can be interesting as such, as ways in which members bring off interview reports as situated actions, but not as a resource to study nonobserved events or "inner states." Only as aids to understanding particular specialized practices can interviews be useful.

The analytic process in ethnomethodology can be seen to occur in two steps. The ethnomethodologist first must understand the actions of the participants in a scene as they understand it. The second step is to analyze that understanding in procedural terms—how, by the use of which concrete methods, have the participants

achieved the actions as understood? To be adequate in these two aspects of ethnomethodological research, the researcher must develop a double-sided competence. On the one hand, he or she must be competent in understanding or even acting adequately in terms of the local culture, which involves practical common sense in local terms. But the researcher must also be able to use that understanding in an analytic way to explicate the procedures used in the actions observed.

Studies of Work

Using one's commonsense competence to understand a greeting does not seem to be very problematic, at least for scenes that are not too much different from one's own experiences. For situations that are not familiar, however, understanding may require a rather extensive period of getting to know the local ways of doing things. Maurice Nevile, for instance, collected his core data by videotaping the activities of flight crews on scheduled flights by commercial airlines to study "talk-in-interaction in the airline cockpit." But before he even approached the airlines to ask for their cooperation, he prepared his research by extensively reading whatever he could find about the operation of commercial airlines, training and operations manuals, official accident reports, and so on. He also watched available information videos showing pilots at work, visited conferences, and talked to research psychologists working with flight crews and accident investigators. In this way, he developed what he called a "disciplinary competence" in his field of interest; without this, he would have understood hardly anything that was happening in the cockpit. This is in line with what Harold Garfinkel called the "unique adequacy requirement of methods," meaning that for any particular topic of ethnomethodological study, the researcher must be "vulgarly competent" in the local practices and adapt his or her approach to what turns out to be necessary in the situation at hand.

Nevile's research is an example of what has been called "ethnomethodological studies of work" or, more generally, "workplace studies." Such studies are often done by a combination of ethnographic field observation and the detailed analysis of videorecordings made during the fieldwork. The ethnographic phase of the research is used mainly to acquire the local competence necessary to understand the practices that constitute "work" in the setting, whereas the recordings are used for the actual ethnomethodological analysis of

those practices. Ethnomethodology's preference for recordings is related to its interest in the details of the local social orders as are actually realized in situ. Ethnomethodological studies of work show that although most specialized work activities are based on a pre-given plan, protocol, or set of instructions, actually working according to the plan involves more than is, or can be, specified in the plan. A plan or script may specify the steps to be taken to do some kind of work in general terms, but doing the work involves adapting the instructions to local circumstances and realizing the work by using one's voice, one's body, various material objects, and so on. Cooperation at work, especially, requires following the activities of co-workers and fitting one's own activities into the situation as it develops. This may involve following the direction of a co-worker's gaze to understand what he or she is attending (e.g., a computer display) or overhearing a telephone conversation and, on the basis of what one hears, taking a next step in a work sequence. Repeated viewing of a videotape shot in a work setting provides the researcher with access to the lived details of work that would not be available in a "one time through" ethnographic observation written down later in the day.

Ethnomethodological studies, then, require an intense immersion into the details of actual social settings. The results of such studies cannot be reported in

generalized formal accounts. What is presented is rather the analytic description of one or more "cases," events, or practices. Such description can be read as instructions to see "more than the plan"—what is ignored or glossed over in any official rendering of the work. Official accounts are done "in terms of the plan" rather than as a concrete report of the work activities. This does not mean that the pre-given plan or the ultimate accounts in terms of it are themselves ignored in ethnomethodological studies; rather, it means that they are studied in the ways they are involved in the actual work of "following instructions" or "producing accounts."

Although ethnomethodologists will take the lived details of the actual practices very seriously, externally formulated official "versions" of that work tend to be held at a distance, so to speak. This is part of a strategy known as ethnomethodological indifference, which refers to a "bracketing" (to use an expression taken from phenomenology), or preconceived notions and evaluations about some activity, so as to be able to study it in its own terms as it is actually accomplished. Such pre-given notions and evaluations can stem from common sense, the social sciences, engineering, or managerial theories; whatever their origin, they are to be bracketed in favor of a close study of the phenomena at hand. This strategy, then, marks a fundamental difference between ethnomethodology and most other social sciences.

An Ethnomethodology Example: "Pilot-Speak"

In Maurice Nevile's book, *Beyond the Black Box: Talk-in-Interaction in the Airline Cockpit*, a major aspect of his analysis of pilots' talk is the use of pronouns. In fact, it takes him two chapters to report his findings on this aspect. The general issue is that by choosing a particular pronoun, such as "I," "you," or "we" (and its derivatives), a speaker relates the utterance in which it occurs to himself or herself to the addressee or to a locally relevant collective. In the case of cockpit talk, there are two pilots, a captain and a first officer, and for any flight there is a division of labor, where one is the "pilot flying" and the other is the "pilot-not-flying." For any action that is announced in speaking, it must be clear who is responsible for it. That is where the choice of pronouns comes in. The work of pilots is based on extremely detailed protocols, which may also prescribe

particular pronouns to be used on particular occasions. Chapter 2 details the use of "prescribed pronominal forms," and Chapter 3 reports on "nonprescribed pronominal forms." Both function to help pilots make explicit the distribution of duties and responsibilities. "I" can be used to claim an action, whereas "you" assigns it to the other. "We," on the other hand, can be used to stress a team identity and, for instance, a team achievement. These functions are recognized by the airlines and, therefore, are prescribed for certain occasions. In their daily practice, however, pilots often add pronouns where they are not prescribed, and in so doing they personalize their exchanges and, thereby, their "actions-in-coordination." A captain who often uses "we" rather than "I" may be seen as fostering a sense of partnership between the pilots.

Ethnomethodology's Mission

In workplace studies, as discussed in the previous section, the specific features of ethnomethodology—its interest and methods—can perhaps be seen most clearly. These include the requirements to attend to details, to immerse oneself into the local relevancies, and to acquire enough of the competencies to understand what is going on from the perspective of the workers while putting external conceptions and evaluations at a distance. Ethnomethodology in its current shape is not limited, however, to the study of specialized work settings. Similar requirements can, for instance, be formulated for the study of observable practices of severely handicapped persons, as David Goode's work makes clear. And although the study of less exceptional situations may make immersion and acquiring local competencies less spectacular, attending to details to understand "competencies in use" remains essential.

When the idea of ethnomethodology was being developed by Garfinkel, its topic—the seen but unnoticed features of ordinary action—was so hard to get in focus that he used very specific procedures, the so-called breaching experiments, to make them "visible." Although he continued to use some of these purposeful disturbances of ordinary situations as a pedagogy, they are no longer necessary as a general study policy today. Closely observing some utterly routine doings, such as greeting and (for pilots) arranging take-off, can provide a basis for understanding what goes wrong in exceptional situations, such as in "cold" encounters and airplane accidents, respectively. To maintain situations, whatever their kind, as in some way "orderly," work must be done systematically and routinely but adapted to local circumstances. Explicating that work is the task that ethnomethodology has set for itself.

ETHNOPOETICS

Dennis Tedlock defines ethnopoetics as the study of verbal arts in all languages and cultures, focusing in particular on the oral communication of proverbs, laments, prayers, praises, prophecies, curses, and riddles shaped by the spoken, chanted, or singing voice. Such studies aim at translating, transcribing, interpreting, and analyzing oral performances to make them cross-culturally accessible as works of art, hoping in the process to free all poetries from the constricting traditions of Western literature and thereby helping to transcend the artificial boundaries of language and culture that modern thinking harbors in separating itself from what it sees as the "others" of the world.

This effort was launched as a special genre of inquiry when Tedlock teamed up with Jerome Rothenberg to create the radical magazine *Alcheringa/Ethnopoetics* in 1970. Although similar work had been done piecemeal for several years, the magazine concentrated on ethnopoetics as a unifying theme. It was strongly committed to exploring new techniques of translating the poetries of tribal societies, especially the work of Indigenous verbal artists from Asia, Africa, Oceania, and the Americas. *Alcheringa/Ethnopoetics* is no longer published, but its goals and methodological experimentalism have continued to characterize the field since it began.

Narrative Verse

One important early development in this field was the recognition of narrative verse patterning—the idea

that Native American oral performances were organized by poetic line phrasings rather than by the sentence/paragraph forms imposed on them by Western transcribers. Pointing out that ethnopoetics is, above all else, committed to understanding the ways in which narrators choose and group words, Dell Hymes asserted in the process that the stories of Native American oral discourse are a form of poetry to be said and heard in lines—an idea he first had in 1960 while working on some of his Northwest Coast materials. Tedlock concluded much the same thing in his influential study of Zuni oral performances in 1972. He and Hymes disagree in part on how to identify the lines themselves, what is actually lost through dictated texts (e.g., not necessarily all paralinguistic features), and what might be saved through phonetically transcribed texts or, perhaps best of all, sound recordings of actual performances. Focusing on the body of the presentation itself (what is said *and* how it “sounds”), Tedlock puts a great deal of emphasis on the timings of sounds and silences in performances. Hymes says that identifying pauses as line breaks is not available for all narratives. He seeks poetic line identification primarily by identifying recurrent particle patterns in narrative structures. Nonetheless, both of them find empowering knowledge in treating oral narratives as dramatic poetry, thereby marking many translations as distortions of the originals forced by the dictation process, defeating the idea that form and content are independent, erasing presumptions of fixed boundaries between poetry and prose, and applauding new techniques of recording together with a sense of oral art as performance “events.” With this innovative thinking at hand, knowledge of Native American oral traditions has been greatly enhanced by the work of both scholars.

Dialogics

It is important to remember the dialogic character of all such communications and to keep in mind Mikhail Bakhtin’s wisdom that language never moves through uncluttered space. Discourse is heteroglossic and mutually constructive in all utterances—in all contexts of development, reception, and discovery—and context is practically everything for determining meaning. Translation (with its attendant nuanced, cultural, aesthetic, intellectual, and mechanical problems) escapes none of this as an activity. In fact, it helps to bring the role of the observer to the fore more readily than in most other domains of ethnographic

research. Ethnopoets want their work to be faithful to the grammatical and semantic patterns, styles, figurative speech and imagery, acoustics, rhythms, and associated paralanguage (including pausing and intonations) of original performances. But they must also see themselves as part of the cross-cultural equation. They know that they are an audience of a different kind. They are imposers and interpreters potentially loaded with distorting subjectivities, favoritisms, biases, inclinations, and cultural presuppositions about the nature of the world and their place in it. Moreover, because performance narratives are bound to be multivocal and polyvalent at one level or another, they are always subject to context-sensitive interpretations that cannot always be determined for the original performers in the case of *representations* or *rereadings*. The very action of *revisiting* and *reimagining* such circumstances creates original material and, thus, another potential source of distortion in the effort to render authenticity.

Getting to some authentic emulation or understanding of traditional oral performances of any kind, but particularly those considered to be “not our own,” forces the issue of meanings in fundamental ways and makes the effort truly an “artful science.” It raises the questions of what is lost from, or created and added to, discourse whenever it is moved from one person or culture to the next by anyone, not just by specialists. It is hard to overestimate the value of that kind of information for linguists, anthropologists, and the applied social sciences, particularly as they engage the rapidly expanding world of global commerce and postcolonial international relations.

Literacy

These “slow motion explosions” of expanding urban frontiers (as Gary Snyder likes to call them) not only call to mind the more or less synchronic changes inherent in the translation process—what to study and how to study it among our living contemporaries—but also serve as reminders that cultures and their associated behaviors have deep roots. Literacy itself, the invention and spread of writing and reading across the planet, has been largely overlooked in the study of oral art. Projecting that most modern of mentalities—reading as an avenue to interpretation—as a facile metaphor on all that we wish to understand (e.g., “reading” oral performances) can be an obstacle in the study of both oral and written traditions. There is a big difference between reading writing and speaking

thinking, especially if the spoken word occurs in the absence of any tradition for writing in preliterate or strictly oral cultures—all of which have been smothered by colonial conquests to some degree since 1492. Times have changed, and our sensibilities have changed along with them. The rise of alphabetic literacy and its dissemination through writing and printing technology have had a profound effect on what Donald Lowe calls the “hierarchy of the senses” and, thus, on the way in which we register and store information as humans. That raises the issue of just how much information about a people’s past oral traditions—preliterate cultural content and contexts—is contained in modern knowledge. The whole problem is bound up with enticing mysteries on how oral performances have changed in the long run, how resolving these puzzles at some satisfactory level might set new standards for estimating authenticity in performance studies, and what having that information might tell us about linguistic and cultural change in general.

Ethnopoetics and Humanism

The great demand of anthropological poetics (and its derivative ethnopoetics as defined here) is that we render these experiences as clearly and accurately as possible through our sense of being-in-place and the guidance of histories—our own and those of others—that appear to contextualize the material best. Such analyses can teach us things that are not available in any other way. Among many other possibilities, they can show us mystery and beauty and the need for being in them as we pass through the landscapes of our lives. Combined with what can be learned from rigorous methods, history, archaeology, and personal experiences, we can bolster our sense of ancient aesthetic and poetic creations by studying the legends, tales, myths, and meanings as they exist today in oral performances. In the quest to understand the rich and abiding nature of oral cultures, however, the bottom line must be more than a study of language and storytelling. It must be a critical exercise in the larger and more inclusive realm of an anthropology of experience, the anthropology of being human, the anthropology of shared humanity. Poetry and related performance arts, after all, are about all of us. They always have been.

ETHNOSTATISTICS

Ethnostatistics and quantification rhetoric are broad fields of study that deploy different sorts of qualitative methods to study the use of statistical, graphical, and numerical constructions in various settings. Ethnostatistical work has taken as its topic how the practices

of quantification are employed in medical, scientific, or media settings. Combined with quantification rhetoric, it has considered the way charts, summaries, and graphical displays are used to make persuasive points. Work in this tradition has also studied the everyday use of numerical constructions of various kinds. Some of this work has drawn on ideas from the sociology of scientific knowledge, some has drawn on ideas from discourse and conversation analysis, and some has drawn on ideas from linguistics. Whatever methodological preference, studies typically use careful analysis of numbers and statistics within particular settings.

This style of work brings to the fore the often hidden assumptions and practices that underlie quantification, whether in technical or everyday settings. It can be usefully split into five broad areas: studies of mathematics as a social practice, studies of the way objects and events are turned into mathematical summaries, research on the way different forms of quantification are built to support arguments, work on everyday uses of mathematical and semi-mathematical notions, and studies of how quantification is achieved in social science and the implications for how we should understand the status of quantification. Note that there is considerable overlap here; these classifications are intended to give a broad indication of the different focus of work.

Studies of Mathematics as a Social Practice

Constructionist approaches to quantification highlighted conventional, culturally embedded, or arbitrary features to mathematical systems. Ethnomathematicians have outlined radically different mathematical systems such as Islamic geometry and Inca data structures. Ethnomathematicians have suggested that the earliest known mathematical objects may date back 37,000 years—a bone with notches that appear to be for counting. At 25,000 years old, the “Ishango Bone” appears to provide a table of prime numbers and a lunar phase calendar, suggesting to some that the mathematician may have been a woman tracking menstrual cycles.

David Bloor has developed constructionist arguments further and attempted to show how different forms of mathematics and concepts of number were fitted to different societies. For example, he argued that moves to a more continuous notion of number were associated with an increasingly involvement of

mathematicians with problems of ballistics. The philosophers Ludwig Wittgenstein and Imre Lakatos both developed arguments that highlighted conventional elements to mathematics. Lakatos in particular attempted to bring philosophy of mathematics closer to history and sociology. He argued that mathematical proofs are not accomplished by formal procedures alone; historical studies of proofs show that they depend on a range of inexplicit or informal procedures.

There are profound debates over how far mathematics can be said to be invented or culturally contingent. For many ethnostatistical researchers, the issue is not whether mathematics itself is culturally contingent but rather how mathematics and various forms of quantification are built in different institutions and how they are distorted by social interests. For example, there is a range of studies in the tradition of radical statistics that explore critical issues such as the production of crime statistics to show increases in criminality or to show the effectiveness of severe punishment. These are not critical of statistical work as a principled project; rather, they are critical of particularly flawed or politically biased uses. In contrast, work in the sociology of scientific knowledge adopts a position of methodological indifference or relativism to the validity or correctness of statistical work and focuses instead on social questions of how it is produced and related to social organizations.

Studies of the Transformation of Phenomena Into Mathematical Forms

A second area of ethnostatistics has focused on the way objects and events are transformed into mathematical forms. For example, Michael Lynch studied the way biological specimens are represented in mathematical terms and the different transformations that are involved with such representation. He noted the way particular specimens are turned into mathematical objects by giving them a specific numerical code. As he put it in 1985, the “naturalistically visible lizard is no longer just a lizard, as it becomes the bearer of a numerical code. Marking preserves a class of lizards, equivalent in all respects except for the unique identity of each mark within the set of marks” (p. 41).

Malcolm Ashmore and others studied the application of economic reasoning to the topic of health. For example, they showed that the outcome of cost–benefit analysis of different configurations of health service

care was fundamentally dependent on a range of often inexplicit assumptions. These researchers found that health economists worked with highly contrasting notions of the precision and impartiality of statistics depending on the setting in which they were used. Their conclusion was that the success of cost–benefit analysis lies in its trading between the world of facts and figures and the world of politics. Although the contingency of cost–benefit analysis was demonstrated, they also showed that it is not easy to dispense with it.

This kind of work blurs into studies that focus specifically on the way quantification can be used to build rhetorical cases. Whereas the studies in this strand of ethnostatistics emphasize the contingency and optionality of producing mathematical versions, the studies in the next strand focus on the way the resources of quantification can be used to build cases and counteralternatives.

Studies of Quantification Rhetoric

Quantification rhetoric involves the use of mathematical, statistical, or otherwise quantified constructions (including figures, graphs, and tables) as parts of arguments in scientific articles, newspaper articles, and official reports. For example, Jonathan Potter and others studied constructions of medical progress in the effectiveness of cancer treatment. They showed the way a range of different calculation, fractionation, aggregation, and presentation practices were selectively drawn on to form the scaffolding of contrasting versions produced by representatives of cancer charities and skeptical critics. They highlighted the importance of inexplicit definitional decisions that constitute phenomena as countable in different ways and the importance of selective translations between numerical and nonnumerical formulations (1% vs. small). Studies of quantification rhetoric have focused in particular on the representation of socially controversial topics such as drug use, crime, and sexual identity. Sometimes the specifics of the statistical construction are related to broader media interests and political agendas. For example, James Orcutt and Blake Turner studied the way the U.S. media constructed a “cocaine epidemic” by using selective graphical representations that greatly exaggerated what original research data suggested was a largely static situation of drug consumption.

Studies of Everyday Measurement Systems

In Harvey Sacks’s foundational work on conversation analysis, he developed a fourth area of study that he called “members’ measurement systems.” He noted that in everyday settings, numbers are used with different logics. There is a different leeway for being late for an appointment made for “2:28” than for one made for “half past two.” In effect, there are different measurement systems implied by these different constructions. “Fast” on a car speedometer is different from “fast” relative to surrounding traffic. Precision is not something that is decided in an abstract manner but rather is something relevant to the interactional context; thus, one of the features of legal and medical interaction is that phrases such as “I have no money” and “it seemed like 3 days,” which have a precisely calibrated and communicative everyday logic, might not satisfy legal or medical criteria for precision. For example, “the water damage occurred at 4:30 AM” may be a description that has legal precision (perhaps in relation to alternative testimony), but “the water poured through the ceiling very early in the morning” may be a description that evokes sympathy for the victim and highlights the ordeal we experience when we are woken up by water penetration.

Problems With Quantification in the Social Sciences

A final cluster of studies is concerned more with the coding, mathematical, and statistical practices through which social science objects are manufactured. Some of this work is purely descriptive, but often such studies develop critical points about the basis of social science claims. Aaron Cicourel’s influential study of research on Argentine fertility showed a range of practical and often implicit procedures and judgments that went into the use of a set of questions to produce a statistical conclusion about fertility rates. Max Atkinson offered one of the clearest illustrations of the social processes that go into counting social facts, taking the example of suicide statistics (which have classically been used as a sociological indicator of community cohesion). He noted that cross-national suicide styles and relative stigma have a major impact on counting. For example, hanging is relatively unambiguous, whereas suicide by driving is often hard to separate from everyday traffic carnage; in strongly

Catholic cultures, coroners may be much more reluctant to treat a suspicious death as suicide. In addition, coroners, the police, and family members draw on culturally available notions of suicide to make sense of ambiguous deaths. All of this means that suicide statistics are already strongly a product of different cultural practices and theories of suicide. As Dorothy Smith argued, the “facts” of suicide are inseparable from the methods through which those facts were constructed. These ethnomethodological studies have sometimes been taken as a critique of quantitative social science, and they certainly have critical potential. However, they can also be viewed as having highlighted the important interactional work that goes into production of any statistics. More recent conversation analytic work that has studied the operation of systematic survey interviews is, in some respects, a development of groundbreaking work by people such as Cicourel and Atkinson.

Emmanuel Schegloff’s article on reflections on quantification in the study of conversation raises important questions not just for conversation analysts but also for any qualitative researchers who wish to introduce a level of quantification into their work. One possibility is that research on ethnostatistics and quantification rhetoric will provide more sophisticated insights into the possibilities and limitations of quantification in areas of research that have traditionally been qualitative (e.g., ethnography, discourse and conversation analysis, grounded theory).

Research in ethnostatistics and quantification rhetoric raises profound issues as to the relative status of qualitative and quantitative research. Robert Gephart’s original book on ethnostatistics was subtitled “Qualitative Foundations for Quantitative Research.” This formulation suggests that whatever the power and success of quantitative studies, qualitative research may be required to explore fundamental issues underlying quantitative work.

EVALUATION CRITERIA

What constitutes a high-quality qualitative study? Evaluating qualitative studies requires criteria. The credibility of a study flows from evaluative judgments based on criteria of excellence and quality.

Diverse approaches to qualitative inquiry—phenomenology, ethnography, hermeneutics, critical theory, grounded theory, and feminist inquiry as examples—remind us that issues of quality and credibility intersect with varying theoretical orientations, the targeted audience for a study, and intended inquiry purposes. Different perspectives about things such as truth and the nature of reality constitute alternative epistemologies and ontologies. People conducting qualitative studies or reviewing findings through different paradigmatic lenses will render different judgments because they use different criteria of quality.

Research directed to an audience of independent feminist scholars, for example, may be judged by substantially different criteria from research addressed to an audience of government economic policymakers. Exploratory research serves a different purpose and, therefore, must be judged by different criteria of quality compared with confirmatory research aimed at making a fundamental contribution to knowledge. In program evaluation, studies aimed at making improvements in implementation of a new program, what are called formative evaluations, are fundamentally different from studies aimed at rendering an overall judgment about the merit or worth of a program, what are called summative evaluations. Thus, it is important to acknowledge at the outset that particular philosophical underpinnings or theoretical orientations and special purposes for qualitative inquiry will generate different criteria for judging quality and credibility.

Five Distinct Sets of Criteria

To illustrate how different criteria lead to different judgments of quality, consider five contrasting sets of criteria for judging the quality of qualitative inquiry from different perspectives. Some of the criteria within these frameworks overlap, but even then subtle differences in nuances of meaning can be distinguished. The five contrasting sets of criteria flow from the following:

- Traditional scientific research criteria
- Constructivist criteria
- Artistic criteria
- Critical change criteria
- Pragmatism

Traditional Scientific Research Criteria

Science has traditionally emphasized objectivity, so qualitative inquiry within this tradition emphasizes procedures for minimizing investigator bias and rigorous data collection procedures; for example, cross-validating sources during fieldwork. In analysis, it means using multiple coders to establish the validity and reliability of pattern and theme analysis. This tradition includes concepts such as validity, reliability, variables, hypothesis testing, causal explanation, and generalizability, especially in combination with quantitative data. Qualitative methods are used to describe and explain phenomena as accurately and completely

as possible so that descriptions and explanations correspond as closely as possible to the way the world actually is. Government agencies supporting qualitative research often operate within this traditional scientific framework.

Constructivist Criteria

Social construction, constructivist, and interpretivist perspectives have generated new language and concepts to distinguish quality in qualitative research; for example, emphasizing trustworthiness rather than validity. Constructivists propose that naturalistic inquiry should be judged by dependability (a systematic process followed systematically) and authenticity (reflexive consciousness about one's own perspective and appreciation for the perspectives of others). Because they view human understandings of the world as socially, politically, and psychologically constructed, constructivists triangulate to capture and report multiple perspectives rather than to seek a singular truth. They are more interested in deeply understanding specific cases within a particular context than in making generalizations. Constructivists embrace subjectivity as inevitable, and their findings are explicitly informed by attention to praxis and reflexivity.

Artistic Criteria

This perspective emphasizes that qualitative analysis is both science and art, with an emphasis on artistic criteria—aesthetics, creativity, interpretive vitality, and expressive voice. Case studies become literary works. Poetry or performance art may be used to enhance the audience's direct experience of the essence that emerges from analysis. Artistically oriented qualitative analysts seek to engage those receiving the work—to connect with them, move them, provoke them, and stimulate them. Creative nonfiction and fictional forms of representation blur the boundaries between what is "real" and what has been created to represent the essence of a reality, at least as it is perceived, without a literal presentation of that perceived reality. The results may be called creative syntheses, scientific poetics, or other phrases that suggest the artistic emphasis. Artistic qualitative analyses strive to provide an experience with the findings where "truth" or "reality" is understood to have a feeling dimension that is every bit as important as the cognitive dimension.

Critical Change Criteria

Those engaged in inquiry as a form of critical analysis aimed at social and political change eschew any pretense of objectivity; they take an activist stance. This includes explicitly explicating system inequalities. The “critical” nature of critical theory flows from a commitment to use research to critique society, raise consciousness, and change the balance of power in favor of those less powerful. Critical theory provides both philosophy and methods for approaching research as political praxis (connecting theory and action) and as change-oriented forms of engagement. Likewise, feminist inquiry, liberation research, and empowerment evaluation are part of this tradition. This category can include collaborative and participatory approaches to fieldwork that are conducted in ways that build the capacity of those involved to better understand their own situations, raise consciousness, and support future action aimed at political change.

Pragmatism

The evaluation profession has adopted standards that call for findings to be useful and practical. This pragmatic orientation judges a qualitative evaluation by the degree to which it provides practical and usable answers to focused questions. Why are participants dropping out of the program? How can the program be improved? Action research in organizational development typically has a pragmatic utilitarian orientation.

Use of Diverse Criteria

These five frameworks illustrate the range of criteria that can be brought to bear in judging a qualitative study. They can also be viewed as alternative lenses for expanding the possibilities available, not only for critiquing inquiry but also for undertaking it. Although each set of criteria manifests a certain coherence, many researchers mix and match approaches, and this means recognizing and dealing with tensions between them.

Operating within any particular framework and using any specific set of criteria will invite criticism from those who judge a work from a different framework and with different criteria. Understanding that criticism (or praise) flows from criteria can help researchers to make explicit what criteria to apply to a particular work.

EVALUATION RESEARCH

Evaluation research is carried out in the social sciences to appraise human activities in a formal systematic way. Qualitative evaluation research refers to the use of qualitative methods in this endeavor. A study can be understood as “evaluation” only in the context of its use. There is no specific set of methods that makes a research study an evaluation. Evaluation research draws on the same pool of methods as do other forms of social research. This entry outlines the conceptual and pragmatic factors that differentiate evaluation from other forms of social research and the contribution of qualitative methods.

Evaluation Research

A distinction is often made between basic (or academic) research and evaluation (or applied) research. Evaluation research is applied in that the aim is to produce knowledge that will contribute to greater understanding of the effect of a defined activity. This activity may be referred to in a number of ways such as intervention, initiative, and policy. An intervention is a specified, but not necessarily specific, activity. It may already be in place or may be a new type of activity. Evaluations are often set up when interventions are being initiated or when unexpected problems arise. It is considered as important to find out what interventions do and do not work and also how things work or what prevents them from working. In this

way, lessons can be learned and taken forward in future attempts to improve the social world in which we live. Developing knowledge of how things work is where qualitative research has a particular contribution to make to evaluation.

Evaluation Design

Evaluation research differs from basic research in that it is usually set out as such at the start, with aims and objectives (defined in the research design) that are closely related to the intervention. A wide range of types of evaluation design exists. However, two main types that are defined by the contexts in which they take place can be identified: program and organizational evaluation. Program evaluation is applied to intervention programs carried out primarily to address social problems in a population or in a community setting. For example, a study may be set up to evaluate a program of activity aimed at reducing levels of crime. Depending on the nature of the intervention, the program and consequently the evaluation can become complex, and multiple evaluation studies may be conducted in parallel. Organizational evaluation is research that is carried out in organizations to examine the factors that influence the production and delivery of goods and services. The focus is on performance and productivity. An example here would be an evaluation of a police communication skills training initiative to improve relations between police and the public.

Quantitative methods have traditionally dominated in evaluation due to the emphasis on outcome. For example, the success of a crime prevention initiative is likely to focus, initially at least, on whether crime had been significantly reduced at the end of the intervention period. Influenced by the use of experimental method in the natural sciences, the “gold standard” approach is the controlled trial. This involves “before and after” comparison between a site where the intervention has been applied and a site where it has not. However, this methodology has limitations in social settings because social variables are difficult to define and control. Consequently, a more realistic approach to evaluation has emerged that highlights the importance of understanding the process of social change or, in other words, the context and mechanism involved. The goal of evaluation in this approach is to understand the relationship among context, mechanism, and outcome.

Using Qualitative Methods in Evaluation Research

The emphasis on describing context and mechanism has led to increasing use of qualitative research in evaluation. The focus in qualitative research on exploring social meanings and processes is valuable in understanding how the intervention works (or fails). The most common qualitative evaluation methods are interviews, focus groups, document analysis, and observation, but other methods such as video-recordings and diaries may also be used.

Evaluation Frameworks

The research design is often set out in the form of an evaluation framework. This will describe the focus and aims of the research at different stages and how the intervention will be assessed. The evaluation may use qualitative methods alone, or qualitative methods may be included as part of the design. In mixed method designs (using qualitative and quantitative methods), a qualitative study may form a discrete project at a particular stage or be an integral part of a larger investigation. Evaluation frameworks often identify ways of assessing the success of the intervention or “indicators.” These help to provide structure and clarity as to the aims and objectives at each stage.

Stages of Evaluation

Evaluation research designs can be considered in relation to three main stages: strategy, process, and outcome.

Strategic Evaluation

Evaluation in social research is about examining social change. Strategic evaluation aims to describe the social system under investigation before change takes place. For example, crime prevention may have been decided on nationally as an important policy goal, but it will be addressed locally and there may be many local factors to consider that cannot be reliably predicted in advance. Qualitative research is often conducted to describe the social context at the start and to help tailor the intervention so that goals and practices are appropriate to the local population. Interviews and/or focus groups may be carried out to assess the key concerns of local people about crime. These will be purposively sampled to represent and gain perspectives

from different demographic groups such as young and old people, various ethnic groups, parents, local professionals, and local businesses. Another possibility would be to undertake observation to describe crime in the locality prior to the start of the study.

Research at this stage helps to define the intervention and how it may be assessed. Indicators may be developed to provide a structure for the process and outcome stages of the evaluation. An important part of any social intervention is consumer involvement, and qualitative methods are valuable for identifying and evaluating concerns of consumers from the start of a project.

Process Evaluation

Once the intervention has been defined, the process of implementation and progress (including problems and setbacks) will be assessed during the intervention period. A particular strength of qualitative methodology is that, in providing detailed descriptions of what happens when interventions are carried out, we can begin to look more closely at how things work (or do not work). This can lead to improved understandings of causal mechanisms.

Qualitative research may be used to elicit the experiences and views of participants throughout and to make comparisons between different groups and different stages. For example, it might be found that setting up a new youth club to divert young people from committing crime was resisted by the target population initially but that involving local musicians who are popular with the young people increased attendance. This in turn could be linked to reduction in crime on the nights when this activity took place. Close attention to the perspectives of the young people in semi-structured interviews at regular intervals during the intervention period would enable such factors to be described in detail.

Outcome Evaluation

The main way of assessing outcome is to consider whether the intervention has worked or not. Outcome evaluation measures the results achieved by interventions in relation to various indicators. For example, have crime rates been reduced? However, understanding outcome is about much more than this. It is about what happens when an intervention is applied. This may include finding out about people's experiences of outcomes. For example, qualitative research may

explore in detail the way in which the crime prevention program has affected people's lives.

The Role of Theory

All research, whether qualitative or quantitative, has a theoretical basis. It influences decisions about both the methodology and the framework used for conceptualizing the problem under study. The influence of theory in relation to how the data are collected, analyzed, and interpreted is often not made explicit in reports of evaluations. This means that evaluation research has been criticized for being atheoretical. It is good practice in qualitative evaluation to describe the way in which theory has influenced the research. This makes it possible to assess the quality of the study. However, stakeholders, participants, and funders often require short accessible reports. One way of attending to this is to write up the research in different ways for different audiences. A descriptive report can be written for the funders, stakeholders, and participants. The research can also be written up in more detail, including further in-depth analysis and explicit reference to theoretical literature for academic audiences (although available to all). Evaluation research needs to be theory driven rather than data driven if it is to contribute to a cumulative body of knowledge in which theory can be built and tested.

Qualitative Research as Evaluation

Studies that are not formally set up at the start as evaluation can be viewed as evaluative in that they may provide useful knowledge about a topic without being considered as applied research. Many research bodies that fund academic research now require those applying for grants addressing particular social concerns to show how their findings will contribute to real-world issues and to include nonacademic audiences in their dissemination plans. In this way, basic research can be treated as a form of evaluation.

Qualitative Evaluation Research in Practice

Evaluation research is not "ivory tower" research. It is hands-on research and often entails a high level of responsibility to funders and people who have a stake in the conduct and outcomes of the research. Project and research goals will usually need to be negotiated with these stakeholders. There will typically be a project

team and an evaluation team. The project team setting up and running the intervention will include people with an interest in the process and outcomes of the evaluation. This may include representatives from professional groups, the public, community groups, the voluntary sector, and/or local businesses. Social interventions work best when there is ownership of them by the populations at which they are aimed. Qualitative research enables consumers to contribute their perspectives from the start of the research so that they can have an influence on the way in which it is developed at the strategic stage and can contribute understandings of why it does or does not work at the process and outcome stages.

Challenges to Qualitative Evaluation

Qualitative evaluation may involve a number of significant challenges. These relate to working collaboratively (with other researchers, funders, and stakeholders), time constraints leading to limited time for detailed data analysis, resistance to the use of qualitative methods, the potential complexity of evaluation designs, disagreement with the findings by stakeholders, and the need to disseminate to diverse audiences. These issues can be difficult to negotiate. The key is to set up a position of strength at the start by being clear and transparent about the methods being used and the research process, having clear quality standards to which you will adhere, and identifying and discussing the different agendas of those involved.

EVERYDAY LIFE

Everyday life experiences refer to the ritualistic, ordinary, and often mundane occurrences that take place

on any given day in a researcher or participant's life. Everyday life as a methodology examines and uncovers the realizations of daily life and how they are communicated and interpreted by an observer and/or a participant. Everyday life combines several disciplines and perspectives, including symbolic interactionism, dramaturgy, phenomenology, ethnomethodology, and existential sociology.

Everyday life as a participatory action research method is not isolated; rather, it is embedded in people and situations. Researchers often negotiate between research that is collected traditionally through means of data collection and creative and introspective research that relies on the positionality, perspective, and viewpoint of participants.

Everyday life research focuses on the details and seemingly insignificant occurrences that collectively contribute to how a situation, phenomenon, or occurrence is interpreted and experienced. Such research seeks to understand social experience based on how people do and experience social life, which privileges experience as knowledge. The perspective becomes a study of social interaction in a natural environment that acknowledges extraordinary happenings while legitimating the ordinary events of life. By privileging people in their natural state and interacting with them in their natural context, research takes on a realistic reflection of life rather than an oversimplified and generalized version.

Exploring everyday life requires the researcher to focus on details, make connections and associations between emergent and repetitive themes, focus equally on sameness and difference (what happened today that did not happen yesterday and how that influences the research topic or focus), and make comparisons between the researcher's experience and the topic being studied. This position allows the researcher to become a character or presence in the story he or she is telling and to deduce a theory or analysis based on the information that is uncovered.

Everyday life is often written in a first- or third-person voice and relies on rich descriptions, sharp detail, creativity, and comparative analysis. Everyday life sociology is a research style that emerged in California during the late 1980s and focused on the philosophical work of interactionism, ethnomethodology, phenomenology, rule response, and ritual engagement. Everyday life research is collected through interviews, participant observation, introspective journal writing, and other qualitative methods.

This approach is useful in analyzing qualitative data because it requires the researcher to consider and

negotiate the ubiquitous themes that occur in everyday life, from work to play. Important details can be discovered through the monotonous recovery of daily occurrences that differentiates individual experiences. By focusing on specific and overlooked details, everyday life has the potential to generate new knowledge and concepts from seemingly marginal and unimportant daily occurrences.

One of the benefits of everyday life as a research approach is the encouragement of diversity. It is widely used among marginalized groups to privilege their personal perspectives and viewpoints that might otherwise be silenced or misinterpreted.

EVIDENCE

Evidence is conventionally defined as the knowledge or principles that substantiate claims to wider truth. Notions of evidence are threaded through qualitative research from the basis for inquiry, through research processes, to the final products of qualitative research.

Addressing the nature of evidence has been and remains central to deliberation in philosophy, law, literature, management science, history, and (more recently) health care around evidence-based practice. The determination of what counts as evidence, who or what determines this, and on what philosophical basis this is done remains subject to debate. Qualitative researchers must address a number of key issues related to evidence.

Evidence and Epistemology

The concept of evidence is linked closely to epistemological notions of truth and of what constitutes

knowledge. Inherently, there is a deeper philosophical or value-laden component when evidence is considered, and how and whether evidence is viewed as such is dependent on an underlying worldview, theory, or paradigm. Although it is important for qualitative researchers to be knowledgeable of method, they should be aware of and reflect critically on these underlying epistemological dimensions.

Evidence as the Basis for Qualitative Research

Evidence can justify and inform a qualitative study. The vast majority of qualitative researchers recognize that evidence regarding the world can be derived from formal knowledge sources such as previous research studies and theory. In many (but not all) instances, qualitative researchers should be aware of this formal knowledge prior to commencing a study and should use it where appropriate to inform their proposed research questions. Before drawing on this evidence to guide inquiry, researchers must also assess whether the research and theory are trustworthy or convincing and should ascertain whether and where important omissions are evident. Hence, comprehensive searching, appraisal, and meta-synthesis of existing literature are important steps in the beginning stages of the qualitative research process. Some approaches, particularly some forms of grounded theory and phenomenology, emphasize far less a reliance on drawing on or responding to previous evidence to guide qualitative inquiry. Evidence for the importance of these studies will rely on personal experience far more.

Evidence and the Process of Qualitative Research

Evidence is equally critical during the qualitative data collection, analysis, and presentation phases of research to ensure methodological rigor. Approaches to qualitative research generally purport that the perspectives and behaviors of humans are integral to understanding and explaining the social world. Appropriate sampling strengthens rigor. Qualitative research should seek to collect data in the right settings with appropriate participants; this is invariably dependent on the research question. However, a common principle of effective sampling is to generate data with strategically selected individuals and settings optimally well placed to generate insights (i.e., provide

credible evidence) regarding the phenomena being explored. In instances where the participants and/or settings are very different from people and/or settings elsewhere, the transferability of findings is reduced and the wider applicability of the qualitative research is compromised.

The rigor of qualitative findings can also be affected by other dimensions of evidence and method during the research process. What is the evidence that data have been analyzed adequately? During analysis, seemingly outlying themes should specifically be sought and explored. What is the evidence that the researcher's interpretations are appropriate and reflect the data adequately? The trustworthiness of findings can be increased via recourse to evidentiary quotations from the data. Audit trails can also be collated to show how the researcher interpreted the qualitative data and addressed issues of reflexivity. In this way, notions of evidence are threaded throughout the process of qualitative research.

Evidence as the Product of Qualitative Research

Finally, the findings of qualitative studies themselves constitute evidence and should be presented in light of preexisting or wider evidence. What are the implications of the qualitative study taking other empirical studies into account? How might the findings generate evidence to guide the practice of a profession? How can mid-range theories amplify and further expand qualitative findings? Researchers need to address the transferability of findings to different people and settings. When doing this, stances are adopted regarding the status of the evidence generated by the qualitative inquiry. This raises issues of how congruent these stances are with the research's stated and unstated epistemological positions.

EVIDENCE-BASED PRACTICE

Qualitative research methods, once seen as peripheral and in opposition to evidence-based practice, are increasingly accepted in research to both facilitate and explore evidence-based practice. Qualitative methods can contribute to the development of more nuanced, context-responsive, practice-based evidence. They can further understanding of why and how evidence informs practice in different locations and can support evidence-based practice through qualitative systematic review and by understanding why and how interventions do and do not work in particular settings or populations. This entry describes the history of evidence-based practice and then reviews both its successes and the challenges it has faced. The entry concludes with a look at the future role of qualitative research in evidence-based practice across many disciplines as well as its relevance to public policy.

The History of Evidence-Based Practice

The conscientious, judicious, and explicit application of best evidence in a profession or to a professional's practice is a contested and frequently divisive concept that is viewed, after David Sackett's work in particular, as a professional imperative, an ideology, or a myopic dogma. Many professions now claim, or aspire to claim, that practice in their domain should be based on "evidence"—including medicine, nursing, teaching, policing, management, social policy, economics, and social work. What this evidence consists of and where qualitative research fits remain contested.

The concept of evidence-based practice dates back to the 19th century but has emerged into prominence in debate and policy since the early 1990s. Reasons for this include growth in the perceived need for greater effectiveness and efficiency during an era of increased public accountability and managerialism, increased capacity for systematic electronic data collection (and monitoring of performance), and developments in communications technology that facilitate rapid dissemination of research findings.

Knowledge derived from research has consistently been recognized as a central (and often *the* central) component of evidence. However, not all research methods have been equally esteemed. Hierarchies of evidence were developed to categorize studies into

levels of strength. These hierarchies frequently positioned expert opinion as the least trustworthy source and randomized control trials and/or systematic reviews as the strongest, most reliable forms of evidence. The most trustworthy research, when synthesized into systematic reviews or practice guidelines, could then be disseminated to practitioners in a parsimonious and accessible form purportedly ripe for application to practice.

The case for evidence-based practice has been promoted through political, empirical, ethical, practical, educational, and ideological means. With such powerful forces at play, it was difficult to argue that practice should be anything other than evidence based. From the early 1990s, numerous influential organizations, commentators, and researchers have championed the ethical and social need for greater reliance on evidence to improve outcomes and make decision making more transparent and effective. Professionals have been urged by government, the scientific community, and regulatory bodies alike that it is not only desirable but also ethically essential for them to practice in accordance with “the evidence.” Practice guidelines proliferated. These guidelines were often developed by professional bodies and/or experts who had a priori screened and appraised studies and reviews in an existing area. These guidelines were replete with the findings of meta-analyses, randomized trials, and larger scale observation studies because they held higher status in the methodological hierarchies. Universities responded by creating new curricula around the need to practice in accordance with the evidence.

The Success and Challenges of Evidence-Based Practice

Those espousing the need for evidence-based practice have been successful in framing debate over the past decade. However, the changes that have actually been made to practice are much less marked. Despite the prominence of the evidence-based practice movement and attendant guidelines, the vast majority of practice remains contrary to the evidence. This is testament not only to the complexities of practice but also to continuing contentions over what counts as evidence and how best to support professionals to practice in accordance with evidence.

After the initial enthusiasm for evidence-based practice subsided, a debate emerged as to why substantial improvements in rates of evidence-based practice

had not occurred. Some argued that hierarchies of evidence were too methodologically restrictive and overly reliant on randomized trials. Research participants often did not represent the broader population. This was most apparent in randomized controlled clinical trials, where restrictive criteria excluded adequate numbers of females, older adults, people with comorbidities, and diverse ethnic groups.

Furthermore, many of the decisions confronting professionals in their practice are not necessarily about effectiveness. However, most of the hierarchies of evidence-based practice focus on research questions pertaining to effectiveness. For example, although meta-analyses and randomized trials may have relevance to some aspects of health care (e.g., prescribing medication) in which the principal issue is efficacy, this does little to guide the professional on how to create a positive therapeutic relationship with the patient, how to empower the individual to use the prescribed regimen, or how best to engage informal caregivers. For this, the professional needs considerable clinical and social skills and insight into the patient’s milieu as well as an environment that provides adequate time and resources.

Arguments have also focused on the ontological assumptions underpinning evidence-based practice. Ray Pawson, David Byrne, and other realists have challenged the overly linear conception of simplistic cause and effect implicit within evidence-based approaches and their disregard of intervening contextual factors. Rather, they argue, causality in practice is generative, arising when multifarious factors come together in specific combinations to generate particular outcomes. Thus, evidence is applied in a much more ambiguous, multifactorial, and context-bound environment than many proponents of evidence-based practice have acknowledged. It has since been recognized more widely that evidence-based practice could be successful only through the development of more practice-based evidence.

The Place of Qualitative Research in Evidence-Based Practice

Prior to 2000, qualitative research had, at most, a peripheral role in debate around evidence-based practice. Hierarchies favored methods that allowed for manipulation and intervention in unnaturally closed systems. Evidence hierarchies, although widely adopted, ascribed far less esteem to methods that collected data

in natural settings (whether based on quantitative or qualitative data) and often made no reference to qualitative research whatsoever. Was this to be a reenactment of a paradigm debate that once more led to the incommensurability of qualitative research with a dominant view?

Opportunities for proponents of qualitative research to influence mainstream debate in evidence-based practice were constrained as the disciplines in which qualitative research was more accepted (e.g., social science, nursing, education) were comparatively marginal to the evidence-based practice debate. This debate privileged supposedly “objective” and unbiased quantitative work. Conversely, even the opinions of experts were viewed negatively as being subjective and biased. To no surprise, proponents of research into human perspectives struggled for validation.

However, more critical comment that cautions the positing of methods into any hierarchy has arisen across methodological divides. These proponents maintain that what matters most in terms of the validity and strength of a method is the applicability of the method to the research question. Many great advances in the natural and human sciences have occurred despite a lack of evidence from randomized trials. In making decisions, professionals must rely on findings from different methods and knowledge bases. This acknowledgment provided an early avenue for the contributions of qualitative research.

There was also a growing recognition that research evidence must capture the personal, social, and contextual complexities that are central to professional practice. Combined with the view that the world was not as ordered or predictable as proponents of evidence-based practice had envisaged, arguments for a more nuanced evidence-based practice emerged within mainstream debate.

Ray Pawson and Nick Tilley captured this well in their plea for research into health and social interventions to examine “what works for whom, when, and why.” Trials were undertaken in artificially controlled closed systems, but findings were then generalized to natural open systems. The moderating effect on outcomes of other factors in the natural world (both contextual and individual) lessened the effectiveness of the intervention. Hence, generalizability of benefit was not achieved. Rather, a qualitative research was needed to understand how interventions led to different outcomes for different people.

The continued relative lack of use of evidence in practice also drove governments and disciplines to

consider why this might be the case. New areas of study around knowledge translation and use emerged. Almost inevitably, these areas needed to acknowledge and explore the complex nature of practice settings and organizations. Disciplines historically more peripheral in the evidence-based practice movement, such as organizational studies, nursing, and the social sciences, were mobilized. Significantly, these were disciplines in which the contributions of qualitative research were accepted.

Other wider methodological developments also supported the increased prominence of qualitative research in evidence-based practice. Acceptance and use of mixed methods research in all disciplines have increased. Furthermore, it is increasingly expected that researchers in the social and health sciences will work in interdisciplinary teams. This has created new opportunities for debate and collaboration across traditional disciplinary and methodological boundaries.

Collectively, these developments reconciled qualitative research and evidence-based practice.

The Future Role of Qualitative Research

How will qualitative research build its influence in the sphere of evidence-based practice in the future? Although critical comment is essential for the continued evolution of evidence-based practice, these developments are unlikely to result from bemoaning or undermining the merits of making practice more evidence based. The movement is far from perfect, but it has sufficient professional, public, and political momentum to continue to frame debate during the coming years. However, a number of opportunities that show considerable promise for qualitative research have emerged during recent years.

Policymakers and practitioners continue to face challenging decisions in which reliance on trials and meta-analyses fails to provide sufficiently qualified and context-responsive answers. Randomized trials and systematic reviews still remain focused on the global effectiveness of interventions. Qualitative research is also suited to understanding the complexities of lay understanding and experience, understanding the influence of context on outcomes, and explaining behavior. Continued exploration of the factors influencing implementation of evidence in practice is likely to occur. Research funding bodies have become increasingly attuned to the need for knowledge translation in studies. Qualitative research will

continue to elucidate the complexities of how and why research should shape practice.

The recognition that knowledge beyond that related to questions of effectiveness is important for practice justifies the applicability of qualitative research for policy and practice. One of the most promising areas of recent progress has been the advent of qualitative systematic review—rigorous syntheses of qualitative findings that can distill the wider body of qualitative evidence in a set area. These reviews often draw on tools for the methodological appraisal of qualitative research and have developed different methods to synthesize study findings. Findings can be used to guide practice in relation to issues such as how interventions work and what different subpopulations value.

Notably, even in areas where systematic reviews suggest a type of intervention, the trials on which those reviews are based often have markedly different levels of effectiveness. Qualitative research can explicate why interventions work or do not work and the influence that contextual factors have on outcome.

EVOLUTION OF QUALITATIVE RESEARCH

In North America, qualitative research operates in a complex historical field that crosscuts at least eight historical moments. In the present, these moments overlap and operate simultaneously. We define them as the traditional (1900–1950); the modernist or golden age (1950–1970); blurred genres (1970–1986); the crisis of representation (1986–1990); the postmodern, a period of experimental and new ethnographies (1990–1995); postexperimental inquiry (1995–2000); the methodologically contested present (2000–2004);

and the future, which is now (2005–). The future, the eighth moment, confronts the methodological backlash associated with the evidence-based social movement. It is concerned with moral discourse, with the development of sacred textualities. The eighth moment asks that the social sciences and the humanities become sites for critical conversations about democracy, race, gender, class, freedom, and community.

Successive waves of epistemological theorizing move across these eight moments. The traditional period is associated with the positivist foundational paradigm. The modernist or golden age and blurred genres moments are connected to the appearance of postpositivist arguments. At the same time, a variety of new interpretive qualitative perspectives were taken up, including hermeneutics, structuralism, semiotics, phenomenology, cultural studies, and feminism. In the blurred genres phase, the humanities became central resources for critical interpretive theory and the qualitative research project broadly conceived. The researcher became a bricoleur, learning how to borrow from many different disciplines.

The blurred genres phase produced the next stage, the crisis of representation. Here researchers struggled with how to locate themselves and their subjects in reflexive texts. A kind of methodological diaspora took place, a two-way exodus. Humanists migrated to the social sciences, searching for new social theory, new ways to study popular culture and its local ethnographic contexts. Social scientists turned to the humanities, hoping to learn how to do complex structural and poststructural readings of social texts. From the humanities, social scientists also learned how to produce texts that refused to be read in simplistic, linear, incontrovertible terms. The line between a text and a context blurred. In the postmodern/experimental moment, researchers continued to move away from foundational and quasifoundational criteria. Alternative evaluative criteria were sought—those that might prove to be evocative, moral, critical, and rooted in local understandings.

Any definition of qualitative research must work within this complex historical field. Qualitative research means different things in each of these moments. Nonetheless, an initial generic definition can be offered. Qualitative research is a situated activity that locates the observer in the world. Qualitative research consists of a set of interpretive material practices that make the world visible. These practices transform the world. They turn the world into a series of representations, including fieldnotes, interviews,

conversations, photographs, recordings, and memos to the self. At this level, qualitative research involves an interpretive naturalistic approach to the world. This means that qualitative researchers study things in their natural settings, attempting to make sense of, or interpret, phenomena in terms of the meanings people bring to them.

The history of qualitative research reveals that the modern social science disciplines have taken as their mission the analysis and understanding of the patterned conduct and social processes of society. To carry out this task, it was presupposed that social scientists had the ability to observe this world objectively. Qualitative methods were a major tool of such observations.

Throughout the history of qualitative research, investigators have always defined their work in terms of hopes and values, ideologies based in professional, occupational, and religious faiths. Judgment of qualitative research (like all research) has always been based on the ability of the work to “say something” to us by showing how we conceptualize our reality and our images of the world. *Epistemology* is the word that has historically defined these standards of evaluation. In the contemporary period, as argued earlier, many received discourses on epistemology are now being reevaluated.

Arthur Vidich and Stanford Lyman’s history covers the following (somewhat) overlapping stages: early ethnography (to the 17th century); colonial ethnography (17th-, 18th-, and 19th-century explorers); ethnography of the “other,” the American Indian (late 19th- and early 20th-century anthropology); community studies; ethnographies of American immigrants (early 20th century through the 1960s); and studies of ethnicity and assimilation (mid-20th century through the 1980s).

In each of these eras, researchers were influenced by their political hopes and ideologies, discovering findings in their research that confirmed prior theories or beliefs. Early ethnographers confirmed the racial and cultural diversity of peoples around the globe and attempted to fit this diversity into a theory about the origin of history, the races, and civilizations. Colonial ethnographers, before the professionalization of ethnography in the 20th century, fostered a colonial pluralism that left natives on their own so long as their leaders could be co-opted by the colonial administration.

European ethnographers studied Africans, Asians, and other Third World peoples of color. Early American ethnographers studied the American Indian

from the perspective of the conqueror, who saw the lifeworld of the primitive as a window to the prehistoric past. The Calvinist mission to save the Indian was soon transferred to the mission of saving the “hordes” of immigrants who entered the United States with the beginnings of industrialization. Qualitative community studies of the ethnic “other” proliferated from the early 1900s to the 1960s and included the work of E. Franklin Frazier, Robert Park, and Robert Redfield and their students as well as William Foote Whyte, Robert and Helen Lynd, August Hollingshead, Herbert Gans, Stanford Lyman, Arthur Vidich, and Joseph Bensman. The post-1960 birth of ethnicity studies challenged the “melting pot” hypotheses of Park and his followers. The emergence of ethnic studies programs saw Native Americans, Latinos, Asian Americans, and African Americans attempting to take control over the study of their own peoples.

The postmodern and poststructural challenge emerged in the mid-1980s. It questioned the assumptions that had organized this earlier history in each of its colonizing moments. In 2000, Vidich and Lyman argued that qualitative research, which crosses the “postmodern divide,” requires one to virtually “abandon all established and preconceived values, theories, perspectives . . . and prejudices as resources for ethnographic study” (p. 56). The postmodern and postexperimental moments were defined in part by a concern for literary expression and the narrative turn—a concern for storytelling, for composing ethnographies in new ways.

In this new era (the future), the qualitative researcher does more than observe history; he or she plays a part in it. New tales from the field will now be written, and they will reflect the researcher’s direct and personal engagement with this historical period. Now at the dawn of this new century, we struggle to connect qualitative research to the hopes, needs, goals, and promises of a free democratic society.

The Eight Moments of Qualitative Research

The history of qualitative research in North America can be divided into eight phases.

First Moment: The Traditional Period

The first moment, or the traditional period, began in the early 1900s and continued until World War II. In it, qualitative researchers wrote “objective” colonizing

accounts of field experiences, reflective of the positivist scientist paradigm. They were concerned with offering valid, reliable, and objective interpretations in their writings. The “other” who was studied was alien, foreign, and strange.

In this period, the fieldworker was lionized, made into a larger than life figure who went into and then returned from the field with stories about strange people. This has been described as the period of the “lone ethnographer,” the story of the man-scientist who went off in search of his native in a distant land. Fieldwork was a rite of passage for the ethnographer, something that must be endured alone. Returning home with his data, the lone ethnographer wrote up an objective account of the culture studied. This account was structured by the norms of classical ethnography. These norms organized ethnographic texts in terms of four beliefs and commitments: a commitment to objectivism, a complicity with imperialism, a belief in monumentalism (the ethnography would create a museum-like picture of the culture studied), and a belief in timelessness (what was studied would never change). The other was an “object” to be archived. This model of the researcher, who could also write complex dense theories about what was studied, holds to the present day.

The myth of the lone ethnographer depicts the birth of classic ethnography. The texts of Bronislaw Malinowski, Alfred Radcliffe-Brown, Margaret Mead, and Gregory Bateson are still carefully studied for what they can tell the novice about fieldwork, taking fieldnotes, and writing theory.

Today this image has been shattered. The works of the classic ethnographers are seen by many as relics from the colonial past. Although many feel nostalgia for this past, others celebrate its passing. In 1989, Renato Rosaldo quoted Cora Du Bois, a retired Harvard University anthropology professor who lamented this passing at a conference in 1980, reflecting on the crisis in anthropology: “[I feel a distance] from the complexity and disarray of what I once found a justifiable and challenging discipline. . . . It has been like moving from a distinguished art museum into a garage sale” (p. 44).

Du Bois regarded the classic ethnographies as pieces of timeless artwork contained in a museum. She felt uncomfortable in the chaos of the garage sale. In contrast, Rosaldo was drawn to this metaphor: “It [the garage sale] provides a precise image of the postcolonial situation where cultural artifacts flow between unlikely places, and nothing is sacred, permanent, or

sealed off. The image of anthropology as a garage sale depicts our present global situation” (p. 44). Indeed, many valuable treasures may be found, if one is willing to look long and hard, in unexpected places. Old standards no longer hold. Ethnographies do not produce timeless truths. The commitment to objectivism is now in doubt. The complicity with imperialism is openly challenged today, and the belief in monumentalism is a thing of the past.

The legacies of this first period began at the end of the 19th century when the novel and the social sciences had become distinguished as separate systems of discourse. However, the Chicago School, with its emphasis on the life story and the “slice-of-life” approach to ethnographic materials, sought to develop an interpretive methodology that maintained the centrality of the narrated life history approach. This led to the production of the texts that gave the “researcher as author” the power to represent the subject’s story. Written under the mantle of straightforward, sentiment-free social realism, these texts used the language of ordinary people. They articulated a social science version of literary naturalism, which often produced the sympathetic illusion that a solution to a social problem had been found. Like the Depression era juvenile delinquent and other “social problems” films, these accounts romanticized the subject. They turned the deviant into a sociological version of a screen hero. These sociological stories, like their film counterparts, usually had happy endings as they followed individuals through the three stages of the classic morality tale: being in a state of grace, being seduced by evil and falling from grace, and finally achieving redemption through suffering.

Second Moment: The Modernist Phase

The modernist phase, or the second moment, built on the canonical works from the traditional period. Social realism, naturalism, and slice-of-life ethnographies were still valued. This period extended through the postwar years to the 1970s and is still present in the work of many. In this period, many texts sought to formalize qualitative methods. Modernist ethnographers and sociological participant observers attempted rigorous qualitative studies of important social processes, including deviance and social control in the classroom and society. This was a moment of creative ferment.

A new generation of graduate students across the human disciplines encountered new interpretive theories (e.g., ethnomethodology, phenomenology, critical

theory, feminism). They were drawn to qualitative research practices that would let them give a voice to society's underclass. Postpositivism functioned as a powerful epistemological paradigm. Researchers attempted to fit the classical traditional model of internal and external validity to constructionist and interactionist conceptions of the research act. They returned to the texts of the Chicago School as sources of inspiration.

A canonical text from this moment remains *Boys in White* by Howard Becker and colleagues. Firmly entrenched in mid-century methodological discourse, this work attempted to make qualitative research as rigorous as its quantitative counterpart. Causal narratives were central to this project. This multimethod work combined open-ended and quasi-structured interviewing with participant observation and the careful analysis of such materials in standardized statistical form. Becker's classic article, "Problems of Inference and Proof in Participant Observation," described this practice as the use of "quasi-statistics." In the 1958 work, Becker articulates the problems of attempting to collect data in the field that conform to statistical needs. He concluded that ultimately a field researcher's conclusions are "implicitly numerical" but do not require "precise quantification" (p. 31).

In the analysis of data, Becker noted that the qualitative researcher takes a cue from statistical colleagues. The researcher looks for probabilities or support for arguments concerning the likelihood, or frequency, that a conclusion in fact applies to a specific situation. In this way, work in the modernist period clothed itself in the language and rhetoric of positivist and postpositivist discourse.

This was the golden age of rigorous qualitative analysis, bracketed in sociology by *Boys in White* at one end and *The Discovery of Grounded Theory*, published in 1967 by Barney Glaser and Anselm Strauss, at the other end. In education, qualitative research in this period was defined by George and Louise Spindler, Jules Henry, Harry Wolcott, and John Singleton. This form of qualitative research is still present in the work of researchers such as Strauss and Juliet Corbin.

The golden age reinforced a picture of the qualitative researcher as cultural romantic. Imbued with Promethean human powers, these researchers valorized villains and outsiders as heroes to mainstream society. They embodied a belief in the contingency of self and society, and they held to emancipatory ideals for which one lives and dies. They put in place a tragic and often ironic view of society and self, and they joined a long

line of leftist cultural romantics, including Ralph Waldo Emerson, Karl Marx, Henry James, John Dewey, Antonio Gramsci, and Martin Luther King, Jr.

As this moment came to an end, the war in Vietnam was everywhere present in American society. In 1969, alongside these political currents, Herbert Blumer and Everett Hughes met with a group of young sociologists, called the "Chicago Irregulars," at the American Sociological Association meetings in San Francisco and shared their memories of the "Chicago years." In 1980, Lyn Lofland described the 1969 meetings as a "moment of creative ferment—scholarly and political." The San Francisco meetings were a watershed event that saw the emergence of "labeling theory, ethnomethodology, conflict theory, phenomenology, dramaturgical analysis" (p. 253). In this way, the modernist phase come to an end.

Third Moment: Blurred Genres

By the beginning of the third stage (1970–1986), or blurred genres, qualitative researchers had a full complement of paradigms, methods, and strategies to employ in their research. Theories included symbolic interactionism, constructivism, naturalistic inquiry, positivism and postpositivism, phenomenology, ethnomethodology, critical theory, neo-Marxism, semiotics, structuralism, feminism, and various racial/ethnic paradigms. Applied qualitative research was gaining in stature, and the politics and ethics of qualitative research—implicated as they were in various applications of this work—were topics of considerable concern. Research strategies and formats for reporting research included grounded theory, the case study, and methods of historical, biographical, ethnographic, action, and clinical research. Diverse ways of collecting and analyzing empirical materials were also available, including qualitative interviewing (open-ended and quasi-structured), observational, visual, personal experience, and documentary methods. Computers entered the situation, to be fully developed as aids in the analysis of qualitative data in the next decade, along with narrative, content, and semiotic methods of reading interviews and cultural texts.

Clifford Geertz's two books, *The Interpretation of Cultures* (1973) and *Local Knowledge* (1983), defined the beginning and end of this moment. In these two works, Geertz argued that the old functional, positivist, behavioral, and totalizing approaches to the human disciplines were giving way to a more pluralistic, interpretive, and open-ended perspective. This

new perspective took cultural representations and their meanings as its point of departure. Calling for “thick descriptions” of particular events, rituals, and customs, Geertz suggested that all anthropological writings were interpretations of interpretations. The observer had no privileged voice in the interpretations that were written. The central task of theory was to make sense out of a local situation.

Geertz went on to propose that the boundaries between the social sciences and the humanities had become blurred. Social scientists were now turning to the humanities for models, theories, and methods of analysis (e.g., semiotics, hermeneutics). A form of genre diaspora was occurring—documentaries that read like fiction, parables posing as ethnographies, theoretical treatises that looked like travelogues. At the same time, other new approaches were emerging—poststructuralism, neopositivism, neo-Marxism, micro-macro descriptivism, ritual theories of drama and culture, deconstructionism, ethnomethodology. The golden age of the social sciences was over, and a new age of blurred interpretive genres was upon us. The essay as an art form was replacing the scientific article. At issue now was the author’s presence in the interpretive text. How could the researcher speak with authority in a period when there were no longer any firm rules concerning the text (including the author’s place in it), its standards of evaluation, and its subject matter?

The naturalistic, postpositivist, and constructionist paradigms gained power in this period, especially in education in the works of Harry Wolcott, Frederick Erickson, Egon Guba, Yvonna Lincoln, and Robert Stake. By the end of the 1970s, several qualitative journals were in place, including *Urban Life and Culture* (now *Journal of Contemporary Ethnography*), *Cultural Anthropology*, *Anthropology and Education Quarterly*, *Qualitative Sociology*, *Symbolic Interaction*, and *Studies in Symbolic Interaction*.

Fourth Moment: The Crisis of Representation

A profound rupture occurred in the mid-1980s. What we call the fourth moment, or the crisis of representation, appeared with *Anthropology as Cultural Critique* (published in 1986 by George Marcus and Michael Fisher), *The Anthropology of Experience* (published in 1986 by Victor Turner and Edward Bruner), *Writing Culture* (published in 1986 by James Clifford and George Marcus), *Words and Lives* (published in 1988 by Clifford Geertz), and *The Predicament of*

Culture (published in 1988 by James Clifford). These works made research and writing more reflexive and called into question the issues of gender, class, and race. They articulated the consequences of Geertz’s “blurred genres” interpretation of the field in the early 1980s.

New models of truth, method, and representation were sought. The erosion of classic norms in anthropology (e.g., objectivism, complicity with colonialism, social life structured by fixed rituals and customs, ethnographies as monuments to a culture) was complete. Critical epistemology, feminist epistemology, and epistemologies of color now competed for attention in this arena. Issues such as validity, reliability, and objectivity, believed to be settled in earlier phases, were once again problematic. Pattern and interpretive theories, as opposed to causal linear theories, were now more common as writers continued to challenge older models of truth and meaning.

In 1987, Paul Stoller and Cheryl Olkes described how the crisis of representation was felt in their fieldwork among the Songhay of Niger. Stoller described the conventional practice of gathering data, categorizing them, and writing them up—at one point creating a series of logical formulas to understand Songhay insults. Stoller became dissatisfied with this form of writing, in part because he learned that “everyone had lied to me and . . . the data I had so painstakingly collected were worthless. I learned a lesson: Informants routinely lie to their anthropologists” (p. 9). This discovery led to a realization that he had, in following the conventions of ethnographic realism, edited himself out of his text. This led Stoller to produce a different type of text, a memoir, in which he became a central character in the story he told. This story, an account of his experiences in the Songhay world, became an analysis of the clash between his world and the world of Songhay sorcery. Thus, Stoller’s journey represents an attempt to confront the crisis of representation in the fourth moment.

In 1998, Patricia Clough elaborated this crisis and criticized those who would argue that new forms of writing represented a way out of the crisis. She argued that it is this insistence on the difference between writing and fieldwork that must be analyzed. In writing, the fieldworker makes a claim to moral and scientific authority. These claims allow the realist and experimental ethnographic text to function as sources of validation for an empirical science. They show that the world of real lived experience can still be captured, if

only in the writer's memoirs, fictional experimentations, or dramatic readings. But these works have the danger of directing attention away from the ways in which the text constructs sexually situated individuals in a field of social difference. They also perpetuate "empirical science's hegemony" (p. 8), for these new writing technologies of the subject become the site, according to Stanley Aronowitz, "for the production of knowledge/power . . . [aligned] with . . . the capital/state axis" (quoted on p. 8). Such experiments come up against, and then back away from, the difference between empirical science and social criticism. Too often they fail to fully engage a new politics of textuality that would "refuse the identity of empirical science" (p. 135). This new social criticism "would intervene in the relationship of information economics, nation-state politics, and technologies of mass communication, especially in terms of the empirical sciences" (p. 16). This, of course, is the terrain occupied by cultural studies.

The preceding arguments have been developed viewing writing as a method of inquiry that moves through successive stages of self-reflection. As a series of written representations, the fieldworker's texts flow from the field experience, through intermediate works, to later work, and finally to the research text that is the public presentation of the ethnographic and narrative experience. In this way, fieldwork and writing blur into one another. There is, in the final analysis, no difference between writing and fieldwork. These two perspectives inform, and in these ways the crisis of representation moves qualitative research in new critical directions.

A Triple Crisis

The ethnographer's authority remains under assault today. A triple crisis of representation, legitimation, and praxis confronts qualitative researchers in the human disciplines. Embedded in the discourses of poststructuralism and postmodernism, these three crises are coded in multiple terms, variously called and associated with the critical, interpretive, linguistic, feminist, and rhetorical turns in social theory. These new turns make problematic two key assumptions of qualitative research. The first assumption presumes that qualitative researchers can no longer directly capture lived experience. Such experience, it is argued, is created in the social text written by the researcher. This is the representational crisis. It confronts the inescapable problem of representation but

does so within a framework that makes problematic the direct link between experience and text.

The second assumption makes problematic the traditional criteria for evaluating and interpreting qualitative research. This is the legitimation crisis. It involves a serious rethinking of terms such as validity, generalizability, and reliability—terms already retheorized in postpositivist constructionist–naturalistic, feminist, interpretive and performative, poststructural, and critical discourses. This crisis asks the question: How are qualitative studies to be evaluated in the contemporary poststructural moment? The first two crises shape the third crisis, which asks the question: Is it possible to effect change in the world if society is only and always a text? Clearly, these crises intersect and blur, as do the answers to the questions they generate.

Fifth Moment: The Postmodern Period

The fifth moment, or the postmodern period of experimental ethnographic writing, struggled to make sense of these crises (1990–1995). New ways of composing ethnography were explored, and theories were read as tales from the field. Writers struggled with different ways to represent the "other," although they were joined by new representational concerns now. Epistemologies from previously silenced groups emerged to offer solutions to these problems. The concept of the aloof observer had been abandoned. More action, participatory, and activist-oriented research was on the horizon. The search for grand narratives was being replaced by more local, small-scale theories fitted to specific problems and specific situations.

Sixth Moment: The Postexperimental Inquiry

The sixth moment, or the postexperimental inquiry (1995–2000), was a period of great excitement, with AltaMira Press, under the direction of Mitch Allen, taking the lead. The "Ethnographic Alternatives" book series by Carolyn Ellis and Arthur Bochner captured this new excitement and brought a host of new authors into the interpretive community. The series was given a mandate to publish experimental forms of qualitative writing that would blur the boundaries between the social sciences and the humanities. Experiments in methods for representing lived experience were present in some volumes of the series.

Seventh and Eighth Moments: Present and Future

In this same time period, three major new qualitative journals appeared: *Qualitative Inquiry*, *Qualitative Studies in Education*, and *Qualitative Research*. The editors of these journals were committed to publishing the very best new work. The success of these ventures framed the seventh moment, what we are calling the methodologically contested present (2000–2008). As discussed earlier, this was a period of conflict, great tension, and (in some quarters) retrenchment.

The eighth moment is now and the future (2008–). In it, scholars are confronting the methodological backlash associated with the evidence-based social movement.

Reading History

We draw several conclusions from this brief history, noting that it is, like all histories, somewhat arbitrary. First, each of the earlier historical moments is still operating in the present, either as legacy or as a set of practices that researchers continue to follow or argue against. The multiple and fractured histories of qualitative research now make it possible for any given researcher to attach a project to a canonical text from any of these historical moments. Multiple criteria of evaluation compete for attention in this field. Second, an embarrassment of choices now characterizes the field of qualitative research. There have never been so many paradigms, strategies of inquiry, or methods of analysis to draw on and use. Third, we are in a moment of discovery and rediscovery as new ways of looking, interpreting, arguing, and writing are debated and discussed. Fourth, the qualitative research act can no longer be viewed from within a neutral or objective positivist perspective. Class, race, gender, and ethnicity shape the process of inquiry, making research a multicultural process. Fifth, we are clearly not implying a progress narrative with our history. We are not saying that the cutting edge is located in the present. Rather, we are saying that the present is a politically charged space. Complex pressures inside and outside of the qualitative community are working to erase the positive developments of the past 30 years or so.

EXISTENTIALISM

Existentialism emerged and achieved its greatest popularity during the years following World War II, chiefly because of the persona and literary works of French philosopher Jean-Paul Sartre. In the realm of philosophy, existentialism is best seen not as a new or distinct philosophy but rather as a revolt against traditional philosophy. Moreover, the word *existential* is used as an adjective to identify styles in art, dance, literature, theater, poetry, spirituality, and even sculpture. Some of the writers, philosophers, and artists identified with this movement have explicitly rejected the label *existential*. Given this complexity, it is best to see existentialism as a sensibility, a passion for living, an orientation to the emerging drama of actual lived experience.

Four Themes of Existentialism

The formal literature of the existentialist perspective emphasizes one or more of the following four themes: the struggle for meaning, the role of emotion and its importance in life, the irrational potential or absurdity of life, and individual responsibility.

The Struggle for Meaning

First is the nature of the individual and his or her struggle to find and create meaning in life. There is an emphatic assertion that individuals are free—not totally or absolutely free, but at least partly free to respond to the conditions that face them in life and to create meanings in this existence. All individuals are born into a family, culture, community, nationality, religion (or none), racial/ethnic group, and so on. Individuals do not so much “choose” these as they are “thrown into” them, embedded in social, cultural, and political contexts. Language acquisition is crucial because as children grow into adulthood they progressively acquire the terms, concepts, vernacular, and

other meanings associated with the collective membership of that social grouping. Are individuals 99% free or 1% free? Existentialists would find this question entirely irrelevant and uninteresting; even if the answer tends more to the 1%, there remains an essential openness to discretion, interpretation, and choice. Even a prisoner in solitary confinement has a choice on how to spend the time, existentialists would insist, whether to explore the nature and meaning of solitude or to fuel the fires of anger and rage. A key concept for existentialists is “choice” and the insistence that individuals possess freedom to respond to the situation or conditions that face them and to elect one course of action (or interpretation) over another. An often-quoted aphorism of Sartre is that individuals are “condemned to be free.” An individual can approach and live his or her life “in good faith,” which means an acceptance of one’s freedom to make choices in response to situations, or “in bad faith,” which means a denial of one’s agency, often with attribution of meaning to external circumstances, people, or structures. Many of the existentialist novels and plays dramatize individuals’ agonizing struggles to find and create meaning.

The Importance of Emotion

The second theme concerns emotion and its fundamental importance in life. Although some of the pre-Socratic Sophists emphasized the central role of emotions in life (and thus are interpreted retrospectively as early or proto-existentialists), from the time of Socrates to contemporary times the primary emphasis has been on reason and rationality. From this traditional view, individuals achieve the pinnacle of their humanity and meaning to the extent that they develop and cultivate their minds—the powers of their reason. A well-known statement of philosopher Immanuel Kant is, “Nothing great was ever accomplished without reason.” Emotions are seen as a secondary or degraded side of existence, as potential obstacles to the higher forms of reason. In contrast, existentialists emphasize the passionate and emotional aspects of life and assert the relative dominance of emotions over reason in many circumstances. This emphasis is prescriptive; one should embrace and passionately engage in the present moment, the here-and-now, and not allow the past or the future to distort the present. Friedrich Nietzsche had a different spin on the aphorism by Kant noted earlier: “Nothing great is ever done without passion.” The subjective emotions are not to be

denied—to be regarded as secondary to reason. They should be embraced and examined. Even superficial reflection shows that our main emotions—love, family loyalty, friendship, joy, ecstasy, appreciation, and many more—are not antithetical to meaningful life (or even reason); they are often the wellsprings of meaning.

The Absurd

The third theme is the irrational potential in life, even the absurd. Absurd is a theme in some existential literature, and here the word *absurd* means without inherent or intrinsic meaning. We are thrown into the world, thrown into specific circumstances, but these have meanings only to the extent that they are created by individuals. This theme is explored in several of Albert Camus's novels, especially *The Stranger*, written during the immediate postwar period.

The Stranger

In *The Stranger*, the protagonist Mersault is an indifferent “everyman,” but one divorced from his own self and feelings; he has no plans, no ambitions, no sense of his emotions, and even only indifference to his own mother's death. A series of exigent circumstances result in Mersault shooting an Arab (six times) on a beach. The subsequent trial becomes a literary vehicle for resurrecting Mersault, and in it he is confronted with others' perceptions of him. He was a stranger to himself, but now in his trial he becomes capable of self-reflection and, thus, guilt for his crimes. At the end of *The Stranger*, Mersault says that he opens his heart to the “benign indifference of the universe,” which is to say a world that is without inherent meaning and, hence, is absurd. The phrase “benign indifference of the universe” is a way of expressing emphatic opposition to what structural sociologists hold as true, the *sui generis* (or independent meaning) of social phenomena. Another literary expression of the irrational in life is Camus's 1948 play *The Plague*.

The Plague

Set in Algeria, the plague spreads throughout society and decimates many citizens. The plague is a metaphor for Nazi occupation. The purpose of the play is to show the different individual responses to this scourge. The protagonist in *The Plague* is the ironically named Mr. Grand, who like Mersault is

a perfectly ordinary “everyman.” In the contemporary times of the 21st century, many postmodern analysts talk about the failure or dissolution of the “grand narratives” of life (e.g., God, capitalism, socialism, communism, democracy, Christianity); this essentially engages the same issue that postwar existentialists called “the absurd.”

Individual Responsibility

The fourth theme is individual responsibility. On this theme, Sartre was the most emphatic about humans' responsibility to themselves. This philosophy is perhaps expressed most forcefully in his 1956 work *Being and Nothingness*, and it is here that Sartre uttered the famous remark, “Everyone gets the war he deserves.” What this means is that although individuals may have relatively little freedom to create the social, political, and economic conditions of their existence, they do have some freedom of choice to make what they can of their situations. They may adopt an attitude of conformity, resignation, resistance, escape, rebellion, or reform, but whatever their choices, those choices then act back on them and define who they are in the world. What does it mean to be human? For Sartre, the Nazi occupation of France and World War II became illustrious of how individuals responded with their feelings, perception, actions, and choices.

Existentialism and Phenomenology

Existentialism and phenomenology share origins and progenitors, so the linkages between them are inescapable. Existentialism emphasizes real individuals in the world, the lived existence of actual experience, so this raises the question of human perception and how the external world appears to and is known by individuals. This is where phenomenology comes in. Phenomenology is the rigorous study of consciousness. The goal or purpose of a phenomenological analysis is to penetrate the taken-for-granted world of common sense (which phenomenologists term “the natural attitude”) so as to grasp and understand how ideas, emotions, and other meanings are seen and interpreted by the self or others. An early writer in the hermeneutic (interpretive) tradition was Wilhelm Dilthey (1833–1911), who asserted that the study of human meaningful action was radically different from that usually employed by scientists. To do this properly

requires that an observer bring to the observation prior cultural knowledge of what it means to be human in that culture and then empathically understand what thoughts and actions mean to specific individuals in actual settings. Phenomenology seeks the origin, the ground of meaning in the manner by which the (external or internal) world becomes known to us. The origins of truth and reality must be sought in the particularities of the relationship that binds the human knowing subject to his or her world. The phenomenological method is essentially descriptive, not explanatory. Understanding (*Verstehen*) is the cornerstone of Dilthey's method; it involves all of one's perceptive, cognitive, and affective capacities in the comprehension of another individual and what objects mean to him or her. This method of *Verstehen* was later developed by the famous German sociologist Max Weber for sociological analyses.

Existentialism and phenomenology have influenced subsequent developments in the social sciences both explicitly and implicitly. At the explicit level, some scholars and social scientists are known by their commitments to an existential sociology or an existential psychology. An early work that sought to translate some of the abstract philosophical ideas of existentialism into sociology was Edward Tiryakian's *Sociologism and Existentialism* in 1962. In this book, Tiryakian tried to reconcile two very different ways of thinking about human social life. The term *sociologism* is usually associated with the many books of Émile Durkheim and his thinking that social reality exists above and apart from any specific individuals. Individuals do not matter much in this way of thinking; "society" exists before individuals come into it and beyond the life of any specific individual. The larger institutional structures of society are seen as superseding and transcending the lives of ordinary individuals and are not dependent on individuals in any meaningful way. Societies and cultures are seen to achieve stability, change, transform, and disintegrate largely independent of the wills, intentions, choices, and decisions of individuals. This is the key idea for those who are structuralists in the social sciences, and such thinkers have traditionally dominated academic thought. The second perspective is that of existentialism, which places a much greater emphasis on individuals, their choices, their responsibilities, their passions, their decisions, their virtues, their cowardice, and so on. Tiryakian proposed to bring together these two seemingly incompatible perspectives in a manner that would retrain the integrity of each.

In 1967, Peter Berger and Thomas Luckmann published *The Social Construction of Reality*, a work that is now known to all social scientists and their students, either through the primary source or through many of the available secondary sources. Like Tiryakian, Berger and Luckmann sought to reconcile two prevalent social science views about life. They characterized these two views as "society in man" and "man in society," but these terms essentially correspond to sociology and existentialism. The first view, society in man, tries to capture the structuralist perspective, which sees social and cultural structures as primary foundations of social reality; in contrast, individuals are seen as largely passive recipients of social and cultural influences. The second view, man in society, emphasizes men and women as active agents of freedom and choice, as persons who choose to conform, resist, rebel, or create. This is the view that is consistent with the existentialist view of freedom. This view of human nature sees men and women as active, as empowered subjects in their cultural milieus.

In their 1977 anthology *Existential Sociology*, Jack Douglas and John Johnson brought together a series of essays that explored the implications of existentialism and phenomenology for the social sciences, specifically sociology. The emphases on individuals and practical action appeared to have a resonance with American pragmatism, especially symbolic interaction, so several of the essays explored these connections. Symbolic interaction also involves the study of real persons in actual social situations, usually (but not exclusively) with an eye to grasping how commonsense actors interpret these situations. Many of the same authors contributed to the 1985 anthology edited by Andrea Fontana and Joseph Kotarba, *The Existential Self in Society*, which brought together a series of empirical studies of the self and identity in our complex culture. And in 2002, the existential sociology trilogy was completed with *Postmodern Existential Sociology*, edited by Joseph Kotarba and John Johnson, which sought to revise and update existential sociology in light of "the postmodern turn" in qualitative sociology. The authors of this anthology sought to expand the existentialist perspective to the new realities of a globalized, mass-mediated culture and to incorporate new methods for studying these.

Existential sociology invariably uses some form of qualitative research. The earlier studies tended to use participant observation or field research. The objective of this research is for the observer to enter some natural setting of everyday life, to participate with and

get to know the members of this setting, and to try to achieve a member's knowledge of how things work and what things mean (if this is possible) for the purpose of studying, understanding, and articulating the members' interpretations of what is going on and why. In many research studies, it was important for the researcher to establish relations of trust so that they would truthfully report what things mean. There are many research studies in which the researcher is a former member and returns to the setting for the purposes of study. In other cases, it is not possible to achieve full membership status (e.g., drug dealing, other illegal activities). There now exists a voluminous literature on the problems and issues involved in doing this kind of research. During recent years, many new methodological approaches have been advanced and developed. Some of these new methods, such as ethnographic content analysis and comparative content analysis, are devised to specifically examine mass-mediated or cinematic realities. Other new methods focus on the observer or writer and his or her cultural meanings; some of these products are performed before audiences rather than merely being reported in scientific journals. One methodological genre is known as performance ethnography and has achieved interdisciplinary acceptance.

The study of emotions has blossomed during recent decades. Although some of the early work was done by existential sociologists or existential psychologists, this burgeoning area of inquiry has grown far beyond these early concerns. Social scientists in many disciplines now take the topics of feelings and emotions very seriously, and a wide range of both quantitative and qualitative methods has been used in these studies. The American Sociological Association now has a separate section on the Sociology of Emotions, numbering hundreds of members who study and teach about emotions. The intellectual battles about emotions were very heated and passionate during the early days of this movement, but now few doubt the centrality of feelings and emotions to human life. The empirical study of emotions has won widespread interdisciplinary acceptance, and here the focus is on individuals in nonclinical settings, the lives of ordinary persons who are functioning in the everyday world of work, family, and institutional lives. It is estimated that perhaps as many as 60 million Americans suffer from depression at some point in their lives. The best-selling books by William Styron, Peter Kramer, Kay Redfield Jamison, and Andrew Solomon attest to this widespread phenomenon. Do feelings and emotion dominate cognition or

vice versa? The jury is still out on this question and many other important questions, but the argument is heated and passionate.

Although the existing literature on postmodernism is very complex and difficult (if not impossible) to characterize, much of it implicitly addresses the absence of inherent or intrinsic meaning. In earlier times, existential writers would have depicted this as the irrationality of life or even as the problem of the absurd. Like the earlier existentialism, postmodernism is perhaps best seen not as a well-developed theory or perspective but rather as a sensibility or orientation to the world; also, like *existentialist*, the word *postmodern* is used as an adjective to characterize representations in art, dance, theater, cinema, spirituality, and so on. Postmodernism is evolving and changing with the times. In one early article, Norman K. Denzin identified four distinct phases or "moments" in the evolution of postmodern thought and sensibility, but then in a later article there were seven identifiable phases. It is likely that the majority of postmodernists would disagree with, reject, or assert the failure of what is called the "Enlightenment Project," specifically the promise of science to bring forth a more just world. This is a sentiment with which many existentialists would also agree. "Science" is problematic in this view—capable of many worthy achievements but also contributing to much suffering and misery.

EXPERIENTIAL KNOWLEDGE

Experiential knowledge was succinctly defined in 1994 as "information and wisdom gained from lived experience" by Marsha A. Schubert and Thomasina J. Borkman. It signifies a way of knowing about and

understanding things and events through direct engagement. Lived experience incorporates the actual experience itself along with the meanings attributed to the experience by the person experiencing it. One form of experiential knowledge, termed *Indigenous* or *local environmental* knowledge, refers to information and meanings gleaned through active participation in an activity that is shared by or distributed among members of a group or community. This can include groups of people who form a community (e.g., people who are part of the same village or ethnic group), people who are linked in other ways (e.g., people engaged in similar activities such as fishermen in a particular geographic region or factory workers), or people who are a group only in the sense that they share a particular experience (e.g., people with a chronic medical condition).

A second thread in the discussion of experiential knowledge focuses on how researchers' own lived experiences frame their decisions regarding research questions, understanding, and interpretations. Arguing that research decisions are selective and that understanding is informed by perspective, postmodernists, feminists, qualitative researchers, and critical race theorists challenge exclusion and marginalization of the experiences of subgroups by mainstream researchers. They argue that the researcher's lens, shaped by identity, gender, race, ethnicity, class, sexual orientation, education, and position, influences how questions are selected and framed as well as how data are collected and interpreted. Experiential knowledge of the researcher is always present in research, and some propose that research benefits when this is made explicit. Beyond mere acknowledgment, the researcher embraces the importance of experiential knowledge constantly exploring the interaction among experience, data, and understanding through an iterative process of inquiry and reflection. For some researchers, this also includes an action phase whereby findings are tested and the results are fed back into the process.

Another aspect of experiential knowledge entails understanding how it is directly embedded in the inquiry process itself and how the researcher taps into the knowledge of the "other." Anthropologists and other social scientists who conduct research in naturalistic settings engage in a process by which knowledge is gleaned through empathic participation in everyday events and in-depth reflection on the experience. The researcher uses all of his or her senses in seeing, hearing, feeling, and understanding. The researcher's toolkit, including participant

and unobtrusive observation and listening, questioning, informal conversation, various forms of interviewing, mapping, elicitation, photography, and survey taking, supports this way of knowing. What is unique is that the researcher uses these tools, particularly observation, listening, questioning, and reflecting, to experience the phenomenon under study, albeit only partially. Experiential knowledge takes many forms, including cultural, social, political, environmental, historical, and organizational knowledge. Through participatory and collaborative research, the researcher joins himself or herself, as well as his or her knowledge, with the wisdom of those engaged in the domain or issue under study in a discovery process that is cooperative and negotiated.

EXPLANATION

In ordinary usage, as well as in philosophy, an explanation tells us not only what happens but also why. This idea is embodied in the distinction between description and explanation. In the literature on research methods, explanation has generally been understood as causal explanation and its pursuit has been limited to quantitative (or even, more narrowly, experimental) methods. Qualitative researchers, in reaction, have generally denied that they were seeking causal explanations, arguing that their goal was the interpretive understanding of meanings rather than the

identification of causes; some (e.g., Egon Guba and Yvonna Lincoln) have rejected the entire concept of causality as outdated and inappropriate for the social sciences.

However, this argument has usually failed to take account of recent philosophical developments in our understanding of explanation and causality. The traditional view of causal explanation, and the basis for its restriction to quantitative methods, derives from David Hume's analysis of causality, generally known as the "regularity theory." Hume argued that we cannot directly perceive causal relationships and, thus, that we can have no knowledge of causality beyond the observed regularities in associations of events. This view treats the actual process of causality as unobservable—a "black box"—and focuses on discovering whether there is a systematic relationship between inputs and outputs.

This view has more recently been challenged by an alternative approach to causal explanation, one that sees causality as fundamentally referring to the actual mechanisms and processes that are involved in particular events and situations. These mechanisms and processes can include mental phenomena as well as physical phenomena and can be identified in unique events as well as through regularities. In philosophy, advocates of this view include Wesley Salmon and Hilary Putnam. In the social sciences, this approach is associated (although not exclusively) with the position known as "critical realism."

This position's emphasis on understanding processes, rather than on simply showing an association between variables, provides an alternative approach to causal explanation that is particularly suited to qualitative research. It incorporates qualitative researchers' emphasis on meaning for actors and on unique contextual circumstances, and by treating causal processes as real events, it implies that these may be observed directly rather than only inferred. Thus, it removes the restriction that causal inference requires the comparison of situations in which the presumed cause is present or absent. It is strikingly congruent with Herbert Blumer's approach to qualitative research, known as symbolic interactionism, as well as with the work of more recent qualitative researchers such as Matthew Miles and Michael Huberman. With its grounding in a realist ontology, however, it is in conflict with "strong" versions of social constructivism that deny the existence of any "reality" outside of our constructions.

A great deal of qualitative research implicitly incorporates such an understanding of explanation as

an understanding of causal processes, a view that is very congruent with commonsense views of explanation. The challenge for these qualitative researchers is to make this view of explanation more explicit, to use it to defend the legitimacy of explanation as a goal of qualitative research, and to further develop qualitative procedures for systematically generating and testing causal explanations.

EXPLANATORY RESEARCH

The term *explanatory research* implies that the research in question is intended to explain, rather than simply to describe, the phenomena studied. This type of research has had a contested history in qualitative inquiry, and divergent views of the appropriateness of such goals in qualitative research are currently held. This entry summarizes the current state of this debate and describes some of the most important qualitative methods for such explanation.

Traditionally, the research denoted by the term *explanatory research* has been quantitative in nature and has typically tested prior hypotheses by measuring relationships between variables; the data are analyzed using statistical techniques. In the narrowest sense, this term is sometimes used synonymously with *experimental research*, with the implication that only experiments are capable of answering causal questions. More broadly, it can also include other types of quantitative research grouped under terms such as *causal modeling* and *structural equation modeling*, which attempt to identify causal relationships through the analysis of correlations between variables.

However, the terms *causal* and *explanatory* have also been applied to various types of qualitative research, although these uses have been controversial both within and outside of the qualitative research community. Such uses were more common in the earlier history of qualitative research, but with the inception of

the “paradigm wars” during the latter part of the 20th century, the very idea of causation became problematic in qualitative research. The prevalence of the view that only quantitative methods can be used to investigate causality led many writers to avoid making explicit causal claims in their work, whereas other qualitative scholars have argued that the entire concept of causality is illegitimate or inappropriate in qualitative research.

The debates about what research counts as “explanatory” have taken on major political dimensions since 2000, as advocates of what they call “science-based research,” which privileges the use of randomized control trials (RCTs) as the “gold standard” for causal explanation, gained control of federal funding for educational research in the Bush administration. (A similar development occurred earlier in Great Britain.) Although there has been widespread criticism of this position, it has many adherents and its influence has been felt beyond educational research.

Despite this, the use of terms such as *influence*, *impact*, *affect*, and *contribute to*, is common in qualitative research reports, and such terms imply causality in some sense. In addition, a growing number of researchers (both qualitative and quantitative) now argue that, in some circumstances, quantitative approaches are not necessarily the best (or only) ways of reaching explanatory conclusions and that qualitative methods can be used to systematically develop and test causal explanations.

There are several important criticisms of randomized experimental designs as the preeminent research strategy for explanatory purposes. First, in many situations, and for some issues, it is difficult or impossible to rigorously implement such designs, and many purported RCTs have in fact been so flawed that their causal conclusions are questionable. Second, many other types of research (ranging from quasi-experiments, to causal modeling, to qualitative approaches) can establish causal conclusions, not with certainty (no method can do this) but beyond reasonable doubt.

Finally, the model of causation assumed by most advocates of RCTs and by quantitative researchers in general, known as the “deductive–nomological” or “regularity” model, has been the object of sustained criticism both in the philosophy of science and in social research. Since the demise of logical positivism, which was closely identified with this model, an alternative view of causation (often identified as “realist”) has gained substantial prominence. The latter model, which sees causation not as regularities in the relationships between independent and dependent

variables but rather as the actual properties and processes that produce causal outcomes, is much more compatible with qualitative research and supports the claims of qualitative researchers to be able to draw causal conclusions.

Probably the earliest explicit systematic attempt to use qualitative methods for causal explanation was analytic induction, developed by the sociologist Florian Znaniecki during the 1930s. Znaniecki believed that this approach, based on the search for similarities in an exhaustive examination of cases, could be used to inductively generate universal causal laws; any exception to a proposed law required reexamination of the data. However, this view, based on a positivist understanding of scientific explanation, has generally been rejected by later scholars, and current uses of analytic induction have largely abandoned any explicit claim to causal explanation.

One of the most widely used qualitative approaches to explanation has been called “causal narratives.” This strategy was developed as an explicit strategy during the 1950s, although it draws on the earlier techniques of historians and political scientists. It was intended to provide an alternative to the quantitative correlational methods that were widely used in the social sciences to develop causal models, methods that many scholars believed were unsuited to the complex, interacting, and contextually specific phenomena that social scientists often study and to the small samples with which they often work. This explanatory strategy is quite different from that of analytic induction in that, instead of seeking regularities in the relationship between proposed explanatory factors and outcomes across cases, the goal is to elucidate the processes at work in one case, or a small number of cases, using in-depth intensive analysis and a narrative presentation of the argument.

Similar approaches have often been used in case study research. Robert Yin argued that, contrary to the traditional stereotype of case studies as a relatively weak method that is useful mainly for exploratory purposes, case studies can provide a powerful strategy for causal explanation. A classic and often-cited example is Graham Allison’s *Essence of Decision: Explaining the Cuban Missile Crisis*. Yin and others have provided a variety of techniques for developing and testing causal explanations in case study research, some that were drawn from quantitative strategies, such as time series analysis and logic models, and others that were developed within the case study tradition, such as narrative approaches.

Likewise, Matthew Miles and Michael Huberman argued that qualitative research is in fact far better than purely quantitative approaches at developing explanations of what they called “local causality”—the actual events and processes that led to specific outcomes. They also suggested that, given multisite data, qualitative methods can develop rather powerful general explanations and can confirm causal models suggested by survey data. John Creswell has incorporated the latter view into his widely cited typology of mixed methods designs. He defined an “explanatory design” as one in which the results of an initial quantitative phase are explained by a subsequent qualitative investigation.

This emphasis on explanation as the understanding of causal processes in specific cases, rather than the formulation of general laws, is strikingly consistent with recent work on explanation within the realist tradition in the philosophy of science. This tradition sees causality as consisting not of regularities in the relationships between variables or events but rather of real (and, in principle, observable) causal mechanisms and processes, the result of the operation of the powers of natural and social entities, within a specific context, to produce particular outcomes, although they may or may not produce regularities. Such views are beginning to have an influence on the theory and practice of social research methods and are much more compatible with qualitative research than are the traditional positivist understandings of causality.

EXPLORATORY DATA ANALYSIS

Exploratory data analysis is the set of steps that qualitative researchers follow in exploring a new area of social or psychological life that they do by collecting open-ended data from which to generate new concepts and generalizations about that area. The most efficacious exploratory data analysis leaves these investigators as much scope as possible for the discovery of new concepts and generalizations. That is, the steps followed are designed to encourage and enhance this inventiveness.

Exploratory data analysis, unlike its confirmatory counterpart, begins when data collection starts in that the researcher examines the record (e.g., written notes, audio- or videorecordings) of what has been observed during each session of data collection. This knowledge then directs subsequent sessions during the same research project. Moreover, as the data are being gathered, ideas about them (e.g., possible concepts, generalizations) emerge and are recorded as memos. Each record and accompanying memos are further elaborated and compared (constant comparative method) as soon after the session of collecting as possible, and additional memos may also be written at this time. This initial analytic phase eventually gives way to the main phase of data manipulation, typically launched once the researcher ceases gathering data.

During data manipulation, the records and memos are closely examined and further compared with an eye, first, to discovering their common properties and, second, to melding these properties into concepts and generalizations about the area of social life under study. Identifying such properties and forging concepts and generalizations from them is at the creative heart of discovery research. A variety of computer programs are available to help manage the data and their emergent concepts and generalizations, although the common warning is that such programs are not themselves creative mechanisms. They cannot make intuitive leaps, those creative or innovative moments during which scientists intuitively, and imaginatively, find such properties, concepts, and generalizations.

They can only help to organize the records and memos, thereby putting the researcher in a position to discover new relationships.

Barney Glaser argued that, during exploratory data manipulation, the most effective route to discovery is not through using these programs but rather through conducting hands-on sorts of the records and memos gathered earlier. He advocated spreading out, on a large table or even on the floor, handwritten versions of them and then looking over the entire set to identify their commonalities. Alternatively, some researchers prefer to write such material into computer files for eventual printing, cutting up, and placing on the table or floor for analysis. At this point in the study, still others choose to avail themselves of the data management features of a computer analysis program.

Discovery proceeds in steps during this main analytic phase. At the beginning, during the sorting process, the researcher first finds and then shapes a number of descriptive concepts and generalizations. Glaser referred to this process as “substantive coding,” whereas Anselm Strauss and Juliet Corbin called it “open coding.” The resultant concepts and generalizations are called “substantive codes” or “open codes.” For Glaser, the second (and final) step moves the discovery process to a more abstract inclusive level known as “theoretic coding,” which produces a set of theoretic codes. These abstract concepts and generalizations enable the researcher to generalize, however tentatively and however hypothetically, beyond the study from which they emerged. They become elements of an emergent theory about the area of social or psychological life being examined and may be developed with data gathered through open-ended procedures such as narrative analysis, focus group sessions, participant observation, and semi-structured interviews.

Turning to grounded theory as a particular kind of emergent theory, Glaser maintained that no further analytic steps are needed. The researcher, having followed the two steps just described, is now ready to concentrate on writing the research report. In contrast, Strauss and Corbin held that a second intermediate step called “axial coding” is needed. It is accomplished using a coding paradigm made up of components such as context, conditions, action/interactional strategies, and consequences as these relate to the area of social life being investigated. Glaser argued that this paradigm “forces” the exploratory researcher who uses it to see his or her data through the lens of preconceived concepts. This, Glaser held, constrains discovery, and

it is unnecessary because these components, where relevant, will become evident during his two-step coding process. Axial coding, with its 18 different coding families, is by far the most complicated analytic procedure in exploratory data analysis. Once this coding is completed, Strauss and Corbin’s approach calls for a third step that they labeled “selective coding”; it is akin to Glaser’s theoretic coding.

Judy Kendall, in a test of both coding schemes, analyzed qualitative data gathered during research on a family raising a child suffering from attention deficit hyperactivity disorder. She concluded that Strauss and Corbin’s approach generates deeper description than does Glaser’s approach but that the latter’s approach is more effective for developing rich grounded theory and the level of generalization needed for further concatenation of exploratory work in the area of study. The approach chosen, then, depends on the researcher’s principal goal—to generate deep description or extensive development of inductive theory.

Exploratory data analysis is the showcase of inductive reasoning in the social sciences. It is here, through this kind of analysis, that new concepts and generalizations are consciously, intentionally, and inductively created directly from data, the hallmark of emergent theoretic (exploratory) research and today the best known of the inductive types of discovery. Other steps in social scientific exploration—such as study design, data collection, and data write-up—are, as it were, supporting actors in this drama of discovering something new.

EXPLORATORY RESEARCH

In the social sciences, the term *exploratory research* or *exploration* refers to broad-ranging, intentional, systematic data collection designed to maximize discovery of generalizations based on description and direct understanding of an area of social or psychological life. Such research is, depending on the standpoint taken, a distinctive way of conducting science—a scientific process. It is both a special methodological approach, separate from verification or confirmation, and a pervasive personal orientation of the exploratory researcher. The emergent generalizations are typically many and varied; they often include descriptive facts, folk concepts, cultural artifacts, structural arrangements, social processes, and beliefs and belief systems normally found in the group, process, activity, or situation under study. This entry examines the nature of exploratory research, its relationship to verification, and its status as a special kind of longitudinal research referred to as *concatenation*.

Nature of Exploratory Research

One fruitful way of understanding social scientific exploration is to describe what it is not. Thus, it is not a synonym for studying, examining, analyzing, or investigating something. Nor is it the exploration sometimes conducted by artists, inventors, and innovators whereby they become familiar with something by testing or experimenting with it. Furthermore, social scientific exploration is not traveling over or through a particular space for the purposes of discovery and adventure, which we might call spatial exploration. This definition does, however, come closest to the one given in the introductory paragraph. On another level, social scientific exploration is not the examination of a thing or an idea for diagnostic purposes—to search it systematically for something. This meaning suggests that because explorers here already know what to look for (e.g., oil, cancer, toxins), they need only methodically hunt for it. Finally, it is not serendipity, which is logically and procedurally a quite separate form of discovery; it is the quintessential form of informal experimentation, accidental discovery, and spontaneous invention.

Researchers explore when they possess little or no scientific knowledge about the group, process, activity, or situation they want to examine but nevertheless

have reason to believe contains elements worth discovering. To explore a given phenomenon effectively, they must approach it with two special orientations: flexibility in looking for data and open-mindedness about where to find them. Oriented in this way, the first step is to try to acquire an intimate firsthand understanding of the group, process, activity, or situation being observed. It follows that the most efficacious approach is to search for this understanding wherever it may be found using any ethical method that would appear to bear fruit. The outcome of these procedures, and the main goal of exploratory research, is the production of inductively derived generalizations about the group, process, activity, or situation under study. Researchers then weave these generalizations into what Barney Glaser and Anselm Strauss referred to as “grounded theory,” which explains the object of study. Such theory is founded on direct observation of social phenomena.

In most exploratory studies, qualitative data predominate even when they are augmented where possible and desirable with descriptive statistics such as indexes, percentages, and frequency distributions. Furthermore, social scientific exploration is described most accurately as primarily *inductive*, whereas verification is primarily *deductive*. In other words, during exploratory inquiry, researchers do think deductively at times, although they do so largely within their emerging theoretic framework rather than within established theory and sets of hypotheses deduced from it. Moreover, they engage in a sort of verification; that is, they (tentatively) confirm their emergent generalizations rather than an ensemble of a priori predictions. Despite constraints of research design, verificational researchers, for their part, sometimes serendipitously observe regularities leading to generalizations about the group, process, activity, or situation they are investigating. Some of these chance discoveries may have been reached by inductive reasoning, but in confirmatory work such induction is not systematic. Nevertheless, because quantitative data can also be explored as well as verified, it is prudent to be unequivocally clear about the nature and scope of particular research projects, describing them as qualitative–exploratory, quantitative–exploratory, qualitative–confirmatory, or quantitative–confirmatory. Not surprisingly, the simpler labels of qualitative and quantitative can spawn confusion.

Exploration and inductive reasoning are important in science, in part because deductive logic alone can

never uncover new ideas and observations. Max Black noted that, with the growth of natural science, philosophers became increasingly aware of the limitations of deductive argument. That is, because such argument can bring out only what can be deduced from its premises, philosophers are now inclined that all new knowledge must come from some form of induction. The limits of deductive argument are effectively illustrated in what Robert Stebbins called “syllogistic reasoning.” The syllogism is the simplest of all deductive systems, where all A is B, all B is C, and therefore all A is C. In this system, it is impossible to learn about Propositions D, E, and F through logic alone because the reasoning connecting Propositions A, B, and C is a closed argument. Given that established social science theory is a vast, albeit less logically tight, version of the simple syllogism, it too is incapable of revealing any information about the social equivalents of D, E, and F. Whether D, E, F, and still other phenomena even exist and, if they exist, whether any of them is important for a detailed and profound understanding of the group, process, activity, or situation in question can be determined only through discovery. In principle, social scientists have a choice at this point: explore (i.e., use inductive logic) or wait for serendipity to light the way. But serendipity is too adventitious and sporadic to serve as a substitute for systematic exploration.

Exploration and Verification

Verification is research designed to test one or more hypotheses derived deductively from preexisting theory. Such theory could be grounded theory that has emerged from a sufficient number of studies that, together, have reached a point warranting confirmation of its many inductively generated hypotheses. Most commonly, however, verification is undertaken on hypotheses derived deductively from theory that has no exploratory grounding. Verification differs from exploration in that the former rests on prediction and control of the research setting.

In general, exploration is the preferred methodological approach under at least three conditions: when a group, process, activity, or situation has received little or no systematic empirical scrutiny, has been largely examined using prediction and control rather than flexibility and open-mindedness, and has grown to maturity along the exploratory/verificational continuum but has changed so much on the way that

it begs to be explored anew. Whichever condition pertains, the accent in exploratory research is always on inductive generation of new concepts and empirical generalizations.

Concatenation

As scientists come to understand more clearly the group, process, activity, or situation chosen for examination, they and their field of research move toward the verificational pole of research. As they proceed in this direction, they eventually come to rely less and less on flexibility and open-mindedness and more and more on prediction and confirmation, a process that typically unfolds over the course of several studies, with each study executed in “concatenated” fashion with reference to the earlier ones. In other words, movement along the continuum is paralleled by an expansion of the grounded theory and the development of generic or overarching concepts, both made possible by the accumulation of research and application of the theory to an ever-wider range of phenomena.

Robert Stebbins coined the term “concatenated exploration” to refer at once to a longitudinal research process and the resulting set of open-ended field studies linked together in, as it were, a chain leading to cumulative, often formal, grounded theory. Studies near the beginning of the chain are wholly or predominantly exploratory in scope. Each study, or link, in the chain examines or, at times, reexamines a related group, activity, or social process or aspect of a broader category of groups, activities, or social processes.

Where this metaphor of a chain of studies becomes inadequate is in its failure to suggest the accretive nature of properly executed concatenated exploration. In the metaphor of the chain, each link is equally important, whereas in scientific concatenation, the studies in the chain not only are linked but also are predicated on one another. That is, later studies are guided, in significant measure, by what was found in earlier research in the same area as well as by the methods used and the samples examined there. Thus, each link plays a somewhat different part in the growing body of research and in the emerging grounded theory. Furthermore, note that the earlier studies only guide later exploration; they do not control it to the point where discovery is hampered by preconceptions.

Ideally, a field of research, pursued according to the canons of exploration reaches a point in the scientific process at which a coherent grounded theory

about a reasonably broad range of related phenomena has emerged. Now concern is chiefly with enhancing precision of the theory, a goal commonly realized primarily through prediction, quantification, and a heavy reliance on inferential statistics. Even here, however, qualitative data occasionally play an important role. Such data, for example, can help to confirm propositions not amenable to quantitative assessment or, through exploration, can bring to light important recent changes in social process and social structure that a narrowed attention on confirmation of hypotheses has led researchers to overlook.

Before closing, a final comment about the process of concatenation is in order. It is noteworthy that most exploratory sociologists have been considerably less inclined than their counterparts in anthropology to stay with a research subject through several rounds of fieldwork, analysis, and publication. Rather, these sociologists typically conduct one or two field projects, which may or may not be related, and then retire to their offices to write elaborations of their data, theoretic and methodological expositions, upper division textbooks in their specialties, and even personal memoirs. The result is that scientific understanding of an area of social life that has been given a good start through exploratory research is, because of neglect, commonly arrested thereafter, for it is rare that someone else takes up the project where the pioneering researcher left off.

Exceptions to this indictment do nonetheless exist, and a few of them should be mentioned to demonstrate that concatenated exploration is not only desirable but also possible. Robert Burgess spent more than 20 years conducting a variety of interrelated studies on different phases of British education, ranging from nursery school, through primary and secondary school, to university and adult education. William Shaffir, since his graduate school days during the late 1960s, has examined various aspects of communal life among Orthodox Jews in Canada and

Israel. Steven Taylor, at times in collaboration with Robert Bogdan, explored the social world of the mentally retarded in the United States. They launched their first research project in this area in 1972. Stebbins's studies of the serious leisure of amateurs, hobbyists, and career volunteers in North America (which began in 1973) also exemplify this genre of research. Alas, the widespread failure to concatenate to the verificational stage is one of the greatest weaknesses of exploratory research.

FEMINIST EPISTEMOLOGY

Feminist epistemology brings together the usual epistemological concerns such as what constitutes knowledge and how it is constructed with the central issues of feminist theory: gender as an analytic category. Although there are multiple complex discourses on feminist epistemology, at their root is the consideration of the role of gender in determining how knowledge is constructed, both by individual knowers and by social and cultural groups of women and men. A theme in many discussions is how power relations based on gender (and race, culture, social class, and other social categories) shape what counts as knowledge in debates not only in epistemology and feminist theory, but also in all academic disciplines. Given that the purpose of all research is ultimately to produce knowledge and since feminist epistemology brings out the role of gender in shaping knowledge construction, gender is important in considerations of all research methodology. It is especially relevant in discussions of qualitative research where the researcher is very consciously involved in and part of the research process. This entry first gives an overview of feminist theories and then describes differences and similarities between theories that focus on the individual; structural, cultural, and standpoint feminist theories; and poststructural, postmodern, and post-colonial feminist theories. Lastly, it discusses the ways in which these feminist perspectives affect the conduct and analysis of research.

An Overview of Feminist Theories

There are many feminist theories. Although there are similarities and points of conflict among them, they all arose out of the fact that feminism as a historical and social movement was intended to challenge women's oppression. There generally has been an assumption that most people have been socialized into sexist ideology and often into particular gender roles and ways of thinking that usually give males more institutional, social, and economic power and access to resources. Feminism assumes that the problem in gender relations is not men, but sexism and the forces of patriarchy that lead to sexism. Feminism seeks to challenge sexism and sexist ways of thinking and living that limit both men and women. As feminist cultural critic bell hooks has discussed, everyone has something to gain from the feminist movement, as its purpose is to create more equitable relations for all people—both women and men.

Over the course of history, in response to the gender climate in society at any given era as well as the academic disciplines that inform scholarship, feminism has taken on different forms and emphases. For example, up until the late 1970s or early 1980s, the feminist movement was intended to address the needs of women in general; however, it in fact focused on the experience and needs of White, middle-class women and did not adequately take into account the impact of race and class. Thus, from the late 1980s and on into the new millennium, there has been much development in research and scholarship by and about women of

color and in scholarship that focuses on differences among women. More recently, much work in feminist theory has foregrounded the effects of globalization. The remainder of this section focuses on the different strands of feminist theory broken down broadly into three areas. In each section, there is a particular emphasis on the major epistemological focus of these strands, as well as a consideration of how these theoretical threads deal with differences among women.

Individually Focused Feminist Theories

A range of feminist theories, including liberal feminism, psychoanalytic feminism, and most discussions of feminist psychology, focuses especially on women as individuals. Liberal feminism has its roots in the enlightenment philosophy of the 19th century that emphasized rationality and shaped the education system of the 20th century. The focus of liberal feminism of the 1960s and 1970s (and to some extent in the current day) is on giving women as individuals equal rights to men in the system the way that it is, particularly in regard to education and job opportunity. Liberal feminism has not tended to directly challenge knowledge construction processes; rather, it has emphasized giving women equal access to all levels of education and enabling them to participate in knowledge construction processes as used by men.

Psychoanalytic feminism and feminist psychology more generally also have an individualistic focus, but from a psychological perspective. The concern here is how individual women construct knowledge in light of gender socialization that emphasizes the importance of caring, connection, and relationship. One key influence in these perspectives is the work of Carol Gilligan, beginning with the publication of *In a Different Voice* in 1982. This book was based on Gilligan's study of women's moral development and found that women tended to make moral decisions based on connection and relationship rather than on an appeal to moral principles, a perspective that is gender-related as opposed to gender-specific. Two years later, Nel Noddings elaborated on the ethic of care from a philosophical perspective, particularly in regard to how it relates to education. Building on the work of both Gilligan and Noddings, another important influence was the publication of *Women's Ways of Knowing* by Mary Belenky, Blythe Clinchy, Nancy Goldberger, and Jill Tarule in 1986. This book was based on a

qualitative study of 135 women and focused on how these individuals came to know and learn, with special consideration of the role of affect, connection, and relationship as well as rationality in learning and knowledge construction in women coming to voice. These individually focused feminisms were critiqued as focusing on the concerns of White, middle-class women because they tend to focus on women as a unitary category or on the generic woman who is often implicitly White and middle-class. These strands also tended not to examine race, class, cultural, and sexual identity differences among women, though in more recent years there has been more attention to these issues of difference in feminist psychology. The unit of analysis in these feminisms tends to be the individual and how he or she constructs knowledge. In regards to research methodology, these feminisms point to the role of voice, affect, and relationship in the research process.

Structural, Cultural, and Standpoint Feminist Theories

Structural, cultural, and standpoint feminist theories tend to focus especially on the role of social structures and power relations that shape knowledge production. There are a variety of these theories, many of which initially emerged in sociology and related disciplines in the 1970s and 1980s alongside the individually focused feminist theories. The structural feminist theories of radical feminism, Marxist feminism, and socialist feminism examine the effect of societal structures and power relations between dominant and oppressed groups on women. The concern of radical feminism has been primarily with challenging patriarchy as a form of structural oppression, while Marxist feminism argues that there are two primary systems of oppression—patriarchy and capitalism—that need to be challenged. Socialist feminists not only focus on patriarchy and capitalism, but also emphasize an examination of other systems of oppression, such as racial oppression, and the intersections of gender, race, class, and sexual orientation in relation to the material realities of women's lives. The units of analysis of these frames are structural as opposed to individual or the psychological.

Closely related to structural feminist theories are cultural feminisms and standpoint feminist theories, which initially developed in the late 1980s and 1990s and today continue to focus more on women in particular

groups defined in terms of race-ethnicity, culture, gender, class, and sexual orientation. The lived experience of a specific group of women is at the center of analysis, rather than at the margins, as, for example, in Black feminist thought, womanism, Latina feminism, or Asian and Asian American feminism. Because the focus is on the dynamics of where women of particular cultural or other groups stand in relation to the dominant culture in understanding their lived reality, such feminisms are referred to as *standpoint feminisms*. From an epistemological perspective, all structural, cultural, and standpoint feminisms focus on the role of power relations in shaping the politics of knowledge production, and they examine what gets counted as knowledge, and by whom, in the construction of knowledge. From a research perspective, cultural and standpoint feminist theories highlight how the race, culture, and gender of the researcher relative to the participants affect methods for getting access to participants, the relationship with the participants, and the data collection and analysis processes.

Poststructural, Postmodern, and Postcolonial Feminist Theories

In addition to the further development of psychological and standpoint feminist theories, the 1990s and the new millennium have given rise to poststructural, postmodern, and postcolonial feminist theories. Although there are some differences among these *post* theories, they also have points of connection. These theories draw on structural and standpoint feminist theories in the sense that they are concerned with social structures. But there are also a number of differences, mostly in the degree to which the poststructural, postmodern, and postcolonial discourses emphasize issues such as deconstruction, power, the notion of identity and knowledge construction as constantly shifting, and subjectivity (and the impossibility of objectivity).

Rather than the unit of analysis being social structures as in structural or standpoint feminisms, poststructural, postmodern, and postcolonial feminist theories view the unit of analysis as the connections between individuals and social structures of race, gender, and class (and/or the forces of colonialism in postcolonial feminism) rather than the social structure itself. Epistemologically, all of the post discourses to one degree or another deal with deconstruction, particularly in regard to the knowledge construction processes used by individuals as well as by various

academic disciplines. They all problematize the notion of truth as something that can be known with certainty because truth is always shaped in part by cultural or social factors and colonial influences; thus, the post discourses recognize multiple truths. These realities or truths are always both constructed and viewed partially through one's positionality or social location. Positionality in this context refers to the notion that where one is positioned based on race, gender, class, sexual orientation, religion, age, disability or ability, and the intersections of these categories (often referred to in the post discourses as multiple subjectivities) relative to the dominant culture or to other social groups in society always affect one's view of the world and how one constructs and values knowledge. Given one can never get completely outside of one's positionality, objectivity is viewed as impossible. Thus, the post discourses emphasize the role of and accounting of multiple subjectivities in shaping knowledge construction, although in the feminist perspectives within this approach gender is always a primary category of analysis.

As in structural and standpoint feminist theories, power is central in shaping knowledge construction processes, but the notion of power is conceptualized often from French poststructural scholar Michel Foucault's perspective, who sees power as always circulating rather than in being completely in one place or another and who suggests knowledge can never be separated from power. The shifting nature of power suggests that knowledge is never static, nor is identity, given that there is always a shifting understanding of identity in regard to various aspects of one's positionality over time.

From an epistemological perspective, those who draw on poststructural, postmodern, or postcolonial feminist theory and pedagogy emphasize how positionality (of teachers and learners) shapes teaching and learning in the classroom and how it affects both knowledge production processes in the lives of individuals and official knowledge production processes in the conduct of scholarship, research, and the publication of results of such work. There is a focus on the raising of consciousness and simultaneous challenge of how structural systems of gender, race, or class inform thinking. At the same time, there is an emphasis on deconstruction of binary categories such as male-female or affective-rational. Thus, there would be a problematizing of ideas that suggests that men are one thing and women, another (e.g., men are rational,

and women are intuitive). Rather, the post discourses would problematize the idea that a particular quality was attributed to one gender or the other and would deconstruct (in the sense of examining and taking apart) how such an idea developed to begin with and what socialization processes were in place that allowed such an attribution to occur. Further, those who adhere to the post discourses would call all binary categories into question and attempt to move the knower beyond black-white thinking in regard to any binary category. Such recognitions of fragmentation, instability of categories, and the shifting nature of identity in light of further thought, emotion, and experience have implications for how research is conducted.

Feminism, Epistemology, and Qualitative Research

A central question in all forms of feminist research is to ask whose interests will be served by the research. The hope in feminist research is that the interests of women will be served or that the research will contribute to an understanding of gender relations and the processes that contribute to knowledge construction through the research process. A number of interrelated issues touched on above warrant further discussion in regard to the feminist (and antiracist, postmodern, and postcolonial) approaches to qualitative research.

Power, Positionality, and Relationship in Research

In most forms of qualitative research, it is generally understood that the researcher is in a position of power relative to the research participants. Although most feminist researchers would agree, they also recognize that participants are not without power; participants have the power to withhold information or to exercise power in other ways. Nevertheless, feminist research scholars emphasize accounting for the ways power is likely at play in the research process. As much as possible, researchers should try to find ways participants can exercise power in the research process and be assured that their voices are represented the way they would like in the research report. Further, as Michele Fine suggests, one should also avoid “othering” participants in the research process by, for example, requesting that participants share much information about themselves while the researcher shares little or no information about her- or

himself. Such a dynamic often further exacerbates the power relationship.

Related to concerns about power relations in the research process are the issues of positionality and relationship between researcher and participant. One’s positionality (gender, race, class, sexual orientation) affects the relationship that the researcher has with participants and affects the research process because participants often speak differently to researchers who are members of their cultural group compared to researchers who are members of another cultural group. For example, African Americans are likely to speak to an African American researcher differently than to a White researcher. With an African American researcher, they may use insider language; they may be more trusting of the researcher and less concerned that what is said will be misinterpreted or misrepresented. Thus, researchers whose positionality differs from that of research participants may need to work more at developing relationship and share personal information related to the topic to create trust and to avoid othering. Further, most feminist and other research approaches that deal with the role of power relations are concerned with the issue of the voice and portrayal of the participants in the research report and also seek to ensure that participants themselves benefit from the research process.

Subjectivity, Shifting Nature of Meaning, and Dependability

As discussed above, many feminist scholars and others influenced by postmodernism, poststructuralism, and postcolonialism argue that identity, knowledge, and meaning are constantly shifting in light of continued interaction with others, and hence, there is a continued reframing of meaning. They also highlight the myth of objectivity and discuss how positionality and multiple subjectivities shape the research process. This argument is not to suggest, however, that the research is then totally subjective and hence not dependable. Rather, the point in these forms of feminist research is to be clear and upfront about the nature of one’s subjectivity by addressing issues such as one’s theoretical perspective in conducting the research, the degree of participation of the researcher in the interview or observation, the role participants had in responding to the write-up, and the ways that the positionality of participant and researchers shaped the interactions and thus the research and knowledge

production processes. This questioning enhances the dependability of the research in that it makes the process and assumptions clear. Paradoxically, by making the subjectivity clear, the research becomes more objective. Thus, the dichotomy between subjectivity and objectivity is replaced by an examination of the dialectic between the two and is dealt with directly, which increases the dependability of the research. This fracturing of binaries—the notion of the shifting nature of power and the fact that at every moment individuals are constructing knowledge anew in light of questions they are asked—continued life experience, and continued reflection (including reflection that is initiated because of the research process) means that meaning and knowledge are always partial and continually unfolding. The qualitative research process itself facilitates that unfolding, but it is never the final word. In fact, there is no final word, but the process itself is part of the product.

FEMINIST RESEARCH

Feminist research challenges traditional researchers to engage gender dynamically as a category of inquiry in the research process. Feminist researchers utilize both qualitative and quantitative research methods and sometimes a combination of methods. What makes research feminist lies in the particular set of theoretical perspectives and research questions that places women's issues, concerns, and lived experiences at the center of research inquiry. Feminist research stresses the importance of considering how gender intersects with other forms of women's oppression based on characteristics such as race, ethnicity, class, nationality, and so on. Feminist research promotes social justice and works to initiate social change in women's lives. Feminist research praxis emphasizes issues of power and authority between the researcher and the researched, offsetting the influence of these factors through the practice of reflexivity throughout the research process. This entry reviews the history of feminist research from the 1960s onward, beginning with attempts to include women as research subjects, then reviewing the result of putting women's lived experience at the center of research, and, finally, exploring the ways in which recognizing the differences in those experiences leads to greater attention to issues of race and ethnicity and to a more global perspective. Attention to these perspectives on research leads feminist researchers to an ongoing examination of the role of power and authority in understanding the research process generally.

Feminist Empiricism

In the '60s, '70s, and '80s, feminist researchers called attention to the pervasive androcentric bias within science and social science research. Feminist empiricists worked to correct these biases by adding women to research samples and by asking new questions that encouraged women's experiences and perspectives to emerge. Feminist empiricists thought that by doing so, they could improve the accuracy and objectivity of claims about the universal knowledge that could be obtained through positivistic research.

Feminist empiricists' insights on androcentrism and their goals of eradicating sexist research cascaded across the disciplines of psychology, philosophy, history, sociology, and education and across the fields of

law, medicine, and communications. The 1970s and '80s saw the publication of many groundbreaking feminist research anthologies critical of androcentric research that made significant contributions to the deconstruction of traditional knowledge frameworks, such as the work of Gloria Bowles, Renate Duelli Klein, Helen Roberts, and Nancy Tuana.

Women's Issues and Lived Experiences as a Basis for Knowledge

In contrast to this endeavor, feminist researchers of the '80s and '90s launched other important challenges to traditional research, starting with a basic foundational question: What is the nature of the social reality? A new set of feminist epistemologies (ways of knowing) and methodologies (ways of asking questions) interrogated, disrupted, modified, and at times radically challenged dominant models of knowledge building within and across the disciplines, beginning with a critique of positivism, the mainstream research paradigm based on the scientific method. Feminists challenged basic tenets of positivism and scientific objectivity, particularly the idea of value-free science that stresses the detachment of the researcher from the researched, universality, and the idea that there is a social reality waiting to be discovered. Instead of working to improve mainstream research by including women, as feminist empiricists had done, some feminists challenged the viability and utility of positivism's hallmark concepts of objectivity and universality. These feminists claimed that knowledge is achieved by paying attention to the specificity and uniqueness of women's lives and experiences rather than by correcting studies by simply adding women.

Feminist researchers such as Donna Haraway, Sandra Harding, and Kum-Kum Bhavnani argue that objectivity needs to be transformed into feminist objectivity. Haraway, for example, defines feminist objectivity as "situated knowledges." Feminist objectivity asserts that knowledge and truth are partial, situated, subjective, power imbued, and relational. The denial of values, biases, and politics is considered unrealistic and undesirable. Historian Joan Scott disputes the positivist notion of a one-to-one correspondence between experience and social reality and argues that experience is influenced by one's particular context—the specific circumstances, conditions, values, and relations of power. Scott introduced a linguistic turn to the understanding of social reality by

illustrating how experience is discursively constructed by dominant ideological structures. Tracing the discourse surrounding experience uncovers the underlying mechanisms of oppression within society that may provide new avenues of resistance and transformation.

Feminist researchers also hope to validate the importance of emotions and values as critical lenses in research. Alison Jaggar recognizes emotion as a critical aspect of knowledge seeking; she thinks it is unrealistic to assume emotions and values do not surface during the research process. Emotions ultimately determine why a given topic or set of research questions is studied and how it is studied. The positivistic dualism between the rational and the emotional for these feminist researchers becomes a false dichotomy. Positivism per se is not the enemy of all feminist inquiry. Some feminist researchers see the merits of positivism, especially when adding validity to feminist research projects. Some research questions may require a positivistic framework, especially if the project's goal requires the testing of a specific research hypothesis on a broad spectrum of data with the goal of generalizing to a wider population (see Sue Rosser, Kathi Miner-Rubino, and Elizabeth Cole).

Feminist Standpoint Epistemologies

Feminists who are critical of feminist empiricism's "add women and stir" approach place women's lived experiences at the center of knowledge building. Feminist standpoint epistemology is an alternative model of knowledge building (see Sandra Harding and Dorothy Smith) that borrows from the Marxist and Hegelian idea that an individual's daily activities or material, lived experience structures understanding of the social world. For both Karl Marx and Georg Wilhelm Friedrich Hegel, the master's perspective is partial and distorted, while the worker-slave's is more complete because he or she must comprehend both his or her own world and the master's to survive. Feminist standpoint scholars argue that a woman's oppressed location within society provides fuller insights into society as a whole; women have a more nuanced understanding of social reality than men do precisely because of their structurally oppressed location vis-à-vis the dominant group, men. Sociologist and standpoint theorist Dorothy Smith stresses the necessity of starting research from women's lives; taking into account women's everyday experiences, she pays particular attention to finding and analyzing the gaps that occur when women try to

fit their lives into mainstream methods of conceptualizing women's situation. Examining the differences between two perspectives gives the researcher a more accurate and theoretically richer set of explanations of the lives of the oppressors and the oppressed.

Early critiques of standpoint epistemology argued that it collapses all women's experiences into a single defining experience and neglects the diversity of women's lives, especially those women who differ in terms of characteristics such as race, class, or sexual preference. Another important question was raised: If knowledge comes from the oppressed, how does one ascertain who is the most oppressed? Feminist standpoint scholars and researchers responded to these concerns, and standpoint epistemology has shifted over time, resulting in the concept of multiple standpoints that consider the interlocking relationships between racism, sexism, heterosexism, and class oppression as additional starting points into understanding the social reality.

Difference Matters: Feminist Research Turns Toward Difference

Although feminist empiricists and standpoint researchers stress the importance of acknowledging women who had been left out of mainstream research models, some important questions remained. Which women's stories were being told? Whose life experiences were included, and whose were left out? Feminism's interaction with postcolonialism, poststructuralism, and postmodernism fostered a turn toward feminist difference research. Feminist researchers became increasingly conscious of the diversity of women's experiences. They argued against the idea of one essential experience and recognized a plurality of women's lived experiences.

Feminist research has also examined biases and inequities in terms of difference. Feminists of color, particularly Chandra Mohanty and bell hooks, critiqued the shortcomings of early feminist research to explore the important interconnections among categories of difference in terms of gender, ethnicity, nationality, and class. Sociologist Patricia Hill Collins stressed the significance of Black feminist thought. Black women, argues Collins, are outsiders within. To successfully navigate White society, Black women must cope with the rules of the privileged White world while they face a marginalized position in terms of their race and

gender. Consequently, sociological insiders cannot understand or be cognizant of the Black experience because of their privileged positionality. Instead, those in power often generalize the diversity of women's lived experiences. Collectively examining the intricately connected matrix of difference helps one truly understand individual life experiences.

Global Perspectives

Feminist scholars and researchers continue to engage in issues of difference across gender, ethnicity, and class. Feminists are currently expanding their focus on difference to include issues of sexual preference, disability, and geographical region. Many feminist researchers, including Bhavnani, Hyun Sook Kim, and Diane Wolf, stress the importance of women's experiences in a global context with respect to issues of imperialism, colonialism, and nationality. Analyses incorporating race, class, and gender differences often ignore the diversity among women with regard to their particular geographical and cultural placement across the globe. Two key questions for feminists who take a global perspective are the following:

1. How does one conceptualize and study difference in a global context?
2. What research frameworks empower and promote social change for women?

Feminists who attempt to speak for the others in a global context should acknowledge the inherent power dynamics of international research. In what sense does the researcher give voice to the other and to what extent is that privilege taken for granted by the others? Feminists working in a global context call for a heightened attention to power and to difference. Is there potential for women to come together across difference and to forge social change? Some feminist researchers call for employing a type of strategic essentialism in their research, encouraging a strategic use of essentialism in order for women to promote their political agenda.

Locating the intersections of women's differences is a way that some feminists have begun to research difference in a global context and empower women's voices. Much of the theorizing and research studies on the international concerns of women, however, remains fragmented. Black feminists, third world feminists, and global, postcolonial, and transnational feminists often

remain uninformed about each other's theories and/or perspectives and research. Creating links between these strands of knowledge building to gather a more complex understanding of the workings of racism, imperialism, and neocolonialism across historical and cultural contexts is still a challenge for feminist researchers. What models of knowledge building will allow feminist researchers to study these interconnections? The answer requires an understanding of how feminists execute their research practices and what overarching principles guide their work.

Feminist Praxis: Issues of Power and Authority in Research

Feminist praxis builds on the understanding of difference and emphasizes the integration of issues of power, authority, ethics, and reflexivity into the practice of social research (see Sharlene Hesse-Biber and Deborah Piatelli). Feminist researchers are particularly keen to examine power dynamics in the entire research process (see Majorie DeVault and Shulamit Reinharz). Feminist research practitioners pay attention to reflexivity, a process whereby researchers recognize, examine, and understand how their social background, location, and assumptions affect their research practice. Practicing reflexivity also includes paying attention to the specific ways in which one's own agendas impact the research at all points in the research process—from selecting the research problem to designing the method and the ways one analyzes and interprets the findings.

The journey we have outlined thus far introduces the theory and praxis of feminist research. Feminists continue to evolve new ways of thinking and of modifying the understanding of the nature of the social world—providing new questions and angles of vision with which to understand women's issues and concerns, while actively engaging in promoting social change and justice for all women.

FICTIONAL WRITING

In the late 1980s, Jocelyn Sheppard and Donald Hartman surveyed 69 authors of novels written as doctoral dissertations, chiefly in the fields of English literature and writing, within 31 North American doctoral programs that had accepted dissertations written in a genre of literary fiction. Other disciplines in the social sciences have been more cautious in taking up such alternatives. For example, at the time of this writing (2007), Timothy Mennel's dissertation *Everything Must Go: A Novel of Robert Moses's New York* appeared to be the first doctoral thesis of its kind in the field of urban geography.

During the mid-1990s, several well-known education scholars debated the question of whether or not a work of fiction could be acceptable as a doctoral thesis; Arthur Saks's edited account of a public debate between Elliot Eisner (for the affirmative) and Howard Gardner (for the negative) is a well-documented example. Nevertheless, Hofstra University had already decided this question several years earlier by

awarding a doctorate in educational administration to Peter Sellitto for his novel *Balancing Acts*. Other universities to accept novels as doctoral dissertations in education include the University of British Columbia (Rishma Dunlop's *Boundary Bay*) and the University of Toronto (Douglas Gosse's *Jackytar*, which also has the distinction of being commercially published).

But how can one accept fictional writing in the literature of social research? In much everyday speech, fiction is equated with falsehood, whereas nonfiction is taken to designate a true story. If one assumes that research is chiefly concerned with documenting facts without distortion in “true” stories, then one might conclude that there is no place for fictional writing in social inquiry. Rob Walker was among the first educational researchers to question such assumptions in his essay “On the Uses of Fiction in Educational Research—and I Don't Mean Cyril Burt.” Walker's reference to Burt gestures toward colloquial understandings of fiction as a binary opposite of truth—Burt was posthumously accused of falsifying data in his influential twin studies that he claimed heredity was a more significant determiner of human intelligence than environment. Walker (1981) argues that fiction might be “the only route to some kinds of truth” (p. 163) and demonstrates that lightly fictionalized case studies (e.g., accounts that use pseudonyms and/or composite characters, places, or events) ameliorate some of the difficulties raised by issues of confidentiality. Such fictions are usually based on extensive empirical data and change the truth very little.

The conventional binary opposition of fact and fiction—and other binaries implied by this opposition, such as real and imaginary—obscures the difficulty of distinguishing clearly between textual representations of the world “out there” and the worlds constructed in texts. It is important to note that having doubts about the referential adequacy of such binaries does not necessarily constitute an antirealist position, but rather these doubts may signal distrust of storytelling practices motivated by what Sandra Harding calls the desire for one true story, a desire which drives much research in the modern Western sciences. Desires for one true story have also driven the construction of narrative strategies in which fact and fiction are mutually exclusive categories and particular kinds of facts, such as scientific facts and historical facts are equated with reality—claims to ontological status for the worlds that scientists and historians imagine.

Fact and fiction might be much closer, both culturally and linguistically, than these narrative strategies imply. A fiction, in the sense in which it derives from the Latin *fictio*, is something fashioned by human agency. The etymology of fact also reveals its reference to human action; a fact is the thing done, that which actually happened (the Latin *factum* is the neuter past participle of *facere*, do). In other words, both fact and fiction refer to human performance, but fiction is an active form—the act of fashioning—whereas fact descends from a past participle, a part of speech that disguises the generative act. Facts are testimonies to experience—events to which we give meaning. For example, historical facts are testimonies to historians' experiences of using disciplined procedures of evidence production and interpretation to construct meaning—to produce events that are meaningful within their traditions of social relationships and organization.

Tom Barone's book, *Touching Eternity: The Enduring Outcomes of Teaching*, is by no means a novel, but it will reward any reader interested in the relationships of fiction to educational research. Barone's book demonstrates the following:

1. What we commonsensically call fiction can advance important purposes of educational research.
2. There is no clear line of demarcation between works of fiction and nonfiction.
3. And apparently nonfictional life stories can sometimes be best utilized as if they were fictional.

Writing from the United Kingdom, Peter Clough similarly brings literary and ethnographic approaches together to demonstrate that fictional narratives can produce truths about educational problems and issues.

FIELD DATA

Field data are the most common type of data collected in qualitative research inquiries. In qualitative research studies, the field is the physical place where data collection takes place. Examples of field data include written words in documents, interview transcripts, observational notes, pictures, diagrams, and memos. Thus, all raw material collected in a qualitative study that will be used for analysis purposes can be considered field data. This entry discusses a few of the most common types of field data and the importance of triangulating the evaluation of data.

The most common source of field data is talk; specifically, people's words or conversations. In many qualitative interviews, talk is audio- or videorecorded to capture as many nuances of the conversation as possible. Otherwise, the talk is recorded by hand. The respondent's entire statements are then transcribed—representing a written account of the recorded conversation or retyped handwritten notes, thereby making the information from the interview more accessible for analysis.

Observational notes are another common type of field data. These notes can be created when the researcher is observing participants and taking notes on what is being observed firsthand. Diagrams of the environment or the proximity of the participants can be a valuable addition to the fieldnotes. The goal of observational field notes is to have a record of what was observed so that this record subsequently can be analyzed.

Another common type of field data is pictures of the environment. Taking pictures of the surroundings is a powerful method for recording the situation where field data are being collected. Other aspects from the environment can be collected as field data, including documents and artifacts as well as the researcher's thoughts, ideas, hunches, and so forth.

Regardless of what type of field data is collected, it is important for the researcher to decide, prior to data collection, the type and scope of data that should be collected. For example, if a researcher is interested in investigating the phenomenon of being a junior high student with severe reading difficulties, the researcher has a multitude of possible types of data to collect. The researcher might individually interview students, take pictures of the environment, observe groups of students, and/or hold a focus group, among other data collection methods. With the array of choices of possible field data, the researcher needs to consider what type of data will help her or him understand the phenomenon under investigation. However, it should be noted that field data also can be collected a posteriori.

Finally, where possible, it is important to triangulate field data. Triangulating data involves utilizing more than one source of data to assess the credibility, transferability, dependability, and/or confirmability of the results, as well as to check the integrity of the inferences stemming from the data. For example, a researcher might collect field data in the form of interviews, documents, and focus groups. By triangulating the results from these three types of field data, the researcher can be more confident that the voices of the participants have been captured.

FIELD METHODS (JOURNAL)

Field Methods is a refereed journal that publishes articles on methods for studying human thought and human behavior. Research articles show the development of

new methods or new uses for existing methods. The “Short Takes” section contains articles with handy tips for working in the field. *Field Methods* also publishes reviews of books and software and think pieces addressing key theoretical issues.

Field Methods began in 1989 as the *Cultural Anthropology Methods* journal. A decade later, in recognition of the increasing interdisciplinary nature of the subject matter, it changed its name to *Field Methods*. Since its inception, it has been under the editorship of H. Russell Bernard. Articles examine data collection techniques and modes of analysis, the link between method and theory, and the impact of new technology on traditional field research activities. Embracing both qualitative and quantitative methods in scientific and interpretive paradigms, the journal operates under the motto “methods belong to all of us.”

Field Methods not only is for researchers in the social sciences and the humanities, but also is for professionals in the delivery of social services, in government, and in the private sector who use field research to acquire knowledge.

Examples of articles include the following:

- “The Active Participant-Observer: Applying Social Role Analysis to Participant Observation,”
- “Adaptation of Venue-Day-Time Sampling in Southeast Asia to Access Men Who Have Sex With Men for HIV Assessment in Bangkok,”
- “Communication Problems Between Researchers and Informants With Speech Difficulties: Methodological and Analytic Issues,”
- “Child Survival in Affluence and Poverty: Ethics and Fieldwork Experiences From Iceland and Guinea-Bissau,”
- “Using Computer-Assisted Qualitative Data Analysis Software to Develop a Grounded Theory Project,”

FIELDNOTES

Fieldnotes can be crucial to any qualitative study, regardless of data collection tool or methods used. In fieldnotes, qualitative researchers record in-depth descriptive details of people (including themselves), places, things, and events, as well as reflections on data, patterns, and the process of research. These details form the context and quality control that shape multiple qualitative data points into articulated, meaningful, and integrated research findings.

Fieldnotes are a type of personal journal, written, in Thomas Schwandt’s (1997) words, “for an audience of one” (p. 115). Thus, they are unique to each researcher, written in the first person and in a free-flowing, spontaneous manner. David Fetterman suggests separating fieldnotes into two sections—observations and speculative-personal reflections. This separation may be most appropriate in ethnography, in which all data from activities such as participant observation might be collected in fieldnotes in the form of observations. In other types of qualitative methods, such as semi-structured, recorded interviews, data may be defined as verbatim interview recording or transcripts and fieldnotes as the descriptive elements that recordings cannot capture—such as dress; demeanor; gestures; facial expressions; off-mic comments; setting characteristics, such as what is on walls and bulletin boards and the furniture arrangement; weather; smells; back story; and researcher impressions, assumptions, and feelings during time in field; and so on.

It is crucial that fieldnotes be written as soon as possible after each field activity and in as much rich detail as possible. These notes should be done prior to discussing the experience with anyone else, for such discussion may dilute memory. Writing notes is a time-intensive, but

Fieldnotes Excerpts: First Winter Fieldwork With Afghan Women Refugees

1/1/02 Old Jalozai Refugee Camp, near Peshawar, Pakistan

. . . electricity had been out for days . . . just now it went out again. Someone got a lantern and we talked in the near darkness . . . For heat there is a kerosene heater that really smells bad, but you only smell it intermittently . . . have to blow it out before sleep so you don't asphyxiate . . .

1/3/02

Woke to a brisk morning . . . put on coat to use outside bathroom. Cold face washing was bracing but not too bad . . . "Shakira" came by early and fussed over me. Talking about finding a warm bathroom, electric blanket, things I don't need and too much trouble . . . To distract them, I said what I really needed were warm socks, which I knew was possible. This led to a day where socks kept appearing. "Zareen" came back with two pairs during the morning. "Shakira" brought me two pairs at lunch . . .

1/7/02

2:15 PM: . . . I have a minute to see where I'm at . . . Need more material, different material, but don't know how to get at it. In some ways I have plenty of stories and perspectives. In others I am missing the facts to string it together . . .

11:45 PM: I'm having trouble figuring my way around the gaps . . . I can't get the confirmation I need . . . I'm getting concrete examples, but also ideology. I think I'm taking too many short cuts . . . Need to ask about thoughts, feelings, actions. Not "why" questions . . .

There's a shorthand to speech that isn't familiar to me . . . "Talk to some people" "He accepted" "He didn't dare" Of course "why not?" is the next question, so maybe banning "why" isn't the answer . . .

(Added 1/17/02)

I asked later about "accepted" . . . It's shorthand for accepted the argument and agreed to change behavior . . . "he accepted that women should be educated and agreed that his sister/wife/daughter could attend classes."

Source: Brodsky, A. E. (2003). *With all our strength: The revolutionary association of the women of Afghanistan*. New York: Routledge.

invaluable process, and the quantity of observations and reflections recorded can be quite large. Robert Bogdan and Sari Biklen suggest that the researcher jot down a topical, sequential outline as soon as possible, and then, as soon as possible after leaving the immediate field, write a chronological account of observations and impressions. They counsel that the language of descriptive fieldnotes, in particular, should dissect the world, objectively describing it with rich adjectives rather than with abstract, evaluative, or summative phrases. Thus, instead of describing a "brave and determined Afghan women," one would describe "an Afghan woman in her mid-30s, head uncovered, whose voice slows and hardens, forehead furrows, and eyes narrow as she holds my gaze in hers and describes working for women's rights, despite death threats, in post-Taliban Afghanistan."

Reflective fieldnotes can be written whenever one muses on the process, findings, problems, patterns, and so on of the study. They capture impressions and the researcher's ongoing analytic process. Reflections often

change iteratively over the study course, as is true of most qualitative work, and serve as a record of progress as well as a place to work out problems. Reflective fieldnotes should also document researcher biases, standpoint, dilemmas, possible mistakes, reactions, and responses to fieldwork and participants. Finally, it is important that all fieldnotes be well organized so that memoing, coding, and other analytic techniques can be utilized to draw meaning from this rich qualitative tool.

FIELD RESEARCH

To understand field research in contemporary qualitative research necessitates some historical perspective—that is, in its original sense—how researchers first began entering their fields of study or research sites to address the subjects or people of their studies face-to-face. The whole notion of fieldwork began with the work of Bronislaw Malinowski, a founder of social anthropology, who decided to study the Trobriand Islanders and live with them between 1915 and 1918 as opposed to armchair ethnological-theorists at the time like Sir James Frazer. Moreover, field research or fieldwork, often interchangeable concepts, have come to mean in the broadest sense the methodological actions of investigation for the whole of the social sciences rather than for anthropology alone. Today, qualitative researchers in the social sciences are not the only ones using the methodological notion of field research or fieldwork; it describes the data gathering of many in the natural and physical sciences as well. Field research is not any one thing, but it implies multitudinous perspectives, not only on how to conduct it, but also on how to place it. With varying traditions and multiple disciplines that define how research is conducted and the philosophical undertones of the social sciences that drive theory-making through its practice and the impetus of empirical data gathering, field research is an ever evolving concept in qualitative research.

History of the Concept

Taken from the widest angle, it is as important to give equal weight to the history of the idea of field research as it is to recognize its common usage and meaning to qualitative research as a whole. There are, for example, the issues and problems associated with doing field research, which are dependent upon different traditions of qualitative research. In addition, the notion of the field in qualitative research does not simply mean a place any longer, the exotic location abroad for the lone anthropologist, but it can signify a range of possibilities for the locus of research.

The field in essence is where qualitative research is carried out by the researcher. The field experience is bounded by time. In other words, one's field experience is referenced by how long one is in the field and may be a recurrent process during several sets of time periods. Its focus depends on the training of a particular researcher in a specific discipline such as anthropology, psychology, or sociology, for example, and his or her employment of different research traditions.

The difficulty often is bridging the epistemological foundations and gaps between the past and present with the conceptual evolution of the idea of field research and methodological practice in the field together with a contemporary divide between entrenched disciplines and the interdisciplinary character of qualitative research. This bridging is significant in order not to ignore the history and philosophy of social theory or the ongoing dilemmas from the production of present day field research.

An honest historical reckoning of field research in the social sciences begins with Malinowski (1884–1942), the founding father of anthropological fieldwork practice and field research in the traditional sense. His now-classic study of Trobriand Island society took anthropologists off the terrace, where the colonial administrator observed colonial subjects, to live with the natives themselves and thereby gain invaluable knowledge from the native perspective. Such proximity to the Indigenous subject became known as participant observation. Field research in this traditional view at the turn of the 20th century meant going out to the field in far-off places to Africa, Asia, Melanesia, Polynesia, and elsewhere. It also meant acquiring the subjective point of view of the so-called native from an observable distance. It signified participating and observing the everyday lives in a study over a prolonged period of time.

This history of field research in anthropology grew out of colonial administration in many of these far-flung field-sites, which in turn has spawned some negative criticisms of the discipline's origins. The transformation of engaged research activity in the field from armchair conjecturing to participation and observation became a significant shift of the research mindset. It represented, in essence, an intellectual rupture from Victorian-minded anthropologists such as Frazer (1854–1941) and his contemporaries against comparative accounts of civilization and culture without true knowledge of the Indigenous other, advocating for a revisionist redefinition of the discipline to one of practice and being with the other for a period of time.

Such a rich history of the discipline of the British School of social anthropology is abridged for purposes of brevity here. Suffice it to state that the history of field research as it developed out of anthropological practice, one of participant-observation followed by ethnographic accounting, began and flourished at the universities of Oxford, Cambridge, and the London School of Economics and Political Science.

In part, the discipline also was influenced during its incipience by the trans-Atlantic and trans-Pacific crossings of British social anthropologists and their appointments to various universities in the United States, Australia, and South Africa, as well as by French sociology and the legacy of the French journal *L'Année Sociologique* through such luminaries as Claude Lévi-Strauss from the lineage of Émile Durkheim and Marcel Mauss. For qualitative research and its influences of present-day field research, there is the interrelated history of the Chicago School, for the discipline of sociology in the 1920s and 1930s, and for psychology at the turn of the 20th century, Sigmund Freud and Carl Jung, their peers and others, and the influences of the Vienna School.

To anthropology and anthropologists, field research is synonymous and coterminous with ethnography and participant observation, in moving closer to the other by being there with the subjects of one's study. Postmodern inquiries questioned the authoritative assumptions of fieldwork and the writing about culture or ethnography in the 1980s through the influential efforts of James Clifford and George Marcus. More recently, as Paul Dresch and colleagues have described, there are new unfolding challenges of self and other or subject-object dichotomies and challenges of how to reflexively address new patterns of social happenings in an increasingly globalized environment and the transformations of peoples everywhere whether from the perspective of far-off worlds or those closer to home. These assumptions have to do with the authoritative point of view of the ethnographer and relate to notions of power in writing and generally are from the critique of deconstructionism in literature and from perspectives of feminist theory. In relation to globalization, the Kayapo Amerindians in Brazil and the Nyae Nyae !Kung San people of Namibia are examples of people who are now able to question the authoritative role of scientists, government officials, and others in relation to their proprietorship of their future as a people.

Doing Field Research

Aside from these historical particularities in comparing five research traditions from qualitative research—biography, phenomenology, grounded theory, ethnography, and case study—various issues and problems arise during the data collection phase or by being in the field and conducting research. As John Creswell explains, these have to do with questions of access, observation, interviewing, documenting, and ethics, to name some of the more pressing dilemmas. Field research methods differ in comparison to disciplinary training whether in anthropology, political science, psychology, or sociology.

To conduct any field research entails proper preparation on part of the researcher. It means that the field researcher must have a well-thought-out research design of a particular topic for field research. It also entails writing a strong research proposal that is then approved by funding committees, dissertation committees, and ethics review boards.

Each qualitative research tradition has its own set of access problems, which are usually addressed by the researcher in the field. For those concentrated in the biographical tradition, the researcher must decide whether to focus on an individual's life or on a number of individuals, and if the latter, how many. A biographer must gain permission from their subjects to be interviewed. Moreover, the biographical researcher must decide if particular interviews will be recorded through notes or be audio- or videorecorded. The researcher must also consider whether archival material is necessary to provide a broader social picture of these individuals' lives.

A researcher working in the phenomenological tradition must decide what phenomenon is important and which individuals to select from who have experienced such a phenomenon. Elisabeth Kübler-Ross's study of terminally ill patients and their experiences facing death is an example of such research. Again, selection here is important; the researcher must gain access to these individuals and obtain their permission to be interviewed.

After deciding which phenomena to study, the grounded theorist must develop a theory based on empirical evidence obtained during the data collection process in the field. Such theoretical insight is supposed to allow the researcher to better address the phenomena in question for future research. The same types of questions arise in regard to access of individuals and their

Field Research and Globalization

Anthropologists at the turn of the century were increasingly questioning the notion of so-called primitive people. This questioning culminated with British anthropologist Sir Edward Evan Evans-Pritchard's (1902–1973) book *Oracles, Witchcraft, and Magic Among the Azande* (1937), a critique of the French philosopher Lucien Lévy-Bruhl and his notion of primitive mentality. Evans-Pritchard argued that there was no distinction between a so-called primitive mentality and a Western mentality because other people's religions had their own inherent logic for explaining the world. Following Evans-Pritchard's legacy, notions about the "other" changed to an appreciation of diversity and to valuing other worldviews (see Johannes Fabian's (2007), *Memory Against Culture*).

Also, the idea of "globalization" is a misnomer. People have been globalized by the West since colonial contact began in the 16th century. Moreover, there is no pristine culture, as different people have been in contact with one another for millennia. Culture is not static but changes over time, and modern aspects of globalizing efforts through technological advances and immediate communication are only recent aspects of people being affected by the world's globalizing processes of contact.

The Kayapo and the !Kung San exemplify cultural change and how these groups relate to Western societies. The Kayapo have been fighting miners and ranchers from encroaching on their lands since the 1970s and against government development projects for hydroelectric dams. The !Kung San have been displaced from their traditional homelands since the 1970s. In the past 30 years they have suffered from alcoholism and have been forced into settlements, quite a change from their nomadic hunter-gatherer traditions.

Anthropologists are increasingly active in protecting the Indigenous rights of the people they study. One example is the lifework of anthropologist David Maybury Lewis (1929–2007) who co-founded with his wife the organization Cultural Survival. Equally important is the work of anthropologist Terrence Turner and his advocacy of the Kayapo Amerindians. Anthropologist Darrell Posey (1947–2001) worked tirelessly for intellectual property rights of Indigenous

people like the Kayapo to prevent the encroachment of pharmaceutical companies on traditional knowledge of the medicinal properties of plants. The !Kung San successfully argued a court case in 2006 for a return to their ancestral land in Botswana's Central Kalahari Game Reserve. Nonetheless, despite legitimate land claims by people like the Kayapo and the !Kung San against their respective governments, officials have been slow to react and provide for these people the right of self-determination. More positive advocacy and intervention is needed to prevent these peoples from disappearing altogether.

Hence, the anthropologist-researcher's role has transformed from that of observer from the "other's" point of view to one of advocacy in protecting the people they study. Whole worldviews and people are disappearing at alarming rates. Hence, the field is not simply a place but, in some instances, an imagined future where people like the Kayapo and !Kung San must be actively protected by researchers, scientists, and nongovernmental organizations. This is about co-existence and respect. The legacy of fieldwork today will be how researchers protect those they study.

agreement to be interviewed for field research. Methodological techniques such as axial coding and theoretical sampling are often employed by researchers focused on the grounded theory tradition.

For the ethnographer, access may imply a whole set of other problems than those listed above. For example, if the ethnographer is studying an Indigenous group in a

foreign country, there may be visa requirements and governmental bodies restricting access to Indigenous groups. It may be difficult to get to the field site or sites. Furthermore, gaining access to any population, whether at home or abroad, may require a certain amount of trust, which will take time to establish. It may take an ethnographer several attempts before

being accepted by a particular group of people, village, or township deemed suitable for study. The methodology of participant observation—living day in, day out with informants and participating in the daily lives of subjects—does not normally allow for breaks from the field, and if so, only sporadically. For many ethnographers such as Carolyn Nordstrom and her colleagues, assimilating into everyday life produces a whole set of other difficulties, such as change of diet and living circumstances, language barriers, harassment of local officials, and for some in some cases dangerous and violent circumstances.

The case study researcher must choose the right cases to research, the sets of individuals to be interviewed, and perhaps the archival material to be transcribed. Cases are bounded happenings or units that are contained in one phenomenon within a defined limitation of time. For such types of studies, researchers must decide whether to approach analysis by focusing on one particular case and examining it thoroughly or most commonly, by comparing multiple cases through sampling and other documentation measures.

All such field research has its own sets of data collection management and analytical problems of association, which vary with the specific research tradition and demonstrate how field research is defined for different reasons. What is more, such concerns of field research express in the most general sense diverse modes of being in the field and show how the focus of research traditions directs specific types of field research. For each tradition, one must decide how best to take fieldnotes, how best to transcribe such notes, and what aspects of data collection are relevant for the project at hand, or perhaps irrelevant, and can be used at a later time. Such fieldnote guidelines have been excellently described by Robert Emerson, Rachel Fretz, and Linda Shaw. The specific disciplines in which field researchers work shape the questions that they ask and are dependent on certain theoretical underpinnings of the specific disciplines—psychology, social psychology, anthropology, sociology, or political science—which involve various epistemological assumptions. However, in qualitative research, researchers are moving away from these disciplinary peculiarities and toward an interdisciplinary epistemology with emergent confrontations.

Things happen by chance in the field, and the field researcher has to adapt to these processes of circumstance. For example, a colleague was in the field in China during the Tiananmen Square protests of 1989 and was able to write about them. Likewise, while I was in the field in the Basque Country, I found that

my informants were only willing to discuss a controversy over the wider inclusion of women in relation to a historical commemoration celebration rather than to discuss my initial interests in their fishing culture.

Other Field Research Guidelines

All field researchers must be aware of their role in the field and of their effects on their subjects in both informal and formal contexts. Therefore, reflexivity is an important aspect of the researcher's work. Field research is guided by past experience and informed by the mistakes of previous research when ethical guidelines were not as strict—for example, in U.S. the Tuskegee Syphilis Project, in which unnecessary harm was caused when the treatment for syphilis was withheld from study participants even when penicillin became available; the U.S. Department of Defense's Project Camelot, a U.S. Army program that was designed to evaluate the causes of warfare, but in actuality was used to undermine revolutionary movements in places like Latin America; psychologist Stanley Milgram's studies of behavioral aspects of authority and obedience, studies that were highly controversial because of the ethical concerns raised by his use of deception in experiments using electric shock; or even the most recent controversy involving anthropologist Napoleon Chagnon and geneticist James Neel about the Yanomami peoples of Brazil and Venezuela. Ethics review boards of universities, especially those in the United States, were created to guarantee against unwarranted deception and to ensure informed consent as well as the privacy and confidentiality of the study participants (as appropriate). Such ethical requirements for the study of human subjects involve the respect for all persons and their well-being and provide a framework for moral standards to follow during field research.

FIELDWORK

Fieldwork is the hallmark of research for qualitative researchers. It is a tool used to help describe and understand a group or culture. It is guided by practical activity, judgment, interpretation, and description. The method involves working with people in their own communities for long periods of time. Company manners or guest behaviors disappear over time. The typical or normative behavior reemerges and is dominant over extended periods of time.

Fieldworkers are typically participant observers. They participate in the lives of the people they work with, observing and recording what they see and experience firsthand. This participation gives them the advantage of being immersed in the culture long enough to understand it from the insider's perspective and distant enough to objectify patterns of behavior in the community, enabling them to share their insights with other colleagues.

Fieldwork requires systematic observation, interpretation of observed behavior, and a plan of action to follow up on observations. Although an overall research design is mapped out in fieldwork, much of the actual work depends on observations and responses in the field. The fieldworker uses judgment and interpretation at every stage to determine the next steps; for example, what to follow up on to better understand the situation, particularly from a specific role or perspective. Fieldworkers often find new leads or paths while in the field as they learn the right questions to ask. The objective in fieldwork is not to decide who is right and wrong. It is to describe the various, and often conflicting, perspectives and worldviews in a culture or community.

Qualitative researchers record their observations and insights in written documents, emails, digital photographs, and video. The fieldworker uses a variety of methods and techniques to ensure the integrity of the data, ranging from sampling strategies to triangulation (i.e., comparing different forms of data to rule out rival hypotheses). In addition, there is much reliance on the use of verbatim quotations to help tell the story in the community member's own voice. Fieldworkers

rely heavily on unobtrusive measures to interpret daily events, including participant's clothing, language, dialect, body piercings and tattoos, graffiti, maps, music, letters, and local newspapers. These measures provide some indication about social status, attitudes, roles, and power. This naturalistic approach avoids excessive filtering, distortion, or bias associated with the researcher's perspective and the artificial response typical of controlled or laboratory conditions. The amount of time devoted to working in the field allows for built-in forms of reliability as the fieldworker observes the same patterns of behavior over time. These methods objectify, standardize, and refine the researcher's insights and perceptions.

The findings or interpretations are typically recorded in fieldnotes. These are often highly personalized records of the day's events. Fieldworkers typically type their notes up each day while they are still fresh and vivid. After fieldworkers have sorted and analyzed the fieldnotes and related data, they share what they have learned with participants in verbal or written form to ensure the accuracy and authenticity of these understandings. Although the focus of fieldwork is to learn about a culture or community, many ethnographers take time to record their own attitudes and behavior to monitor their own behavior and perceptions. Fieldworkers attempt to be unobtrusive and minimize their impact on the community. However, the presence of an engaged human instrument will always have some effect on the people in the community. Fieldwork is always guided by ethical principles and standards, ranging from honesty to reciprocity. These principles protect people's rights, such as the right to privacy, and ensure the viability of qualitative research (by allowing community members to trust fieldworkers enough to continue letting them in their lives). Fieldwork combines rigor with the serendipity of real life experience. The combination contributes to the production of a compelling story in a way that is rigorous and gives voice to the human experience.

FILM AND VIDEO IN QUALITATIVE RESEARCH

Film and video are used in qualitative research as data collection tools, as sources of information and dialogue between researchers and participants, and as mechanisms for disseminating research results. The 20th century was the century of film; the 21st is the century of digital video. The 20th saw major innovations in recording and filmmaking, many applicable to ethnography. But owing to characteristics of the technology itself, visual approaches never became a prominent feature of qualitative research. A methodology may be viewed as the application of a technology to some feature of the world, producing the traces that serve as a basis for analysis. Current video technology offers a spectacular methodological promise, making it the first choice for ethnographers of the future. Video is a more robust and transparent data collection technology. As a reflexive prompt, it can help individuals or groups provide richer data; and in the hands of subjects, it expands the scope of inquiries, while substantially minimizing the interviewer effect. Moreover, as a presentation medium, it can be edited to reach both specialist and lay audiences. This entry begins with a brief history of visual ethnography, followed by a discussion of the role of technology. It then reviews differences between video for data collection and presentation, provides a critique of past ethnographic techniques, and ends with a distinction between documentary and academic films.

A Brief History of Visual Ethnography

Nanook of the North, produced in 1922 by Robert Flaherty, is often considered the first ethnographic film. Flaherty openly staged some scenes in the movie, which worried few and entertained many. Russian Dziga Vertov, a contemporary of Flaherty's, is credited with developing a realistic film style that came to be

known as *cinéma vérité* (filmic truth), which was later popularized by 1950s French documentary maker Jean Roach in his work on the lives of Parisians. Anthropologist Margaret Mead's collaboration with Gregory Bateson during the mid-century was highly influential in the development of visual approaches to ethnography. Today, students and scholars are quick to appreciate her idea that notepad and pencil are not enough and that cameras are important field technologies. For much of the mid- to late century, though, survey methods and quantitative analysis dominated social science data gathering. However, the means and technical capabilities of present-day scholars, combined with the massive technical changes over the past 40 years, have seen a resurgence of audiovisual methods.

Technology and Visual Ethnography

Although technology does not determine social practice, it does provide opportunities and sets constraints. Celluloid film was an expensive medium. Cameras were large and difficult to control. Data collection could not readily be accomplished by a lone ethnographer. It could even be argued that film was not used, in any serious sense, to collect data but only to provide a record of interesting social practices and rare or disappearing cultures. Rapid innovations in technology over the past 2 decades have resulted in four new characteristics of relevance for qualitative research. First, the technology needed to produce audiovisual recordings of extremely high quality has become smaller, lighter, less expensive, and easy to use. Driven by tourists, parents, and the private surveillance industry, manufacturers invested significant resources in innovation that resulted, unintentionally, in arguably the best means of collecting and presenting data on social life. Second, analogue media degrade, if only a little, with each copy, but digital audiovisual records may be reproduced in perpetuity with no loss, facilitating the archiving and sharing of data and results among qualitative researchers. Nonlinear editing systems are the third crucial advance for digital ethnographic research. New generations of ethnographers need not worry about the cumbersome and destructive editing systems used by the editors of anthropological films. Fourth, the internet represents a wealth of information and technical assistance while providing innovative platforms for the storing, viewing, and coding of raw audiovisual data and for editing and the presentation for entertainment, educational, and scholarly purposes.

Distinguishing Use: Video in the Field and in the Presentation Hall

Collection of audiovisual data must be clearly distinguished from their use in various presentational settings. For data collection, digital recordings are just as useful for standard quantitative purposes as they are for qualitative analysis. Drive-by footage has been employed to test the broken windows crime theory; fixed cameras have been used to examine cultural accounts of ritual disrobement at Mardi Gras. Cameras in the hands of subjects to document interactions in a Brazilian prison or the home life of an asthmatic child have increased the scope of qualitative research into social realms that were once beyond reach. Moreover, this latter technique substantially minimizes the interviewer effect when the presence of an outsider influences the responses and behaviors of insiders. Another application is the use of video itself as a stimulus to prompt informants. This use has provided a reflexive mechanism for focus group program evaluations in education, and organizational and rural development research.

However, the standard use of digital video is for the simple record of social life it provides. Interacting with participants in the presence of recording devices provides a videoactive context for research. The familiarity of most people with video technology quickly makes the camera an actor in the research process, a subject of commentary and focus of action. It is not difficult for informants to neglect its presence, yet observation occurs in both directions. Sometimes it is useful to let subjects become operators themselves. The fluid wall created by a camera is an opportunity and not a hindrance so long as the researcher is willing to switch between the four main types of record: standard audio-video, audio only, fieldnotes, and memory.

The presentation of data is one of the key differences between audiovisual and other forms of qualitative methods. Text-based forms of output (books and articles) have dominated social research since its inception, but lectures and professional meetings have long relied on a combination of talk, graphs, and pictures to build a case. Nonlinear editing systems such as Final Cut Pro enable the scholar to capture data, to build sequences clip by clip through the setting of In and Out points in a data file with three tracks (one video and two audio), adding voiceovers. Evident is the flexibility of the medium that allows for the editing of multiple versions to address both specialist and

lay audiences. This ability suggests two possible presentation formats. One is a complete movie, with titles and credits. The other is production of a clip sequence that allows for starting, stopping, and reviewing in real time.

One of the key advantages, indicated above, is that widespread exposure to alternative shooting styles (e.g., reality television) have immunized audiences to shaky camera work and framing that would have been unacceptable in an era where Hollywood productions dominated visual thinking. An unintended, but highly desirable, constraint of audiovisual presentations is that while one can speak about anything one likes, the only content that can be shown to the audience is, quite simply, what one has filmed. One cannot luxuriate in the abstractions of social theory for long without returning to the real world of social interactions. This inability facilitates a focus on questions of interest to real people and not just to specialists.

Comparing Video to Other Ethnographic Techniques

The size and user-friendliness of modern camcorders cast doubt on the exclusive use of audiorecorders or still photography for qualitative research. Archival audiorecordings and photography as media are still worthy for discourse and content analyses, respectively. But apart from their use as a stimulus for respondents, there would appear to be no advantage to ordinary research encounters of tape recorders and still cameras over digital camcorders. When considering data collection for a new research setting, it is productive to keep in mind that a typical camcorder captures audio of equal or higher quality than most tape recorders, and the lens cap can readily be used where respondents prefer audio only. Standard DV-NTSC format records nearly 30 frames per second, any of which can be freeze-framed if a still shot is later desired. There is no real-world research situation where the size difference between a still camera and a video camera would make the former preferable over the latter, and nearly all would agree that collecting more data (digital video) is better than collecting less (photographs). But the crucial consideration is an approach to the social world: audiovisual ethnography is committed to the position that an understanding of social life occurs through a full examination of the processes that comprise social interactions. A still photograph is a moment in time, while an audiorecording misses spatial context and

physical gesture and expression. Both appear insufficient for qualitative research when compared to the flexibility of digital video. A final note is the ethical research concerns that emerge in the digital age. There are downstream market applications that can magnify the vulnerability of at-risk groups.

Documentary and Academic Films

It is important to distinguish between scholarly and documentary uses of video. Although some academic movies might be indistinguishable from documentaries, there are important differences in audience, in emphasis, and, particularly, in the time frame. Academic films are more intellectually rigorous and do not follow market forces. A documentary that requires several years to make, responds to issues in the research literature, is produced for presentations at meetings and classrooms, and is provided without charge on the internet is indistinguishable from the academic movies that characterize qualitative research products in the 21st century.

FINDINGS

Qualitative research findings are typically defined as the researchers' interpretations of the data they collected or generated in the course of their studies. In naturalist (or empirical or analytical) qualitative studies, findings are viewed as derived from data collected in the course of study. Here, results and data (e.g., quotations, fieldnotes, case descriptions) are viewed as readily distinguishable from each other and from the data analysis procedures used to produce those results. For example, the finding in a grounded theory study is a theoretical rendering of an event, not the data in which this rendering is grounded or the coding procedures used to create it.

In contrast to the data-based view of findings in naturalist qualitative studies is the constructed view in interpretive or critical qualitative research in which data are conceived to be generated by both researcher and participant in interaction and, therefore, not easily differentiated from findings or from any other element of the research process. The word *finding* implies that some reality exists that can be found, an objectivist stance at odds with the constructivist position that everything about the research process is generated within the unique social interactions and sociocultural and historical milieu constituting inquiry. Here, findings have no existence independent of researchers. Indeed, in certain types of life and oral history projects, autoethnography, and arts-based qualitative inquiry, findings as a concept does not exist at all.

Findings in Naturalist Qualitative Research

Findings conceived as data-based in naturalist qualitative research may be classified as topical or thematic surveys, conceptual-thematic descriptions, or as interpretive explanations. Topical survey findings feature inventories and quasi-qualitative and quasi-statistical (e.g., illustrative quotations and frequency counts) summaries of data derived from manifest content analyses. Thematic survey findings convey a latent pattern or repetition researchers discerned in their data. Findings in the form of conceptual or thematic descriptions appear as abstract renderings either derived directly from the data collected within a study or imported from theoretical or empirical literature outside the study. Analogous to each other in degree of data transformation, conceptual descriptions are

theoretical renderings of phenomena, experiences, events, or cases, while thematic descriptions are narrative, phenomenological, or discursive renderings of them. The most transformed of qualitative findings are interpretive explanations, or the grounded theories, ethnographies, or otherwise fully integrated explanations of phenomena, events, or cases considered the quintessence of qualitative research. Interpretive explanations offer a coherent model or single thesis or line of argument. Accordingly, whereas a topical or thematic survey might consist of a list or more detailed description of a set of actions a group of participants reported using after receiving a diagnosis of cancer and a conceptual description, a reframing of these actions as coping strategies, an interpretive explanation might consist of a theoretical model linking these strategies to different conditions for selection and different outcomes.

FIRST-PERSON VOICE

Writing in the first-person voice involves using the first-person pronoun (I, we, me, us, my, our) to represent your ideas. In some disciplines, the first-person is commonplace; in others, third-person voice is expected, and therefore demanded by dissertation committees, journal editors, and researchers themselves. Authors who avoid using the first-person pronoun in academic writing seem to believe that it interferes with the impression of objectivity and impersonality they seek to create. However, in many reports of qualitative research, scholars prefer to use the first-person in their writing, as this matches the intention of giving voice to their participants' perspectives. Indeed, style guides published by specific associations provide guidance on this issue. The *Publication Manual of the American Psychological Association*, 5th edition, for example, states, "When referring to the author(s), use the first person, not the

third person. That is, say 'I injected the subjects with the appropriate dose of Atenolol,' not 'the experimenter injected . . .'" (p. 37). Related to this, the manual advises authors to use the active rather than the passive voice; that is, to write "we injected . . ." rather than "the subjects were injected with . . ." (p. 41).

Although the American Psychological Association did not explicitly encourage use of the first person until 2001, other academic associations have long urged its use where appropriate. For example, in 1979 the *American National Standard for the Preparation of Scientific Papers for Written or Oral Presentation*, which represents the views of many scientific organizations, recommends that when a verb concerns action by the author, the first person should be used, especially in matters of experimental design. However, it also warns against excessive use of the first person, principally for reasons of stylistic felicity. For example, if a first-person pronoun is repeatedly the first word and/or subject of sentences, then it quickly becomes monotonous.

As long ago as 1966, Henrietta Tichy wrote (in the first edition of *Effective Writing for Engineers, Managers, Scientists*) that arbitrarily avoiding necessary and common words such as *I* and *we* leads to awkward writing marked by over reliance on the passive voice and other weak indirect speech. Writers who discard these words turn to evasive and pompous substitutes such as *the author*, *one*, *the researcher*, or *the present writer*. Perhaps more important, indirect and passive constructions allow authors to evade responsibility for what they write.

Novelist and critic Ursula Le Guin points out that writers often use the third person and the passive voice because these forms are indirect, polite, and unaggressive; they make thoughts seem as if nobody had personally thought them and actions seem as if nobody had actually done them so that nobody need take responsibility. Thus, she notes, these constructions are popular among "bureaucrats and timid academics" (Le Guin, 1998, p. 68) and generally avoided by writers who are prepared to take responsibility for their interpretations and assertions.

FOCUS GROUPS

Focus groups are a form of qualitative interviewing that uses a researcher-led group discussion to generate data. Since their reintroduction to social science research in the mid-1980s, focus groups have become a popular method because, like individual interviews, they can be modified in a wide variety of ways to suit an equally wide range of purposes. They can thus be used for exploratory research, where the participants are relatively free to discuss the topic as they see fit, or they can be used in a more structured fashion, where the interviewer or moderator takes a more active role in controlling the issues to be discussed.

The defining element of focus groups is the use of the participants' discussion as a form of data collection. In particular, there is no requirement to reach consensus or produce a decision; instead, it is the participants' conversation about the research topic that is of interest. Although various versions of group interviewing have been used throughout the history of the social sciences, the term *group interview* is currently synonymous with focus groups for almost all forms of group-based data collection, the major exception being the observation of naturally occurring groups.

Compared to more long-standing methods of qualitative data collection such as participant observation and individual in-depth interviews, focus groups have a rather unusual history. Despite the fact that Robert Merton and Paul Lazarsfeld developed the focus group in the 1940s, that early work was followed by nearly 40 years when focus groups were almost unknown in the social sciences. During that same time, however, focus groups became the primary qualitative method in marketing research (where individual or one-on-one interviews have only recently gained in popularity).

Starting in the 1980s, two of the earliest places where focus groups reappeared in the social sciences were in survey research and evaluation research. The practice of relying on focus groups as an exploratory

tool for developing survey content was a common technique in marketing research, a technique which has also become widespread in academic survey research, especially in projects that involved previously unexamined topics. For evaluation research, focus groups are used in both preliminary phases, such as needs assessment or program development, and in follow-up or summative evaluation, to hear about the participants' experiences with a program.

By bringing together people who share a similar background, focus groups create the opportunity for participants to engage in meaningful conversations about the topics that researchers wish to understand. This ability to learn about participants' perspectives by listening to their conversations makes focus groups especially useful for hearing from groups whose voices are often marginalized within the larger society. Focus groups are thus widely used in studies of ethnic and cultural minority groups, along with studies of sexuality and substance use.

Focus Groups and Individual Interviews

Qualitative researchers often face a choice between using focus group or individual interviews, but the underlying similarities between these are two methods are at least as important as their differences. Most important, they both have a strong tendency to base the content of the interview on the researcher's interests, and they both give the researcher a potentially large role in determining how the conversation will proceed. The extent to which the researchers influence the content as well as the dynamics of the conversation produces the same set of options for both focus groups and individual interviews, ranging from less-structured to semi-structured to more-structured interview formats.

The most obvious differences between focus groups and individual interviews arise from two closely related aspects of these procedures: the total number of participants in a typical project and the amount of data provided by each participant. One way to think of this is to compare the kinds of the data that would be provided by a set of focus groups in comparison to a parallel set of individual interviews. The focus groups would typically provide access to a greater number of participants, while the in-depth interviews would typically provide more detail about each participant. Hence, the simplest summary of the

differences between these two methods is to say that individual interviews are more useful when the goal is to obtain depth and detail about each participant, while focus groups are more useful when the goal is to hear from a range of participants.

Choosing between focus groups and individual interviews is often not a matter of using either one or the other, however, because the two often work well in combination. One common option is to use one method as a first step, followed by further data collection with the other. For example, focus groups could provide an introduction to the views of a variety of participants, a step that would be followed by a purposive selection of several participants for in-depth follow-up interviews. Alternatively, a series of individual interviews could provide the interviewer with the background necessary to gain access to and conduct more effective focus groups with an equivalent set of participants. Another useful combination of individual and group interviews is to use one method as a source of member checking for data collected through the other so that individual interviews could provide a cross-check for conclusions reached from focus groups or vice versa.

One final note about group and individual interviews is that they will not necessarily yield identical data, even from the same participants. This point should be obvious because the same person is unlikely to provide identical data in individual interviews with different interviewers or in focus groups with different sets of participants. In both those cases, researchers would expect the changes in social context to create the potential for different subjective interpretations and responses. Even so, some qualitative researchers still seem to believe that the interview participants should have one, single set of “facts” to share and that any deviation between what is heard in focus groups and individual interviews implies that one method or the other is in error. As an ironic commentary on the simplicity of this assumption, some social scientists claim that individual interviews produce better data than focus groups because the presence of others in a group biases what each individual says, while some marketing researchers advocate focus groups over individual interviews because the interviewer exerts such a large influence in the one-on-one setting. An alternative explanation would be that these two sets of researchers each have a tendency to prefer the method that has a longer historical traditional choice in their own field.

Design and Analysis of Focus Groups

Group composition is one of the most important aspects of research design for focus groups. As a starting point in the selection of participants for a focus group project, it is crucial to take into account both the needs of the researcher and the interests of the participants. Too often, researchers make the mistake of determining the group composition based on their own needs, without giving enough attention to the participants' point of view. At a minimum, the participants need to feel comfortable talking to each other about the research topic; beyond that, lively conversation requires a set of participants who are actively interested in talking to each other about the interview topic.

Selecting participants who share a similar perspective toward the topic is the most common strategy for producing the kind of group composition that will generate active exchanges. This strategy is usually summarized as creating homogeneous groups, where the homogeneity is based on what the participants share with regard to the research topic rather than simple similarity in demographic characteristics. For example, a set of focus groups on time management issues for working mothers would select participants who were women, who were employed, and who had children under age 18 living at home—but those choices would all be directly defined by the topic. The value of homogeneity in group composition is that it encourages the participants to relate to the topic in terms of both their similarities and differences. On the one hand, their similarities make it easier for them to share their thoughts and feelings about the research topic; on the other hand, their differences create an interesting basis for comparing where they each stand with regard to the topic.

This same principle of homogeneity is also at work in the common practice of segmenting the group composition in focus group projects. These designs separate the participants into two or more distinct categories or segments. Extending the previous example on working mothers, the total set of groups might be divided between some groups where the participants were single and other groups of participants who had partners, or the segmentation might divide the groups between mothers of either younger or older children, and so on. Using segmentation serves two purposes. First, it increases the comfort level of the participants in each segment, due to their shared background. Second, it

allows the researchers to make systematic comparisons across the factors that distinguish the different categories of groups. Segmentation in focus groups can thus contribute to higher quality of data by both increasing the participants' sense of shared interests and giving researchers the ability to compare the discussions across different types of participants.

Of course, making appropriate choices about group composition will be of little value if the research design does not include equally good choices about the interview questions. Once again, the content of the questions has to meet the needs of both the researchers and the participants. In particular, it is important to write questions that will get the participants involved in active discussions about the topics that are of most interest to the researchers. In situations where the participants are not already highly engaged with the topic, the first one or two questions are often more oriented toward the participants' interests, in order to encourage the kind of lively group dynamics that will lead to an equally active discussion when the questions get closer to the researchers' core topics.

The style of moderating by the interviewer is another area that typically receives a great deal of attention in research designs for focus groups. The most common distinction is whether the moderator takes a more directive or less directive approach, which corresponds to the difference between less structured and more structured groups that was mentioned earlier. In more structured groups, the moderator plays a relatively directive role by assuring that the conversation stays focused on the research topic. This strategy is best suited to goals that emphasize hearing as much as possible about a well-defined research agenda. In contrast, less structured groups allow the participants to follow their own paths while the moderator mostly facilitates rather than directs the discussion. This strategy matches goals that emphasize exploration and discovery.

Turning from research designs to data analysis, focus groups once again show many similarities with individual interviews. Further, most of what can be said about qualitative analysis of textual data applies equally well to transcripts of audiorecordings from focus groups. The most distinctive issue in the analysis of focus groups results from situations where a single participant may repeatedly mention a particular topic or theme within a group. From an analytic point of view, this repetition leads to what focus group researchers call the need for group-to-group validation—so that any result that is considered to be important should be

a major element of the discussion in most of the groups. More generally, the analysis of focus groups should pay special attention to the topics that consistently generate high levels of interest from almost every participant in almost every group. Thus, the process that began with asking the participants to focus on the topics that were most important to the researchers ends with the researchers focusing on the topics that were most important to the participants.

FORUM: QUALITATIVE SOCIAL RESEARCH (JOURNAL)

In 1999, *Forum: Qualitative Social Research*—a peer-reviewed, open-access, multilingual, and multidisciplinary online journal—was launched. The journal publishes empirical studies using qualitative research methods and also encourages submissions that discuss the theories and methodologies reflected in qualitative research. The contents of *Forum: Qualitative Social Research* can be viewed online and downloaded for free. Moreover, journal subscribers receive email updates when new content is published.

This journal's goal is to create a place where discussions among qualitative researchers flourish in the

social sciences and across international boundaries. By redefining the traditional format of published journals, *Forum: Qualitative Social Research* offers a more interactive periodical that serves as a conversation place for researchers, students, and others interested in qualitative research. In addition to soliciting theoretical, methodological, and research articles, the journal also encourages suggestions for revisions to its design. Conversation points, including reviews, debates, reports on conferences, and interviews, are also provided. For example, the editors may encourage debate of the journal's review of a particular book, interview a prominent scholar, or encourage discussion of new and/or controversial issues in the field.

When *Forum: Qualitative Social Research* was created, there were few conversational outlets for qualitative researchers. The founders of this journal saw this as problematic as qualitative research was typically marginalized within the social sciences, and many researchers had few opportunities to engage within their departments or disciplines around methodological issues. In addition, the journal's founders believed international boundaries between qualitative researchers were quite rigid. Grounded in their own German perspective, the founders noticed that German concepts gained little press in the United States, while few American methodologies were explored in Germany. *Forum: Qualitative Social Research* was formed to address this lack of international communication and to take advantage of the internet's ability to transcend geographic and disciplinary boundaries.

The creators of *Forum: Qualitative Social Research* note three characteristics that differentiate this journal from its traditional counterparts. First, publication timelines are more malleable in an online context; articles can be published immediately after peer review, leaving little lag time between research project completion and dissemination. Second, the amount of available space for each article is more flexible, allowing researchers to document the research process in more detail. Finally, free online publication provides for more interactivity, allowing researchers, readers, and editors to communicate electronically.

FOUCAULDIAN DISCOURSE ANALYSIS

The work of the French social philosopher Michel Foucault provides one of the theoretical frameworks often used to inform and shape studies employing discourse analysis. Foucauldian-influenced discourse analysis has gained increasing prominence in qualitative research since the late 20th century. Studies drawing on this approach have focused on diverse substantive areas, ranging from urban and business studies to health related areas such as nursing and occupational therapy. Foucauldian discourse analysis offers the potential to challenge ways of thinking about aspects of reality that have come to be viewed as being natural or normal and therefore tend to be taken for granted. It can enable us to explore how things have come to be the way they are, how it is that they remain that way, and how else they might have been or could be. This entry first examines Foucault's concept of discourse with its emphasis on the nexus between power and knowledge. It then discusses how this approach to discourse analysis might be operationalized, including an exploration of what might constitute data for a Foucauldian-influenced discourse analysis. Issues arising from the use of such an approach are raised, along with suggestions as to how some of them might be addressed.

The terms *discourse* and *discourse analysis* do not have single, absolute definitions because understandings of discourse and discourse analysis are derived from different disciplinary and theoretical traditions. Whatever the theoretical frame that is informing the understandings of discourse will also inform and shape the understanding of discourse analysis that is in use. Consequently, like other qualitative analytical approaches, discourse analysis is not a unified, unitary approach. However, although the principles of analysis may differ according to the approach to discourse analysis that is adopted, it is not a case of anything goes in discourse analysis. The theoretical premises on which the research being reported has drawn need to be clearly articulated.

In one sense the term *Foucauldian discourse analysis* could be considered something of a misnomer in

that Foucault did not develop a method for doing discourse analysis *per se*; in fact, he actively resisted doing so. Indeed, rather than specifying one way of doing discourse analysis, it is Foucault's theoretical work that provides us with a number of understandings that underpin both the framing and the conducting of research using this approach, including the type of question(s) or issue(s) being explored, as well as the way in which data are thought about and analyzed. Drawing on a metaphor Foucault used, the understandings derived from his work provide a toolbox or set of tools that can be used to shape the discursive analysis undertaken.

Foucault challenged the idea that knowledge is objective and value-free, inevitably progressive, and universal. Instead, he argued for an inextricable link between power and knowledge and used his concept of discourse to explore this power-knowledge nexus. Put simply, drawing on Foucauldian understandings, discourse refers to ways of thinking and speaking about aspects of reality. Discourses operate to order reality in certain ways. At any point in time, there are a number of possible discursive frames for thinking, writing, and speaking about aspects of reality. However, as a consequence of the effect of power relations, not all discourses are afforded equal presence or equal authority. Foucault described power as a network or a web that enables certain knowledge(s) to be produced and known. Somewhat paradoxically, such power can also constrain what it is possible to know in certain situations. Thus, in Foucault's analysis, power is a productive concept; it is not simply repressive. Nor is power a hierarchical concept, but rather it is an effect of sociohistoric processes in that knowledge underpinning a discourse can be used by proponents of that discourse both to claim authority and presence in certain settings and to exclude other possible discursive framings or ways of viewing those settings. Thus, while discursive frameworks order reality in a particular way, rendering it visible and understandable, they may also constrain or even exclude the production of understandings and knowledge that could offer alternative views of that reality. Thus, Foucauldian-influenced discourse analysis offers the possibility of illuminating the effects of power Foucault posited as being exercised from innumerable points within a given context, and this possibility is one of the attractions of the approach in qualitative research.

Foucauldian discourse analysis uses conventional data collection techniques to generate texts able to be

analyzed within Foucauldian theoretical frames. These texts could be interview transcripts, newspaper articles, observations, documents, or visual images. The sample of texts would need to be justified in terms of why they were chosen, how they were collected, and so on. The task of the discourse analyst is to make explicit the ways in which discourses operate and their effects within particular contexts. For example, health care research using this approach has explored and challenged understandings and practices pertaining to health care procedures such as cervical and other forms of screening, the assignment and maintenance of a diagnosis, construction of case notes, routinized practices such as handover at the end of nursing shifts, and notions of patient compliance.

Questions the researcher might ask of the texts that constitute the data for their study include those posed by Mark Philp: What rules permit certain statements to be made? What rules order these statements? What rules permit us to identify some statements as true and some as false? What rules allow for the construction of an explanatory map, model, or classificatory system for this text?

Drawing on Foucauldian theoretical perspectives, discourse analysis thus involves more than analyzing the content of texts for the ways in which they have been structured in terms of syntax, semantics, and so forth. Rather, it is concerned with the way in which texts themselves have been constructed, ordered, and shaped in terms of their social and historical situatedness. Texts are thus both product of and in turn, produce, discursive-based understandings of aspects of reality. But any text will only ever convey and produce a partial perspective of the reality being presented. The image of an object represented in a text is formed according to the frame or focus that shapes what is to be seen. This formation challenges the notion that texts are neutral and value-free receptacles, or simply conveyors, of information. An important assumption that underpins Foucauldian discourse analysis is that language cannot be considered to be transparent or value-free. Even the language that researchers take to be the most natural—that is, the spoken word or talk—does not have universal meaning, but is assigned particular meanings by both speakers and listeners, according to the situation in which language is being used. Ian Parker suggests asking the following questions: Why was this said and not that? Why these words? Where do the connotations of the words fit with different ways of talking about the world? Texts

are thus interrogated to uncover the unspoken and unstated assumptions implicit within them that have shaped the very form of the text in the first place.

As with any research approach, issues arise when using Foucauldian discourse analysis. Researchers will find that they are confronted by an ongoing tension between the text and its context in terms of how much consideration needs to be given to the contexts in which the written or visual texts are generated or from which they emanate. Put another way, this analysis is about how best to situate texts in their wider contexts, what these contexts are and where to stop in such contextualization. Further, when undertaking discourse analysis, researchers are in a position to impose meanings on another's text. The position of the researcher must therefore be made explicit throughout the research process. It is important to take into consideration, as pointed out by Parker, that researchers are also producers of discourse.

Another point of consideration is that analytic approaches to discourse often refer to partial or situated reality, viewing texts as constructed by and in turn constructing understandings of reality rather than describing a or the reality. Discourse analysis can thus be perceived by some as not providing a sufficiently rigorous methodology in which the reader is satisfied that the analysis has produced the only possible reading. Yet discourse analytic approaches do not necessarily aim to seek closure in terms of producing the only possible reading; to seek to do so may, in fact, be in conflict with the tenets of the approach employed.

Similarly, results of discourse analysis studies are often criticized for not being generalizable. However, generalizability can be viewed as a discursive construct that draws on particular understandings of what it means to generalize. Developing a form of decision trail can be of use to address some of these issues. Such a trail involves explicating what theoretical understandings of discourse and discourse analysis are in use and articulating clearly the theoretical framework underpinning the analysis. It must also contain detail about which texts were analyzed, why they were chosen, and how they were generated. In other words, there must be a rationale given for the choice of texts, and it must stand up to scrutiny.

Finally, a word of caution. In many ways, Foucauldian discourse analysis is as much a plural term as is discourse analysis itself. Foucault's work does not represent a linear, homogenous body of work. Rather it reflects the development of his thought over

a considerable period of time. As with all thinkers, Foucault's emphases and foci changed and evolved. It is important to be aware of this change and to clearly situate the research being undertaken, not only in terms of it being discourse analysis that draws on Foucauldian understandings, but also in terms of which understandings, derived from which parts and emphases in Foucault's work. Put another way, Foucauldian discourse analysis is about identifying, selecting, and using tools from those in the extensive tool box provided by Foucault's work to shape and frame the research conducted and analysis undertaken.

FRAMEWORK (SOFTWARE)

Framework is a matrix-based tool for qualitative data analysis developed by the Qualitative Research Unit

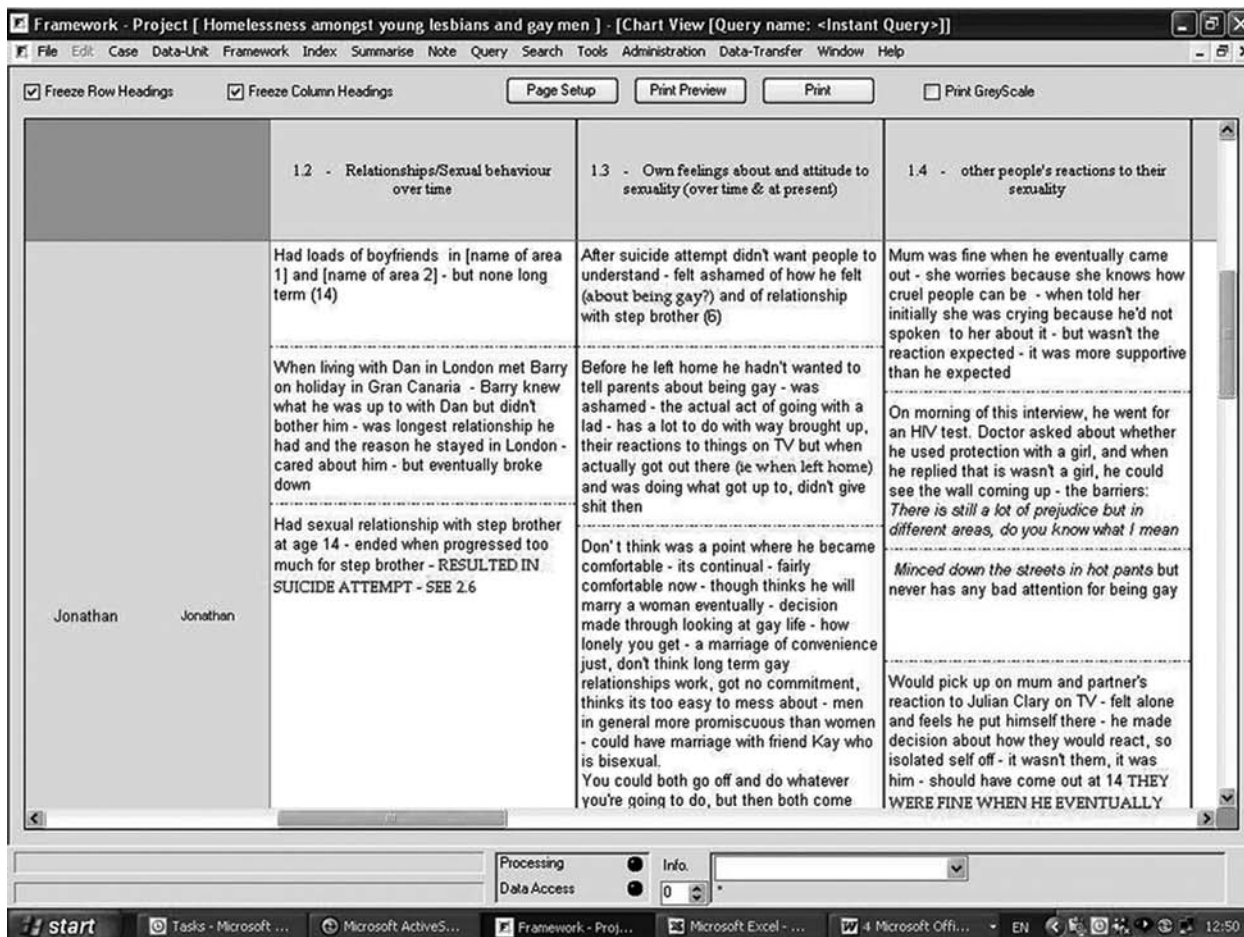

at the National Centre for Social Research in the United Kingdom. Key to the approach is that it organizes data into a series of matrices from which it is possible to conduct case-based and thematic analysis. It facilitates the systematic analysis of all qualitative data sets from the straightforward to the more complex.

Framework was conceived in the mid-1980s and has since then developed a reputation as a tool that supports transparency, consistency, and quality in the analytical process. It is an approach that has been adopted widely by other researchers both in the United Kingdom and internationally.

Initially an entirely paper-based method, it has evolved over the past 20 or so years into a unique software package, released in 2008, which can be run on all Windows-based computers. Key to the Framework approach is the captured synthesis of data; that is, the

creation of summaries of verbatim data that maintain context, language, and meaning. Other CAQDAS (i.e., computer-assisted qualitative data analysis software programs) packages either do not enable this ability or do it in a slightly cumbersome way. In addition, the unique output of Framework—the thematic matrix—in which these data summaries are displayed is not supported by other CAQDAS packages.

Although Framework has been developed to suit the needs of those who wish to use this approach, it also offers qualitative researchers the choice to use the key functions of other code and retrieve packages so that the analytical methods used can be driven by the requirements of the research. In addition, the software has broadened the applicability of Framework to a wider range of research activities including longitudinal qualitative research, secondary analysis of qualitative data,

An Example of Framework’s Matrix Output

and systematic reviews, basically any activity that requires the navigation of large bodies of textual data. The package is available in two formats. A networked version allows the creation of a secure repository of qualitative data that multiple users can access, thus supporting teamwork. The stand-alone version for single users will have the same functionality without the data sharing capabilities, although it will still be possible to export to and import data from other stand-alone version users.

FREE ASSOCIATION NARRATIVE INTERVIEW

Guided by the psychoanalytic principle of free association and designed to elicit narratives, the free associative narrative method employs open questions that encourage interviewees to remember specific events because these, unlike generalized answers, are replete with emotional meanings. The principle of free association, based on a psychoanalytic ontology emphasizing unconscious conflict and its management as the basis of psychic life and self-presentation, is that emotional significance, often unconscious, is contained in the links between one idea and the next as they are produced in a specific relationship to the listener. The method is particularly appropriate for exploring emotionally charged

and identity-based issues as opposed to topics where only opinion, beliefs, or facts are sought.

Unconscious conflict produces anxiety. It follows that anxiety will feature more or less prominently in research relationships (interviews and data analysis), varying with the interview topic, the setting, and the interviewer's ability to contain anxiety. Unconscious defenses against anxiety will affect how interviewees remember and narrate events and their part in these. In contrast to most interview methods, the method therefore presumes unconsciously defended subjects in relationship (thus including researchers as well as researched). This account of subjectivity understands unconscious desires and defenses against anxiety as products of interviewees' biographically unique psyches dynamically engaging with their social experiences (intersubjective, historical, and discursive). This psychosocial ontology resists simple explanation and reductive analysis.

Questions inviting specific accounts avoid emotionally drained generalizations and defensive rationalizations. Such questions are then followed up in a similar open fashion, echoing interviewees' chosen ordering and phrasing. In this way, participants' frames dominate rather than the researcher's. A second interview affords opportunity to listen to the record, notice patterns missed at the time, and devise a subsequent set of unique questions based on this first listening. Wendy Hollway and Tony Jefferson originally developed the method as an adaptation of the biographical interpretative method in the course of research into the relationships among gender, anxiety, and fear of crime. In a variety of subsequent applications, the key principles have been used to produce revised designs. For example, research questions exploring changes over time require a longitudinal design to accommodate the need to space a set of interviews over an extended period.

Based on the holistic principle of gestalt (that the whole is more meaningful than its parts), analysis involves keeping in mind the whole data set for a given individual when interpreting a part of it, in particular the associations that led up to it. However, rather than expect a coherent relationship between parts, the researcher remains alert to inconsistencies, contradictions, and conflicts as well as changes in emotional tone and avoidances.

Following psychoanalytic epistemology, based on using one's subjectivity as an instrument of knowing, researchers learn to use their emotional responses to the interview and to subsequent data analysis. This

ability is aided by detailed, reflexive fieldnotes that ideally are available for group analysis.

FUNDING

Funding is increasingly being recognized as an enabler for qualitative research, usually in the form of financial support that is given so that the research can be both undertaken and completed in a timely manner. With respect to qualitative research, such support can take various forms. One example is when researchers and/or research institutions are granted a certain amount of money to be used directly for research-related costs. These costs might include salaries, equipment, travel, or other expenses identified as necessary to enable the conduct and completion of the research. In other cases, in-kind funding support for projects may be offered. For example, rather than being given cash, the researchers could be provided with access to certain equipment or to specialist staff such as professional transcribers if interviews are part of the research, translators if the research involves working across different ethnic and language groups, and sometimes experts in particular substantive fields whose expertise is needed for particular parts of the research being undertaken. Equipment can range from computing resources such as laptops or specialized software such as NVivo to company or pool cars or office space and furniture. Often both cash and in-kind support are offered as funding for particular research projects. Thus, when researchers talk about funding for qualitative research, this refers not only to monetary support, but also can

take various forms and guises. This discussion aims to describe and explain some different funding options for qualitative research and to highlight the processes and issues involved in each.

Historically, and particularly when compared to more quantitative or basic science types of research, qualitative research has not attracted large amounts of funding, if any. This, Janice Morse notes, has led to a false assumption on the part of some funders, even some researchers, that qualitative research does not require funding or at least not to the same extent as other types of research projects. Although some qualitative research projects may indeed not need funding or not much funding as they are relatively small in focus and located in the researcher's local area, other studies cannot happen unless they are funded in some way. Such studies may be located in more than one geographical area and could involve a relatively large number of participants. On the other hand, in one sense all qualitative research is funded, as it is supported by the time spent on research by the researcher. In the current workplace climate, with its emphasis on cost recovery and accountability for time spent, many qualitative researchers find their available time for doing research being constantly eroded by workload in other areas, and this problem creates pressure to seek monetary and in-kind funding for the research, which can include buying the researcher's time. Increasingly, for researchers to be given time to carry out their research, they must attract funding that can either pay outright for their time or bring money into the institutions where they work so as to cover the cost of their time spent on research.

This need in turn raises another set of issues for qualitative researchers. In the past, many qualitative researchers have carried out all parts of the research process themselves as part of their day-to-day work as academics, students, or practitioners. They have recruited participants, gained relevant permissions, collected the data, analyzed that data, and written the report in its entirety. In fact, some qualitative researchers have argued that in order to maintain the integrity of their particular approach to qualitative research, it is imperative that they do so. This belief highlights one of the issues pertaining to the place and role of funding in qualitative research studies—how much of the research needs to be done by the researchers themselves and how much can be done by others? For example, is it necessary for researchers to conduct or transcribe or even listen to the text of every interview

in a study, or is reading the transcripts of interviews conducted by research assistant staff and produced by a professional transcriber sufficient? There is no right answer to this type of question. Depending on which type of qualitative research is being used in a particular study, the answer may vary. It is, however, important that these questions are considered so that sound methodologically based answers and research design related rationales can be produced for the decisions made.

Seeking, gaining, and accepting funding for qualitative research is not a neutral, value-free process. A number of issues arise for qualitative researchers when seeking and/or accepting funding. Many of these issues pertain to relationships between the funder, those being funded, and those who are part of the research. When doing funded research, it is important for researchers to inform participants about who is providing the funding and for what purpose that funding is being given: some participants may not wish to participate in a study that is funded by particular agencies. With respect to the relationship between the funder and those funded, offering and accepting funding involves entering into a form of contractual agreement that has consequences for the research being undertaken. Whether or not the involvement of a particular funder is appropriate can be considered on a number of fronts. One of these pertains to the ethics of the funder's involvement. A question that qualitative researchers must consider and, if necessary, grapple with, is whether or not they should apply to certain funding bodies for funds. They will need to consider what the funder stands for and also the role that the funder may want to have, or even insist on, in the research; for example, a funder may want input into any or all of the design, focus, and results of the research. At times, researchers may find themselves asked to modify proposals in ways that appear to compromise the approaches they wish to take, so their funding choice raises methodological issues as well. Qualitative researchers will need to think about to what extent appeasing requests is appropriate, what these requests mean for them and for the project, and how they will navigate disagreements should they arise.

The extent of funding bodies' involvement in research can vary considerably, from a very hands-on approach to a form of involvement that comprises little more than a series of reporting relationships over the course of the project. However, no matter what form the involvement takes, the point remains that accepting funding from a funder creates a new set of

relationships for the researcher to navigate, and these relationships need to be worked at, developed, and clarified as part of the research process. Funding creates another dimension to relationships between the various players in the research process. When there is clear communication between funder and those being funded, these relationships can enhance the research effort and assist its smooth functioning. However, if they are fraught, then in some cases the research itself can be compromised. What is certain is that this set of relationships cannot be ignored or assumed.

Two major pathways are available to qualitative researchers in locating funding for projects. The first is applying for funding for a particular project, the concept and design of which have already been developed to some extent by the researcher and research team. In other words, researchers have an idea for a project and then seek out funding sources for that project. The other main pathway is responding to tenders that have been advertised by industry or government for clearly defined and clearly delineated research projects, usually of very short duration. In this case, the researcher and research team are essentially funded to conduct someone else's research project or perhaps to develop a predetermined research idea into a research project. The research team is often put together in response to the tender advertisement. Each pathway warrants close scrutiny.

With respect to seeking funding for a particular idea or project that has been developed by the researcher and research team, it is crucial to be able to identify where funding for that project or idea might come from. One starting place would be to make note of the funding sources referred to in journal articles on qualitative research, especially if the reported research is in a similar area or uses a similar methodology to that of the researcher reading the publication. Another is to obtain publications that list the names of potential funders for their type or area of research. It is important to become aware of the relevant procedures and preferences involved for each funder. For instance, funders may call for proposals only at certain times of the year; if the research team knows that a likely funding body calls for applications in April each year, then it can plan to be ready for that due date well in advance. Thus, it is important for researchers to familiarize themselves with the research funding cycles of particular funding schemes so as to enable forward planning and adequate preparation of the application. Proposals for funding are sophisticated

documents and take much time and effort to develop. Each funding body will have their own requirements for what needs to be submitted to them and what form the proposal must take. Many have formal guidelines and application forms. The outline and description of the research will need to conform to the guidelines provided. This requirement could mean that, if funding is sought from several funders for the same research project, different applications must be written because the requirements will vary in terms of level of detail, presentation, and style. Further, the content and style of the application form and the directions provided are often a good guide as to whether a particular source is open to funding research that employs qualitative approaches. If the form or guidelines insist, for example, that the research must have a hypothesis, and/or if they clearly use notions of research that are laboratory or experimentally based, then it is unlikely that the scheme will be open to, or sympathetic toward, qualitative research. This likelihood is not necessarily to suggest that these funders will not consider funding qualitative research; however, it does indicate that winning this funding will be difficult. Another means of ascertaining the likelihood of funding for a qualitative project is to ask for a list of projects that the body has funded in the past. This list will also give a good guide as to the funder's research related emphases and foci.

The second major pathway for gaining funding for qualitative projects—namely responding to calls to conduct a predetermined research idea or project, often by means of competitive tender processes—is one that needs to be considered carefully. Such considerations center, to a large degree, on a particular inflection and outworking of the issues alluded to previously with respect to the control and ownership of the research and to the concomitant research relationships in the project. Essentially, in this type of research funding, the funder is buying researcher and/or team expertise to have a particular piece of research carried out. There will be varying degrees of freedom for the researcher's input into the actual project design, ranging from none or very little input to being given quite a free hand. Qualitative researchers will need to think carefully about what this freedom might mean, both for them as researchers and for the types of outcomes or research products that they will be expected to deliver. In fact, the contract entered into by the researcher with a particular funding body will often assume research outcomes to be synonymous with time-delimited products

such as dates for production of reports, schedules of presentations, and deadlines for the preparation of research-related materials. Such a contractual arrangement can have the effect of reducing to a series of deliverables the way the research is viewed and understood. Although at one level this contract can contribute to accountability in the way funds are used, at another level it shifts the emphasis, in terms of ways of thinking about research related products, from bearing directly on the integrity of the research itself to being more focused on the processes associated with the research being undertaken. Indeed, in this situation, more emphasis may come to be placed on meeting deadlines than on theoretical and/or methodological integrity.

Any discussion about funded qualitative research must consider the influence of the political context in which the funding is being sought, both on the way funding for research is thought about and on the way it is allocated. As researchers enter the 21st century, funding for qualitative research is increasingly being used for purposes other than supporting and enabling particular research projects to be conducted. For example, the absolute amount of funding received by individual researchers in terms of cash received and the sum total of the amount of funding received by the research active staff at an institutional level, such as in universities, is being used to measure research performance and to make judgments about the worth of both researchers and institutions. Thus, funding creates the possibility of determining relative rankings and worth in a type of research marketplace premised on competition between researchers and institutions. Such a development reflects the influence of the neoliberal-oriented governments in power in many countries at this time, particularly in the West, and the outworking of policies and practices derived from such an orientation. Carlos Torres highlights the following notions as being promoted by neoliberal thought: "open markets, free trade, the reduction of the public sector, the decrease of state intervention in the economy and the deregulation of markets" (p. 368). In such thought, the emphasis is clearly on economic aspects of government. Research, researchers, and the institutions to which researchers belong are viewed as part of a research market place. In this market place, researchers and institutions must compete for funds and establish their relative worth in relation to each other.

The effect of such thinking on ways in which the nexus between funding, qualitative research, and qualitative researchers is thought about operates in a

series of cascading contextual levels of influence. These range from a macropolitical level, such as at the policy level of government, through to the local level, such as within the researcher's university department or research unit. For example, with respect to the macrogovernmental level and the understandings emanating there from, some countries (such as the United Kingdom, Australia, and New Zealand) have developed research assessment exercises designed to ensure value for money in terms of research investment by governments, as well as to make researchers accountable and able to be ranked against each other. Government funding for research infrastructure and development has been directly linked to the outcomes of such exercises in the institutions undergoing this form of assessment. Winning such funding from government is imperative in a climate of fiscal restraint. Researchers who can attract funding are highly prized in such an environment—so too is the type of research that they do. This change marks a shift in emphasis from the original intent of funding being an enabler or means by which research may be undertaken to funding itself being an end in its own right—as important as the research itself, or even more so, in the eyes of administrations in many university and other research-oriented institutions.

Such a shift creates issues for qualitative researchers who have traditionally found it more difficult to compete on methodological grounds under mainstream funding bodies that are historically premised on assumptions about research drawn from basic science. Further, low success rates when applying for funding (in Australia, it is less than 20% in some schemes) are increasingly the case in most countries, as competition for shrinking funding sources grows relentlessly. It is much more likely for researchers not to be funded as a result of an application process than it is for them to be successful. If qualitative researchers are not able to attract funding, then there is the very real possibility that they, and the type of research they do, could be marginalized, deemed irrelevant, and even thought of as not of high quality. These results are due to a conflation of research quality with the amount of funding gained in many of the research assessment exercises. Such conflation has spin-off effects at more microlevels with, for example, the amount of funding certain individuals have attracted for their research being used to develop hierarchical rankings of researchers in institutions. Such rankings are then used when making

decisions about which staff to recruit or whether researchers will be successful when applying for tenure, and they are also a factor in determining whether researchers should be promoted. All of this is part of the outworking of the notion of a research marketplace in which a researcher, like research, can become thought of as a commodity, and the amount of funding obtained for research becomes a type of currency that influences each researcher's relative position in such a market.

None of this is to suggest that funding is in itself a bad thing. Used well, funding enables qualitative research to proceed when otherwise it could not. However, funding is more than just the support given to the research project or research team; it is a political process as well. Inherent in the thinking about funding, from the initial consideration of where to seek funding right through to what form the funded research outcomes eventually take, are assumptions about what is and what is not fundable research. There are also assumptions about appropriate methods and the question of who will control the research in terms of its design and what it will deliver. These must be considered and taken into account by qualitative researchers who contemplate applying for and/or accepting funding from a particular funder, as must the effect of gaining funding, which can become an end in itself and is often used as a measure of a researcher's worth. In such a climate, all qualitative researchers must be alert to the ways in which these funding issues affect them as researchers, the places in which they conduct research, the things that they research, and, in fact, the very notion of qualitative research itself.

GENDER ISSUES

Is there a systematic relationship between gender and methods in social science and educational research? Scholars in social science and educational disciplines address this question in multiple ways. Some have sought to establish whether or not a scholar's gender affects choice of methods and subsequent publication and reception of scholarly work. Others have probed ways in which gender affects access in fieldwork, relationships between researchers and those who are researched, and ethical standards applied in conducting and publishing fieldwork. Other commentators, especially those writing from a feminist perspective, have explored whether gender affects research practices, ethics, and perspectives on the production of knowledge itself.

In sorting through the voluminous research on gender and methods, it is helpful to consider distinctions between the three concepts of methods, methodology, and epistemology initially outlined by feminist philosopher of science Sandra Harding and elaborated further by sociologist Marjorie DeVault. Methods refer to the tools that researchers use to collect and evaluate evidence in addressing questions of theoretical importance in their disciplines. Methodology refers to theorizing about methods and research practices. Epistemology involves the bases for knowledge claims, assumptions about the nature of reality, and critical reflection on the processes of knowledge production. Among feminist and critical theory researchers, epistemology usually involves critiques of claims that knowledge can be, or even should be, objective and value free. Although there

are some overlaps between these concepts, it is nevertheless useful to separate them in exploring relationships between gender and methods.

Methods

If one defines methods as tools for use in conducting research, it is hard to draw any tight associations between methods and gender. Historically, most academic disciplines were dominated by men, and men were the original pioneers of most methods used in educational and social scientific research, from ethnography to survey research. Although some analyses of contemporary published scholarship suggest that women might use qualitative methods more frequently than men, this was not the case historically. In disciplines such as sociology and political science, it was women rather than men who were quantitative analysts at the point when these disciplines became institutionalized in Western universities. One example is the careful quantitative work carried out by women associated with the so-called Chicago School of American sociology, who conducted careful, detailed censuses of dwelling units on Chicago's South side and drew upon quantitative data from police and social work files to publish quantitative papers at a point when many of their male colleagues were writing non-empirical theoretical treatises. Mary Jo Deegan has shown that in the precomputer era, routine ciphering was seen as an appropriate task for women. It was only with the introduction of computers and sophisticated analytical methods in the 1950s and beyond that evidence collection and evidence analysis by computer-assisted statistical packages became separated, and

men began to dominate the latter. In writing about more recent eras, Judith Stacey and Barrie Thorne suggested that disciplines that have been more accepting of qualitative methods such as ethnographic observation and intensive interviewing—for example, anthropology—have experienced more of a feminist revolution in the content and perspective than those such as economics or psychology that have not. However, it is hard to discern the direction of such a relationship. Were women attracted to fields where qualitative methods were used, or did women's participation popularize qualitative approaches?

Despite the contemporary trend toward greater popularity of qualitative methods, especially among women scholars, the link between gender and methods is by no means absolute, and women scholars in quantitatively oriented disciplines continue to publish more quantitative than qualitative research. In disciplines such as education where women have entered in growing proportions and qualitative methods have become more dominant, male scholars use these methods frequently. Subject matter may also affect methods. For example, scholars contributing to the relatively new fields of men's studies and studies of sexuality, many of them men, often rely on qualitative methods.

Commentators such as DeVault, Shulamit Reinharz, and Joey Sprague, who have written feminist-oriented reviews of methods, have concluded that most methods, in and of themselves, are not explicitly linked to either gender or feminism. Women researchers, and researchers writing from a feminist perspective, have employed a variety of methods, sometimes combining approaches or adapting methods in creative ways. These writers suggest that the impact of gender and feminism likely is greater in the areas of methodology and epistemology than in methods themselves.

Not all scholars agree, however, and some have suggested that the dense, emotion-laden lives of women call for qualitative methods to enable faithful portrayals. An early critique by sociologist Jessie Bernard made a distinction between the *status-nexus* versus the *cash-nexus* quality of women's lives as compared to men's. Bernard argued that important nuances of women's experiences slipped between the matrix of quantitative analysis strategies dominated sociology at the time. The labor-intensive, but not necessarily technology-dependent, nature of most qualitative methods makes them accessible to scholars working from all types of institutions, making them potentially more democratic. Some scholars contend that qualitative

methods are especially well suited for the study of phenomena and domains of social life typically excluded from scholarly analysis. Qualitative methods allow for greater independence from the traditional apparatuses of knowledge construction, and they do more to preserve the voices of nondominant groups. For example, many of the large data sets based on survey or census data exclude information on women, making it impossible to study their lives.

Recently popular qualitative methods, such as narrative analysis and oral history, blur the boundaries between social scientific and literary analysis and are used frequently by women scholars. These methods have been especially prominent in the study of the lives of working class women and women of color, who historically have been marginalized from formal mechanisms of knowledge production. Scholars who use such techniques—for example, Patricia Bell-Scott and Juanita Johnson-Bailey—turn to qualitative methods to avoid distortion of women's words and experiences that might occur with the use of a more heavily researcher-constructed method. These approaches also preserve nuances of speech and forms of expression that convey valuable information, but which usually are lost in many other forms of research. These scholars are also concerned with empowering women who participate in their research by validating the importance of their lived experiences and knowledge derived from everyday life.

However, scholars such as Toby Jayaratne, Barbara Risman, and Sprague contend that in certain contexts quantitative methods can be as effective, if not more effective, in addressing women's concerns. These scholars argue that methodological choices should be based on the question at hand and the audience for which the research is intended. Sprague points out that in the policy arena, hard statistical data are frequently the coin of the realm, and one is most persuasive when presenting information in this form. Qualitative research is often complex, subtle, and context bound, and perhaps therefore harder to convey faithfully in brief reports in public settings or in media sound bites.

Methodology

A lively dialogue has emerged around the issue of gender and methodology, or thinking about the utilization and application of methods. Whether and how gender affects access in research and relationships with research participants has been widely discussed in the literature. Some scholars have argued that in

Western cultures, norms define women as the confidants of women and of men, thereby providing women researchers with advantages in conducting any research involving face-to-face contact with informants. Obviously there are exceptions to this pattern, and there are some areas of social life in many societies from which women are explicitly excluded. Furthermore, as scholars such as Josephine Beoku-Betts and Catherine Kohler Reissman have pointed out, other attributes such as social class, age, marital status, and race-ethnicity also affect access and field relationships in ways that are by no means simple or straightforward. Sharing gender or racial attributes with research subjects may be helpful, but is rarely sufficient for transcending all barriers. Insider status may be essential for researching certain groups, and qualitative methods have sometimes been thought to be less exploitative of disempowered groups because they involve intensive face-to-face relationships. Nevertheless, as writers such as Lynn Cannon, Elizabeth Higginbotham, and Marianne Leung and Stacey have demonstrated, qualitative approaches can also engender issues of exclusion, misrepresentation, and exploitation. Recruitment strategies in qualitative research may exclude some groups from participation. Close emotional ties developed in the course of research may enhance the power of the researcher to manipulate research subjects. Maxine Baca-Zinn and Patricia Zevalla have shown that insiders can be caught in conflicts between their roles as scholars and participants in communities. Such power imbalances can sometimes be addressed by explicit efforts to engage in collaborative or action research, where concerns of research subjects are central to the research endeavor and participants have a voice in the research process and its products. Another strategy frequently suggested is full disclosure of the researcher's stance, personal history, and relationships to participants, even if this disclosure makes her or him vulnerable and subject to criticism within academia.

Feminist scholars have been particularly attentive to issues of exploitation of participants and have been in the forefront in developing ethical standards and practical strategies to minimize such risks. Women scholars have also been prolific contributors to a burgeoning literature on research ethics. Some have been actively engaged in efforts to apply the knowledge gained through research to address real-life concerns of research participants, even if such efforts fail to bring scholars rewards within the academy.

Many feminist scholars argue argued that knowledge must be for women and not simply about women. This perspective implies a critical stance of scholarly knowledge, and a careful analysis of who benefits, and who does not, from the seemingly value-neutral scholarship valued in many academic fields. A primary example is the work of Dorothy Smith, who argues that most scholarship is written from the perspective of the relations of the ruling. She outlines a methodology (institutional ethnography) designed to ground research in the everyday concerns of women. The emergent, flexible character of qualitative research helps to keep research grounded in the real-life experiences of participants. Producing knowledge for women creates practical ethical dilemmas, such as whether or not one reports potentially damaging information about subjects that could serve as a rationale for their oppression.

Epistemology

Women scholars have been prominent in critiques of objectivity and value neutrality that frequently accompany the use of quantitative methods. Again, the association must not be drawn too tightly, as many women scholars subscribe to traditional notions about value-free scholarship and many men critique claims of objectivity. Especially prominent among these critics are Smith and Patricia Hill-Collins, who are often identified as *standpoint* theorists in that they see all scholarship as being written (inevitably) from a distinctive standpoint that can attain only partial truths. These scholars reject notions that through professional training or rigorous application of "objective" methods researchers can produce a form of scholarship that is divorced from their subjectivity. Instead, the topics that scholars find intriguing, the methods that they find most fruitful, and the analyses they produce all reflect the life experiences of the researchers and the institutional contexts in which they work. Mentors, disciplines, local institutions, funding agencies, and the like all influence the process of knowledge production, including which methodological approaches are considered legitimate, whether or not scholars are aware of these influences.

Other scholars have argued that women, as a group, have a distinctive way of knowing that lends itself particularly well to qualitative methods. Although there is substantial variation in perspectives among scholars who have advanced such arguments, most see women's

vision as more focused on care, relationships, and connection rather than on rights, justice, and formalized ways of generating knowledge. Most do not regard such gender differences as innate or as linked to biology, but rather as the product of women's cumulative life experiences, their lifelong greater involvement in dense and emotionally rich relationships, and their lesser involvement in abstraction.

Both standpoint and women's way of knowing theorists have been critiqued as reflecting a form of essentialism and as perhaps assuming too great a similarity among all women, despite differences among them. Scholars writing from non-U.S. locales and within the postcolonial tradition, such as Chandra Mohanty, Maria Mies, and Maria Lugones, have critiqued this scholarship for implicit first world bias and a tendency to exclude or decenter nondominant women from non-Western societies. These theorists also have been criticized for reifying a socially constructed category of gender, giving it a permanence and stability that it may not deserve. Postmodernist-influenced scholars have raised questions about how norms of presentation of scholarly work, discipline-based concepts and vocabularies, and taken-for-granted assumptions within the academy shape and constrain what can and cannot be known. They have also problematized concepts such as sex and gender and simplistic understandings of the relationships between the two. Scholars such as Judith Butler and Anne Fausto-Sterling point out that notions of sex as a dimorphic, dichotomous category are more a social construction than an accurate reflection of human biology. But the conventions and the vocabulary tend to structure our perceptions, rather than the reverse. How can we study links between methods and gender if gender itself is unstable?

The postmodernist critique has implications not simply for the gathering of evidence by use of research methods, but also for the reporting, interpreting, and evaluating of research. Research reports are essentially interpretations that are inherently personal and dependent on dynamic relationships between subjects and researchers. Multiple studies of similar groups or phenomena are likely to yield conflicting, irreconcilable accounts (as is seen in some accounts of female and male anthropologists who studied the same cultures) because the world is changing and differently perceived by persons of differing backgrounds. There is no single truth, and therefore the quest to find it through careful application of rigorous

methods is misguided. Criteria for evaluating quality of accounts are ambiguous. Power relationships are important and must be understood and deconstructed, because alternative, nondominant interpretations also are present. Readers may come away from accounts with variable understandings, often quite different from those intended by the writer. Knowledge is neither stable nor cumulative. These perspectives conflict with assumptions underlying most quantitative research, which values replicability, cumulateness, and generalizability. They also conflict with some forms of qualitative research, especially with what Jaber Gubrium and James Holstein refer to as *naturalism*, which assumes a one-to-one correspondence between observation and reality.

Qualitative methods frequently are used by researchers influenced by postmodernism because they allow a more detailed accounting of how the report was produced. Qualitative accounts typically contain more contextual detail and permit greater exploration of difference and diversity, rather than being framed primarily around analysis of central tendencies. Patti Lather, Laurel Richardson, and Marianne Paget are some of the feminist scholars who have experimented with nontraditional forms of presentation of qualitative research, such as multivocal text, poetry or song, and live performance, in attempts to more faithfully represent the complex and contradictory elements of the phenomena they have studied.

Women are not the only postmodernists, but women scholars in many fields have been influenced in particular by postmodernist critiques of power inherent in knowledge production processes. Some feminist scholars have criticized the postmodernist turn in scholarship as being post-feminist because women and women's concerns are not necessarily prioritized in research. In addition, some scholars have feared that postmodernist-oriented research is less oriented than other forms of gender scholarship toward producing knowledge applicable to real-world problems in women's lives. This is an explicit aim of many who label their work as feminist.

Conclusion

In summary, relationships between gender and methods are complex. If methods are regarded as tools for conducting research, the link between gender and methods seems tenuous at best because women and men draw upon similar toolkits of research methods,

albeit perhaps in different proportions. Oral history and narrative analysis might be exceptions and may be more directly linked to gender. An influence of gender is easier to discern in the realm of methodology, or theorizing about methods, and there has been substantial writing about links between gender, ethics, and numerous practical concerns in conducting research. With regard to epistemology, the links are even stronger, with women scholars and scholars who research nondominant groups in society especially prominent in critiques of objectivity, value neutrality, and the quest for a theoretical master narrative that will guide understanding of much of social life. It is important to recall, nonetheless, that the linkages between gender and methods, or gender and methodology, or gender and epistemology are neither absolute nor deterministic. They also are constantly evolving.

GENEALOGICAL APPROACH

The genealogical approach confronts ideas or practices that present themselves as universal. It reveals that they actually issue from and reflect a narrower source. Once this revelation is accomplished, genealogy evaluates the more limited meaning of the practices. Ultimately, genealogy attempts to show that all practices have variable meanings and reflect different forces rather than possess intrinsic meanings and point to a permanent reality. In the social sciences and humanities, the works of the major progenitors of genealogy, Friedrich Nietzsche and Michel Foucault, have given rise to those forms of discourse analysis and ethnographic studies that emphasize the preeminent role of language and other practices in constructing or establishing the identities of the subjects and objects with which we interact. The constituting role of these practices applies also to us: we are simultaneously the vehicles and the products of our discursive and nondiscursive social practices. This entry reviews the meaning of genealogy for Nietzsche and Foucault and then discusses the presence of genealogy in the social sciences and humanities.

Nietzsche and Foucault on Genealogical Critique

The genealogies of Nietzsche and Foucault assume (and simultaneously attempt to establish) that society is composed of mutually contesting forces. Nietzsche refers to the interplay among these value-creating forces as a will to power. Some of these forces are active; that is, spontaneous affirmations of the contest among the forces that make up society. Others are reactive; that is, exist as denials or negations of the contestatory but also creative nature of society. When

active forces dominate the social body (or the individual), Nietzsche refers to the latter as an *affirmative* will-to-power; when reactive forces are in the ascendancy, a *nihilistic* will to power. Similarly, Foucault refers to the forces of the social body as *power*. This power is not primarily the coercive sort or laws that say “thou shall not ...”; rather, it refers to the practices that construct objects, subjects, and criteria of truth. For example, the modern form of power, bio-power, consists in the disciplines that organize and regulate bodies in the social arena—workplaces, schools, armies—and the policies that control the health, size, and other parameters concerning the utility of the population. Bio-power also requires forces that resist it. They permit it to continue exercising and increasing the practices that make up its anonymous disciplinary activity. In turn, the resisting forces require bio-power in order to be what they are. The social body is therefore ultimately both of these types of forces, power and resistance.

The Critical Dimension of Genealogy

Given this brief sketch of society as the interplay among value-creating forces, we can now elaborate on the specific characteristics of genealogy. Genealogy has a critical dimension and an affirmative dimension. Its critical dimension involves three tasks. The first two tasks are to reveal the social forces that cultural codes and social institutions serve, and often conceal, and to evaluate these codes and institutions on the basis of that revelation. The third task is to show how one and the same word, practice, or institution often serves successive and distinct, even opposed, forms of life and thereby takes on a new significance at every turn. In other words, the third task is to show that society is fundamentally grounded in contestation among the value-creating forces that genealogy takes to be its domain of operation. Genealogy, like every other discourse, is itself a value-creating force; thus, it is subject to the same sort of analysis it provides for other discourses.

The critical side of genealogy and its three tasks are a form of critique: they reveal that no one can detach a value-code or institution from its history—from the successive value-creating powers it serves—and thereby make the claim that this code or institution has an intrinsic and universal meaning. For example, the moral term *good* is usually presented as an absolute value; that is, as transcending the social arena in which it is operative. But Nietzsche argues

that its meaning varies, depending on whether it is paired with *bad* or with *evil*. When it is coupled with *bad*, good is the spontaneous self-affirmation of a group whose social position allows its members to be truthful—to be themselves freely and fully—in contrast to those who are bad off; that is, those who have been placed in and adversely affected by unenviable circumstances and consequently cannot exercise their full powers. When this impotent group has the opportunity to invent its own value code, it expresses its resentment of the other group and its members’ spontaneity or freedom. This resentment is captured by the impotent group labeling the other group *evil* and by imposing the value code *good and evil* on all of society if and when the group gains power. Whereas the first group exists as an active force, as the spontaneous affirmation of its human powers, the second group exists only as a reaction to the first; it calls itself good only in the sense of not being what it deems evil. When this reaction is against the world as a flux of forces and when this rejection of reality is reflected in the religious doctrines, political constitutions, philosophies, and other important social discourses that shape our perceptions and thoughts as well as guide our actions, society becomes a nihilistic will-to-power, in Nietzsche’s terminology. His critique, therefore, functions to reveal the social origin and meaning of a code that presents itself as a transcendent value or truth.

Although he uses the notion of power and resistance rather than will-to-power, Foucault follows Nietzsche in adopting genealogy as a means of undermining any discourse that tacitly or overtly presents itself as transcending the arena of power and resistance. Foucault attempts to reveal, for example, that truth is relative to the power or micropractices that establish the identities of the subjects and objects of a social body. In the case of bio-power, truth consists in the conclusions of the social sciences insofar as the latter are structured to advance the disciplining processes of modern society; that is, truth is relative to and in the service of bio-power. If the forces that resist bio-power should ever become the new power, then truth would presumably take on a meaning other than that which increases the utility of the population and advances bio-power. Thus, Foucault attempts to reveal the meaning of truth, evaluate it in terms of the forces it serves, and show that difference (e.g., the many meanings of truth) is closer than the notion of identity to how things are.

The Affirmative Dimension of Genealogy: Beyond Discourse Analysis

If we stick to the first two tasks of the critical dimension of genealogy, we are doing what discourse analysts typically do: identifying the discourse (including associated nondiscursive practices or structures) that provides the initial compellingness of certain particular practices or actions and thereby showing that the latter do not merit the universal or otherwise privileged status that they been assigned. The third task of the critical dimension consists in showing that society is in fact the interplay among contesting forces that genealogy supposes.

This third task and the entire critical dimension of genealogy are related to the second, affirmative, dimension of genealogy. Genealogy drops the pretense of neutrality that is characteristic of the social sciences and conventional discourse analysis. For the genealogist, and particularly for Nietzsche and Foucault, genealogy is, as we have seen, a means of undermining claims to neutrality as well as racist, sexist, and other doctrines that present as transcendent what is really the desire or outlook of a particular group. Simultaneously, this undermining of neutrality and claims to transcendence—the critical dimension of genealogy—is the endorsement or valorization of those forces, genealogy included, that support the interconnectedness, heterogeneity, and creativity of the positions contesting with one another for their place in society. This valorization is the primary meaning of the affirmative dimension of genealogy. This affirmative dimension shows up implicitly in much of discourse analysis and explicitly in many ethnographic studies. For example, some authors (see Further Readings below) debunk strict identity claims in order to show that culture is hybrid in nature; others argue that the individual is saturated with many selves; still others reveal that race and gender are not univocal concepts and, more generally, that scientific, linguistic, and other academic categories hide the proliferating diversity of natural and human characteristics.

Although genealogy eschews neutrality, it does not cast aside relative merit: in the exchanges among the positions that contest with one another, and in the particular context in which these exchanges take place, one of these positions can always put forward considerations for its social discourse that might be found more compelling than those for the other discourses—though,

once again, only for the time being and within a particular crucible of contestation. These exchanges among the competing positions have the added virtue of amounting to the very kind of contestatory and creative society that genealogists affirm.

GENERALIZABILITY

In the quantitative tradition, the term *generalizability* is a synonym for *external validity*. In addition to ensuring that a study is valid internally by, for instance, administering to a study's research subjects only instruments that actually measure what they claim to measure, quantitative researchers also normally are concerned that their findings will apply to other people and/or other situations that the study's sample supposedly represents. Qualitative researchers, who normally play a very different research game, have been forced to rethink the generalizability notion.

Generalizability in Quantitative Research

In quantitative research, a study's generalizability is assessed by focusing on a study's sampling procedures and by using statistical analysis designed to determine the likelihood that the study's results might have occurred by chance. If a study's sample is large enough and was selected randomly, the statistical analysis is likely to show that there is only a very slim possibility that the study's results are a product of chance. In such cases, the study is said to exhibit external validity and the study's findings are judged generalizable.

For a variety of reasons, including the complexity of social phenomena and the ever-changing cultural dimension of social life, quantitative researchers have had difficulty producing even probabilistic findings that can be generalized even to delimited populations. In the 1970s, this failure led one prominent quantitative researcher, Lee Cronbach, to suggest that quantitative researchers should add a qualitative component to experimental studies so that qualitative researchers' thick descriptions could be used *ex post facto* to generate grounded hypotheses about why idiosyncratic results occurred. By the 1980s, Cronbach went even further: He argued that action in the social world was constructed, not caused, and, consequently, that those who were waiting for social scientists to produce generalizable findings were, in essence, waiting for Godot.

Generalizability in Qualitative Research

Cronbach's position in the 1980s is quite similar to the position articulated by qualitative researchers from the symbolic interactionist, ethnomethodologist, and other constructivist traditions. But, in fact, virtually all qualitative researchers have been forced to rethink quantitative researchers' generalizability notion, if only because of their small samples.

Because of small sample sizes, most qualitative researchers simply cannot play the traditional generalizability game. Instead, they have redefined the generalizability question in more commonsense terms: Why will knowledge of a single or limited number of cases be useful to people who operate in other, potentially different situations?

Qualitative researchers have answered this question in a number of ways. Yvonna Lincoln and Egon Guba, for instance, took note of the same sort of complexity that Cronbach had discussed and concluded

that only consumers of research could determine whether the setting studied was sufficiently similar to the consumer's organization to entertain the working hypothesis that findings would transfer. Robert Donmoyer, on the other hand, suggested that reading qualitative accounts of radically different cases could produce enriched cognitive schema and that these schema would allow for a kind of intellectual generalization even when settings are radically different.

GRAND NARRATIVE

Most qualitative researchers will ground their work within certain epistemologies. One such epistemology is based upon postmodern thinking and influences how we view Western society. *Grand narrative* or *master narrative* is a term introduced by Jean-François Lyotard in his classic 1979 work *The Postmodern Condition: A Report on Knowledge*, in which Lyotard worked to critique institutional and ideological forms of knowledge. Lyotard suggested that there is a modern or grand narrative that society has used to define itself. The grand narrative is usually linked to the mainstream or status quo. Some examples of the grand narrative in the modern world are capitalism, the Enlightenment, Christian ideology, Freudian psychology, political democracy, natural science, positivism, and patriarchal order. Outside of these narratives is the other.

In postmodernism, the grand narrative of the modern story is a privileged competition between the polarities of those who are in the story and those who are not. The other is always present and will work to

disrupt or interrupt the grand narrative in some way. At the same time, the grand narrative needs the other to justify the modern story. For example, modernists used women to justify the patriarchal dominance of the modern reality. The essence of postmodernism is to disrupt the modern story and the grand narrative.

Within the grand narrative are privileged sites. The goal of people within the modern story is to hold as many of the privileged sites as possible. The goal of marginalized communities is to acquire these privileged sites so that they can join the modern story. The other option is to try to rewrite the grand narrative so that the voices of marginalized communities are included. For example, the privileged color in the modern Western world is White. The privileged gender is male. The privileged race is Caucasian. The privileged age is 25 to 40. Our relationship to nature is consumers. Our preferred means of production is mass production.

According to Lyotard, grand narratives are seen as oppressive because one grand narrative excludes another. With this continual conflict and attack on the modern grand narrative, modern society has opened up the narrative to include and to absorb the other. The notion is that the other has a legitimate history that can be added to the social story of our time; for example, including Aborigines in the intellectual history of North America.

This process has created a lot of confusion in the modern grand narrative as a pastiche of influences impact the story. In this mix of signs, images, and stories, members of the grand narrative no longer have a clear vision of how they fit into the mainstream story. In this confusion, members of society can look to a remembrance of the good old days when we knew what the grand narrative was and how we fit into it. At the same time, we are searching for new signs and schemata that will more adequately describe and explain the grand narrative we are creating because the old ones do not work anymore. The shift from a mere consumer of knowledge to a knower of knowledge or a meta-narrative is the essence of the new grand narrative.

GRAND THEORY

Grand theory is the broadest form of theory within a discipline. A theory can be described as a set of concepts and the relationships among them. In the human sciences, theories are often classified by their scope, from the narrowest in scope to the broadest. Micro theories, sometimes referred to as partial or situational theories, have the narrowest scope. Micro theories are restricted to a particular phenomenon or, as the name suggests, situation. Some scientists have equated micro theories with research hypotheses because their narrow scope makes it possible for such theories to be tested with as little as one research study.

Mid-range theories, which have been described as being particularly useful for practice disciplines, are more abstract and inclusive than micro theories but remain testable, although such testing may require a program of research or series of studies in which specific concepts and relationships in the theory are tested individually. Mid-range theories have been described as particularly useful for practice disciplines and have been the focus of recent theory development efforts in (for example) nursing.

Grand theories, sometimes referred to as conceptual frameworks or conceptual models, develop overall explanations for a discipline or body of knowledge. The concepts addressed by grand theories are highly abstract and cannot easily be operationalized into variables or used in hypotheses. Thus, grand theories are untestable. Some authors have described grand theories as normative; that is, that grand theories describe not the way a discipline is, but the way that discipline should be. Grand theories, though untestable, are often useful as organizing frameworks for knowledge development or as foundations for mid-range theory development. Examples of grand theories can be found in many disciplines. Theoretical physicists are at work on a grand unified theory, which would reconcile electromagnetism with weak and strong nuclear forces. In sociology, Talcott Parsons's structural-functional theory, developed in the 1960s, has had considerable influence. In nursing, a number of grand theories were developed in the 1970s and 1980s in an attempt to describe nursing's unique disciplinary body of knowledge. Examples of grand theories of nursing include the theory of health as expanding consciousness and the self-care deficit theory. Qualitative researchers use an array of grand theories from symbolic interactionism to general systems theory. In

addition, explicitly normative grand theories such as Marxism and feminism are common in qualitative research, although there is disagreement about whether these approaches are grand theories, ideological orientations, or epistemological traditions.

The scope of grand theories has of course led to criticisms. Grand theories have been described as too broad, leading to oversimplification of complex issues; as lacking in clear definitions of central concepts; as empirically unverifiable (i.e., untestable); and as static and unresponsive to changing conditions. Despite these criticisms, grand theory continues to hold an important place in knowledge development in the human sciences.

GROUNDING THEORY

Grounded theory refers simultaneously to a method of qualitative inquiry and the products of that inquiry. Like most discussions of grounded theory, this entry emphasizes the method of inquiry. As such, the grounded theory method consists of a set of systematic, but flexible, guidelines for conducting inductive qualitative inquiry aimed toward theory construction. This method focuses squarely on the analytic phases of research, although both data collection and analysis inform and shape each other and are conducted in tandem. The analytic strategies are inherently comparative and interactive; this method guides researchers to make systematic comparisons and to engage the data and emerging theory actively throughout the research process.

Grounded theory developed from the codification of the methods that its originators, sociologists Barney G. Glaser and Anselm L. Strauss (1967), used in their study of the social organization of dying in hospitals. Their pioneering book, *The Discovery of*

Grounded Theory, set a new course for qualitative research in sociology and beyond and left a lasting imprint on both the grounded theory method and social scientific inquiry, in general.

The significance of Glaser and Strauss's book must be placed in its historical context. Despite long-standing qualitative traditions largely at the University of Chicago and the impressive contributions of its faculty and students, qualitative research had waned by the early 1960s as sociologists and other social scientists increasingly turned to sophisticated quantitative methods. At that time, survey research was gaining dominance in sociology. As Antony Bryant and Kathy Charmaz (2007) point out, survey research commanded funding, positions, and the development of research institutes while its proponents controlled departments, students, and major journals. A few doctoral departments had specialties in qualitative research and a small cadre of ethnographers published vibrant studies; nonetheless, qualitative research became increasingly marginalized in sociology.

Publication of the *Discovery* book stood as a methodological marker that countered the increasing hegemony of quantitative methods and changed the status of qualitative research. Glaser and Strauss challenged numerous sociological conventions of the day. They disputed the sharp divisions between data-collection and analysis phases of research. Throughout their book, Glaser and Strauss argued against the growing division between theory and research. They contended that the grand theory of mid-century scholars failed to explain empirical phenomena and the narrow empirical studies of quantitative researchers failed to generate theory. Moreover, Glaser and Strauss proposed that scholars could develop theory from qualitative research.

Not only did Glaser and Strauss put forth a powerful rhetorical statement about the place and promise of qualitative research, but also they provided a set of flexible strategies that guided the analysis of qualitative data. They presented the first detailed, systematic attempt to codify qualitative analysis—and, simultaneously, to develop middle-range theories through subjecting data to rigorous analytic scrutiny. Since 1967, Glaser and Strauss's message inspired both students and seasoned researchers to pursue inductive qualitative research. Perhaps ironically, many more researchers claimed allegiance to grounded theory to justify their research than actually used the method itself for conducting it.

The guidelines that comprise the method reflect Glaser and Strauss's divergent backgrounds. Glaser's

doctoral training in quantitative methods at Columbia University gave grounded theory its rigor. He sought to codify qualitative methods in an analogous way as his mentors had codified quantitative methods. Much of the logic and language of grounded theory reflects Glaser's background and simulates that of quantitative research. This language has distinguished grounded theory from other qualitative approaches, but also it has led to obfuscating several of its major strategies.

Strauss's contrasting background emanated from his doctoral studies at the University of Chicago where the traditions of pragmatism, symbolic interactionism, and ethnographic fieldwork permeated his consciousness and lengthy career. Strauss brought pragmatist emphases on action, meaning, language and the provisional nature of truth to grounded theory. Strauss's pragmatist and symbolic interactionist foundations imparted notions of individual agency, interactional indeterminacy, and the multiplicity of perspectives, all of which gave grounded theory its open-ended character. Both Strauss and Glaser emphasized inductive inquiry, emergent processes, and the modifiability of theory.

The *Discovery* book outlined key methodological strategies but Glaser's (1978) manual, *Theoretical Sensitivity*, first elaborated the grounded theory approach, and Charmaz (2006) and Corbin and Strauss (1998) later offered distinctive versions. (See all these works for detailed descriptions of grounded theory strategies.) Glaser (1978) delineated his concept-indicator model of theorizing, outlined sets of loosely related theoretical codes, advocated line-by-line coding of data, and established the analysis of basic social processes as the focus of grounded theory studies. In all versions, grounded theory begins with very early close coding of collected data. The initial coding aims to ask what is happening in these data and invokes short analytic labels in the form of gerunds to identify specific processes and treat them theoretically. From the beginning, then, grounded theory coding differs from most types of qualitative coding, which rely on pre-established static topics and general characteristics. When researchers define a set of tentative codes, they use these codes to compare, sort, and synthesize large amounts of data. Throughout the process, grounded theorists write memos elaborating their codes by identifying their properties, the conditions under which the code arises, and comparisons with specific data and other codes. Memo writing (a) engages researchers with their data and emerging comparative analyses, (b) helps them to identify analytic gaps, (c) provides

material for sections of papers and chapters, and (d) encourages researchers to record and develop their ideas at each stage of the research project. By writing successively more analytic memos, researchers raise the theoretical level of their work.

The strategy of theoretical sampling distinguishes grounded theory and makes it much more than a coding system. Theoretical sampling means that researchers seek and sample data that informs their theoretical categories. Thus, theoretical sampling differs markedly from representational sampling with which it is often confused. Researchers engage in theoretical sampling after they have selected key categories and need to elaborate and or refine them. Such further analytic work may prompt grounded theorists to sample in entirely new empirical areas from those in which they began their study.

Another major methodological concept, but one that is not so well articulated, is theoretical saturation. For grounded theorists, theoretical saturation means seeking data to identify and fill the properties of a theoretical category. Researchers often erroneously believe that they have achieved theoretical saturation when their data become repetitive. They may gather repetitive data without filling the properties of their categories. Further problems arise concerning what constitutes saturation. Most researchers assert saturation rather than provide evidence for it. Trite categories are easily saturated, thereby leading to low-level analyses that do not account for variation in the category or process being analyzed.

After researchers have constructed a set of developed categories, they sort their memos, explicating these categories according to the logic of their theoretical analysis. This theoretical sorting of memos forms integrates the sections of the paper or chapter. Grounded theory strategies enable researchers to avoid being overwhelmed by unanalyzed data and incomplete ideas because grounded theorists write memos all along that give them readily available materials to sort and integrate. The method fosters developing sections of the analysis throughout the research process.

At least two other versions of grounded theory methods have emerged since publication of *The Discovery of Grounded Theory* and of *Theoretical Sensitivity*. Strauss and Corbin's 1998 methodological manual, *Basics of Qualitative Research*, first published in 1990, constituted the first major departure from the earlier books in that it lacked their depiction of a flexible approach, emphasized verification rather than emergence of concepts, and added two new technical procedures.

Strauss and Corbin added another type of coding, axial coding, in which researchers would treat a category as an axis around which they identified the dimensions of its properties and established its relationships to other categories. In addition, they proposed that researchers develop a conditional matrix to map intersections of micro, meso, and macro conditions on actions and to outline connections between these levels of analysis. In Glaser's (1992) rancorous response to *Basics of Qualitative Research*, he requested that Strauss and Corbin withdraw their book and rename their approach. Glaser viewed their emphases on preconceived procedures and verification as undermining the method, which he had based on emergent concepts and theory construction. Since then, he has presented his concept-indicator version of grounded theory as the classic statement, despite having abandoned several of his main strategies such as line-by-line coding and the analysis of basic social processes.

Constructivist grounded theory, as Bryant and Charmaz each first articulated separately (Bryant, 2002, 2003; Charmaz, 2000, 2005, 2006) and recently together (Bryant & Charmaz, 2007) has emerged as the major alternative to the earlier versions. Constructivist grounded theory assumes that both the research process and the studied world are socially constructed through actions, but that historical and social conditions constrain these actions. The constructivist version of grounded theory retains, and even stresses the key facets of the method as outlined above, but recognizes that the researcher plays an active and vital role in the research process, particularly in the developing dialogue between researcher and data from which codes and categories, and eventually a grounded theory should result. Hence, this form of the method strengthens the basic guidelines by attending to issues such as reflexivity, the research context, the inescapable effect of prior knowledge and existing literature. It also offers insights into the ways in which new theoretical insights develop by engaging with epistemological issues, and so provides a more sophisticated account of induction and deduction than that contained in the early books on the method.

Adele Clarke (2005) also adopts constructivist principles and combines them with postmodernism in her revision of grounded theory, called situational analysis. Bryant, Charmaz, and Clarke advocate adopting key grounded theory strategies devoid of their positivistic underpinnings that include the discovery of an external reality, an objective social

scientist, quest for explanation and prediction, and erasure of how the conditions of the research process, including the researcher's experiences and subjectivities affect the research process. Instead, constructivism takes a relativistic view and emphasizes: (a) the social conditions of the research situation; (b) the researcher's perspectives, positions, and practices; (c) the researcher's participation in the construction of data; and (d) the social construction of research acts, as well as participants' worlds. Constructivism retains the central foci of action, process, and meaning in earlier versions, but favors theoretical understanding over explanatory generalizations. Constructivists attend to locating their analyses in the specific historical, social, and interactional conditions of their production, rather than constructing concepts abstracted and separated from their origins. In short, constructivists seek abstract understanding of empirical phenomena as situated knowledge.

GROUP INTERVIEW

See FOCUS GROUPS

H

HARM

Nonmaleficence, a core principle of many ethics codes, is a duty to avoid, prevent, or limit harm to others. In qualitative research, the concept also includes harm or injury to feelings, privacy, confidentiality, or reputations of participants. Sometimes considerations about harm are extended to the larger population from which participants are sampled. For example, embarrassing findings of misconduct within a specific group category may be perceived as harmful to the larger group.

There is controversy about how researchers should practice nonmaleficence. A common rule to prevent or limit harm is to employ methodologies that present minimal risk to participants. Minimal risk is usually defined as the degree of harm or discomfort that research participants would encounter in their routine daily lives relative to the research design. For example, if interviewees were first exposed to extreme heights and then asked to report on their feelings, the potential harm (fear, panic) would be different for a sample of cliff divers versus a sample of acrophobics (people who are afraid of heights). Therefore, in order to evaluate the threshold of harm, it is important for researchers to have an understanding of the everyday lives of their participants.

Two well-known examples of harm in social research are Philip Zimbardo's 1973 Stanford Prison Experiment and Stanley Milgram's series of experiments on obedience to authority in the 1960s. In the Zimbardo experiment, students played the roles of guards and inmates in a mock prison. In this controversial study, the students who were taking the part of guards soon began to act sadistically toward the prisoners, who were humiliated

and experienced severe stress. Although a 2-week experiment had been planned, it was terminated after 6 days because of the psychological harm the participants were experiencing.

In the Milgram study, participants were led to believe that they were giving ever-increasing electric shocks to another person who was concealed behind a wall. The majority of the participants continued the shocks to the highest level, as instructed by the experimenter, but they also demonstrated significant emotional distress, even seizures. Although the Milgram study has been criticized for its use of deception and the distress caused to participants, a follow-up study showed that fewer than 2% of the participants had negative feelings about the experiment. The interpretation of harm is therefore highly subjective and difficult to measure.

While considering the nature of harm that may arise in qualitative research, it is also important to anticipate potential benefits of the research, to question whether participants are aware of the potential harm before they give consent, and to develop strategies either to minimize the harm as they occur or to remedy them afterwards. The principle of proportionality suggests that the greater the potential harms arising from research, the greater is the care required to address those harms. Finally, it is important to determine whether participants perceive harm in the same manner as the researchers or ethics review boards. Researchers and ethics boards sometimes try to prevent all harm, although this concern may not be shared by participants.

HEALTH SCIENCES, QUALITATIVE RESEARCH IN

Qualitative inquiry has made an important contribution to our understanding of health and illness over the past 40 years. Since the 1920s, qualitative research has been used by anthropologists to delineate beliefs about health and illness in various cultural groups, often in what they called “primitive natives.” In the 1960s and 1970s, sociologists began using ethnography and ethnomethodology to study health and illness in American cultural groups. From this era, several classics arose—most notably, *Boys in White*, an ethnography of medical students by Howard Becker and his colleagues, published in 1961.

In the late 1960s and early 1970s, qualitative research made inroads into nursing through nurse-anthropologists, such as Madeleine Leininger (University of Washington), Pamela Brink (University of California, Los Angeles), and Marguerita Kay (University of Arizona) and through the development of grounded theory by Barney Glaser and Anselm Strauss (University of California, San Francisco). These researchers, with their colleagues and students, made important contributions to qualitative inquiry in three ways: (1) they conducted qualitative research and published the results in nursing journals, thus bringing qualitative inquiry to the attention of the nursing academic community; (2) in the training of their own doctoral students and the publication of qualitative methodology, they built a strong foundation for qualitative health research and the mentoring of a new generation of students; and (3) they brought qualitative inquiry into basic graduate programs and to the attention of funding agencies. Four decades later, qualitative inquiry is integrated into most graduate curricula and is used by most allied health disciplines (such as physical therapy, occupational therapy, and medicine). Specialized qualitative journals (such as *Qualitative Health Research*) and qualitative proposals are funded at the federal level.

Qualitative health research conferences are well attended, and conducting qualitative health research is no longer a marginal activity.

Qualitative research has made significant advancement to the understanding of health and illness, to the provision of care, and to professional development and education. In order to achieve this advancement, qualitative methods have been modified for use with the ill and data collection in institutions. The perspective or context is unique in qualitative health research and certain qualitative methods have been more suited to this task than others. This entry reviews the major areas of qualitative research in the health sciences and describes the modifications made in adapting qualitative methods to this field.

Major Areas of Qualitative Health Research

The main areas within qualitative of research and the ways that qualitative methods are adapted when used in health research are as follows:

Delineating Health

Qualitative methods have made a major contribution in the understanding of health, in developing definitions of health, in eliciting perspectives of various populations about health, and in describing processes used for attaining health. Most commonly, this work is conducted using ethnographic methods and with a variety of types of interviews. Participant observation has also been particularly successful in eliciting this information by revealing discrepancies between what people say they do and what they actually do to become healthy.

Nevertheless, these studies have remained at the descriptive level, and relatively few models or theories of health have developed from this work. This research has identified the most optimal way to provide health education in community programs, to evaluate health programs, and to ascertain why various programs have failed. This important research could not have been achieved through quantitative methods.

Impediments to Health

Also categorized under health are a large number of studies investigating discrepancies in health; that is, why individuals in communities, cultural groups, or segments of the population are not uniformly healthy.

Many of these studies use participant action research (PAR) and ethnography, exploring community and cultural beliefs and values, determining what conditions result in poor health behaviors (such as infant bottle-feeding, smoking behaviors, or drug and alcohol use), and identifying what impedes the acceptance of care (such as noncompliance with immunization programs and poor diabetes care). This research provides valuable insights into programming so that community services may be targeted and become more effective. When a large survey or expansive geographic area is involved, both qualitative and quantitative methods combine to provide a comprehensive understanding of the phenomena under study.

Understanding Illness

Some qualitative health research has focused on patients with diseases, describing what it is like to experience various medical conditions. In this research, it is assumed that each disease produces a unique set of symptoms, and these in turn result in a different experience of illness for those who are afflicted. This research is important for symptom and disease identification, which occurred informally in the 18th and 19th century, and continues as new diseases are identified. The significance of recognizing symptoms using qualitative methods is clear when one examines the research describing cardiac symptoms, particularly in women. The onset of myocardial infarction symptoms is often vague and ambiguous, yet morbidity and mortality may be greatly improved if people with symptoms report for care early. Careful qualitative description of these symptoms can then be communicated and included in brochures and other lay reading materials, hence enabling those developing these symptoms to report for emergency care earlier than they would otherwise.

Experiencing Illness

By far the largest category of qualitative health research is referred to as *experiencing illness*. These studies may be categorized as dealing with the meaning of illness to the afflicted, the ways in which illness disrupts everyday life, and the experience of becoming a patient.

Studies exploring the context of illness are focused across the life span—for example, studies of the pregnant mother's diabetes, the child's or adolescent's

management of diabetes, an adult living with diabetes, or the coping of the elderly diabetic. This research may also be gendered, as in research on how illness affects males and females, and causes role-disruption. There are also descriptions of the illness experience of for individuals of different cultural backgrounds. There are ethnic studies about the language, food, and beliefs and values (such as religion, modesty norms, and caregiving), as well as studies of illicit behavior, such as drug and alcohol use or abuse, or variation in the experience of pain and pain behavior cross-culturally. Qualitative researchers often focus on vulnerable populations—the hospitalized who may be dying, mute (due to mechanical ventilators or to Alzheimer's disease), incarcerated, homebound, or homeless.

The Experience of Caregivers

Qualitative researchers have studied professional caregiving and have written extensively about becoming a physician and the doctor–patient relationship. They have documented the uncertainties of medical students, beginning with the initial shock of anatomy dissection, then first surgical procedures, and the first encounters with death. Qualitative researchers have also documented the moral and ethical dilemmas that occur in the practice of medicine and have uncovered the nature of the decisions that physicians make in daily practice. For example, there are a large number of qualitative studies that examine the breaking of bad news. This research, written primarily from the physician's perspective, uncovers the harm that may occur to patients and their families when information regarding the prognosis is given insensitively or without consideration that the patients are people. These findings inform practice and instruct physicians how to provide shattering information gently.

There is a parallel literature on becoming a nurse. These studies describe what it is like to be a neophyte nurse; to be a more experienced nurse, yet carry a caseload beyond one's capabilities; or to cope with emergencies that one has not previously encountered. Some of this research gets to the heart of these problems, describing the human side of caring and the developing nurse–patient relationship. Some of this literature is phenomenological, providing insights into the meaning of caring, suffering, and fatigue. Some of this research uses grounded theory, showing how one develops relationships or how one copes with the

nuances of nursing, developing mid-range theories. Some of this research uses ethnography, describing, for instance, nurse–patient interaction in the intensive care unit (ICU) when the intubated patient cannot verbalize, and providing clear and concise strategies to enhance communication with these patients. Other research uses narrative inquiry so that nurses may learn from patients’ or other nurses’ stories about what a certain experience is like, hence informing their own practice. Some of this research uses videorecorded data and microanalysis so that nurses can study, for instance, implicit patterns of touch or the pain responses of infants. Finally, some of this research is evaluative, and from this research, modifications to care, or new patterns of care, are developed.

Although qualitative inquiry was introduced later into allied health care professions than nursing, similar areas of expertise are developing in these professions and, as equally important, are being incorporated into practice. Qualitative theories are providing frameworks for practice, enabling the identification of concepts particular to illness or to each profession, and qualitative meta-synthesis is enabling assessment of aggregated research, enhancing the understanding of caregiving.

Rarely do caregivers nurse individual patients; rather, they nurse families, including the sick person as well as his or her significant others. Qualitative researchers describe how family units respond to the threat of illness, assist each other when one member is ill, and how the family constellation forms a mutually supportive unit in times of crisis. Qualitative research informs one on how to interact with the family as a unit and on how to support the family so that family members may support each other and the sick family member. Similarly, qualitative research informs caregivers on how to support groups and on how to care for the communities.

Research and the Context of Care

The context of care is important in qualitative inquiry, for unlike laboratory research, the researcher has no control over the research interventions and is a guest of the participants. Most important for successful fieldwork is the gaining of trust prior to commencing data collection, for until the participants become accustomed to being observed, the reactive effect of the researcher’s presence may invalidate the data. Thus, all fieldwork data collection is invariably

preceded by a period of “getting in,” during which the participant gets to know the researcher, and the researcher becomes a part of the group.

Research on the family unit often takes place in the participants’ homes. This research may be done through regularly scheduled visits, or the researcher may even live with the family. These research topics include patterns of family caregiving, social support, patient dependency, nutrition, care of the mentally ill, bereavement and grief, or dying alone. Often, this research is disease focused—for instance, on persons living at home following a stroke or persons with AIDS who are cared for in the home—and family units as participants are selected accordingly.

Frequently, the focus of research is on studies of small groups; for instance, gangs in the community. In this case, researchers overtly seek to become a part of the group, without being involved in illicit or illegal behaviors. Studies of drug use, homelessness (including street kids), and prostitution have been conducted and have provided important insights into the lives and health of these marginal groups.

Often, the institution is the domain of the research project. If the researcher is a physician or a nurse, accustomed to hospital norms, fitting in is relatively easy. These researchers know who to approach, when, and where and can identify the best time, for instance, for interviewing or observing care. However, researchers who are not accustomed to hospital routines, sights, sounds, and smells will have to spend some time becoming familiar with the setting and with getting to know what is going on before beginning fieldwork. They must learn how to enter certain areas, where they can and cannot go, and when. Finally, they must learn institutional standards of conduct, such as the ethics of confidentiality.

Exploration of health care in the community is a large component of qualitative health research. Ethnographic methods are used to identify those persons with unmet needs who are falling through the cracks in the health care system or who refuse, for instance, to seek care in the clinics.

Much research is conducted in community organizations: Focus group research is often used for identifying community needs, examining programs of care, or evaluating the efficacy of health promotion programs. Although some of this research is quantitative, using quasi-experimental design and statistically measuring the efficacy of program outcomes, qualitative research is used to investigate the processes of

changing health behaviors and to determine insider perspectives within programs.

Some qualitative inquiry may be classed as urban and rural, with the rural sociologists focusing on health in farmers, their wives, and families or of isolated small communities. Urban health may study factories, city apartment buildings, or even construction sites.

Qualitative health research is conducted at the sites of major disasters. These disasters usually involve large populations and high morbidity and mortality, such as natural (e.g., the Sichuan, China, earthquake) or weather-related disasters (e.g., hurricanes, such as Katrina in and around New Orleans in the United States) or terrorism (e.g., the September 11, 2001, attacks on the World Trade Center in New York City). Qualitative researchers study the effects of survivorship, such as grief and bereavement; forced relocation and migration; adaptation following the loss of one's family, home, and community; and adjustment following injury.

The experience of rescue workers is also an important area of inquiry. Firefighters or soldiers may experience posttraumatic stress or other serious and disabling psychological problems; qualitative inquiry provides important knowledge regarding their experiences, debriefing, and recuperation.

The Education of Health Professionals

The last substantive category of qualitative research in the health sciences is the examination of educational processes in health professionals, role acquisition, and patterns of care.

Becoming a nurse or a physician is a complex process. In addition to the disciplinary lecture style learning, students must learn anatomy and pathophysiology in the anatomy lab (initially on models and then with cadavers), then with patients in rounds, in supervised practicum, and when they become more expert, as they provide care. Qualitative researchers have documented these processes of learning extending from student to expert practitioner, and have documented the intuition and its role in client assessment. Conversational analysis has documented exactly what is said in the caregiver-patient encounter, how nurses care during childbirth in the ICU and in trauma care or how they care for palliative patients.

Finally, evaluation research has been used to evaluate care and patterns of care in time-and-motion studies and studies of nurse workload and physician caseload. Patient satisfaction is an important part of

evaluating services, and usually, such studies use mixed-method design, with qualitative interviews a major component of the evaluation and accompanied by statistical indicators of care.

Modification or Adaptation of Qualitative Methods for Health Science Research

Developing concepts and theories that describe illness and health seeking behavior is essential in qualitative research in the health sciences. In nursing, the theoretical base is thin and in need of theoretical development—something that can best be achieved using qualitative inquiry. Further, to achieve the knowledge domains discussed above, there has been considerable modification of qualitative methods. This adaptation was essential not only because methods must be changed to access ill participants, but also because the priority of care in the hospital supersedes research agendas. Both of these features are discussed in the next section.

Methodological Strategies for Approaching Health and Illness

Qualitative inquiry's greatest contribution is in the identification of knowledge, concepts, and theories. Interpretative description identifies the unspoken, enabling insights into care. Similarly, microanalytic description, using videotape, enables the examination of facial expression, of transient nurse touches, and the fleeting responses of patients.

Important work over the past decade is in the delineating or development of concepts. The abstract nature of this work allows for the generalization of concepts across contexts and populations and ultimately the development of higher-level explanatory theories.

The majority of theories developed thus far in health care have been mid-range theories developed from grounded theory. The earliest of these was about dying in hospitals by Barney Glaser, Anselm Strauss, and Jean Quint Benoliel. Since that time, a number of mid-range theories has developed about normalization (Janice Morse & Sharon Wilson; Kathy Knaf), hope (Kay Herth), transcendence (Pamela Reid), fatigue (Karin Olson), reformulation (Barbara Carter), enduring (Janice Morse), caring (Madeleine Leininger and others), and comfort (Janice Morse). Of importance are the mid-range theories that describe processes and change, primarily trajectories of care (Julie Corbin).

Higher-range theories are less common, and there is a need to develop theories of broader scope by linking concepts and mid-range theory. Suffering is a higher-range theory that is moving toward this level of theory development, building on the work of Eric Cassell, on social suffering (Arthur Kleinman, and colleagues), and enduring and emotional suffering (Janice Morse and colleagues). Other theories are developing in the area of social support (Miriam Stewart & Ann Neufeld) or with the parturient woman (Joyce Roberts), but these have not been consolidated to a single theory thus far. However these areas hold tremendous potential, and it is only a matter of time before major theories emerge.

Physical Alterations and Data Collection/Analysis

Data collection when the participants are ill requires special skills and adjustment. Sick patients may not, for instance, be able to be interviewed because they are mute—for example, even if they are cognitively aware, intubated patients are not able to speak. They may communicate by other means, using a pen and paper or by signaling, but such means of communication gives poor data for research purposes. Some researchers have elicited the experience of being on a respirator by asking these patients to tell their story after they have been weaned from the respirator or have used observational research—participant observation or videorecorded data.

Researchers who have tried to conduct qualitative inquiry with confused patients as participants have encountered similar problems. Again, depending on the level of confusion, observational methods were found to be more useful than interview methods. However, in her study with psychiatric (schizophrenic) patients, Beverly Lorencz noted that, after asking a question, if she waited, an answer would eventually come. These disturbed patients first talked to the other voices, and Lorencz had to wait her turn. Alterations in reality are part of the patient's reality and must be included in the data, no matter how bizarre.

Patients in hospitals, especially if they are on certain medications, may not be able to be interviewed because a dry mouth or the lack of dentures may make speaking difficult. The patient may be in pain, have a headache, be on pain medications, and/or be too sleepy to be disturbed. In my own research with trauma patients, interviews were not possible, but the patient could

sometimes answer single questions. Nevertheless, the primary data were obtained from video cameras attached to the wall of the treatment room. Such shooting without any control of the camera means that one's data is poor when caregivers surround and obscure the patient, but the sound is still clear. The best data are often only what one can get.

Because of the responsibility that the hospital has to patients, their next of kin, and to society in general, security is essential when data are collected in the hospital setting. The researcher must gain permission from hospital administration both to conduct the study and to enter the premises. Researchers cannot then simply walk into a patient's room. Researchers must get permission from the charge nurse and the patient's primary care nurse to check that it is convenient to visit the patient, that the patient is well enough to be interviewed or observed, and that such a visit will not interfere with family visiting or any scheduled treatments or rounds. Once all of these conditions are met, researchers may place a sign on the door stating that an interview is in progress. If the participant is critically ill or injured, it goes without saying that his or her care has priority over data collection activities.

HEGEMONY

Most basically, hegemony refers to the domination of one group of people over another. More specifically, and more relevant to critical qualitative research, it refers to the domination of the ideas of one group over those of another. As such, hegemony refers to the mainstream deployment and acceptance of ideologies that justify the inequities inherent in modern society including capitalism, sexism, racism, and so on. Hegemonic domination can take place with or without the use of

physical force; however, it is often domination achieved not by force, but through ideological means.

Hegemony as a concept was first employed in Marxist thought in the mid- to late 1800s. Marxist conceptions focused on political leadership and domination by the ruling bourgeois over the subordinate working class proletariat through politically endorsed systems of economic and material distribution. The term *hegemony*, however, was coined by Antonio Gramsci (1891–1937) and most fully explicated in his work *Selections From the Prison Notebooks*. This work was conducted from 1929–1935 by Gramsci while he was imprisoned in Italy for his role in the development of the nation's Communist Party. Gramsci's work extended Marxist thought beyond its focus on capitalist struggle to an analysis of intellectual struggle and the role of external forces such as the mass media in stifling creative thought. He contended that the masses remained in their oppressed position because society did not allow them to imagine a different way of living; lacking such a conception, they were unable to conceive how they could challenge the prevailing system. Thus, Gramsci freed Marxist thought from economic determinism as he allowed for autonomic individuals, yet placed them within a system of communicative power that encompassed the state, the media, and social interaction.

Hegemony is of interest to qualitative researchers as a lens through which ideologies can be identified, documented, exposed, and used to create alternate ideology. Given the political nature of such research projects, it is no wonder that research into hegemonic thought is concentrated within critical research approaches, such as critical ethnography and critical discourse analysis, which aim to make explicit and often challenge power hierarchies.

No one method suits the collection of data useful to the examination of hegemonic structures or thought. Rather, as Gramsci notes, hegemonic ideologies operate through such social systems as the media, the state, and everyday communicative action. As such, a variety of social artifacts can produce data on prevailing hegemonic thought, including key informant interviews, documents, media analyses, observation, and diaries. These sources can reveal prevailing ideologies used to maintain and enforce existing social structures. Critical data analysis techniques such as critical discourse analysis and reconstructive analysis, as outlined by Phil Carspecken with reference to critical ethnography, can then identify sites of hegemonic thought that can be

woven together to produce a picture of how ideologies are circulated, produced, and reproduced to perpetuate existing inequities that benefit the ruling group.

HERMENEUTICS

From the Greek *to interpret* or *to make clear*, *hermeneutics* is the study of the theory and the practice of understanding and interpretation. It is built on the assumption that interpretation is not a straightforward activity even though people do it all the time when they interact with others and the world. The concept is based on Hermes, the Greek mythological god of boundaries and of those who cross them, who is said to have translated the gods' messages for humans. To do so successfully, he had to understand both the language and the mind-set of the gods (so as to communicate the intended message) and those of humans (so as to communicate it in a way they could understand). It is this space of encounter, this boundary between person and text, person and person, or person and world where meaning is open to interpretation that is of interest to researchers who draw from hermeneutics. This entry explains the nature of hermeneutics and provides a brief overview of its influence on Western thought since the 18th century. Then focusing on philosophical hermeneutics, it describes how the interplay of tradition, language, dialogue, experience, and context contribute to its theory of interpretation. Finally, the role of hermeneutics is examined in qualitative research.

Hermeneutic Traditions

Hermeneutics originally focused on the interpretation of sacred and legal texts and has developed into an influential school of thought in continental philosophy as well as in applied social research. Immanuel Kant's (1724–1804) insight that there is no access to an uninterpreted or atheoretical world of knowledge but rather that the mind actively makes sense of the world based on prior conceptual frameworks paved the way for hermeneutics as it is known today.

Friedrich Schleiermacher (1768–1834) was one of the first philosophers to theorize that hermeneutic thinking is a universal and natural part of being human in a social world rather than simply an application of strategies for interpreting texts. Schleiermacher distinguished between two forms of interpretation: acts of interpretation that happen all the time as people encounter texts or the world around them and on which they act without much thought and those that deal with ambiguous, complex texts or situations where understanding is not immediately available or clear and for which a doctrine of interpretation—hermeneutics—is needed.

The door Schleiermacher opened up—that understanding and interpreting are naturally occurring, innate human abilities, as well as human inabilities—is at the core of modern hermeneutics. If people always understood correctly or readily, then bureaucrats, teachers, therapists, researchers, and other social interpreters would not be needed to assist with obscure texts or unfamiliar points of view. It is because understanding can be manipulated, mistaken, and misguided that hermeneutic theories of understanding take into account the social, cultural, and political contexts, past and present, in which understanding and misunderstanding take shape. It is also because humans continue to make sense of the world around them and act on those interpretations regardless of their familiarity, interests, or knowledge that understanding the process of understanding is a core issue in social research. Contemporary hermeneutic approaches are, therefore, concerned with the processes through which understanding and interpretation occur, the truthfulness of interpretative statements, and the conditions for new understanding. They differ, however, in their focus and purpose.

When discussing the interpretation of a text—for example, a story told by another—conservative hermeneutic theorists follow a methodical approach

involving bracketing out their foreconceptions to find the true meaning of the story that is determined as the author's intent. Wilhelm Dilthey (1833–1911), Emilio Betti (1890–1968), and Eric Donald Hirsch, Jr. (1928–) have all been interested in developing a methodical approach to hermeneutics. For these theorists, preconceptions are identified and controlled in order to get to the truth of that which needs interpreting. *Critical* hermeneutic theorists—suspicious that any text can reveal the meaning of an author—seek instead to uncover the shaping presence of history, power, and ideology evident in the author's expression as well as in the reader's interpretation. Exposing ideological traces involves a critical and reflective process that ideally allows the author and reader to create more empowering interpretations from which to act. Paul Ricoeur (1913–2005) and Jürgen Habermas (1929–) are most often associated with this approach. In contrast to both of these approaches, *philosophical* hermeneutics emphasizes neither the text nor the reader; rather, the focus is on the event of understanding or interpretation as it occurs in the encounter between reader and text. Unlike conservative hermeneutics, the reader's foreconceptions are not bracketed out; they are understood as creating the intersubjective link necessary for engagement with the text. However, like critical hermeneutics, the purpose of philosophical hermeneutics is the creation of deeper or new understanding, and that means disrupting, to a certain extent, the imposition of one's preconceptions on the text as it is encountered. This process cannot be controlled, however, since there is no method that can predict in advance which prior conceptions or judgments will enable understanding from those that might obscure or distort it. It is during the interpretive process that these influential forces are revealed, and so it is only then that they can be contended with. The question of what this self-examination entails is at the core of philosophical hermeneutics. Martin Heidegger (1889–1976) and Hans-Georg Gadamer (1900–2002) are primary figures behind this approach.

Although Schleiermacher advanced the notion that a method for interpretation was essential to guard against misunderstanding and paved the way for Dilthey, he also pointed out that the human potential for misunderstanding was the result of limited exposure to alternative viewpoints and that increasing the plurality of experience would increase the likelihood that understanding, not misunderstanding would occur. It is on

this transformative potential of experience that Heidegger and Gadamer have built their hermeneutics. Furthermore, they argued that the experience of being in the world is the basis for understanding and interpretation, not a separate event. Humans do not first look at the world and then understand it, but they live out their understandings every day. For this reason, interpretation cannot be reduced to a predetermined method, but it occurs interpretively during the interpretive process itself.

Historically Effected Consciousness

As Kant made clear, an unsituated and uninterpreted state of being does not exist. Gadamer spoke of “historically effected consciousness” to describe the condition of being shaped and continuously reshaped by multiple horizons of meaning or traditions and the conscious self-awareness of being so effected. In contrast to theorists who suggest suspending the influence of tradition during the interpretive process, Gadamer believed that it is only by engaging tradition that understanding is possible. Tradition may not only constrain understanding by limiting available perspectives, but it also enables it by providing points of connection to the text or words of the other. Furthermore, tradition is not a stable, unitary perspective from which everything is viewed, but is made visible in the prejudices and assumptions that are aroused by the text or another. The idea of bracketing, therefore, misunderstands the role of tradition and the role of the other in understanding. That is, different prejudices emerge and different words are spoken about a topic in a conversation with a friend or a researcher because each situation gives expression to a different structure for understanding and thus to a different interaction between tradition, the object of consideration, and the person with whom people are in dialogue. Like Hermes, the interpretive event is affected simultaneously by prior experiences with the topic and the audience with whom the topic is being explored. The meaning that is made, therefore, is not prethought, but is brought forth in the event of participating in dialogue with another.

Heidegger used the image of a circle to convey the dynamic interplay between the object in the world that one seeks to understand and the subjective experiences of the object, past and present. When hearing a story, people project their own meaning (informed by tradition) into it. In turn, however, a point in the story might provoke an alternative interpretation, thus

promoting a new relationship between the person and the tradition. This new relationship informs one’s continuing interpretation until a new idea is similarly provoked. This process is not a linear, however, but happens in the process of understanding itself. In other words, everyday interpretive work is embedded in historical, cultural, and linguistic traditions, but as much as it is always oriented to present concerns—the topic at hand—is always under revision.

Understanding as Dialogue

Gadamer used the metaphor of a fusion of horizons to describe this process. *Horizon* denotes both the space (and the limiting conceptual framework) that one is located in and the presence of a beyond. Simply traveling a short distance, spatially or through one’s interaction with another, shifts both the location one is in and demarcates a new possible beyond. As people move and experience other frames of reference, their understanding of self and the world cannot help but to incorporate some of this worldly text into their own. Simultaneously, however, because people carry forward their prior experiences, people orient themselves to understanding in particular ways. Gadamer believed that the potential to develop new understandings occurs because of this interplay between one’s perspectives on the world (our traditions) and that which one’s current situation or concern arouses in one. It is during this encounter that people are most able to reflect upon the historically effected nature of their state of being in the world. It is in dialogue, Gadamer explained, that the experience of understanding is most productive because the other person, and therefore, his or her horizon, is simultaneously seeking expression alongside ours. The arousal of questions that the voice of the other awakens in people, or does not awake, is at the core of what Gadamer calls a genuine hermeneutic experience and is that for which a fusion of horizons strives.

Genuine Hermeneutic Experience

Heidegger argued that propositional statements, those that were used to “measure” or to account for understanding “scientifically,” could not account for the complexity of experience. To understand human experience, Heidegger explained, one must think beyond the statement to the experience itself or, as he put it, to that which strives to be brought forth in language.

Although Heidegger emphasized the experience of experience, Gadamer went on to develop the role language plays in bringing experience to understanding. Gadamer explained that the point of contact between self and others and between one's embodied experience and the expression of that experience is language. This point of contact necessarily means that in the process of bringing forth understanding in language, some aspect of experience remains unsaid. Simultaneously, the voice of the other or the topic at hand arouse some but not other aspects of what one and the other might mean. For Gadamer, new understanding requires that people allow themselves to engage in all that the conversation offers. As language unfolds, it reveals the prejudices of both speakers while also concealing areas where contact did not occur. Gadamer argued that a genuine hermeneutic conversation calls simultaneously for engagement in the experience of understanding, one that seeks out the possible meanings in both what is said and what is unsaid, and critical reflection on the structure of understanding that one is engaged in. This need requires a stance of active questioning and reflection that does not rest on first impressions, but seeks to expose and examine understanding's deeper, hidden meanings.

Hermeneutics in Qualitative Research

Hermeneutics challenges both the aim of social science and its reliance on a narrow conception of understanding encouraged by scientific methods. It alters the conception of inquiry from seeking explanations or understanding about someone or something to one of engaging with the dynamic and historically situated nature of human understanding. Inquiry, therefore, is no longer framed as a separate event from that which is being inquired into; both must be acknowledged in the final analysis.

Although not having an explicit method, hermeneutics has influenced the theory and practice of qualitative research in several ways. First, because language (and other symbolic meaning systems) mediates people's experiences of the world, qualitative inquirers are paying closer attention to the language used by research participants while also acknowledging the symbolic systems they too inhabit and that give shape to their study. Theorists, such as Clifford Geertz (1926–2006), have written extensively about the dynamic interplay involved when interpreting the interpretations

of others. Second, these contributions have informed how qualitative researchers talk about data collection, analysis, and representation, as each is seen as part of a dialogic, dynamic, holistic, and self-reflective process where interpretation and understandings are developed continuously along the way rather than as separate stages of a study. Finally, the hermeneutic potential that the space of difference between self and other opens up has caused theorists, such as Charles Taylor (1931–), to call on social inquirers to reenvision their role not as elicitors of information that benefit social science, but as promoters of cross-cultural dialogue where understanding of self and other occur concurrent to inquiring into the world people share.

HETEROGLOSSIA

Heteroglossia refers to the multivoiced nature of language. For studies of discourse, narratives, and text, heteroglossia and associated concepts provide a sophisticated sociological approach to analysis. Utterances and texts are populated with a multitude of social languages attached to specific ideologies or perspectives. Examples include professional jargons, peer group argots, and political or religious discourses. These “sociolects” are characterized by the social

stratum of speakers associated with particular social groups that are not equal in power or prestige. One sociolect may be authoritative and hegemonic, suppressing other voices, but all societies contain multiple social languages, some of which are engaged in opposition and struggle.

For Mikhail Bakhtin, who theorized heteroglossia, every utterance is multivocal, containing both a social language and a speech genre. A speech genre is not necessarily associated with a particular social group, but with particular forms of utterance and speech situations. Speech genres include poems, parodies, scholarly treatises, sermons, biographies, prayers, confessions, life stories, and everyday conversations. Genres enable creativity, but they also contain rules and structures that place parameters on utterances. Utterances, then, are shaped by social languages and genres, but they are also dialogic, containing at least two voices: the speaker's voice and the voice of the social language through which this is ventriloquated. The speaker as author incorporates the words and voices of others, but the utterance becomes the speaker's own when it is populated with his or her own intentions and accent and is appropriated for the speaker's own purpose.

An analysis of text or utterances from this perspective examines the sociolects and speech genres used and how the author combines different voices—words with different socioideological histories—into a unique utterance. Analysis also focuses on how utterances are socially charged and dialogically engaged with past, present, and future audiences and how they position the speaker vis-à-vis others. Anthropological linguists have used Bakhtin's ideas of heteroglossia, voice, utterance, and dialogism in the analysis of conversation and performances and the social work that speaking accomplishes. Others have employed these concepts to examine relations between social and personal facets of human development, especially the development of identity in cultural worlds. From this perspective, individuals' utterances are analyzed for the ways in which speakers orchestrate voices from their sociocultural worlds to create distinctive images of self and to envision their (future) social positions. To do these kinds of analyses, sociolinguistic diacritics or textually inflected ethnographies of speaking are useful.

HEURISTIC INQUIRY

The heuristic approach to qualitative research was pioneered by American humanistic psychologist Clark Moustakas. Although it is an exploratory approach to research, it is really quite different from other approaches in that it is not concerned with discovering theories or testing hypotheses, but is concerned directly with human knowing and especially, with self-inquiry. The term *heuristic* derives from the Greek word *heuriskein*, which means to *find* or *discover*, and is used by Moustakas to describe the process of an inner search for knowledge, aimed at discovering the nature and meaning of an experience. It is an approach that offers a significant departure from mainstream research in that it explicitly acknowledges the involvement of the researcher to the extent that the lived experience of the researcher becomes the main focus of the research.

In this respect, heuristic inquiry (HI) anticipates the growing awareness of the participatory position in which researchers find themselves placed. Although rarely acknowledged, in general research is often autobiographical in the sense that the research topic and research question are usually motivated by personal interests and concerns, and the results and findings of the research can have personal impact on the researcher in both subtle and profound ways. In the capture of data, the researcher can accumulate and access a range of tacit knowing that results from the participatory nature of the process. What HI does is make this participatory process explicit, and moreover, it makes this the major focus of inquiry.

To some extent, HI has remained on the periphery of the qualitative approach, and it is easy to overlook

its relevance to almost all research in the human and social sciences. It is a method that is being taken up gradually in such fields as education, psychology, psychotherapy, and counseling, as well as in theological and transpersonal studies.

There is clearly more involved in HI than researchers simply analyzing their own experience. Nor is it merely a variation on phenomenological inquiry. The strength of HI is in the way it sets out a systematic and transparent methodology for self-inquiry. Indeed, the heuristic approach is more systematic and rigorous than might usually be imagined, and as a consequence it is extremely demanding.

Moustakas stresses that HI is a way of knowing, involving a personal encounter; as he puts it, “there must have been actual autobiographical connections” (1990, p. 14). The self of the researcher is present throughout the process, the researcher experiences growing self-awareness and self-knowledge, promoted by self-search, self-dialogue, and self-discovery. In effect, it is the salience of the research topic and research question for the researcher that is being acknowledged. Indeed, what explicitly can be the focus of the approach is the transformative effect of HI on the researcher’s own experience.

The Development of HI

Heuristic research follows in a long and ancient tradition of self-inquiry, a method of inquiry that was desperately in need of being reinvented. It re-emerged in the 1950s and ’60s, when Moustakas developed the idea of HI through his own self-exploration of loneliness. In 1985, Bruce Douglass and Moustakas, in an influential paper, outlined a model of the heuristic process that included three phases: *immersion* (exploration of a question, problem or theme), *acquisition* (collection of data), and *realization* (synthesis). Then, in 1990, Moustakas elaborated the model further, identifying a core conceptual framework, with seven basic phases of inquiry.

In many respects, HI bears a striking resemblance to such approaches as autoethnographic research, which emphasizes the cultural context of experience, and also with autobiographical research, which emphasizes the life-story. There are also many similarities with William Braud and Rosemarie Anderson’s transpersonal inquiry, with John Heron’s idea of lived inquiry, and with mindful inquiry, a synthesis of four intellectual traditions: phenomenology, hermeneutics,

critical social theory, and Buddhism that has been developed by Valerie Bentz and Jeremy Shapiro. It is a matter of note that integration in the literature of these overlapping methodologies is sadly rather lacking.

The Influence of Michael Polanyi

The influence of the ideas of Michael Polanyi, a philosopher of science, on Moustakas cannot be overestimated. The concepts of tacit knowing and indwelling, and even the term *heuristic* itself, all stem directly from the work of Polanyi. These ideas were central to his major work, *Personal Knowledge* (1958). Polanyi’s critique of “scientific detachment” has been characterized as a *participative realism*, and a *heuristic philosophy*. Polanyi argues that at the root of all claims to objective scientific knowledge there is always a reliance upon personal knowledge. Such ideas may have been a little before their time, and marginalized by other philosophers, but it is to Moustakas’s credit that he has taken Polanyi’s ideas and used them so effectively.

The influence of Polanyi can be seen most clearly in Moustakas’s core conceptual framework. This includes: the need to identify with the focus of the inquiry; self-dialogue with the phenomenon being explored; the power of revelation in tacit knowing; and the key processes of intuition, indwelling and focusing. This is all set within the context of an internal frame of reference, within which all experience needs to be understood.

The Seven Phases of Heuristic Research

In practice, HI entails creating a story that captures the qualities, meanings and essence of a human experience. The process begins with a question or problem to which the researcher seeks an answer. This question or problem, whether explicitly or implicitly, will always reflect a personal concern of the researcher with respect to understanding them self, and the human world in which they live. Moustakas’s heuristic approach offers a structured sequence involving seven phases of inquiry.

1. *Initial Engagement*. Research begins with the discovery of an intense and passionate interest or concern with respect to important social and universal meanings that have personal implications. Initial engagement involves self-dialogue and an inner search helping to clarify the

chosen topic and the research question. Turning inward taps into tacit awareness and knowledge, and requires disciplined commitment in order to discern the underlying meanings and clarify the context.

2. *Immersion.* Following the discovery and clarification of the question, the researcher immerses in anything and everything connected with the question. This involves intense exploration, following trails of data, self-dialogue, self-searching, seeking out co-researchers with similar concerns and experiences, and facilitating the tacit dimension of knowing. It is a phase that might seem quite boundless.

3. *Incubation.* This is period of consolidation. Focus is relaxed, such that emerging ideas are allowed to take root. It may be important to take “time out” in order to create a space for ideas to germinate, or it may involve further more-focused work with co-researchers.

4. *Illumination.* This occurs naturally and spontaneously out of the relaxed and tacit state of the previous phase. There is a meeting of conscious and unconscious aspects of the phenomenon and the beginnings of a synthesis of fragmented knowledge emerges. There is insight, and emotional connection is made. The universal significance of the phenomenon is realized. A completely new discovery is made.

5. *Explication.* This requires a further period of indwelling and focusing in order to deepen, clarify and refine the new discovery, to gain a more complete understanding of the phenomenon. This is a more detailed process, involving continuous self-exploration and awareness. The researcher explicates the major components of the phenomenon in readiness for the final phase of integration.

6. *Creative Synthesis.* This is achieved through mastery of the data and inspiration from the tacit and intuitive dimensions. The focus is upon integration and synthesis, and the mode of its expression as a fully realized picture of the discovery. The researcher may explore any creative means that feels appropriate—for example, art, poetry, music, metaphor, and so on as well as description and narrative—in order to convey the purest essence of the phenomenon to the world.

7. *Validation of the Heuristic Research.* Moustakas regards the question of validity as one of meaning. The

heuristic researcher returns again and again to the data to check that the depiction of the experience is comprehensive, vivid and accurate. This is a judgment that in the first instance can only be made by the primary researcher. Validation is further enhanced through co-researcher validation. Nevertheless, a final validation must be left to how the research is received, through publication, presentation, or perhaps performance. Indeed, it is in sharing the creative synthesis with others that the validity of heuristic work is established.

Practical and Critical Issues

HI will not be for everyone, but for anyone interested in self-inquiry who wants a structured approach within which to work and who is not intimidated by research that can lead to unpredictable avenues of inquiry that can become a quest with no seeming closure, then it is to be seriously recommended.

It is useful to point out that, in effect, it is not the researcher who chooses the research question, but the research question that chooses them! Invariably, the research question is deeply personal in origin, and it may come to light as a major preoccupation that has been around for a significantly long time.

HI is a research process that is difficult to set any clear boundaries to, particularly with respect to duration and scope. It is a method that can be best described as following one’s instinct, but at the same time requiring the highest degree of transparency and thoroughness. It is a method of inquiry that should not be undertaken lightly.

HI highlights the importance of working with the heuristic process of others, especially with the historical recordings of previous inquiry. Indeed, it turns out that the works of writers, poets, artists, spiritual leaders, and scientists can all be usefully treated as the creative products of HI, which are validated by a participatory sharing with others, who in turn may be inspired to engage in their own heuristic study. And so the great chain of HI is moved along, originally as part of the ancient oral tradition, then down through the centuries as recorded and written tradition, and most recently as part of the empirical scientific tradition.

From a clinical perspective, there is a very striking similarity between the methods of HI and the practices of counseling and psychotherapy, particularly with respect to the use of the “self.” It is therefore a method of research that particularly resonates with inquiry into counseling and psychotherapy-related issues.

HI is not just a methodology, since it is possible to adapt the heuristic approach for specific purposes within other approaches to research. At the heart of the approach is a process of heuristic discernment, which can be recognized as a fundamental skill or process useful in any type of inquiry. This notion of discernment describes a participatory process of reflection and discovery, leading to fresh insight, greater awareness, or new conceptual or practical distinctions. It is at work at both the macro and micro levels of inquiry, and it not only helps promote reflexivity, but also is involved in the planning of inquiry, the collecting and analyzing of data, and the dissemination of the findings. It can be regarded as the basic skill that every qualitative (and arguably, every quantitative) researcher must develop.

Another example is the skill of heuristic indwelling, which is especially important with helping in the development of the skill of reflexivity. In addition, it is possible to view qualitative analysis as a process involving the systematic and rigorous application of indwelling or discernment. This process is particularly important in at least three ways: (1) indwelling especially stresses the participatory nature of tacit knowing, (2) indwelling is crucially involved in the sifting through and interpretation of data, and (3) indwelling seems to offer the possibility of a specific methodological tool within qualitative research.

HI is of importance to any researcher who is faced with the dilemma of the inauthentic exclusion of his or her own experience from his or her field of research. The promise of HI is that it offers a systematic way of incorporating the self into inquiry methods while ensuring a high level of reflexivity and transparency. Furthermore, it holds out the promise that some of the most significant, exciting, and urgent life events and extraordinary human experiences might be researched more closely.

HISTORICAL CONTEXT

Qualitative research addresses specific psychosocial and cultural issues in context. Context refers to the external characteristics of the situation to be studied that are situated outside the individual, group, or even institution or community that are the focus of interest. Historical context refers to past conditions, which influence the present. Most social scientists would agree now that individual behavior is shaped by broader social, economic, political, and physical factors that interact with psychological characteristics in specific place and time. To understand these broader factors, which are influential in the present, it is important to know how they evolved and what shaped them.

The historical context refers to political, social, environmental, and cultural decisions or events occurring over time that can be described and linked to the situation under study. Political decisions might include policies that promote warfare, attempt to control population migration, eliminate of social welfare benefits, or decide to move or amalgamate a neighborhood hospital or to introduce a school voucher program—policies that all would have significant consequences for people with limited incomes or for those attempting to improve their life circumstances by crossing national borders to wealthier areas or whose efforts to improve their health and educational status are impaired. A critical perspective on historical context would examine those factors that have, over time, contributed to current situations marked by disparity, discrimination, or stigma. It would be impossible, for example, to ignore

the history of slavery, plantation life, and manufacturing when considering the circumstances confronting impoverished African American families in the rural areas of the United States or in inner-city neighborhoods in the Northeast or Midwest. Understanding the differences, for example, in migration history and struggles of Puerto Ricans and Mexicans from the Mexican–U.S. border areas calls for understanding the political and economic history of the U.S. relationship with each of these countries, as well as understanding local differences in economic and other factors that may play a role in these immigrants' current status.

Social conditions might include population decentralization as a consequence of neighborhood redevelopment or the transformation of clubs and bars from moderate cost to expensive, thus shifting the nature of the clientele with implications for social relationships among former and current users. Environmental history might include the development of large urban garbage dumps and unsuccessful efforts to remove them or the history of the environmental conditions promoting high rates of asthma. And cultural history might include the history of migration and resettlement of people of distinct national origins and stories about their efforts to preserve and reconstruct their lives through festivals, music, storytelling, dance, and other cultural manifestations.

Researchers who examine historical context must find ways of bounding the period of time they are considering. These ways may differ depending on whether researchers are considering relatively recent shifts, as in the case of illegal drug trends or the consequences of the destruction of public housing in Chicago, or long-term trends, as in the case of institutionalized discriminatory practices directed toward specific groups of minority students such as African Americans or Native Americans. Information on historical context may be found in archives, written histories, oral narratives of older residents and recent arrivals, and on the internet. As with any historical research, references and sources must be cross-checked and cross-validated before they are recorded as accurate. And, as with other forms of research, the theoretical perspectives, values, and biases of the researcher guide the reconstruction and portrayal of history and should be transparent.

HISTORICAL DISCOURSE ANALYSIS

Historical discourse analysis is a poststructuralist approach to reading and writing history; a mode of conceptualizing history through a theorized lens of critique. Historical discourse analysis works against the objectivist fallacy of traditional positivist historical methods in decentering the authority of the historian as a neutral recorder of facts and the claim of historical writings as objective reconstructions of past events. In line with its intent to disrupt taken-for-granted ways of conceptualizing history, the task of historical discourse analysis is not to find truths about past events or to identify the origins or causes of past events, but to expose history as a genre—contingent, ambiguous, and interpretive. Historical discourse analysis is, therefore, less a set methodology than a set of postmethodological methodologies.

Grounded in the works of poststructuralist (or post-modernist) theorists such as Michel Foucault, Jacques Derrida, Roland Barthes, and Jean-François Lyotard, historical discourse analysis approaches history as discursively produced and, more important, understands discursive productions as always and already power-laden enterprises. The task of the historian is, from this perspective, to uncover and critique the technologies of power that have come to legitimate certain ideas as truths. Historical discourse analysis is a mode of critical social analysis.

All histories from this perspective are a subjective sampling of materials, selectively organized and presented. All histories are interpretations. Derrida's blurring of the boundaries between philosophy and literature, his insistence that philosophy is a kind of writing that employs the same kinds of discursive devices (e.g., metaphor, metonymy, etc.) as literature is applied here to history. History is too conceived as a kind of literature.

From this perspective, then, no full accounting of history is possible, and no true accounting of history is achievable. No discrete sampling of materials, no matter the criteria used to guide the selection, can be

proffered as the definitive representation of a historical event. The aims of historical discourse analysis are at once more modest and more complex.

The Concept of Discourse

Historical discourse analysis is founded on a post-structuralist conception of discourse: an antiessentialist perspective on language, identity, society, and social practices. From this perspective, language and discourse are viewed not as impartial tools that describe reality, but as constitutive modes of power that construct reality in unequal ways, demarcating the center from the periphery, truth from opinion, and reality from interpretation. Discourses are understood as central modes and components of the production, maintenance, and conversely, resistance to systems of power and inequality; no usage of language is considered a neutral, impartial, or apolitical act.

This concept of discourse, thus, works against the commonsense understanding of language that assumes a signifier has a stable and consistent meaning—in which meaning appears to be fixed. The poststructuralist reworking of the term *discourse* is then a critique of the ontological and epistemological foundations of the modern, including the structuralist, understanding of being and its relation to the world. It problematizes the usually unproblematized link between epistemology and ontology, repudiating the foundational idea in Western metaphysics that a direct correspondence exists between being and knowing, the thing and its name, and in doing so disrupts the reigning Enlightenment notion of objective science and the free subject, as well as the structuralist discourses that valorize structure in place of human agency.

This discourse is not, despite persistent misreadings, a nihilistic denial of empirical reality or an absurdist refutation of existence. The claim is not that the world does not exist—only that metaphysical truth does not exist. Events occur, but that which people demarcate as events, and the meaning people give such demarcations derive only through the mediation of language and discourse. Derrida's famous declaration that there is nothing beyond the text and Foucault's insistence that no one and no thing is free from the workings of power are expressions of this idea that all meanings are constructed through language and discourse and all knowledge is, therefore, interpretation—unstable, contingent, and constituted always and already through the play of power that legitimates some interpretations and not others.

The Role of the Historian

The positivist view of history, which presupposes the historian as an unencumbered subject who stands outside of discourse, is according to Derrida the original fallacy at the heart of Western metaphysics. Working against the disciplinary assumptions of traditional history (scientific historiography or historical realism), historical discourse analysis contests the ideal of the historian as an objective observer or recorder of facts, an author who stands outside the texts she or he reads and writes.

The role of the effective historian, according to Foucault, is to unmask the demagoguery of traditional histories (as well as science and other such knowledge-claims). The point is to challenge the very assumptions that enable the hierarchical distinction between history and literature, fact and interpretation. The aspiration of the historian is not to produce a better history or to exchange the wrong history with the right. The historian's role, from Foucault's perspective, is not the impossible task of writing the true historiography or the revisionist aim to produce a truer history, but the task of uncovering the processes through which history becomes established as such.

Challenging the Medium

Given its poststructuralist theoretical frame, an important element of historical discourse analysis is the decentering of the historical itself. Foucault's approach to history, for instance, serves a double function: it is a social critique aimed at dislodging the usual story, as well as a counter-history aimed at dislodging the usual method of telling the usual story. The content of Foucauldian history works against the tendency to invoke profound historical constants and meaningful progressions, against both a presentist fallacy that conceives the past in terms of the present and a fallacy of finalism that formulates a past event as the genesis of a present circumstance. The sources of Foucauldian history resist the usual chronicles of heroes and kings, treaties and wars (and in an analogous move to Derrida's notion of "reading at the margins"), in looking to hitherto disregarded and discounted sources and stories for occurrences and practices that may have been slight and inconsequential in their original circumstances. The Catholic practice of the confession, a minor religious practice begun in the 17th century, gets taken up as a significant thread of analysis in Foucault's *History of Sexuality*, for example.

The form of Foucauldian history contest the traditional linear narrative, working against the pull of the chronological trajectory—the legitimated structure for organizing historical facts. It seeks, in other words, to make visible the dynamic of power central to the systemic production and perpetuation of both the “true” and “legitimate” story and the “authoritative” and “correct” manner of its telling.

Uses of Historical Discourse Analysis

Historical discourse analysis is used generally to trace the ways in which the particular discursive devices found in examined texts or discourses functioned to construct certain normative ideas and views of events and people. Such analyses tend to examine both formal and informal practices of a given period through the examination of the social, political, legal, and disciplinary codes and their discourses to see how a particular category of subject (e.g., the child, the immigrant, the insane, the criminal, the dependent, the homosexual, etc.) and subject categories (e.g., race, culture, gender, age, sexuality, etc.) become constructed. Thus, to paraphrase cultural studies critic Stuart Hall, the hallmark of historical discourse analysis is the study of discourses as systems of representations.

An example of historical discourse analysis at work is the Foucauldian analysis of madness in the Age of Reason. Underlying this analysis of how the category of madness and the identity of the insane was formulated through the particular sets of knowledge available in that episteme was the illustration of the idea that in any episteme, claims of truth and falsity are made in a conflictual economy: that some discourses are legitimated as being able to pronounce that which is true or false while others are not, and some disciplines become established as *science* or as *knowledge* while others do not. His point, ultimately, was that such identities and categories were, and are, contingent not essential—discursively constructed rather than found in nature. There are no absolute and objective bases for making those distinctions where they are made, and therefore, no unassailable reason that certain behaviors or characteristics get grouped as descriptors of sanity, health, or Americanness while others are grouped as their opposites.

Because historical discourse analysis is an approach to history rather than a set methodology as such, the specific analytical method for the examination of texts or discourses can vary. Methods of close reading, such

as Derridean deconstruction, or the many techniques of discourse analysis in general can be applied to historical texts as ways of analyzing texts or discourses as the means of understanding linguistic practices as social practices.

HISTORICAL RESEARCH

Whether studying a contemporary social issue, such as drug abuse or terrorism, or the history of an individual person or of a concept, such as freedom, historical research provides the critical contextual link of the past to the present. Using a historical research design is of particular relevance to research about contemporary social and cultural issues, as it enhances an understanding of the present. Any contemporary issue is bound intrinsically with the social and historical milieu of the past. Most historical research involves some type of conceptual idea, theme, or person in history. This entry discusses the stages in historical research design, the types of data used, and the forms such research can take. It also explores issues in the evaluation and analysis of such data and briefly reviews the impact of technology on historical research.

Definition of Terms

Historical research is most often associated with historiography as the primary research method. Historiography goes beyond data gathering to analyze and develop theoretical and holistic conclusions about historical events and periods. It includes a critical examination of sources, interpretation of data, and analysis that focuses on the narrative, interpretation, and use of valid and reliable evidence that supports the study conclusions. Although a historian studies history or may teach history, the historiographer writes, analyzes, and interprets history.

Stages in Historical Research Design

Historical researchers are often depicted as detectives, looking under many different stones for clues of existence rather than simply describing the appearance and location of the stones.

1. The first stage of a historical study is the identification of a researchable phenomenon and includes reading relevant literature, listening to present ideas about the phenomena, and even more important, reflecting on the researcher's interest. Before the researcher begins the formal search process, examining background information on the topic can provide valuable information in developing the focus of the study. The researcher then selects a particular time period, person, phenomena, or era related to the focus of the study.

2. The second stage involves developing hypotheses or research questions and identifying a theoretical perspective to guide the data collection process and interpretation of results. A theoretical framework can provide a guide for the historical study, both in data collection and analysis. Although some historians dispute the need for such a framework, most historiographers contend that a theoretical perspective helps the researcher focus and interpret historical events as recorded.

3. The third stage is the data exploration and collection stage, which can be the most time- and labor-intensive part of the research process depending on the subject and accessibility of data sources.

4. The fourth stage, following data collection, includes fact-checking, evaluation of the validity and reliability of data, and the analysis of evidence from each source. During this stage, the researcher evaluates

the data, including the analysis and meaning of missing data, and forms generalizations. It is at this stage that the researcher answers the research question or accepts or rejects the hypotheses and forms conclusions.

5. The final stage of historical research involves the writing of the report in which findings are described along with their interpretation and which provides detailed supportive evidence in defense of the conclusions.

Data Collection

Historical researchers in their investigation of the past often treat data as "witnesses in a trial." From this perspective, the historical method is more than the simple search for facts about the historical story. A historical investigation includes interpreting the meaning of events, which are analyzed based on the available of surviving data. Data sources can be primary sources in the form of documents, paintings, music or media, or they can be secondary resources, such as stories, literature of the era, and other accounts of the event or phenomena. All the data should be evaluated with a critical eye, using a variety of primary and secondary sources.

Primary Sources

Primary sources refer to first-person accounts of events in original documents, letters, artwork, literature, music, observational notes, journals, and photographs. Primary sources enable the researcher to get as close as possible to what actually happened during a historical event or time period. Primary sources were either created during the time period being studied or were created at a later date by a participant in the events being studied (as in the case of memoirs), and they reflect the individual viewpoint of a participant or observer. Primary sources may be in their original format or may have been reproduced later in a different format, such as in a translated document, book, microfilm collection, or video or on the internet. These original sources of data hold the greatest value in the validity and reliability of historical analysis.

Generally, a primary source is one that was created at or very near the time of the historical event it describes. These primary sources are also usually the product of either the person(s) involved in the event or an eyewitness to the event. Primary sources also include materials transcribed, translated, printed, created, produced, and/or published later, so long as

the later version is an authentic and accurate word-for-word rendering of the original. Handwritten documents, for example, are sometimes published in printed collections by academic presses in an effort to make them easier for researchers to access and to read, such as those that have been translated from the original language. An example of a primary source is the trial transcripts of the official trials of Joan of Arc. Although originally written in Latin, they are now available in English translations on the internet and have been verified by French historical experts.

Although primary sources are the most critical data for historical research, the use of these sources as data, such as first-person accounts, is not sufficient proof that the described event even occurred. A critical analysis of primary resources may reveal that the author, writer, or creator of the primary source reflects the perception of the writer, observer, or witness, and the accuracy of what occurred is inaccurate. This possibility must be considered and carefully evaluated by the researcher as to the validity and authenticity of the original source.

Further, historical researchers must recognize that original documents are only a trace of what remains of a historical event. They are greatly influenced by the perception, biases, and selective survival of the document and are limited to specific groups of people in society whose accounts have survived, such as the educated and literate. People who had little power in a culture—such as women, members of the lower classes, and minorities—have produced few primary resources. This result is primarily because of illiteracy, because of their use of oral rather than written historical records, or because their work has not been considered valuable. For example, the trials of witches during the medieval period in Europe reflect only the officials who conducted the trials and interrogations. There are few first-person accounts from the perspective of the women themselves, other than forced confessions. The women who were accused, convicted, and eventually burned at the stake as punishment were usually illiterate, and their stories as primary sources are unavailable to researchers. As George Orwell once noted, “History is written by the winners” (“As I Please” newspaper column, *Tribune*, February 4, 1944).

Secondary Sources

Secondary sources are data from letters, diaries, and account descriptions of persons who were not eyewitnesses of the event or who did not personally

know the person who is the focus of the study. This category of sources is significantly easier to define, understand, and access. A secondary source is any item that was created after the events it describes or is related to or is created by someone who was not directly involved in or was an eyewitness to the events. Secondary sources also include summaries, personal interpretations, and views and include simple descriptions of primary sources. Types of secondary sources include biographies and accounts written years after the event, even if written by a witness to the event (e.g., a first-person account of a child written as an adult). Other examples are scholarly or popular books and articles, reference books, biographies, and textbooks. Critical analysis of secondary sources follows the same criteria as mentioned above for primary resources.

Sampling can be quite diverse in nature depending on the available archival resources. More than in other research designs, the researcher attempts to locate every relevant documentary source related to the phenomena.

As previously discussed, the researcher should assume that many documents and other data sources have been lost, destroyed, or deliberately distorted. The literate and educated of societies and cultures were in positions of power, such as church and political leaders. They were the primary authors of the vast majority of official primary and secondary sources until the past 2 centuries. Young girls and women often wrote letters or kept diaries, when possible, and are considered valuable first-person accounts. A well-known example is the *Diary of Anne Frank*, a primary source, written by a young teen girl who experienced the Holocaust by hiding with her family in Amsterdam. Anne Frank’s diary gave historians a valuable perspective of the Holocaust, a persecution that did not exist in official documents. Artwork created by those in concentration camps of World War II and propaganda films made by the Third Reich are other examples of primary data that add validity and reliability to historical research. Secondary sources in the example of the German Holocaust would include diaries, journals, and interviews with children and relatives of those who died during World War II.

The selection of data samples is based on the purpose of the research. This selection may seem obvious, but historical relics are often broad in nature, while only a small portion of the documentary evidence is relevant to the research question. Due to the nature of what humans leave behind, there exists varying degrees of archival value in historical data. For example, finding unfamiliar documents or information that

is unrelated to the research focus can be a distraction and is time-consuming. However, this discovery phase can assist the researcher in refining the study and/or research question. Essentially, historical research is a translation of translations.

Data Sources

Diaries, photographs, art, literature, minutes of meetings, eyewitness accounts in newspapers or other official documents, court records, letters, maps, and other relevant sources can often be found in university and specialty collections. Government websites and collections are also excellent beginning points for locating data sources, as are special collections from museums and art galleries. Many of these can now be located on the internet. Historical research that is often overlooked includes a variety of art and media forms, such as paintings, sculpture, poetry, music, film, television, and literature. These resources can depict the shifts and changes in the social, cultural, and political context of history.

Many of the senses are used in historical research: listening to music or recordings of the era, reading and knowing the language and expressions of the era, taking extensive notes from primary sources, observing art and other media, and examining available artifacts. Rigor and systematic data collection is critical, which includes seeking assistance from archivists and historical experts in the subject area and visiting relevant physical locations. Data should always be labeled and dated and authorship identified, including all critical details of the data source.

Types of Historical Research

Historical research can take many forms, depending on the purpose of the research as well as on the availability and quality of data and resources available to the researcher. The following types of research methods represent the most commonly used. Historical researchers often combine approaches and include other innovative data collection methods as well.

Oral history is a biographical approach in which the researcher gathers personal recollections of events from a living individual through audio and videotape recordings. Oral history can include written works of an individual who has died, but is primarily limited to a living individual. Most researcher questions and comments are unstructured, although a general interview schedule

may be employed to guide the story depending on the nature of the oral history. This method provides the respondents, or storyteller, a natural and effective environment that allows a reciprocal interchange between the researcher and the respondent. Many oral histories are located in university collections and are available on the internet.

Autobiography narrative is an account of a person's life that has been written or recorded by the individuals themselves. A biography narrative account of a person's life can be either told to the researcher or found in archives, documents, and other sources.

Life history is a biographical writing in the form of an extensive record of a person's life, as told to the researcher. The life history of a person involves a living individual.

Case study is a type of historical research that sheds light on a phenomenon through an in-depth examination of a single case exemplar of a phenomenon. The case can be an individual person, an event, a group, or an institution. Case studies take a relatively small subsample of research subjects as a source of in-depth, qualitative information.

Reliability and Validity

Establishing authenticity is a challenging and critical aspect of historical research. As has been previously discussed, artifacts of history are often a result of "selection bias." The survival of the documents is significant. Validity is related to the external critique of the data. In other words, is the document or artifact an authentic representation? This answer can be determined by age of the document, such as the paper, writing style of the author, origin, and consistency with other evidence. Verification by experts is often included in the external validation process. Data should include at least two or more sources of the same type of information. These sources can be two primary sources, which concur without conflict or disagreement, or one primary source and one independent secondary source, which corroborates with the primary source and does not contain any substantial contradictory information. The researcher, even with intense scrutiny of the data sources, must always consider that primary sources have been altered after the original event.

Internal criticism of data constitutes the reliability of data sources. The researcher attempts to establish

the meaning in the data and the context from which it was derived. Researchers question the trustworthiness as a source, such as the author's biases and perceptions of the event, and if the authors are reporting from intimate knowledge or from others' descriptions of the phenomena. The researcher must be vigilant about including both positive and negative criticism of all data sources, including missing accounts, the lack of relevant viewpoints, and persons involved in events. Understanding the way in which cotemporary words and phrases are used in contrast to past usage and meanings is a critical aspect in establishing reliability. Abortion, for example, has not historically been used to describe the present social and medical definitions. Reading and analyzing secondary sources can often provide the researcher with clarification of language use, artistic interpretations, and alterations of historical events.

Data Analysis and Reporting of Findings

Interpretation occurs at the analytic stage through interpretation of meaning. Extensive examples should be used, with excerpts from documents and other artifacts. Although most historical research is based on incomplete data, the researcher must extend and derive opinion beyond what is discovered and is known from the research data collection process. A critical description of historical evidence, an evaluation of its historical significance to contemporary society, and creative narratives should be included in the written research report, including the derived inferences. The researcher should include all sources in the reference list, footnotes about data sources, and multiple references. This list should reflect the corroboration of facts, as evidence of reliability and validity of the findings.

Future Trends in Historical Research

During the past several years, technology has advanced the use of the internet for correspondence of both primary and secondary sources. As technology has advanced, few people keep diaries or journals or write letters. Those who deliver speeches often do not write them verbatim, as in the past. Storytelling has most often been associated with the oral traditions of the undereducated and less developed cultures and was often expressed for society's entertainment rather than for leaving historical evidence. Yet, storytelling is

an important historical method since it is a way of communicating values and cultural paradigms. Contemporary storytelling may now take the form of emails, blogs, and instant messaging, creating challenges for historians accustomed to depending on handwritten letters and traditional data sources. Historical research will change as more correspondence and eyewitness accounts are recorded on the internet and become available as new data sources for historical research.

HISTORIOGRAPHY

Historiography is concerned with historical interpretations and representations of the past—put another way, the writing of history as opposed to history itself. Although historiography is primarily a disciplinary phrase introduced by contemporary academics, the inquiry it represents can be traced back to the very

earliest origins of historical writing in the work of ancient Greek writers who reflected on each others' historical conclusions.

At one level, focused on specific historical accounts, historiography reflects on the theories and philosophies that inform and motivate them and how they both might influence the conclusions drawn. This reflection might involve, for example, critical reflection of the authenticity, subjectivity, and authority of various information sources. At another level, taking a broader perspective, historiography sheds light on the dominant or collective interpretations of groups of historians within particular time periods and how they reflect disciplinary progress and change (this reflection might be thought of as reflecting on the disciplinary history of studying history). Importantly, however, what particularly characterizes historiography is, crosscutting both these levels, an exploration of the various contexts that affect historical thinking in any one time and place. In this sense, historiography involves consideration of the broader cultural, social, economic, and political forces that shape historical writers and their writing. This scholarship acknowledges that there is no pure historical truth that can be obtained totally impartially. Indeed, it is recognized that all historical accounts are produced by individuals who are products of their environments that affect their focus, what they include or leave out, and the conclusions they draw.

As a practice, historiography has progressed and changed. Over recent years, it has moved from practical concerns on data sources to include far greater consideration of these aforementioned contexts and forces. As the social sciences have gradually become more interested in historical reflection, historiography has played an important role in the development of subdisciplines such as historical sociology, historical geography, and historical economics in terms of reflecting both on how social sciences influence history and on how they represent history (and the people and groups who make history—such as women, working classes, and numerous ethnicities and cultures). Moreover, because of the reflection on the practice of writing history, the lessons learned from historiographical accounts help shape the future of history as a humanity.

Historiography—both as a critical way of writing history and as a reflection on the writing of history—has involved the use of a range of methods, often in combination, which includes the use of archived material and

written historical accounts (including research, autobiographies, memoirs, diaries, and oral histories). For more recent historiographies, representation in the television, media, and other forms of mass communication might also be consulted. The distinguishing factor, however, in historiographers' uses of these sources is a critical comparison and critical perspective on their origins, uses, and biases.

HORIZONTALIZATION

Horizontalization stems from the idea that the researcher should be receptive to and place equal value on every statement or piece of data. Being universally receptive allows the researcher initially to grant equal value to each statement uttered by the participant and thus promotes a rhythmic flow between the researcher and the study participant—an interaction that motivates full disclosure of the experience. The metaphor of a horizon is utilized when discussing horizontalization. A horizon can be thought of as a perspective, or way of seeing the world. Thus, a horizon refers to that which comes into a person's conscious experience and acts as a foundation or condition of the phenomenon. Horizons are believed to be unlimited because humans can never entirely use up their experiences of things regardless of how many times they are reassessed. Although no horizon lasts indefinitely, whenever one horizon diminishes, a new horizon emerges.

Phenomenologists believe that we experience phenomena that exist in the world via self-awareness, self-knowledge, and self-reflection. The horizontal (i.e., lived experiences) brings to the forefront the experiences of individuals and forms perceptions of experiences that

will always prevail even though the elements of conscious life appear and disappear. Thus, horizontalization helps the mind to discover its own essence.

Horizontalization is a method for understanding data through a phenomenological reduction by reducing the number of words and replacing the vocabulary with similar terms in which the researcher places equal value on each statement or piece of data. As such, horizontalization is a continuous process, and even though a person may reach a termination point in which a perception of something is discontinued, the potential for discovery always remains—thereby making a complete reduction impossible. When utilizing horizontalization, the researcher is trying to consider each horizon in the data that enable him or her to understand an experience.

After engaging in horizontalization, the researcher can ignore or delete statements that are irrelevant or repetitive in the data. By eliminating redundant and immaterial statements, only the horizons, or the unique aspects of the participants' perspectives, are left. As the researcher considers each horizon and its textural qualities through self-awareness and reflection, an understanding of the experience emerges. At this point, significant statements are identified that provide information about the experiences of the participants. The researcher carefully examines the identified significant statements, and then clusters these statements into themes or meaning units. Examples of researchers engaging in horizontalization occur in many interviews. When the researcher is nondirective and open to the participant disclosing information, the researcher is utilizing horizontalization techniques. Using statements and questions that are reflective, nonjudgmental, and inquisitive can reveal multiple horizons in the participants' perspectives.

The process of horizontalization assists the researcher by reducing potential researcher bias. When giving each statement equal value, the researcher cannot hone in on one aspect of the participants' perspective; instead, the whole perspective is considered. In other words, each statement is taken individually as an indicator of truth. By engaging in horizontalization, the researcher moves from seeing the raw data as representing empirical information and thus can begin to identify the underlying meanings and essences in the data.

HUMANITIES, QUALITATIVE RESEARCH IN

The humanities are the study of the meaning humans attribute to their experience through analysis and interpretation of the products of that experience, be they conceptual, cultural, or physical artifacts. Disciplines in the humanities include modern and classical languages, linguistics, literature, history, philosophy, jurisprudence, archaeology, comparative religion, ethics, and the history, theory, and criticism of the arts. The humanities have had a significant influence on the conduct of qualitative research in the social sciences and in education; for example, in the way that hermeneutics inspired the interpretive turn in the social sciences and how literary and art criticism influenced the development of arts-based research in education (e.g., Elliot Eisner's development of educational connoisseurship). Educational researcher Frederick Erickson, whose early studies focused on historical musicology, asserts that the wisdom and empathy cultivated through the humanities is especially needed now in educational research, which is in danger of being desiccated by a misguided scientism.

One may speak of the humanities as inherently qualitative, as they intend to understand human experience by interpreting the constructs of that experience. Although quantitative methods are also critical to humanistic disciplines, such as using census data in historical investigations or conducting chemical analysis of artifacts, much work in the humanities is accomplished through the qualitative methods of interview, observation, and document analysis. This entry focuses on how these methods are employed, especially in history and in the history, theory, and criticism of the arts (including literature).

History and Narrative

Research in this area may be focused on a topic, event, or individual and be represented through oral, written, or film or video documentary, biography, or autobiography. Historical research refers to topics, events, or

individuals existing in the past (or past experience); it is narrative research when the topic or individual, or individual experience, is studied in the present.

Recent work in historical research reflects a linguistic turn in the discipline, influenced by postmodernism and the poststructuralist deconstructionism of Jacques Derrida and Michel Foucault. Historians working in this vein reject the possibility of an objective historical truth that can be uncovered empirically, asserting instead that there are multiple truths and ways of interpreting and representing a historical phenomenon that are perspectively situated and influenced by sociopolitical power structures. For example, Foucault's method of archaeology sought to unearth discursive rules that were sociopolitically constructed to understand the representation of past events. In his later writings, Foucault's analytic method of genealogy, significantly inspired by Friedrich Nietzsche and exemplified in *Discipline and Punish: The Birth of the Prison*, interpreted history as the product of continuous shifting power relations.

The poststructuralist linguistic turn raises significant concerns regarding the relativity of knowledge and possibility of empirical historical or narrative research. Other movements in postmodernism, such as semiotics (the reading of signs as signifiers of meaning so that anything might be called a text that can be read and interpreted—human action, a painting, etc.) and social and cultural history, acknowledge the sociopolitical construction of experience as one of constant change instead of a linear progression and of the situated nature of knowledge, but without yielding to complete relativism. Clifford Geertz's work in anthropology and writing on interpretation (e.g., the importance of providing a thick description) was influential in history as well as in social science, especially in social and cultural history.

Working within the postmodern paradigm, many historians and narrative researchers assert the possibility of conducting empirical research, while recognizing that any understanding is sociopolitically situated in a particular time and place and according to the perspectives of the researcher in dialogue with his or her sources. The researcher is not able to uncover a single causal explanation or truth, but rather an interpretation of what a phenomenon may have meant to specific individuals as described by them orally or through written documents or other artifacts. As in other forms of qualitative research, the reader or viewer plays an active role in constructing an interpretation and understanding

of the assertions presented by the researcher. The researcher (and reader or viewer) can establish the trustworthiness of presented interpretations in ways similar to qualitative research in the social sciences and education, for example through triangulation of sources, transparent descriptions of the acquisition and analysis of sources, and so on. Historical and narrative research is conducted primarily through interview and document analysis.

Interview

The interview is used to record oral histories. Historical and narrative research recorded through oral histories has traditionally straddled the realms of the humanities and social science, situating itself in either realm depending on the topic of investigation. Significantly, the federal government of the United States, on the recommendation of the National Research Council, has recently exempted oral history research from review by institutional (ethics) review boards, thereby complicating its use in topics of relevance to social science and educational research.

Oral histories can provide access to insights about a topic that are not available through archival or written documents or artifacts. Oral histories also provide a different kind of insight because they reflect the memories of a witness to an event. In her book on recording oral history, Valerie Raleigh Yow devotes an entire chapter to the significance of memory in oral history, discussing issues related to psychological and physical influences on memory, individual, and collective memory, and effects of the interviewer–narrator relationship on memory. Oral histories also give access to the experiences of disenfranchised or powerless groups, whose information is less commonly documented in writing. A significant objective of feminist scholarship is to tell the stories of marginalized or disempowered individuals and groups. Oral history interviews are typically audio and possibly video-recorded, in-depth, and lengthy, lasting from a 1 hour-long session to numerous sessions.

Oral histories may be presented as life histories (or stories), biographies, or autobiographies. Yow defines a life history or story as an account written or told by an individual about his or life that is then edited and presented by another person. A biography is a narrative about an individual's life constructed through life history accounts, personal documents, artifacts, and photographs. Unlike a life history, which stands on its

own, the biographical account puts the individual's life within a historical context. For example, historian Theodore Rosengarten interviewed farmer Ned Cobb to document the 1930s Sharecropper's Union movement. Autobiography is written by an individual on his or her initiative. Yow recommends the use of autobiographies in biographies and life histories when available.

There are numerous examples of oral history projects available online. For example, the U.S. Library of Congress has a collection of over 2,900 life histories collected through the Federal Writer's Project of the U.S. Work Projects Administration (1936–1940). Also a part of the Federal Writer's Project is a collection of over 2,300 narratives of first-person accounts of slavery. The Archives of American Art at the Smithsonian Institution has transcriptions of interviews with over 180 American artists from diverse regions and cultural backgrounds.

Document Analysis

In biographies and other historical accounts, documents and artifacts are used to develop interpretations (sometimes in conjunction with oral histories). Documents and physical artifacts (e.g., photographs, clothing, books, tools, etc.) may come from archives or from an individual's personal possessions or an institution's private or public collection. The method of analysis will depend on the kind of document or artifact and the research questions. Regardless of the analysis method, the researcher will attempt to put the document or artifact in sociohistoric context and consider; for example, the motivation for its creation and who the audience or user might have been. Feminist theorists have been influential in this area as well in their efforts to use the documents and artifacts of marginalized groups as a means for making their voices heard in historical and narrative accounts.

A good example of the application of postmodern theory's emphasis on sociohistoric context in a work of cultural history is the five-volume series on private life, spanning Pagan Rome to modern times, examining Western European cultural artifacts (architecture, clothing, pottery, tools, art, etc.) to understand the private life of Western European people from different eras. For example, in the first volume focused on Pagan Rome to Byzantium, a chapter dedicated to the Roman household and its freed slaves analyzes domestic architectural remains, fresco paintings, sculptures,

and personal items (such as a woman's toilet kit) among other things to understand the hierarchical structure of human relationships in domestic settings in ancient Rome.

Official documents are also commonly used to investigate a historical topic. For example, probate inventories (legally mandated inventory of possessions of a deceased person) have been used in early American cultural research. These inventories would record in exhaustive detail items located in a deceased's household room by room, ranging from beds and linens to specific books, numbers of food items, farming tools, and so on. The presence or absence and amounts of various items gives historians insight into the nature of that person's existence and can serve as an example of lifestyle for a certain group of people at that time (e.g., a farmer, tradesman, landowner, etc.). Probate inventories have been used to investigate topics ranging from literacy in 18th-century Westborough, Massachusetts, to Rhode Island hand-loom weavers to household sleeping arrangements in early Massachusetts, as documented in the book *Early American Probate Inventories* by Peter Benes and Jane Montague Benes.

History, Theory, and Criticism of the Fine Arts

Recent qualitative research in the history, theory, and criticism of the fine arts reflects the influence of postmodernism as discussed above in relation to history, but the difference is that the focus of inquiry in these disciplines revolves around cultural practices manifest in art objects or performances. Essentially, postmodernism has challenged the formalism of modernism so that most researchers in these disciplines do not search for a single, grand interpretation or meaning of an art work or performance that may be discerned from an analysis of its formal properties, but that there may be multiple interpretations and meanings to an art work or performance. These interpretations are dependent upon the interaction of the inquirer's prior knowledge and life experience and on the sociocultural situation of the artwork or performance's creation, including characteristics of the creator and the time and place of the creative act. This analysis applies to art history, aesthetics (theory of the fine arts), and criticism. In art history, Michael Baxandall's 1972 *Painting and Experience in Fifteenth-Century Italy* was seminal in moving art history away from connoisseurship to studying art objects within their sociocultural context—as both a reflection

Former Slaves Tell Their Stories: An Example From the American Memories Project of the Library of Congress

The American Memories Project of the Library of Congress includes almost 7 hours of interviews conducted with 23 former slaves born between 1823 and the early 1860s. In the interviews, which took place between 1932 and 1975, the interviewees discuss how they felt about slavery, slaveholders, coercion of slaves, their families, and freedom. Several individuals sing songs, many of which were learned during the time of their enslavement. It is important to note that all of the interviewees spoke 60 or more years after the end of their enslavement, and it is their full lives that are reflected in these recordings. The individuals documented in this presentation have much to say about living as African Americans from the 1870s to the 1930s, and beyond.

The following is an excerpt from an interview with Mr. George Johnson, Mound Bayou, which took place in Mound Bayou, Mississippi, in September 1941. The interview was conducted by Charles S. Johnson (1893–1956), a sociologist who served as the director of research for the National Urban League and later became the first African American president of Fisk University. The interview was transcribed by John Wesley Work III (1901–1976), an educator, composer, choral director, and ethnomusicologist who held a variety of positions at Fisk University until his retirement in 1966. With Fisk University sociology professor Lewis Jones, Johnson and Work also collaborated with the Archive of American Folk Song on the Mississippi Delta Collection project, which was a two-year joint field study conducted by the Library of Congress and Fisk University during the summers of 1941 and 1942.

Interview with Mr. George Johnson, Mound Bayou, Mississippi, September 1941

Dr. Charles S. Johnson: Ah, do you, ah do you remember the first blues you heard that you didn't like? Do you remember what it was? Do you remember when you first heard it and didn't like it?

Mr. George Johnson: I don't know. The first blues I heard—oh, I hear a little old boy sing that thing here. I forgot it now, anyhow, right here in Mound Bayou.

Dr. Charles S. Johnson: Hmm.

Mr. George Johnson: Because that's something I didn't care for. It was a little stupid for me; I didn't care nothing about it.

Dr. Charles S. Johnson: A little stupid for you, huh?

Mr. George Johnson: Yeah, sir. Yeah, sir. I didn't care no kind of blues. Didn't care nothing about it. I hear niggas, niggas sing the blues and I didn't want to hear it.

Dr. Charles S. Johnson: You didn't want to hear it?

Mr. George Johnson: Never want to hear it. [I think (?) he is crazy. That's right, [he is (?) crazy.

Dr. Charles S. Johnson: [laughter] What did it sound like?

Mr. George Johnson: Oh, it wasn't, sound like nothing. Just some—oh, lord most of, it wasn't nothing. Just some Negroes just acting monkey. Nigga act like he got shortcoming. That's right. He shortcoming. He uncouth. See. Nigga ain't got some kind of stuff in his head, why he just going be a monkey all his life, right. Care about it.

Dr. Charles S. Johnson: Naw, I like the blues.

Mr. George Johnson: You do! I don't care nothing about it.

Dr. Charles S. Johnson: [laughter]

Mr. George Johnson: Nothing. Nothing about the blues. Want to get me to know something, like something, you get a brass band start let's go do a quickmarch out there. Show you what I'll do. quickmarch go I'll go play ??? St. Alderman's Command, St. Alamo ??? you up. [Mr. George Johnson taps his cane for emphasis]

Dr. Charles S. Johnson: St. Alamo? That's another, another one—

Mr. George Johnson: St. Alamo, my god all mighty! Man. Yes, sir. quickmarch.

Dr. Charles S. Johnson: Quickmarch?

Mr. George Johnson: Quickmarch. Every foot [tip scratch sidewalk (?) every, every fellow's foot just right there. Every fellow's foot.

Dr. Charles S. Johnson: Ah, do you remember any other quickmarch titles?

<i>Mr. George Johnson:</i>	Yeah. St. Alderman's Command quick, quickmarch.	<i>Dr. Charles S. Johnson:</i>	Hmm.
<i>Dr. Charles S. Johnson:</i>	Huhmm?	<i>Mr. George Johnson:</i>	See. I got it in my mind. In my head stuck since I was a little boy. You take a man [stick it in his head (?)] he soon forget that thing. You get them boy here he wanna learn it. He get to learn that stuff. Learn, if he's a boy, he can learn. Learned mine sixty-years ago. Sixty-five-years ago.
<i>Mr. George Johnson:</i>	St. Alderman's Command.	<i>Dr. Charles S. Johnson:</i>	Hmm.
<i>Dr. Charles S. Johnson:</i>	Saint whose command?	<i>Mr. George Johnson:</i>	Got it from Daddy. Grandpa. Got it from pa, he wasn't ??? blacksmith but he know it, understand. You see. He's engineer. Civil Engineer. Now, he, master Jeff, sent my dad across Louisiana to chain [peg (?)] the chain to white folks land, you understand. And across the river Ashford Landing, niggas be in the field farming, you know, breaking up ground and cutting stalks like that. "See that nigga?" That nigga say, "What nigga you talking about?" He looks at them. "That Jeff Davis' nigga. That Jeff Davis' free nigga. That Jeff Davis, see nigga got them chains [pegging (?)] ??? , part nigga." When they meet day, you understand, that ain't no white man.
<i>Mr. George Johnson:</i>	Yes. St. Alderman's Command quickmarch. And the Final Quickstep quickmarch.	<i>Dr. Charles S. Johnson:</i>	Hmm.
<i>Dr. Charles S. Johnson:</i>	Final Quicksteps?	<i>Mr. George Johnson:</i>	"Yes, sir. That's Jeff Davis nigga. That nigga belong to master Jeff. I'm scared of that nigga." Now he come back with that ??? Mound Palmyra. Be on master Jeff's place, you understand.
<i>Mr. George Johnson:</i>	Yes, sir. [Mr. Johnson intones] These are quicksteps to these quicksteps. Man, been all through that stuff. Been through it. Been through. See I, the reason I know everything, because when you, fellow got to learned it from a blacksmith. He had lived had something in his mind and he's young. And he knew he'd get old. See. That's why I can tell you something about drilling a piece of iron. Because my dad learned me. He showed me how.	<i>Dr. Charles S. Johnson:</i>	Right.
<i>Dr. Charles S. Johnson:</i>	Hmm.	<i>Mr. George Johnson:</i>	??? man on a chain, you understand. ??? . Give you money for it.
<i>Mr. George Johnson:</i>	I don't fool with no kind of iron, you see. I played brass band long enough not to fool with a blacksmith. I play every now, you see. But don't take me like, can't use no, I know what, like I tear up a piece of iron like a rock.		

Endnote: The interviewer goes on to ask him what he said, and he says "I cussin' you out." But actually, Mr. George Johnson doesn't use any profanity. The basic translation of the passage is: I'm not a child. I'm not waiting on [you (?)]. I don't know, I don't know, yes ??? . Which in slavery times would most certainly have been considered impertinent and insubordinate, but it wasn't cursing. Mr. George Johnson seems to be having a bit of a joke on the interviewer, using the Creole to express some impertinence and resistant attitudes that don't at all come through in the English majority of his testimony. Whether this is indicative of some wider sociolinguistic trend or not would make a fascinating research topic. We do know that in the 19th century, the Creole language was often used for satire and expressing emotions that would have been socially unpermissible in either international French or English.

Voices From the Days of Slavery: <http://memory.loc.gov/ammem/collections/voices/title.html>

of and influence on that context. In aesthetics, Morris Weitz declared in the 1950s that there is no single definition of art, which influenced the development of aesthetic theories such as George Dickie's institutional theory of art in which stakeholders in the art world determine what is valued as art. In art criticism, professionals moved beyond the modernist formalism of Clement Greenberg's writing on abstract expressionism, for example, to investigate other sources of meaning, such as Donald Kuspit's work on the influence of psychology and spirituality on interpretations of art. Within each of these disciplines, there is the recognition of multiple interpretations and the sociohistoric situation of knowledge and understanding about an artwork, including the sociohistoric situation of the artist. Although the artist's intent is considered in postmodern art history (visual and performing arts), aesthetics, and criticism, it is not considered the sole source for understanding an artwork's meaning, as the possible meanings reside in the dialogic exchange between artist, artwork, and viewer.

As in history, however, the possibility of multiple interpretations does not necessitate rampant relativism. In art history, like history, there are archival documents and documents from individual, public, and private collections to use as primary and secondary sources. For example, in researching the provenance (history of ownership) of an art object, an art historian might consult auction sales records, estate sale inventories, exhibition catalogues, and an individual's correspondence. Information from these sources may be triangulated to ensure the validity of the interpretation. In art criticism, the critic draws on knowledge of the artist's intent (provided, perhaps, through an interview, artist's statement posted in an exhibition or catalogue, or in the artist's correspondence—consider the numerous letters Vincent van Gogh wrote to his brother Theo), as well as on the knowledge of the sociohistoric context of the work's creation and on what is observable in the art object. In this way, art criticism may employ the qualitative methods of interview, observation, and document analysis.

Numerous writers on criticism, art and literary, provide some criteria for determining the value of an interpretation. Umberto Eco asserts that a text has rights, limiting to what extent it can be interpreted or that there is a range of interpretations it will allow. These limits are set by the author's (or artist) intent, the signifiers in the text (whether verbal, visual, auditory, or kinetic), and the sociocultural circumstance of the

work's creation and presentation. Terry Barrett offers three main tenets for interpreting art: (1) it reflects what one sees in the artwork and knows about the sociocultural circumstances of its creation, (2) the interpretation is presented with evidence that can be referenced (observational and art historical), and (3) the interpretation is meaningful and insightful to the inquirer and others. Indeed, Eco, Barrett, and others judge the reasonableness of an interpretation by admitting it to a community of interpreters. This judgment relates to the practice of peer debriefing or the confirmability audit in social science qualitative research.

In essence, qualitative research in the humanities embodies the interpretive turn discussed in the social sciences. The aim of research in the humanities has consistently been to interpret meaning manifested in human constructs, both conceptual and physical, in order to better understand human experience. Indeed, qualitative research in the social sciences and education has learned and borrowed much from the humanistic disciplines.

HYPERRESEARCH (SOFTWARE)

HyperRESEARCH is a commercial software package used by researchers within the sciences, social sciences, and professions including education and medicine. HyperRESEARCH helps the qualitative researcher analyze a range of multimedia data in

addition to text-analysis of data, including graphics, video, and audio. It is useful for visual research including visual ethnography and visual narrative inquiry and provides excellent visual data displays. HyperRESEARCH supports multimedia formats including MPEG-4 and 3GPP and was developed as a cross-platform product to be used on Windows and Macintosh systems.

HyperRESEARCH can also implement grounded theory analyses. It allows the researcher to perform analytical induction on emergent code categories. The program facilitates the coding and retrieval of qualitative data for myriad coding strategies. Its proximity code function allows the researcher to apply a heuristic inquiry to data by establishing potential causal relationships between code categories. The software can auto-code data and create spontaneous memos about specific codes and definitions. One can manage large data sets with the software as a powerful

Screen View of the HyperRESEARCH Interface

Source: <http://www.researchware.com/>; used by permission.

content analytic tool. The researcher can draw concept maps from qualitative data that hyperlinks to original data. It performs network analyses that attach memos, images, and graphics to network maps.

HyperRESEARCH allows the researcher to conduct mixed-methods analyses by exporting data to table-building software programs like CHIPendale. The software also provides for optional automatic backups of all one's data and the quick ability to restore older files.

A team approach to coding and data analysis encourages the comparing and contrasting of code categories to establish intra- and intercoder reliability and validity of coding categories. Off-site tutorials also help researchers practice their analytical skills. HyperRESEARCH is a powerful program, but its simplicity makes it an excellent teaching tool. The software was developed in the college classroom with students possessing varying data analysis skills. HyperRESEARCH contains an easy-to-learn user interface that students can learn intuitively.

HyperRESEARCH developers released HyperTRANSCRIBE, a program that can easily transcribe interview and multimedia material with both Macintosh and Windows systems. Audio and video files can be transported into HyperRESEARCH. Graphical and keyboard controls allow one to play, pause, and loop playback, and QuickTime technology provides for multiple media files, including MP3, WAV, MPEG, AVI, and MOV. Transcriptions can then be exported in other formats.

HYPOTHESIS

A hypothesis is a prediction or tentative statement about the relationship between variables. There are two main research paradigms, or ways of seeing and studying reality: the positivist (typically quantitative) paradigm and the interpretivist or naturalistic (typically qualitative) paradigm. Research paradigms define fundamental concepts and aims in fields of study and determine how evidence is defined, identified, and interpreted.

A hypothesis is typically presented for quantitative research, provided there has been sufficient prior research conducted on the topic to be able to make a prediction. Because much qualitative research is interpretive, exploratory, and broad based, hypotheses are not typically used in this type of research.

Etic and Positivist Approach

Research under the positivist paradigm assumes a measurable objective reality about which a claim or prediction can be made and tested. This etic approach to research studies behavior from the outside, from a distance. It uses hypotheses (prior expectations of how something is supposed to be) in order to define and operationalize the variables and units under study, to build in measurable absolute criteria, and to make predictions about schemas and theories. Because the entire research process is built upon testing these a priori predictions, this approach to research relies on researcher control. This paradigm believes that reality is objective and thus can be represented, predicted, tested, measured, and controlled.

In this approach, a specific prediction is obtained from the hypothesis by deductive reasoning, and research measures the similarities or differences between observed or measured behavior and the predicted behavior (the hypothesis). Knowledge emerges from testing of the hypothesis and is significant as measured by this difference or sameness.

Emic and Interpretivist Approach

Research under the interpretivist or qualitative paradigm assumes the existence of multiple realities. In this type of research, the purpose is to describe, understand, or explain those multiple realities in their

complex and ever-changing nature. This approach is an emic: behavior is studied from inside the system. This standpoint assumes multiple realities and views behavior relative to other behavior, devoid of prior expectations. The ethnographer who is a participant in the field has an emic standpoint, studying the system in depth, from inside, letting the data explain itself with few preconceived notions or predictions.

Because in this paradigm the entire research process assumes emergent findings, this approach to research relies on flexibility, reflexivity, and openness to discovery. Variables are defined and redefined during the analysis. They are discovered, not predicted. In the same vein, schemas, theories, and criteria are discovered as a result of the research, from the analysis, relative to the system and data studied. Knowledge is relative rather than absolute and is significant in its meaning relative to the discovery process.

This process is an inductive approach to decision making that focuses on discovery and constructed reality. Predictions, if made at all, are made as a result of the research findings as they generalize to similar cases or phenomena.

IDEALISM

Idealism as a systematic philosophy derives from thought's reflecting on itself and comparing the integral unity it discovers with the contingent and apparently contradictory dynamics of the external material world. The outcome of this form of self-reflection is a conception of rational unity as the highest and most perfect form of reality. The internal unity that thought discovers in itself is taken to be definitive of the essential nature of reality as a whole. The possibility of meaning, purpose, and freedom in material nature is grounded, from the idealist perspective, on the truth of the universal rational order that thought discovers when it takes itself for its object. The abiding need of humans to understand the universe as meaningful and purposive and to understand themselves as free explains the enduring importance of idealism long after its methodical theorizations have ceased to be convincing as scientific expositions of the essential nature of the universe in its totality. To explain more concretely what idealism means and what it has contributed to the understanding of natural and social reality, it is perhaps best to begin by considering what the term means in ordinary language.

In colloquial English, *idealist* is generally used as a term of good-natured criticism of anyone who hopes for social changes that rest on principles assumed to be too pure for flawed humans. Hence, *idealism* typically means a form of thought that studiously ignores reality. Reality is taken to be a hard-and-fast limit on human hopes, whereas ideals are regarded as mere aspirations for a world fundamentally different from

idealistic. In this ordinary sense, a hard-and-fast division between reality, on the one hand, and human ideals, on the other, is essential. This division between ideals and reality is the very opposite of their relation in idealist philosophy. Understanding the internal connection between thought and reality is the key to understanding the philosophical meaning of idealism.

The Unity of Thinking and Reality

In all forms of thinking, there is always a distinction between the subject that thinks and the object that it thinks about. In everyday human life, there is rarely occasion to investigate the relationship between subject and object. Humans open their eyes and see, open their ears and hear, touch a surface and feel its texture. These sensory experiences generate content for different mental maps of the world that humans use to negotiate the spaces they have practical reasons to negotiate. In nonphilosophical thought, people do not usually notice that what they are employing to negotiate these spaces are precisely mental maps; people simply assume (and usually there is no cause to assume otherwise) that their mental maps are accurate reproductions of a reality that exists independent of their thoughts. In contrast, the idealist, while not disputing the reality of material structures and processes, points to the necessity of the mental map as the essential condition of there being a meaningful extramental reality. Contrary to the colloquial meaning, idealism does not claim that reality is an arbitrary product of individual minds; rather, it contends that reality is a synthetic unity of material content and

ideal or cognitive form. In the classical way of putting this point, idealism rests on the claim that thinking and reality are identical.

Of all the obscure propositions of speculative philosophy, this claim is the most apt to be completely misunderstood. The bald form of the assertion leads people to conclude that what is really being asserted is that reality is thought and that the subject of thinking is an individual mind. The individual mind is assumed to be posited as free from the constraints of material nature and, thus, at liberty to simply create its own reality. Because reality regularly disconfirms the best-laid plans of people, idealism is (as noted earlier) rejected as mere wishful thinking. However, asserting that thinking and reality are identical is not the same as asserting that reality is whatever each ego thinks it is. Indeed, the principle of idealism imposes the most rigorous constraints on what can count as real. To understand what those constraints are, it is necessary to investigate more closely the difference between the content and form of thought.

The content of thought is as diverse and contingent as the sensory experience and imaginations of every human who thinks, has thought, or will think. Because these experiences and imaginings cannot guarantee their own truth given that they are always changing and obscure (seeing might be believing for the idealist, but it is never knowing), philosophical reflection is obliged to investigate the truth conditions of ordinary experience. To do so systematically, the idealist, noting that there is no immediate access to material reality but that such access is always mediated by consciousness, turns inward or reflects on the subject of experience. The subject is nothing other than the act of thinking itself. Once the act of thinking itself is taken as the object of thought, the focus is no longer on the contingent and individuated content of thinking but rather is on its universal form. By *form*, the idealist means the common principles to which all thinking, if it is to be true, must conform. These principles are, considered abstractly, the foundational principles of classical logic. The idealist does not treat these principles simply as rules for proper inference; rather, the idealist treats them as an objective form of necessary order and unity definitive of the essential nature of thinking and reality. Because these features are common to the act of thinking and not relative to the content of this or that ego, they are universal constraints on true thought. In other words, idealism claims to discover necessary and universal conditions of truth that any and all minds, as well as that which

minds know truly, must obey. The proof of the necessity of the principles is precisely the fact that they are not invented but rather discovered. Hence, individual minds not only are not, but also cannot possibly be, the creators of the reality they claim to know. All minds discover that they must obey the universal principles of thought that they discover in themselves once they reflect on their form in abstraction from the diverse contents of thought. Because all objects are necessarily objects for thought, both the object and the subject must conform to these principles.

The most basic principle of thought uncovered by self-reflection is the law of noncontradiction. In its original formulation in classical Greek philosophy, this principle asserted that it is not possible for that which is to be and not be of the same substance, in the same respect, and at the same time. If a substance is an apple, then it cannot simultaneously be an orange (not apple) at the same time and in the same respect. If this principle is interpreted in light of the basic principle of idealism, then it must hold universally both for that which is thought and for that which exists outside the individual mind. Thought is true when it corresponds to its object. If thinking operates according to necessary and universal principles, and it is true when it corresponds to its object, then it follows that the object also must conform to these principles. In other words, the identity of thinking and reality and the necessary and universal truth of the principle of noncontradiction entail the following conclusion according to classical idealism: That which must be the case according to valid deductions from necessary and universal principles must be the case, for if it were otherwise a contradiction would result, and contradictions can never be true. Generalizing from this conclusion, the basic idealist picture of reality emerges: What well-formed thinking knows to be the case is the case. In other words, reality and thinking (in its formally universal aspect) are identical. Things might exist apart from thinking, but there can be no truth, purpose, or meaning outside of rational cognition.

This conclusion has further important implications for the idealist understanding of reality. If it is the case that the form of thinking determines the content of truth (nothing that does not conform to the universal principles of thinking can be true even when sensory experiences seem to indicate it is true), then it must be the case that thinking is free in relation to the object of thought. *Free* here must be understood in both a negative and a positive sense. First, negatively, thought's freedom means that it is not determined by

experience. Truth does not mechanically imprint itself on the mind through sensory experiences. This negative definition implies a positive corollary: Truth is determined by rational thought discovering the operation of its own principles in a material reality that as appearance is contingent and contradictory. If it is true that reality and thinking are identical, and the essential nature of thinking is freedom in relation to the object (as superficial appearance) of thought, then it follows that the essential nature of reality is freedom. The truth of reality and the truth of thought are identical. The truth of thought is (negative and positive) freedom. Therefore, the truth of reality is freedom as well. The real, for idealism, is a self-unfolding or self-determining objective rationality manifesting itself through various contents to subjective rationality. Thus, true knowledge is a subjective grasp of the underlying rational order and purposes of reality as a whole. Superficial appearances lead rational thought beneath the surface to the underlying truth concealed within. Once one has true knowledge, one understands the universe as a rationally ordered whole or totality. In other words, one understands what it really means to say that reality and thinking are identical. In whatever manner reality presents itself to individual minds as appearance, its truth is determined by the universal necessity that thought discovers. To be true and yet not universally necessary is a contradiction, and contradictions ultimately cannot be true. Therefore, to put the point in the simplest terms, reality is as thinking determines it necessarily (not subjectively wishes it) to be.

Hegel's Absolute Idealism

The most systematic development of this understanding of reality is found in the work of G. W. F. Hegel. Hegel's work reconstructs the history of philosophy and the historical development of reality as a unified process of progressive knowledge of truth. In the terms adopted here, Hegel understood the development of philosophy as progressive insight into the meaning of the basic principle of idealism. Because that principle asserts the identity of thinking and reality, the progressive development of philosophical knowledge depends on the progressive manifestation in objective reality of the rational truth that organizes it. In other words, for Hegel, because truth depends equally on the subject and object of thought, progressive understanding of the truth depends on the progressive manifestation of that truth in the object. This

does not mean that reality literally tears off cloak after cloak in history until finally the truth is revealed in its naked abstraction; rather, it means that human thinking progresses not only by discovering more content (through natural science) but also by gradually learning how to synthesize all of its modes of knowledge into an internally unified, systematic, and meaningful whole. On the one side, human knowledge presents itself as abstract metaphysical systems of thinking (of which the various forms of idealism are the highest expression); on the other side, it presents itself as the distinct research programs of natural science. The truth of both can be found only in their synthesis. This synthesis, which Hegel attempted to articulate in his *Encyclopedia of the Philosophical Sciences*, claims to reconcile the mechanism of nature as disclosed by the natural sciences with the purposiveness and freedom of the underlying rationality that governs the whole. In Hegel's view, material nature is real but not independent of purposive rationality. To employ a somewhat misleading metaphor, material nature is one "level" of reality but not the most basic one. Natural science explains how nature operates but not its purpose. Because reason demands an answer not only to the "how" of things but equally to the "why" of things, there must be an object that corresponds to the question "why" on analogy with the way in which material nature corresponds to the question "how." This object can be none other than a universal reason. Therefore, reality is the process whereby universal reason progressively realizes itself in the subjectively rational consciousness of humans (the only rational beings that exist). Thus, truth is not simply an individual epistemic achievement; it is the realization of the purpose of reality itself—to come to fulfillment by becoming the object of full knowledge. Truth really exists, for Hegel, only when it is known. Its reality depends equally on the subject and the object. The object cannot be known without a fully developed subjective consciousness. Equally, however, a fully developed subjective consciousness cannot exist without a fully developed object. The entire history of the universe in its natural and human development is the substance of the development of truth.

Hegel's extraordinary attempt at a total synthesis of human knowledge did not survive the continued development of the natural sciences. The dominant tendency in the development of knowledge became methodological specialization, leaving a systematic philosophy like Hegel's "on the wrong side of history" (to employ a Hegelian phrase). No one after

Hegel tried to unite mechanism and purpose, empiricist and rationalist forms of understanding in the absolute systematic fashion attempted by him. Given the intrinsic links between idealism and the demand for an overall rational unity of human knowledge, it is questionable whether idealism, at least in its classic signification, is a living method of social and natural inquiry today. For idealism, the system really is essential, such that if overall systematic unity is no longer credible, then neither is idealism.

Idealism and Contemporary Qualitative Research

That is not to say, however, that the problems posed by idealism, and in particular the problems of purposiveness and freedom, have been solved either by natural science or by naturalistic philosophy. In this sense, idealism lives on in the form of human interpretation of the meaning and purpose behind events and actions. The dichotomy between natural scientific and rational explanations of events first rigorously theorized by Immanuel Kant during the 18th century remains. Kant understood human reason as being driven by an internal demand to demonstrate that what natural science understands as meaningless causal relations between material substances in a spatiotemporal continuum adds up to a whole whose reality is purposive. The sciences can never grasp the universe as a whole as organized in such a way as to provide meaning and direction for human (rational) life. Therefore, it remains the province of philosophy to speculate about that which can never be known. Thus, idealism lives on in spirit, if not in system, everywhere that humans conduct their minds to the ultimate questions of existence—whether our place in the universe is somehow special because of our intellect, whether our lives and actions amount to anything substantially meaningful, and whether our ability to decide on courses of action is an instance of real freedom or only an illusion born of ignorance of the material causes. The tremendous progress of natural science in expanding the content of human knowledge has not brought us closer to answering these basic questions. Thus, the problems that idealism sought to solve remain relevant to qualitative research today even if its historical systems are no longer credible.

Two areas of research in particular disclose the continuing influence of idealist principles. The first is the critique of reductionist and mechanistic methods in the social sciences as developed by, for example, Charles

Taylor, Clifford Geertz, and Jürgen Habermas. Although none accepts any particular idealist system as such, all are concerned to demonstrate that social reality cannot be reduced to a set of objective material facts existing independent of participants. Instead, all argue in different ways (convincingly) that social facts depend as much on the interpretations and background beliefs of social actors as on the objective structures and forces operative in any social formation. This argument clearly depends on a qualified version of the key idealist principle that reality is always essentially linked to the way in which objectivity is cognized and understood by thinking beings. The second crucial area of qualitative research in which idealist principles remain important is the inquiry into the relationship between social context and self-understanding. During recent years, pragmatic interpretations of Hegel (e.g., by Terry Pinkard) have sought to release Hegel's social philosophy from its systematic metaphysical pretensions. This effort has yielded rich insights not only into Hegel's contemporary significance but also, more important, into the intrinsic and irreducible relationship between individual self-identity and social relations. This research has bolstered "communitarian" interpretations of the meaning and value of human action in the debate with liberal conceptions of an abstractly rational self motivated by nothing but rational calculations of self-interest. Thus, although idealism as a metaphysical system has outlived the historical context in which it could thrive, its implications for social philosophy and interpretive social science remain living elements of contemporary qualitative research.

IDENTITY

Identity is a social process involving perception and differentiation. It can be defined as the ways in which individuals and groups regard themselves as similar to, or different from, each other. These perceptions can change over time, so identity is a fluid construct rather than a static one. Identity has both individual and collective dimensions; people identify as unique in certain respects and as members of social groups in other contexts.

Some people are more willing to openly disclose an identity than are others, particularly if the identity is subject to prejudice or negative stereotypes and may result in discrimination. The process of disclosing a previously hidden identity is known as “coming out,” whereas the process of hiding such an identity is called “passing.” However, the danger with these terms is that they tend to imply that identities characterized by ambivalences, fluctuations, contradictions, hybridities, and in-between affiliations are in some ways less developed, or less politically sophisticated, than those with clear-cut affiliations. Qualitative researchers seeking to understand such complex identities disagree with the idea that particular identities must be expressed in certain ways.

Different methodological approaches may be suited to demonstrating particular aspects of identity. For instance, researchers who are interested in the ways in which people change their identities over time, or change the weight they place on particular aspects of their identities, might adopt a longitudinal approach. Qualitative researchers may also adopt a life course approach toward identity to study the impact of both individual agency and social structure. On the other hand, researchers who use narrative methods to study identity often seek to understand how individuals make sense of their world as well as what incentives, constraints, and values influence their choices and how their identities change over time.

People have multiple identities framed around characteristics such as gender, sexuality, race, ethnicity, age, disability, nationality, and so on. Qualitative researchers adopting a focus on intersectionality and identity examine how these factors interact and under what conditions particular identities become salient. They may focus, for instance, on the contexts in which some identities are privileged while others are marginalized. By focusing on one particular identity, researchers may be able to gather detailed information that helps them to discover similarities and differences among a group's members. Such studies may illustrate the forms of power that influence particular identities.

Some social movements, such as feminism, have been criticized for assuming that identities (e.g., the identity of “woman”) are stable and clear-cut. Spawned in part by Judith Butler's influential critique of “identity politics,” there has been a massive increase in the study of the ways in which identity is performatively produced; that is, discursively constructed in a social environment. Butler's approach focuses on the ways in which identity is performed, produced, cited, and reiterated—raising questions of power, subjectivity, and politics. Because identity always involves a sense of “us” and “them,” this approach highlights the forms of exclusion inherent in any particular identity.

Another approach to the study of identity has been associated with psychoanalysis and has focused on the fantasies, excesses, projections, hesitations, attractions, and other psychic responses to particular individual and collective identities. Psychoanalytic approaches may examine the conscious and unconscious assumptions underpinning conceptions of particular groups or individuals.

IDEOLOGY

In ideology studies of qualitative research, meaning becomes a political site. In this sense, ideology is defined as the problem of social relations of domination made

intelligible through discourse. Ideology includes multiple responses to social relations of domination, sometimes distorting an accurate understanding of them and sometimes penetrating their structures. Social relations of domination comprise the problem of ideology; depending on the discourse that researchers adopt and the political project on which they are grounded, ideology may promote or negate domination. In addition, ideology is made known through systems of intelligibility, one of which is language as a social practice or discourse. Qualitative research is inscribed by discourses that position both the researcher and participants as subjects of language that is politically regulated. The regulation of discourses defines in a research context what questions may be asked, repressed, or challenged. In other words, ideology studies pose the labor of meaning as part of the political process over power and representation

Background

Historically, ideology has been a pejorative concept, amounting to falsehood and avoided by the astute researcher. It was first studied by French philosopher Destutt de Tracy, who patterned his thoughts after the natural sciences and reacted to metaphysical or idealist constructions of ideas. His study of ideology purported to be a science of ideas. Not long afterward, Karl Marx conceived his own version of ideology with his thesis on false consciousness. To Marx, ideology was falsehood based on the idealist notion that consciousness produced social life, as opposed to the materialist notion that the production of social life gives rise to consciousness. In the Marxist sense, ideology is less a trait that an individual possesses and is more a characteristic of social relations found in capitalism. A qualitative researcher would rather not be implicated with keeping such company, preferring instead a materialist analysis.

Whereas the Marxist perspective regards ideology as a distortion of scientific understanding, textualists consider ideology as an organizing framework necessary for subjectivity. Seen in this second sense, ideology is not something that people need to overcome, as in the Marxist notion of false consciousness, but rather something that is necessary for consciousness itself. As a text, ideology is made known to social subjects through language as a social and regulated practice. Ideology is a way of reading the world and becomes a particular position that people take up through discourse. Compared with the Marxist theory

on ideology, a poststructural rendition of it as text suggests that ideology is constructed out of discourse not as a coherent system but rather as one that is characterized by contention among discourses. Here, qualitative research has been transformed through its focus on linguistic statements and cultural themes through interviews and ethnographic studies.

In a third sense, ideology has been used as a positive or enabling concept. Some intellectuals, such as Vladimir Lenin and Georg Lukacs, spoke of a revolution grounded on a socialist or working-class ideology. Likewise, Antonio Gramsci posited the importance of a power bloc with leadership abilities and a counterhegemonic ideology. Seen in this way, ideology is neither negative nor neutral but rather negating. That is, positive ideology negates structures of domination and relations of exploitation. Qualitative researchers accomplish this move partly by building a critique of the social through concepts that demystify commonsensical assertions in civil society such as progress, meritocracy, and objectivity.

Barney Glaser and Anselm Strauss's project of grounded theory has now become common practice in qualitative research. Most ethnographies and case studies claim to have derived their research narratives out of social interactions that are grounded in a field-site. However, ethnographic researchers who are convinced of the need to ground theory are now struggling over a different kind of geographical terrain—the ideological meanings of a research context. Besides arguing that meanings should be “grounded” in a research site, Glaser and Strauss also used the metaphor of “emerging” to describe how meaning was derived from empirical data. Contributing to this debate, we discuss the feature of grounded theory that suggests that meanings emerge through a natural nonideological process during qualitative research. Instead, we argue that there is ideological friction or the productive rubbing of worldviews between researchers and participants. As such, we propose that the passive view of emergent meanings must be countered by the consideration of ideology in research encounters because meaning-making is far from a natural, politically neutral endeavor.

Ideology in Qualitative Research

By turning to ideology, we invoke a critical qualitative methodology that emphasizes the repressed dimensions of members' meanings or what we call “dismembered meanings.” Dismembered meanings

represent the struggle over ideology in ethnographic research that traditional researchers usually repress because they are reminders that politics exists at the level of discourse. By exposing dismembered meanings, a methodological framework that uses ideology critique labors to make the construction of meaning more apparent. A fundamental goal in traditional ethnography has been to represent “members’ meanings.” Despite the impossibility of pure meaning, many ethnographies or case studies are driven by the researchers’ desire to get the “correct” (or at least an acceptable quantity of the whole) meanings of the group members they observe so that the groups can be understood to the researchers and their intended audiences. Some may admit the impossibility of this task. Nevertheless, many researchers insist that, with appropriate methods, one can arrive at a close approximation of true and complete meanings. This discourse on members’ meanings is linked to the researcher’s emphasis on methods that procure accurate meanings from members located in “natural” environments with little interference from the researcher. This curious closing of the “meaning of meaning” necessitates a vigorous emphasis on methodology as the meta-analysis of methods.

The notion that researchers can reflect members’ meanings without mediation is problematic. In mainstream ethnographies, there is a strong emphasis on method and not enough emphasis on methodology; that is, there is much attention spent on “getting meaning right” and not enough spent on addressing the ideological struggles over meaning and research. In ideological studies of qualitative methods, however, meanings are neither transparent nor fixed; rather, they are sites of contestation for representation of history and social life. Moreover, critical ethnographers are in a position to critique meaning and not merely re-present them. To mimic Marx’s thesis on Ludwig Feuerbach, qualitative studies have merely described the world, whereas the point is to change it. A critical study of methodology uncovers links among ideology, meanings, methodological systems, and power.

One of our goals is to enter the debate surrounding the concept of members’ meanings. By doing so, we hope to extend the dialogue on qualitative studies by suggesting that research is a problem of meaning. How meaning is represented in research and the political consequences around the terms of the debate are central concerns for critical qualitative research at the intersection of ideology and meaning. Second, we stress that meanings do not speak for themselves but

instead are spaces of ideological struggle within and among groups for status and privilege. Thus, in focus groups, we see that disparities in power subvert what Mikhail Bakhtin called the *heteroglossia* where meaning exists in a natural state of slippage or multiplicity. Instead, power relations create the impression of what Valentin Volosinov called *uniaccentuality* or meaning that appears to be fixed and settled. Meanings are not simply stories to be passed along to an imagined audience but rather are points of intersection between members’ worldviews and researchers’ previous ideological commitments. Third, a study of ideology emphasizes the role of critical ethnographers in interrogating the construction of meaning as well as how meanings construct them during the research process.

Traditionally, ethnographers have made apprehending members’ meanings one of their fundamental goals in field research. As strangers to the research site, ethnographers induce the relevant themes for the site participants and the meanings they derive from events that transpire around them. Although researchers readily admit that the members’ meanings they gather fall within the limited universe of their research questions, this perspective does not regard the rendition of meaning ideologically problematic. Within this traditional discourse, participants are meaning-makers and researchers are meaning-getters. Getting meaning may come with difficulties, but meaning itself is not conceived as a problem. Many distortions come between the two parties as researchers attempt to represent the participants’ meanings. Likewise, biases, sympathy with certain participants, and interviewer cues are some of the ways in which researchers taint their quest for objectivity during data collection. However, with greater design and tenacious cross-sampling for different perspectives, it is believed that ethnographers can come to an accurate picture of the meanings members make of their social context. It is assumed that researchers can “get” these meanings with a level of confidence. In other words, grounding interpretation in collected data ensures that members’ meanings are secured. These commonsense assumptions have become a hegemonic core of ethnographic research for several decades.

Ideology Critique as a Method of Inquiry

The centrality of ideology becomes more clear when meaning is regarded as the outward sign of larger material relations. Thus, critical studies of meaning

expose the objective patterns that script subjectivities. In other words, they emphasize ideology critique as a method of inquiry. In this sense, ideology is studied as if it not only has material effects but also is a material entity of social relations. In a mainstream ethnographic study, accuracy of rendition is prioritized over the critical engagement of the social totality that informs the participants' worldviews as well as the ethnographer's predispositions from his or her entrance into the site to the moment he or she exits. We argue that there is currently a problematic separation between ideology and the results of a researcher's protocol. Members' meanings never speak for themselves but rather are mediated by the ethnographer's previous ideological commitments that guide his or her decision-making and interpretive processes. What does or does not count as a meaningful theme is related to the ethnographer's semantic map. In this scenario, the meaning of most worth ultimately becomes a methodological issue rather than an ideological one.

This does not suggest that meanings have nothing whatsoever to do with the participants because their interactions compose the very "stuff" of ethnography. Instead, it implies that meanings resulting from encounters between the researcher and members are always already interpreted, filtered, and then translated by the researcher. Ethnography is a hermeneutical process involving members' ideologies that are themselves interpretations of social life. Ethnographic evidence does not represent the members' meanings as such; instead, the members' meanings result from the interactions and collisions among discourses represented by the totality of discourses that enter the research process.

This shift from the belief in apprehending meaning to the plane of ideology raises the question: At what point is the qualitative researcher warranted to suggest that a meaning has been confidently apprehended? This is indeed a central problematic of good solid research. Yet one only needs to present the written document, whether an ethnography or an interview, to the participants for review to discover that their meanings have somehow been translated into what many laypeople may perceive as "academic jargon." That is, participants are wont to refuse researchers' representations of them. In their zealous attempts to "get meaning right," researchers sometimes double-check with participants only to find out that they failed to represent the issues in their totality. Representations are partial, especially when they are critical of the perspectives the participants embody.

Partiality of Representations in Qualitative Research

Representations are partial in four ways. First, they are partial in the sense that they signify a limited slice of the object of study. This point is acknowledged by most conscientious researchers. However, the multitudinous ways in which researchers select the very data they record in "normal" interactions with their participants often go unrecognized. Because researchers are bodies that enter the site already ideologically inscribed, Leigh Berger would suggest that some choices they make are coded into their instruments of perception. In any research, there are repressed trajectories of meaning—what we have called dismembered meanings—neglected by the researcher's own hermeneutical horizon, discursive spaces in the site to which the researcher has no access, and/or blind spots resulting from hegemonic or unquestioned assumptions.

Second, qualitative research is partial in the sense that researchers do not enter the site *tabula rasa*. Ethnographers and interviewers espouse ideologies that enable them to understand their lifespace and that preclude neutrality. In other words, they are never innocent observers. Certain epistemic systems influence, but by no means guarantee, the qualitative researcher's problematics, some of which are constructed actively and others of which are inherited. Standpoints are constructed with discourses that represent some order of meaning out of an otherwise vertiginous social existence. Communities of discourse, of which researchers are part, signify events in a concrete language practice. As already implied, these discourses in turn create material perceptions that actually register some phenomena and not others.

Third, human representational systems are structured vis-à-vis metaphors. Languages are filled with metaphors that have become so commonplace that we hardly recognize them as such. These metaphors go unnoticed because they have become normalized to the point where their meanings are apparently universal and natural. Yet attempts at truth are steeped in imperfect metaphors that pose problems for researchers. This becomes clear when ethnographers use their own systems of metaphors in an attempt to understand the systems of metaphors used by members of the studied group. It reminds us that there are no universal metaphors absent of geographical, historical, and cultural contexts. As such, apprehending meaning is always open and precarious.

Fourth, the discourse that researchers bring to bear on the evidence constructs their meaning in light of the epistemic rules that regulate discourses. Recent dialogic or collaborative research guards against misrepresentation by co-constructing the interpretation with the participants themselves. In this approach, researchers and participants negotiate the representation of meaning not only (once again) to ensure that the meaning is right but also to empower participants in what has been a historically objectifying process for them. However, a possible outcome of collaboration is the repression of critique in exchange for a “feel good” relationship. A compromise between researchers and participants does not seem to be the answer; that is, co-construction of analysis is not enough. Participants’ increased involvement in the research process does not necessarily address what Paulo Freire termed “limit situations” or those inscriptions that limit the possibilities for liberatory interpretation. Researchers and participants may work together to excavate the meanings that have mystified them, a process in which they have unfortunately participated, but this also suggests that discourse in the research process is constitutive of a particular “reality” that ethnographers observe. Depending on the discourse being deployed, the nature and purpose of meaning will change. For example, a conservative discourse on meaning may emphasize the transcendental value of certain meanings, whereas a critical discourse may render the meanings historical and contingent.

There is also the problem of the context of representation. Sometimes ethnographers and interviewers are charged with taking a statement “out of context,” especially when the interpretation is less than praiseful. Indeed, some researchers engender a less than respectful agenda and wreak representational violence, as in the case of a researcher who is not self-reflexive and treats research as a spectacle where one gathers as much “dirt” as possible. However, like meaning, context is slippery. There is no single context for an utterance, as Bakhtin showed, because speech anticipates its receiver as well as its respondent. Therefore, meanings are in constant conversation with each other in a way that precludes any rigid ownership. This condition of anticipatory dialogue suggests that participants in research studies are members of simultaneous discourse communities as well as constrained by them, sometimes producing dismembered meanings.

Dismembered meanings are semantic domains that are excluded from the official discourse. That is, mainstream ethnographies often represent mainstream

meanings. They marginalize repressed meanings instead of bringing them to the forefront. Even worse, mainstream ethnographies leave ideologies intact and leave the history that interpellates them untouched. Members’ meanings are scaffolded on the mounds of the dismembered meanings they repress. Dismemberment involves an element of discursive violence. It is a process of castrating—of cutting off from view—certain formations of meanings from official discourse. Castration is the incomplete project of representation in which qualitative researchers participate each time they signify an event or render it intelligible through discourse. It is part of the ideological craft of qualitative research when an observer first decides to ask a relevant question and by asking becomes noцент.

Conclusion

Because ethnographic interactions are social, there are multiple contexts that act on and create any singular moment. In any given context, a researcher has a universe of meanings to represent. Derridean deconstruction has shown us how meanings recall the traces of other meanings. In other words, there is an underside to meaning that is repressed, a present absence that is silent but subverts the security of the apprehended meaning. It is this silence that sustains the presence of perceptible data. With a critical lens, it now becomes problematic to charge that a researcher has “read too much” into his or her data. We do not suggest that researchers are free to frame their analysis any way they want. Arguments must be lifted from the data at hand. Yet for an analysis to testify to the complexity of the evidence, a researcher must also venture into meanings that are not readily perceptible in the data but must be deconstructed out of the discursive silences they repress. As such, reading into the data what “is not there” is warranted if the purpose is to excavate muted and marginalized voices. The problem of context is undecidable for the critical researcher who must decide to represent it, albeit on a contingent basis.

As researchers, we have emphasized the ideological nature of meaning. With understanding comes the risk that we have only peered into the appearance of meaning. Thus, ethnographies, interviews, and case studies involve a great amount of uncertainty in the face of needing to decide which meanings to represent. Inescapably, qualitative work is a vocation of interpretation and translation. Members’ meanings do not await us but rather are constructed in the course of

study. We do not re-present meaning as it “exists”; instead, we signify it through signs. As researchers, not only do we make meaning of our site, but also meaning makes something of us in the process. It changes us and potentially transforms our ability to self-reflect on the nature of agency, subjectivity, and ideological purpose. In the end, qualitative work is a political project around the transformation of meaning.

IMAGINATION IN QUALITATIVE RESEARCH

Although seldom singled out in discussions of qualitative methodology, imagination—a cognitive capacity sometimes described as “the creative power of the mind”—shapes the direction and content of research in multiple ways. A better understanding of imaginative processes and their cultural context, therefore, may improve the quality of research and help researchers to avoid common pitfalls associated with inquiry within or between the disciplines.

Imagination and Understanding

Research consists of working to understand something better or accumulating evidence that supports and clarifies a prior insight. Both of these involve coming to perceive a kind of order in the world that was hidden previously. The mysterious quality of this gain in knowledge has occupied philosophers since the time of Plato, and imagination has been portrayed as an impediment to the process far more frequently than it has been seen as a key ingredient. Above all, it is the unreliability of the imagination—its capacity for fantasy and self-deception—that has marginalized it in the principal Western philosophical traditions. Only the Romantics and Existentialists have had much good to say about it, and that is because both traditions cast themselves in an oppositional role to the modern quest for certainty.

As positivism has gradually waned over the past half-century, the iconoclastic, boundary-crossing quality of the imagination has become much more central to the theory and practice of qualitative research. Imagination has rarely been singled out as an object or a means of inquiry, but a better understanding of the functioning and limits of the imagination provides another lens through which the process of research itself can be examined, critiqued, and refined. Arguably, the imagination is a fundamental mode of thought, as integral to Cartesian rationalism as it is to postmodern skepticism, although it is developed in different directions and deployed for very different purposes in each case. Understanding some of the underlying processes could be helpful to researchers from a wide range of disciplines and traditions.

Imagination is “possibility thinking”—thinking of things as possibly being other than they are or both what they are and something else simultaneously. It is clearly linked to the capacity for metaphor, in which we draw selectively on knowledge in one domain to illuminate our thinking about an apparently unrelated domain. Imagination can involve visual imagery, as its etymology implies, but it can equally well involve any other kind of feature from the worlds of direct bodily experience, including sound, taste, smell, touch, movement, effort, and change, and of socially mediated experience, including activities, narratives, personalities, and relationships. Because of this, the imagination is strongly influenced both by personal history and by culture—a point that was overlooked by many Western thinkers but that emerged strongly

during the 20th century through work in psychology, anthropology, literary studies, education, and other fields.

Imagination is also clearly tied to the emotions in the same way as our sense of aesthetics. This strong affective quality seems to be implicated in our ability to choose relatively productive pathways through a huge range of possibilities. It also furnishes another reason that imagination has been distrusted by rationalist thinkers. Emotions muddle thought, and that has long been a central tenet of Western modernity. Ironically, behind this distrust, one can infer a particular imaginative—indeed, metaphoric—conception of reason invested with a strong emotional charge and rendered nearly invisible by its assimilation into habits of thought, speech, and action. Thus, imagination is to be sought not only in the unusual and desirable but also in the routine, unacknowledged, and unwanted—the shadow side of thought.

It follows that imagination in qualitative research is not only a means and an object of inquiry but also a perennial obstacle. Researchers are dependent on imagination for the pursuit of insight and understanding, they are continually confronted with the processes and outcomes of imagination in the ways in which people order and make sense of the world, and they must struggle against the tendency of the imagination to become channeled and restricted over time.

Imagination and Culture

In all of these aspects of the imagination, culture plays a crucial role. In fact, the relationship is a reciprocal one. As imagination is externalized in the form of language, buildings, artifacts, rituals, and so on, it helps to shape the environment and the experiences that will influence imaginative development on an ongoing basis. Humans are peculiarly dependent on their cultural milieu to provide “tools for thinking,” as the Russian psychologist Lev Vygotsky pointed out many decades ago. The paradigmatic example of such a tool, or rather an indefinitely extensible cultural toolkit, is oral language—a general capacity that must take on specific form in a particular language community to be useful. Over time, such a language system accumulates certain sets of metaphors, descriptive terms, narrative templates, and so on that are central to the culture of the community and, by the same token, vital imaginative resources for its users.

Although such cultural particulars obviously vary greatly, one may ask whether there are also some general features of imaginative thinking in oral language communities. This thesis has been argued by scholars of oral and written culture such as Jack Goody and Walter Ong, and was extended by educational theorist Kieran Egan into a fivefold typology of what he termed “kinds of understanding,” unfolding within the cultural history of modernity and recapitulated in the imaginative development of individuals. The acquisition of written language does not lead directly to the kind of literal understanding that is highly prized in technorationalist societies; rather, it opens the door to a distinctive imaginative style that Egan called Romantic and that is characterized by a fascination with great deeds and extraordinary people, the extremes of reality and limits of experience, and the use of classification and rules to impose human order on natural complexity. Largely excluded from formal education, this form of imaginative understanding is ubiquitous in mass media and popular culture, incorporating within itself elements of older Mythic (oral) and Somatic (embodied) understandings that are rarely acknowledged or examined.

Although qualitative researchers will often take cultural manifestations of Romantic understanding as objects of study (e.g., popular films, books, music, television), their objective is not usually to give a Romantic account of them. Instead, most research—to the extent that it is hospitable to imagination at all—is dominated by two contrasting kinds of understanding that Egan termed Philosophic and Ironic. The former produces theories, methodologies, research traditions, and paradigms, whereas the latter nurtures practices, approaches, communities, and viewpoints. Philosophic understanding underwrote the traditional modern intellectual ideal of steady collective progress toward definitive knowledge; Ironic understanding is Philosophic understanding that has gone reflexive, abandoning some of its pretensions to universal desituated truth telling and taking a more favorable view of the older forms of understanding on which it is built. This, however, is a “best case” scenario, for just as Philosophic understanding can become trapped in its own conceptual schemes, Ironic understanding can be ensnared by un-self-critical skepticism or a totalizing relativism. These are human attempts to bring the universe within our mental compass and, therefore, are flawed and fallible.

Imagination and the Researcher

Limited as this sketch of the contemporary imaginative landscape necessarily is, it serves to highlight three significant challenges to the qualitative researcher. The first of these stems from the way in which we are the products of a particular cultural context—a particular historical moment—that has made available to us only a small fraction of the imaginative resources invented and used by humankind. Among other contemporary illusions, the spread of English has encouraged the notion that one language can be adequate for all intellectual tasks—an impoverished view indeed. There is a similar temptation to limit one's writing and presentations to the safe middle ground of academic discourse, dragging the imagination along familiar ruts, even for avowedly critical purposes. To take imagination seriously is to question some of the most basic assumptions of our scholarly worlds.

Second, releasing the imagination, to borrow Maxine Greene's phrase, is not just a matter of using different language; it also requires different practices. Qualitative researchers need ways of connecting with the worlds they study that transcend their disciplinary or theoretical commitments so that they remain open to surprise, contradiction, and wonder. Some researchers find such a connection through the arts or literature, others may be involved in grassroots activism of various kinds, and still others may participate in some kind of physical or spiritual discipline. Usually these practices will come to inform the research in some way, serving as a guard against routine and complacency.

Third, little is known about ways in which to ensure that groups or institutions become and remain hospitable to imagination. This should be of concern to researchers because all of us are influenced by the cultural milieu in which we work and communicate with others on a daily basis. Some of the policies and practices that have been successful in technological and scientific institutions could perhaps be adapted to the university departments and research centers in which most qualitative researchers find themselves. How different would our research be if we were asked annually to evaluate our contributions to the imaginative vitality of our field and our intellectual community?

IN-DEPTH INTERVIEW

In-depth interviews are interviews in which participants are encouraged and prompted to talk in depth about the topic under investigation without the researcher's use of predetermined, focused, short-answer questions. The researcher is not required to prepare an extensive list of questions; rather, the researcher is required to be aware of the major domains of experience likely to be discussed by the participant and be able to probe how these relate to the topic under investigation. In-depth interviews are suitable for data collection in a variety of research methodologies, including grounded theory and ethnography, and are often used as a stand-alone method of data collection without reliance on an underlying philosophical approach.

In-depth interviews are often referred to as semi-structured interviews because the researcher retains some control over the direction and content to be discussed, yet participants are free to elaborate or take the interview in new but related directions. A distinction can be made between structured interviews where a list of preconceived topics are responded to by the participant, unstructured interviews where no preconceived topics or questions are devised, and semi-structured or in-depth interviews where the conversation oscillates among the researcher's introduction of the topic under investigation, the participant's account of his or her experiences, and the researcher's probing of these experiences for further information useful to the analysis. Careful interviewing within this middle ground between rigid structure and complete uncertainty provides the researcher

with in-depth information on the topic of interest without predetermining the results.

Given the versatility of the in-depth interview, it is no wonder that it has rapidly become one of the most common methods of data collection in qualitative research. However, in-depth interviews are not without their criticisms. One criticism is that the in-depth interview provides limited opportunity for interpretation by the researcher because recalling an experience in an interview does not replicate actual observation of the experience or provide insight into the intentions or motivations of the various actors involved. Reliance on the in-depth interview as the sole method of data collection in realist research might not allow a full investigation of the topic because the participant and researcher are limited by the recall of the participant, the ability of the participant to articulate his or her experiences within the timeframe of the interview, and the ability of the researcher to ask the “right” questions to prompt more detailed discussion and aid the analysis. As such, in-depth interviews are often combined with other forms of data, such as observations, diaries, and documents, to produce a rich account of the research setting or phenomenon under investigation. Despite this criticism, in-depth interviews, due to the relative ease and cost-efficiency with which they can be conducted, will most likely remain one of the most popular and effective methods of data collection in qualitative research.

communicative events suggest more indexicality than do others. This includes indexical expressions, which draw meaning from their surrounding content or context (e.g., personal and demonstrative pronouns such as *you* and *that*, temporal-spatial expressions such as *here* or *then*). In addition to expressions or phrases, larger chunks of discourse can take on indexical meaning, including inside jokes that refer to another occurrence, code switching between languages or dialects, and reported speech or quotes. Indexicality implies these other occurrences' existence and relevance in relation to the current communicative event. Examining indexicality is common in various modes of discourse analysis, including conversation analysis, critical discourse analysis, membership categorization analysis, and semi-otic analysis.

Indexicality relies on assumptions that communicative contexts reveal and/or create meaning. In contrast to the referential or denotational capabilities of language use, indexicality requires that the context of communicative production must be considered for meaning to be inferred. Instead of directly naming, or drawing attention to, an unambiguous referent, indexical elements of language draw meaning from their variable contexts (e.g., time, situation, surrounding content). In addition, such “pointing to” requires that surrounding grammatical, semantic, or pragmatic context (other words, available meanings, or inferred content) be observed to be understood.

When examining or analyzing language use, attention to its indexical functions provides insights into speaker intention and sensemaking in ways that attention to more literal referential functions of language do not make available. For instance, in conversation analysis, indexicality directs interlocutors to relevant pieces of the current discursive interaction (e.g., roles, other events, prior turns at talk). This can reveal implied intent or meaning that, for various reasons, is not represented explicitly in talk. In linguistic anthropological treatments of discourse analysis, indexicality is seen as directing interlocutors to power-laden, authorized, and sociocultural aspects of the situation. Thus, from this perspective, indexicality includes attention not only to indexical expressions but also to larger chunks of discourse such as other texts, sociocultural discourses, and power-related mediating symbols.

The conversation analytic treatment of indexicality differs from anthropological treatment in that the former considers indexical referents as grammatically and sequentially manifest, whereas the latter requires consideration of the sociocultural background of speakers

INDEXICALITY

Indexicality is the capacity of language to point to something without directly referring to it. All language has the capacity for indexical function, but some expressions and

and hearers to analyze indexicality. For example, although race might not be mentioned explicitly in an interaction, knowledge of its potential relevance to the situation may be required to understand an indexical reference to a well-known sociohistorical event that is politically and ideologically loaded. These references point to circulating discourses and sociocultural moments, including the power, opportunity, and membership they imply.

INDIGENOUS RESEARCH

Indigenous research is systematic inquiry that engages Indigenous persons as investigators or partners to extend knowledge that is significant for Indigenous peoples and communities. Indigenous research is distinct from studies of Indigenous societies and issues that adopt a positivist position that behavior and meaning can be derived best from objective, value-neutral observation and data collection. The emergence of Indigenous research during the latter decades of the 20th century was advanced by parallel developments in qualitative research methods, although divergence from certain conventions of academic practice continue to generate discussion and challenges.

Identifying Aboriginal Peoples

It is estimated that there are more than 370 million Indigenous people spread across 70 countries from the Arctic to the South Pacific. According to a common definition, Indigenous peoples are the descendants of those who inhabited a country or a geographical region at the time when people of different cultures or ethnic origins arrived. The new arrivals later became

dominant through conquest, occupation, settlement, or other means.

Most Indigenous peoples have retained distinct characteristics that differ from those of other segments of the population. They display resolve to maintain and adapt their heritage and historical links to their territories and associated natural resources.

Indigenous peoples may identify as a single people, such as the Maori of New Zealand, or as belonging to diverse tribes of Native Americans in the United States or distinct First Nations in Canada. Related peoples may span several national boundaries, as do the Inuit of the Arctic region. Inter-marriage with persons of other ethnic origins, urbanization, and lifestyle changes contribute to increasing diversity within Indigenous communities. Self-identification and acceptance by the community are the criteria suggested by United Nations (UN) agencies as the most fruitful approach for identifying members of the collective.

An Evolving Research Paradigm

Indigenous peoples and societies have been objects of research interest since the 19th century and the rise of social anthropology as a distinct field of research led by U.S. and British scholars. Indigenous peoples in the Americas and other colonial sites provided case studies for the development of theories of cultural evolution that implicitly legitimized the introduction of civilizing institutions to govern Indigenous homelands.

The 1960s and 1970s were times of social ferment around the globe, characterized by the dismantling of colonial empires, the civil rights movement in the United States, and the articulation of human rights in the international sphere. Particularly in nation-states with a British colonial connection, Indigenous peoples sought redress for neglect and violation of historic treaties. In concert with social movements to link Indigenous peoples within nation-states and across international boundaries, Indigenous writers began publishing trenchant critiques of the power relationships that fostered and maintained marginalization, poverty, and powerlessness among their peoples.

Custer Died for Your Sins: An Indian Manifesto, published in 1969 by Vine Deloria, Jr., was a call to consciousness that reached tribal people in their communities and helped to animate collective action. Harold Cardinal's *The Unjust Society: The Tragedy of Canada's Indians*, also published in 1969, had a similar impact. During succeeding decades, increasing numbers of Indigenous peoples pursued higher education, acquired

research skills, and turned them to the service of political and community development.

Maori scholar Linda Tuhiwai Smith, in her 1999 influential book, *Decolonizing Methodologies, Research, and Indigenous Peoples*, was able to document the transition of Indigenous peoples' research agenda through four phases: from addressing *survival* as physical, social, and spiritual beings; to *recovery* of territories, rights, and histories; through *development* of inherent capacities and resources for a good life; toward the goal of *self-determination* by which peoples freely determine their political status and freely pursue their economic, social, and cultural development.

Indigenous Knowledge Systems

Whereas research is intertwined in many ways with political and social development, another more philosophical discourse has developed among a growing cadre of Indigenous scholars—colleagues who are engaged in research with Indigenous communities and others of a more skeptical bent. Exchanges among American, Canadian, New Zealand, and Australian researchers have fostered dialogue particularly on health research and ethics. Developments in international forums have highlighted the practical and potential value of traditional environmental knowledge.

Traditional techniques of sustaining environmental systems in balance with human use are attracting interest, as is knowledge of plant life for agricultural, medicinal, and cosmetic purposes. Commercial exploitation of Indigenous knowledge has prompted efforts to protect the interests of holders of Indigenous knowledge through instruments such as state legislation in Peru and the 1992 international Convention on Biological Diversity.

Indigenous scholars during recent years have attempted to map the contours of Indigenous knowledge in terms that are comprehensible in Western knowledge systems. A common theme in these expositions is the dynamic nature of Indigenous knowledge, a way of engaging with reality rather than an artifact surviving from the past. Indigenous knowledge is specific to place and rooted in history, described in some traditions as reaching back seven generations and looking forward seven generations. It is holistic, involving body, mind, feelings and spirit. It emerges in dialogue and is acquired over time. Indigenous knowledge is expressed in symbols, arts, ceremonial and everyday practices, narratives, and

(especially) relationships. A recurring theme in Indigenous knowledge of diverse peoples is relationship with the land as a living entity that reveals the way of right living.

Indigenous peoples continue to value traditional ways of knowing, looking to elders as the keepers of oral tradition and the sources of wise counsel. Today they are affirming their right to conserve, elaborate, and transmit their knowledge using culture-based methodologies. They maintain that this knowledge base is essential to resolution of the range of problems that confront them. They further affirm that Indigenous knowledge, when shared appropriately, can contribute to well-being in the world at large.

The desire to conserve and develop Indigenous knowledge and to benefit from modern applications of such knowledge is a motivating force in community initiatives to assume a decisive role in research. The emergent field of Indigenous research being defined by Indigenous scholars privileges Indigenous concerns, Indigenous practices, and Indigenous participation as researchers and researched. The seminal question posed in this enterprise to Indigenous researchers and non-Indigenous collaborators alike is the following: Whose knowledge is extended by this research?

Transforming Research Relationships

From an Indigenous perspective, the need to transform research relationships arises from varied but similar historical experiences that have included being displaced from their traditional territories, having their languages and knowledge systems devalued as primitive, having their children removed to undergo aggressive resocialization, and meeting exclusionary and racist responses to their attempts at participating in the dominant society.

As Indigenous peoples contested the alienation of traditional lands, the effects of relocating communities, and harms suffered in residential schools and penal institutions, documentary research was often used to refute their claims. Research was seen at best as a tool of non-Aboriginal experts and at worst as an instrument of oppression. As represented in Figure 1, Indigenous knowledge was largely invisible outside the boundaries of Indigenous communities as it was obscured by hegemonic knowledge systems and the research that affirmed them.

By the 1970s, spaces in academic institutions were opening up to accommodate ethnic students and ethnic

Figure 1 The Need to Transform Research

studies. Intercultural research recognized the legitimacy of insider perceptions of cultural experience, and participatory research explicitly supported voices from the margins in speaking, analyzing, building alliances, and taking action. Despite these shifts, the power to create legitimate knowledge continued—and still continues—to rest with researchers and institutions working within conventional conceptual frameworks. Figure 2 represents the location of intercultural and participatory research in intersecting knowledge systems.

The relatively small size of most Indigenous populations, embedded in larger societies and interacting with them on many fronts, dictates the continuing necessity of intercultural knowledge exchanges. Indigenous scholars and traditional knowledge keepers assert, however, that such exchanges must take place in a more equitable and respectful manner than has occurred to date. In Canada, the concept of creating ethical space is gaining currency. In ethical space, represented in Figure 3, parties acknowledge different ways of knowing and learning; they nurture collaborative relationships and negotiate mutual responsibilities.

Figure 2 Intercultural and Participatory Research

Figure 3 Creating Ethical Space

The goal of self-determination for Indigenous peoples, although endorsed in 2006 by the UN Human Rights Council, remains visionary. The essential work of articulating and conserving Indigenous knowledge and applying it to contemporary challenges requires autonomy of effort that is still constrained by the requirements of institutional funding protocols. The evolution of Indigenous research will undoubtedly continue, motivated by pressing needs within communities and shaped by social and political developments nationally and internationally.

Convergence With Qualitative Research Methods

It is evident from the forgoing discussion that many of the goals and approaches that are characteristic of Indigenous research are supported, and indeed have been enhanced, by the growing recognition of qualitative research methods. Inductive processes for gaining understanding that can be transferred and adapted to new situations are congruent with narrative metaphoric modes of learning in Indigenous societies that favor oral communications. Valuing diverse perspectives, maintaining flexibility in techniques, and negotiating ongoing collaborative relationships between researchers and participants can help to bridge differences between cultures. As noted earlier, participatory research has been embraced by Indigenous peoples in many varied settings.

Critical theory and feminist research have been particularly valuable in altering the landscape in which Aboriginal research is practiced. Critiques by Indigenous intellectuals and activists such as Deloria challenged the representations of Indigenous peoples that appeared in outsider accounts. They laid bare the failure of societal

institutions to deliver justice and humane treatment to disenfranchised peoples. They deconstructed the power relations that perpetuate social inequality.

Coming as it did from outside the academy, this social analysis would have had little impact beyond the populations whose members lived the realities about which Deloria and others wrote without a complementary shift in research in the larger world. Although critical research has been cited for failing to induce change in the conditions it exposes, it nevertheless has reinforced voices from the margins and instilled confidence in young Indigenous scholars that research can be relevant to their experience.

Feminist researchers have given impetus to Aboriginal research by challenging the patriarchal assumptions that underlie language, perceptions, and interpretations in the standard canons of research in various disciplines. They have won recognition that the same phenomenon viewed from different standpoints can produce different “truths”—all of them with legitimate claims to validity. Debates within the feminist research community between women of color and academically trained, predominantly White women have pointed to the distortions of voice and silencing that can occur even when researchers are deliberately reflexive, questioning their perceptions and biases.

Ethics

Indigenous peoples and communities in a number of countries have developed protocols for ethical review and oversight of research involving their members or conducted on their territories. Government agencies in some countries, including Canada, the United States, New Zealand, and Australia, have instituted Indigenous-specific guidelines that complement and supplement ethical guidelines of general application. This section highlights some of the concerns around research practice that are addressed in such guidelines.

Ethical guidelines for research involving Indigenous peoples or communities typically recommend or require engagement of community representatives in reviewing research proposals in addition to institutional ethics review. Community review may be as straightforward as approval of a researcher who is known to be trustworthy or as complex as a formal agreement setting out goals, methods, review, and dissemination of results and the risks and benefits anticipated for both the community and researchers in the

Learning Within a Blackfoot Paradigm

Red Crow Community College, a Blackfoot-governed institution in the province of Alberta, Canada, participates in initiatives of the Canadian Council on Learning and the Social Sciences and Humanities Research Council while applying Blackfoot methodologies in research. In the project “Learning From Place,” core concepts derive from the Blackfoot language and the conduct of research is guided by elders with a deep understanding of traditional knowledge.

For example, *aokakio’ssin* (systems awareness) is described as the requisite pursuit of any hunter and/or gatherer who must seek to embody an ever more nuanced knowledge of regional and local ecologies so as to gain immediate benefit while simultaneously ensuring a sustainable affluence and avoidance of various hazards. Transmitting *aokakio’ssin* to Indigenous and non-Indigenous students involves experiential, ceremonial, and ethical education as well as intellectual formation carried out on the land.

Maintaining the integrity of a Blackfoot paradigm of knowledge requires continuing negotiation with institutions of Western culture through which research support flows.

project. Key issues addressed by such engagement are ensuring respect, relevance, and rigor.

Respect for human dignity is a keystone value in research ethics codes around the world. Guidelines that require informed consent of participants and protection of privacy may require adaptation to be effective in Indigenous contexts. For example, some stories of interest to a researcher may contain knowledge that is communally owned or that can be disclosed only by authorized persons. Formal leaders may be the preferred mediators with outsiders in some cases, whereas their involvement may pose a risk to vulnerable members of the community in other cases. Equitable participation of persons knowledgeable in the local culture to guide the research process is desirable whether or not it is mandatory.

Relevance of research to a participant community is increasingly a condition for engagement in projects. Participation of Indigenous communities is often solicited on the basis that the research will do good for society—if not for the immediate community. Indigenous peoples are fatigued with research often presented by outsiders that neither promises nor

delivers any visible benefits. On the other hand, there are many research needs identified by Indigenous communities—environmental degradation, epidemic health threats, and culturally appropriate economic development, to name a few. Meaningful participation in setting the research agenda at the outset is necessary to practice the ethical values of justice and inclusion.

Rigor in research involving humans surely means producing results that faithfully reflect lived reality that has validity or truth value for both the Indigenous and scholarly communities. People who perceive research as irrelevant or disrespectful are unlikely to volunteer participation or provide reliable information. A dual test of the validity of results is implied in participatory research, although the degree of influence that the community exercises may vary a great deal. Methods for validating research findings might not even figure in ethics protocols. Nevertheless, it is a criterion that community research bodies are imposing with increasing frequency. Indigenous concepts of rigor may conflict with scientific emphasis on objectivity in data collection or generalizations based on statistical formulas, whereas qualitative and participatory methods appear to attract confidence from Indigenous participants.

The ethical response to challenges is to communicate where approaches are similar and to negotiate space for differences, some of which may turn out to be congruent at certain levels. Other differences may just need to co-exist.

Issues in Ongoing Dialogue
