Bomohs are more knowledgeable and powerful than *dukuns*, especially in treating illnesses caused by social, psychological, and spiritual problems. They are general practitioners with a specialization in therapies similar to psychiatry in cosmopolitan medicine. Most *bomohs* utilize a powerful theatrical therapeutic routine, *main puteri* (“playing the princess”), which varies depending on

details of the patient's personal history. But they treat ordinary health problems as well. Teachers of "traditional personal self-defense" (*bersilat*) and master puppeteers (*dalang*) are also considered to be *bomohs* because they utilize the same classical Malay knowledge system as medical *bomohs*.

A *pawang* ("wizard") is more powerful and knowledgeable than even a *bomoh*. He can heal all kinds of illnesses, and he can conduct public rituals that ensure an excellent rice harvest or protect the whole community from a plague. Most *pawang*s and *bomohs* began their formal careers as *dukuns*.

All of these kinds of traditional healers tend to treat patients rather than illnesses, sometimes attempting to help clients gain the affection of other persons, or even win the public lottery. Successful healers and needy patients are not necessarily place bound and many travel great distances, even crossing international borders between Thailand, Malaysia, and Indonesia.

Cosmopolitan medicine did not begin to successfully challenge traditional *bomoh* medicine until after the successful independence movements following World War II, when nationalized health facilities and services and university training of natives in cosmopolitan medicine expanded rapidly. Since then, from time to time, government publicity campaigns have been directed against traditional medicine. *Bomoh* medicine survives, even prospers, but many practitioners have become more selective in the health problems they accept for resolution; perhaps, in response to the rising proportion of patients whose ordinary illnesses are resolved expeditiously and inexpensively through cosmopolitan medicine at government clinics and hospitals. However, psychological disorders of almost any sort are still likely to be dealt with by a traditional healer, and it is in the treatment of these disorders that traditional medicine continues to be an especially important health resource for Malays, and even for some members of other ethnic groups.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

Many aspects of traditional Malay medicine are known to ordinary persons. Malay adolescents and adults usually know how to stop the flow of blood from wounds and

how to clean and dress minor wounds so that the risk of infection is reduced. Those who live along the seashore know how to treat the stings of jellyfish by applying a dressing made from crushed fish or crustaceans that are naturally immune to jellyfish stings. And ordinary Malays know about some plants and parts of plants that cause illness. Some ordinary individuals know how to set and splint simple fractures, although a bone-setter (*tukang patah, tukang tulang*) is more skillful. Also, the bone setter would have a method for speeding the mending of the bone, for example, by teaching the patient to relate the feeling of the fracture to a rhythmic sound produced by the patient.

As noted above, illnesses can result from a diet that is not balanced according to commonly known humoral (non-thermal but sensual) concepts of "heating" (*panas*) and "cooling" (*sejuk*) foods; but the most basic foods in traditional diets, rice, and fresh fish, are "neutral." This relates to the common knowledge prescription of fish soup with rice as part of conservative therapy for illnesses caused both by excessive "cooling" or by excessive "heating" elements in the diet. Virtually everyone knows that foods that are "heating" cause a feeling of warmth and foods that are "cooling" cause a sensation of coolness, but that the effect of particular foods and substances on individual patients may vary. Generally, "cooling" foods include juicy, sour (*masam*), or "almost bitter or unripe" (*kelat*) fruits and vegetables. Really bitter (*pahit*) foods, as well as "filling" foods (carbohydrates, fats, and animal proteins) and salty foods are "heating" (*panas*). Spicy foods, such as chili are "pungent" (*pedas*) but not necessarily *panas*. Also, the terms "hot" (*panas*) and "cold" (*sejuk*) are regularly used to characterize social relationships. This classification of kinds of food, and the emphasis on balancing the perceived effects of the different kinds of food, usually results in a balanced diet in terms of cosmopolitan medicine (Laderman, 1987).

Food and drink are also perceived as media that can be manipulated in order to control attitudes and actions of other persons. Word charms and potions put into refreshments or meals can affect the emotions and thinking of the person who consumes them. A *dukun* or *bomoh* may help a client to become more attractive to potential spouses, business associates, or even customers by "treating" the client or by providing the client with a prescription to "treat" other persons—a potential spouse, business associate or customer. When these ingredients are appropriately effective, it is an instance of "affection magic";⁴

but if they cause serious illness or death, it is a case of “poisoning” (*racun*), or “slow poisoning” (*santau*). There are traditional poisons for killing one’s rivals and tormentors. But mostly, as in some cases of “perfumed rice” (*nasi uap*), illnesses or deaths are seen as instances of an “over-dose” and/or a result of the victim’s resistance to magical persuasion.

Malays enjoy delicious foods and drinks, but they are deeply concerned with purity. This is related to Islamic rules regarding diet in which alcoholic beverages and pork are forbidden as well as the flesh of other mammals and fowl that have not been ritually slaughtered. Additionally, animals that are seen as “powerfully unnatural” (e.g., a fish with legs) or known to cause health problems if eaten are classified as *bisa*. *Bisa* also refers to deadly poisons applied to the blades of knives, spears, and swords; and to speech that causes others great pain or death (Gimlette, 1971).

There are some variations in the degree to which individuals apply *halal* (ritual purity) rules to their own diets; but all are deeply aware of the rules. Non-*halal* food is often referred to as “dirty” (*kotor*), just as *halal* food is said to be “clean” (*bersih*). And the distinction between dirty and clean food is also extended to include food or drink to which word spells or magical substances have or have not been added. Also, food and drink are necessary parts of the celebration of religious, familial, and organizational feasts, in which the complex formal rules of salutation and comportment regarding differences in social rank are prominent. Food, drink, and speech—clean, dirty, or poisonous—lubricate the celebration of rank differences. All three are strongly related to beliefs about health.

In Malay language, *angin* has many meanings (wind, air, intestinal gas, rumor, attitude, desire, or temperament), depending upon the conversational context. As a very common descriptive medical symptom it is usually associated with intestinal gas, or with swelling, or strong pain. It can also refer to patients’ attitudes, desires, and temperament. All of these symptoms and problems are common among Malay patients. Some scholars have suggested that *angin* is a concept borrowed from Medieval European, Middle Eastern, South Asian or East Asian, ideas about the so-called four (or five) basic elements of material reality: earth (wood & metal), air, fire, and water.

Two behavioral syndromes, *amuk* (amuck) and *latah* (similar to LaTourette’s syndrome), are relatively

common in Malay populations. Both are probably related to the pressure of complying with complex rules of traditional social manners, which vary according to levels of formality in different behavioral settings and according to the ranks of different participants. The lower one’s rank in a given setting the more one must know and perform proper terms of address, forms of gesture and posture, and registers of language. Symptoms of these two disorders differ markedly, but both are probably expressions of psychological depression and of individual resistance to the pressures of the traditional Malay social order.

Amuk is viewed as a temporary state of physically aggressive insanity. In a suicidal attack, the *amuk* person attempts to maim or kill virtually everyone present. Traditionally, if the *amuk* survived the defensive attacks of others and returned to normal behavior, he was allowed to go free on the basis of having been temporarily insane. This, of course, is no longer true. Cases of murderous *amuk* have been rare for almost a century; but instances of unseemly and abusive verbal and physical aggression by males and females toward members of their communities, rural and urban, occur and are often referred to as instances of *amuk*.

Latah continues to be fairly common, especially among low ranking women. Unlike *amuk*, *latah* does not involve physical aggression. Rather, the affected person seems to satirize traditional manners and to mimic the words and gestures of others with whom they are interacting. Many Malays are less offended than entertained by this stereotypic behavior, which can be initiated by startling the *latah* person, forcing the *latah* person to “perform” until she or he is exhausted. Most traditional healers do not consider *latah* or *amuk* to be curable health problems.

There are apparent instances of *latah* in which an individual who has never had *latah* behavior begins to yell obscenities and becomes aggressive, as in *amuk*. These instances are often diagnosed as a case of *tuju*, a victim of a magical curse (*jampi*) by a rival or person who feels jealous hatred (*dengki*) toward the victim, and who has directed an evil spirit to enter the body of the victim. The victim may be treated almost immediately by a knowledgeable person, who subjects the victim to excruciating but not damaging pain, while asking, “who are you.” The question is directed to the evil spirit who has entered the victim’s body. It is the spirit who feels the pain and cries out its name. Repeating the spirit’s name forces it to answer all questions truthfully; so the *dukun*

or *bomoh* asks it “who sent you.” The truthful answer forces the intruding spirit out of the victim’s body, and the victim recovers.

Hantu dadah (the evil spirit of drugs) has become a scourge of Malay youth and young adults in the last four decades. Traditional formulae for love magic and murder contain opium, and *ganja* (marijuana) is a common ingredient of traditional health elixirs consumed by Malays. Until 1952, in Malaysia, opium smokers had to register with the government, but were not otherwise prosecuted. Drug addiction was not seen as a serious public health problem among Malays until the late 1960s, when large numbers of adolescent Malay individuals began to migrate to urban centers to seek employment and adventure. Movies, television, and magazines sponsored the idea of personal freedom and individualism. Possession of addictive drugs became a capital offense, and many young Malays were hanged. *Ganja*, smoked (combined with tobacco, and/or filtered through a water-pipe device), became the usual drug of choice among most young Malay addicts, although there is some use of heroin and even cocaine, especially among the more affluent.

Traditional treatment usually involves cleansing the patient’s body of the drug’s “spirit” (*hantu dadah*). The first meeting of patient and *bomoh* is like that for most kinds of illnesses. A close family member or friend of the patient contacts the *bomoh*, describing the patient and symptoms, to set a date for the first visit. Then, patient, family members, and friends meet with the *bomoh*, who examines the patient to determine what the health problem is and whether the *bomoh* can cure it. The patient or a family member may have been instructed to purchase three, four or seven limes (*limau nipis*) for the latter purpose. Physical examination includes inspection of the eyes, mouth and ears, and palpitation of limbs and body. The patient’s pulse is usually taken in a special way, with the first three fingers of the right hand of the *bomoh* on the radial blood vessel of the left wrist of the patient. The “reading” of the first finger relates to health conditions from the feet up to the navel, the second from the navel to the shoulders, and the third to the neck and head. Other examination procedures may include inspection of the curve of the spine, elasticity of forehead skin, examination of nails and skin of the hands, neck pulse, thumping the back of the rib cage, listening to stomach noises, clotting time, and appearance of a drop of blood (humors). After the examination and some discussion with patient and family members, the *bomoh* may cut a thin slice from

each lime, in turn, which fall into a bowl of water that has absorbed powerful words spoken by the *bomoh*. Some slices float peel-side up and others float peel-side down. The sequence and proportion of each of these two possibilities signals whether or not the *bomoh* will take the case. The details vary, of course (Provencher, 1984; Werner, 1986).

If the *bomoh* decides to take the case, she or he usually prescribes a routine of prayer and bathing, using *bomoh*-blessed water and herbs as additives to the bath water, and the patient is given instructions concerning diet, and scheduling of work and other activities. The patient or a relative is delegated to purchase ingredients (*ramuan*) to be used for treatment at home and for the next session. In subsequent sessions, the *bomoh* will probably: (1) administer herbal medicines that purge the contents of stomach and bowels; (2) provide other blessed ingredients to be added to bath water; (3) outline a course in religious devotion; and (4), if the patient completes the course of treatment successfully, celebrate success with a small ritual feast (*kenduri nasi guru*) with patient and family providing a special tray to feed any good spirits involved and a gift/payment to the *bomoh*.

The beginning and ending of treatment, the divining of whether or not the *bomoh* can cure the victim’s illness and the payment/celebration in successful cases are standard. Details of diagnosis/treatment vary according to the perceived cause of the illness, and according to the routines of particular *bomohs*. There are many different Malay “psychiatric” therapies, sometimes glossed in the literature as “playing the princess” (*main puteri*), in which the *bomoh* begins to pray, goes into a trance, speaks in another voice, collapses, revives, and magically extracts “dirty things” (*kotoran*) from the body and soul of the patient. The “dirty” extracted things vary: oddly shaped artifacts and thorns, parts of insects, hair, dirt, and rusty needles. And the means of extraction vary too, including: grasping odd shaped objects and insect parts out of thin air, collecting hundreds of red hairs by rubbing a ball of semi-dry dough over the body of the patient, collecting rusty needles and dirt by rubbing the body of the patient with an unbroken raw chicken egg, and collecting dirt and objects by rubbing the body of the patient with a previously unbroken betel nut pod. In all of these, the symbolism is that of “unnatural,” “intrusive,” or “dirty” things and food. From a Malay perspective, these broken dirty things symbolize broken and improper social relationships. *Bomoh*, patient’s relatives and friends, and even the

patient may join in trying to explain the “evidence.” The explanation is the most important part of the cure. It works to the extent that the *bomoh* and her/his helpers know quite a bit about the patient and the patient’s relationships with others. Successful practitioners usually have helpers, often knowledgeable practitioners, who gather information about the patient, the patient’s family, work mates, other acquaintances, and friends. And the most successful of these *bomohs* write their cases in notebooks, which they read and reread for comparison with new cases.

SEXUALITY AND REPRODUCTION

Knowledge of sexual activity is gained early and naturally in the context of familiar and relaxed back region behavior of the Malay house, where dress, speech, and behavior are extremely relaxed and casual. Older children, especially girls, take care of their younger siblings. If a woman has no daughter, a son often takes the role of mother’s helper, especially in the care of babies and infants. Malay children know the anatomy of gender and where babies come from. Most Malay couples share active and imaginative sex lives, and joke about the formality of what they imagine to be the standard position for sexual intercourse in English culture. Nonetheless adolescent girls are secluded and their virginity is protected, as much as possible, until they are married. Pregnancy before marriage is a matter of scandal. And, under Islamic law, a private meeting of a man and woman who are not married to each other constitutes the crime of *khalwat* (“close proximity”), which is punished under the jurisdiction of the Islamic courts. Adolescent boys and men, however, are expected to be sexually promiscuous before, and even after marriage.

Marriages are supposed to be arranged, and sometimes they are. But beginning in the 20th century, when Malays and most of the rest of the world began to experience rapidly increasing secularization through mass media, individuals more frequently exercised personal choice regarding marriage. For example, interviews in the 1960s of elderly Malay women who had migrated to Kuala Lumpur from Indonesia in the first three decades of the 20th century revealed that many had married more than once and that most of their marriages had been with men of their own choice. Nonetheless, even in the 1990s, the ritual details of most Malay marriages were traditional and they projected images of arranged marriage.

Some *bidans* perform very early abortions for adolescent girls and unmarried women and for married women who do not want more children. Several common traditional methods do not utilize surgical instruments and are applied as soon as possible, usually just after the first missed menstrual period: (1) deep massage of the abdomen by a *bidan*; (2) *bidan*-made pills containing a mixture of drugs and other ingredients that are *panas* “heating”; and (3) the juice of plumbago root, consumed as a drink.⁵ Often, these methods and others are applied in a single case.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

Conception is easier if both male and female are “cool” (*sejuk*), so both prospective parents should watch their diets if they want to have children. Traditionally, conception is said to be possible only during the first three days, the three middle days, and the last three days of each month . . . a sort of “Malay roulette.” At first the embryo is just a blood clot, a combination of the parents’ seeds. Later, in the third month, it is said that the fetus’s “elder sibling,” the placenta, comes to join the fetus in its journey toward birth. As the pregnancy progresses into the seventh month, there is a formal ritual inspection and “rocking the belly” (*lenggang perut*), by the *bidan*, to verify or correct the position of the baby in the womb, so that its legs are up and its head is down, ready for an easy birth. If it is not in the proper position, the mid-wife, through massage and manipulation, can maneuver it into the proper position. It is said that a good *bidan* is more expert in this procedure than a doctor or midwife trained in cosmopolitan medicine. A male *bomoh* is not called to pregnancy cases unless there are serious complications, and his task is that of spiritual assistance. The *bidan* does the work of massaging the mother’s abdomen to relieve pain and of applying gentle pressure appropriately to facilitate a difficult birth (Laderman, 1987). Traditionally, the umbilical cord is supposed to be cut with a bamboo knife, but nowadays steel scissors are used. The umbilical cord and placenta are set aside, to be buried with a viable coconut near the house where it will grow into a tree, from which the “elder sibling” can easily participate in the birth of future “younger siblings” (*adik*). Throughout the Malay world, since the 1960s, the frequency of hospital births

has increased, but many, perhaps most Malay women still go to a *bidan* during pregnancy even if they intend to enter hospital for the actual delivery. A traditional 40-day postpartum period in which the new mother follows a restricted diet is still common in rural areas, but many (perhaps most) urban women follow diets compatible with cosmopolitan medicine.

There is no particular preference for boys or girls. Daughters perform more service to the family. Sons provide more opportunities for ritual display. Women often prefer the first baby to be a girl, so that the mother has a good helper early in the marriage (Provencher, 1971).

Infancy

A woman's first baby, female or male, receives a great deal of attention from adult relatives, neighbors, and friends of the family. Subsequent babies receive less attention, depending on the spacing of births, and they are tended by older siblings. Roles of boys and girls begin to diverge at five or six years of age. Psychological problems in later life are more common among the eldest and the youngest of a sibling set, perhaps because as infants and children their experiences in the ranked relations between siblings were less balanced, lacking deep experience either of being junior or of being senior in a society where rank is the most basic aspect of social relationships (Provencher, 1999).

Female babies are brought symbolically into the fold of Islam at a much earlier age and with less physical trauma and social fanfare than males. Forty days after a Malay baby girl is born, adult female neighbors and relatives gather at the mother's home to celebrate the end of the postpartum period of the new mother and to perform a ritual clitorodectomy (actually a clitoridotomy) of the newborn baby girl (Laderman, 1987). In this Malay ritual, unlike the equivalent ritual in some other Islamic societies, the clitoris is not removed or even damaged. It is barely scratched. The physiologically equivalent traditional entrance to Islam for Malay boys, circumcision (*sunat*), comes at a later age and involves more physical and psychological trauma.⁶

Childhood

By the mid 1960s most of the serious epidemic diseases of childhood had been controlled or mitigated by public health systems of the post-colonial governments of

Southeast Asia, and treatments for simple ailments with commercial patent medicines were easily available and inexpensive. Nonetheless, intestinal ailments remain common among Malay children. After they can walk, they move easily from one neighbor's or relative's house or apartment to others', eating and drinking as they go. Especially in instances of prolonged illnesses that have been treated but not cured by cosmopolitan medicine or patent medicines, traditional healers are consulted.

Infancy ends with the beginning of schooling, which can be a traumatic psychological experience for some Malay children, especially those who are spoiled (*manja*). In Malay folklore and popular culture, the spoiled child (*si manja*) is one who does not have serious responsibilities. In some instances, this is a female with many older sisters who do most or all of the household chores; or it may be a male who is the eldest in a sibling set (*si long*), but whose sisters are almost his age, so that he would not have done the household chores. Sometimes such a favored child, usually a boy, has great difficulty adjusting to the new disciplines of schooling, even to the point of having tantrums. A *bomoh* or *bidan* may be consulted if tantrums continue.

Adolescence

Adolescence is not a clearly marked age in traditional Malay culture. For example, most males are circumcized after religious instruction, sometime between 9 and 13 years of age, but the range is 6 to 20 years of age. Traditionally, the circumcision ritual and feast (*kenduri bersunat*) is a public event, sometime hosted by a single household with one or several boys and sometimes by several households in a neighborhood. In the latter case, an arbor or open-wall tent may be erected in an empty space near the street to ease access for on-lookers and guests. This also reduces costs and labor for each household, and the ritual of the feast and the actual operation of circumcision of each boy can be viewed by all who attend. After prayer, the circumcision expert (*tukang sunat* or *mudim*) pulls the foreskin over the end of the glans of the penis, clamps the foreskin with a traditional implement, and cuts off the excess foreskin with a bamboo knife. Then he applies a medicinal compound (*obat tasak*) and bandages (*tali kundang*). The boys, now fully Islamic males, lie down on cots or bedding dressed only in their sarongs, and are on public view the first day. Night-lights are lit in their houses until the wounds heal,

several days later. Health problems attending circumcision are rare, although newspapers occasionally print stories about a slip of the knife by an incompetent *tukang sunat*.

There is no similar coming of age celebration for girls. The onset of menarche does not define the beginning or ending of adolescence for Malay females. However, a part of marriage ritual involves an exhibition of the bride's ability to read and recite the Koran; and some female *bomohs* have said that this is more equivalent to male circumcision than the cutting of the clitoris, because it is evidence of being fully Muslim. School systems in southern Thailand, Malaysia, and Indonesia provide another, institutional means, by which Malays discuss the stages (*darjah*) between childhood and adulthood.

The virginity of girls until their first marriage is closely protected through modest dress and careful chaperoning. And the possibilities of being attractive to boys through fashionable clothes are still dampened by the common requirement of school uniforms for public as well as private schools in Southeast Asia. Nonetheless, adolescents are regarded to be naturally *gatal* ("itchy" or easily sexually aroused), flirtations occur, and girls become pregnant. The pregnancy may lead to marriage, an early abortion, or birth, and informal adoption of the child by an adult relative. Adoption is not encouraged in Islamic law, but as a traditional practice among relatives in Malay society it is fairly common (McKinley, 1975).

Young unmarried men may be seduced or be driven sexually mad by a woman through her feeding him "perfumed rice" (*nasi uap*), a common diagnosis of young men caught engaged in lewd sexual behavior in public. Adolescent girls, too, are thought to be driven crazy by love magic. The cure may involve ritual discovery of the "real" perpetrator and/or sending the victim to live with a relative in a distant place.

Prostitution is common in towns and cities, and venereal diseases and AIDS are serious health problems. But these are dealt with almost entirely within the context of the cosmopolitan health services.

Adulthood

Marriage marks the beginning of adulthood, both for women and men. But full status as adults is attained only after one's first child is born. Rural women have more children than urban women. This is a choice based on the

economic value and costs of children and on access to inexpensive birth control. A husband, to the extent that he is interested in girlfriends who might become secondary wives, is often viewed by his first wife as a health risk (venereal diseases and AIDS). According to law, a man must obtain formal consent of his present wife or wives in order to marry subsequent wives (only four wives are allowed). Most Malay women do not want co-wives because it reduces their own household income (by law, each wife is entitled to a separate household and reasonable household expenses) and they also understand the health risk. Sometime, however, as the first wife of a wealthy man ages she may welcome a husband's younger second wife, especially a friendly kinswoman without health problems who would also be an ally. Malay men who were born poor in rural places and have nonetheless become very successful in the modern urban world often suffer seriously from hypertension, obesity, and early death. This may be a matter of richer diet and less exercise than their ancestors.

The Aged

The aged are revered in formal courtesy and are commonly cared for by their children in their last years. This care of elderly parents is often given as a reason for having children. Men are viewed as more likely than women to become senile, and women who live beyond child-bearing years usually live long lives.

Dying and Death

Death of a young or middle age person is often suspected to have been the result of sorcery or poison. Death of the elderly is viewed as natural and even a blessing. Funerals and burials follow standard Islamic practices. Notice is immediately given to close relatives and friends who will come to the wake, and the appropriate Islamic religious functionary is contacted to arrange for burial in an Islamic cemetery.

NOTES

1. The basic difference between Malay and Minangkabau cultures is in rules of inheritance. Malay kinship organization is bilateral and Minangkabau kinship organization is matrilineal. This difference may be related to different regional strategies for effectively

combining in a single community two major and different economic activities: wet rice cultivation and commerce.

2. There is anthropomorphic folklore about the trickster mouse deer (*kijang*) that resembles that of the trickster rabbit of Africa, but this may even support the other evidence of traditional Malay disinterest in the rainforest.
3. One of the fairly common ingredients in such concoctions is lead arsenate, which even in small accumulative doses can eventually cause death.
4. "Love magic" does not clearly suggest the range of kinds of attraction that bomohs claim to achieve for their clients: *kasih sayang* = familial love, as in a mother's love for her children; *suka* = preference, as for a particular restaurant; *kasihan* = pity, as in pity for an unfortunate person; *cinta* = romantic love; or *syahwat* = sexual lust.
5. See, especially, Gimlette, 1971.
6. There is mention in the literature of ritual haircutting of boys at birth and also at forty or forty-four days after birth. I witnessed several of the latter during my dissertation research in 1964–65, but none during later ethnographic fieldwork among Malays. In classical Malay literature, relevant to pre-16th century AD, heroes of Melaka wore their hair at shoulder length. A century ago, a boy's hair was shorn, except for a top lock, shortly after birth, and was often not cut until just before circumcision or marriage. And in modern Malaysian comic books a certain child-like mischievous spirit is pictured naked and with a top knot [Provencher, 1999; Skeat, 1900].

LOCATION AND LINGUISTIC AFFILIATION

Maori are the indigenous people of New Zealand. Of Polynesian descent, the first voyagers arrived in New Zealand around 1000AD in a series of planned migrations from Eastern Polynesia (probably Tahiti), by way of Rarotonga. Although there are minor tribal dialectal differences, there is a single Maori language that has similarities with other Polynesian languages especially Hawaiian, Tahitian, and Rarotongan.

OVERVIEW OF THE CULTURE

Maori society was essentially tribal. There were forty or fifty major tribes (*iwi*) and many more smaller tribal groups (*hapu*) who occupied specific territories and had distinctive customs and dialects, though subscribing to a single common language. While tribes were largely autonomous, complicated social networks were formed to gain political and strategic advantages and so leading to a dynamic set of interacting alliances.

Within all tribal narratives emphasis was placed on a close affiliation with the surrounding landscape and distinctive landmarks or waterways often reinforced tribal identity. This symbiotic relationship with the natural environment was reinforced in the creation story. *Rangi* (the sky father) and *Papa* (the earth mother) were forced apart by their children (the forests, oceans, winds, plants, fish) who subsequently challenged parental authority. By personifying the laws of nature, human motivation was attributed to the elements and by the same token, the human condition was linked to the often harsh natural environment.

Perhaps for that reason tribes were constantly on guard for the unexpected and placed great store on maintaining mana (authority) over their own territories and people. Attempts by other tribes to diminish mana, either through plunder or trading insults, led to war and, not infrequently, cannibalism. The ultimate act of asserting mana was to devour the heart of a foe. But there were also more subtle forms of retaliation including the imposition of a makutu or spell on an individual or group.

Loss of life through warfare was a common hazard, greatly exacerbated by the 19th century musket. Changes to the definition of Maori make it difficult to draw comparisons over time, but there is strong evidence of a substantial and sustained increase in the Maori population since 1900 when, at 45,000, extinction had been widely predicted. For the past three census takes it has been possible to determine the number who are descended from a Maori as well as the number who elect to identify as Maori. Both are valid measures though identity is regarded as the more meaningful measure. In the 2001 census 604,110 people indicated they were descended from a Maori, and 87%, 526,281, actually identified as Maori (Statistics New Zealand, 1998).

While accounting for some 14% in 2001, by 2051 the Maori ethnic population will almost double in size to close to a million, or 22% of the total New Zealand population. By 2051 33% of all children in the country will be Maori, and Maori in the working age group, 15 to 64 years, will increase by 85% (Statistics New Zealand, 1998).

Yet though the younger age groups will continue to grow, an equally significant change will be an increase in the number of older Maori. By 2051 the proportion of Maori elderly would have risen from the current 4% to 15%. Though still youthful, the population will have a larger cohort of over 60 year olds. At ages 65 and over, the growth is projected to be in excess of 300%.

Like many New Zealanders, Maori are mobile. Following World War II urbanization resulted in major

migrations from country areas to towns and cities and by 1976, more than 8% of Maori were living in urban settings, a quarter in the greater Auckland area. Emigration overseas has also become a significant trend, some 30,000 Maori now being recorded as residents in Australia. More recently still, there has been a shift in internal migratory patterns away from urban areas where unemployment is high and back to tribal areas such as Northland, from where grandparents had moved some thirty or forty years earlier.

Over the past two decades, in addition to demographic change there has been a dramatic revitalization of Maori language and culture with a renewed sense of commitment to indigenous values and knowledge. It has been accompanied by a demand for increased autonomy and a parallel rejection of policies of assimilation and dependency. Maori providers of health and education services have been part of the trend and their emergence has resulted in pressure for theoretical and methodological frameworks that can incorporate Maori perspectives as well as scientific practice.

THE CONTEXT OF HEALTH: ENVIRONMENT, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

Epidemiological Trends

Prior to European colonization of New Zealand, the Maori population was thought to have reached a steady state, around 150,000 to 200,000. The major life threatening diseases were associated with pneumonia, physical injury, child birth, and gastro-intestinal disorders. In the 19th century when settlers from Europe began to arrive, there was a dramatic epidemiological shift. Infectious diseases, such as typhoid fever, tuberculosis, measles, and influenza took a heavy toll. A lack of natural immunity combined with the impacts of new lifestyles and diets led to high mortality rates (in 1854 there were over 4,000 deaths during an epidemic of measles) and depopulation. The situation was aggravated by a high number of deaths attributable to muskets—an innovation that altered the nature and scale of tribal encounters and battles with the British imperial troops.

As depopulation was arrested and population increases began to occur disease patterns changed again. Although still a major problem until the middle of the

20th century, tuberculosis as a major cause of illness and death was eventually to give way to heart disease, cancers (especially cancer of the stomach, lung, cervix), non-infectious respiratory disorders, and metabolic disorders especially diabetes and obesity. By 1976 it was also apparent for the first time that mental health problems were a significant cause of morbidity, reflected in high hospital admission rates, a high prevalence of conduct disorders, alcohol and drug misuse, and quite recently, high rates of youth suicide.

Although Maori life expectancy has improved substantially over the past century and is now 68 years for men and 73 years for women, Maori and non-Maori disparities in health are evident in almost every disease category and in admission rates to hospital. Similarly, the increased burden of disease experienced by Maori, as measured by disability adjusted life years (DALYS) is approximately 75% greater than the age-standardized DALY rate for other New Zealanders (excluding Pacific peoples) (Ministry of Health, 2001). At the same time, if Maori standards of health are benchmarked against the health standards of earlier generations of Maori and the health standards of other comparable first peoples, it is clear that major improvements have occurred so that the Maori population is not only more numerous than at any time in history but also enjoys greater longevity and a higher overall standard of health.

Socio-Economic Circumstances

Collectively Maori are over-represented in lower socio-economic groupings, but between Maori individuals there is also considerable variation that is not immediately obvious when comparisons between Maori and non-Maori are made. At an aggregated level the gap between Maori and non-Maori is wide but there is also an emerging gap between Maori who are employed and well qualified and those who are unemployed with poor prospects of employment. Health status and housing standards are likely to be reflected in that differential. On the other hand, it is unusual for middle class Maori to live entirely apart from wider family networks. Each Maori family group is inevitably represented across the social strata (Henare, 1994). In this regard it is often difficult to separate socio-economic conditions from cultural and historical factors, even though some individuals may be relatively well-off.

Educational achievement is probably the most significant determinant of socio-economic advancement and although achievement levels lag behind non-Maori, there are signs that Maori are making gains. The establishment of alternatives such as Kōhanga Reo (Maori language early childhood education centers) have provided an incentive but within the mainstream higher Maori participation rates in early childhood education have also been evident, growing by over 30% between 1991 and 1993. However, despite the fact that over 40% of all Maori children under 5 years of age are enrolled in early childhood services, the growth has failed to keep pace with the increase in enrollments of non-Maori so that the disparity is not reducing and may even be increasing (Ministry of Education, 1998).

Educational underachievement is directly linked to work force participation and Maori levels of unemployment bear out the relationship. As well, and perhaps of greater significance, Maori unemployment has mirrored macro-economic swings and has been exacerbated by the move toward free market policies that occurred in New Zealand after 1984. Up until 1987 Maori were more likely than other New Zealanders to participate in the labor force. However, by 1988 a sudden rise in unemployment had occurred, and continued for a further 4 years reaching 27% in 1992. Non-Maori unemployment had also increased but the rates were relatively low (4% rising to 7%) so that the disparity was high, and remains so (Maori unemployment is now close to 14%, non-Maori around 5%). Of particular concern is the relatively high youth unemployment rate; in 1996 the overall unemployment rate was nearly 8% for all New Zealanders but 20% for 15–19 year olds and 30% for Maori aged between 15 and 19 years (Childrens Agenda, 1999).

Because of their dependence on employment, income levels for Maori are significantly lower than for non-Maori. But there are other reasons that contribute to Maori economic disadvantage including long term unemployment, disability and sole parent households (New Zealand Government, 1994). Maori are over-represented in all categories of beneficiaries, have uptake rates of more than three times the non-Maori rate for the domestic purposes benefit and are twice as likely to receive an unemployment benefit. In 1996 one in every two Maori women aged fifteen and over received a government benefit compared with one in five non-Maori women, and 45% of Maori women lived in households where the

annual income before tax was \$30,000 or less (Te Puni Kokiri, 1999).

Political Position

In 1840 the British Crown signed the Treaty of Waitangi with Maori tribes. The Treaty guaranteed continuing property rights and a degree of tribal autonomy. However, it was largely ignored and by 1975 Maori discontent with the appropriation of land, forests and fisheries, together with concern about the erosion of Maori language and culture, led to the establishment of the Waitangi Tribunal. The Tribunal has the authority to investigate grievances against the Crown for breaches of the principles of the Treaty and is able to recommend remedial action to the Government. Over 800 claims have been lodged. A continuing emphasis on the Treaty of Waitangi has created irritation for many non-Maori New Zealanders but, in the absence of a written constitution, it remains a pivotal focus for Maori especially in defining their position in modern New Zealand and their relationship with the government. The Treaty is included in health legislation and imposes an obligation of government agencies to actively address Maori health issues.

Maori have been active participants in the indigenous rights movement and are increasingly seeking opportunities for greater autonomy, not necessarily as an independent nation-state but in decision-making over Maori resources, the delivery of services to Maori, and full participation in the affairs of the nation. Progress has been considerable. In the current parliamentary system, out of 120 members of parliament, 17 are Maori and seven seats are reserved for members who represent Maori electorates. Maori are also represented in the judiciary, within the state services, in all professions, and in the diplomatic corp.

Medical Practitioners

Traditional healing was practiced by *tohunga* who were skilled in the use of *rongoa* (treatments derived from plant products) and the recitation of *karakia* (chants used to encourage healing through spiritual pathways). The Tohunga Suppression Act 1907 prohibited traditional healing methods but after the repeal of the legislation in 1964 there has been a resurgence of traditional methods and a number of healers have established large practices. There is a greater spirit of co-operation between medical

and customary approaches to healing with mutual agreement that all treatments have limitations and a combined approach may heal mind and spirit as well as body. Traditional healing as part of the modern health care system is now recognised by government and some contracts have been offered for traditional healing services (Ministry of Health, 1999a).

The earliest Maori medical practitioner was Maui Pomare. He graduated from the American Medical Missionary College in Chicago in 1899 and was followed in 1904 by Te Rangi Hiroa, the first New Zealand trained Maori doctor (Durie, 1998). There are now 198 Maori medical practitioners, a little over two percent of the total registered medical practitioners (Health Workforce Advisory Committee, 2002). Important to the recruitment of Maori doctors have been affirmative action programs, first introduced at the University of Otago Medical School in 1900, and continued at the University of Auckland. Some 10 to 15 positions are reserved for Maori students each year. To be eligible for the scheme, students are required to demonstrate Maori descent, some involvement with Maori communities, and support from their own tribe.

In 1999 Maori medical practitioners formed an association, Te ORA, that provides a professional focus for Maori doctors and arranges scientific and cultural enrichment programmes. It also acts as a conduit for information relating to Maori health including opportunities for practice within Maori communities. Maori medical practitioners occupy a range of positions in hospital and private practice. Generally their clinical skills are indistinguishable from other practitioners but in addition they tend to be competent in Maori language and custom and are able to modify practice to accommodate Maori health perspectives. Their active involvement in Maori communities in a variety of roles inevitably confers expectations that will provide leadership beyond the health sector and not infrequently places demands on them that are difficult to meet.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

Customary Maori disease classification systems recognized *mate tangata* (i.e., diseases caused by human error or misadventure) and *mate atua* (diseases that could not

be accounted for in rational terms). Underlying both types of illnesses was a system of knowledge based on *tapu* and *noa*. There are many interpretations of *tapu*. Now, most emphasize a sacred quality and are linked in some way to gods or divinities. Anthropologists and missionaries for example conceptualized *tapu* as a product of religious observations, highly spiritual and somewhat apart from everyday life. They were inclined to overlook the more practical goal of survival and environmental adaptation.

A more utilitarian view of the purpose of *tapu* was proposed by Dr. Te Rangi Hiroa. He drew a connection between the use of *tapu* and the prevention of accidents or calamities, implying that a dangerous activity or location would be declared *tapu* in order to prevent misfortune. In his opinion, the conferment of *tapu* was linked to healthy practices. *Tapu* was a type of public health regulation, basically concerned with the avoidance of risk, protection of the environment and its resources, and the promotion of good health. *Noa* was a term used to denote safety; harm was less likely to come to anyone who entered a *noa* location, ate food rendered *noa* by cooking, or touched a *noa* object. In Maori society the concepts of *tapu* and *noa* remain integral to Maori world views and color contemporary Maori attitudes to illness and injury.

Of equal importance has been the emergence of Maori health perspectives. The best known, *te whare tapa wha*, compares health to a four-sided house in which there is balance between spiritual, physical, intellectual/emotional, and family domains (Durie, 1985). This particular model has been incorporated into health planning as well as the delivery of health services and the construction of monitoring tools, such as outcome measures. Maori health workers adopt a more holistic approach to treatment and healing though as a result are often in conflict with the narrower goals of clinical agencies and funding arrangements that fail to recognize spiritual dimensions, or the links between health status and wider socio-economic environments.

SEXUALITY AND REPRODUCTION

Sexuality in early Maori society was not treated with the same level of prudishness that Victorian settlers displayed although marriage and conception were more closely scrutinized. Arranged marriages were not uncommon,

and certain women (puhi) were carefully cosseted until political alliances could be negotiated. Sexual unions between members of different tribes required permission from elders although were by no means infrequent and were sometimes actively encouraged for strategic purposes. Because birth rights were jealousy guarded and lines of descent prized for their connections to illustrious ancestors, parenting was far from arbitrary and coupling required tacit community approval. From genealogical records it is possible to conclude that childbirth occurred at relatively young ages, and that polygyny was practiced, though within narrow circles and usually to maintain a secure system for child care or to uphold family honor. The failure of a young wife for example to bear children might lead her husband to marry her sister, with the sanction of her own family. Sometimes a second wife or husband was procured for political reasons and occasionally prisoners of war were forced to enter into marriages both as a sign of victory but also as a token of reconciliation. The new spouse, though a former enemy, was usually afforded the full rights of marriage.

In modern times sexual activity among young Maori is common by fourteen years of age and contraception is used less frequently than for non-Maori. Sexual risk taking stands in sharp contrast to other elements of lifestyle and development and may be exacerbated by alcohol and drug use (Ministry of Health, 1997b). Termination of pregnancy is still regarded as offensive since it breaks a line of descent, though it is by no means infrequent. There is also some circumstantial evidence that homosexuality was practiced in pre-European times without attracting discrimination, and homosexuals were known as takatapui (Te Awakotuku, 1991).

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Childbirth

Fertility rates for Maori have declined sharply since 1964 and rates between Maori and non-Maori women are now similar (2.4 and 1.9 children respectively). However, Maori mothers are considerably younger. The average age for the first birth is 19 years, compared to 29 years for non-Maori. The potential health risks associated with younger mothers is compounded by the increasing number of sole parent households. In 1996 about 43% of Maori women with dependent children were sole parents

(Te Puni Kokiri, 1999). Maori children under 5 years are more likely to live in one-parent households than non-Maori; in 1996 there were as many as 23% (Davey, 1998). Although that does not necessarily mean the children are more at risk than they would have been if there were two parents, children in two parent families are more likely to have a mother who is in the labor force. As a consequence, income levels for sole parent families are low. As it is, over half of all Maori children under 5 years live in households with incomes in the bottom two quintiles.

Interestingly, hospitalizations for complications of pregnancy, childbirth, and the puerperium are only slightly higher among Maori than non-Maori (1.2) and are lower for perinatal conditions (0.8) (Ministry of Health, 1999b).

Infancy

Although the Maori infant mortality rate declined more rapidly over the past half century than the rate for non-Maori, it remained significantly higher at 11.6 per 1000 compared with 5.3 per 1000 in 1996. Sudden infant death syndrome (SIDS) accounted for the major difference but there are signs that the mortality rate is falling for both Maori and non-Maori, due mainly to a reduction in SIDS since 1996 (Ministry of Health, 1999b). During an active campaign to reduce SIDS a number of risk factors were highlighted including smoking, lack of breast-feeding, the prone position, and sleeping with the baby. Prematurity still remains a significant problem for Maori infants. It appears to be associated with younger mothers, smoking, poorer antenatal care, and economic hardship.

Childhood

In Maori children under the age of fifteen years there is an over-representation in disability statistics; 16% as against 11%. And under the age of 5 years, Maori children are more than twice as likely to be hospitalized, most often because of respiratory diseases. Hearing impairment, though less prevalent than a decade ago is still significantly more common among Maori pre-schoolers, about twice as many fail hearing tests; and hearing loss is usually detected later at about 4 years compared to 21 months for a European child (Ministry of Health, 1998a). Most telling, in 1994 the mortality rate for Maori under the age of 15 years was 125 per 100,000

compared with 68 per 100,000 for non-Maori. Rheumatic fever, an uncommon disease in most developed countries continues to affect Maori children at rates that approximate those of industrialized countries a hundred years ago. Current rates for Maori are about 50–70 per 100,000 per year for Auckland children aged 5 to 14 years (compared with 2 per 100,000 for European) (Ministry of Health, 1997b).

There is also some evidence that the rates of physical abuse toward Maori children are high and that the capacity of family to provide adequate care is taxed. The large number of Maori children who are admitted to hospital because of accidents, including burns, for example is one indicator while the fact that fewer than a half of all Maori children under the age of 5 years are accessing early childhood care and education or that a third of Maori school leavers will have no qualification are others.

Adolescence

While mortality rates and hospital admissions tend to be lower for youth and young Maori adults, the health risk behaviors are high. They include smoking, alcohol and drug misuse, motor vehicle accidents, suicide, and attempted suicide. Between Maori and non-Maori the risks are similar but the rates show disproportionately high consequences for Maori, especially Maori males. The major cause of death remains motor vehicle accidents, often associated with alcohol use. The 1997 mortality rate for all New Zealanders was 14.1 per 100,000 population (Ministry of Health, 1998b); Maori rates, previously higher, have now converged with non-Maori. But the Maori and non-Maori rates for suicide have moved in different directions. Suicide was rare among Maori but over the past decade the rates for both groups have increased. An analysis of the suicide rates for the period 1957–91 showed an overall lower Maori rate; it was not until 1987 that Maori youth suicides had reached similar levels to non-Maori (Skegg, Cox & Broughton, 1995). By 1990 Maori male rates had risen to 10 though non-Maori rates had risen even more to 35. But by 1993 the differences in youth suicide between Maori and non-Maori males had virtually disappeared, both rates being around 33 per 100,000 (Skegg, 1997). Maori rates have escalated even further so that in 1997 the Maori male suicide rate (26.8 per 100,000) was 28% higher than non-Maori while the Maori female rate (8.6 per 100,000) was almost 60% higher than for non-Maori

females (Ministry of Health, 2001). Factors thought to be relevant to the increase include deculturation, family adversity, social disadvantage, and a significant mental health problem in adolescence (Durie, 2001).

There have been few estimates of mental disorders within the community but a cohort study among 18 year olds concluded that the prevalence of mental disorders among Maori youth was exceptionally high. The mental health state of 115 Maori 18 year olds was assessed. Higher risks of disorder than non-Maori on all measures of disorder were shown. Overall 55% of Maori met criteria for at least one disorder in comparison to 41% of non-Maori. Maori males emerged as the group with the highest rate of disorder attributable to the elevated rates of conduct disorder and substance abuse disorders (Horwood & Fergusson, 1998).

Although striking, neither hospital admission rates nor community estimates of mental disorder give a comprehensive picture of either the prevalence of poor mental health or mental health status generally. Other indicators should also be taken into account. Young Maori are, for example, disproportionately represented in prisons, forensic services, child health camps, supervisory care, women's refuges, alcohol and drug services, and injury services (Dyall, 1997).

Adulthood

Deaths from stroke have been relatively stable for most New Zealanders but rates for Maori have fluctuated in an upward direction since 1988 and are now about a third as high as for non-Maori. Diabetes occurs more frequently amongst Maori, with a death rate of 47.4 per 100,000, compared to 10.3 per 100,000 for the total population (Ministry of Health, 1998b). For Maori and other New Zealanders the main causes of death are heart disease and cancer. While Maori mortality rates for both conditions have improved, the disparities are still significant. Mortality rates from ischemic heart disease are 257 per 100,000 for Maori and 150 per 100,000 for all New Zealanders (including Maori) while the gap between Maori and non-Maori death rates due to cancer has actually widened since 1988 to 348 per 100,000 compared to 250 per 100,000 (Te Puni Kokiri, 1998).

Since the mid-1970s mental health problems have emerged as a major health concern. Maori first admission rates to psychiatric services had surpassed non-Maori rates for all age groups by 1974. Not only are the rates

of admission different but Maori patients also have different needs, receive different diagnoses, enter hospital through different pathways, and have higher rates of readmission. Between 1984 and 1993 the rates for first admissions for Maori men and women had been steady, 120 per 100,000 for women and 180 per 100,000 for Maori men. But readmission rates increased, greatly for men (64%) and significantly for women (28%). While Maori women and non-Maori women had similar rates of first admission over the decade, Maori male rates have been consistently higher by about a quarter than non-Maori rates.

Drug and alcohol abuse and psychosis accounted for 32% of all Maori first admissions. Admissions for schizophrenia had increased as well and by 1993 were two or three times higher than non-Maori rates and rates for Pacific peoples. Schizophrenia, affective disorders, and other psychotic disorders made up 40% of Maori first admissions and 78% of readmissions (Te Puni Kokiri, 1996).

The Aged

Despite several generations of Western influence, Maori society generally retains a positive view toward aging and older people (kaumatua), affording them status and at the same time expecting them to fulfill certain defined roles on behalf of the whanau (family) and hapu (tribe and community). In order to meet those obligations, however, kaumatua must contend with a range of issues that impact on their health and material well-being. In other words, the cultural role cannot be isolated from the conditions in which older Maori live.

Although the great majority of older Maori are not in dire circumstances, there is nonetheless a relatively high rate of disadvantage, poverty, and material hardship levels being around three or four times those of non-Maori. This has major implications because the proportion of older Maori is going to increase quite rapidly over the next two or three decades.

Age related disability is more likely among older Maori than non-Maori, affecting one in three (Ministry of Health, 1994). Major causes of death for this age group include coronary artery disease, cancer, and respiratory diseases, while the common reasons for hospitalization include respiratory disease, cancer, hypertensive disease, coronary heart disease, cataracts, stroke, and diabetes. In a survey of 400 older Maori men and women,

self-assessed health status suggested a generally positive attitude toward aging, despite high levels of disability and a myriad of health problems (Te Puni Kokiri, 1997). The finding may reflect the positive roles older Maori play in their communities as carriers of culture and representatives of family and tribe. In the survey, higher standards of health were significantly associated with active participation in tribal affairs and strong cultural affiliations.

An important consideration for Maori society will be how to maintain positive roles for older people in the face of increased numbers and higher levels of deculturation. If kaumatua are valued for their cultural leadership, an urban cohort may struggle to meet obligations if their material circumstances do not permit full participation, or their health prevents active involvement, or they have not been inducted into the culture and are therefore not able to provide leadership. For many now in the 40–60 years age group, traditional kaumatua roles may never be seriously entertained. That in turn will have implications for the ways in which Maori elderly might participate in society, both Maori society and the wider New Zealand society.

Dying and Death

Maori views on death and dying tend to be philosophical. Death is an essential part of the life cycle and even though grief is unconstrained there is a sense of inevitability. Hospice care for the terminally ill is an increasingly acceptable alternative, but families prefer to nurse relatives at home, especially when it is obvious that death is imminent. If death has occurred away from family oversight there is sometimes a sense of shame and a fear of reproach for not providing adequate care.

Following death the body is usually taken back to a tribal cultural centre (a marae) for a three or four day period of mourning (the tangihanga). It is important that the body is intact. Unless the coroner insists on autopsy, permission for post-mortem is likely to be withheld; if it does occur the return of all body parts is imperative. For similar reasons, the harvesting of body parts remains highly controversial, possibly a reflection of earlier times when an enemy could inflict a final insult by desecrating a slain corpse. However, because Maori are over-represented as potential recipients of donor organs, recent attempts to encourage a more permissive attitude have led to a reconsideration of that position, guidelines have been

developed that will offer some safeguards against cultural offence (Te Puni Kokiri, 1999).

During the tangihanga, the deceased is addressed as if still alive and close family members, as well as others, spend their time sitting and sleeping around the coffin. Grief is openly expressed as elders offer farewell laments, encouraging the hovering spirit of the deceased to join other family members who have died. A sense of union with the wider world of the departed is established, diminishing somewhat the impact of loss and reinforcing the boundary between the living and the dead. Most families have traditional burial sites (urupa) and avoid cremation. But urbanization has often made it difficult to travel back to rural areas and in many cases contact with tribal relatives has been lost, so burial in a local cemetery occurs.

As a final tribute, children born around the time of death are often named for that person. Continuity has been restored to the family life cycle.

Matsigenka

Carolina Izquierdo and Glenn H. Shepard Jr.

ALTERNATIVE NAMES

Machiguenga, Matsiguenka, Kogapakori, Kugapakori.

LOCATION AND LINGUISTIC AFFILIATION

The Matsigenka are people of the *montaña*, the rugged rainforests of the upper Amazon fringing the eastern slope of the Andes. They currently number about twelve thousand people inhabiting the Urubamba, upper Madre de Dios, and Manu River basins in south-east Peru. Matsigenka belongs to the pre-Andine group of Arawakan languages that also includes Ashaninka (Campa) and Yine (Piro).

OVERVIEW OF THE CULTURE

Traditionally, the Matsigenka have lived in small, scattered, highly autonomous settlements organized around the household and the residence group showing a strong preference for matrilineal residence. Kinship follows a Dravidian pattern prescribing bilateral cross-cousin marriage (Johnson & Johnson, 1975). Polygamy was common in the past but has become less frequent. The Matsigenka continue to make important decisions within the household and residence group. At certain historical moments, political and economic integration under tyrannical leaders called *kurakas* has emerged, always in response to outside forces (Camino, 1977; Renard-Casevitz, 1991).

The Matsigenka subsist on a combination of fishing, hunting, forest foraging, and long-fallow swidden agriculture. They grow the staples of sweet manioc, plantains, and bananas alongside diverse other crops, medicinal plants, and fruit trees that mature as gardens are abandoned to forest regeneration. Women spin native cotton and weave tunic-like garments on backstrap looms. Women spend tremendous time and effort in preparing manioc beer (*ovuiroki*), the centerpiece of Matsigenka

social life, consumed in great quantities at cathartic drinking parties.

The principal rites of passage—birth, adolescence, death, and mourning—are private, family matters accompanied by quiet, symbolic acts: dietary and behavioral restrictions, a degree of social isolation, and the use of special medicinal plants. Codes for good and bad behavior, though not expressed in legal or religious institutions, are reflected in folklore, interpretations of illness, and many aspects of daily life. Traditional medicine addresses many kinds of misfortune and serves as an arena for expressing and resolving social strife.

Missionary activity throughout the 20th century provoked major changes. Catholic missions were established at strategic points along the main river courses, serving as hubs of commerce and points of departure for colonization and development projects. Beginning in the 1950s, Protestant missionaries of the Summer Institute of Linguistics (SIL) began evangelical work in the hinterlands, contacting and settling dispersed Matsigenka households into large, permanent communities. Although SIL's main goal was evangelical, their work also included health care, linguistic, and ethnographic study (Snell, 1964; Snell, 1998; Snell & Davis, 1976), community organization, and bilingual education. Communal land rights and democratic representation were established formally in 1974 by the populist "Law of Native Communities." Currently there exist some thirty-five legally recognized Matsigenka communities with populations ranging from a few dozen to over three hundred inhabitants.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

The health status of the Matsigenka depends upon tightly interwoven cultural, environmental, epidemiological, economic, and historical factors. Their dependence on scattered forest resources provides a centrifugal force that

is opposed by the centripetal forces of agriculture, social life, and more recently, education, health care, and economic opportunities available in permanent communities. Each family and community strikes a unique balance, affecting health, nutrition, and livelihood in complex ways. Protein in the Matsigenka diet comes mostly from high quality, animal sources, though it accounts for only 10% of caloric intake. Over three quarters of dietary calories come from the staple starches of manioc and bananas. Research among the Matsigenka has judged child health to be compromised by protein deficiency (Cueva, 1990), although deficiencies were not as marked as in other Amazonian populations. Game depletion around sedentary communities exacerbates existing deficiencies, prompting migrations or alternative economic strategies.

The health and destiny of the Matsigenka have been shaped by powerful exogenous forces. During the “rubber fever” (1895–1917), native people throughout the Amazon were enslaved, brutalized, and exposed to devastating epidemics. Von Hassel (1904) notes that the Matsigenka were highly sought after as laborers in Manu’s infamous rubber camps, and estimates that more than 60% of those conscripted died. Slave raiding, debt peonage, violence, and tribal dislocation continued throughout much of the 20th century (Alvarez-Lobo,

1996; Lyon, 1984; Shepard & Chicchon, 2001; Townsley, 1987). Many native groups, including many Matsigenka, survived these grim years only by isolating themselves from outsiders, some through the present (Shepard, 1999a, p. 47). Yet isolation has severe consequences: interethnic warfare; fragmentation of intermarrying units; inability to obtain trade items; reduction or abandonment of agriculture; and high rates of mortality when Western contact is re-established.

The efficacy of antibiotics proved to be crucial in the missionaries’ success in settling the Matsigenka in permanent communities. Today, contacted Matsigenka depend on Western medicines for their survival. Medicinal plants are effective for treating some common ailments, but epidemic diseases, especially the feared and deadly grippe (*merentsi*), have overwhelmed the capacities of traditional medicine. Moreover, some missionaries have been intent on stamping out traditional medicine, especially shamanism.

Gastrointestinal and respiratory conditions are the most common causes of disease and death among the Matsigenka and other Amazonian indigenous populations (see Figure 1). Respiratory illnesses cause extremely high rates of mortality in the initial years of Western contact (note Panoan cases in Figure 1). Even in acculturated

Figure 1. Attributed causes of mortality, all ages.¹

communities, new cold and flu strains arrive continually, often developing into virulent pneumonia. In communities without adequate latrines or potable water, fecal contamination of soil and water leads to a high incidence of roundworm, amoebas, and other parasites, especially when seasonal flooding exacerbates existing sanitation problems. Snakebite and other accidents (e.g., falling from a tree) are not infrequent and sometimes fatal among children and adults, and interethnic warfare was a significant cause of death in some populations until recently. Tuberculosis has become prevalent in some areas, while malaria, sexually transmitted diseases, and rabies break out sporadically in the Urubamba region, but are not yet documented in Manu. Eye and ear infections, dental caries, and a variety of skin conditions (mycosis, leishmaniasis, scabies, boils, bot fly larvae, chigoes, infected wounds) are common but do not contribute to mortality.

Studies with other Amazonian groups suggest that health status declines with initial Western contact (Jelliffe, 1966; Neel, 1974). Nonetheless, improvements in sanitation and health care in acculturated communities may be effective in eventually reversing this trend. A biomedical study at Kamisea (Izquierdo, 2001, 2002) following up on a similar study 20 years prior (Strongin, 1982) suggests that objective health indicators have improved significantly. Yet ironically, the people of Kamisea report a subjective experience of increasing illness, social strife, and distress for the same period. This discrepancy illustrates the complex and sometimes contradictory health implications of rapid social change. The proliferation of sorcery accusations in Westernized communities testifies to the coincidence between exotic illnesses and new kinds of social and economic stress (Izquierdo 2001, p. 250; Shepard 2002c, p. 9). Western media images also exert a perverse influence on traditional concepts of health and beauty (Yu & Shepard, 1998). Most Peruvians and some Matsigenka welcome the economic development that promises to accompany the exploitation of the Kamisea gas fields in the Matsigenka heartland. Others, however, are worried about negative social, environmental, and health consequences (Rivera, 1991). Echoing traditional cosmological and etiological notions, some Matsigenka fear that the perforation of wells might unleash demons and illness from the bowels of the earth (Shepard, 1999b). The plight of indigenous peoples in Ecuador, Colombia, and Nigeria at the hand of transnational petrochemical companies appears to justify these fears (see Kimerling, 1991).

MEDICAL PRACTITIONERS

Shaman-healers among the Matsigenka are known as *seripigari*, “tobacco-intoxicated ones” (Baer, 1992). Seripigari use tobacco and psychoactive plants to enter into a trance, communicate with spirits, and treat spirit-based illnesses (Shepard, 1998). They are usually men, but women are sometimes mentioned. The seripigari undergoes an apprenticeship with an experienced shaman and gains special powers by fostering a relationship with benevolent spirits known as *Saangariite*, “Invisible/Pure Ones.” The seripigari sing esoteric songs to invoke spirits or call wayward souls, and use their magical breath to locate and suck sorcery objects (spines, stones, herbs, etc.) from the patient’s body. More than healers, the seripigari are ambassadors to the cosmos who negotiate with the forces of nature to ensure the availability of game, acquire new crop varieties, and control the elements. The seripigari are heroes in Matsigenka mythology, however in actual practice, they are beset by moral ambiguity. The same powers required to cure illness can also be used to cause it. The Matsigenka distinguish between healing shamans and illness-causing sorcerers (*matsikanari*), however any shaman may be a suspect for sorcery accusations. This inherent moral ambiguity has been fueled by Christian missionaries’ denunciations of shamans as “Devil worshippers.” Furthermore, shamans were ineffective in halting the devastating epidemics. The seripigari have been apparently driven into hiding or extinction in many communities. Recent ethnographies note that the Matsigenka deny the existence of seripigari in their communities (see Bennett, 1991, p. 380; Shepard, 1999a, p. 82; Izquierdo, 2001, p. 233). Yet after years of such denials, Shepard (1999a) discovered that seripigari were in fact active (albeit discreetly) in several communities in the Manu and Madre de Dios Regions.

A new breed of practitioners known as “steam bath healers” (*itsimpokantavagetira*) has emerged in acculturated communities of the Urubamba, apparently filling the void left by the absent (or secretive) seripigari. Like seripigari, steam bath healers are able to remove intrusive pathogenic objects from patients suffering sorcery and other spirit illnesses. Unlike the seripigari, steam bath healers do not use tobacco or psychoactive plants and do not enter trance. Instead, they subject the patient to a steam bath by placing scalding hot river stones in a pot of water with special herbs layered in the bottom. The patient stands over the pot covered in a cotton tunic as the healer

fans the hot steam. When the water cools, the healer removes the contents of the pot and discovers a variety of objects (nails, sorcery herbs, plastic containers, etc.) that have apparently emerged from the patient's body. The healer converses in detail with the patient about the history of the illness, focusing on social conflicts and possible sorcery suspects. Multiple treatments are usually required, and the healers charge a moderate to considerable fee. The technique of steam-bath healing is open to men and women, is learned from a practitioner for a large fee, and was introduced to the Matsigenka by the neighboring Ashaninka.

Another medical treatment alternative is the government health post. Each full-scale health post (*Posta de Salud*) is manned by one doctor and two nurses who remain (in theory) for twelve-month stints as part of a required rural service program, making trips to outlying communities for check-ups and vaccinations. Health posts are generally well stocked with pain relievers and antibiotics, though they lack laboratory facilities. There are three health posts in the Urubamba region, serving approximately 25 communities, and two in the upper Madre de Dios serving about 10 communities. Some communities have small village health posts (*Posta Sanitaria*) manned by regional Peruvian or resident Matsigenka *sanitarios*, health care workers with basic training who receive a small government salary and minimal medical supplies. Native health promoters (*promotor de salud*) work on a volunteer basis, sometimes combining biomedical with traditional healing methods. Health posts are largely underutilized because of the urban-educated professionals' typically paternalistic views, begrudging attitude, and poor communication with community members. Few complete the full twelve-month stint, leaving lesser-trained regional nurses, *sanitarios*, or *promotores* in charge for extended periods of time.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

Classification of Illness

The Matsigenka distinguish and classify illness according to a number of criteria: symptoms, body part/organ

system affected, acuteness, duration, and population at risk (see Table 1). Other salient criteria include external (visible) versus internal (invisible) pathology, native versus foreign origin, and natural versus supernatural causes. Some illness terms correspond with Western categories such as leishmaniasis (*tsirivaito*), colds and flu (*merentsi*), malaria (*mogekari*), and measles/pox diseases (*saarontsi*). Other syndromes rely on culturally particular understandings of illness and etiology that are not translatable into biomedical terms. A simple sorting exercise resulted in the following general classification scheme: gastrointestinal, gynecological, respiratory, heart and chest conditions, fevers, body pains, ear/eye/dental, animal bites/stings, animal/plant spirit revenge, spirit attack and sorcery, and miscellaneous signs and symptoms (Shepard, 1999a). A great deal of overlap across categories was observed as illustrated in Figure 2. Multidimensional scaling of pile sorts carried out with 43 common illness terms (Izquierdo, 2001) revealed seven illness groups. The low stress (0.135) for the 43 items suggests that people distinguish illness along two major dimensions. We interpret the dimensions as acute and chronic and serious and non-serious. However, these categories often are associated with each other. For example, in some cases, duration and etiology are closely related: and ongoing or chronic illness is generally associated with spiritual etiology (sorcery, spirit attack).

Theories of Illness

The Matsigenka concept of well-being is summarized in the verb *shinetagantsi*, which means to be happy, productive, and well-fed as well as free of illness. Concepts antithetical to well-being include illness (*mantsigarantsi*), suffering (*tsipereagantsi*), thinness or weight loss (*matsatagantsi*), sorrow or worry (*kenkisureagantsi*), anger (*kisatsi*), and soul loss (*gasuretagantsi*). Health and well-being and, conversely, illness and malaise, embrace physical, emotional, and spiritual states as well as harmony (or lack thereof) in productive, social, and environmental interactions. In the Matsigenka cosmos-as-ecosystem, illness, misfortune, and death are often interpreted through the ecological metaphor of predation: just as humans hunt for sustenance, so also demons, illnesses, and dangerous animal spirits look on human beings as game animals (Shepard, 2002c).

Matsigenka theories of illness demonstrate complex notions of etiology and efficacy that challenge Western

Table 1. Matsigenka illness classification

Illness category/gloss	Matsigenka name	Etiology	Severity
Gastrointestinal			
"Intoxication," vomiting w/ fever (Yellow fever?)	<i>Pigarontsi, kepigari</i>	falls from sky, sorcery	Highest
Diarrhea w/ blood	<i>Shiarontsi</i>	(as <i>tseritsi</i>), from foreigners	High
Diarrhea	<i>Tseritsi</i>	falls from sky, "worms", mixing foods, dirty or spoiled food	Medium
Vomiting	<i>Kamarankagantsi</i>	(as <i>tseritsi</i>)	Medium
Indigestion	<i>Sametsi</i>	(as <i>tseritsi</i>)	Low
Stomachache	<i>Katsimotiatagantsi</i>	(as <i>tseritsi</i>)	Low
Gynecological			
Retained placenta	<i>Terira okontetake iranonta</i>	taboo activities (arrow resin use)	Highest
Difficult childbirth, post-partum bleeding	<i>Okatsitake oanekite, voaasetagantsi</i>	no reason, taboo activities (cutting bamboo)	High
Miscarriage (fetus)	<i>Omechotaira ogairi</i>	sorcery	High
Miscarriage, induced abortion (early pregnancy)	<i>Oseriakotake oanekite</i>	animal spirit, plant-induced	High
Menstruation (painful, excessive bleeding)	<i>voaasetagantsi katsiri / kogapage</i>	no reason, sorcery, animal spirits	Medium
Menstruation (normal)	<i>Voasetagantsi, seriagantsi</i>	moon	Low
Respiratory			
Bloody cough, tuberculosis	<i>Voreagantsi iraatsi</i>	foreigners	Highest
Cold, flu	<i>Merentsi</i>	foreigners	Highest
Throat abscess (tonsillitis)	<i>Vompotsanotagantsi</i>	falls from sky, mixing foods, trauma	High
Cough	<i>Voreagantsi</i>	falls from sky, mixing foods, foreigners	High
Sore throat	<i>Katsitsanotagantsi</i>	falls from sky, mixing foods, trauma	Medium/ High
Nasal congestion, runny nose	<i>Shirinkasetagantsi</i>	no reason	Low
Nosebleed	<i>Voatagantsi iraatsi girimashiku</i>	mixing foods	Low
Heart /Chest			
Heart failure, cardiac arrest	<i>Vitantagantsi negiku</i>	lethal illness	Highest
Chest pain ("needle pain")	<i>Kentarontsi, kitsogirontsi</i>	animal spirits, demons, ghosts	Highest
Heart pain, epigastric pain	<i>Katsinegitagantsi</i>	bee spirit, demons, ghosts, sadness, falls from sky, mixing foods	High
Heart palpitations ("fear in the heart")	<i>Tsaronegintagantsi</i>	fright, love filters, demons, ghosts	High
Fevers			
Shivering, chills (malaria)	<i>Mogekari, shigekari</i>	(as <i>kovaagantsi</i>), foreigners	Highest
Fever w/ chills	<i>Anatiri, janatiri</i>	(as <i>kovaagantsi</i>), cold weather	High
Fever	<i>Kovaagantsi</i>	falls from sky, demons, ghosts	Medium

Table 1. Continued

Illness category/gloss	Matsigenka name	Etiology	Severity
Body pain			
Bone pain, rheumatism	<i>Shinkogiitagantsi</i>	demons, ghosts, sorcery	High
Body pain, (back, knee pain)	<i>Katsipagetagantsi,</i> <i>(katsitishitagantsi,</i> <i>Katsigeretotagantsi)</i>	trauma, old age, demons, ghosts	Medium
Headache, migraine	<i>Katsigitotagantsi</i>	falls from sky, demons, ghosts, w/ fever	Medium
Rib pain	<i>Katsimeretagantsi</i>	trauma, bee spirit	Medium
Waist, kidney pain	<i>Katsitsakitagantsi,</i> <i>tsatsakirontsi</i>	trauma, demons, ghosts, falls from sky, w/ urinary pain	Medium
Ear/Eye/Dental			
Earache (w/ pus, abscess)	<i>Sakempitagantsi,</i> <i>sompokempitagantsi</i>	hygiene, "worms", foreigners	Medium/ High
Earache (simple)	<i>Katsikempitagantsi</i>	hygiene, "worms", falls from sky	Medium
Toothache	<i>Okatsitake itsi (jitsi)</i>	"worms", food	Medium
Eye pain, infection	<i>Katsiaari</i>	hygiene, trauma, falls from sky, foreigners	Medium
Eye opacity (cataracts? trachoma?)	<i>Tsororoaari</i>	old age, animal spirit, trauma	Medium
Skin			
<i>Wound-like</i>			
Abscess, boil	<i>Sompotsi</i>	insect bite, botfly larvae, wound	High
Cut, wound, (arrow wound)	<i>Teretsi</i>	wound, hygiene	High/ Medium
Sore, leishmaniasis	<i>Tsirivaito, katsinori</i>	insect bite, insect spirit	Medium
Pustule, infected wound	<i>Shomporentsi</i>	falls from sky, insect bite, wound, hygiene,	Medium
Burn, blister	<i>Saatagantsi, meregagantsi</i>	heat, friction	Medium/Low
Scab	<i>(Teretsi)</i>	Wound	Medium/Low
<i>Inflammatory</i>			
Inflammation, swelling	<i>Nonarontsi</i>	no reason, w/ infection, fever	High/Medium
Hives, urtication	<i>Kepigisetagantsi</i>	plants (urticating), animal spirits, mixing foods,	Medium
Peeling, shedding of skin	<i>Patsaatagantsi</i>	falls from sky, wounds, hygiene,	Medium
Rash	<i>Piikitagantsi,</i> <i>pirikitagantsi</i>	hygiene, urticating plants	Medium
Itching, (mycosis)	<i>Kaenitagantsi, tsomiri</i>	"worms", water, foreigners,	Low/Medium
Scabies	<i>Patsetsi</i>	foreigners	Low
"White spots", (mycosis)	<i>Kutatagantsi</i>	no reason, worms	Low
<i>Oral (esp. in Children)</i>			
Candida, sores (thrush)	<i>Kotsetsi</i>	no reason, animal spirits, w/fever, (as <i>kotsetsi</i>)	Medium
Fever blisters	<i>Patsaavagantetagantsi,</i> <i>tereavagantetagantsi</i>		Medium
"White tongue", (thrush)	<i>Kutanenetagantsi</i>	(as <i>kotsetsi</i>)	Medium
<i>Measles, Pox</i>			
Measles, smallpox	<i>Saarontsi, "sarampion"</i>	demons, foreigners,	Highest
Chicken pox	<i>Morokisetagantsi</i>	animal spirit (cowbird)	Medium
<i>Animal bite/sting</i>			
Snakebite	<i>Maranki yatsikanti</i>	bad dream, demon	Highest
Jaguar bite	<i>Matsontsori</i> <i>yatsikanti</i>	accident, sorcery	High

Table 1. Continued

Illness category/gloss	Matsigenka name	Etiology	Severity
Peccary bite	<i>Shintori yatsikanti</i>	—	Medium
Spider bite	<i>Jetyo yoganti</i>	—	Medium
Stingray sting	<i>Inaro ikentanti</i>	accident, bad dream	Medium
<i>Paraponera</i> ant sting	<i>mushi yoganti</i>	—	Low
Caterpillar sting	<i>Soromai</i>	—	Low
	<i>iporonganti</i>		
Wasp sting	<i>Sani yoganti</i>	—	Low
Animal, plant spirit revenge	<i>Pugasetagantsi</i>	causes gastrointestinal, fever, skin conditions (esp. children)	Medium
Mixing foods improperly, animal spirit revenge (food allergies?)	<i>Tamampegagantsi</i>	causes gastrointestinal, fever, skin conditions	Low (except in ill, old)
Sorcery, demon attack			
Sorcery (general)	<i>Matsitagantsi</i>	due to envy, jealousy, personal conflict; causes severe or chronic illness	Highest
Footprint sorcery	<i>Ampaseri,</i> <i>gagitetagantsi</i>	causes swelling, numbness in legs, legs turn black, “burned”	Highest
Sudden death, demon attack	<i>Komutagagantsi</i>	causes sudden death	Highest
Rape by demon (deer)	<i>Itsitanti kamagarine</i> (<i>maniro</i>)	causes high fever, body pains, severe illness, wasting death	Highest
Demon, ghost (seeing)	<i>Tsavitetagantsi</i>	causes high fever, body pains, severe illness, quick death	Highest
Demon, ghost (hearing)	<i>Amumpava</i>	causes high fever, chills	High
Demon, ghost (dreaming)	<i>Kisanitagantsi</i>	causes headache, fever	Medium
Epileptic fit	<i>Kamakamatagantsi</i>	eyes roll back, foam at mouth, fainting; spirit attack, sorcery	Medium
Miscellaneous signs/symptoms			
Muscle cramps	<i>Tsoritsi</i>	w/ severe GI illness, trauma, falls from sky	Highest (w/ GI) Low (alone)
Pallor, anemia, jaundice (“yellowness”)	<i>Kitetagantsi</i>	w/ severe GI, heart illness	High
Fatigue, difficulty in breathing	<i>Shigopirentsi</i>	w/ severe respiratory, GI, heart illness	High
Liver pain	<i>Katsiriraapanatagantsi</i>	no reason, w/ severe illness	High
Spleen pain	<i>Taratagantsi</i>	trauma, w/ severe fever (malaria)	High
Urinary pain, STD’s	<i>katsitsinitagantsi,</i> <i>tsomiri</i>	no reason, foreigners, “worms”	Medium

dichotomies such as mind/body, individual/society, culture/nature, and natural/supernatural. Pneumatic (see Wilbert, 1986), germ-like, personalistic, and biomedical etiology models are found side by side, as are allopathic, homeopathic (“doctrine of signatures”), and spiritual models of efficacy (Shepard, 1999a). Illness episodes for

the Matsigenka are not bounded by time or defined by symptoms. A series of apparently unrelated ailments are, for the Matsigenka, a single, ongoing illness linked by a common cause, often of supernatural origin. Accidental trauma is a frequent problem, but the most severe accidents (snakebite, falling from a high tree) are blamed on

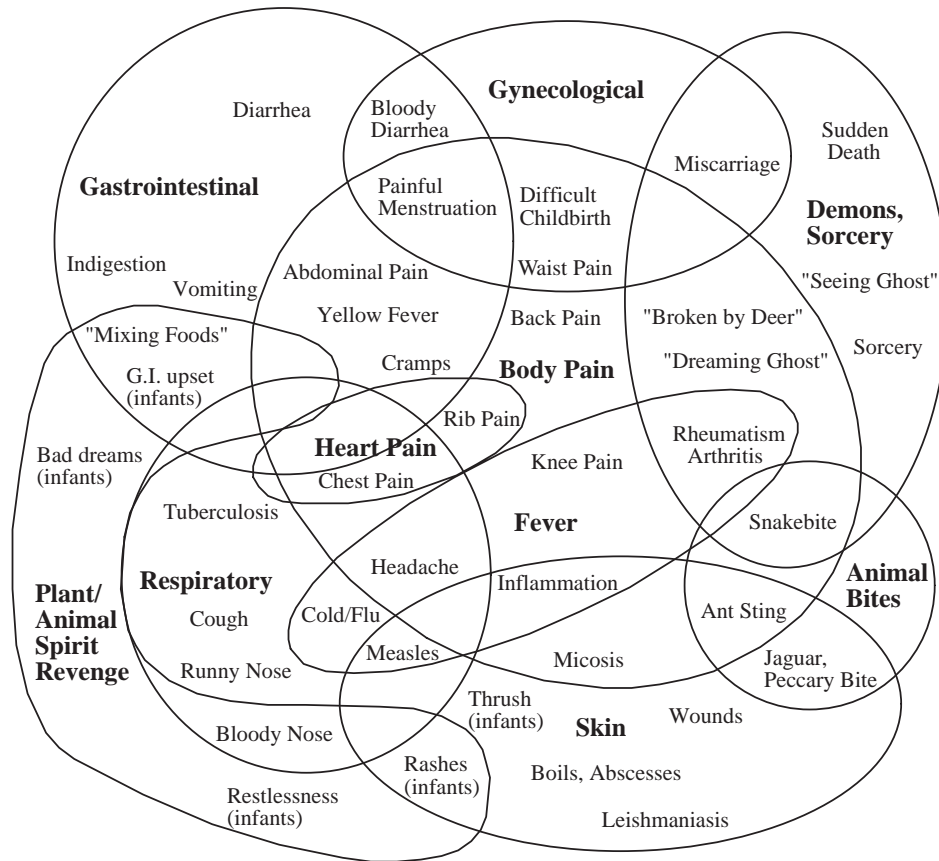

Figure 2. Matsigenka illness classification.

supernatural causes. Even common, self-limiting illnesses may include cosmological or spiritual elements: for example, one type of bee (*yamposhto*) is believed to cause diarrhea by feasting on uneaten food, thereby stealing a piece of the person's soul.

Many illnesses are conceived of as foul vapors that rise from the bowels of the earth where demons reside. They are released into the atmosphere by landslides or earthquakes, causing "yellow vapor in the sky" (*okiterienkatake*), rainbows, and other unusual sky coloration. With rainfall or fog, illness "falls as mist from the sky" (*oparienkatake*), adhering to the skin and entering the body through the nose, mouth, and eyes. This etiology pattern is associated with epidemic and seasonal illnesses (notably *pigarontsi*, apparently yellow fever), and implies a naturalistic, germ-like theory of contagion that is nonetheless linked with cosmological and spiritual notions.

The Matsigenka attribute most acute gastrointestinal conditions to the presence of "worms" (*tsomiri*) in the gut. Though aware of helminthic parasites (also *tsomiri*), the Matsigenka are not necessarily referring to these when they invoke "worm" etiology. *Tsomiri* is a broader concept, resembling Western germs or microbes, and is also used to explain toothache, earache, conjunctivitis, and various skin infections. Threadlike or like maggots, and so small as to be invisible, *tsomiri* are found in overripe fruits, spoiled food, and garbage. With poor hygiene, *tsomiri* enter the skin, ears, eyes, mouth, or gut. In the Urubamba, sexually transmitted diseases are likewise referred to as *tsomiri*.

Certain transitory gastrointestinal, skin, and other conditions (notably food allergies) are attributed to the improper mixing of foods (*tamampegagantsi*). Tapir should not be eaten with armored catfish (*etari*) to avoid scabies, characterized by dry, scaly skin like *etari*. Eating

carnivorous fish such as piranha with other meats causes bloody diarrhea. These beliefs are closely associated with the concept of revenge (*pugasetagantsi*) by plant and animal spirits. Strong-smelling, carnivorous, and other salient fish and game species are said to have vengeful spirits that attack young children if either parent eats their meat. (The notion implies the existence of a shared “social body” that transcends individual body boundaries.) Vengeful spirits frighten or steal the soul (*yagasuretakeri*) of children, causing a wide range of illnesses including colic, restlessness, rashes, nosebleed, and sudden death. Children are painted with red dye on the face and crown of the head, the portal of the soul, to dispel harmful spirits. Plants with noxious, toxic, or other symbolically dangerous properties can also take revenge. It is impossible to separate spiritual from empirical aspects of these beliefs, since the spirit or soul (*suretsi*) of an organism encompasses supernatural as well as nutritional, toxic, or medicinal properties.

Many conditions, especially those associated with emotional disturbances, affect the heart. Death occurs when illness “grips the heart” (*avitantake negiku*). Heart palpitations, (*tsaronegitagantsi*, “fear in the heart”) can be caused by bad dreams, sadness, gossip, unrequited love,

sorcery, or a love potion gone awry. *Katsinegitagantsi*, “heart pain,” combines in a single category a number of symptoms that in English would be described separately as “heartburn,” “heartache,” heart palpitations, anxiety, chest pain, pneumonia, and heart attack (Shepard, 2002a).

The Matsigenka are especially fearful of apparitions of demons (*kamagarini*) and ghosts (*kamatsiri*), believed to cause among the most severe illnesses. Dreaming (*kisanitagantsi*) about the ghost of a close family member causes fever, headache, and body pain, not necessarily life-threatening as long as treatment is undertaken. Dreaming in general for the Matsigenka involves a vulnerable state where the soul wanders and may encounter dangerous spirits or omens of illness and misfortune. Seeing a ghost while awake, *tsavitetagantsi* (“to see something that later vanishes”) is the most serious illness recognized by the Matsigenka, leading to almost certain death. The Matsigenka believe that the deer (*maniro*) is a demonic seducer who appears as an alluring member of the opposite sex to a person walking alone in the forest or in a garden. The seducer offers food and entices the victim to have intercourse. Those who fall victim to the temptation suffer severe illness (fever, chills, body aches) or death, and those who resist must tell no one of the

Figure 3. Multidimensional scaling of pile sorts of 43 Matsigenka illnesses (N=30).

encounter for three days and take numerous precautionary measures and remedies. Paralysis or sudden death in old people is attributed to assault by the deer demon: *otingarantira maniro*, “broken by the deer.” People who are ill or at vulnerable junctions in the life cycle do not eat deer meat, and some people avoid it altogether.

Whereas predatory demons, animal spirits, and ghosts were blamed for inexplicable illnesses in the past, sorcery is frequently invoked in Westernized communities. Footprint sorcery (*gagitagantsi*) is carried out by collecting dried bits of mud from the victim’s footprint and boiling them with special herbs, causing the victims leg to swell, become tingling or numb (*ampasetagantsi*), and turn black as if burned (*shinkogitagantsi*). The Matsigenka believe that love magic (*posanga*) is a kind of sorcery brought by outsiders, causing physical–emotional symptoms in its victims (dizziness, heart palpitations, sadness, insanity), as well as infidelity and social strife in the community. Sorcery accusations are often aimed at those same groups of outsiders (Ashaninka, Piro, Shipibo) who served as intermediaries for Western economic interests throughout the 20th century. However, in increasing numbers other fellow Matsigenka are being accused and identified as sorcerers. Ethnically diverse communities and mission towns are thought to be especially dangerous, and Matsigenka who have lived among them are prime sorcery suspects. Thus sorcery theories reflect Matsigenka constructions of interethnic relations and notions of culture change (Izquierdo & Johnson, 2003).

Treatment of Illness

Treatment decisions often relate as much to social dynamics as to the choice of the appropriate remedy, and may involve self or family care, consultation with kin, informal networks, local healers, and medical personnel. The Matsigenka incorporate biomedical and local knowledge in assessing health care options. Some 300 species of medicinal plants—mostly primary forest shrubs and herbs but including some cultivated plants and weeds—were identified in an ethnobotanical survey of seven communities (Shepard, 1999a), and the average informant knows 80 or more species (Izquierdo, 2001). Medicinal plant knowledge is widely shared, though a degree of specialization is found along gender lines: women are more knowledgeable about plants for child care and fertility control, while men specialize in hunting medicines and treatments for wounds and snakebite.

Medicinal plants are attributed sensory properties (taste, odor, color, etc.) that are directly related to notions of etiology and efficacy (Shepard, 2002b). Plant extracts are administered as herbal infusions, eye drops, inhalants, poultices, or warm baths. Bitter medicines are administered externally for skin conditions or internally for gastrointestinal conditions in order to “embitter,” hurt, and expel the “worm” pathogens, a clearly allopathic model of efficacy. Fragrant plants are used to repel the foul odor of demons, ghosts, and vengeful animal spirits, or to undo the “intoxicating fragrance” of love potions. Painful eyedrops are used to improve a man’s aim while hunting and to dispel ghosts, headache, sadness, or social strife.

Medicinal plants appear to be somewhat effective in addressing many common health problems, notably gastrointestinal and skin conditions, broken bones, snakebite, and other hazards of the forest. Hunting medicines, some of which may have tonic or stimulating properties, reflect the uncertainty and importance of game animals in the diet. Core Matsigenka values throughout the life cycle are reflected in plant medicines used to treat excessive crying in babies, promote weight gain, instill desired personality traits in children (industriousness, honesty), give young men good eyesight for hunting, improve garden productivity, make women attentive and careful at spinning and weaving, and reign in dangerous emotional excesses such as anger, grief, and passion.

The health post is an important treatment alternative, especially for illnesses deemed to be of mundane or foreign origin. Visits to the health post show apparent group differences across gender and age (Figures 4 and 5). Boys under five are taken to the health post twice as often as girls while among teenagers, the number of visits by girls increases, likely for gynecological inquiries. Among the middle-aged and elderly, females are much more frequent visitors. Several older men said they had never been to the health post because it was “a place for dying.” In all age groups, respiratory and digestive problems were most frequently reported. Nonetheless, it is difficult to capture actual disease incidence because record keeping is not reliable, and because of the complexities of local diagnostic categories and treatment options.

Patients consult a traditional healer when specific symptoms or ongoing illness signals sorcery or spirit attack. Still, those who seek healers may continue using multiple other approaches (medicinal plants, dietary restrictions) to cover all possible vulnerabilities. In narrative accounts of such illnesses, the Matsigenka revealed

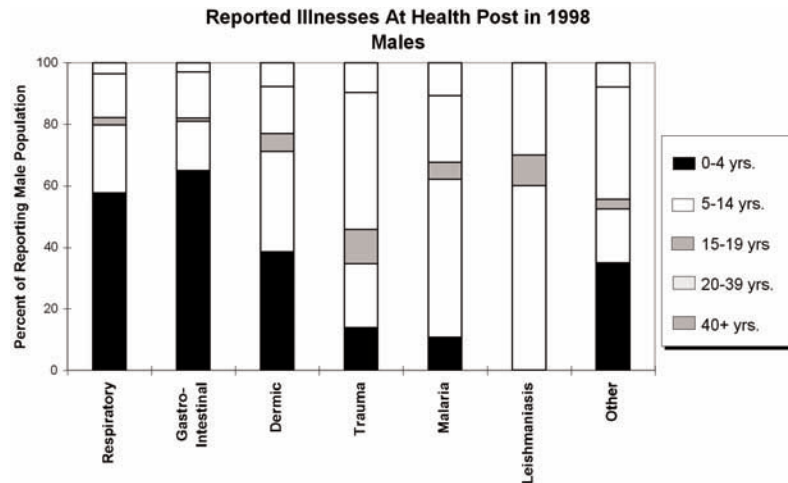

Figure 4. Illnesses treated at Kamisea health post in 1998: Males (percentages).

Figure 5. Illnesses treated at Kamisea health post in 1998: Females (percentages).

a great deal about bodily, emotional, and social distress in communities undergoing cultural and economic change (Izquierdo, 2001).

Despite Strongin's (1982) prediction, biomedicine has not replaced traditional medicine. More than just a therapeutic alternative, traditional healing is an expression of indigenous religion, values, and world-view. Not only do local therapies provide cultural and moral meaning to illness, they also function very effectively in alleviating symptoms.

SEXUALITY AND REPRODUCTION

Although typically sex-positive in their orientation, Amazonian societies reveal an undercurrent of ambiguity regarding the dangers posed by improper sexual relations (Gregor, 1985). Incest for the Matsigenka is among the most shameful offenses, and is thought to result in punishment for the perpetrators as well as the offspring, who show physical deformities and moral perversions. Several Matsigenka myths relate mother-son, father-daughter,

and brother–sister incest, which all result in exile or death (Johnson, 2002). Other tales tell of the tragicomic outcomes of sexual relations between humans and animals. Demons including the deer (*maniro*) are hypersexual, have gigantic genitalia, and engage in perversions such as anal sex, thereby causing severe illness or death in their victims.

Hunting lore includes a series of sexual and behavioral taboos that establish an ethic of proper conduct between husband and wife, and depict a balance between reproductive and productive responsibilities of the family. Matsigenka men avoid sexual relations the night before hunting. Contact with menstrual blood, said to smell like carrion or raw meat, takes away a man's hunting skill, as does eating raw meat or improperly cooked food. Taboo violations accumulate in the hunter's body/soul, making him smell of carrion like the vulture and thus lose his aim. A man restores his aim by using hunting medicines taken as emetics, purgatives, or as painful drops in the eyes. Notable are the *ivenkiki*, cultivated varieties of sedge (*Cyperus* sp.).

Sedge varieties cultivated by women are used to control fertility. Depending on the variety and dosage, sedges are said to temporarily or permanently lower fertility, induce abortions, facilitate difficult childbirth, or reduce postpartum bleeding. Cultivated sedges have been found to host fungal parasites that produce ergot alkaloids (Plowman et al., 1990), whose physiological activity is consistent with many Matsigenka uses of sedge (fertility, headache, tonic, wounds).

Decisions about fertility are generally left to women. Women who want to terminate a pregnancy may prepare an herbal abortifacient or ask an experienced older woman to do so. There is no stigma attached to abortion practices, though improper use is very dangerous. Western birth control is now available in some communities, though use is not yet widespread. Though the reasons are not clear, a significant change in average family size occurred in the late 1960s, from 6.7 in 1965 to 4.7 in 1972 (Strongin, 1982), and remaining at 5.1 in 1998 (Izquierdo, 2001). Sexually transmitted diseases were first brought to the Urubamba region during petrochemical exploration by Shell Oil in the early 1980s.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

Pregnancy and childbirth are a special source of concern. Expectant parents avoid a wide range of vengeful fish and game species, notably carnivorous fish. Expectant fathers

are prohibited from manufacturing arrows: cutting bamboo is thought to cause uterine hemorrhage, and sticky arrow-fletching resin (*taviri*) causes retained placenta. Parents avoid specific foods and behaviors believed to result in unwanted physical as well as personality traits (anger, laziness) in the developing fetus.

Traditionally, births were attended by elder female relatives but in many communities today, midwives are chosen based on experience and given basic training by the medical personnel. Women give birth in a squatting position, gripping a vertical support such as a house post. Birthing in the health post—prone and surrounded by lights, instruments, and strangers—is viewed as unattractive and frightening.

The immediate concern upon birth is the passing of the placenta and the cutting of the umbilical cord. Medicinal plants are used to aid in the passing of the placenta (*iranonta*) to avoid dangerous complications. Traditionally, the umbilical cord is cut with a grass-like bamboo with razor edges (*tiposhi*). Metal implements are now used, though improper hygiene has been known to cause tetanus. The cut cord is treated with arrow-fletching resin (*taviri*) and other “umbilical cord plants” (*shirimogutopini*), or Western antiseptics when available. The mother and baby are washed in warm water and herbs. Both the placenta and later, the umbilical cord are buried to avoid contact with carrion animals or evil spirits.

Infancy

The time between birth and the falling of the umbilical cord is especially dangerous. Both parents remain indoors and follow strict dietary and behavioral restrictions. Through the first few months of life, parents maintain certain restrictions to avoid mishaps and illness in their infants. Strong-smelling and carnivorous fish and game are avoided because of their vengeful spirits, as are urticating or caustic plants, thought to cause rashes in newborns. To dispel vengeful spirits, the mother bathes the baby daily (once or more times) in warm herbal mixtures including sedges as well as fragrant, viscous, and colorful plants. In addition to their role in hygiene, these practices reflect the general anxiety of parents about newborns in a setting where infant mortality is considerable.

Quickly, the couple must return to the productive routines of daily life to provide a good example and prevent the child from growing up lazy or inactive. Babies are carried at all times by their mothers in a woven cotton sling (*tsagompirentsi*), nursing on demand. Babies

and young children share bedding in close contact with both parents. Mothers masticate boiled manioc and feed it mouth-to-mouth (*aviakeri*) to infants as young as 3 months to facilitate weight gain. Sweet or tart herbs are sometimes mixed with this mash to stimulate appetite. Broth, and later meat of bland, non-vengeful fish and game, is introduced soon thereafter. Babies are breast-fed an average of 2 years, and may be weaned using chili pepper if they insist on nursing beyond that time.

Childhood

Diarrhea, especially when combined with vomiting, quickly dehydrates infants and young children, and is a frequent cause of death in this age category. Increasingly, health workers are teaching oral rehydration therapy. The extended abdomen visible in most children and many adults is evidence for a moderate, practically normative parasite load. Extreme parasite loads are known to cause anemia and even life-threatening intestinal blockage, especially in children. *Ficus latex* is a common and effective folk remedy for intestinal worms, though some Matsigenka fear the powerful purgative properties of an improper dose. (Matsigenka men's use of purgative and emetic plants may also help reduce parasite loads.) Pharmaceutical antihelminthic treatments are distributed with increasing frequency, however without sanitation and potable water, reinfection is rapid.

Mothers are the main care providers for small infants, though fathers come to take on an important role in education and discipline in later childhood. Socialization of appropriate emotions as well as competence, autonomy, and sociability is a strong focus even in infancy. Children are cherished and protected by an ever-present network of family members. However, once children have gained a strong footing, they are given great freedom. Children learn from a young age to participate in subsistence activities. Young girls help their mothers in cooking, cleaning, childcare, and gardening, while boys roam a bit more freely, playing at hunting, fishing, building shelters, and making fires.

Children may be given a series of herbal treatments to ensure fast growth, protection from illness, and positive behavioral traits (honesty, industriousness, emotional control) in later life. Children are also taught to show respect toward particular animals and plants, because mocking, handling, or bothering them may provoke spirit revenge. Children are taught to control their expressions of pain and other negative emotions, leading to a marked stoicism among Matsigenka adults.

Adolescence

By about age 15, children should be proficient in subsistence responsibilities and know right from wrong. Adolescents who act inappropriately are publicly humiliated and punished. Stealing is considered a serious offense. Adolescents are also punished for bullying, laziness, and overly precocious sexual behavior. Girls are generally permitted to engage in an open sexual relationship at a somewhat younger age than boys, who must first prove their abilities in hunting and gardening. Teenage boys may be given a series of purgatives and eye-stinging remedies to develop their hunting skills. They are not allowed to touch or eat their first several kills, and are taught to avoid bragging about or being selfish with meat, lest they lose their stamina and aim. Teenage girls may learn herbal remedies for learning to spin cotton, gaining weight, having strong and durable teeth, removing pubic hair (considered unaesthetic), or regulating fertility.

Transition into womanhood begins with first menstruation, marked by an extended ritual of seclusion (*oantarotira*, "she becomes an adult") during which the girl lives in a small hut, eats special foods, avoids the sun and the gaze of males, receives special instructions from close female kin, and spins and weaves cotton to produce a tunic for her future husband. She emerges from seclusion after completing the tunic, shaving her head to mark the transition. Her emergence is generally greeted by a manioc beer party held in her honor, during which suitors may express their intentions to her and her parents.

Adulthood and Aging

Adult life is characterized by the extreme self sufficiency of the Matsigenka household and the division of labor between husband and wife. Complementary gender roles are reflected in medical botany: whereas men use emetic and painful plant remedies to improve their hunting skills, women use fragrant herbs to protect children from vengeful game animal spirits. People with deficiencies (e.g., cleft palate, atrophied limb) are not ostracized, and usually engage in a fairly normal economic and social life, sometimes compensating for their deficiency in one area with special skill in another.

Couples remain autonomous in most subsistence activities through middle age and well into old age, and only a very small number of school teachers and health workers receive government pensions. As a man ages and loses his stamina, he tends to leave the more strenuous

hunting and garden-felling to a son-in-law, but continues active garden work, fishing, and hunting from blinds. Women, too, remain active and productive through old age. Given the many hazards of life in remote rainforest villages with minimal or non-existent Western medical care, it is surprising that as many Matsigenka make it to old age as they do. The term for old age is *gatavaigetagantsi*, which translates literally as “to be done, to be satisfied after a long life,” implying a sense of completion and fulfillment that contrasts with Western notions of old age as decay and decrepitude. The elderly among the Matsigenka are highly respected for their knowledge of medicinal plants, mythology, history, and folklore, and for their entertaining yarns about a past that was more difficult, more treacherous, and more mysterious than life today.

Dying and Death

Life and death for the Matsigenka are not mutually exclusive states. Instead, death belongs at the far end of a continuum of more and more permanent degrees of separation of the soul (*suretsi*) from the body (*ivatsa*). The soul leaves the body through the crown of the head (*vankagantsi*), nostrils, and eyes during illness, sadness, sleep, trance, and unconsciousness (the verb *kamagantsi* means both “to fall unconscious” and “to die”). The soul is a life force that infuses and activates the bodies of humans, animals, and animate beings with growth, appetite, and purposeful action. At variance with Western metaphors, skin and bones, rather than flesh and blood, are considered to be the inert, soulless aspects of the body. Flesh (*ivatsa*), blood, fat, and muscle are physical manifestations of the soul’s presence in a healthy body. A person who is extremely emaciated due to illness, sadness, or old age is as good as dead: the soul has already left the body, and all that remains are the lifeless skin and bones. In the past, frail, elderly people who could no longer care for themselves simply walked off alone in the forest, since their souls had departed and they were already as good as dead. The dead were exposed in fetal position in the buttress roots of a large tree or in the floodplain down river from the settlement, though burial has been adopted since missionary contact. Shamans are believed to be immortal, awaking from death to join the benevolent spirits in safeguarding humanity.

Matsigenka mourning practices invert common-sense Western understandings of grief, since it is the dead who grieve for the living (Shepard, 2002a). The living sit

in stoic silence while the dead roam in the vicinity of the village for several days, gathering up lost and discarded belongings and seeking loved ones to take as companions to the Land of the Dead. Grief is potentially lethal because the dead are still emotionally attached to the living and capable of stealing their souls to keep as company. Pensiveness, inactivity, and loss of appetite in grief are early signs of soul loss; seeing a ghost in dreams or apparitions is a very dangerous sign, requiring special treatment. The short mourning period (about 3 days) aims at protecting the living from the dangerous attentions of the ghost, speeding it on to the Land of the Dead as quickly as possible. No one wanders far to avoid encountering the ghost, which is feared, shunned, and dehumanized. Family members of the deceased shave their heads, paint their face with red or black dye, burn chili peppers, and may wear the tunic or garments of others, hoping to disguise themselves from the ghost. Often, family members temporarily or permanently abandon the dwelling or residence group where the person died. Crying and overt expressions of grief are strongly repressed. After 3 days, the family slowly returns to normal life, taking warm, medicinal herbal baths and eye-stinging drops to dispel sadness and visions of the ghost.

NOTE

1. Data from three Matsigenka populations (Sotileja, Yomybato, & Kamisea), organized from least to most acculturated, and two neighboring Panoan-speaking populations, the Yora, contacted forcefully in 1985 and the Chitonahua, contacted forcefully in 1995. Data are taken from extensive genealogical interviews (Shepard 1999a: 105–107), except Kamisea which represents deaths occurring during fieldwork conducted from 1996–1999 (Izquierdo, 2001).

Maya of Highland Mexico

Elois Ann Berlin, Brent Berlin, and John R. Stepp

ALTERNATIVE NAMES

None.

LOCATION AND LINGUISTIC AFFILIATION

The Highland Maya of Mexico are located in the central highland region of Chiapas, the southernmost state in Mexico. The two largest groups in the Highlands include the Tzeltal and the Tzotzil (see linguistics). These groups are closely related both culturally and linguistically. Beginning in the 1970s some Highland Maya began to emigrate into the lower elevation Selva Lacandon region of Chiapas, to other parts of Mexico, and to the United States. This migration has been largely due to economic reasons and land shortages but is also often related to religious conflict between the traditionalist catholic religious hierarchies, newly converted evangelical Protestants, and modern Catholics. Other Maya groups in Chiapas are the Chol in the northern mountains of Chiapas; Tojolobal in eastern Chiapas; the Zoque in western Chiapas and the Lacandon in the Selva Lacandon rainforest on the eastern Guatemalan border. In addition, there are approximately 25 other Maya socio-linguistic groups living in Guatemala, Belize, and the Yucatan Peninsula of Mexico.

The Maya language family is comprised of approximately 25 distinct languages distributed throughout southern Mexico, Guatemala, and Belize. Five of these languages represent the principal linguistic groups of the family presently found in Chiapas—Tzeltal, Tzotzil, Tojolobal, Chol, and Lacandón. Three Maya languages originally spoken in Chiapas are extinct or close to extinction—Coxoh, Chicomuceltec, Mocho, and Motozintlec (see Figure 1, after INEGI, 2001). Speakers of several other Maya languages Kanjobal \approx 6,000 speakers, Mam \approx 5,500 speakers, Chuj 1,500 speakers, Jacalteco and Cakchiquel \approx 500 each, Maya \approx 100, Chontal and Kekchi $<$ 100 each) several of these represent recent migrants from Guatemala.

Of the native Chiapas Maya groups, Lacandón (with perhaps fewer than 900 speakers) is linguistically most distinct, sharing close affinities with the Yucatecan branch of the family (Yucatec, Mopán, and Itzá). Chol (\approx 141,000 speakers), is the next most distinct, followed by Tojolobal (roughly 38,000 speakers). Tzeltal (\approx 279,000 speakers) and Tzotzil (\approx 292,000 speakers) are the most closely related of the group, having separated as little as 800–1200 years ago. These two languages are spoken throughout the Central Highlands region (Mexican national census data, INEGI 2001).

Since the early 1950s, speakers of each of the four larger Maya groups have migrated in large numbers and are today found dispersed throughout the southeastern portion of the state.

OVERVIEW OF THE CULTURE

Chiapas has been the site of some of the most intensive anthropological research in the world and there is abundant literature describing most aspects of Highland Maya

Figure 1. Map of Maya linguistic groups in Highland Mexico.

culture. With colonization the Spanish encouraged and cultivated ethnic distinctions between indigenous populations leading in large part to the diversity of dialects and municipal affiliations found today. Most Highland Maya continue to be subsistence farmers; although many have become involved in wage labor that has become available in the last two decades. Over the last several years, environmental degradation and political conflict have intensified in Chiapas, leading to political unrest and violence although there are currently negotiations taking place as part of a peace process in the region.

The Highland region was sparsely populated prior to Spanish conquest in the early 1500s. Even during the classic Maya period the Highland remained a relative backwater and there are few archaeological sites of significance in the area. Population grew at a rate of between 1–2% after contact up until the 20th century. Recent times have seen a much higher growth rate. Between 1970 and 1990 the indigenous populations of Chiapas grew at an astounding annual growth rate of 4.5%, however this rate has subsided with the rate from 1990–2000 at 2.0%. The average number of children born per woman is 3.4. The current population of Highland Maya over the age of 5 is approximately 571,000 (279,000 Tzeltal Maya and 292,000 Tzotzil Maya). Infant mortality is extremely high (9.5%) among the Tzeltal and Tzotzil Maya. This is double the rate for the country of Mexico as a whole.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

Environment

Chiapas is one of the richest areas of biodiversity in the world with more than 9,000 species of vascular plants and more than 1,150 species of vertebrates. The Highlands of Chiapas range in elevation from 700 m to 2,900 m above sea level and as such display a wide range of habitats from broad leafed evergreen tropical forest to temperate pine oak forest.

Because of imminent extinction threats to both flora and fauna, environmental nongovernmental organizations have given the area highest priority for conservation. Recently, many relatively heavily forested regions in the proper Highlands have undergone extreme disturbance due to new settlements and clearing for traditional

swidden agricultural fields. Clear-cutting for timber and charcoal has occurred widely, in spite of government regulations prohibiting such practices. The region is best viewed as a patchy mosaic of a wide variety of different vegetational succession stages. These habitats are widely utilized for procurement of medicinal plants (Stepp & Moerman, 2001).

The primary influences of the environment on health relate to geomorphology, climate, including seasonal variation, and conditions of sanitation. The broken terrain of rugged mountain slopes and valleys provides for some variation in health risks. One would predict a higher rate of heat preferring bacterial diseases in the lower climes and more cold tolerant viral conditions in the higher altitudes. The primary leveling factor in the disease risk patterns across elevational boundaries is the quantity and quality of water supplies. Although some programs have been undertaken for construction of water storage and distribution facilities, water probably still represents the most serious environmental factor in current disease patterns. Inadequate water supplies inhibit adequate hygienic practices. Contaminated water resources promote disease transmission. Sanitary waste disposal is the second greatest environmental risk factor. Sewer systems are almost non-existent in the Maya communities. Indoor plumbing for water and sewage is available normally only in some houses in the municipal centers. Latrines are sometimes but not always used in the more remote hamlets and some houses of the municipal centers.

As more and more families rely on some cash-based economic activities, and as road construction makes transport of construction supplies more feasible, house construction types tend to provide greater protection from the elements of nature. Cement block walls replace wattle and daub, or bound-board walls that are permeable or open to drafts. Corrugated tin, cardboard, or asbestos, and in some cases, cement and/or ceramic tiles are replacing thatch roofing that can harbor disease-transmitting fauna. Ventilation is better in the newer constructions that provide windows and flues for light, air circulation, and smoke release. Gas stoves are slowly replacing wood cooking fires and further reducing irritating smoke inhalation, which can be a risk factor for respiratory problems. Cement floors provide a barrier between soil based organisms and human hosts. Figure 2 compares the highland Maya, the State of Chiapas, and Mexico national death rates from gastrointestinal and respiratory diseases.

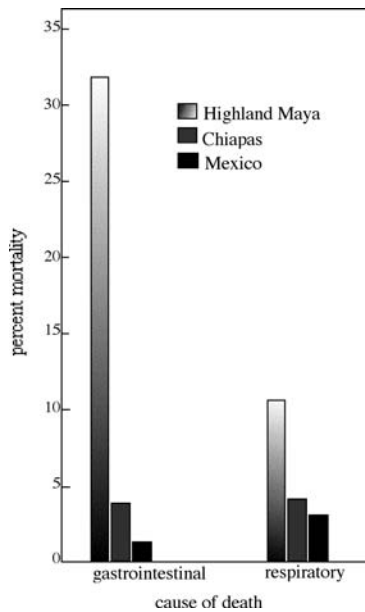

Figure 2. Gastrointestinal and Respiratory Disease Mortality Rates Reported for Maya Communities, Chiapas, and Mexico.

Diet

The Maya peoples of Highland Chiapas have a long tradition of swidden agriculture based primarily on corn, beans, squash, and chili peppers. Small flocks of chickens provide a generous quantity of eggs. Turkeys, pigs, and cattle provide occasional meat. Some sheep are raised but these play a very minor role in indigenous diet as their primary value is the wool they produce for warm clothing and a few tourist items. Availability and consumption of these cultivated and domesticated species is complemented by a rich variety of non-domesticated or “lightly managed” species. In more recent times, the non-domesticates have predominantly been of plant origin as population pressures have virtually eliminated the large game animals (such as deer, agouti, peccary etc.) and restricted the number and distribution of smaller ones (e.g., field rodents, squirrels, rabbits, gophers, and lizards) in the region. The small edible creatures are often opportunistically captured in traps, though a few people may still “go hunting.” In a few areas, streams provide fish, snails, and frogs on occasion. A few wild birds are sometimes eaten. Some people still keep nests of native bees for their honey. The rainy season provides an

abundance of wild mushrooms and there is growing cultivated mushroom production, primarily for market sales.

The period between last harvests, when agricultural stores are lowest is also the period of greatest consumption of non-cultivars. Subsistence agriculture is so marginal in the area that it is not terribly uncommon in bad years for some families to run short on beans or corn and be forced either to eat some of their seed stock or find a means of supplementing supplies through market purchase or exchange.

As in all such contexts of marginal resources, it is the children who are most affected. Chronic childhood nutritional stress is evident in the generally short stature of the population. Those families who are most well-off economically follow the universal pattern of short stature and overweight for first generation adults. Continued economic and dietary stability results in a second generation of (sometimes dramatically) increased stature.

There is also potentially a hidden danger in the change of lifestyles that frequently accompanies economic success. These typically include a shift from traditional food, especially wild species to foods of higher “prestige” such as beverages and snack foods with high sugar, salt, and/or fat content that are low in nutrients. Fortunately the classic shift from breast to bottle, with all the attendant health consequences, has not become a major problem for the highland Maya.

When peoples whose dietary problem has normally been getting enough to eat achieve food sufficiency and the potential for excess, the concept of restriction or balance is not operative. The usual pattern elsewhere is a trend toward obesity and an increased prevalence of diabetes. Such dietary consumption and nutritional health changes may be beginning to occur in the Highland Maya. People frequently report *asukcar* (< Spanish *azucar* “sugar”) as a diagnosis. That there is no Maya term for diabetes (although they do recognize such signs as ants being drawn to urine) suggests that it is a relatively new problem. Based on the number of informal reports of the disease, a systematic study and potential early intervention program would be appropriate.

The weedy species (listed in Appendix 1) that contribute to traditional Maya diet provide high quality nutritional supplements, especially when agricultural resources are lowest. They appear to be the primary sources for vitamin A and thiamine and to add an important amount of calcium to the diet. Vitamin A deficiency is a major problem in many third world populations. It has not been

reported as a problem for this group, although the association of vitamin A deficiency with increased susceptibility to diarrhea could potentially play a role in the high rates of diarrheal disease in this population. An early symptom of vitamin A deficiency is poor night vision. There appears to be no term in Maya for such a condition.

Iodine deficiency, represented by goiter and possibly dwarfism, is often reported in populations inhabiting mountainous regions, including Maya populations of Highland Guatemala. For reasons that are not as yet clear, this does not seem to represent a major health problem in the Highlands of Chiapas. Discovering the sources of this positive deviance in health pattern could possibly provide a model for other highland peoples.

Recent research (Luber, 1999) suggests that protein calorie nutrition is identified by a native term, *cha'lam tsots* "second layer of hair" and studies have shown that this is a significant health problem in the highland region (Berlin & Berlin, 1996). In a diet based on corn and beans, it is frequently difficult for small children to consume sufficient amounts to meet total nutritional needs. Simple addition of a fat source is usually sufficient to compensate for this. For both children and adults food quantity is currently more of a problem than the nutritional quality of the foods themselves. This has the

potential to change for the worse as life-styles change and especially if diet shifts toward higher prestige, nutrient poor foods.

Disease¹

As seen in Figure 3, gastrointestinal diseases are the greatest cause of both morbidity and mortality. The high frequency of gastroenteric conditions in both the ethnoepidemiological and epidemiological data is a reflection of the virtual universal parasitism and frequent diarrheal episodes typical of populations living in the socio-economic conditions characteristic of these communities.

Respiratory infections are the second most frequent cause of illness. Respiratory problems are surely related to the altitude (on average 2,000 m), to cold weather and traditional house construction which affords little protection from cold wind, as well as the smoke of cooking fires. Respiratory problems represent the fourth most frequent reported cause of death. This would suggest that many of these illness are more minor colds and coughs with low mortality.

Fever or, to use a bio-medical gloss "fever of unknown origin", is mentioned as the third most frequent

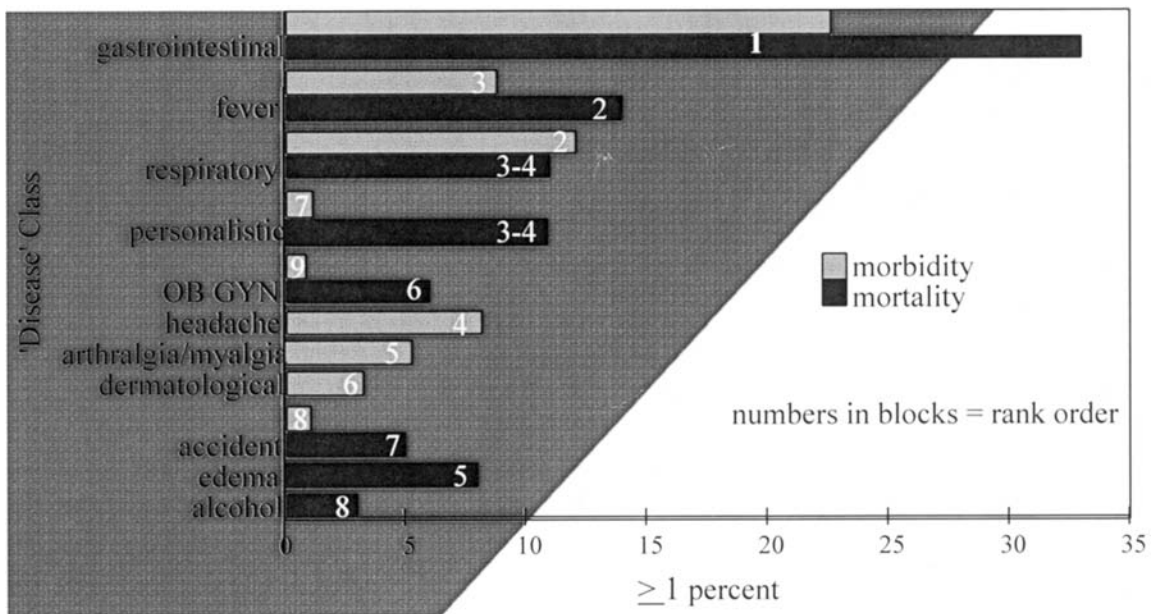

Figure 3. Rates for Morbidity and Mortality Reports in Maya Communities.

illness but the second ranked cause of death. Headaches and general aches and pains (glossed here as “arthralgias and myalgias”) are the fourth and fifth most frequently reported health problems. People relatively seldom mention dermatological inflammations and infections (ranked sixth) as a cause of sickness. The lack of access to water and generally poor hygienic conditions promote high rates of dermatological problems, as evidenced by the variety of named dermatological conditions, probably making them so common as to not merit mention.

Personalistic health problems (ranked seventh in morbidity etiology) cross-cut many categories of disease. Despite the rather low frequency of report of so-called “personalistic” conditions in the morbidity files (ranking seventh as a cause of morbidity), conditions with an attributed personalistic etiology tie with respiratory disease as third and fourth causes of death. This supports the pattern, one that holds across many cultures, that most health conditions are considered at least initially to be naturalistic in nature and those that are more life threatening or more resistant to treatment may become re-diagnosed as personalistic. Further analysis of the conditions reported in association with personalistic deaths shows that more than half of the personalistic deaths were preceded by gastrointestinal symptoms and about 25% were associated with edema. This pattern of reported high fatality from gastrointestinal disease and edema of personalistic etiology form a significant cluster that merits further evaluation. Culturally, it reaffirms the attribution of personalistic etiology to serious illness. It also demonstrates a culturally defined link that also makes sense from a scientific physiological perspective.

The data for sex adjusted death rates due to accident or violence (which is the eighth most frequent cause of morbidity) show about 85% of males and 39% of women were attributed to homicide. A large proportion of both statistics were likely due to violence initiated by males and probably while drinking.

Eye problems in most municipalities consist of standard conjunctivitis and infections. However, in a few areas, particularly the municipality of Oxchuc, trachoma is a serious health problem that can lead to blindness if untreated. A diagnosis of mental illness may encompass advanced cysticercosis affecting the brain and this may account for the relatively high ranking of mental illness (Castille, 1996).

General “women’s problems” are not often reported as a cause of morbidity. Death associated primarily with obstetric problems occurs at much higher frequency than

is reported for morbidity. This is an artifact of the absence of reports of uncomplicated live births in a population with a very high birth rate. It also quite possibly reflects the fact that mortality is high when complications do occur and women might be more remiss to mention more minor problems of this nature. Death precipitated by accidents or violence is reported at about equal frequency with deaths related to obstetric/gynecological problems. The precipitating events for both either occur at very low frequency but carry high fatality or are relatively unremarkable when death is not the outcome.

The general distribution of reported health problems by age group, shows that more cases are reported in the lower age groups, with decreasing illness events with age. However, when adjusted for age, the infants and preschool aged children have a lower report of illness than most other groups, in relation to the total number represented in the sample (Figure 4).

MEDICAL PRACTITIONERS

It is more accurate to define areas of medical specialization in Maya medicine and note that aspects of one or more of these specialties may be incorporated in any given healer’s armamentarium of skills. These specialties include diviner/healer, one who prays to the mountains, pulse-reader, mid-wife, bone-setter, massager, and (in Yucatan) herbalist (*tsak xiu* lit. “herb grabber”).

Diviner/healers incorporate the more traditional shamanic healing practices. Prayers to the mountains might best be considered as preventive medicine specialists in that they pray to the hills and in caves for the protection of the population and for the prevention of periodic and epidemic diseases (such as the classic childhood diseases). Pulse-readers are able to diagnose and monitor the progress of disease based on the detection of

Figure 4. Proportion of population reporting illness by age group.

the type and quality of the pulse at various points on the body. The term mid-wife is somewhat misleading as the knowledge and skills of these practitioners generally is more inclusive of women's health problems and, like other medical specialists, may include various aspects of the other healing specialties. It is interesting to note that there is no specialized role with a distinct term for "herbalist" among the Maya of Highland Chiapas. Individuals with special knowledge of plants are sometime referred to with the descriptive phrase *ja'mach'a ya sna ta poxil wamale* "one who knows medicinal plants." In this region, knowledge of medicinal plants is broadly, if not equally, shared. Many people can identify a plant as medicinal and name the condition it treats, even if they have never used it and/or do not know exactly how it is prepared. Interest in medicinal plants and traditional healing has stimulated an emerging role for herbalists among the Tzeltal and Tzotzil and a widely accepted name for this role may eventually be coined.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

General Principles

The Maya medical system is holistic in that there is a close relationship between the health of an individual and his/her relationship with other people, various environmental factors and forces and members of the spiritual realm as well as elements of contagion. Both problems of health and their treatments can be divided into two distinct systems (following Foster, 1976);

1. The naturalistic system encompasses a majority of health conditions and is the diagnosis of first resort even for many conditions that are later classified as personalistic.
2. The personalistic system comprises a set of conditions that are intentionally or conditionally specific to the individual and/or incorporate extranatural origins.²

Naturalistic Health Problems

Diagnosis of naturalistic health problems is founded on complex ethnomedical understanding of anatomy, physiology, and the symptomatology of specific health conditions. Because these conditions are symptom-based,

people readily group conditions with similar symptoms together although these sickness clusters do not have standard Maya names, they can be glossed as follows: gastrointestinal conditions (alimentary paths), respiratory conditions (airways), dermatological conditions (skin), fevers, headaches, arthralgias and myalgias (general aches and pains), urinary problems (urinary paths), women's conditions, malaise (weakness and wasting), mental conditions, edemas, breaks/sprains, ophthalmic problems (eyes), buccal-dental problems (mouth), emotional conditions (emotion), bites/stings (Figure 5).

These classes, being symptom-based, relate roughly to physiological organ systems. Notably lacking for comparative purposes with biomedical medicine is the cardiovascular system. The close relationship between the heart and lungs (blood circulation and respiration) in Maya ethnophysiology and the general imprecision of cardiovascular symptoms probably accounts for this.

Any sickness that begins with a naturalistic diagnosis may eventually require reanalysis and referral to a personalistic healer. This reevaluation occurs normally when a condition is exceptional in that it does not respond to normal treatment (often with herbal remedies), or alternatively, if symptoms become very severe or life-threatening.

Causes of illness and disease in the naturalistic system range from the mundane life events to more existential reasons. Consumption of spoiled, contaminated, or inappropriate (e.g., causing humoral imbalance) foods and beverages, and prolonged hunger are particular sources of alimentary tract problems. Hard work can

Figure 5. General Classes of Naturalistic Health Problems for Highland Maya.

cause health problems. In addition to breaks and sprains, falls can cause organs to dislodge and malfunction. Sorrow, embarrassment, and anger can all trigger physical illness as can environmental conditions such as rain, cold, heat, and contact with (being struck by or stepping on the landing site of) St. Elmo's fire.³ Airs and wind are a prominent source of illness, especially among the Maya of Yucatan. These may be literal breezes or metaphorical winds that harbor substances that enter the body and cause disease. Airs and winds can also cause humoral imbalances in the body, as can many other substances and phenomena.

Treatment of naturalistic health problems is founded on a complex ethnopharmacopeia of primarily plant-based natural products. Appendix 2 lists the plant species most commonly used by the Highland Maya of Mexico for each major set of health conditions, as well as some of their known pharmacological properties and the medicinal virtues attributed to them in Maya medicine. These plants are readily available, usually within a 1 km radius of the household, and grow along trailsides and fallow fields (Stepp, 2001). Dietary and behavioral restrictions and recommendations accompany herbal treatments. Many of these are based on humoral balance, however, other factors such as digestibility may also be considered. The most frequent behavioral recommendation is rest, either in bed or by avoiding strenuous effort. Infrequently a patient may be prohibited from going outside and being exposed to sunlight.

The majority of Maya formulary are administered orally as teas, infusions, and concoctions, however other therapeutic measures include plasters, massage, blood letting/acupuncture,⁴ bone-setting, and heat application.

Personalistic Health Problems

Personalistic health problems are directed specifically at the individual and originate from numerous sources that can be divided into the following classes: human given, God-given,⁵ fright, problems of the soul/spirit, destiny. Human given illness include those that are intentionally caused (witchcraft), and those that are unintentional (e.g. evil/strong eye). Problems of the soul or spirit include soul loss and effects to one's animal companion soul. Deities (such as the Spiritual Ancestors, Sacred Father Sun, Sacred Mother Moon, Earth Lord, Thunderbolt, Mother Wind) control numerous aspects of life and can punish evil-doers as well as become irritated or angry

and cause illness. Destiny (primarily determined by date and time of birth) is more significant in Guatemala as a health determinant than in Mexico. For serious believers, a considerable amount of time may be spent in maintaining good relations with the various deities. This is, in many respects, preventive medicine.

Diagnosis of personalistic conditions is made on the basis of divination and pulsing. Such diagnosis requires intervention of a specialist healer who first of all diagnoses the true cause (ultimate cause) of illness. Appropriate interventions can then be undertaken on behalf of the patient. These interventions include prayers and incantations on behalf of the patient, including the sacrifice (such as a black chicken in substitution for the patient's soul). Calling the soul's return, sweeping disease from the body with herbs, blowing liquids over the patient to dispel agents of disease and the offering of incense, candles, and liquor to the spiritual ancestor or deity in supplication, atonement, or appeasement. Natural medicines may also be administered at this time, but the primary intervention is non-secular.

Until very recently the concepts and methods for scientifically evaluating personalistic healing were lacking. As yet, few studies have been undertaken to elucidate the psycho-neuro-physiological processes involved in effecting healing through such practices. Recent developments in biomolecular medicine verify that personalistic healing can effect cures, precisely in those cases that are most resistant biomedical treatment, just as our traditional practitioner colleagues have previously informed us.

SEXUALITY AND REPRODUCTION

Pregnancy is said to be the result of the combination of the sexual fluids (strength) of both male and female. Sex of the child is said by some to be determined by the father because a woman produces only female substances but a man may produce male and female substances. Others say that the child's sex is determined by whether the substance of the man or the woman is strongest at the time of conception. Certain plants that can be used to ensure the birth of a male or female. All of these notions seem to conflict with the practice of the mid-wife to count the veins and arteries in the umbilical cord to determine the number of children that a woman will have and, by some reports, the darker vessels signify a male child and the lighter indicate a female child.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

Most children are born at home with the aid of a mid-wife. The birth attendant may administer plant and/or animal derived natural medicines as birth aids. Where the traditional steam bath is still in use, the birth may take place inside the sweathouse and the mother and infant may remain there for a while afterward. In other areas the woman is placed over a steaming pot of water and herbs. After childbirth, a woman is given warm foods and beverages. The mid-wife may return to administer baths and massages to the new mother over a period of days post-partum.

Dietary and behavioral proscriptions and prescriptions are intended to ensure a healthy baby and a safe delivery. Many of these have strong humoral elements. Others simply ensure that the mother not jeopardize the pregnancy through risky behavior.

Infancy

A new child of either sex is generally welcome, although there may be a slight preference for boys. Prayers and rituals are begun shortly after birth to make certain that the ancestral spirits and deities protect the child and a variety of preventive measures are undertaken to keep the baby's soul intact. During the first few weeks, the mother and child avoid social contacts and stay close to home to prevent illness, especially of the infant. The infant's soul is considered to be weakly attached and various precautions are taken to prevent the baby's soul from wandering, becoming lost, or returning to the cosmic pool. The infant's wrists and ankles may be tied with string or small bracelets to tether the soul. An infant may wear amulets, such as amber bracelets to prevent illness, especially from evil eye. When mother and child begin to go out, the mother must place branches or other items to across all paths crossing where her pathway to guide the baby's soul safely home.

Within a few months a baby is often be in the care of older siblings who learn from a very early age to carry a child in a shawl on their backs. Birth defects and undesirable physical and mental characteristics may result when a pregnant woman makes fun of a person or animal who has the particular characteristic. Sometimes just looking at an animal, especially a dead animal, will cause developmental problems for the child to be born. An envious woman may disrupt a pregnancy and take the

fetus into her own body. A fetus resembling a frog, or other creature (probably abortion in early stages of development) may be sent to a woman through witchcraft.

Childcare practices are reflected in the morbidity patterns for infants and toddlers. Inability of very small children to communicate symptoms dictates that health problems must be interpreted on the basis of overt signs. Figure 6 depicts the cumulative frequency of sickness reports. Fever, which may accompany any number of conditions, is the primary diagnosis in small children. The early months and years breast-fed children are relatively protected by maternal antibodies and from dietary contaminants. The number of reports of all conditions, but especially fever, peak during the third year range when children are weaned and consuming regular foods, achieve greater freedom to wander around and come into contact with ambient pathogens. Since toddlers still have limited language skills, fever remains a frequent diagnosis. By five years of age, children begin to approach the adult pattern. Mothers report fewer illnesses overall and gastrointestinal and respiratory become the most significant health problems.

Childhood

Childhood is a training period for adulthood. Children are included in all aspects of life and, as their understanding and abilities grow, they gradually assume a greater role in daily household activities as well as special occasion rituals. Pre-pubescent girls are initiated into the art of tortilla making by wrapping their hands with hot tortillas to toughen them as they begin their training in this fundamental activity. Pre-pubescent boys begin accompanying their fathers in their agricultural duties. As they assume the roles of adulthood, their health risks are those of adults and these are reflected in their health patterns. Forces of change for these patterns derive from the increased numbers of children attending school for longer periods, as well as increased involvement in cash-based

Figure 6. Relative Rates of Sickness Reports for Children 5 Years and Younger.

economic activities and a switch to pre-processed, machine-made tortillas.

Adolescence

Perhaps because adolescents are inclined to high risk behavior, there is an overall higher report of illness during this period (Figure 4 above).

Adulthood

While the causes of illness are similar for men and women, the causes of death vary considerably. Although mid-wives seem to have a high success rate for live births, maternal mortality is high when complications occur. Many women still know a number of herbal formulae for birth control reportedly that may effect temporary or permanent infertility, including *Dioscorea floribunda*, the plant source of the primary modern contraceptive prescribed for hormonal suppression of female fertility. Biomedical health care providers and well-meaning family planning programs have discouraged the use of herbal controls. However, the Maya are joining the alternative medicine revolution and returning to their traditional medical formulations.

Death precipitated by accidents or violence is reported at about equal frequency with deaths related to obstetric/gynecological problems. Males, on the other hand, have a disproportionate mortality due to these causes. Over 85% of men's deaths due to accident or violence were attributed to homicide (39% for women). The old patterns of violence toward women are changing very slowly. It is possible that a large portion of those were due to violence initiated by (inebriated) males, which plays a tragic role in morbidity and mortality among the Highland Maya.

The Aged

As can be seen in demographic data from the Highlands of Chiapas, the elderly comprise a small percentage of the population. The extended household appears to be common enough to accommodate those few who reach advanced age. It is recognized that the older generations are sources of cultural knowledge that is not being learned by many youths. When occasions arise in which this knowledge is attributed special value, the aged gain in prestige. However, many of the young aspire to the knowledge and skills of the national and international community and their appreciation of traditional

knowledge tends to be lessened. Those who have reached advanced age appear to suffer no greater frequency of health problems than their other adult peers.

Dying and Death

Any loss of consciousness, such as fainting is viewed as a near-death experience. When illness strikes, the first recourse is to attempt self treatment, either with traditional remedies or, when cash is available, with medicines purchased at a local pharmacy, store or occasionally vendors in the local markets. Serious illness or one resistant to treatment is likely to require intervention by a personalistic healer. Consultation at a clinic or hospital usually comes late in the course of sickness, if at all, primarily because of the high cost and lack of respect with which Indians are frequently treated by biomedical personnel. Persons who suffer a life-threatening illness are cared for and kept warm by family members. Precipitous death of the young and relatively healthy invites a causal attribution of personalistic intervention by deities or ill meaning humans.

The soul of the recently deceased is thought by some to linger for a while after death and to pose some risk to the living, especially family members and those whose souls are easily lost, such as children. A pregnant woman may be at risk of having the soul of the deceased enter her unborn fetus, which seems to be undesirable.

CHANGING HEALTH PATTERNS

Analysis of changes over time from "traditional" to "contemporary" involves an essentially arbitrary decision concerning a starting point. Most of the texts on the Ancient Maya that would have given us detailed information on their medical system and general health were destroyed by the Catholic priests accompanying the conquering Spanish armies. Early writings describe many aspects of culture, including medical beliefs and practices and even some diseases. Since these early texts were written after Spanish contact and under the guidance of priests who themselves administered to the sick, we cannot be sure that there is no old world medical influence.

One thing that is clear from all the studies that have been undertaken to date. Many of the plants that are currently in use in Maya medicine are native to the region and have most likely been employed for centuries, if not millennia.

APPENDIX A

Species Contributing Nutritional Supplements to Traditional Maya Diet

<i>Acacia</i> spp.	<i>Galinsoga caracasana</i>	<i>Piper umbellatum</i>
<i>Amaranthus hybridu</i>	<i>Guazuma ulmifolia</i>	<i>Portulaca oleracea</i>
<i>Amaranthus spinosus</i>	<i>Lantana camara</i>	<i>Psidium guajava</i>
<i>Bidens pilosa</i> , <i>B. bicolor</i>	<i>Lantana hirta</i>	<i>Psidium guineense</i>
<i>Brassica campestris</i>	<i>Linum nelsoni</i>	<i>Rubus</i> spp.
<i>Bromelia plumieri</i>	<i>Lycopersicon esculentum</i>	<i>Saurauria scabrida.</i>
<i>Byrsonima crassifolia</i>	<i>Mangifera indica</i>	<i>Solanum nigrum</i>
<i>Chenopodium ambrosioides</i>	<i>Morus celtidifolia</i>	<i>Solanum douglasii</i>
<i>Cirsium horridulum</i>	<i>Optuntia guatemalensis</i>	<i>Solanum nodiflorum</i>
<i>Diastacea micantra.</i>	<i>Parathesis chiapensis.</i>	<i>Solanum nudum</i>
<i>Erythrina chiapasana</i>	<i>Physalis gracilis</i>	<i>Sonchus oleraceus</i>
<i>Eugenia acapulcensis</i>	<i>Physalis gracilis</i>	<i>Tagetes filifolia</i>
<i>Eugeniatenejapensis</i>	<i>Piper auriatum</i>	<i>Vitus bourgaeana</i>

APPENDIX B

The Tzeltal-Tzotzil “Cuadro Básico” of Medicinal Plant Species for use in Treatment of the Twelve Major Classes of Health Conditions

Major illness category (and sub-class)	Primary species (in order of importance by sub-class)	Demonstrated pharmacological properties and Maya medicinal virtues
<i>Gastrointestinal conditions</i> general diarrhea	<i>Verbena litoralis</i> (Verbenaceae) <i>V. carolina</i> (Verbenaceae) <i>Ageratina ligustrina</i> , <i>A. pringlei</i> (Asteraceae) <i>Baccharis trinervis</i> , <i>B. serraefolia</i> (Asteraceae) <i>Lantana camara</i> (Verbenaceae)	strong spasmolytic and antimicrobial activity, antifertility, pergative “bitter,” “warm” antibiotic, spasmolytic, anticancer (both spp.)
bloody diarrhea	<i>Cissampelos pareira</i> <i>Calliandra grandiflora</i> , <i>C. houstoniana</i> (Fabaceae) <i>Psidium guineense</i> (Myrtaceae) <i>Byrsonima crassifolia</i> (Malpighiaceae) <i>Sonchus oleraceus</i> (Asteraceae) <i>Acacia angustissima</i> (Fabaceae) <i>Crataegus pubescens</i> (Rosaceae) <i>Nicotiana tabacum</i> (Solanaceae)	antiseptic, digestive antibiotic, antispasmodic, carminative, diaphoretic, digestive, expectorant, hemostatis, nervine, pectoral, sedative, stomachic, tonic, vulnerary diuretic, emmenagogue, expectorant, stimulant astringent strong spasmolytic, antimicrobial, and hemostatic, activity, “cold” alexiteric, astringent, diuretic antibacterial, antifungal diuretic, anodyne, anorexiac, anthelmintic, anticonvulsive, antidote (various insect, arachnid venom), cathartic, CNS stimulant, cyanogenic, diaphoretic, emetic, entheogen, expectorant, hemostatic, intoxicant, laxative, narcotic, parasiticide, pediculicide, purgative, sedative, stimulant

Major illness category (and sub-class)	Primary species (in order of importance by sub-class)	Demonstrated pharmacological properties and Maya medicinal virtues
abdominal pain	<i>Baccharis vaccinioides</i> (Asteraceae) <i>Stevia ovata</i> (Asteraceae)	
epigastric pain	<i>Tagetes lucida</i> (Asteraceae) <i>Chenopodium ambrosioides</i> (Chenopodiaceae)	anesthetic, entheogen, strong spasmolytic abortifacient, amoebicide, analgesic, anodyne, anthelmintic, antiseptic, diaphoretic, diuretic, emmenagogue, febrifuge, fungicide, lactagogue, narcotic, nervine, parasiticide, stimulant, stomachic, tonic, vermifuge "warm"
intestinal worms	<i>Helianthemum glomeratum</i> (Cistaceae)	strong anthelmintic, antimicrobial, anti-candida, "caustic"
<i>Respiratory problems</i> cough, "colds"	<i>Litsea neesiana</i> , <i>L. glaucesens</i> (Lauraceae) <i>Salvia lavanduloides</i> (Lamiaceae)	antimicrobial and spasmolytic activity, "warm"
"croup" ("whooping cough")	<i>Hibiscus unicellus</i> (Malvaceae) <i>Malvaviscus arboreus</i> (Malvaceae) <i>Myrica cerifera</i> <i>Liquidambar styraciflua</i>	emollient anthelmintic, astringent, deobstruent, emetic, febrifuge, laxative stimulant, tonic
<i>Skin Infections</i> "skin eruptions often with pus"	<i>Clematis dioica</i> (Ranunculaceae)	carminative, diuretic, expectorant, vesicant "rube-facient and blistering agent" [Morton 1981: 215], "caustic," "cold"
boils, open sores	<i>Lycopersicon esculentum</i> (Solanaceae) <i>Anoda cristata</i> (Malvaceae) <i>Solanum nigrescens</i> (Solanaceae) <i>Erigeron karwinianus</i> (Asteraceae) <i>Monnina xalpensis</i> <i>Kearnemalvastrum lacteum</i> (Malvaceae) <i>Rumex crispus</i> <i>Rhus schiedeana</i> <i>Ranunculus petiolaris</i> (Ranunculaceae)	antiseptic, aperient, digestive, pectoral "antifungal alkaloid tomatine" [ibid., 795], "cold" analgesic, astringent, blood cleanser, blood purifier, cathartic, diuretic, emetic, emollient, hemostatic, laxative, parasiticide, refrigerant, preproductive aid, stimulant, strengthener, suppurative, tonic antiseptic
<i>Wounds</i> due to accidents, violence	<i>Solanum lanceofolium</i> (Solanaceae) <i>Phytolacca icosandra</i> (Phyt.) <i>Croton drago</i> (Euphorbiaceae) <i>Pinaropappus spathulatus</i> (Asteraceae) <i>Asclepias currisavica</i> (Asclepidaceae)	antimicrobial, "leaves and fruit of <i>P. icosandra</i> contain unnamed alkaloid; sap is acrid and irritates the skin" [ibid. 200], "warm" antibiotic, astringent, hemostatic astringent, emetic, hemostatic, pectoral, purgative, sudorific, venereal, vermifuge, vulnerary
<i>Breaks and Sprains</i>	<i>Brugmansia candida</i> (Solanaceae) <i>Ricinus communis</i>	antimicrobial activity, antiinflammatory, "warm" bactericide, cathartic, contraceptive, cyanogenetic, emollient, fatal poison, lactagogue, laxative, purgative, tonic, vermifuge
<i>Fever</i>	<i>Sambucus mexicana</i> (Caprifoliaceae) <i>Satureja brownei</i> (Lamiaceae) <i>Bryophyllum bipinnata</i>	Anodyne, expectorant, febrifuge, hydragogue, sudorific, "cold"
<i>Headache</i>	<i>Tagetes nelsonii</i>	
<i>Teeth and Mouth Infections</i>	<i>Rhus terebinthifolia</i> (Anacar.) <i>Rubus coriifolius</i> (Rosaceae) <i>Nicotiana tabacum</i> (Solanaceae)	antimicrobial, "cold" ("warm") (see above)
<i>Eye Infections</i>	<i>Solanum americanum</i> (Solanaceae)	"in Panama' dropped in inflamed eyes" [ibid. 799] "cold"

Major illness category (and sub-class)	Primary species (in order of importance by sub-class)	Demonstrated pharmacological properties and Maya medicinal virtues
Edema	<i>Gaultheria odorata</i> Willd. <i>Buddleia americana</i> L. <i>Buddleia crotonoides</i> A. Gray	antibiotic, anticancer analgesic, anodyne, diuretic, hypnotic
Obgyn	<i>Salvia cinnabarina</i> M. & G. <i>Salvia polystachya</i> Ortega <i>Ranunculus petiolaris</i> H.B.K. ex DC	antiseptic
Aches and Pains	<i>Senecio salignus</i> DC. <i>Ricinus communis</i> L. <i>Salvia cinnabarina</i> M. & G. <i>Salvia rubiginosa</i> Benth	anodyne (see above)

NOTES

1. Data from two ethnoepidemiological surveys, conducted by E. A. Berlin in 1987–88 and J. R. Stepp in 1999–2000, form the basis of this report. These patterns generally fit the epidemiological reports from health clinics of the region.
2. The original proposition of Foster and Anderson limited personalistic illness to those directed specifically at an individual, however, it is clear that there are other non-natural or beyond natural etiologies that would not fit within a naturalistic classification and are therefore included here in the personalistic category.
3. St. Elmo's fire is the term used to refer to the atmospheric phenomena that produces ball-lightening that seems to shower on earth.
4. This aspect of Maya curing has been poorly studied except among the Maya of Yucatan, where García, Sierra, and Balán (1996) have made an interesting comparison between Maya and Chinese Medical systems.
5. In at least one municipality of the Highlands of Chiapas, this classification has come to be associated with naturalistic conditions, primarily through the influence of a local priest who has emphasized illness and disease as coming from God but more in the nature of things. This in the sense of God's will be done as opposed to particular punishment or penalty for transgression.

Mongolia

Daniel J. Hruschka and Brandon A. Kohrt

ALTERNATIVE NAMES

Mongolian, Mongol.

LOCATION AND LINGUISTIC AFFILIATION

The Mongolian People's Republic (MPR) is a landlocked country in northern Central Asia flanked by Russian Siberia to the north and surrounded by China to the east, south, and west. Many authors have referred to the region as Outer Mongolia in contrast to Inner or Southern Mongolia, which is now an autonomous region within the People's Republic of China. The majority (> 90%) of the MPR's 2,374,000 inhabitants (NSO, 2000) are ethnically Mongolian, speakers of an Altaic language distantly related to Turkic. Although Mongolian speakers also reside in Russia (308,000; SCRFS, 1994) and China (4,800,000; Tianlu & Rongqing, 1996), this article will concentrate on Mongolians living within the MPR.

OVERVIEW OF THE CULTURE

Three cultural systems—Central Asian mobile pastoralism, Tibetan Buddhist lamaism, and a Soviet model of development—have profoundly shaped Mongolian society. Although it is difficult to trace the ethnic term “Mongol” much farther back than Genghis Khan's 13th century confederacy of nomads (Morgan, 1996), today's Mongolian pastoralists maintain cultural patterns that are characteristic of many traditional Central Asian societies (Humphrey & Sneath, 1999). Most economic activity revolves around livestock grazing. The steppe's sparse vegetation constrains population density and requires frequent moves between pasture sites. Horses, which are the most prized of domesticated animals, have historically served to connect the territory's sparse human population. To accommodate annual mobility in a rugged climate, traditional Mongolian dwellings (the circular felt-lined

ger) combine structural stability, heat insulation, and a flexible framework that can be dismantled and rebuilt in hours. The annual cycle revolves around herd animals, and involves long stretches of relaxed activity punctuated by intense periods of work during the birthing, shearing, branding, and slaughter seasons.

The household and labor organization of Mongolian pastoralists is surprisingly consistent across regional space and historical time (Cheney, 1968; Humphrey & Sneath, 1999; Shombodon, 1996). Nuclear households, consisting of parents, children, and elder family members, serve as the primary economic unit (Neupert, 1995). These households own herds, while higher social bodies administer the rights to grazing land. Settlements rarely grow larger than several *ger* households that converge for the sharing of person and animal power (*khot ail*) or circles of *gers* that are set up for defensive purposes (*khuree*; Bold, 1996; Vreeland, 1962). Marriage, generally monogamous, is deeply tied with the establishment of a new *ger* household and further reinforces a complex gendered division of labor (Cheney, 1968; Neupert, 1996; Shombodon, 1996). Senior males hold the highest authority (Cheney, 1968). Numerous Mongolian women, however, have possessed political or military authority, and socialist policies in the 20th century have further encouraged the economic and political participation of women in Mongolian society (Cheney, 1968; Skapa, 1995).

Tibetan Buddhism firmly infiltrated Mongolian culture in the 17th century when religious missionaries established a network of monasteries throughout the current MPR's territory. Monasteries served both as religious centers and as sites of education, and with 1/3 of all male Mongolians educated as lamas in these monasteries, the philosophy, art, ceremony, and medicine of Tibetan Buddhism soon became embedded in Mongolian life (Cheney, 1968; Heissig, 1980). Although the new religious regime persecuted non-Buddhist knowledge specialists, their indigenous forms of knowledge and practice eventually merged with Tibetan Buddhist forms

to generate a uniquely Mongolian syncretism (Heissig, 1980).

During the three hundred years that Tibetan Buddhism reigned in Mongolia, the Manchu Qing dynasty administered the region. When the Qing dynasty fell in 1911, Mongolia quickly declared independence, and after a series of failed governments and foreign occupations, the Mongolian People's Republic was formed in 1924. Under the guidance of its Soviet neighbor, the MPR embraced a centrally planned socialist model for society. Buddhism and other traditional practices were suppressed, with a series of purges killing tens of thousands of Tibetan lamas and other political dissenters in the late 1930s (Batbayar, 1999). Key goals of the socialist regime were universal education and health coverage and by the 1970s, all Mongolians had access to free health care and all children were provided with at least 8 years of full-time education (Smith & Lannert, 1995). In the late 1980s, Mongolia, with many of its former socialist allies, transitioned from a socialist to a free-market system (Bawden, 1989; Bruun & Odgaard, 1996).

As heirs of mobile pastoralists, Tibetan Buddhist, and socialist traditions, Mongolians today engage in a wide range of lifestyles. Less than one third of the population remains in rural areas, while another third lives in urban settlements, and another third resides in the MPR's capital city, Ulaanbaatar (NSO, 2000). A universal mandatory education system with post-secondary training opportunities has generated a highly literate (> 80% literate) and specialized society. At the end of the socialist period, for example, only 33% of the population was involved in agricultural production, with 17% in manufacturing and mining, 7% in specialist areas such as medicine, law, and teaching, and 33% in the service industry (NSO, 2000). Although, Mongolia is classified as a low-income country, with per capita gross national income hovering from \$350 to 450 (World Bank, 2000), the country ranks surprisingly well on a number of worldwide indicators. Women have achieved a relatively high level of equality (Skapa, 1995), universal education in the second half of the 20th century has raised literacy rates to higher than 95% (NSO, 2001), and a comprehensive health infrastructure extends to most parts of the country. Mongolians stay tuned to modern forms of media, with 80% getting information from the radio, 75% from newspapers, and 68% from televisions (Avirmed & Marckwardt, 1999). In a post-socialist atmosphere of

religious freedom, two thirds of the population is Buddhist and one third claims no religious affiliation (Avirmed & Marckwardt, 1999). Despite the eclectic set of cultural resources now available in the MPR, Mongolians continue to maintain a relatively coherent set of traditions and attitudes that places them in contrast to their international neighbors (China and Russia) and to other cultural systems.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

At the border of dense Siberian forests and the vast Central Asian plains, the MPR is the most sparsely populated state on the planet (1.4 persons per km²). Life expectancy at birth is 64 years for men and 68 for women (WHO, 1999). The leading causes of mortality are cardiovascular disease (31%), cancer (20%), and respiratory infections (13%) (WHO, 1999). The infectious diseases with highest incidence in the 1990s have been viral hepatitis (22–39 per 10,000), tuberculosis (11–14 per 10,000), brucellosis (4–6 per 10,000), gonorrhea (9–14 per 10,000), and syphilis (3–9 per 10,000) (NSO, 2000). As of 1998, there were only 2 confirmed cases of HIV/AIDS (WHO, 1999). However, the dramatic increase of HIV/AIDS in the Russian Federation and China coupled with an increased incidence of other STIs in Mongolia suggests that the country may soon experience its own increase in HIV/AIDS incidence (Purewdawa, 1997). Women suffer from increased rates of depression and indigenous forms of mental illness (*yadargaa*) (Kohrt et al., 2003a), but men seem to have been hit hardest (in both mortality and morbidity) by the recent shift from socialism to a market economy (see section on sociocultural change).

Mongolia's culture, society, and environment have deeply influenced the country's health profile. This section will discuss several of the most important influences on health: environment, mobile pastoralism, diet, and infrastructure. Sociohistorical changes dramatically transformed the health profile of Mongolians in the last century, and these changes will be discussed in the final section of this article.

Environment

Mongolia has an extreme continental climate, with low precipitation, long, cold winters (average January temperature ranging from -35°C in the north to -15°C in south) and short, hot summers (average June temperatures ranging from 15 – 30°C). Temperatures are generally below freezing for 7 months out of the year (Academy of Sciences, 1990). The country's low population density and cold climate have limited potential disease vectors (humans or otherwise), and Mongolians have had only rare encounters with a number of infectious diseases. Cholera, for example, was first reported in Mongolia in 1996 (WHO, 1999). Similarly, Mongolia experienced smallpox epidemics much later than did its southern neighbors (Fisher, 1988; Serruys, 1980). At the same time, the extremely cold, dry environment provides a fertile bed for respiratory infections, which contribute to nearly half of all newborn, infant, and child deaths (Neupert, 1995; WHO, 1999). In contrast, diarrheal diseases contribute to fewer than 15% of infant and child deaths (WHO, 1999).

Mobile Pastoralism

Mongolia's unique environmental regime has further influenced health by constraining the population's subsistence activities. Several aspects of the climatic regime—low precipitation, poor water supplies, and short summers—render crop agriculture a risky venture, while salty soils and an abundance of good feed grasses make most of the country ideal for sustained livestock production. The general reluctance of Mongolians to “cut” or disturb the earth, to fence the earth into agricultural plots, or to eat “grass” likely also contributes to the reliance on pastoral production (Williams, 1996). Although fewer than half of Mongolians now engage in herding (NSO, 2000; Shombodon, 1996), the lifestyle continues to affect the health of a sizeable portion of the population (Foggin et al., 1997).

Mongolians who maintain a rural lifestyle breed and raise different proportions of the traditional five domesticated animals (*tavan hoshuu mal*, horses, cattle and yak, sheep, goats, and camels). One of the greatest health concerns for herding populations is the threat of losing herd animals, either to poaching, to natural predators, to severe weather, or to infectious disease. Perhaps the most serious threat to Mongolian herds is extremes in winter

weather, or *dzud*. In response to the extreme climate, herd animals are adapted to foraging in snow, surviving long periods of famine, and raising young in the severe weather conditions. Mongolian horses, for example, are adapted to the climate, with a short stocky build. They can survive solely on grass and can dig through the snow in winter to find grass. Despite these adaptations, severe *dzuds* can devastate herds with two consecutive *dzuds* in 1999 and 2000 killing over 4,000,000 heads of livestock (more than 10% of all livestock). Although little is known about the human health impact of losing substantial portions of a herd in Mongolia, a study of child nutritional status after the 1999–2000 *dzud*, suggests that herd loss has a deleterious effect on child growth (CDC, 2002).

In addition to affecting well-being indirectly through herd loss, several zoonotic diseases are capable of infecting human populations. Most notably, tuberculosis and brucellosis, which comprise 20% of all reported infections in the MPR (NSO, 2000), can be contracted from herd animals via contact with animals or ingestion of animal products (Foggin et al., 1997).

The traditional Mongolian *ger* also structures health risks. In 1990, 60% of Mongolians still lived in traditional *gers*, including 20% of the urban population (Mongolian Ministry of Health, 1992). Although a *ger*'s outer felt layer and circular design provide an insulated environment even in the coldest months, the close quarters, hot and arid air, and smoke from the central fire may explain the increased deaths from respiratory illness among infants living in *gers* (versus apartments) (Neupert, 1995).

Diet

Early Chinese chroniclers confirm that the Mongolian diet has for centuries consisted of meat and dairy products, with rice, grain, and wine either traded or captured from agricultural areas in China (Cheney, 1968; Jagchid & Hyer, 1979). Fat is accorded special value, with sheep bred for their fatty rumps and honored guests given the first portion of solid white fat from a cooked sheep's tail.

Mongolians prepare numerous milk derivatives (*tsagaan idee*)—cream from boiled milk (*orom*), yogurt (*tarag*), fermented milk (*airag*), raw milk (*suu*), varieties of dried milk curd (*aaruul*), butter (*tos*), cream (*tsotsyii*), dried cheese (*eetsyii*), and distilled sour milk (*nermel*). Salted milk tea is a mainstay. Mongolians consume a limited range of vegetables (potatoes, carrots, turnips, cabbage, onions, and garlic), a restriction that is due

partly to availability, and partly to an ethic that “Grass (which can mean any plant food) is for cattle and meat is the food for man.” Mongolians consider rice and grain flour as staples and most dishes involve some use of rice, noodles, or flour dumplings.

The diet follows an annual cycle that rural residents adhere to by necessity and urban residents by habit: meat is the staple for most of the year, while dairy products predominate in the summer months (Foggin et al., 1997). Mongolians traditionally slaughter animals in large numbers in December to prepare dried meat (*borts*) for the coming winter (Foggin et al., 1997; Jagchid & Hyer, 1979; Seidenberg, 1991). Dairy replaces meat in the summer due to ample supplies of milk products and the high spoilage rate for meat. Although there is geographical and individual variation in this cycle, it is recognizable throughout Mongolia (Foggin et al., 1997). *Tsagaan sar* (the Mongolian new year) and *Naadam* (a national holiday in July) are the exceptions to the rule. During *Tsagaan sar* frozen milk products are thawed for consumption. Conversely, in the summer heat of *Naadam*, large amounts of meat are consumed.

The country’s cold climate and high altitude (average elevation = 1,580 m) exact significant metabolic requirements on organisms. A high-energy diet, as well as relatively high rates of excess fat and central fat deposition, may serve as buffers against these environmental challenges (Beall & Goldstein, 1992). However, this consumption combined with relatively high salt intake may also put Mongolians at risk for later cardiovascular disease. Although cardiovascular disease currently accounts for over 30% of deaths (WHO, 1999), it is difficult to place responsibility for these high rates on the diet, since these rates have increased dramatically in the last decade with few equally dramatic changes in eating habits.

Infrastructure

The central challenge for all health systems in Mongolia has been to equitably distribute medical knowledge and health resources to a thin mobile population ranging over huge areas. One grass roots solution to this problem has been a distribution of medical knowledge whereby households maintain moderate levels of know-how concerning local medicines and illnesses, with more experienced traditional practitioners dispersed but common enough to be accessible in times of need (Hruschka, 1998).

Both Tibetan and socialist medicine also employed some form of dispersed care (Academy of Sciences, 1990; Roerich, 1933). Today rural and urban populations differ most significantly in reproductive health, with maternal mortality twice as high in rural as in urban areas (WHO, 1999), and infant and child mortality also elevated in rural areas in the 1990s (Tserendulam, 1999).

Alcohol and Tobacco Use

Many Mongolian and foreign observers have noted an increase in alcohol consumption during the social transformations of the 1990s. Unemployment, poverty, lowered living standards, and a visibly widening gap between rich and poor have all been posited as reasons for the trend. The availability of alcohol has also changed considerably, with lax state regulations facilitating an influx of cheap foreign alcohol, an increase in domestic production, and a rise in the number of public drinking establishments. In addition to recent social pressures and increases in availability, Mongolians’ cultural attitudes toward alcohol have likely also played a role in the increase in alcohol use. Although Russians are often blamed for the introduction of heavy alcohol consumption, Mongolians had developed a culture around drinking alcohol well before the introduction of Russian practices. For centuries, Mongolians have produced *airag*, or fermented mare’s milk (2–5% alcohol) (Montell, 1937), and a brandy distilled from sour milk (Underdown, 1977).

Alcohol has long been a central part of gatherings, with an emphasis on compelling others to drink as much as possible that was established prior to extensive Russian influence (Montell, 1937). However, the speed with which such liquor spoiled (2 to 3 days in summer) and natural limits on the production of milk (Cheney, 1968; Montell, 1937) likely inhibited chronic alcoholism. Mongolians writing from previous centuries noted the drink’s destructive side. Indeed a number of laws and proverbs discouraged excessive alcohol consumption (Bawden, 1976; Underdown, 1977). What likely changed with the socialist regime was the introduction of highly alcoholic mass-produced distilled spirits. Controlled during communism by ideological indoctrination, strict cell discipline, and limitation of sales, alcohol became a rare and treasured item and common means of transaction in the underground economy (Bulag, 1998). Although no longer controlled, alcohol still retains a precious image that may also drive its current consumption.

A public health concern which will likely come to the forefront in coming years is the high prevalence of smoking among Mongolians—both youth and adults. In 2001, 68% of adult males and 26% of adult females smoked regularly (Kirby et al., 2001). A more recent study of children (9–17 years old) in 17 East Asia and the Pacific countries and territories indicates that Mongolian children have the highest prevalence of smoking (> 55%), with 50% of Mongolian children listing that they had friends who wanted to quit, but could not (UNICEF, 2001).

MEDICAL PRACTITIONERS

The majority of medical practitioners in Mongolia belong to one of three major traditions—modern Russian medicine, Tibetan Buddhist medicine, and pre-Buddhist traditional medicine.

Pre-Buddhist Traditional Health Specialists

Healers, trained neither at government medical schools nor from Tibetan Buddhist sutras, have dominated much of Mongolia's medical history and continue to participate in healthcare today. These traditional healers specialize in distinct, but overlapping, arenas of knowledge rather than comprising a homogenous set of practices and theories (Hruschka, 1998; Humphrey & Onon, 1996). *Bariach* (*barishi*) generally perform massage and musculoskeletal manipulation to treat maladies including concussions, broken bones, headaches, and bone or organ displacements (Hruschka, 1998). *Boo* (male) and *udagan* (*idughan*, *yadgan*) (female) employ ecstatic trance to master spirits with power over maladies and misfortunes (Humphrey & Onon, 1996). *Ekh barigch* (*bariyachi*) hold knowledge of female birth-giving and are comparable with traditional birth attendants. *Otoch* (*otoshi*) have had different roles in different Mongolian contexts. Among the Dagur Mongols of Manchuria, *otoshi* were charged with female fertility and child development (Humphrey & Onon, 1996), while in other contexts the term has signaled a general medical specialist (Kriegel, 1997; Jagchid & Hyer, 1979) or someone skilled with medicinal plants (Lessing, 1982). Each of these specialists is believed to possess the power of spirits and forces related to his or her field of knowledge, much as blacksmiths (*darkhan*) in

the same areas are believed to have access to spirits controlling metal-smithing (Hruschka, 1998; Humphrey & Onon, 1996).

Mongolians generally feel that traditional practitioners whether they are *boo*, *bariach*, or *eck barigch* do not choose to become healers, but rather are chosen by deceased ancestors (*ug*) who once practiced the specialty. An individual is usually “called by the ancestors” in the form of an untreatable illness, and the only way to cure the illness is to ritually take the ancestral talent (*udam*) and begin healing (Hruschka, 1998; Humphrey & Onon, 1996). These healers were persecuted under both Tibetan Buddhist and socialist regimes, and only since 1990 have they begun to experience a resurgence in public practice (Hruschka, 1998).

Buddhist Medicine

With the destruction of monasteries and the mass purging of monks in the 1930s and 1940s, the socialist regime effectively erased Tibetan Buddhist medicine as an institution (Bawden, 1989). Before that time, however, prominent Tibetan Buddhist monasteries in Mongolia often maintained a college of medicine (*mampa datsan*) where future physicians (*maaramba*, *emch*, or *otoch*) trained in the diagnosis and treatment of illness (Jagchid & Hyer, 1979). The Tibetan Buddhist medical canon in Mongolia was a vast collection of sutras, theoretical commentaries, and case studies compiled and revised over centuries of practice. To become skilled in this field of knowledge, a student was obliged to study at least 20 years in the *datsan* before becoming a physician (Cheney, 1968). In recent decades, Tibetan medicine has returned as a legal form of healing.

Russian Modernist Traditions

Although Russian-trained doctors and paramedics are the most recent addition to the Mongolian medical landscape, they quickly came to dominate healing under the 20th century socialist regime. Within two decades of the revolution in 1924, the MPR had established a school of modern Russian medicine to train nurses and paramedics, and by 1961, a central medical school was training physicians to staff the growing network of clinics throughout the country. During the first years after the revolution when doctors and clinics were still in short supply, Tibetan-trained *emch* and other healing specialists were

allowed to continue practicing. This soon changed, however, when in 1938 the government extended a universal ban on non-modern forms of medicine. Coincident with a set of purges, this ban ensured that most medical care took place within Soviet-styled clinics and hospitals staffed by paramedic feldshers (*baga emch*) and doctors (*ikh emch*) (Academy of Science, 1990; Bawden, 1989).

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

The theories and treatment of illness in Mongolia derive primarily from three medical traditions—pre-Buddhist traditional, Tibetan Buddhist, and Russian modern. Mongolians do not generally envision these predominant modes of health care as mutually exclusive, coherent wholes. Rather, individuals synthesize the basic tenets and classificatory systems of each tradition into frameworks that fit their past and current illness experience. Although it is impossible to completely disentangle the “original” theories and treatments from these traditions, this section will attempt to identify aspects particular to each tradition.

Pre-Buddhist Traditions

The pre-Buddhist, or shamanic, medical tradition deals with a broad range of misfortune ranging from inconveniences as benign as losing things to maladies as deadly as the plague (Bawden, 1960; Humphrey & Onon, 1996). Misfortune in its many forms (truck accidents, depression, miscarriages) is explained by recourse to a field of powers personified as malignant humans, animals, or ancestors (e.g., *ongon*, *lus savdag*, *elriye*, *chidkun*, *tuidker*, *ada*, *eliye* [Bawden, 1960; Heissig, 1980; Humphrey & Onon, 1996]). These forces can be set in motion by external actions, such as a curse, or by an individual’s own actions, such as the breach of a taboo.

Treatments under this system usually invoke the powers of specific spirits. *Tsagaan ovgon* (the white old man), for example, was known among the Buriats to protect humans from poxes and various feverish illnesses (Heissig, 1980). The task of a healer is to prevent misfortune by appealing to specific spirits or to correct (*zasa-*) a

misfortune or malady by severing the oppression (*dara-*) of specific forces. Different spirits require different ritual activity such as ecstatic trance induction (Humphrey, 1996), manipulation of a patient’s bones and muscles (Hruschka, 1998), or more material forms of treatment (Cleaves, 1954). The workhorses of this ritual repertoire are effigies that absorb an individual’s illness or misfortune (Heissig, 1986; Humphrey & Onon, 1996). Another force that has been especially consistent across space and time has been the purifying fire, which cleanses all forms of polluted individuals and items (Bulag, 1998). Although the practices and theories associated with this collection of forces maintain some theoretical consistency, the orientation is foremost pragmatic, incorporating those practices and concepts that work and eschewing those that do not (Heissig, 1980; Humphrey & Onon, 1996).

Tibetan Medicine

Tibetan medicine in Mongolia, although predominantly influenced by traditional Tibetan/Ayurvedic thought, has some unique facets related to Mongolia’s prior theories of illness. The three humors of Tibetan medicine—*khii* (wind/air), *badgan* (phlegm), and *shar* (bile)—constitute the categorical backbone of the medical theory (Kohrt et al., 2003a; Kriegel, 1997; Matignon, 1895). Diseases are classified according to the interruption of flow or imbalance of these three humors (Cheney, 1968). In the Mongolian context, these humors map onto concepts that may have pre-dated the influx of Tibetan Buddhism. *Badgan* (derived from Tibetan *bad-kan*) and *shar* (the Mongolian word for yellow and jaundice) are opposed according to a cold-hot (*seruun-khaluun*) set of dichotomies (moon-sun, slow-fast, female-male, water-fire, and *arga-bilig* which is often described as yin-yang) (Kriegel, 1997). *Khii*, resembling both the Tibetan humor “wind” and the Chinese concept of *chi*, dominates the humoral triad, and is responsible for neurological and local idioms of distress, such as *yadargaa* (Kohrt et al., 2003).

Initial diagnosis involves taking a history, reading a person’s pulse, and examining the patient’s urine. A combination of pulse attributes reveals type of illness, location of pathology, personal temperament, and childhood history of disease. Urine, illuminates humoral constitution when assessed by smell, taste, temperature, color, and foaming potential (Cheney, 1968; Kriegel, 1997; Matignon, 1895).

Treatment depends upon the type of illness. Plant and mineral compounds (*tan*) are often taken in hot water

or tea. Since the humors are strongly affected by climate, behavior, and state of mind, patients are often told to change their lifestyle for improved health (Cheney, 1968). Visits to the countryside, spending less time outside in cold weather, cessation of drinking or smoking, and mental relaxation are often encouraged. Illnesses related to karmic offenses in a previous life require the reading of sutras and *tarin* (short sutras). Treatments could include acupuncture (*zuu*), bleeding (*khanuur*), moxibustion (*toonuur*), and cupping (*bumba*) (Kriegel, 1997; Matignon, 1895). Dietary practices have both preventative and curative impacts. Foods possess different humoral and cold/hot properties and are consumed to adjust a person's constitutional imbalance (Kriegel, 1997). Seasonal dietary shifts accommodate climactic changes, for example "hot" foods, such as mutton, warm the constitution in winter, while "cold" foods, such as fermented mare's milk, cool the body's constitution and eliminate toxins taken from "hot" foods during the summer (Bulag, 1998).

Russian Medicine

The biomedical approach employed in Mongolia derives from the Soviet model. Physicians currently diagnose and treat according to the International Classification of Disease-10 (ICD-10). Mongolian biomedicine also emphasizes lifestyle and integrates therapies such as cupping, acupuncture, massage, and various forms of naturopathy. Injections (glucose, vitamin complexes, calcium chloride, and saline) are a popular form of treatment for myriad health problems (Kohrt et al., 2002).

SEXUALITY AND REPRODUCTION

Sexuality

Pre-socialist Mongolia is stereotyped as having promiscuous sexual norms, and consequently high rates of venereal disease (Bawden 1989; Cheney, 1968; Rupen, 1964; Jagchid & Hyer 1979). During socialism sexual activity outside of marriage was discouraged, and sex is not normally an acceptable topic in public discourse. Most education about sex and sexuality occurs through peers and via the media. Sexual or gender forms different from a standard heterosexual dichotomy are little understood and treated with either confusion or disdain. Consequently little information is available on the subject. Post-socialist

changes, such as increased freedom of movement, less strict partner tracing, new attitudes about sexual behavior, and increases in sex workers, have been implicated in a marked rise in sexually transmitted diseases (syphilis, gonorrhea, and trichomonas) since 1990 (Purevdawa et al., 1997; WHO, 1999).

The Fertility Boom

For the last half century, Mongolia has witnessed a dramatic demographic transition. With decreased mortality and increased fertility achieved during the socialist period, the country witnessed a growth spurt that more than tripled the population in 60 years (Neupert, 1995; Randall 1993). Consequently, Mongolians are relatively young, with 32% of the population under the age of 15 years, and only 4% over 65 in 1999 (NSO, 2000). In 1970, however, Mongolia began to see fertility rates decline (Neupert, 1995; Randall, 1993), and it is likely that the population structure will include a much larger proportion of older individuals in the coming decades. Although the fertility boom has been linked with pronatalist policies of the MPR, Randall argues that improved medical treatment, especially for sexually transmitted diseases, provides a more consistent explanation for the sudden burst in fertility (Randall, 1993).

The strict pronatalist policy under socialism included strict control of abortions and contraceptive technologies. Since 1989, however, both abortion and contraception have become legal forms of fertility control. Since that time, nearly 2/3 of women with an unwanted pregnancy take steps to stop pregnancy, with one of every six pregnancies ending with an abortion. The termination of pregnancy is much more common among urban and educated women, with only 1/3 of rural women and uneducated women with unwanted pregnancies terminating the pregnancy (Chagnaadorj, 1999; Panday, 2002). The trend in abortions has been paralleled by changes in contraception. By 1995–1998, 60% of women aged 15–49 (compared to less than 15% in the 1980s) were using some form of contraception, with IUD the most common form (32%), followed by periodic abstinence (13%) (Mongolian Ministry of Health, 1993; Luvsantseren, 1999).

Ideal Household

The ideal Mongolian household, which is captured in socialist art and contemporary movies, is a heterosexual

couple living in either a city apartment or traditional *ger*. It includes several children and potentially the couple's parents. The ideal number of children has changed over the years, with younger women wanting on average fewer than 3 children, compared with older women (> 35) who state a preference of around 4. These ideals are surprisingly uniform across region, education, and sex (Dashtseren & Marckhvardt, 1999). Despite the ideal of a couple participating in the production of a household, about 10–20% of households are headed by single women (NSO, 2000), and out of wedlock births seem to be accommodated well (Randall, 1993). Cohabitation is common with 48% of registered couples living 2 or more years together before marriage (NSO, 1999). Such cohabitation often occurs within the *ger* or apartment of other family members.

Reproduction and Risk

Due to the socialist emphasis on reproductive health, 98% of women were receiving prenatal care and 87% of one-year-olds full immunizations by the mid-1980s (Griffin, 1995). However, although maternal mortality in Mongolia has decreased considerably in the last century, pregnant women, especially in rural areas, have a significant risk of dying with rates hovering around 120–240 per 100,000 live births over the last two decades (Randall, 1993).

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

The course of pregnancy for Mongolian women has changed dramatically in the last century. Prior to the establishment of maternal clinics in the mid-20th century, births occurred at home, usually with the aid of a traditional birth attendant (*ekh barigch*, *kuisutu eej*, or *udghan*) (Jagchid & Hyer, 1979). With the advent of universal socialist health coverage and countryside birth clinics, the incidence of home births delivered by midwives declined. In the 1990s, only 0.1% of births were attended by traditional mid-wives (Lhagvasuren et al., 1999). In addition to providing free antenatal and postnatal care, the state also allowed at least a month of leave both before and after birth (Goldstein & Beall, 1994).

Infancy

Infancy (*balchir nas*) in Mongolia, as in many other regions of the world, is an especially risky period of the life span. Even with the expansion of a socialist medical system that made child health one of its primary concerns, infant mortality rates are still high, with 50–60 of every 1000 live births not surviving past the first year of life (NSO, 2000). At this sensitive period of development, efforts are made to protect children from all kinds of disturbances, including states of fright or “soul loss.” Among the Buriats, for example, black ash is smudged on a child's forehead before leaving a *ger* at night in order to protect the child from being frightened by wandering spirits. This protects the child from “loss of soul,” a disorder accompanied by listlessness or recurrent illness, and if untreated, potentially death (Humphrey, 1996).

Breast-feeding is nearly universal, with over 96% of children born in the 1990s fed with breast milk. Mongolian mothers continue breast-feeding their infants far longer than world standards, with a median age of cessation at 25 months. One fifth of children receive breast-milk up to three years. The median duration (8 months) of postpartum amenorrhea is consequently quite long. This pattern of sustained breast-feeding does not differ by education or by residence (rural vs urban) (Dashtseren, 1999). Supplementation generally included animal milks and boiled mutton soup (*bantan*) (Randall, 1993).

Rickets is widely reported in Mongolian children. Due to concerns about cold weather, infants are rarely taken outside in winter, and even then only when heavily swaddled. The consequent lack of exposure to sunlight during winter combined with depleted maternal supplies of calcium may contribute to this problem (Randall, 1993). Respiratory illnesses are by far the largest cause of death in both infants and children (see Environment section).

Childhood

Childhood generally begins when a child reaches 3 “Asian” years of age, which overestimates years from birth by an average of 18 months (Beall & Goldstein, 1992). In Ulaanbaatar, children (*okhin* refers to girls and *khuu* to boys) are generally cared for by their mother (57%) and/or grandmother (31%); fathers are caregivers in 26% of homes (Kohrt et al., 2003b). A big step in rural enculturation is reached when children (at about age 5)

begin to ride a horse alone with the parent galloping alongside, holding the reins (Jagchid & Hyer, 1979). The post-socialism privatization of herds has led some families to keep children, especially boys, at home to help with herding, instead of attending school (Humphrey & Sneath, 1996; World Bank, 2000). Parents do not generally condone physical force as a means of enculturation (Kohrt et al., 2003b). Survival for children is much better than it was prior to socialism, when frequent smallpox and influenza epidemics could lead to the death of half of all children before the age of 4 (Cheney, 1968).

Adolescence

Today Mongolians enter school at around the age of 8, a time when children are beginning to have a sense of the world around them, and when they would traditionally begin to ride horseback independently and to assist in herding large animals (horses, oxes and camels) (Cheney, 1968). Little data exists on sexual maturation among Mongolians, but a recent study in the rural West recorded a median age of menarche at 14 years of age (Beall & Goldstein, 1992). There is no clear rite of passage related to sexual maturation, but once children begin looking and acting more like adults, they take on a set of gendered terms different than those assigned to children (*hovguun* for boys and *busgui* for girls).

Knowledge of sexual behavior most often comes from friends, with surprising homogeneity of attitudes given this horizontal mode of transmission. A number of these attitudes engender behaviors that increase the chance of sexually transmitted infection (STI) (Hruschka, 2001), which could partly explain the high rates of STIs among youth aged 15–25 (Purevdawa et al., 1997).

Adulthood

A number of criteria are associated with “someone who has come of age” (*Nasan hursend hun*). In the past, these criteria were related to the establishment of a household—finding a spouse, having children, and developing a herd. Today, they can also be associated with getting a job. Women normally marry around 20–24, and marriage is nearly universal for women, with only 1% of women at age 49 unmarried (Tsendjav & Marckvardt, 1999). Men marry a few years later than women (NSO, 2001). Most women report the end of menses around 45–48 years old (Tsendjav & Marckvardt, 1999).

The Aged

Ancient Chinese chronicles noted with condescension that the nomads to the north “honor the strong and despise the old” (Jagchid & Hyer, 1979). Upon closer inspection, however, Mongolians maintain entrenched cultural patterns devoted to the aged. Those individuals who live a long life (*nastai khun*) are treated with great respect and often referred to with honorifics (*guai, ahai, avgai*). This deference to the aged is perhaps most apparent during the Mongolian new year, *Tsagaan sar*, when younger members of families and communities visit their elders and present them with gifts. During the socialist regime, the state provided generous pensions and state services to the elderly. Since 1989, however, pensions have not kept up with inflation, and the elderly must depend on family members for support (Briller, 2000).

Dying and Death

Death is treated delicately in the Mongolian language. Although there is a word for the death of animals or unhonored individuals (*ukhekh*), when discussing the death of a close individual, Mongolians use euphemisms—*ongorokh* or *burkhan bolokh* (to become a spirit) or *nasu bolokh* (to come of age) (Humphrey & Onon, 1996; Jagchid & Hyer, 1979). Great concern is taken to ensure that the essence of the dead person departs appropriately. A lama may be called in to chant sutras while the spirit of the dying person leaves. Lama or other ritual specialists decide whether the body should be cremated, interred, or abandoned in the steppe (Kler, 1938; Jagchid & Hyer, 1979).

CHANGING HEALTH PATTERNS

Tibetan Buddhist Medicine

Little epidemiological data exists for Mongolians before regular health censuses were begun in the 20th century. It is difficult to judge, therefore, where the Tibetan Buddhist medical system succeeded or failed in terms of public health. Bawden has suggested that the services of Buddhist lamas were beyond the reach of most people (Bawden, 1989). Considering, however, that the population

of Outer Mongolia was about 500,000 people (NSO, 2000) at the turn of the century and assuming conservatively that one lama at each monastery was medically trained (Roerich, 1933), there would have been about 14 Tibetan trained doctors per 10,000 inhabitants. Contrary to Bawden's judgment, this ratio compares favorably with physician-to-population ratios during much of the later socialist period (Academy of Science, 1990). Indeed, several scholars have hypothesized that the success of Tibetan Buddhism in Mongolia was due in part to the ability of Tibetan doctors to treat or prevent illnesses, including smallpox (Fisher, 1988).

Despite the hypothesized health benefits of Tibetan medicine, the accounts of foreign travelers, researchers, and medical missions in the 19th and early 20th century often noted the poor health of the Mongolian people (Cheney, 1968; Rupen, 1964). The most common theme in these accounts was the high prevalence of venereal and skin diseases, especially syphilis, among the general population (Bawden, 1989; Cheney, 1968). Reports indicate that prior to the revolution, smallpox and influenza periodically rose to epidemic proportions (Cheney, 1968; Rupen, 1964). Official statistics further suggest that at the eve of the revolution the mortality rate totaled 25–30 person per 1,000 year, and half of newborn babies died before the age of 1 (Academy of Sciences, 1990). These statistics, however, must be considered as the estimates of a regime that had a vested interest in painting a bleak portrait of pre-socialist times.

Socialism

Given official statistics, the development of socialism beginning in the 1920s seems to have improved the health of Mongolians in profound ways. The socialist goal was to spread the benefits of modern medical technology to all citizens of Mongolia free of charge—a plan that mirrored the larger socialist platform of equitable distribution of economic, social, and cultural fruits of modern development (Academy of Sciences, 1990; Farkas, 1993). Based on a rational Soviet model of strong central planning, the system grew rapidly after World War II to form a comprehensive hierarchy of health care. Ideally, medical outposts staffed by a nurse practitioner catered to residents within a 35 km radius, county clinics with 1–3 doctors (general practitioners and maternal/child health specialists) provided primary and maternal care, and more specialized hospitals in cities treated referrals from

more diffuse clinics. To staff these new posts, the system made extensive use of *baga emch* (equivalent to Russian feldshers) as paramedical personnel for scattered rural populations, complemented by more specialized practitioners located in central settlements (Academy of Sciences, 1990).

The expansion of socialist medicine is partly responsible for the dramatic changes in health profiles observed during the 60 years of socialist rule. Immunization programs and a comprehensive system of maternal child health played a role in the reportedly 8-fold decrease in infant mortality from the early 20th century to 1990 (Academy of Sciences, 1990). Overall, mortality rates dropped 3-fold, and average life expectancy at birth rose steadily from 38 in the early 20th Century to 65 years by 1991, in large part due to a reduction in child mortality (Academy of Sciences, 1990). The introduction of penicillin in the postwar era combined with the establishment of venereal disease clinics in the late 1940s dramatically reduced rates of syphilis and other infectious diseases (Bawden, 1989; Randall, 1993; Rupen, 1964).

Post-Socialism

By 1990, in step with other post-socialist countries, Mongolia had begun a series of social and political transitions toward multi-party governance and a decentralized economy. The initial years of the transition were difficult for Mongolians. With the subsequent loss of Soviet subsidies (30% of its GDP prior to 1990), the state was not able to continue funding its massive social support system (Smith & Lannert, 1995). Inflation skyrocketed from near zero during the socialist period to 325% in 1992 (NSO, 2000). Unemployment rose as collectives and public corporations were privatized or simply ceased operations (Griffin, 1995). GDP per capita dropped 1/5 from 1990 to 1998 (UNDP, 2000). At the end of the 1990s, however, many of the same indicators now suggest that Mongolians have weathered the transitional storm (NSO, 2000). On the other hand, several disturbing trends have continued their course. With reductions in state expenditures in Mongolia, education and health infrastructure continues to deteriorate (Humphrey & Sneath, 1999; World Bank 2001), while a clearly visible gap continues to grow between the rich and the poor (Griffin, 1995).

Reductions in state funding have had serious consequences for the medical delivery system (Medvedeva, 1996).

Between 1989 and 1992, most of the MPR's maternity-waiting homes were closed, while the referral system that had relied on jeep ambulances and planes for critical emergencies went into disuse (Randall, 1993). There is evidence that increased dependence on women's work coupled with decreased state control is further leading pastoralist women to have home births and return to work quickly (Mongolian Ministry of Health, 1999). Rural fieldsher's posts, which cost about 3 to 4 times as much per bed as any other health unit were discontinued in 1990 (Center for Health Statistics, 1993).

Disruption of health services in the first years of the transition has been implicated with the increase in maternal mortality from 120–175 per 100,000 live births (1985–1990) to a peak of 240 in 1993. With a stabilization of the health system, this rate has subsequently declined to around 150 in 1997 and 1998 (WHO, 1999). Nonetheless, the difference between maternal mortality in Ulaanbaatar and the rest of the country has increased in the last few years (WHO, 1999), suggesting increasing disparity in access to perinatal care. An opposing trend is that of infant and child mortality, with estimates of infant mortality actually decreasing (NSO, 2000; Tserendulam, 1999).

In contrast to infant and child mortality, adult mortality rose dramatically after the end of socialism with a 25% increase for all age groups between 15–44 years (1990–1993) (WHO, 1999). This increase in mortality disproportionately effected young males (15–34). Indeed the mortality of young men continued to increase throughout the 1990s, while that for young women experienced a slight decline after an initial increase (WHO, 1999). These gender differences in mortality rate changes are reflected in life expectancy trends, with male life expectancy at birth having stayed around 64 since the 1980s, and female life expectancy increasing from 64 in the 1980s to 68 years from birth in 1997 (WHO 1999). The incidence of several infectious diseases has also increased in the last decade. Perhaps related to the collapse of veterinary services, brucellosis and tuberculosis incidences have both doubled (NSO, 2000; WHO, 1999), while transitions in sexual behavior are likely implicated in the recent increases in sexually transmitted diseases (Purevdawa et al., 1997).

The stress of the socio-economic transition has also had a marked impact on the mental health of many Mongolians. For example, Mongolians who self-reported more changes in the past decade suffered from more

depressive symptoms and higher rates of one indigenous idiom of distress—*yadargaa* (Kohrt et al., 2003). In tandem with social changes in the early 1980s, the prevalence of psychiatric disorders more than tripled, (Center for Health Statistics, 1993), while rates of suicide have increased dramatically with a rate in 1997 (17 per 100,000 per year) reaching nearly double the global average (WHO, 1999). Not all health transitions began abruptly in 1990s, however. In the early 1980s, for example, the mortality profile began a profound transformation, as the proportion of deaths due to respiratory illness decreased steadily from 50% to less than 15%, while deaths due to cardiovascular diseases increased steadily from 6% in 1980 to more than 30% of total mortality. In the same period, the proportion of the deaths due to cancers increased from one in 20 to one in five of all deaths (WHO, 1999).

Post-Socialist Medical Pluralism

Although the socialist regime suppressed the open practice of non-modern or religious forms of healing, Tibetan-trained physicians as well as non-Buddhist healing specialists continued to practice behind closed doors. Many practitioners received modern Russian medical training and transformed their practice into suitably modern forms, such as one *bariach* who trained as a nurse and was known for practicing “strengthening massage” (Hruschka, 1998; Kriegel, 1997). With the change of political climate since 1989, Mongolians have gained a renewed interest in “traditional” forms of healing (Hruschka, 1998; Humphrey & Sneath, 1999; Kriegel, 1997; Medvedeva, 1996). The Buddhist medical traditions have returned most strongly, with the renovation of traditional Buddhist monasteries and the re-establishment of several Tibetan medical colleges (Kriegel, 1997). Although many Mongolians show an aversion to pre-Buddhist practitioners, much as they did prior to socialism (Jagchid & Hyer, 1979), the growing number of pre-Buddhist traditional specialists suggests that Mongolians are beginning to view these traditions as viable forms of healing. Within this pluralistic environment, it is also becoming more difficult to discern to which traditions practitioners belong. Traditional specialists may take pulses similar to the Tibetan methods, while Tibetan-trained healers send individuals to sites an academic would likely classify as “shamanic” (Humphrey, 1993). Similarly, private clinics now prescribe combinations of

traditional bleeding and vitamin or saline injections, while shamans may supplement trance therapy with prescriptions for factory-produced pain relievers.

The Nahua¹

Brad R. Huber

ALTERNATIVE NAMES

Aztec, Nahuatl, Nahuatl, Mexicano, Mexijcatl.²

LOCATION AND LINGUISTIC AFFILIATION

The Nahua are the largest Native American group in contemporary Mexico. Approximately 1 to 1.5 million people speak Nahuatl³ or one of its dialects. Nahuatl is the southernmost member of the Uto-Aztecan language family. As Dow and Van Kemper (1995, p.182) observe, most Nahua currently live around the periphery of what was once the core of the Aztec Empire in the modern states of Puebla, Veracruz, San Luis Potosí, Hidalgo, and Guerrero. They can also be found living in smaller numbers in the Federal District, the states of Mexico, Tlaxcala, Morelos, Michoacán, Durango, Nayarit, Jalisco, Tabasco, and Oaxaca, and the country of El Salvador (Dakin, 1995).

OVERVIEW OF THE CULTURE

The Nahua generally live in rural areas where they cultivate subsistence and cash crops such as maize, beans, chili peppers, tomatoes, squash, maguey, sugarcane, and coffee. Maize is the most important caloric component of

their diet. It is a good source of complex carbohydrates, but is low in niacin, calcium, riboflavin, and protein, especially the amino acids lysine and tryptophan. These deficiencies are offset by the custom of combining maize with beans at the same meal, and boiling maize in water to which ground mineral lime has been added. The Nahua also raise chickens, turkeys, pigs, and to a much lesser extent, sheep, goats, cattle, horses, and mules. They generally consume animal proteins very sparingly, usually eating meat on festive occasions only. Many Nahua are also known for their production of crafts such as woven goods and pottery. In addition, young men and women may periodically work as migrant farm workers in Mexico and the United States or as masons and domestic servants in nearby towns and cities.

Nahua houses are often one- or two-room, rectangular structures with bamboo, wood, adobe, concrete block, or stone walls, thatch, tar-paper, concrete, or tiled roofs, and packed-earth or cement floors. Personal hygiene and household sanitation vary from community to community. In some communities, people bathe regularly, wear clean clothes, and sweep their homes frequently. The opposite is true in other communities. Regardless, the majority of rural residents do not have indoor plumbing or use a latrine. Furthermore, pigs, sheep, and fowl are kept in a shelter close to or adjoining the home. Fleas are common in houses and lice infest some school-age children and their parents. Because many people are poor,

they cook using a floor level hearth, sit on low stools, and sleep on a *petate* (woven mat) directly on the floor or on wood planks supported by concrete blocks. These living conditions permit the spread of infectious diseases of the skin, and of the respiratory and gastrointestinal systems.

Households are composed of nuclear or patrilocal extended families whose adult members may own arable land or have access to *ejidos* (government land grants). In general, the Nahua trace descent bilaterally, avoid marrying a blood relative or *compadre* (ritual coparent), and marry within the community or municipality. *Compadrazgo* ties are often very important socially and economically, and may be established on the occasion of a birth, marriage, severe illness, or death as well as for a first communion, confirmation, and the acquisition of a saint's image, car, or house. Fiestas that accompany these life-cycle events have banquets in which abundant amounts of food rich in carbohydrates, proteins, fats, vitamins, and minerals are served. They are also occasions for the ritual sharing of cigarettes and alcohol. The extent to which adults are addicted to nicotine and ethanol is not known, but fiestas are occasions during which some men and a few women become very inebriated.

Nahua social organization is generally based upon men agreeing to perform for little or no financial remuneration civil, political, and religious works (*cargos*) that benefit the community. Cargo holders and other community authorities participate in the distribution of *ejido* lands, the settlement of minor disputes, and the sponsorship and celebration of saints' feast days. Community social organization is variable with respect to the presence and influence of a council of elders, state-level political officials, teachers, biomedical personnel, Catholic priests, and Protestant missionaries.

As is the case with other aspects of contemporary Nahua culture, religious beliefs and practices are a complex blend of Native American and Spanish elements. Pre-hispanic religious beliefs and practices can be found in relatively unacculturated communities where native religious practitioners celebrate rituals coinciding with the winter-solstice, planting, and harvesting, and preside over disease-prevention and curing rituals, ceremonies petitioning rain, and divinations. The influence of Spanish Catholicism is evident in more acculturated Nahua communities where Spanish-speaking priests have encouraged community members to observe the Catholic liturgical calendar for nearly 500 years.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

Nahua settlements can be nucleated or dispersed, and may consist of Nahua-speakers only, or of speakers of Nahua, Spanish, and other Native American languages such as Otomí, Tepehua, or Totonac. When Spanish-speaking *mestizos* (people of mixed Spanish and Indian ancestry) are present, they tend to occupy town and village centers. They may denigrate Nahua culture, and try to dominate local and regional political, economic, and religious activities. Locally powerful *mestizos* form ties with Spanish-speaking Mexicans living in other towns and cities of the region and state. Together they implement state policies that benefit them, and which often exploit the Nahua and integrate, assimilate, and subordinate them to the nation's social, economic and political processes.

As a result, land tenure is precarious and the soils the Nahua cultivate have deteriorated. The Nahua have experienced illegal encroachments on their lands, land shortages and conflicts, and low prices for cash crops and the artisan products they produce. Many Nahua are illiterate and impoverished, and have restricted access to biomedical health services.

MEDICAL PRACTITIONERS

Nahua medical specialists are usually consulted only when the herbal remedies and special diet recommended by members of an individual's family (e.g., wife, mother, grandmother) are ineffective in treating an illness. The most common Nahua medical practitioners are the shaman (*tepahtihqui*,⁴ *tepahtiani*, *tlamátiquetl*, *pajchijquetl*, *curandero/a*), midwife (*tetejquetl*, *partero/a*), bone-setter (*texixitojquetl*, *huesero/a*), herbalist (*xiutepatique*, *hierbero/a*), and massager (*tlatitilanki*, *sobador*). Less common are specialists such as curer of fallen fontanel, spirit exorcist, prayer leader, snake bite healer, sucking healer, injectionist, and spiritualist. The majority of medical practitioners heal on a part-time basis, devoting most of their energy to farming, housework, child care, wage labor, and crafts work. A small minority of medical practitioners practice two medical specialties, and a few undertake three or more. Nahua medical practitioners

range in age from approximately 15 years old to more than 90, and are often recruited from the most impoverished households.

There is a sexual division of medical labor in many communities. Nahua midwives are almost always female; only 5% are men. Shamans are also generally women, but shamans who combine healing with the performance of public, communal rituals are male. Male shamans-priests officiate at rites concerning animal and crop fertility, the control of the weather, the installation of public officials, and events associated with the Catholic church calendar. Roughly an equal proportion of men and women become massagers and herbalists. Approximately 75% of Nahua bonesetters are men.

Each of the above five specialties have practitioners who claim to have received a divine call to the healing role. However, it is generally the case that the more often a practitioner is required to deal with the supernatural, the more likely it is that the healer claims a sacred calling. Shamans and many midwives claim to have been recruited after being attacked by supernatural beings in the guise of lightning bolts, large snakes, or a *mal aire*, taking hallucinogenic drugs, or more commonly, after experiencing premonitory dreams. Supernatural beings are encountered during these experiences and they tell future healers of their special destiny to heal as well as provide instruction in the medicines they should use. These premonitions are often followed by severe and recurrent illnesses which are thought to be punishment for their not immediately heeding their calling. They only begin to heal reluctantly, usually after another healer reveals to them that they must either begin treating clients or die. This may be followed by an optional apprenticeship to an experienced healer that varies in length from several months to several years, the novices' successful healing of his or her first few patients, and a corresponding increase in clientele and prestige.

Some midwives, and most bonesetters, massagers, and herbalists do not claim a supernatural calling. Instead, they are recruited to the role after apprenticing themselves to an established healer or because an emergency arose (e.g., someone broke a bone, went into labor), and they decided to help out because an experienced practitioner was not available. Regardless of the mode of recruitment, Nahua healers tend to have had opportunities to observe and talk to relatives who are also healers.

The shaman is the practitioner who is generally accorded the most prestige. A shaman is respected for his or her knowledge of medicinal substances and for the considerable skill and courage it takes to negotiate with powerful, supernatural beings. Requests for a shaman's services are always accompanied with gifts of food or drink, and compensated with gifts of food and cash that are generous by local standards. A shaman is also respectfully greeted when met on the street. The status of a shaman, however, is ambiguous. Sometimes, spouses, other family members, neighbors, and residents privately criticize shamans as people who are lazy, interested only in financial gain, and sexually promiscuous. Shamans are also feared because they are thought to have the ability to supernaturally harm as well as heal people. On rare occasions, shamans are killed by a group of angry residents who blame them for the misfortunes they are experiencing.

Midwives receive some of the same criticisms that shamans do but are not thought to intentionally harm people. The better known midwives are respected, and compensated well by local standards. For prenatal visits, attending a birth, and providing postpartum services, they receive the equivalent of 3 to 47 US\$, approximately one to fifteen times the daily wage paid to laborers in rural regions. On average midwives make two to three house calls per week. The bonesetter's skills are appreciated but their caseload is generally light (several cases per month or per year). The bonesetter is essentially a farmer who has acquired a medical skill that is valuable at times.

The five main types of Nahua healers can be placed on a scale according to the kind of conceptual model they tend to use to explain and treat illness. Shamans are found near the sacred end of the scale, and bonesetters, herbalists, and massagers are near the secular end. Midwives fall in the middle since they employ both supernatural and naturalistic models for understanding and dealing with pregnancy, childbirth, and the postpartum period.

CLASSIFICATION, THEORIES, AND TREATMENT OF ILLNESS

A formal ethnoscientific study of the way(s) the Nahua classify and conceptualize illnesses has not been undertaken. Nevertheless, Alan Sandstrom (1978, 1989, personal communication) has identified several principles the Huasteca Nahua use to explain and understand disease

and health.⁵ First, is the notion that balance and harmony in social, psychological, and spiritual matters are necessary for health. Closely related to this idea is a second principle: Extreme and antisocial behaviors that disrupt the social fabric or threaten an orderly universe (e.g., drunkenness, spouse abuse, too much aggression or sex, gossiping, lying, cheating) are believed to attract *ejecamej* (*malos aires*, bad winds) which are disease-causing spirits. A number of the *ejecatl* spirits have compound names that include the word *tlasoli* (filth, refuse, trash) and are thought to originate in tangled underbrush and filthy water. Moreover, the *ejecamej* that cause illness (*cocoliztli*, *enfermedad*, *pestilencia*) can also cause infertility, afflict domestic animals, cause crop diseases, droughts, and floods.

Nahua shamans deal with the above kinds of supernaturally-caused maladies. For example, they treat *mal aire* (a type of spirit intrusion), object intrusion due to sorcery, *mal ojo* (evil eye, a type of witchcraft), and *ahmo tonalcahua* (*perdida de alma*, soul loss). They also treat illnesses with naturalistic causes, such as those due to incorrectly mixing activities or foods that are considered hot or cold. For example, fever (*atonahuistli*, *huey-tonotqui*, *calentura*), one of the most frequent illnesses (or symptoms of illnesses) treated by Nahua healers, is often attributed to being exposed to a sharp change in temperature or remaining too long in wet clothes. As can be seen, illnesses with naturalistic causes are also governed by the principle of balance and harmony.

Collectively, the illness symptoms shamans treat include: lack of energy, sadness, fever, vomiting, diarrhea, headache, coughing, soreness, aches, dizziness, swelling, bleeding, rash, alcohol abuse, cramps, depressed fontanel, and lack of appetite. From a biomedical perspective, Nahua shamans treat maladies that include gastrointestinal, respiratory, and cardio-vascular diseases, skin lesions and sub-cutaneous infections, and female reproductive problems.

Shamans diagnose by verbally, visually, and physically examining patients, and through divination. Divination techniques include entering trance-like states after becoming intoxicated with rum, marijuana, and hallucinogenic substances, egg, corn kernel, water vapor, crystal, and dream divination, and pulsing the wrist, neck, temples, waist, and chest. Illnesses with supernatural causes are treated primarily by using rituals (e.g., ritual cleansings, soul callings), during which the shaman may claim to make face-to-face contact with supernatural

beings (e.g., rain dwarfs, lightning-bolt spirits), the lost souls of their patients, and spirits of deceased people. In the Huasteca, shamans use cut-paper figures to portray the *yolotl* (heart-soul) of various spirits. Shamans control spirits for the benefit of clients by making offerings to the spirits' heart-souls during curing and disease-prevention rituals. The length of these rituals vary from a few hours for the simplest ones to several days for the most complex. In addition to ritual, shamans prescribe rest, baths, poultices, and teas and infusions made from a wide variety of plant, animal, and mineral substances (Argueta Villamar et al., 1994). They are holistic healers who treat body, mind, and spirit.

Uncomplicated fractures, dislocated joints, musculoskeletal pain and dysfunction, and sprains, cuts, and bruises are generally thought to have a naturalistic cause such as an unfortunate slip or an accidental fall. Nahua bonesetters treat these kinds of maladies by using massage, joint manipulation, herbs, splints, and casts. To arrive at a diagnosis, bonesetters palpate for the point of fracture or dislocation, and in the case of a bilateral anatomic structure, such as a shoulder, may use the healthy shoulder as a normal control against which the painful shoulder can be compared. Bonesetters treat fractures by setting them. Upon being set, uncomplicated fractures, such as those to an arm, may be immobilized with a cast made of reed splints, cloth, and pine resin. Dislocated or painful joints are treated by inducing motion in them. Inducing motion in a joint involves a thrust or a pull which pressures the joint slightly past its normal range of motion in an effort to set a dislocated joint, decrease pain, and increase range of motion. This kind of joint manipulation may be followed by joint massage during which preparations made from medicinal herbs, rum, rubbing alcohol, cooking oil, and iodine are applied to the painful area.

Less research has been undertaken with Nahua massagers and herbalists. Massagers appear to treat the less severe conditions that are also treated by the midwife, bonesetter, and shaman. They treat stomachache, headache, sore throat, and fallen fontanel in addition to massaging pregnant women, women with fallen uterus, and people with bruises and sprains. Some evidently use massage to treat culture-bound syndromes such as soul loss, evil eye, and *mal aire*. Herbalists specialize in making herbal remedies and using them to treat a variety of symptoms including diarrhea, vomiting, fever, tooth ache, malnutrition, coughing, intestinal parasites, dysentery,

and some culture-bound syndromes such as soul loss and bewitchment.

SEXUALITY AND REPRODUCTION

The contemporary Nahua disapprove of both premarital and extramarital sexual relationships. Sexually promiscuous men and women are likened to dogs that mate indiscriminately. Premarital sex is disapproved of much more strongly for girls than for boys, and parents and brothers are vigilant of their daughters and sisters. Nevertheless, premarital sexual relationships are not uncommon, and a couple may decide to live together or make plans to marry as the result of a girl becoming pregnant.

Some men regard women as sexually voracious and suspect their wives will be unfaithful if given a chance. Women may suspect the same about their husbands and complain about promiscuous husbands to municipal authorities. Some men seek out prostitutes and find lovers when working outside of their community as migrant laborers and a few women find a lover in their home community (Taggart, 1997).

The Nahua think of planting as analogous to sexual intercourse. Men make holes with a dibble stick in the feminine earth into which they place seed. The Nahuatl word to plant (*tatoca*) connotes sexual intercourse. They are aware that pregnancy can result from sexual intercourse. For some Nahua, conception is regarded as seating an infant in the womb (Taggart, 1997, pp. 135–136). In communities with government-sponsored clinics, some women are provided with contraceptives including birth control pills, IUDs, implants, and condoms.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

A small percentage of women give birth without the assistance of midwives. The majority, however, request that midwives attend them during childbirth and ask them to provide prenatal and postnatal care. Midwives massage the abdomen and legs of pregnant women during their second and third trimesters in order to make them more comfortable, to determine the position of the fetus and, when necessary, to change it. The latter procedure is known as external version. Some may also use a sash to

perform a more rigorous massage known as a *manteada*. A *manteada* consists of placing a sash underneath a pregnant woman's waist while she is lying down. Straddling the client, the midwife pulls firmly on each end of the sash and rocks the woman back and forth. Some clients ask midwives to enter a *temazcal* (sweatbath) with them in order to heat their bodies, and make the bones, ligaments, and muscles of their pelvis more flexible. *Limpias* (ritual cleansings) may also be performed.

Pregnancy is thought to be an illness of sorts by many of the Nahua. Pregnant women may experience lack of energy, headaches, nausea, and chills. Occasionally, husbands of pregnant women have similar symptoms. However, there is no report of Nahua fathers customarily going to bed at the birth of children and simulating the symptoms of labor and childbirth (i.e., the *couvade*).

Nahua midwives generally attend births in their clients' homes. One or more additional adult women (e.g., the mother-in-law, mother) and, in some cases, the clients' husbands may assist at birth. Herbal teas are administered to speed delivery. Delivery generally takes place with the pregnant woman kneeling or squatting on a *petate* or blanket on the floor. Midwives position themselves behind, beside, or in front of their clients, and apply pressure to their abdomen with their hands. After delivery, the newborn's eyes, nose, and mouth are cleaned, the umbilical cord is tied and cut with a small knife, scissors, or a sharp piece of cane, and the infant is wrapped in a blanket. Following the delivery of the placenta, midwives clean and dress the mother, bind her waist with a sash (*ilpicat*), and place a ball of cloth (*fiador*) underneath it so that additional abdominal pressure is applied. In cases of problematic births, midwives administer medicinal teas made from the dried tail of an opossum, perform a *limpia*, or seek the assistance of other midwives or biomedical practitioners. If the placenta is slow in coming, midwives stimulate their patient's gag reflex by placing the end of a woman's braided hair in her mouth.

Midwives provide post-partum care during two or three visits to the home of the mother and newborn. They bathe the infant, massage and rebind the woman's abdomen with a sash, and wash soiled blankets and clothing. Midwives may also accompany their patients to the sweat bath and use bunches of herbs, whose species varies from community to community, to fan and warm a woman's body. Or, they may perform ritual cleansings instead. In addition to using herbs in the *temazcal*, midwives prepare herbal teas to stop heavy post-partum

bleeding and to stimulate milk production as well as to facilitate labor, ease labor pains, and to treat sterility. In some communities, there is a 40-day period of sexual abstinence and rest after childbirth known as the *cuarentena*. In practice, rest and post-partum sex taboos vary in length from 40 days to six months or longer (Taggart, 1997, p. 234). In the Sierra Norte de Puebla and the Sierra de Zongolica (Veracruz), recently delivered women eat special foods to help keep them warm and regain their strength.

The Nahua of the Sierra Zongolica thank midwives for attending births at the end of the *cuarentena* during a hand- and house-cleansing ceremony. In the Huasteca, Nahua midwives make offerings to the earth spirit after a woman has given birth. Offerings are made because there is a concern about offending this spirit with the afterbirth, blood, and amniotic fluid of a recently delivered woman. Nahua midwives from this region also play an important role in village-wide religious ceremonies such as the *Tlacatelilis*, a winter solstice ceremony meaning to cause to be born, and the *Xochitlalia*, a crop fertility ritual (Sandstrom, 1991; Sandstrom & Sandstrom, 1986). *Xochitlalia* can be literally translated as to place flowers, but its metaphorical meaning is probably to seat something delicate or precious, thus paralleling the Nahua view of conception.⁶

There are a number of food and behavioral taboos related to pregnancy. Pregnant woman should not travel about at night, especially during a lunar eclipse, since the latter can lead to an infant being born with a cleft palate. Nor should pregnant women view dancers at a fiesta because their children may be born with a face similar to the masks that dancers wear. Working hard while pregnant is to be avoided; it can lead to a miscarriage. Weaving or embroidering while pregnant is also dangerous because it can result in a child being born with its umbilical cord wrapped around its neck. Collectively, these taboos, if observed, would encourage pregnant woman to remain close to home at night, work in moderation, and avoid fiestas.

Some pregnant women have food cravings that husbands are encouraged to satisfy. These cravings are attributed to the fetus. If they are not satisfied, a miscarriage is thought to result. Giving birth to twins is attributed to a pregnant woman eating twin fruits, such as double bananas or plums. The color and number of bumps on the umbilical cord can be counted to divine the number of boys and girls a woman will bear in the future.

The sex of a child can be divined by feeling for the position of the fetus while massaging a pregnant woman. It is thought that a couple's adult children will always live close to them if their placentas are buried beneath the floor of the house. The sheer number of beliefs surrounding childbirth, and this is by no means an exhaustive list of them, show the Nahua's concern with having many healthy children.

Infancy

Babies are carried with a shawl on their mothers' backs and breast-fed on demand for the first six months of their lives. In some parts of the Sierra Norte de Puebla, a mother applies a bitter herb (*chichicxihuit*) to her nipples to discourage a child from breast-feeding. Weaning foods (e.g., *atole*, tortillas, beans) are gradually introduced until the child is fully weaned, which occurs about the sixth month of a woman's next pregnancy (Taggart, 1997, pp. 234–235). By age 2 or 3, children eat the full repertoire of local foods, and begin to talk and walk. There is a widespread belief that a woman's children, especially the youngest one, may become *tzipitotoc* when she becomes pregnant again. A child who is *tzipitotoc* is said to ache, lack an appetite, and cry constantly. These symptoms are attributed to the jealousy a young child feels toward the expected baby.

Some Nahua mothers bottle-feed infants and serve cow's milk to their children. However, many Nahua children are probably lactase-deficient to some degree, and experience diarrhea, abdominal pain, flatulence, and bloating after consuming cow's milk (Cifuentes & Limón, 1985).

Nahua healers indicate that there are a number of illnesses that infants are likely to suffer. Those characterized by respiratory problems include *opatzmigui* (*oguío*, bronchitis), *mitetaxis* (*tos ferina*, whooping cough), and *pulmonía* (pneumonia). Others are characterized by fever (e.g., *aferecía*, epilepsy), and diarrhea, vomiting, and other kinds of gastro-intestinal distress including *ahuetzí* (*caída de mollera*, fallen fontanel), *caída de cuajo* (fallen or dislocated cuajo, an organ believed to be inside the stomach), *cólicos* (colic), *ocuiloua* or *chincual* (worms), *mal de ojo* (evil eye), and soul loss.

In a number of cases, these illnesses are attributed to something that happened to the mother or something the mother did while she was pregnant, for example inappropriate conduct, becoming angry frequently, eating

excessive amounts of lard or sweets. In other cases, such as in Tlaxcala and the Sierra Norte de Puebla, a child's illness or death is attributed to nocturnal animals or witches who suck the blood of newborns. Babies and small children of all regions are thought to be especially at risk for *mal de ojo*, a culture-bound syndrome brought on by the strong or envious gaze of admirers. The affliction is caused involuntarily.

In communities that government medical teams visit or have government-sponsored clinics, infants and children receive vaccinations against diseases such as measles, tetanus, and diphtheria, and are given vitamin A. Nevertheless, the infant mortality rate is still relatively high during infancy and many Nahua parents intentionally wait to name their infants until they are reasonable sure of their survival, for example, at 6 to 12 months of age.

Childhood

Childhood begins around age 4 and lasts until the child reaches 13 or 14 years of age. In some villages, anthropometric data suggest that 50 to 70% of preschool and school-age children are underweight and malnourished. Intestinal parasites are also common in children. Biomedical practitioners treat children (and adolescents and young adults) for acute respiratory conditions (e.g., pneumonia, bronchitis, tuberculosis), diarrhea, and wounds sustained in accidents that occur at home, at school, at work, and while traveling by taxi, truck, or bus. Males are treated for wounds at a higher rate than are females.

Nahua healers indicate there are a number of culture-bound illnesses that children suffer, including *apisuilo* (*tiricia*, jaundice), which is characterized by yellowish skin and eyes and attributed to a variety of causes including being reprimanded continually or being a victim of envy. *Netatil* (*quemadas*, burns) is another culture-bound syndrome that children as well as adult men are thought to suffer. It is attributed to close contact with a woman who recently gave birth, and characterized by a rash or yellowish skin. Urinary infections (*mal de orín*) and eye irritations (*ixtemoleulixli*, *mal de los ojos*) are also common among children.

Adolescence and Adulthood

Adolescent boys and girls are generally given no parental instruction in or preparation for sexual activity and the

sexual aspects of adulthood. Girls begin to menstruate around age 15, and menstrual blood is thought to be particularly dirty. At this age or even before, a girl's mobility, both within and outside of her natal village is severely restricted in some communities. Nevertheless, some adolescents have their first children when they are in their early and middle teens. Most marry and begin to have children in their late teens and early 20s.

Men find medium-weight women to be more attractive than thin ones because the former are considered healthier, stronger, and better able to stand up to demanding household chores. Both men and women tend to gain weight as they mature, but men tend to be thinner due to the more strenuous physical activity required by the kind of work they do. There is no mention of healers treating people in Nahua communities for obesity but doctors do treat a small percentage of adult Nahua patients for diabetes.

In general, both men and women desire children; couples with 6–8 children are not unusual. In some communities it is believed that God punishes women who remain childless. Childless women may be likened to men and may be pitied or severely criticized. Women are often blamed for infertility, a condition attributed to a woman bathing with cold water or burying a doll while she was a young girl. Infertility is grounds for divorce in some communities.

Women are thought to suffer vaginal hemorrhages because they lift heavy loads when pregnant or due to placenta previa. *Caída de matriz* (fallen uterus) is attributed to excessive work. It is thought to be a “loosening” and “displacement” of the uterus from its normal position in the abdomen. *Recaída de parturienta* (“post-partum relapse”) is an illness experienced by young women, especially first-time mothers, after having given birth. It is characterized by fever, headache, diarrhea, and joint and stomach pain, and is attributed to working or being frightened during the *cuarentena*.

Some of the illnesses that adults experience are attributed to their working very hard, often under difficult conditions. *Envaramiento* (stiff tendons) is an illness thought to result from bathing an excessively hot body too soon after working hard for a long period of time. It is characterized by muscular pain throughout the body. *Estiramiento de cuerdas* (stiff muscles) is characterized by intense muscular pain due to straining oneself while working. *Garrotillo* (“croup”) is an illness that adults suffer after they have worked outside for a long time

under a strong sun. Its symptoms include an intense headache, fever, a “dry” cough, sore throat, and leg and arm pain. *Cabeza abierta* (“open head”) is attributed to carrying heavy sacks with a tump line or receiving a heavy blow to the head.

The Aged

People are considered older adults when they are in their late 50s and 60s. Most men and women remain active until their deaths, and it is not unusual to see 70 or 80-year-old men farming or elderly women weaving, cooking, and washing clothes. Men and woman expect their children to care for them when they become elderly. The very old (and the very young) are thought to be relatively weak, and especially prone to illness, including *mal aire* and soul loss. Sometimes, couples are faced with the difficult decision of allocating scarce financial resources to treat a sick elderly parent or grandparent, or to purchase food and clothing for their children.

Dying and Death

When a child or adult dies, a doctor may be summoned to determine the cause(s) of death, especially if the municipality has a government-sponsored clinic. The deceased usually lies in state for a day, and is washed and dressed by a widow. A married woman does not handle the deceased. If she handles a corpse, she might bring the spirit of the deceased to her home where it could attack her husband and children, and cause *mal aire*. The deceased is generally buried the day following death, after a wake has been held during the night. If a municipality has a cemetery, burials within it are regulated by a councilman, topiles (local police), or relatives of the deceased.

Beliefs concerning the afterlife are variable and depend upon the extent to which a community has been influenced by Catholicism over the past 500 years and by 20th century Protestant missionaries. In many acculturated communities, the fate of the soul is thought to depend upon an individual’s conduct during life, including his or her meeting of religious obligations. In the Sierra Norte de Puebla, for example, souls of people who conducted themselves well go to heaven. Souls of infants who die before being baptized go to limbo and cannot see God; sinners become the slaves of the Devil.

In less acculturated communities, beliefs surrounding death and the fate of an individual’s soul show more

continuity with those of the prehispanic period. In the Huasteca, a person’s *yolotl* soul generally travels to *Mictlan*, an underworld place of the dead. However, souls of those who die from water-related causes (e.g., drowning) go to a watery paradise (*Apan*). Disease-causing wind spirits are thought to be the spirits of people who die prematurely.

CHANGING HEALTH PATTERNS

There are a number of changes related to health and illness in Nahua communities. Visitations to biomedical personnel, acceptance of the germ theory, and the use of pharmaceuticals are increasing. In some communities, shamans prescribe medications that their clients are instructed to purchase in a pharmacy. Healers are also now much more likely to charge a fixed fee for their services than they were in the past. In the past, healers accepted as compensation whatever their patients could afford to give them. In addition, there have been changes in beliefs and practices. The use of the *temazcal* has declined dramatically, so much so that some people are no longer repairing or building them. Many people question the belief that burying the placenta inside the home will assure them that their children will always remain closeby. They observe that adult children are migrating to and living in distant cities and towns regardless of how carefully they dispose of the placenta.

In general, doctors and nurses are reluctant to work with shamans. Biomedical practitioners as well as schoolteachers, priests, missionaries, and village authorities often belittle or seek to eliminate shamans and shamanistic practices and beliefs. This is leading to a reduction in the number of Nahua shamans and a narrowing of the scope of their healing role. However, Mexico’s National Indian Institute (*Instituto Nacional Indigenista*, or INI) has encouraged Native American groups throughout the country to form organizations for traditional medical practitioners. These organizations are designed to reinforce the knowledge of traditional healers, legalize their practice, and provide people with an alternative to the formal health sector. There are at least nine such organizations to which Nahua shamans and other types of healers belong: four in the state of Puebla, three in the Huasteca region of the states of San Luis Potosí and Veracruz, and one each in the states of Guerrero and Michoacán. In the case of the organization whose center is in Cuetzalan, Puebla,

INI doctors work with Nahua and Totonac healers in a hospital where both biomedical and traditional medicine are practiced. It remains to be seen how much impact INI and these organizations will have on the maintenance and promotion of shamanic healing practices.

Nahua childbirth beliefs and practices have been changing dramatically over the past 25 years. Mexico's Ministry of Health (*Secretaría de Salubridad y Asistencia*, or SSA) and Social Security Institute (*Instituto Mexicano de Seguro Social*, or IMSS) have established a large number of health clinics and hospitals in rural and urban areas. It is increasingly common for pregnant Nahua women to seek out the services of these institutions. Some Nahua women prefer doctors and nurses because they administer injections to control pain during childbirth and because they charge relatively little for their services. At the same time many Nahua midwives have received biomedical training from the SSA and IMSS. As a result, the use of a sharp piece of cane to cut the umbilical cord, cauterization of the cord end, and the kneeling birth position are declining in popularity while the use of pincers to cut the umbilical cord, a sterile tie, gauze, and tape to wrap the cord, and alcohol to sterilize hands and equipment are increasing. INI has promoted the continued use of the *temazcal* and teas made from local medicinal plants for use before, during, and after childbirth. Nevertheless, Nahua midwives are gradually being incorporated into Mexico's biomedical health care system. Many Nahua midwives are essentially auxiliary health workers whose primary role is to funnel pregnant women to SSA and IMSS clinics and take orders and training from doctors and nurses.

NOTES

1. The author would like to thank Alan R. Sandstrom (Anthropology, Indiana University-Purdue University Fort Wayne) and James M. Taggart (Anthropology, Franklin & Marshall College) for critically commenting on this article. The author, of course, is solely responsible for any errors of fact or interpretation.
2. The way in which Nahua terms were rendered in the original sources has been preserved. There is no standard orthographic system used by all Nahua scholars.
3. Many of the Nahua, especially school-aged children, young adults, and men speak Spanish as a second language.
4. The Nahua, Spanish, and English terms used for different types of healers and illnesses are terms of reference rather than strict translations.
5. To varying degrees, these principles are applicable to Nahua living in other regions and to many other Mesoamerican groups as well.

6. The author thanks James M. Taggart for pointing out that "*tlalia*" means "to seat or place", and that a parallel might be drawn between conception and the Xochitlalia ritual.

Navajo

Joanne McCloskey

ALTERNATIVE NAMES

Diné, means “The People” in Navajo, and is often preferred throughout the Navajo Nation.

LOCATION AND LINGUISTIC AFFILIATION

Located in the Four Corners area of the Southwestern United States, the Navajo Nation occupies 26,649 m² on the Colorado Plateau in portions of Arizona, New Mexico, and Utah. The language spoken is Navajo, an Athapaskan language.

OVERVIEW OF THE CULTURE

Relative to the Pueblo Indians, the Navajo were latecomers, arriving in the Southwest sometime before or around 1500 AD (Brugge, 1983). Originally hunter–gatherers, they adopted agriculture from the Pueblos and sheep and horses from the Spanish. The Navajos thrived as pastoralists and agriculturists, moving their sheep with the changing seasons between winter camp and summer camp where they raised corn, squash, beans, and melons.

After their release from imprisonment at Bosque Redondo in Ft Sumner, New Mexico in 1868, the Navajo continued their reliance on livestock and crops until the 1930s. The initiation of livestock reduction by the commissioner of Indian Affairs, John Collier, in 1933 sounded the death knell for the land-based economy. Unable to support themselves with the drastically reduced herds, Navajos had no alternative but to seek work in the labor force. At first Navajo men worked, often at off-reservation jobs on the railroad, ranches, in construction and mining, and as migrant field hands. Women stayed at home to maintain the fields and reduced herds, while weaving rugs to sell at trading posts.

With the increase in reservation schools, hospitals, agencies, and stores after mid-century came expanded opportunities for Navajo women to enter the labor force.

The foundation of Navajo social organization rests on the matrilineal kinship system. The basic principle of *k'ée*, meaning relationships comprised of kindness, love, cooperation, thoughtfulness, friendliness, and peacefulness (Morgan, F., 2002; Witherspoon, 1983), guides interactions among family members in the extended matrilineal kinship network and among clan members. Besides the primary affiliation with his mother's clan, a Navajo also identifies with his father's clan as his “born for” clan and with the clans of his maternal and paternal grandfathers. Egalitarian relationships exist between Navajo men and women, a reflection of the premise that all entities and aspects of life consist of male and female components.

Fundamental to Navajo philosophy and religion is the concept of *hózhó*. Not easily translated from Navajo, *hózhó* involves everything that a Navajo thinks is good or favorable in the world (Morgan, F., 2002; Wyman, 1983). *Hózhó* means goodness everywhere and beauty in the sense of harmony and balance (Morgan, F., 2002). The fundamental purpose of Navajo traditional ceremonies is to restore a state of *hózhó* to the individual through songs, prayers, and ritual activities. Navajo ceremonies focus on healing the patient, “the one sung over,” who may have a physical illness, a mental ailment, or distress brought about by improper contact with the natural or spiritual world.

Formerly, traditional leaders, *naat'áanii*, were selected on the basis of their wisdom, traditional knowledge, community citizenship, membership in a respected family, and the ability to successfully live in harmony and to conduct at least one ceremony (Office of Navajo Government Development, 1998). Replacing the traditional political system, the election of a tribal council began in 1923 as a way to authorize oil leases to extract oil discovered on Navajo lands. The Navajo Nation consists of 110 grassroots organizations known as chapters, which elect representatives to the tribal council.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

Three distinct climatic environments contribute to the striking beauty of the Navajo landscape: humid, steppe, and desert. Mountains rising between 7,500 and 10,416 ft characterize the high elevations of the relatively small humid area, including the Chuska and Carrizo mountains, the Fort Defiance Plateau, the highest ridges of Black Mesa, and Navajo mountain. At the intermediate elevations between 6,000 and 8,000 ft, the pinon and juniper-covered mesas and high plains dominate the steppe area, which makes up about one third of the total land area. Over half of the Navajo Nation lies between 4,500 and 7,000 ft, where sagebrush and grasses grow in a desert climate (Linford, 2000; Young, 1961).

The abundant energy resources on Navajo land—oil, natural gas, coal, and uranium—constitute a double-edged sword for the Diné. Although the extraction of energy resources provide an important source of tribal revenue and employment (Choudhary, 2001), major profits benefit large corporations, which operate under leases negotiated with the Navajo Nation. “In sum, Navajos have no control over their nonrenewable energy resources; profits from extracting and processing them flow elsewhere” (Aberle, 1983a, p. 651).

The 2000 U.S. census counted 173,987 Navajos residing within the Navajo Reservation (Choudhary, 2003), making the Navajos the largest reservation-based tribe in the United States. The Navajo population is young, with a median age of 24.0 years. Despite significant recent gains in educational attainment, unemployment and poverty plague the Diné. The 2000 census reported that 54.22% of the Navajo Nation population 25 years or older had a high school degree yet 42.90% of persons live below the poverty level (Choudhary, 2003). The unemployment rate for the Navajo Nation in the year 2000 was 43.4% (Choudhary, 2001). The annual per capita income for 1999 was \$6,217 compared with \$28,542 for the entire United States (Choudhary, 2001).

In 1990 most Navajos, 82%, spoke their native language at home. Also in 1990, 51.6% of housing units lacked complete plumbing, and 77.5% of occupied housing units were without a telephone. The average life expectancy at birth is 72.7 years compared with

75.8 years for the entire U.S. population (Navajo Area Indian Health Service, 2002).

MEDICAL PRACTITIONERS

Navajo medical practitioners include diagnosticians, healers, and herbalists. Three types of traditional diagnosticians are stargazers, listeners, and hand tremblers, of which hand tremblers are by far the most common. After praying to Gila Monster, one of the Holy People, a hand trembler goes into a mild trance (Milne & Howard, 2000). Hand tremblers may be either male or female, with a predominance of females among practitioners who function only as diagnosticians (Adair, Deuschle, & Barnett, 1988). In addition, road men in the Native American Church also act as diagnosticians. Although not all road men diagnose, many use charcoal gazing, the second most common method of diagnosis (Milne & Howard, 2000).

Three primary types of Navajo healers are medicine men, or singers, who conduct traditional ceremonies; road men who lead Native American Church meetings; and pastors of fundamentalist Christian churches who perform faith healing. In addition, western biomedical practitioners may be used alone or in combination with religious forms of healing. Similar to the many years of education required to prepare medical doctors, medicine men undergo many years of apprenticeship to learn a single ceremony. Depending upon the apprentice's other activities and the ability to memorize hundreds of songs, prayers, and rituals, the learning period may last as long as 15 years (Morgan, W., 1977).

Herbalists, who use their vast knowledge of local flora for medicinal as well as ceremonial purposes, are usually elders. They may use their herbal remedies only for members of their extended families or their cures may be in demand for a wider group. As an example, an herbalist from the Crownpoint area on the eastern portion of the reservation uses her knowledge of plants to prevent births, to facilitate an easy childbirth, and to treat sores, bruises, the common cold, and broken bones.

Some Navajos seek cures from healers belonging to other tribes. For example, on the western portion of the reservation, Navajos may travel to Hopi Indian villages for treatment to extract objects from the patient's body that cause illness and problems (Levy, 1983; Morgan, F., 2002).

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

Classification of Illness

Etiologic agents believed to cause disease include animals, insects, natural phenomena, mistakes made during healing ceremonies, contact with ghosts of deceased humans, and contact with living or dead foreigners, particularly enemies (Wyman & Kluckhohn, 1938). Among the animals and insects that cause illness, the most frequently identified are the bear, coyote, porcupine, snake, eagle, moth, ant, long-horned grasshopper, and camel cricket. The most commonly named natural phenomena responsible for illness are lightning and whirlwinds (Levy, 1983). Failure to observe the taboo regarding abstinence from sex during or four days after a ceremony can cause illness. Illness can result from contact with the dead or from the location where a person died. Because pregnant women and their husbands are particularly vulnerable, they cannot attend funerals.

These etiologic factors may lead to a variety of symptoms and illnesses. There is no direct correlation between a causative agent and a disease process. "A single cause may produce any of several symptoms and conversely, a single symptom may be caused by any of several etiologic agents." Likewise, "No Navajo disease is known by the symptoms it produces, or by the part of the body it is thought to affect" (Levy, 1983, p. 132). For instance, bear sickness and porcupine sickness have been caused by contact with these animals. The time frame for symptoms to appear after exposure may loosely be sooner or later. For example, a diagnostician may find that an adult's health problem originated during gestation because either parent came in contact with lightning or a dead person.

Theories of Illness

The ultimate source of illness is a lack of harmony between an individual and the natural or supernatural world. To restore health, evil must be driven out and replaced with good (Adair, Deuschle, & Barnett, 1988; Reichard, 1974). Rather than treating the physical symptoms of an illness, a ceremony focuses on exorcising the intrusive factors (Wyman, 1983). Purification rites, such

as cleansing, sweating, taking an emetic, and brushing, remove the evil from the patient's body (Reichard, 1974). Also, the unraveling portion of a ceremony symbolizes a patient's release from evil and danger (Wyman, 1983). The removal of evil from the patient and the depiction of deities in a sandpainting attract the deities, the Holy People, to help the patient.

If a singer recites prayers, sings songs, and performs rituals according to the dictates of the Holy People, "the Holy People are compelled to participate and restore the one-sung-over to hózhǫ́" (Frisbie, 1987, p. 6). Each ceremony recounts the story of the exploits of one or more of the many Holy People who acquire the specific ceremony from the supernaturals and then make it available to the earth people (Spencer, 1957). These powerful stories guide and empower the patient as he or she identifies with the deities in the stories.

Treatment of Illness

Three types of Navajo healing, traditional ceremonies, Native American Church, and Christian faith healing, together with western biomedicine make up the contemporary Navajo health care system (Csordas, 2000). Traditional Navajo healing employs a didactic approach through rituals, songs based on stories of obstacles overcome by the Holy People, and prayer that immerses the patient in "the contextualization of life experience within a cosmological and physical 'home,' the Navajo land and people" (Csordas, 2002, p. 167). Crucial to the successful performance of ceremonies is the perfect recitation of prayers. Themes found in prayers, songs, and sandpaintings include the directions, colors, jewels, and simple numbers like four and its multiples (Reichard, 1944). Besides reciting prayers and songs and performing or directing the ceremonial rituals, medicine men talk to patients, emphasizing the positive (Carrese & Rhodes, 2000). As one man told how a medicine man had helped him, "They don't just sing. They also talk to you" (McCloskey, 1998b, p. 22). All participants in the hogan pray with corn pollen by taking a pinch, then putting some in their mouths, some on top of their head, and trailing the remainder in an upward gesture. Knowledge of the Navajo language is pivotal to understand and appreciate the progression of events during an all-night ceremony. One participant stated that he was "too absorbed in the beauty of what's going on even to think about sleep" (Csordas, 2002, p. 168).

Navajo ceremonies may be divided into two major groups, chantways, in which the singing is accompanied by a rattle, and all others, which are rites. Three kinds of chantways are Holyway, Evilway, and Lifeway ceremonies. While Holyway ceremonies are concerned with the attraction of good, Evilway ceremonies must first expel evil influences before invoking the good. Lifeway ceremonies treat injuries suffered from accidents (Wyman, 1983). Although the Blessingway and Enemyway are grouped together as rites, these two ceremonies are distinct from each other. In the Blessingway rite is found the backbone of Navajo philosophy, and from the Navajo perspective it is identical with Navajo culture (Farella, 1984). The purpose of a Blessingway rite is to promote the positive blessings of life, while an Enemyway rite exorcises alien ghosts (Wyman, 1983).

The Navajo pantheon of supernatural beings, the Holy People, *Diyin Dine'é*, are the protagonists of stories on which ceremonies are based, and they figure prominently in the songs and prayers of all ceremonies. Changing Woman, unlike other Holy People who have good and bad qualities and must be persuaded to help restore the patient to a state of good health, epitomizes goodness exclusively. Blessingway recounts the story of Changing Woman's discovery by First Man, her puberty ceremony, and the adventures of her twin sons, Born-For-Water and Monster Slayer, who were fathered by the Sun. During the Blessingway ceremony, the patient holds the mountain soil bundle, a medicine bundle containing stones and soil from each of the four sacred Navajo mountains.

The second major Navajo healing tradition is the Native American Church (NAC), also known as the peyote religion because of the sacramental use of peyote, a cactus that contains mescaline. The NAC employs the therapeutic principle of confession and seeks to build patients' self-esteem (Csordas, 2002). NAC road men work with patients in the same manner as do medicine men, talking to them in a positive, supportive way.

The NAC combines elements of Christianity with aspects of Plains Indian religions. Not until the 1930s did Navajos begin embracing the NAC, when Shiprock area Navajos were exposed to NAC meetings held by Ute Indians. The new religion appealed to the Navajo after the trauma of livestock reduction. The early Navajo NAC faced opposition from the Tribal Council, which made the NAC illegal in 1940, a statute that was not overturned until 1967 (Aberle, 1983b). However, "By the 1970s, the

Native American Church was seen by most Navajo people as simply another chantway, 'azee'jí or Medicine Way" (Wyman, 1983, p. 536). By the 1980s, estimates of the number of Navajos participating in the NAC were as high as 40–50% of the population (Quintero, 1995). Although some conservative traditionalists do not participate, many traditional Navajos attend both ceremonies and NAC meetings.

A peyote meeting may be held in a specially constructed teepee or in a hogan also used for ceremonies. Aided by the power of peyote, participants communicate with God, the supreme being said to be the same God worshipped everywhere. A meeting may be held to cure a sick patient or to solve an economic, social, or legal problem, but also meetings are held to assure success in school, to marry a couple, or to celebrate birthdays and holidays.

Beginning in the late evening and lasting until morning, an NAC meeting consists of four segments: the opening, the midnight water ceremony, the morning water ceremony, and the peyote breakfast. Besides the road man in charge of the meeting, other officiants are the fireman, the drummerman, and the cedarman. Events throughout the night include prayers, songs, ritual smoking, and ingestion of peyote in the form of a tea, whole, dried, or powdered. The early portion of the meeting focuses on sin, suffering, and shortcomings, which later shifts in the early morning hours to an emphasis on hopes for the future and the right way to live (Aberle, 1983b).

The pairing of male and female pervades all aspects of Navajo life and thought.

In brief, the male aspect of men, women, mountains, storms, or just about anything else is considered to be "powerful" and in need of restraint. As a corollary, the female aspect of everything in the universe is characterized as restraint. A balance may be achieved by the proper coupling of these two essences. (Quintero, 1995, p. 79)

An NAC meeting, likewise, incorporates male and female elements. The early part of the ceremony, when the focus is on the patient's problems, is the male part of the ceremony, while the latter female portion shifts emphasis to renewal and healing. Consistent with this symbolic division, the male fireman conducts the midnight water ceremony whereas a woman brings in the water for the morning water ceremony (Quintero, 1995).

Christian faith healing by Navajo practitioners is a significant presence on the Navajo Nation. At fundamentalist churches and in revival meetings held in tents during the summer months, Navajo pastors lead services

that incorporate faith healing. The congregation becomes the family that helps to effect a cure through spontaneous prayers to God. Besides prayer, healing techniques include the laying on of hands, anointing with oil, reading from the Bible, and counseling (Lewton & Bydone, 2000). Fundamentalist healers demand that Navajo members give up sinful traditional and NAC practices, even requiring that participants destroy their *jish*, or medicine bundles (Csordas, 2002).

Common elements in all three types of Navajo healing and practitioners' approaches are the goal of helping the patient to achieve a culturally shared way of understanding, the lack of division between physical and mental problems, and the emphasis on the family. Navajo practitioners work to achieve success with patients by talking to them so they understand in the sense of incorporating a Navajo specific view of life experiences. Instead of sharp distinctions between physical and mental afflictions, Navajo illness may arise from a single source that may be expressed either physically or mentally. The participation and support of family members are extremely important in ceremonies and NAC meetings.

Before 1955, when the United States Public Health Service (USPHS) took over the responsibility for American Indian health care throughout the United States, the Bureau of Indian Affairs faced barriers to their efforts to provide western biomedical care to Navajos due to limited facilities, inadequate funding, and early resistance from Navajo patients. After the transition to care by the Indian Health Service, the most significant result has been the reduction of morbidity and mortality rates (Trennert, 1998). Replacing the threat of infectious diseases, contemporary health care challenges include cancer, accidents, diabetes, and alcoholism (Davies, 2001). Most medicine men recognize the value of western medicine and distinguish between diseases best treated by medical doctors such as gall bladder disease, appendicitis, and tuberculosis and those best treated by Navajo ceremonies such as lizard sickness (Adair, Deuschle, & Barnett, 1988). Western medical practitioners today recognize the need to take the time with Navajo patients to communicate effectively, particularly when discussing negative information (Carrese & Rhodes, 2000). Increasingly, medical personnel incorporate culturally appropriate elements into western medical practices. For example, both Navajo and Anglo personnel in a mental health clinic integrate the principle of *k'é* in treatment to relate more effectively to patients (Willging, 2002).

Theories of Efficacy

From a western perspective, three main theories of efficacy attempt to explain the success of Navajo healing. These theories interpret Navajo healing as psychotherapy, as social acts, or as cultural performances. As a form of native psychotherapy, Navajo healing relies on a powerful practitioner. A medicine man is an imposing figure who "becomes the epitome of success, spiritual harmony, and culturally appropriate behavior" (Topper, 1987, p. 221). He is respected as someone who, like a grandparent, can resolve conflict. Psychotherapeutic elements of healing such as confession, therapeutic alliance, transference, suggestion, and the manipulation of symbols unite to effect a cure (Topper, 1987).

The social dimension of Navajo healing offers a second explanation of efficacy. The presence and support of extended family, clan members, and friends act as powerful affirmation of belonging in a support network, identifying the patient as a significant link in a web of relationships. When an individual suffers a crisis that indicates a disruption of harmony, the family rallies to make arrangements for a ceremony. Enlisting aid from family and friends acknowledges the patient's importance to the group. The patient becomes the center of supportive attention (Spickard, 1991, p. 201). The Navajo educator, Ruth Roessel (1981), also emphasizes the social support integral to a ceremony in her discussion of the *Kinaaldá*, the Navajo girls' puberty ceremony. The planning, gathering of items to be used such as the grass brush and cornmeal, cooking meals for guests, tending the fire while the corncake cooks, and participating in the all-night ceremony require the cooperation of many helping hands.

The third explanation for the efficacy of Navajo ceremonies is that they are cultural performances, a re-enactment of cultural values and beliefs. The role of sandpaintings in ceremonies dramatically portrays their performative nature. A ceremony tells the story of a specific adventure of the Holy People, which is retold in the songs and prayers as well as in the sandpaintings. When a patient sits on a sandpainting, he or she identifies with the Holy People who have been attracted by their likenesses in colored sands. "It is too little to say that for the person, this identification must be a very significant event" (Gill, 1987, p. 55). The healing power of the supernaturals absorbs the sickness and restores the health of the patient seated on the sandpainting (Griffin-Pierce, 1992).

SEXUALITY AND REPRODUCTION

Accompanying the dramatic changes in Navajo lifestyle during the 20th century are changes in sexual attitudes and practices as well as ideas about reproduction. The former admonition to girls to stay away from boys and men was relatively easy to enforce when children and adolescents herded sheep in a rural environment. After an arranged marriage, women began giving birth to children until they reached menopause. A pronatal ideology favored large families that were considered a gift from the Holy People (McCloskey, 1998a). Since the 1960s, when 90% of Navajo children were enrolled in school (Bailey & Bailey, 1986), boys and girls have been in daily contact. During the middle decades of the 20th century, arranged marriages disappeared and women accepted the educational messages about the benefits of family planning, limiting their family size to three or four children.

The limitation of family size signaled an abrupt change from former fertility patterns when women had large families, often ranging between 5 and 11 children with a mean of seven children (McCloskey, 1998a). Contemporary birth rates continue to decline, from 55.4 births per 1,000 in 1965 (Broudy & May, 1983), to 34.4 per 1,000 in 1988, and 21.7 per 1,000 in 1997 (Navajo Area Indian Health Service, 2002).

Respect for Changing Woman, the beloved deity who celebrated her ability to bear children with the first Kinaaldá, and veneration of the earth's capacity to sustain life and growth promote a pronatal ideology. At the same time, women bestow matrilineal clan membership at birth. In a society that reveres motherhood, infertility is a burden, but frequently women who cannot bear children will raise a sister's child or children, who, in any case, refer to their aunt as *shimá*, or mother.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

In the past Navajo men and women observed an array of pregnancy taboos to ensure an easy birth and a healthy baby (Bailey, 1950). The most commonly mentioned contemporary taboo is the proscription against tying knots, which can contribute to a difficult birth or having the umbilical cord wrapped around the baby's neck. A variant of this belief is that weaving a rug or crocheting

during pregnancy can prolong labor (Milligan, 1984). Another current taboo prohibits parents from coming into contact with the dead, even at funerals.

Although Navajo women have accepted birth control as an effective way to plan their families, they remain strongly opposed to abortion. With few exceptions, women, regardless of age and marital status, bring a child to term. If a woman does not feel that she can raise a child, a preferred option is to give the child to a sister or another close female relative. Matrilineal clan membership for all children contributes to the assertion that "No such thing as a bastard or illegitimate child exists in traditional Navajo society" (Roessel, 1981, p. 38).

In the past, Navajo women had a Blessingway ceremony toward the end of pregnancy. In effect, prenatal care at the Indian Health Service has replaced ceremonies during pregnancy (Hartle-Schutte, 1988). However, if a woman has problems during her pregnancy, she will arrange to have a ceremony performed by a medicine man. Traditional births took place at home where Navajo women kneeled on a bed of sand while holding on to a woven belt looped over a roof beam. The initial resistance to hospital births (Bailey, 1948) gave way to acceptance as a safer and more comfortable way to give birth. By the 1980s, 99% of women gave birth in the hospital (Boyce et al., 1986).

Infancy

When an infant's umbilical cord dries and falls off, parents save it for burial in a nearby location related to traditional economic pursuits and appropriate to the sex of the child. A boy's umbilical cord is buried near a corral to promote his successful work with livestock while a girl's umbilical cord is buried close to a loom to assure her future success as a weaver.

A baby's first laugh marks him or her as a social being and is celebrated with a gathering of family and friends. The person who made the baby laugh provides the sheep to be butchered. The baby, sitting on the mother's lap, "hands out" small gifts to guests, including salt. Distributing these gifts assures that a child will grow up to be a generous adult.

Many infants spend much of their first year of life in the protective and comforting environment of a cradleboard, which in Navajo means "baby diaper." In his study of Navajo infancy, Chisholm (1983) found that infants are quieter and less irritable at birth than white babies.

Parents use cradleboards as a soothing, quieting device until their behavior indicated that they no longer wanted to be there. He observed that mother–infant interaction was slower and less intense than that of white mothers, a pattern of behavior adaptive to the relatively dense and crowded environment of extended family residence groups.

Contemporary mothers' patterns of breast-feeding differ markedly from those of grandmothers who used breast-milk as the sole source of nutrition for a young infant. The majority of Navajo mothers now use a "combination feeding" pattern in which they feed the infant both breast-milk and formula. Mothers breast-feed their infants as a way to promote the baby's growth and to protect it against illness while enhancing a sense of security and closeness between mother and child. More traditional beliefs expressed were that breast-feeding makes a child well behaved and that mother's milk transmits the mother's values and attitudes (Wright, Bauer, Clark, Morgan, & Begishe, 1993).

Childhood

The traditional attitude toward children equated them with wealth. Not only were children important sources of labor in the land-based economy, but also they were looked to as companions and sources of help in old age. Although children now spend their childhood years in school, they nevertheless are viewed as blessings and as evidence of the sacred process of increase (Farella, 1984). Despite the trend toward nuclear family households, children often benefit from the influence of grandparents, who may care for children for extended periods during childhood while parents complete their education or work in an urban area. Approaches to discipline vary, but the ideal continues to be talking to children, calmly explaining the difference between right and wrong.

A major health concern among Navajo children is the increasing tendency toward obesity. This secular trend is a culmination of changes in diet and activity level, with traditional foods and high levels of physical activity replaced with foods high in fat and calories and a sedentary lifestyle. The trend toward obesity constitutes a risk factor for future health problems. Findings from a nutritional survey carried out in 1989 (Sugarman, White, & Gilbert, 1990) contrasts markedly with earlier studies. Earlier studies in 1955 and 1968 found some cases of malnutrition among Navajo children but few cases of

obesity. In the 1989 study, among Navajo children between 5 and 17 years of age, twice as many children exceeded the 95th percentile of weight-for-age as among other U.S. children. Among all age groups, mean weight had increased 28.8% among boys and 18.7% among girls.

Disabled Navajo children are likely to be accepted and integrated into the family without great disruption of the family's lifestyle and alteration of parents' roles (Joe, 1982). Respecting their individuality, parents saw children's limitations as an indication of personal distinctiveness rather than as a deviation from normal. Regardless of chronological age, children with disabilities were "perceived as 'becoming persons' in the process of defining their own identities" (Connors & Donnellan, 1998, p. 175).

A study of Navajo middle school students conducted in 2000 found that the percentage of students who had ever used cigarettes, alcohol, and marijuana sharply increased between the sixth and eighth grade years. Among sixth graders, 43.9% had tried cigarette smoking compared with 73.8% of eighth graders. Of Navajo area sixth graders, 34.2% had had a drink of alcohol compared with 63.7% of eighth graders. Of sixth graders, 28.4% had ever used marijuana compared with 58.1% of eighth graders. (Navajo Area Indian Health Service, 2000, pp. 13, 18, 20).

Adolescence

For Navajo girls menarche is a notable event, celebrated by family, kin, clan relatives, and friends with a Kinaaldá, the Navajo puberty ceremony. Acknowledging her ability to bear children and ushering in her status as a woman, a girl's Kinaaldá is a 4-day event. Major events are running to the east at dawn; grinding corn for the alkaan, or corn-cake, to be distributed to guests; and participating in the all-night ceremony conducted by a medicine man. In the words of Mary Shepardson, "One cannot overestimate the importance of this rite in creating a positive self-image in a young girl" (1995, p. 164). The Kinaaldá reenacts the first Kinaaldá held for Changing Woman, the beloved Navajo deity and model for Navajo womanhood (Frisbie, 1993). The ceremony continues to thrive today, sometimes being arranged by mothers who themselves did not have one when they were students away from home at boarding school (Frisbie, 1993; McCloskey, 1998a). Compared to the Kinaaldá held for Navajo girls, the performance of a ceremony for boys at puberty is rare.

Harry Walters described a ceremony held for boys when their voices change, consisting of a sweat bath that may be followed by a Blessingway ceremony. Some activities, such as running to the east, are similar in the boys' and girls' ceremonies (Schwarz, 1997).

Overweight and obesity continue to be prevalent among Navajo adolescents, and risk factors for coronary heart disease and diabetes mellitus appear in this age group. In the Navajo Health and Nutrition Survey, among 160 adolescents (between 12 and 19 years) about 35% of boys and 40% of girls were overweight as defined by having a body mass index (BMI) exceeding the 85th percentile for their sex and age. They also found that these adolescents had low median HDL cholesterol levels, high median triglyceride levels, and a high prevalence of impaired glucose tolerance (Freedman, Serdula, Percy, Ballew, & White, 1997). Eight percent of the adolescents had either impaired glucose tolerance or diabetes. In another study of 234 Navajo high school students, 24% were overweight as defined by having a BMI exceeding the 95th percentile for their sex and age. However, only one (0.4%) had diabetes mellitus, and eight (3%) had impaired glucose tolerance or impaired fasting glucose (Kim, McHugh, Kwok, & Smith, 1999).

In a study of Navajo alcohol abuse, most men and women reported that they first started drinking during their adolescent years. However, only Navajo men who met the American Psychological Association criteria for alcohol dependence began drinking regularly when they were adolescents, while women and alcohol non-dependent men did not begin drinking regularly until they were in their 20s (Kunitz & Levy, 2000).

Adulthood

The transition from a physically demanding lifestyle while caring for livestock and crops and a diet based on corn to a sedentary lifestyle and high fat diet has affected the health of the Navajo people. Findings from the 1991–92 Navajo Health and Nutrition Survey of a representative sample found a high prevalence of coronary heart disease risk factors, particularly overweight, hypertension, and diabetes mellitus (Mendlein et al., 1997). Among persons aged 20 years and older, there was an age-standardized prevalence of diabetes mellitus of 22.9% (Will et al., 1997). A high proportion of Navajo women who experience gestational diabetes mellitus later develop impaired glucose tolerance or non-insulin dependent

diabetes (Steinhart, Sugarman, & Connell, 1997). The age-standardized prevalence of hypertension was 19% (Percy et al., 1997). Among Navajo adults, major illnesses leading to Indian Health Service hospitalizations are respiratory infections, digestive system disease (gallbladder), and genitourinary system diseases (NAIHS, 2002). Dietary analysis suggests that "much of the increase in chronic diseases among the Navajo is due to nutritional factors" (Byers & Hubbard, 1997, p. 2075S). Common foods include fry bread and tortillas, home-fried potatoes, mutton, bacon and sausage, soft drinks, and coffee and tea, which provided 41% of the energy and 15 to 46% of the macronutrients in the diet. Dairy products, fruits, and vegetables were each consumed less than once per day per person (Ballew et al., 1997).

A random sample of the adult Navajo population indicates that alcohol dependence constitutes a major health and social problem. Among men, 70.4% have a lifetime history of alcohol dependence, and 29.6% of women have such a history. The consequences of alcohol misuse include domestic violence and other family problems, health problems, alcohol-related deaths, and legal and economic problems (Kunitz & Levy, 2000).

Traditional Navajo women, like newly immigrated Latina, experienced fewer negative associations and physical complaints about natural menopause (Mingo, Herman, & Jasperse, 2000). Overshadowing menopause as a life event, the achievement of the status of grandmother, a venerated role in matrilineal society, assumes greater importance.

The Aged

In Navajo society elders enjoy high status, respected for their knowledge of ceremonies, traditional foods and clothing, livestock, clan relationships, and many customs such as the shoe game, the first laugh celebration, and burying the baby's umbilical cord. Navajo elders actively participate in ceremonies, in family activities and decisions, and often continue to make an economic contribution with their traditional activities such as weaving or by working in programs such as Foster Grandparents.

Chronic diseases increasingly affect Navajo elders. The rapid rise of the incidence of diabetes and its serious complications constitute a serious health problem for Navajo elders. Among Navajos 65 years of age and older, 41.3% had diabetes (Will et al., 1997). Among those 60 years or older, 44% of men and 28% of women had

hypertension (Percy et al., 1997). Both diabetes and hypertension constitute risk factors for coronary heart disease (Mendlein et al., 1997).

A retrospective study of 28 Navajo uranium miners with a mean age of 66 years found that these men were adversely affected by chronic illness. Despite historically low rates of lung cancer for Navajos, former uranium miners have abnormally high rates of lung cancer. Other health problems include eye disease, hearing loss, and psychological trauma (Servilla, 1997). "A lower health-related quality of life was related to more years worked as an underground miner" (Servilla, 1997, p. 193).

For many Navajo elders, the expectation that children will care for them in old age may not be fulfilled. Kunitz and Levy (1991) documented the transition from family to institutional support on the Navajo Reservation. Although many elders live with family members, social service programs contribute by serving meals at the local Senior Citizens Centers and by visits from Indian Health Service Community Health Representatives. Because the Navajo Nation has limited on-reservation nursing care facilities, the majority of elders in need of nursing home care must go off-reservation. Elders at an on-reservation nursing home appeared content with culturally sensitive care in contrast with elder Navajos in off-reservation homes who reported loneliness, depression, and isolation (Mercer, 1996).

Dying and Death

According to the Navajo Area Indian Health Service (2002), the five leading causes of death in 1998 were accidents, heart disease, cancer, influenza/pneumonia, and diabetes. Of these, only accidents disproportionately affect young people. Death rates for accidents involving motor vehicle, diabetes, and pneumonia are many times higher than rates for the United States as a whole (Navajo Area Indian Health Service, 2002).

The traditional fear of death dictated that a person close to death be moved to a shelter apart from the family hogan (Mitchell, 2001). If a person died while in the family hogan, family members abandoned the home and moved elsewhere. After a death, family members did not eat or wash for four days. If these patterns of showing respect for the dead are not adhered to, the dead can become angry and cause ghost sickness (Mitchell, 2001).

In accordance with traditional burial practices, family members buried the dead as soon as possible and

without any public ceremony. Those who prepared and buried the deceased participated in a purification ritual and a four-day mourning period before resuming normal activities. With many Navajos more recently converting to Christianity, funerals and burials in local cemeteries have become commonplace (Levy, 1978; Shepardson, 1978).

Nepal

Gregory G. Maskarinec

LOCATION AND LINGUISTIC AFFILIATION

The Himalayan constitutional monarchy of Nepal is a small landlocked country located in South Asia between India and the Tibetan Autonomous Region of China. Nepal is roughly shaped as a rectangle that extends approximately 500 miles (800 km) from southeast to northwest with an average width ranging from 90 to 150 miles (140 to 240 km) from north to south. Nepal is home to seven of the world's highest mountains, including the highest, Everest, known in Nepal as Sagarmatha. In 2000 Nepal's population was estimated to be 24 million. Nepal's significant cultural and linguistic diversity is indicated by the 120 distinct languages that have been recorded in the country, of which at least 60 are still

used as the primary language of a local community. Most inhabitants understand the national language, Nepali, an Indo-Aryan language derived from Prakrit resembling Bengali and Gujarati but with an increasing number of loan words via Hindi of Persian or Arabic origin. Other Indo-Aryan languages of Nepal include Maithili, Rajbansi, and Bhojpuri. Major Tibeto-Burman languages in Nepal include Newari, Tamang, Gurung, Magar, Sherpa, Thakali, Tharu, and various Kiranti languages.

OVERVIEW OF THE CULTURE

The modern state of Nepal emerged in the late 18th century as the king of one local hill principality, Gorkha,

began a successful campaign of conquest, conquering the sophisticated Newari city-states of the Kathmandu Valley in 1769. Military interventions by the British established the present borders of the kingdom but preserved Nepal's nominal independence, an autonomy that was strengthened by Nepal's strong support of the British during the Indian sepoy mutiny of 1857. Democratic government was introduced in 1991 after years of absolute monarchy, but the contemporary political system is extremely factionalized, with frequent changes of government. Since 1996, an increasingly violent Maoist insurgency has spread throughout the country.

Never having been colonized and rigorously outlawing all missionary proselytizing, whether by Christians or Muslims, Nepal has preserved vibrantly its diverse cultural traditions, which includes many varieties of shamans, oracles, and spirit mediums. In keeping with Nepal's self-proclaimed identity as "the world's only Hindu state," more than nine tenths of the population is classified as Hindu, a designation that officially includes Buddhists as well as the many local variations of ritual practice, so long as they observe in some way the Hindu caste system. Outside of this system, there are also very small groups of Muslims and an even smaller scattering of Christians, mostly repatriates from elsewhere in South Asia.

As a result of its geographical inaccessibility and a repressive political system sustained by inequitable land distribution and exploitive methods of agricultural taxation, Nepal is one of the least developed countries of the world, with an extremely low standard of living. Nepal's per capita annual income remains less than U.S.\$200, with more than half of the population living below the absolute poverty level. Average life expectancy is around 55 for both males and females. No more than half of the population is literate. (All statistics regarding Nepal are only reasonable guesses; no accurate demographic data exists.)

The climate of Nepal ranges from subtropical monsoon conditions in the Tarai (the Gangetic plains in the south of the country) to alpine conditions in the Great Himalayas. Throughout the country, subsistence agriculture and animal husbandry are the most common economic activities, employing most of the work force. Productivity is low, leading to chronic food shortages and periodic famines in parts of the country. Rice is the leading staple, but is a luxury in more remote parts of the country, where corn (maize), wheat, or millet are

the staple crops. Most houses are small, two storied buildings made of mud-bricks, without electricity or running water. Wood and dried dung are the standard fuels for cooking. The Nepalese economy, such as it is, is sustained by foreign aid and tourism; trade is dominated by India.

Despite a relatively high death rate along with migration to India, Nepal's population continues to grow rapidly, with 40% of the population younger than 15 years of age. Except for the urban concentration of the capital, Kathmandu, and a scattering of provincial towns, nearly all the population remains in small rural villages. Complicating its economy as well as its foreign policy, Nepal provides refuge to nearly 100,000 recent refugees from Bhutan, as well as to more settled communities of Tibetan refugees, who began arriving after the Dalai Lama fled Tibet in 1959.

Family structure in Nepal remains very traditional; most marriages are arranged and are caste-endogamous but frequently village-exogamous. Girls tend to be married by age 16, boys slightly older. In some groups, however, such as the Newars of the Kathmandu Valley, both men and women tend to be married at later ages. Newari girls are ritually married at a young age to a *bel* fruit (*Aegle marmelos*), a ceremony that de-emphasizes both the urgency and the solemnity of later marriages. Most Brahman girls, in contrast, are married by age 10, since Brahmans obtain religious merit by giving away very young daughters—according to tradition, the preferred age for a Brahman girl to marry is six, although modern families no longer follow this custom. In groups with Sanskritic influenced cultures, girls are expected to be virgins at marriage, but this stricture is ignored in most Tibeto-Burman communities. The status of Hindu wives may be inferred from a rite within the marriage ceremony during which the bride must wash her husband's feet (considered the most impure part of the human body) and sip the water. In traditional families, a wife always greets her husband by touching his feet.

The estimated average number of births per woman for the country is six. Most families are patrilocal and patrilineal. Depending on the ethnic group, both polygyny and polyandry are found in Nepal; variations on dowry or bride-price are also found in different communities. Divorce remains uncommon, as does widow remarriage, although some groups, including Kiranti populations and low caste groups, practice marriage by levirate.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

Given the widespread poverty, poor nutrition, overpopulation, unfair land tenure systems, exploitive wage labor, political corruption, poor sanitation, and lack of clean drinking water, the overall health situation in Nepal is extremely poor. Overall infant mortality is at least 100 per 1,000. There are widely varying estimates of this and all other health-related statistics, all unreliable and all concealing enormous disparities between the relatively rich and the desperately poor. Personal observation over the past 25 years suggests that in some of the poorest villages of the western hills, the mortality of children under five is as high as 400 per 1,000.

While it is officially reported that there are 150 hospitals in Nepal (two of them ayurvedic, one homeopathic), only a few of these have sufficient staff, equipment, or stocks of medicines to provide a reasonable standard of care. Outside urban areas, the 1,000 health posts established throughout the country are poorly managed, corrupt, and sensibly avoided by much of the population until all other options have failed.

The prevalence of tuberculosis in Nepal is estimated at 15 per 1,000, with some 50,000 new cases a year and 20,000 annual deaths. Nepal has the second highest incidence of iodine deficiency disorders in the world with cretinism rates as high as 10% in some remote areas, where goiter rates can reach 80%. After substantial declines in the 1960s, malaria is resurgent and increasingly resistant to treatment. There are some 30,000 registered cases of leprosy in the country. There are periodic outbreaks of typhoid. The most recent cholera outbreak was in 1995. Plague may have occurred as recently as August 1994, when there was an outbreak in India; the most recent well documented outbreak in Nepal was in 1967/1968. Other severe diseases that are common include encephalitis, meningitis, hepatitis, and gastrointestinal disorders. It has been estimated that all of the adult population suffers from intestinal parasites. Partial blindness as a result of vitamin A deficiency affects at least half a million people. Half of females of childbearing age are anemic.

MEDICAL PRACTITIONERS

His Majesty's Government of Nepal (HMG) officially acknowledges four systems of medicine: allopathy, Ayurveda, homeopathy, and Unani as being practiced in Nepal, although the latter two are not widespread. Ayurvedic practices tend to be localized in Kathmandu or the areas adjacent to India. Locally, Ayurveda is considered most efficacious in the treatment of hepatitis. HMG reports that there is one biomedically trained physician for approximately 19,000 persons and one nurse per 5,000 persons, but these numbers, bad as they are, are severely misleading unless it is concurrently noted that nearly all physicians and nurses are to be found in urban areas, leaving the rest of the country either to poorly trained health workers or to traditional practitioners. Nepal has one 40-bed acute care hospital for the mentally ill, and 13 trained psychiatrists, all in Kathmandu. Even in urban areas, health care delivery is systematically biased in favor of the wealthy and the middle class, while the poor are denied services both because of the cost and the structure of the traditional society. Although Nepal is a signatory to the 1978 Alma Ata Declaration and despite the rhetorical commitment of successive governments toward committing resources for better health, improved health care remains a low priority in Nepal, as it would necessarily require a more equitable social system.

Outside the Kathmandu Valley, drug therapy is almost inevitably mismanaged. Nevertheless, injections and capsules have acquired a nearly magical status, so that villagers who do consult a "modern" medical practitioner, even if it is only the lowest paid health post peon who may lack even a high school education let alone any medical training, expect their treatment to include these. Unrealistic expectations of biomedical efficacy coupled with poor patient education contributes to many villagers' disillusionment with the government's promotion of Western medicine. Self medication is common, as "medical halls" (drug stores) that lack trained pharmacists supply pharmaceuticals on demand. In rural areas, these medications are often expired stock from India.

Traditional practitioners, a diverse group including oracles, shamans, spirit mediums, Buddhist lamas, Tantrics, astrologers, wandering ascetics, and herbal healers, all remain more familiar, less frightening and less intrusive than is Western-style medicine. Traditional practitioners are less condescending and far easier to

understand than are allopathic physicians, and their success rates appear no worse than those of their competitors. The variety of “traditional healers” is considerable. Defining the category of “shaman” fairly strictly as ritual intercessors whose divination, exorcism, and healing practices incorporate command over well-defined groups of spirits, who use elaborate paraphernalia, and who often enter trance states to conduct ritual journeys, one finds Gurung *poju* and *hlewri*, Tamang *lambu* and *bonpo*, Yolmo *bonpo*, Tharu *gurau*, Rai *bijuju*, *padem*, and *lambu*, Limbu *yeb*, Sunuwar *puimbo* and *ngiami*, Chepang *pande*, Sherpa *lhapa* and *mindung*, Magar *ramma*, and the low caste *jhangri* throughout the country. While each of these terms can be translated as “shaman,” each has distinct characteristics, including different ritual practices, different costumes and paraphernalia, and different oral texts. Still, some generalizations are possible. Most shamans are male, although highly motivated women occasionally overcome the biases of patrilineality and gender discrimination to become shamans. Many future shamans undergo possession crises as adolescents that prompt their interest in the profession. For most groups, preparation of new shamans concentrates on their learning oral texts. Most important is to memorize the secret mantras that control the spirits that shamans must manipulate in their rituals, since, unlike other circumstances that involve involuntary or spontaneous spirit possession, shamans must control the spirits that they summon to their ceremonies, rather than be controlled by them. For the shamans of western Nepal, the variety of spirits that they use include local gods and goddesses, spirits of animals and inanimate forces, souls of human suicides (particularly vengeance spirits—men or women who were unable to find justice in their lifetime and committed suicide to become such a spirit), souls of other dead humans, especially those who died untimely deaths, and the souls of other shamans. Some of these groups are protective and therapeutic, others are malicious, oppressive, and threatening. Nearly all demand blood sacrifices, a key element of every major shamanic ritual. Communicating with these spirits allows shamans to diagnose problems, treat afflictions, and restore order and balance to the lives of their clients and their communities.

Distinct from shamans are the oracular spirit mediums found throughout the greater Karnali drainage area of western Nepal. Each oracle is associated with one particular spirit located at one particular shrine to that spirit. The oracle is regarded as the passive mouthpiece of

the spirit, in contrast to the control over a wide variety of spirits expected of shamans. Only upon the death of one oracle does a new one emerge to take the position, as distinct from shamans, who study with a teacher to learn the profession. Oracles most often treat poorly differentiated misfortune, often for entire families. Such cases may also be taken to less well-established spirit mediums, who sometimes emerge without a well defined social position, often women who become spontaneously possessed and who temporarily exhibit healing powers, whose popularity rapidly waxes and then equally rapidly wanes.

Many villagers use herbal remedies for a wide variety of somatic complaints, and many may also informally consult other villagers about such treatments, although there are not well defined “herbalists” as such. Many herbal treatments are used in conjunction with mantras, knowledge of which is also widely diffused. Nepal has a significant source of medicinal herbs from its higher altitudes, which are exported to India for use in ayurvedic preparations.

Astrologers and various fortune tellers are also frequently consulted for a wide range of problems, including medical conditions. They offer both diagnosis and advice, but do not perform healing roles.

In the Tibetan refugee community, and to a small extent among the Tibeto-Burman groups within Nepal, classic Tibetan medicine is practiced, which is based to a considerable extent on the use of herbs and natural substances within a theory of Buddhist religious teachings, and is considered most effective for chronic conditions.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

Nepalis tend to be extremely fatalistic, observing that in this Age of Darkness (Kali Yuga), inevitable deterioration of the world, at all levels, personal, social, and cosmic, is all that can be expected. All concepts of life, death, and suffering are permeated by the theory of Karma, with its cycles of rebirth that connect morality with retribution and reward. One’s caste and gender, for example, are generally recognized as reaping what has been sown in one’s previous lives. Karma, then, is ultimately responsible for all illness and affliction. Nevertheless, Nepalis distinguish proximate causes to their illnesses, and most accept

a classification of their problems into either *rog* (illness) or *dokh* (spiritual affliction/misfortune). Illness has many natural causes, including imbalances of hot and cold foods, violation of the laws of purity and pollution, or unpredictable accidents loosely connected to one's Karma.

One of the most elaborate local etiologies is found among the shamans of western Nepal. Shamans diagnose their patients' afflictions as commonly involving some combination of seven possible causes: (1) curses, and spells, particularly those of witches and other shamans; (2) misfortunate astrological configurations, foremost of which are dangerous planetary configurations called star obstructions; (3) the intrusion of alien substances into the body, whether by acts of sorcery, by violation of sacred space, or by violating rules of ritual purity, such as coming in contact with a woman's menstrual blood; (4) weakened life forces, including soul loss, lost wits, dullness, and several recognized forms of madness; (5) social disorder, especially disputes within families and communities; (6) fevers of autonomous origin; (7) the activities of spirits, ghosts, or demons, provoked by acts of neglect, pollution, or disrespect. When spirits are involved, the most common types are patrilineal family gods, recently deceased relatives, or the numerous minor local spirits who inhabit particular hilltops, trees, waterfalls, springs, and rivers. At other times, major local gods, minor deities of non-human origin, quasi-spirits thought to have a one-dimensional degree of corporeality, or even shaman tutelary spirits may be diagnosed as causing affliction (Maskarinec, 1995).

Much of the treatment for these conditions is through logotherapy, using ritual language, with each intervention involving a distinctive ritual. Most interventions can be described as either propitiatory or symbolic. Propitiatory rituals include sacrifices and offerings, while symbolic ones include rituals of binding and burying, sucking or blowing, raising the patient toward the heavens, and diverse acts of divination.

SEXUALITY AND REPRODUCTION

Large families are seen as insurance in old age, and as a guarantee of sufficient agricultural labor for the future. Many families wish to have as many children as possible, in hopes that some, at least, will survive to adulthood. Sons are expected to maintain the family's lineage,

inherit property, and provide support to parents when they are old. For Hindu families, a son is necessary to complete the proper funeral rites for his parents, without which they are condemned to become restless spirits. "Ideal" family size (first reported by Worth and Narayan, 1969) remains in the range of four or five children, which is slightly higher than the number of children who survive to adulthood in most rural families. Daughters, who leave the family when they marry, tend to be seen as liabilities. However, there is no evidence that female infants are less likely to survive than are males, since Nepalis regard all children as divine gifts, but girls are certainly less likely to be sent to school, and are given more household chores, at an earlier age.

Knowledge of family planning is widespread, having been promoted by the government for decades with extensive media campaigns. Family planning itself is slowly spreading, primarily among the educated urban population but with some impact at the village level. The 1996 Nepal Family Health Survey (Pradhan, Ajit et al., 1997) found that sterilization accounted for more than half of current contraceptive use. Abortion is considered sinful; a woman who has an abortion will be reborn, it is widely believed, as a dog. There have been recent efforts to decriminalize abortion, but as of March 2002 these have so far been unsuccessful. Nepal's abortion law only permits abortions to be performed on the ground of "benevolence," but does not indicate which abortions are covered by this term, and few, if any, pregnancies have been terminated on this ground. A three-year study conducted in the early 1980s revealed that two thirds of all female inmates in Nepal were imprisoned on charges related to abortion and infanticide. (Population Policy Data Bank; Department for Economic and Social Affairs, United Nations Secretariat); it is estimated that illegal abortions cause the death of hundreds of women every year. Miscarriages are regarded as shameful; women try to conceal them.

Inability to have children, to have miscarriages or stillbirths, or for children to die in infancy are all blamed on a wife's Karma. All are extremely damaging to her status, and may lead to the husband marrying a second wife. Appeal to spirits held responsible or who may intervene against witchcraft are the most common attempted remedies. One oracle, that of Bijuli Masta in Jajarkot District, is considered particularly effective, with many families that have long been childless returning to dedicate their firstborn sons in the temple.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

There are no traditional prenatal ceremonies, nor do most pregnant women receive medical care. Pregnancy is socially recognized by the fifth or sixth month, when it is held that the life-breath has entered the embryo. From this point, the woman, regarded as being two individuals, may not participate in religious ceremonies.

Traditional midwives assist in many deliveries in Nepal, but it remains common for a woman to deliver alone or with only a close relative or female neighbor assisting. There have been government efforts dating back to the 1920s to provide midwife training, though resources are limited. Most deliveries take place in the husband's home. The umbilical cord is usually cut on the same day that birth takes place, but it may be tied and the cutting postponed to avoid astrologically determined complications, or to allow a scheduled ritual or wedding within the immediate family to take place, as these must otherwise be postponed for 11 days. The placenta of a male child is buried under the kitchen floor near the hearth, that of a female child outside. A section of the umbilical cord may be dried to be used to treat colic. The newborn is washed and rubbed with mustard oil, regarded as essential to "warm" the infant. Women remain in seclusion after giving birth, with both mother and child treated as untouchable until the eleventh day. Female relatives do massage and oil both baby and mother, but they must bathe to purify themselves afterward. Breast-feeding begins as soon as milk is available. No other foods are ordinarily given to infants.

Medical risks associated with birth include, predictably, low birth weights, premature deliveries, neonatal tetanus, sepsis, and other infections. Multiple births and birth defects are regarded as inauspicious, and may lead to the infants being neglected or, in rare cases, abandoned.

Infancy

As soon as possible after a birth, an astrologer is consulted, to calculate the child's future and to choose an auspicious name, which is based on the time of birth. The most serious of astrological disturbances is that of *mul*, which occurs when certain planets of both the child and

either of its parents occupy the *mul nakshatra*, one of 27 subdivisions of the lunar elliptic. *Mul* is a crisis that lasts for a finite, calculable length, sometimes a lifetime, sometimes for just a few moments. The parent who shares the configuration is fated to die quickly if he/she sees the child within *mul*'s duration, so that a *mul* birth may have to be placed outside the family to be raised as an orphan. Only after an astrologer has been consulted does the baby's father see the child.

On the sixth night after birth Bhabi, Goddess of Fortune, comes to write a child's fate on its forehead. Parents traditionally leave a light burning all night in the room with the baby so that she makes no mistakes, sometimes supplying a pen and inkpot.

Among many groups a first rice feeding ceremony is held six months after birth, though this is not to be confused with weaning. Breast-feeding often continues for two or three years. This is regarded as a natural contraceptive measure. Male children tend to be breast-fed longer than are female children, sometimes for five or six years if no sibling is born. Special consideration is given to the mother's diet when she is breast-feeding, with foods regarded as having "cooling" properties most often avoided.

Childhood

Nepal's last major smallpox epidemic was in 1963–64. Official eradication of smallpox by 1974 is concrete evidence of what a well-focused public health campaign might do for the six vaccine preventable diseases of childhood—diphtheria, whooping cough, tetanus, poliomyelitis, tuberculosis, and measles—all of which contribute significantly to childhood morbidity and mortality.

For high caste, "twice-born," males, the most important childhood ceremony is to receive the sacred thread. Brahman boys usually receive this at age seven or nine, while Chetris may wait until their teens. Once invested with a thread, a boy has many new ritual responsibilities and privileges, such as now being allowed to eat in the company of adults. There is no parallel ceremony for girls.

Children are, in general, treated with considerable affection and are rarely disciplined. They are gradually integrated into the family's daily chores. Older children assume responsibility for caring for their younger siblings.

Adolescence

As most Nepalis are married by their mid-teens, there is no real “adolescence” in Nepal, just a quick transition from childhood to adulthood.

Adulthood

First menstruation marks the beginning of adulthood for women. No special ceremonies are performed, but in some communities the woman is secluded for 15 days, during which time she may not be seen by males. Menstruation is considered ritually unclean, and there are many rules that a menstruating woman must follow. She is treated as an untouchable, even for other women, and should maintain physical isolation for the first four days of her period; she must not cook nor fetch water; she may not perform any religious rite.

The Aged

In all cultures of Nepal, to reach an old age is a guarantee of respect. A special ceremony is held to honor a person who reaches the age of 84. Elderly persons continue to contribute to household labor and childcare, to the extent of their abilities, and take major roles in family decision-making. Care for the elderly is regarded as a responsibility of the extended family.

The major medical problems of the elderly in Nepal are not significantly different than those found throughout the world.

Dying and Death

All Nepalis prefer to die at home, though some indigent elderly are cared for in hospices maintained by charitable organizations, primarily in the Kathmandu Valley.

A coin is placed under the tongue of a dying person; if not spat out, death is considered imminent. A drop of water purified by having had gold immersed in it is poured through the dying person’s lips. After death, the body must be handled properly, touched only by persons of equal or higher caste, or the deceased may later trouble his family. Immediately following the last breath, a body is wrapped in a white or saffron shroud and tied to two bamboo poles to be carried to the cremation or burial site. Cremation on a riverbank is the preferred method for funerals, although

both earth and “sky” burials are practiced in some communities, the latter found in some Tibeto-Burman communities who expose the body on an elevated platform to be consumed by vultures, graphically “paying back” to nature the debts incurred in a lifetime of dependence on the world.

For Hindu funerals, the eldest male circumambulates the pyre and is responsible for lighting it. Mourners remain in attendance until the skull splits, releasing the soul. Ashes are scattered in the river. If a family can afford it, a piece of bone is preserved, taken to Benaras in India, and cast into the sacred Ganges River there.

Those who suffered from leprosy may not be cremated, as the disease is traditionally regarded as a curse that denies human rebirth. Smallpox victims were also buried, a practice explained by their having been possessed by the smallpox goddess, Sitala. Children under the age of five are ordinarily buried, with little ceremony, as are those too poor to afford cremation. Muslims and Christians in Nepal also bury their dead, in graveyards.

Mourning by the immediate family is marked by fasting, including abstinence from salt, oil, and meat for 13 days. More distant relatives observe one day of fasting. Males have their head shaved as a sign of mourning, while women dress in white, without jewelry, and leave their hair uncombed. The death of progenitors is commemorated by annual *sraddha* rituals, in which they are symbolically fed balls of rice offered by all male descendants.

In Nepal, the Hindu custom of “sati,” the immolation of widows with the husband’s body, was never common except among the royal families. It was firmly abolished by Prime Minister Chandra Shumsher Rana on June 28, 1920 AD, at which time it became illegal and punishable as culpable homicide. The “sati” gate of Pashupati temple, the holiest site in Nepal, through which widows had been taken to their husband’s pyres, was bricked shut at that time.

CHANGING HEALTH PATTERNS

Screening for HIV was begun in Nepal in 1986; the first case of HIV/AIDS was identified in June 1988. By September 1998 a total of 1,132 HIV positive cases and 108 deaths from AIDS had been recorded. Given the increasing number of young Nepalis who seek work

elsewhere, as well as the widespread trafficking of Nepali girls into the sex trade of India, AIDS is expected to have major future consequences on the economics of health in Nepal.

It is too soon to predict whether the sudden flourishing of new medical colleges throughout Nepal, beginning in 1994, will have any major impact on the country, since standards of education are problematic and most students are expected to come from India.

It has been recently reported that Nepal hopes to become a center for inexpensive kidney transplants (Rising Nepal Daily Newspaper, 24 December 2001), projecting costs at less than half of those in India.

In the last 20 years Nepal has seen more rapid social change than at any time in its history, with large segments of the population increasingly marginalized economically and politically. Consequently, the overall prognosis for the state of health in the country is poor.

The Northwest Coast

Peter H. Stephenson and Steven Acheson

ALTERNATIVE NAMES

The Northwest Coast is the standard name for the culture area. The main constituent cultures are from north to south, Eyak, Tlingit, Haida, Tsimshian, Haisla, Haihais, Heiltsuk (formerly Bella Bella), Nuxalk (formerly Bella Coola), Oowekeeno, Kwakwaka'wakw (formerly Kwakiutl), Coast Salish, Nuuchahnulth (formerly Nootka), Makah, Quileute/Chemakum, Chinookans, Takelma, Alsean, Siuslaw, Coos, and Athapaskans.

LOCATION AND LINGUISTIC AFFILIATION

First coined by European explorers to the region in the late 18th century, "Northwest Coast" is now firmly entrenched in the anthropological literature to describe a culture area extending some 2600 km from Prince William Sound in the Gulf of Alaska, along the coast of British

Columbia, to the California-Oregon border. At the time of contact with Europeans, an estimated 200,000 people lived in the region (Boyd, 1990) making it one of the most densely settled in the Americas north of Mexico (Suttles, 1990). Northwest Coast peoples do not constitute a single biological population or even a series of discrete populations, but are grouped together on the basis of shared cultural practices and geography.

This chapter focuses on the peoples north of California including southeast Alaska, Washington, and Oregon in the United States, and British Columbia in Canada. Most of the peoples of northern California were destroyed in violent encounters with gold miners and by infectious diseases by the late 1800s. Although the people of this region have long shared similar cultural patterns which stem from environmental factors, trade, and a system of raiding which involved captive workers, they belong to a dozen different language groupings. Typical of extremely mountainous terrain, cut by major rivers, the

linguistic differences in the region are profound, and occur at the level of language families. Therefore the classification, conceptualization, and treatment of illness vary quite distinctively throughout the region. The Northwest Coast exhibited the greatest linguistic diversity within aboriginal North America, next to California. Over 40 languages, representing 12 language families, were once spoken on the Northwest Coast. Distribution of these language families, and particularly some discontinuities, indicate a complex settlement history within the region. Athapaskan speakers include the *Eyak*, the northern most Northwest Coast group, and two branches on the lower Columbia and southwest Oregon. The other 11 linguistic families ranging from north to south include: *Tlingit*, *Haida*, *Tsimshian*, *Wakashan*, which includes four major branches—*Haisla*, *Heiltsuk*, *Kwakwaka'wakw* and *Nuu-chah-nulth*; *Salishan*, represented by the *Coast Salish*, *Nuxalk*, *Tsamosan*, and *Tillamook*; *Chimakuan*; and five possibly related families belonging to the Penutian Phylum—*Chinookan*, *Takelman*, *Alsean*, *Siuslaw*, and *Coos* (after Thompson & Kinkade, 1990).

OVERVIEW OF THE CULTURE

Culture and Environment

There are at least 40 different culture groups in the Northwest Coast; we describe here the common and the variable features. The Northwest Coast is often described as a “classic” culture area in North America due to its distinctive and rich artistic traditions of monumental wood carving (“totem poles”) and masked ritual performances of dance and song (See Drucker, 1965; Suttles, 1990). The importance of early anthropological fieldworkers and ethnographic writers (including Boas, Benedict, and Sapir) has also contributed to the visibility of the region and its peoples (Hawthorn, 1965). The Northwest Coast also stands apart as a distinct cultural region based on a number of widely recognized, shared cultural traits. Northwest Coast peoples were truly maritime, possessing a sophisticated fishing and sea mammal hunting technology, with river-run Pacific salmon of particular importance to many. Coupled with this was an efficient preservation technology for the long-term storage of foodstuffs. These technologies sustained dense population aggregates where people resided in semipermanent or permanent villages, with a system of rigid

social ranking and stratification, and the creation of an elaborate art and architectural tradition. Social classes were recognized based on a combination of birth and wealth with chiefs and immediate kin forming the nobility, their followers or commoners, and slaves, who were acquired as property either by capture or purchase. Attention to social standing varied greatly, however, with class distinctions being more pronounced and rigidly maintained among the more northerly coastal groups. The importance of kinship shows a similar north–south trend with kinship ties being most rigidly defined among northern groups. As well, the kinship organization of people in the north is strongly matrilineal, and subsequently shifting to patrilineal descent as one moves southward.

The coastline of the Northwest Coast region is characterized by a chain of extremely rugged mountains which rise in places to over a thousand meters directly out of the sea. One need only precede a few kilometers inland to encounter even more precipitous mountains, glaciers, and dormant volcanoes rising 3,000 m and more. These mountain ranges are partially submerged in places, creating the many large island archipelagos that skirt the coast of Alaska and British Columbia. The mountains capture warm pacific air masses transiting from the Hawaiian Islands, and thus receive a heavy annual rainfall along the coast, with major snowfalls in the mountains during the winter. The region is also warmed by the Japanese current and so coastal climates are temperate and very moist, making large parts of the region a true rainforest—the only major one in a temperate region. Summers throughout the region tend to be very dry however, so the Pacific northwest is also the only major rainforest in the world comprised of evergreen trees—pines, cypress, hemlock, fir, and spruce. The deciduous trees are mainly found along rivers and streams and include wide variety of willows. Many fungi are found throughout the region (Suttles, 1990b). A wide variety of plants were collected by all of the peoples of the region and used as medicines and teas.

The major rivers of the region (the Stikine, Nass, Skeena, Bella Coola, Fraser, Columbia, and Klamath) and their systems of tributaries, as well as even very minor streams, are home to many varieties of fish: especially migrant salmon species, eulachon, lampreys, and cutthroat trout. There are still massive sturgeons in some of the larger rivers, although their numbers are seriously depleted, and their size reduced. A wide variety of fish are

also available just offshore (especially many types of cod, halibut, rockfish, herring, and hake) and many varieties of shellfish can be collected (clams, oysters, crabs, octopus). Sea mammals—especially whales and seals—were traditionally hunted; and still are in some locations. Although a large proportion of the coastal traditional diet came from the sea, land animals and plants were and are also important foods; these include most large mammals, birds, and bird eggs. Plant foods included a wide variety of berries, a great many root vegetables (over 25), and seaweed. Seaweed covered in recently deposited herring roe is a widespread nutritious delicacy throughout the region (Hopkinson et al., 1995). Because the migratory salmon species required intensive processing and storage (gutting, drying, and smoking) during very brief annual periods, captives (especially women and children) were often taken in raids and used as labor (Donald, 1997).

Ritual practice and religion throughout the Pacific northwest was complex, and involved masked dancing, feasting, title giving, and property distributions (the “potlatch”). The mythology of the people throughout this region is elaborate and characterized by a belief in distant deities associated with the sun and sky and much more important proximal supernatural beings who co-inhabit the world of forest and beach with mortals. These supernatural beings may cause all manner of problems—including illness—as well as intercede to assist people in their daily lives. Many of these spirits act as guardians of the living and can guide one through life; they are often associated with animals and may appear in animal form. Other spirits are more monstrous and take the form of ogres, dwarfs, and giant man-eating cave dwelling birds. On the very highest peaks dwell “thunderbirds,” said to keep lightning in the shape of large reptiles (Drucker, 1965).

To successfully deal with spirits, a person must be ritually “clean” by a combination of fasting, dietary proscriptions, bathing, and the use of purges or emetics. Maintaining a ritually cleansed state was a way to stay healthy, to receive good luck, and to avoid harm. If in the course of maintaining ritual purity a man encountered a supernatural being, he might receive the gift of a special power. In some groups these powers were associated with success in hunting or warfare, but in many they were associated with the power to heal (Drucker, 1965).

Historical contact wrought many changes to the indigenous peoples of the region, ranging from dislocation and the restructuring of the traditional social structure to outright extinction. Symptomatic of these events have also

been changes in the ethnonymy for a number of surviving groups who have chosen to reidentify themselves by more traditional names from those assigned within the contact period. Among these are the *Heiltsuk*, who were formerly known as the Bella Bella, Kwakiutl have now become *Kwakwaka'wakw*, Nootka are now *Nuu-chah-nulth*, and the Bella Coola are now known as the Nuxalk.

Social Organization

Aside from their linguistic diversity, the ideas of family, ancestry, descent, and kinship differed greatly, though there are similarities across cultural boundaries. Small, localized groups of people formed the principle unit of production and consumption organized around a core of kin defined according to the local rules of kinship. Ownership of resources typically resided with the kin group, whose members associated themselves with specific localities and village sites. Traditional village life included permanent winter villages, which often grew in population size through the winter feasting and ceremonial season to include hundreds of people. In the summer, families often dispersed to annual settlement camps to collect shellfish, fish and hunt.

Among the *Eyak*, *Tlingit*, *Haida*, *Tsimshian*, and neighboring *Kwakwaka'wakw*-speaking *Haisla* on the northern coast, autonomous matrilineal households or lineages formed the basic units of a village. Typically “towns” were comprised of one or more matrilineal lineages. Each lineage was represented by a hereditary chief who acted as trustee of the lineage properties while house chiefs managed the affairs of their own individual houses. With the possible exception of the *Tsimshian*, these northern groups divided their societies into moieties, as a means of organizing relationships between individuals, families, and lineage groups. According to Halpin and Seguin (1990), traditional *Tsimshian* society at the village level was a moiety, like that found among the *Eyak*, *Tlingit*, and *Haida*, and not the four-fold structure commonly reported. The basic social unit was the corporate matrilineage called a “house” whose members, together with affines, children belonging to other lineages, and slaves, occupied one or more dwellings.

The *Eyak* represent the northernmost Northwest Coast group, and are linguistically related to the Athapaskan family and more remotely to the *Tlingit*. Within the historical period, the neighboring *Tlingit* were to exert considerable cultural influence on this group

through trade, intermarriage, purchase of lands, or conquest (de Laguna, 1990). To the south, the *Heiltsuk*, *Nuxalk*, *Kwakwaka'wakw*, and *Nuu-chah-nulth* had corporate kin groups, described as "ancestral families," which functioned as crest-holding units based on extended bilateral descent. The neighboring *Haisla* are a northern Wakashan language isolate related to the *Kwakwaka'wakw*, who occupy the upper reaches of Douglas Channel and Gardiner Canal on the inner coast. The *Haisla* resembled the *Tsimshian* in technology and social organization, but maintained a set of secret societies typical of other Northern Wakashans (Hamori-Torok, 1990). The neighboring *Heiltsuk*, and related *Haihais* and *Oowekeeno*, occupy the shores of Queen Charlotte Sound from Price Island on Milbanke Sound to the southern shore of Rivers Inlet and inside channels and inlets. Though neither rigidly exogamous nor matrilineal, both residence and descent among these groups mirrored that of exogamous matrilineal northern groups (Hilton, 1990).

On the adjacent mainland coast are the *Nuxalk*, Salishan speakers who formally occupied a number of permanent villages alongside and at the mouths of major salmon rich rivers and creeks in the Bella Coola valley, North and South Bentinck Arms, Dean Channel, and Kwatna Inlet (Kennedy & Bouchard, 1990). *Nuxalk* society consisted of descent groups who held in common a set of ancestral names and prerogatives based on an origin myth. Though a number of descent groups might share a village site, the household remained the primary social and economic unit. Descent was traced ambilineally while residence was patrilocal which tended to reinforce bonds with the father's side (McIlwraith, 1948).

The *Kwakwaka'wakw* of the Wakashan language family occupy northern Vancouver Island, the adjacent mainland and intervening islands of Queen Charlotte and Johnston Straits. They once consisted of some 30 autonomous groups each consisting of several corporate kin groups or "*numaym*," who were the owners of resource sites, myths, and crests. The southern branch of this language family includes the *Nuu-chah-nulth*, the west coast people of Vancouver Island, and the *Makah* on the Olympic Peninsula within Washington State. Local kin groups linked by ambilineal descent held defined territories. Local kin groups did on occasion unite to form "tribes" and at one point the Northern *Nuu-chah-nulth* formed a number of local confederacies consisting of a series of distinct "tribes" whose ranked chiefs shared a common summer village. Political authority, however,

remained with the local group in the absence of any formal political office for these larger aggregations (Drucker, 1951, 1983).

The salmon rich waters between Vancouver Island and the mainland stretching from Johnstone Strait to the Strait of Juan de Fuca and adjacent Puget Sound are the home of the *Coast Salish*. The *Coast Salish* were similarly bound together by bilateral kinship ties (Duff, 1964). Clusters of villages were so closely identified with each other by virtue of locality, dialect, culture, and intermarriage as to become distinct units and bear a common name (Kennedy & Bouchard, 1990; Suttles, 1990). Like all Northwest Coast groups, the *Coast Salish* recognized three "classes" of people, but the distinction was neither as rigid nor as pronounced as that found among the more northerly groups (Suttles, 1990).

In addition to an enclave of *Coast Salish* (*Tillamook* and *Tsamosan*) and *Chimakean* speakers, a mosaic of smaller language groups, collectively assigned to the Penutian Language Phylum, occupy the coasts of Washington and Oregon. The basic social and political unit amongst these groups, as well as a neighboring group of *Athapaskan* speakers, was the autonomous winter village group, consisting of one or more residence groups of paternally related kin. Residing on the coast and major rivers of southwestern Oregon, this Pacific branch of the *Athapaskan* language family represents the southerly most Northwest Coast group.

Contact, Contagions, and Change

The introduction of various high-mortality, density-dependent diseases, previously unknown to pre-contact populations, contributed in no small measure to the erosion and restructuring of traditional lifeways. Their severity varied from group to group according to their specific contact histories. Some, like the *Haida* and *Kwakwaka'wakw* experienced abrupt, catastrophic population loss. For others the process of depopulation was more gradual. In some cases the outcome was outright extinction of local groups, while in other instances new creative cultural practices emerged to cope with the changes of the period such as nativistic movements like the Prophet Dance. Smallpox proved by far to be the most devastating disease, and in the wake of this contagion, which struck on at least three occasions between the late 1700s and the late 1800s, were a host of other serious

illnesses. Measles, influenza, whooping cough, tuberculosis, and scarlet fever reached epidemic proportions among an increasingly weakened and vulnerable native community throughout the 1800s. In the case of the *Haida*, the *Nuu-chah-nulth*, and many others, a lethal combination of disease, warfare, dislocation, and stress worked to destroy many family groups with weakened or remnant groups joining more powerful neighbors to create new political structures (Acheson, 1998; Arima and Dewhirst, 1990). For small-scale societies everywhere, catastrophic population losses required, if they were to survive, new social, economic and political alignments.

The concept of “composite bands” and “tribes” as a product of the merging of various like bands due to the “initial shock, depopulation, relocation, and distribution of the early contact period” is certainly not new. Among the *Nuu-chah-nulth*, for example, declining populations and extended warfare throughout the late 1700s and early 1800s worked toward creating or maintaining tribes and confederacies (Drucker, 1951).

The move away from matrilineal kinship toward more patrilineal oriented descent observed among the *Haida*, for example, can in part be attributed to severe population fluctuations. The need to restructure social groupings as a result of population decline, coupled with the growth of a market economy, increasing economic cooperation between father and son, and the growing advantages of politically important rank in a father, conspired to break down the matrilineal descent group.

The implications of these trends are equally significant to traditional native experiences with illnesses and medicinal practices, the role of shamans, and religious practices. Shamans occupied an ambiguous position within the community in their role as both caregiver and a potentially malevolent force that possessed unique supernatural curing, divining, or witchcraft capabilities. They also had an extensive practical knowledge of pharmacologically active plants and herbs. The introduction of new, destructive illnesses not readily understood, placed shamans in a particularly precarious position. The discrediting of their role and diminishing value placed on traditional healing practices, and even the outright loss of such cultural knowledge, created a vacuum that gave rise to the messianic movements of the 1800s and enabled the missionary movement to make significant inroads by the late 1800s. The emergence of “revitalization” or “nativistic” movements, such as the Prophet Dance and Shaker religion among a number of coastal groups, underscores

this relationship. But it also demonstrates resourcefulness on the part of the people confronting a new political and economic reality, who sought to relieve the afflictions of mind and body through a creative blend of traditional healing and Christian practices.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

Diseases of the Pre-Contact and Early Contact Periods

At least four infectious diseases—viral pneumonia, non-venereal syphilis, tuberculosis, and trachoma—were known to pre-contact peoples of the Americas. Most acute infections rarely involve bone, however, making the detection of disease among pre-contact populations extremely difficult to detect. The kinds of high-mortality density-dependent infectious diseases common to the Old World are thought to have been absent prior to cultural contact (Boyd, 1985).

Chronic bone infections likely due to tuberculosis or treponematosi, and malignant bone tumors (both primary and secondary) were present among coastal populations (Cybulski, 1990). Of these three disease groups, only treponemal infections, likely a form of endemic non-venereal syphilis, appear in the prehistoric record for the Strait of Georgia and Prince Rupert Harbour (Cybulski, 1994; Skinner, McLaren, & Carlson, 1988). A form of conjunctivitis or trachoma often resulting in blindness and leprosy is documented within the initial contact period, suggesting a pre-contact origin. While known to pre-contact New World populations, the presence of tuberculosis on the coast is so far confined to the historical period, first appearing among the *Nuu-chah-nulth* at Nootka Sound in 1793 (Boyd, 1990).

Cribriform orbitalia (porotic hyperostosis), cited as a possible indicator of iron-deficiency anemia, has been detected in coast-wide prehistoric and historical populations at frequencies of 13–14%. Causes of iron-deficiency anemia are varied, but the low frequency of cribriform orbitalia is seen to indicate a population’s successful adaptation to the pathogen load of its local environment, including all fungi, viruses, bacteria, and parasites. Nutritional health among coastal populations generally

appears to have been stable from 3500 BC to the post-contact period (Cybulski, 1994). Mortality rates, on the other hand, underwent an unprecedented increase with the introduction of a suite of highly infectious diseases following contact.

Described as “the most terrible single calamity” to strike the Aboriginal community (Duff, 1964), smallpox was a reoccurring pandemic resulting in the progressive and catastrophic decline in population from the outset of culture contact. Following in the wake of the major smallpox epidemics of the late 1700s, 1837–38, and 1862–63, were a host of other diseases, including measles, influenza, whooping cough, tuberculosis, and scarlet fever, that reached epidemic proportions among an unsuspecting and highly susceptible native community (Table 1). Lingering diseases such as influenza, scrofula, and syphilis, observed among later native populations, can also be inferred for the early contact period.

By far the deadliest of all the “virgin soil” epidemics to strike the Northwest Coast was smallpox, which appeared in cycles as a result of contact with outside carriers and a sufficiently large enough population of non-immunes for the disease to take hold and spread. The disease afflicted people of all ages, and not just successive generations of children, which had the effect of fragmenting families and dissolving kin groups. Caring for the ill was thus made much more difficult and mortality rates soared.

Historical accounts provide indisputable evidence of smallpox on the coast by the 1770s, appearing among the *Haida*, *Ditidaht* (*Nuu-chah-nulth*), the *Coast Salish*, and the *Chinookan*. It struck the *Tsimshian* in 1795 and the *Coast Salish* again a few years later. Though the severity of these early outbreaks can only be inferred in the absence of detailed population records for this period, it is reasonable to expect a catastrophic population decline equal to (if not greater than) the population losses of the late 1800s. Trade, warfare, and even attempts to escape an outbreak spread the virus rapidly. For the period 1835 to 1890 the number of lives lost on the coast is estimated to be in the realm of 62%, and possibly as great as 90% (Boyd, 1985, 1990, 1994) (Tables 1 and 2).

Within the first quarter of the 19th century another epidemic, variously identified as smallpox, measles, or simply “the mortality”, was reported among the *Cowichan* on southern Vancouver Island (British Colonist, 1862). On the North coast, smallpox reappeared among the *Tsimshian* at Fort Simpson in the early autumn

of 1836, spreading north to the Nass by December and by the spring of 1837 had reached the *Haisla*, *Haihais*, *Heiltsuk*, and *Nuxalk* in the south (Boyd, 1990; Tolmie, 1963). Hudson’s Bay Company officials maintained that the epidemic claimed a third of the population on the North coast, which corresponds closely with recent estimates based on the detailed work by Boyd (1985, 1990) (Table 2), while the *Haida*, *Nuu-chah-nulth*, and *Kwakwaka’wakw* were seemingly spared.

The measles epidemic of 1848, and a subsequent outbreak of smallpox in 1862, spread throughout most of the coast with the possible exception of the *Nuu-chah-nulth*. The *Ditidaht*, a subgroup of the *Nuu-chah-nulth*, however, were struck by smallpox in 1853 and again in 1874 along with the Central *Nuu-chah-nulth* around Barkley Sound (Boyd, 1990; Drucker, 1951). This, and the increased presence of tuberculosis and respiratory diseases, pushed the population to a low of 1605 in 1939 (Duff, 1964). Their immediate neighbors to the north, the *Kwakwaka’wakw*, suffered a second outbreak of measles in 1868 (Boyd, 1985). The 1862–63 smallpox epidemics, while only marginally affecting the Central *Coast Salish*, due in part to the widespread use of smallpox vaccine around missions and white populated areas, devastated the Northern groups. From a preepidemic population of 6,693 around 1840, the *Haida* numbered just 741 in 1881, reaching a low of 588 in 1915 (Canada Census, 1881; Duff, 1964). For the same period, the *Tsimshian* experienced a decline approaching 35% due to the combined impact of the 1848 and 1868 outbreaks of measles and intervening outbreak of smallpox in 1862–63. The *Tlingit* had fallen to 4501 in the same period, representing less than a third of their estimated pre-contact population. The *Haihais* were reduced to just one village site by 1870, having vacated all their villages for a former seasonal camp at Klemtu (Hilton, 1990). The same pattern was repeated among the *Heiltsuk*, who united at the one settlement at Bella Bella by the 1870s (Olson, 1955). Of the more than 45 known *Nuxalk* villages inhabited in 1793, they numbered half that by 1889 and had declined to three when McIlwraith (1948) conducted his fieldwork in 1922–24. At the end of the 1800s there was a comparable decline in the number of *Kwakwaka’wakw* villages and kin groups with only 19 *Kwakwaka’wakw* of some 30 “tribes” surviving in just a handful of communities (Codere, 1990).

The scale of destruction in terms of population loss is only part of a complex picture concerning the impact

Table 1. Coastal Population History

Athapaskan (Lower Columbia; Oregon)	8,640	7,500											
Bands not visited													8,522

Some discrepancies in the figures exist due to differences in identification and ethnolinguistic grouping as well as calculation errors in some of the original tables. Entries prior to the mid-1830 are estimates only. ^aDouglas, 1856; ^bKane, 1859; ^cMartin, 1848; ^dCurtis, 1915; ^eDominion of Canada 1882: 164.

Table 2. Projected North Coast Population Losses from Smallpox, 1836–37

Group	Pre-epidemic population	Post-epidemic population	Total loss	%
Tlingit	9,980	7,255	2,725	27
Nishga	2,423	1,615	808	33

of these diseases on coastal populations. These losses not only posed a threat to the stability and continuity of social institutions through the loss of cultural knowledge, but the occurrence of these diseases also posed a direct challenge to traditional religious beliefs, placing even greater duress on the community. Demoralization itself undoubtedly worked to compound the clinical impact of the epidemics. At the same time we see evidence of a creative accommodation by the native community to new circumstances that drew on traditional medicinal practices and beliefs.

MEDICAL PRACTITIONERS

The practice of ‘medicine’ embodied an array of ideas and concepts along with highly practical and effective remedies and treatment. Alongside the skillful practical treatment of injuries such as fractures and wounds, there is a long history on the Northwest Coast of shamanic practices, which invoke the spiritual both as the cause and in the treatment of the suffering.

Shamans

Shamans act as a medium for the supernatural, possessing unique curing, divining, or witchcraft capabilities acquired through birth, visionary experiences, contact with some form of supernatural force and, in some cases, through vocational training. Among most Northwest Coast groups a person who received healing powers had to apprentice with an established shaman in order to learn to control his newfound powers. The period of apprenticeship varied, but normally ended with a major healing performance. Illnesses cured by shamans were (and are) of essentially three types: soul loss, spirit disease, and spirit or object intrusion. Shamanic practice is now much reduced, but elements of it can be found in many groups,

and some much respected shamanic practitioners can be found throughout the region.

Traditional Ethno-Biological Knowledge: Herbalists

Shamans also possessed an extensive knowledge of pharmacologically active plants and herbs. Herbal healing is seen, however, as somewhat distinct though not entirely separate from the magical or supernatural healing practices by shamans. This distinction between “ritualists” and “herbalists” is near universal in the region. Certain plants were considered “personal property” while other medicines, such as the cascara bark laxative, were universally known (Bouchard and Turner, 1976). The Green or Indian hellebore of the Lily Family (*Veratrum viride*), for example, had widespread use in North America for curing wounds and alleviating toothaches (Vogel, 1970). An extremely poisonous plant due to a combination of toxic alkaloids, hellebore was widely known to coastal peoples for its medicinal properties “as a blistering agent, local anaesthetic and decongestant, and internally as a physic” (Turner, 1978). The effectiveness of many herbal medicines, however, was dependent on a level of secrecy about the type of plant used and its application, and in practice most treatments combined herbal use with shamanism.

As privately held secret knowledge, plant remedies retain potency and also secure some respect and power for those who maintain the knowledge. Much of this practical knowledge was lost over generations confronting severe depopulation from waves of epidemic diseases like smallpox, tuberculosis, influenza, and pneumonia. Confidence in shamans to be able to deal with these terrible epidemics has also meant a loss of knowledge in dealing with psychological anguish.

Today, many people with plant knowledge confront a difficult ethical dilemma; if they choose to share their knowledge the plants upon which they depend may become desirable commercial commodities and be overharvested (as happened with Pacific Yew in the treatment for breast cancer). Losing control over traditional knowledge therefore may not benefit local people and may harm their environment. Yet local indigenous people often wish to assist a wider humanity with their knowledge. As well, the efficacy of teas and decoctions may vary greatly between locally prepared and ritually administered herbs and synthesized commercial preparations.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

The treatment of externally caused injuries, such as fractures, dislocations, wounds, skin irritations, and the like was highly practical and effective. The use of splints to set fractures, for example, was universal and included the steps of straightening and use of pain-allaying medicine. Evidence of the cauterization of teeth to alleviate severe periodontal disease and trephination in accordance with the surgical principle of fracture decompression, is cited for pre-contact populations. Drawing on the affected part effectively treated snakebites and the cleaning of wounds. Such a practice extended to the treatment of internal ailments attributed to supernatural agencies or spirit intrusion.

Generally, disease was the result of either a human or supernatural agent, though natural causes could be considered. Acts such as sorcery, taboo violation, disease-object intrusion, spirit intrusion, and soul loss called for culturally prescribed treatment by a shaman. Confession often forms part of the treatment, serving as a powerful catharsis in helping to alleviate sickness due to broken taboos.

Soul loss is often associated with what could be glossed as depression, possibly including a degenerative disease as well. Although soul loss does not kill its victims immediately, it can be lethal if the soul is not retrieved in a reasonable period of time. Only the most experienced shamans treated (and continue to treat) soul loss. In traditional ceremonies the shaman, or his spirit helper, retrieves the lost soul. Often the shaman brings the soul back to the person in a bed of eagle down; he may also have to struggle against many hostile spirits to return the soul to the person. In our experience soul loss is often associated with people whose close friends and relatives have recently died in a sudden and unexpected manner—indeed, the departed may wish the individual to come and live with them in the realm of the dead. Spirit diseases are generally associated with ritual impurity and the afflicted individual may either become possessed by the spirit itself, contract a fatal disease, or become contaminated by the spirit. Although some shamans have claimed to be able to treat spirit illnesses, most appear to have regarded them as terminal. Spirit and object intrusion is associated with belief in witchcraft: malevolent spirits or shamans hired

by others or acting on their own can send illness producing objects (bone slivers, etc.) into a person's body. The shaman, in a dramatic performance, removes these objects. This kind of classic shamanic performance transforms a person from the subject of hatred by unknown spirits or people into the object of community concern and assistance. It is in essence restorative whereby sick individuals become the focus of family and community concern.

Aside from, though often combined with these practices, is the widespread medicinal use of plants and plant products. Commonly utilized plant medicines throughout the region include various rejuvenating teas made from aquatic plants that grow in streams; treatments for relief of pain obtained from tree bark (willow, as the source of aspirin is known) or especially Devil's Club root (Turner, 1982). Diuretics created from stinging nettle teas are widely used. Bark preparations taken from a wide variety of trees are also used for respiratory, digestive, gynecological, and dermatological ailments throughout the area. Tree barks have also been used to treat fevers, diabetes, kidney problems, sore eyes, and hemorrhaging, and also as general tonics. In most cases, infusions or decoctions of barks are used. The medicines are drunk or applied externally as a wash and are particularly well described for Coast Salish people on Vancouver Island (Turner, 1990).

As well, at least 20 species in *Ranunculaceae*, the buttercup family, are reported as having been used medicinally by 19 different groups of native peoples in British Columbia and adjacent areas. These species are known to contain the skin-irritating, blister-causing compound, protoanemonin, in their fresh state and it is probably the active principle involved in many of these medicinal applications. Most groups utilized the plants as external poultices for boils, cuts, abrasions, and other skin sores. Other disorders treated with *anunculaceous* species include: muscular aches, colds, and other respiratory ailments (Turner, 1984). The slime from slugs, which numbs skin surfaces and serves to protect the animal from predation, also appears to have been widely used as a topical anesthetic.

Many plants or plant products used on the Northwest Coast have made their way into Western medicine, and include a variety of laxative, diuretic, emetic, and febrifuge drugs (Vogel, 1970). Examples include sarsaparilla (*Aralia nudicaulis*) used by the *Nuxalk* and the *Kwakwaka'wakw* for stomach pains.

The use of Oregon grape root (*Berberis aquifolium*) as a bitter tonic among the *Kwakwaka'wakw* was adopted by Europeans. Cascara bark was similarly valued by Europeans as a tonic and laxative long recognized by coastal peoples (Boas, 1932; Turner, 1975; Vogel, 1970).

An array of medicinal treatments was added to an already formidable native pharmacopeia to cope with introduced diseases, including smallpox, whooping cough, tuberculosis, and syphilis. Attempts to arrest these diseases, however, met with little success. One of the cruelest ironies for a community exposed to new contagions was the universal use of sweat baths as a panacea for most diseases. Certain plant medicines were felt to be most effective when taken in the sweathouse. The use of steam baths to fight febrile infections such as smallpox, however, only exacerbated the illness and aided in its spread. Complications arising from this practice, such as pneumonia and pleurisy, greatly increased the probability of death.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

Birth traditionally necessitated the seclusion of both mother and father and enforced dietary restrictions throughout the Northwest Coast. Infants have also long been regarded as particularly vulnerable to illness through the machinations of malign spirits, including ghosts, which may cause sickness. Twins were often thought to be special people but there is little evidence of their receiving special treatment except among the *Nuxalk* where Kennedy & Bouchard (1990, p. 331) report that during the 1970s it was believed that twins resulted from the spirit of Salmon entering the body during pregnancy. In later life *Nuxalk* twins also had to be careful not to offend the spirit of the Salmon, but were said to be able to induce salmon runs. Likewise the birth of people with defects, while felt to be unfortunate, does not normally lead to poor treatment. In British Columbia death from congenital anomalies among infants is actually slightly lower for Native populations than the rest of the province (Foster et al., 1995, p. 69). Infanticide and abortion was originally reported by McIlwraith (1948, pp. 702–712) among the *Nuxalk*, and is suggested for the *Tillamook* as well (Seaburg & Miller, 1990, p. 564). These practices appear to have been associated with the disgrace of

illegitimate births in the past. The practices, however, are not widely reported throughout the region. The extent of breastfeeding is unknown for the region although Aboriginal midwifery and its revival after colonial suppression is well described in British Columbia among coastal peoples (Benoit & Carroll, 1995).

Infant care ideally takes place within extended families, and children often spend a great deal of time with grandparents, and “aunties” and “uncles” of their own clan. Sudden infant death syndrome is disastrously high in many Northwest Coast groups and well documented in British Columbia but is often associated with older birthmothers among Native people, rather than younger ones as is more common in the general population (Foster et al., 1995, p. 70). Adolescent pregnancy is currently relatively high as are the numbers of low birth weight babies (Foster et al., 1995, p. 58).

The umbilicus was traditionally treated with great ceremony, as well as early childhood belongings—especially the cradle and infant clothing. The belongings of children who die are often ritually burned, often on an isolated strand of beach. When newborns die in hospital, ritual destruction may include sonograms, clothing, toys and the like and can be very helpful to grieving mothers. Ritual purification, through bathing in private ceremonies for parents ended their seclusion, and is still practiced in modified form in some groups today.

Adolescence

Seclusion of girls at puberty accompanied by dietary restrictions is traditional and premarital sex has long been frowned upon throughout the region. In many areas where potlatch ceremonies and feasting continues, a major public ceremony for the daughters of high status chiefs may take place announcing their changed status as a mature woman, ready for marriage. Boys throughout the region did not have a traditional feast to announce their arrival at manhood but often went on quests to obtain a guardian spirit. This practice made them vulnerable to potentially dangerous supernatural powers. Some features of this quest still survive throughout the region and include ritual bathing in the sea during the early morning. Visits to hot springs and arduous hikes or canoe trips are also relatively commonplace along with travel to cities, or distant relatives, and friends. Elevated causes of “external” death among young people throughout the region include motor vehicle road accidents, suicide,

drowning, poisoning, homicide, fires, and falls. Reliable data on these exist for British Columbia, especially (see Cooper, 1995; Foster et al., 1995, p. 74).

The Aged

The aged are widely respected for their knowledge, and if they are especially wise and known for their rectitude they are designated as “elders” throughout the region. Because early mortality is commonplace, and the Native population bears a young profile due to high birth rates, there are not a large number of elderly people in the Native population of the region. However, serious degenerative illness is commonplace among those seniors who survive into old age, and it increasingly centers on Non Insulin Dependant Diabetes Melitus (NIDDM), and all its *sequae*, including limb loss, organ damage, heart disease, and blindness (Heffernan, 1995). Rates of autoimmune diseases are also elevated for Native populations on the Northwest Coast, especially rheumatoid arthritis and systemic lupus erythematosis.

CHANGING HEALTH PATTERNS

The most important factors associated with health and illness among Aboriginal people throughout the region is related to economic poverty and a history of political and religious subordination. Following in the wake of waves of epidemic diseases which obliterated cultural knowledge and greatly reduced population sizes, surviving children were sent to residential “schools” in the United States and Canada as part of a policy of assimilation in both countries. These were run by Christian religious denominations. At these institutions children were systematically stripped of their culture and language, inadequately fed non-traditional foods, and separated from cultural traditions during the winter ceremonial period. It has now been documented that abuse, both physical and sexual, was appallingly widespread. The impact of residential institutions on dietary change associated with rapidly rising rates of diabetes is well described for British Columbia’s coastal populations (Hopkinson et al., 1995).

Impacts on health as a result of these trends have been far reaching. Death from digestive system diseases (associated with alcohol overconsumption) is excessively high for many groups, and gastrointestinal cancer rates are

also especially high, as are neoplasms of the female reproductive system, and blood/lymph. Premature death from Ischemic heart disease, cerebrovascular strokes, and cardiomyopathies are also higher than for base populations throughout British Columbia. Mortality from infectious diseases, especially those affecting the respiratory system are uncommonly high and affect many age groups; these include: pneumonia, influenza, asthma, pulmonary fibrosis, and tuberculosis. Septicemia and viral hepatitis rates are also elevated, as are HIV infections, especially in urban areas such as Vancouver (Foster et al., 1995). No systematic comparative epidemiological or vital statistics data appear to have been published for American jurisdictions, where socialized medicine is not available, and statistical data are not comprehensively compiled.

Traditional belief emphasizes that death is associated with dangerous ghosts, whose powers include those which may make the living seriously ill. The great epidemics of the past, and current high mortality from many causes, have certainly provided a steady supply of ghostly spirits for over a century. Throughout the region the dead were traditionally disposed of in myriad ways: by suspension in trees, in mortuary boxes set atop memorial poles, in caves or in canoes suspended on scaffolds, or by cremation. After the creation of missions, cemeteries were widely used and stand in sad testimonial to the loss of young lives during the waves of epidemic diseases that struck many Native villages throughout the region. Many gravestones are those of children. Today, both burial and cremation are commonplace, along with a major memorial ceremony for high status and chiefly persons where the title is passed on and where the participants receive gifts of food and clothing.

The last half of the 20th century also witnessed a massive migration into cities throughout the region and consequently Anchorage, Vancouver, Victoria, Seattle, Prince Rupert, Bellingham, and Portland all have large populations of Native People. These populations come from the Northwest indigenous groups but are also migrants from other areas including the interior plateau, the Arctic, the Canadian prairies, American Middle West and the Southwest. The traumas—physical and psychological—associated with epidemic diseases, residential institutions, urbanization, and poverty are also deeply connected to a loss of traditional lands and water. The destruction of forests, salmon streams, pollution from mining and paper mills, and a great reduction in marine resources have all contributed to widespread despair,

impoverishment, high rates of stress related illnesses, and deaths associated with substance abuse and addiction. Attempts to deal with these problems are now quite extensive (Stephenson & Elliott, 1995) and include the use of innovative and traditional healing techniques (Harris, 1995; Wade, 1995), diets (Hopkinson et al., 1995), and a shift in decision-making over health planning to local Native communities (Modeste et al., 1995; Read, 1995). However, ceding control over health care by paternalistic federal powers in both the United States and Canada, to local Native communities with conflicting interests, has proved frustrating, and difficult to achieve.

Ojibwa

Linda C. Garro

ALTERNATIVE NAMES

“Anishinaabe; Ojibway, Ojibwe; Chippewa (U.S.); Mississauga or Southeastern Ojibwa (southern, central Ontario), Nipissing, Algonquin, Plains Ojibwa (sometimes known as Bungi); Northern Ojibwa; Saulteaux or Saulteurs (Manitoba); Ojicree or Oji-Cree, Southwestern Chippewa (based on Goddard, 1978, p. 583 cited in Brown, 1997).” Geographically, this entry primarily concerns present-day Canada, particularly Manitoba and Ontario. Anishinaabe (plural Anishinaabeg) is the preferred ethnonym in Manitoba and Ontario (Peers, 1994, p. xvii).

LOCATION AND LINGUISTIC AFFILIATION

Most of the estimated nearly 50,000 speakers of Ojibwa are found in the area ranging from southwestern Quebec through Ontario, Michigan, northern Wisconsin and Minnesota, southern and central Manitoba, and southern Saskatchewan (Mithun, 1999, p. 334). The eight Ojibwa dialects belong to the Algonkian language family (Rhodes & Todd, 1981). Ojibwa and Cree are linguistically, culturally (Rogers, 1969), and genetically related (Young, 1988, p. 12), with considerable intermarriage starting in the fur trade period.

OVERVIEW OF THE CULTURE

Records of Ojibwa contacts with Europeans date from the 1640s (Hallowell, 1992). Within a century after European contact, the Ojibwa began to migrate into southern Ontario and Michigan from a “homeland” located “somewhere within an area extending from the eastern shore of Georgian Bay (Lake Huron), west along the north shore of Lake Huron, and a short distance along the northeast shore of Lake Superior and onto the Upper Peninsula of Michigan (Rogers, 1978, p. 760).” It is unclear how unified Ojibwa culture was prior to the 1600s (Hallowell, 1992, p. 20).

A reasonable starting point is a glimpse at late 18th century life in the region northwest of Lake Superior—a forested region with numerous lakes, rivers, and swampy regions. During this historical period, the Ojibwa complemented their subsistence activities of hunting, fishing, and gathering with participation in the fur trade, which had been ongoing for over a century in this region (Peers, 1994, pp. 22–26). The effective unit of social and economic organization was the extended family, typically composed of several close relatives and their spouses, children, and other kin, which ranged in size from six to about a dozen people (see Hallowell, 1992, pp. 56–57 on bilateral cross-cousin marriage as the prototypical pattern and pp. 29–30 on polygyny). Generally there were patrilineal, exogamous clans (descent groups named after totemic animals)—see Rogers (1978, p. 763) and Brown (1997). The seasonal harvesting round emphasized fish and wild rice (Peers, 1994). In early spring, leaving their winter hunting grounds, several extended families would gather to make maple sugar. Families subsisted on small game, and caches of meat and wild rice from the previous summer. Men might leave on short trapping excursions lasting several days. After the sugar run, people from many camps gathered together at sturgeon-fishing sites for a month. Sturgeon was an important food source, both fresh and processed, to be stored for future use and as sturgeon oil (Holzkamm, Lytwyn, & Waisberg, 1988). As the largest gatherings, spring fishing villages ranged in size from several hundred to over a thousand. Trading exchanges of furs for goods occurred at local trading posts in close proximity to the fishing sites, or with visiting traders. Maple sugar and sturgeon might also be traded.

Activities associated with the Midewiwin, a ceremonial organization concerned with curing (Hallowell, 1992, p. 11) only took place during large gatherings. Hierarchically organized in degrees or grades of membership, initiates were instructed under the leadership of Mide priests (Steinbring, 1981, p. 251). As seeking a cure for illness was one means for entering the society, almost all were inducted into at least the lowest rank. Novices

were taught to identify and prepare botanical medicines and to commune with other-than-human persons in order to enhance individual power to heal (Waldram, Herring, & Young, 1995, p. 112). Advancement in the Midewiwin's structured organization contrasts (see below) with the individualized "gifts" of "power" granted by other-than-human persons through private sensory encounters.

After spring fishing, the Ojibwa dispersed for the summer to engage in fishing, berry picking, and hunting. At the end of the summer, larger groups gathered to hunt migrating waterfowl and collect wild rice. Harvested wild rice was stored for winter use and traded. Autumn activities included visits to trading posts to obtain goods for winter activities. Individual extended families would move to winter hunting grounds and carry out a fall hunt for summer-fattened deer, bear, and moose. The amount of cached food and availability of small game determined how much effort was directed to trapping activities rather than fishing or hunting larger animals. As spring approached, several families might come together for a last intensive period of trapping before rejoining other families to make maple sugar (Peers, 1994).

As Peers (1994, p. 25) notes, "the Ojibwa moved within a world that was at once spiritual and physical. . . . The forest, streams, and lakes were alive with supernatural [other-than-human] 'persons' and powers, all of whom had to be treated with respect to prevent misfortune, accident, and illness from befalling the human persons who moved among them." Feasts and other offerings conveyed respect and gratitude to other-than-human persons (Hallowell, 1992). Everyday objects and clothing were designed to tap into beneficial powers and protect from harmful powers. Sent alone into the forest around the time of puberty, young men and women actively sought to enter into relationships with other-than-human persons, fasting and begging other-than-human persons to take pity on them and to help them throughout their lives. The "gifts" and "objects of power" bestowed by other-than-human persons, who occupy the "top rank in the power hierarchy of animate being" (Hallowell, 1960, p. 377), enabled human being" to do things that would otherwise not be possible. In entering into lifelong personal relationships with their attendant gifts, individuals incurred specific and general obligations founded on respectful behavior toward the other-than-human persons. Examples of gifts include: ability to change the weather, ability to call wild game, unusual success in warfare, knowledge of healing skills, and the ability to communicate with other-than-human persons to learn things

that would otherwise be unknowable (Hallowell, 1955, p. 104, Peers, 1994, p. 25). At times some communications took place in public settings (Hallowell, 1942). Black (1977a) has proposed an "Ojibwa power belief system" underlying interpersonal relationships, including relationships with other-than-human persons.

Both learned skills and practices, as well as knowledge and abilities granted by other-than-human persons, were important in the maintenance of well-being and care of illness. Teachable skills and practices included blood-letting (Pettipas, 1977; Steinbring, 1981, p. 249), enemas (Pettipas, 1977), a range of herbal preparations, and sweat baths (Peers, 1994; Waldram et al., 1995).

From the woodlands northwest of Lake Superior, the Ojibwa subsequently fanned out in a westerly direction into areas rich in furs, large game, fish, and other resources (see Ray, 1974, ch. 2), coming into increasing conflict with the Dakota. By the last decades of the 18th century, small groups of Ojibwa began to move even further west into the prairies and parkland (Peers, 1994, p. 3).

Peers maintains that the fur trade "may not have been as central to their lives as it seems" (1994, p. 27) and notes (p. 43): "Where some trade goods reinforced and elaborated many aspects of Aboriginal cultures, others caused rapid cultural change and damage. Some trade goods did both." For example, alcohol and the "destructive nature of fur-trade drinking parties—even when these were conducted as redistribution events or ceremonies—hints at great stresses generated by the fur trade and at cultural changes resulting from participation in the fur trade" (see also Waldram et al., 1995, pp. 137–140).

Later sections of this entry concern the contemporary context of health based on field research carried out in the 1980s in a southern Manitoba community. Classified by Howard (1965) as plains Ojibwa, the community is located in the "transition parkland belt" which historically provided "most of the resources of both the forest and grasslands" (Ray, 1974, p. 28). It is an Anishinaabe community where members report the long-standing annual observance of the Thirst (Sun) Dance found historically in the plains region and closely associated with the plains Cree (see Pettipas 1994 for a description). Yet, as noted below (and complementing an analysis by Peers, 1994, pp. 152–153, 179, 210–211), there was also considerable commonality with work carried out to the east by Hallowell (e.g., 1955, 1976, 1992) and Black (e.g., 1977a, b). To help situate the discussion of the contemporary community, the next section begins with an abbreviated

synopsis of some key social forces starting around the time that the fur trade began to wane.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

Missionaries, Treaties, and Newcomers

As the importance of the fur trade declined and the animal resource base became depleted, missionary activities by Roman Catholics, Anglicans, Methodists, and others intensified during the 1830s and 1840s (Brown, 1997; Hallowell, 1992; Peers, 1994). The response to missionization varied (see Peers, 1994, ch. 5). Early missionary schools did not attract large numbers of Ojibwa students. But for some, baptism was seen as protective against the covert use of evil powers by others and/or providing a connection to new other-than-human persons that could prove helpful in the changing times (Peers, 1994, pp. 162 and 169). Accepting Christianity did not necessarily entail renouncing what has been referred to as the “Ojibwa power belief system” (see Black, 1977a). Peers (1994, pp. 167–169) writes of the turmoil and uncertainties, both social and personal, occasioned by these missionary efforts, of missionary attacks on the Midewiwin and of struggles between missionaries and Midewiwin leaders to attract adherents. And although the Midewiwin began to wane, and continued to do so as time passed, it remained visibly active up through the 1930s, with the report of a ceremony in 1942 (Steinbring, 1981, pp. 252–253; see also Hallowell, 1936). In some communities, the Midewiwin may have continued without coming to the attention of outsiders after that time (see Black-Rogers, 1989).

The intensification of missionary activities heralded the increased intrusions, restrictions and encroachments of the coming years, which escalated following the formation of Canada in 1867, and subsequent treaty negotiations. Hallowell (1992, pp. 35–38) asserts that the signing of treaties and creation of bands and chiefs through the treaty process was more drastic than the earlier impact of the fur trade and Christianity in that the Ojibwa were asked to give up all legal claims to the great majority of lands they occupied, as well as become subject in the future to decisions of a national state. Efforts to negotiate continued access to land resources

were ultimately disregarded (Peers, 1994, p. 204). Lands were opened up to settlement and cleared for agriculture by Euro-Canadian settlers in the southern regions and the First Nations groups became increasingly constrained by the boundaries of reserve lands. Off-reserve involvement in wage labor, often in agriculture, became more common. Hunting and fishing rights were restricted while newcomers engaged in the commercial exploitation of natural resources, such as logging and fishing operations. Destructive environmental impacts include: the expropriation and overexploitation of sturgeon fishing by commercial non-Indian fishermen which led to the near-extinction of the sturgeon; impacts on fishing, trapping, and wild rice caused by hydroelectric projects; the clear cutting of forested lands; and mercury poisoning from pulp and paper mills raising individual health concerns while also curtailing fishing and jobs as fishing guides.

The Indian Act of 1876 and later amendments gave sweeping powers to federal Indian administrators to “transform ‘Indians’ into ‘Canadians’” (Pettipas, 1994, p. 17). While First Nations negotiators wanted schooling provisions included in the treaties to adapt to the future, the educational policy developed by the Canadian government became entwined with the efforts of missionaries to “christianize and civilize” (Reading, 1999) and the day-to-day management of the schools was placed under the control of churches. Children were often removed to schools distant from their homes and, among other hardships, often forbidden to speak their own language, while the ways of their parents were disparaged. Missionary aims were furthered when government representatives enforced repressive statutes aimed at eliminating indigenous religious ceremonies, including the Midewiwin (Pettipas, 1994, p. 157). Since the 1950s, fundamentalist Christianity has attracted a significant following in many communities (Steinbring, 1981, p. 253; Young, 1988, pp. 16–17), with messages censuring alcohol and Aboriginal healing traditions. However, healing traditions, like the Midewiwin and the sweat lodge, have been held once again in communities after a hiatus lasting many years (e.g., Pettipas, 1994, p. 7). Some hospital administrators accommodate healers and their practices within hospital settings (O’Neil, 1988; Waldram et al., 1995, p. 205; see for hospital-based case studies illustrating some of the complexities involved).

While missionaries dispensed medicines (like traders before them) and cared for the sick, government increasingly took a role in providing health services

(see Young, 1988, pp. 101–102). A recurring debate throughout much of the history concerns responsibility for the provision of health care, with “status Indians” from groups who signed treaties contending that health services are a treaty right and Federal government officials claiming that health services are provided on a humanitarian and not on a legal basis. This controversy lessened with the introduction of universal health insurance in Canada in the 1960s, but First Nations and Aboriginal organizations refer to federal responsibility for health in proposing efforts to enhance, as well as in voicing concerns about reductions to, health programs and existing services for status Indians. Leaders of First Nations bands and political organizations have long asserted that the improvement in health for First Nations people requires radical changes in the historical relationship between Canada’s first peoples and those who came later. For example, Phil Fontaine, formerly the Grand Chief of the Assembly of Manitoba Chiefs and later of the national Assembly of First Nations, stated: “The present state of ill health among aboriginal people is a reflection of their placement in the social and political structure of Canadian society” (Fontaine, 1991, p. 21).

Health in Historical Perspective

While no reliable information is available about the size of the pre-contact population, Bishop (1999) states that from “perhaps 10,000 persons at contact whose descendants are now called Ojibwa, the population grew to around 140,000 (registered) in 1996.” The trend is not one of a smooth linear increase. The population figures at the time of contact declined through time and reached their lowest points at some point around the transition from the 19th to the 20th century (Ubelaker, 1988).

The pre-contact and the early fur-trade periods were characterized by a relatively healthy population (Young, 1988). Acute infectious diseases swept through the region at intervals starting in the 18th century. The smallpox epidemic of 1780–82 (Young, 1988, pp. 35–36) not only caused extremely high mortality rates, but also fear and despair contributing to suicides and other premature deaths, as well as the vulnerability of survivors because of a reduced labor force: “In a hunting-and-gathering society... the death of a single hunter or female worker could be a threat to the survival of an entire extended family” (Peers, 1994, p. 20; Young, 1988, p. 38). Indirect effects—reduced fertility and post-epidemic mortality

linked to malnutrition and dehydration—may have contributed significantly to population decline (Thornton, 2000; Waldram et al., 1995, p. 59). Around 1825, as westward expansion progressed, epidemic diseases such as measles, influenza, and scarlet fever began to strike with more frequency. Disease impact was amplified by malnutrition and undernutrition associated with the depletion of local game and fur resources around the mid-1800s (Waldram et al., 1995).

By the early 1900s, relocation onto reserves or other semipermanent settlements with insufficient food, inadequate sanitation, and crowded housing ensured the continued prominence of infectious diseases, as did the concentration of children in residential schools. Infant mortality was extremely high; for every 1,000 live births there were over 200 deaths during the first year (Young, 1988, p. 124). Social conditions fostered the emergence of tuberculosis—a “genuine plague of enormous proportions”: a review of residential schools over a 15-year period indicated that from 25–35% of all children had died, primarily of tuberculosis but also from other diseases like measles (Waldram et al., 1995, p. 156). Tuberculosis “continued unabated throughout the 1930s and 1940s as dwindling economic resources kept the population at mere subsistence level” (Young, 1988, p. 124).

Since World War II health has improved with national universal health insurance, improvements in accessibility to biomedical health services in rural and remote communities, economic assistance programs, and greater control of infectious disease. Still, morbidity and mortality rates for infectious diseases remain at a persistently higher level when compared to the rest of the Canadian population (Hallett, 2000; Waldram et al., 1995; Young, 1988) and are associated not with the quality of or access to health services, but with continuing socioeconomic marginalization.

According to Young (1994, p. 94): “Over the past several decades Native Americans have undergone the ‘epidemiological transition’ characterized by the decline, though not disappearance of infectious diseases and the increasing importance of the chronic, noncommunicable diseases, accidents, and acts of violence as causes of mortality and morbidity.” For the chronic diseases, particularly striking has been the emergence of the so-called “diseases of modernization” or “diseases of westernization,” such as type II diabetes, hypertension, obesity, cardiovascular disease, and cancer. Many chronic diseases are seen to be “the result of rapid changes in

lifestyle, particularly in dietary habits and physical activity levels” (Young, 1994, p. 216). The prewar situation of low body weights has changed to one where obesity is common (Young, 1988). While type-II diabetes was rare before the 1950s, the current situation is described as “an epidemic in progress,” one that is “still on the upswing, with a trend toward earlier age at onset” (Young et al., 2000, p. 561). Type-II diabetes is also known as maturity-onset diabetes as it typically develops later in life, but it is increasingly diagnosed in children and adolescents in Manitoba and northwestern Ontario (Young et al., 2000). In recent years, the discrepancy in life expectancy for Aboriginal peoples compared to others in Canada has steadily decreased but still remains, with recent reports indicating 8 years less for males and 6.7 less for females (Hallett, 2000, p. 34) and primarily reflects more deaths occurring relatively early in life (Young, 1994, p. 37).

With those under the age of 5 years suffering disproportionately from infectious disease (Young, 1988, 1994), the most important causes of morbidity and mortality for the younger age groups (upper limit of 45 years of age) are injuries sustained as a result of accidents and violence (Hallett, 2000; Young, 1994). In the years from 1972–81, over one third of the deaths in the Sioux Lookout region of northwestern Ontario were attributed to accidents and violence, mostly involving alcohol. Suicide rates were almost twice as high as for Canada as a whole. The rates for accidents and violence, with the exception of suicide, have declined since the 1980s (Hallett, 2000; Young, 1994).

Consider the case of Grassy Narrows, one of the more southerly Anishinaabe First Nations in northwestern Ontario (Shkilnyk, 1985). Looking at the 20-year period from 1959–78, Shkilnyk examines the detrimental impact of the government’s decision to relocate the community in 1963 and the discovery in 1970 of mercury poisoning in the river that was so central to the life and livelihood of the community. Prior to the relocation, from 1959–63, 91% of all deaths were due to natural causes and 9% were attributed to violence, including suicide. From 1964–68, the frequency of violent deaths rose to 14%, and from 1969–73 to 49%. For the period from 1974–78, violent deaths associated with alcohol or drugs accounted for 75% of all deaths. Although presented as relatively unique (Shkilnyk, 1985), Grassy shares commonalities with many other Ojibwa and First Nations communities and that serves to illuminate the development and nature of the relationship between the first

peoples and the wider society (see Garro, 1993 for a more extended discussion). Like Grassy Narrows, the traditional resource base of other communities has been eroded with the resulting dependence on government-sponsored welfare programs and other forms of economic assistance (see also Waldram, 1985). In addition, separating children from their families and removing them to off-reserve locations has increased the feelings of demoralization and hopelessness. Exposure to mercury poisoning and forced relocations, often because of flooding of land by hydroelectric dams, has occurred with other communities. Many First Nations communities, like Grassy Narrows, have in recent years worked toward achieving a greater degree of self-determination which involves greater involvement in such institutions as education, child welfare, health care, and the justice system. Actions directed at regaining control over a land resource base, through settling land claims or by other means, are another important part of this ongoing process (see Garro, 1993). The struggle for self-determination, for resource rights and lands rights, is also a struggle for better health (Culhane Speck, 1989, p. 90).

The Community Context

The remainder of this entry draws on field research carried out in the 1980s in an Anishinaabe First Nations community in southern Manitoba. It is a community where a substantial majority of adults and children, and essentially everyone over 40 years of age, speaks their own language, Anishinaabemowin; it is the language predominantly used in most social interactions in the community. Many individuals identify as Catholics.

There is insufficient land on the reserve or surrounding it to allow a subsistence or trapping-based means of livelihood, except for a few fishermen. Over time, much of the land surrounding the reserve has been acquired for cultivation, although not by reserve members. A few families farm some small tracts of reserve lands and some households have large gardens. Wild game and fish supplement the diets of most families, and some rely heavily on such products. Because of the lack of on-reserve employment, young people used to move back and forth between the reserve and work sites in agriculture or in the city. This still occurs to some extent. Some elders state that a major shift occurred in the late 50s when welfare assistance became available, making it possible for people to live full-time on the reserve and to

purchase store-bought goods. Like many other First Nations communities, increasing numbers of registered members have relocated, permanently or semipermanently, to urban settings over time (Thornton, 2000).

The majority of fulltime on-reserve employment opportunities are through local First Nations government or related services—mainly positions in teaching, administration, and health care services. There is high unemployment and many depend on economic assistance. Until relatively recently, the highest level of schooling attainable without leaving the community was the eighth grade. Many older individuals attended residential boarding schools where progression through the grades was slow. Proportionally, few adults have completed many years of formal schooling. However some young adults in their twenties and thirties, many of whom work for the local government, spent considerable time in boarding schools off the reservation and then often proceeded to obtain a university degree or take college-level courses. On the reserve, much of the housing is overcrowded and of substandard construction; there is a lack of plumbing and water services with many homes relying on water delivered to outside barrels.

Physicians, other biomedical health professionals, schools, television, printed material, radio, and alternative forms of medicine, including diverse Aboriginal healing traditions, have all influenced local understandings. It was not uncommon for community members to contrast the health-sustaining characteristics of the foods and lifestyle of the Anishinaabe past and sickness-inducing propensities of contemporary ways of living from which the Anishinaabeg cannot escape.

MEDICAL PRACTITIONERS

Outside of urban centers, few communities have resident physicians. The health center was staffed by visiting physicians approximately three afternoons a week with other physicians and hospitals located in towns approximately an hour's drive distance. All expenses of biomedical care, including transportation costs and prescription drugs, are either covered by universal health insurance or the federal government. Public health nurses and community health workers (residents of the community who have participated in training courses and whose work is supervised by nurses) focus on public health, health education, and prevention. They also make home visits to

provide ongoing care and guidance to new mothers and others deemed in need of help with a health problem.

In this community, the most respected healers see themselves as descendants, in spirit if not through direct familial connections, of other Anishinaabe healers reaching back into the community's past. Two general types of Anishinaabe healers are important. First, there are individuals, usually women, who "know how to make (herbal) medicine," the special knowledge of which is learned from another healer and generally passed down through the family. Some are known for their skill in making one specific preparation, for example, medicine to help teething infants, dissolve gallstones, or to control diabetes. Others treat a variety of conditions. Herbal remedies may be used by women for a variety of reproductive health functions, for example, to control menstrual cramping, and to prevent miscarriages or premature birth. For services outside the family, herbalists receive tobacco along with some form of payment, usually money. Second, there are curers who are regarded as "gifted" with special powers. Most often the "gifts" of these medicine persons are manifested by their ability to communicate with other-than-human persons, through dreams, visions, or other altered states of consciousness to diagnose, establish cause, and prescribe and/or carry out remedial actions. If truly gifted, these medicine persons are able to ascertain whether a condition is best treated by a physician or can only truly be resolved through the mediation of a medicine person with other-than-human persons.

Although youths no longer routinely go into isolation and fast for blessings, healing gifts are still granted through visions and dreams. Medicine persons may also guide an individual to interpret his or her own personal experiences as indicating the likelihood of special powers that may manifest themselves or can be called upon in the future. Most medicine persons are not recognized as gifted and consulted by others until they have reached middle age. While it is not as common for women to be recognized as medicine persons, when it does occur it is after menopause.

Medicine persons do not charge for their services but they are always given tobacco and usually a sum of money or goods. Although what is given is at the discretion of the individual seeking help, the value tends to reflect the complexity of the case and the affluence of the giver. Families may incur considerable travel expenses to consult with a respected medicine person in another community.

An important component of being helped by a medicine person is a belief in their “gift” and the culturally embedded rationale for Anishinaabe sickness. This is not true of treatment by an herbalist. While individuals in this community can generally be said to share knowledge of Anishinaabe theories about the causes of illness and misfortune, there is considerable variation in the extent to which individuals espouse these theories and rely on them in evaluating events and making treatment decisions. Indeed, some individuals, particularly those who went to boarding school, express strong skepticism about the existence of “Anishinaabe sickness” and the gifts attributed to medicine persons. (Sometimes a household member consulted a medicine person without informing other family members who were not favorably disposed toward Anishinaabe healers [Garro, 1998, p. 350].) In this community there is no perceived contradiction between accepting a medicine person’s abilities and being a Christian. The Midewiwin is not present in this community.

Black (1977a, p. 149) notes that those who heal also potentially have the power to cause death, illness, or misfortune at a distance. Uncertainty about the potential to misuse power may enter into interactions with medicine persons.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

Illness Treatment Decisions

Patterns of care-seeking are diverse and complex (Garro, 1998). During the course of fieldwork, thirteen separate visits were made to 61 randomly selected families over a six to eight month period. The total number of illness case histories is 468. Of these, 189 (40%) were cared for at home without recourse to any other source of care. Among the remaining 279 cases, 225 (81%) were seen by a physician, 98 (35%) were seen by medicine persons who were consulted as mediators with other-than-human persons, 21 (8%) sought remedies from a herbalist, and 10 (4%) consulted another type of practitioner (non-Anishinaabe herbalist, chiropractor, acupuncturist, psychologist). The percentages add up to more than 100% because some cases involved multiple treatment alternatives outside the home. Of the 225 cases seen by a physician, 66 (29%) also consulted a medicine person.

In cases where both physicians and medicine persons were consulted, physicians tended to be seen first. All but 13 families reported consulting a medicine person in the past five years. Six families (10%) reported never seeing a medicine person.

Classification and Explanatory Frameworks for Illness

In Anishinaabemowin, there are a couple of generally applicable terms indicating the state of being sick that can be used to refer to any illness condition. These “sickness” terms can be modified in a way that connects them with two broad causal categories or explanatory frameworks—“white man’s sickness” and “Anishinaabe sickness.” Named illness conditions (e.g., diabetes, measles, arthritis) are not fixed exemplars of any one of the categories (see Garro, 1990). Uncertainty is common, an explanatory framework may be framed in terms of possibilities (or probabilities) open to debate, and an illness may be linked to multiple explanatory frameworks. One mother with a sick infant consulted both a physician and a medicine man, who diagnosed an Anishinaabe sickness. When asked which interpretation she thought was correct she replied: “I think they both were right. I believe them both.”

Sickness. Sickness encompasses a diverse range of explanations, many of which are widely found throughout Canada and the United States. For example, overeating or eating the wrong thing, including “food poisoning” due to spoilage can lead to illness such as stomachaches or diarrhea. Colds, the flu, and tuberculosis could be talked about as something “caught” from someone else and transmitted by means of “a bug,” “germs,” or a “virus.” Similarly, measles was talked about as a common childhood illness that could spread to anyone. An unchecked illness can develop into something more serious, such as a child’s fever developing into convulsions. Another concept likely based in biomedical teachings is that of an illness being inherited or passed down through the family. Talk about the possibility that an illness could “run in the family” was generally understood, but heredity is not a common explanation (Garro, 1995, 1996).

Colds, fevers, and respiratory conditions, like bronchitis and sometimes tuberculosis, may be attributed to excessive cold, or to being overheated and catching a chill. A minor illness, like a cold, may leave one in a

weakened state and thus more susceptible to the effects of cold and the danger of having the illness worsen into something more serious such as pneumonia or bronchitis. Rheumatism and arthritis were also attributed to getting wet or being exposed to the cold; fishermen were considered to be particularly vulnerable. Women are considered vulnerable to the effects of cold during their menstrual periods (but unlike other illnesses linked to the cold, remedies from physicians were not seen as providing any benefit).

There are also a number of things that, if in excess, have the potential to stress the body and tip the balance toward ill health. Smoking too much can lead to cancer as well as other problems involving breathing and the lungs; eating too many greasy foods can lead to gallstones; drinking too much precipitates a variety of problems, including damage to one's liver and birth defects, such as fetal alcohol syndrome; and being under too much emotional stress can cause sickness by itself as well as exacerbate most illness conditions. To provide a more complex example, high blood pressure is commonly seen to result from any number of sources of bodily imbalance (Garro, 1988). Although the most frequently cited cause for high blood pressure is that of being under too much emotional stress or having too many worries, a number of other catalysts included overexertion or working too hard, drinking too much alcohol, eating too much of particular foods (e.g., salt or greasy foods), and being overweight. These can act either singly or jointly. The same set of multicausal possibilities may be used to explain diabetes, though for this illness the most commonly given explanation centered on ingesting too much sugar through either foods or alcohol, or being overweight as a consequence of eating too much, particularly sweets.

White Man's Sickness. "White man's illnesses" are seen as occurring after Europeans came to North America. This phrase is commonly coupled with measles, chickenpox, tuberculosis, high blood pressure, diabetes, and cancer. To use the label of "white man's sickness" is to make a statement, at times with overt political overtones, about the social epidemiology of these diseases, embedding their presence in the community within the continuing disruption and destruction of the Anishinaabe way of life. Reference to "white man's sicknesses" affirms that these diseases were introduced by European settlers. Health problems linked to alcohol may also be

referred to as "white man's sickness" since alcohol was not present before contact with Europeans. Discussions about diabetes, high blood pressure, and cancer often highlighted strongly articulated contrasts between the healthy and fortifying foods obtained through Anishinaabe subsistence activities in the past and the comparatively unhealthy reliance on the store-bought foods of the Anishinaabe present. For some, it was simply the inferiority of the present day foods that predisposed one to illness whereas "wild food" was inherently fortifying. There were several explicit comments targeting the large amount of junk food and sugar laden foods eaten by the Anishinaabeg in the present day. By far the most commonly cited source of bodily disturbance associated with "white man's sickness" was the contaminating and rather insidious omnipresence of "poisons" in comestibles. These "poisons" included chemicals and other substances sprayed on crops and injected into animals as well as those added during food processing and canning. Referring to diabetes, high blood pressure or cancer as "white man's sicknesses" shifts responsibility away from the individual (e.g., for eating too much sugar) to a societal etiology that is based in outside actions and is consistent with the local perception that contemporary Anishinaabeg are powerless to reverse such trends. Actions taken in response to illness, including "white man's sicknesses," relate to causal understandings (Garro, 1996, 2000a). Still, only a few individuals (Garro, 1995) consistently affirmed the primacy of "white man's sickness" in accounting for a given illness. It was more common for individuals to mix this explanation with other potential sources of bodily imbalance.

Anishinaabe Sickness. Hallowell (1960, p. 410) maintained that the "causes of illness are sought by the Ojibwa within their web of interpersonal relations, rather than apart from it." This assessment remains relevant to an understanding of Anishinaabe sickness. Three features recurred across the case histories and apply to the two explanatory frameworks mentioned below: (1) sickness originates in discrete and identifiable, or potentially knowable, actions of human beings, alive or dead; (2) it involves breaches of certain rules that govern social relationships within the Anishinaabe behavioral environment; and (3) effective redress can be achieved only through the guidance of other-than-human persons.

Most visits to a medicine person take place when one or both of two explanatory frameworks are suspected.

The first is “bad medicine”; its use contravenes the high cultural value on an individual’s right to autonomy (Black, 1977a, p. 150). Although “bad medicine” often strikes the intended target, there is some unpredictability in its use; victims may accidentally come into contact with “bad medicine” and suffer unintended consequences. In addition to causing direct harm to others, “bad medicine” can be used, for example, to win a competition, to induce someone to fall in love with the user, or to influence a courtroom judge to dismiss charges. Other misfortunes include flat tires, losing a talent contest, a house fire, minor physical problems such as backaches and headaches, striking alterations in an individual’s behavior, loss of a spouse’s affection, seemingly accidental injuries, acute illnesses and prolonged illnesses, “twisted mouth,” miscarriages, and sudden death. A series of misfortunes or even relatively minor illnesses and/or events may raise suspicions that “bad medicine” may be involved, suspicions that may not be acted upon, at least not immediately, but kept in mind and reevaluated in the future in light of other events (Garro, 1998). The ability of a medicine person to remove “bad medicine” from a person or otherwise counteract its effects depends on the relative powers of the sender and the medicine person. The ability to wield “bad medicine” is hidden and not advertised; it is understood that a skilled user’s private evil intent may be masked by public amiability.

The second explanation for Anishinaabe sickness links illness and other problems to transgressions that lie outside the realm of everyday and observable interactions between normal living human beings. Participation in the Anishinaabe behavioral environment requires that one enters into respectful relationships with other animate beings, with obligations to behave appropriately toward sources of power. In addition, it is imperative that obligations to other-than-human persons be fulfilled. When these respectful relations and obligations are breached, illness and misfortune may result. The term *ondjine* is used to indicate an illness or misfortune has occurred “for a reason,” with the reason attributable to something that someone did at some point in the past. It is typically under the guidance of a medicine person that the individual gains insight into the specific circumstances under which normative expectations were breached. Recalling the past incident is an integral part of treatment; through the medium of the medicine person the other-than-human persons convey what needs to be done to make amends for the past incident and may make other requests for the

future. These behests may include such things as holding an annual feast, preparing offerings, or participating in an annual Sun Dance.

There are many different actions with the potential to result in *ondjine* (see Garro, 1990, 2000b, 2001, 2002). The most common explanation for *ondjine* involves improper relationships between human beings and animals, such as causing an animal to suffer or to otherwise interfere with its autonomy. Such interference is considered a violation of norms governing social relationships. Animals may be killed to sustain human life, but this must be done gratefully and without causing undue suffering. *Ondjine* is also an inevitable consequence of the use of “bad medicine.” Any crippling illness or painful death may be seen as a confirmation that the afflicted individual or a close family member has used “bad medicine” (see Garro, 1990; Hollowell, 1942, p. 77).

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

The local health center tries to ensure the health of the expectant mother and her unborn child through prenatal classes, home visits, and by “arranging prenatal care and other help during pregnancy. Canadian government actions and resources relating to maternal and child health have contributed to reduced infant mortality. Almost all births take place in hospitals about an hour’s drive away.

For those who recognize Anishinaabe sickness, during pregnancy, an unborn child is considered vulnerable to *ondjine* and birth defects may be attributed to something the mother did when pregnant (or, rarely, the father). Interaction with animals is to be avoided, as is staring at or making fun of a mentally or physically handicapped person (which could lead to one’s child being born with the same disability). If steps to acknowledge and redress a transgression are not taken, *ondjine* can continue to affect subsequent births. A miscarriage may also raise concerns about “bad medicine”.

Life is respected and comments made about contraception and abortions censured such practices. Actions with the potential to interfere with beings who wish to be born can result in *ondjine*. This was the explanation converged upon by several women discussing another woman who had an abortion in her teens and was now unable to carry other pregnancies to term. A woman with a very large

family was told by a medicine person that her chronic lower back pain was due to *ondjine* caused by the sterilization procedure carried out by the doctor after the birth of her last child. Another expressed similar concerns about taking birth control pills. (Yet, birth control pills were dispensed at the health center and one herbalist said that she was at times asked to make a medicine that could help bring on a menstrual period for a woman who was “late.”)

Infancy

The health center encourages breast-feeding through home visits. This is seen as an important public health concern for the Canadian Aboriginal population because of the potential impact on elevated morbidity rates for infectious diseases (Martens & Young, 1997) and rates of breast-feeding for Aboriginal women in Manitoba are considerably lower than non-Aboriginal women (Hildes-Ripstein, 1998). Another activity to which health center staff devote considerable effort is a vaccination program for infants and children. A yearly, and popular, baby show is sponsored by the health center with the judging based on vaccination records, breast-feeding, and other health promoting activities.

When infants cry and cannot be comforted a number of possible reasons may be considered—teething, a temperature, or simply a child just “born” that way. One often-considered possibility for the fussiness of a “colicky” infant is that this signals the need for the child to be given an Anishinaabe name. An Anishinaabe name confers some protection on the infant and serves to establish relationships between the child and other-than-human persons. The power to bestow names is a gift given to some individuals in the community. A feast for those invited is given at the time that the name is bestowed and commemorative feasts are given in subsequent years.

Childhood

A central goal for Ojibwa individuals is “not to be controlled by one’s ‘environment’ including other people” with “acts that are attempts to control others ... negatively evaluated” (Black, 1977, p. 145). Even in childhood, autonomy is respected and parents tend not to interfere with what children choose to do. Children are allowed considerable scope to discover the world for themselves and learn from mishaps. Providing food and shelter for children is the responsibility of the parents, but bedtimes,

eating times and what is eaten are essentially under the control of the child. Parents have expressed concerns about health education programs that instruct parents about what children should eat or what children should do. Physical punishment of children is rare, and like spousal abuse, the instances recorded involved occasions when the perpetrator was seen to be under the influence of alcohol or “bad medicine”. Adults help children learn about responsibilities to others and standards for respectful behavior through their actions but do not overtly control the actions of children, though there may be some verbal commands to desist when children are particularly noisy or troublesome. Many transgressions that later in life result in *ondjine* are remembered as occurring during childhood.

Many children still speak Anishinaabemowin as their first language and others receive instruction through the school system. Like many other First Nations schools, an original language program is an integral part of education efforts.

Adolescence

Suicide, alcohol, the use of drugs, sniffing (solvents, glue, and gasoline), break-ins, and vandalism among adolescents are significant concerns for community members. Living in a community with a high level of unemployment and low incomes dependent on social assistance, many youth do not see the future as having much to offer. Manitoba has the lowest rate of school attendance among Aboriginal youth of any province or territory in Canada. At the time of the 1996 census, only 44.1% of those aged 15–24 reported attending school either full or part-time, with a considerable gap in school attendance between Aboriginal and non-Aboriginal youth (Hallett, 2000). Many of the youths who do not attend school are also not employed (37.5% of Aboriginal youths) and Aboriginal youths in Manitoba are 3.5 times more likely to be unemployed as non-Aboriginal youths. Aboriginal youths are over-represented in correctional facilities and in urban gangs (Hallett, 2000). Teen births also occur at a rate three times higher for “status Indians” than for others in the province.

Adulthood

National figures show Aboriginal women having fewer children, steadily declining from an average of 5.7 births

per woman in 1970 to 2.55 in 1995 (Hallett, 2000). In recent years, many men and women return to the classroom as adults to make up for missed educational opportunities or to acquire new skills.

The start of menstruation adds an additional expectation for women's behavior. Menstrual blood is considered to have the power to cause illness in males and there were several cases involving young boys who were inadvertently affected. Women are expected to respect this power through appropriate behavior. While the danger is greatest when a woman is menstruating, generally speaking, women should not step over a male or even over a piece of clothing that will later be used by a male, and women should take care that males do not use the same bath towels. There are other associated proscriptions. Hunting may be unsuccessful if women touch hunting equipment, such as guns, while they are menstruating. The objects used by a medicine person should also not come near or into contact with menstruating women. Women who are gifted only come to be known as medicine persons after menopause.

When adults in the community talk about the "old days," reference is being made, not to some time beyond individual memory, but to time within an individual's lifetime, before the introduction of social assistance programs like welfare in the 1950s. The time before is recalled as one when people worked much harder and had little material wealth. Young people assumed more responsibility and had chores to carry out every day. Gardens were more common, as was home canning. Game was more available as were plant foods that could be gathered in the nearby bush. Simply prepared fish, stews, and bannock (bread) were everyday mainstays. But, by those who remember, this harder life was also considered a healthier life. There were no sodas or other junk foods. Wild meats, fish, and gathered foods were seen as more fortifying. Diabetes and high blood pressure were unknown diseases.

The Aged

Elders are treated with respect and are often consulted for advice. For example, as part of the transfer of control process, the health center's director and staff decided to consult with a group of elders on a regular basis and especially before implementing any changes in their services or policy. Although being a respected elder is a matter of recognition rather than something achieved simply by

age, a party given for elders invited everyone over the age of 55. At the same time, an increasing number of elders are living on their own, although if grown children are still living in the community they are often nearby and visit often. Increasingly, the long-term consequences of diabetes are evident—including blindness, renal failure, and amputations.

Dying and Death

Most individuals have wide kinship connections throughout the community and a funeral often led to the cessation of most activities because many were in attendance. Prior to the burial, wakes can last for three days and three nights. Offerings, of food or drink, are often left on top of graves. Graves must be treated respectfully or it is said that *ondjine* may result. A man said to steal whisky and tobacco from graves became an alcoholic and his death was the result of drinking. A man who stepped on a grave over the location where the head was buried was said to have become bald because of this.

Interpersonal relationships may continue after death. It is not uncommon for an individual to dream of someone who is dead and be informed about something new through this encounter. Such interactions can become problematic, however, when the dead person desires to be joined by another family member, usually a beloved child. The dead person's efforts to bring this about results in the living person's enduring despondency over the preceding death and typically the individual regularly dreams of the dead person. These indicators of the dead person's continued and quite real presence in the living person's daily life suggest the need for the intercession of a medicine person lest the dead person's desire be realized.

Oklahoma Choctaw

Joseph Neil Henderson and Linda Carson Henderson

ALTERNATIVE NAMES

The official name for the tribe is the Choctaw Nation of Oklahoma. Other terms that are locally used include “Choctaws,” and sometimes “Chocs.” The linguistically correct name is “Chattah.” This is occasionally used by native speakers in oral discourse and for some official occasions such as tribal ceremonies and, on occasion, at political speeches.

The two largest Federally recognized Choctaw tribes are the Oklahoma Choctaw and the Mississippi Choctaw who live on a Federal reservation north of Jackson, Mississippi. They are descendants of families that were not removed to Indian Territory. These Choctaw tribes are not politically affiliated with each other, although there are friendly relations between the two.

LOCATION AND LINGUISTIC AFFILIATION

At European contact time, the Choctaws were on lands mapped today as Mississippi, and had dispersion that also reached into present day northern Florida, Georgia, Alabama, Louisiana, and Arkansas. Today, the Oklahoma Choctaws are located in the southeastern quadrant of Oklahoma, with the administrative headquarters in Durant, Oklahoma. At Tushkahoma, Oklahoma, is the tribe's council house used into the early 1900s, but now

occupying a largely symbolic tie to the past. The Choctaw Nation of Oklahoma is bounded on the west by the territory of the Chickasaw Nation, and to the north is the Creek Nation.

The current location is the product of the creation of Indian Territory in the early 19th century. The earliest mapping of Indian Territory, in preparation for “receiving” the southeastern natives, assigned the Choctaws the entire lower portion (east to west) of the land. Later, this was divided in half so that the western half of the former Choctaw land was made available for the natives from the plains. Then, later, the Choctaw land was cut in half again to assign the Chickasaws adjacent land (McKee, 1989).

Today, the former Indian Territory is the State of Oklahoma. As a result of its Indian Territory history, it has 37 Federally recognized tribes. However, the Oklahoma Choctaws, like the other Oklahoma tribes, have only tiny fractions of their former Indian Territory land space that is reservation status. The old tribal boundary lines still exist, but the State of Oklahoma is co-mapped onto them.

Linguistically, the Oklahoma Choctaws are Muskogean speakers (Swanton, 1946). There are numerous native speakers living. However, language extinction is a real risk. The tribe has language courses offered on the internet, and at one time required those working at the tribal headquarters to take Choctaw language courses during the work day, if they did not speak the language.

OVERVIEW OF THE CULTURE

Before contact time, Choctaws lived in the southeastern woodlands and were intensive horticulturists. Primary food items included corn, beans, squash, pumpkins, and meat items from deer, rabbit, turtle, birds, fish, and others. Their neighbors were the Chickasaw, Creek, Cherokee, and Seminoles. The Choctaws were encountered by the DeSoto Expedition and were reported to have extensive body tattoos, forehead flattening, and short hair styles. They also used bow and arrows, blow guns, and snares for trapping land animals and for fishing. Ceramics and baskets were also commonly used for storage, cooking, and carrying. Extensive foot trails facilitated travel and communication. The society was organized as matrilineages and politically structured as a chiefdom at contact time (Galloway, 1995; McKee, 1989; Swanton, 1946).

Today, the population of the Oklahoma Choctaw living in Oklahoma is about 40,000. The total enrollment of the tribe is over 200,000. The southeastern portion of Oklahoma is woodlands with rivers and rolling hills whose elevations reach about 2,500 feet. The highest elevations are in the east, and the lower, flatter lands are in the west. It is in the higher elevations with lower population density where tribal members note that the most traditional Choctaws live. "Traditional," or colloquially, "following the old ways," is indicated by speaking the native language, living on old allotment lands, being as separate from the local white society as possible, going to an "Indian Church," eating traditional foods, and engaging in Choctaw rituals. However, two communities, considered by many to be "traditional," are located inside the former Choctaw boundaries which are now designated as Chickasaw. In spite of the category "traditional" and its unstated opposite "progressive," the best approach to understand contemporary Choctaw culture is to assume great heterogeneity in all aspects of culture.

Religion is based on exposure to Protestant missionaries from the early 18th century. While many Choctaws go to the conventional Protestant churches in the Oklahoma towns of the area, many Choctaws go to "Indian Churches." These are located remotely, may or may not have an ordained pastor, and often are conducted in Choctaw language only. The Indian Church is actually a hub of community cultural dynamics. In addition to the church building which looks like a small Christian chapel with steeple, the surrounding few acres have family

"camp houses" used for weekends or longer stays. The Indian Church provides an exclusive place away from the otherwise dominant white society. It is here that cultural identification is fully reinforced, communications and alliances maintained, and children enculturated in Choctaw ways.

It should also be noted that many non-Christian beliefs are present and actively practiced. These include beliefs about cosmology, ghosts, disease-object intrusion, love medicine, use of traditional "Indian doctors" which are called "*Chattah alikehi*" (Choctaw "doctors"), belief of medicinal (i.e., supernatural) power in eagle feathers, releasing "medicine" in sage and cedar through smudging, and use of numerous herbal remedies.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

Many of today's late middle aged and older aged Choctaws had been forced to go to Indian Schools operated by the Bureau of Indian Affairs or by denominational interests. In these schools, the tribal culture was devalued and punishment meted for speaking their native language. The chiefs, at the time of removal from their homelands, were rewarded for being "progressive" by the government of the United States. The Chief today is elected according to a tribal constitution modeled after the U.S. constitution (Faiman-Silva, 1997). However, there are some who still prefer to have a model of government that is based more on the pre-removal form of governance.

The Oklahoma Choctaw tribe is now also a multi-million dollar corporation. The Chief serves much like a CEO (Chief Executive Officer) with the responsibility of many diverse for-profit businesses. The tribe is proud of its economic successes and has received awards of commendation from the U.S. government for innovation in enterprises. The Chief is informed and counseled by an Assistant Chief, and a 12-member tribal council, all of whom are elected. It is fortunate that the success of the economic engine of the tribe has been, in part, applied to the health and social service provisions owned and operated by the tribe.

The economy is one based on participation in the area's commerce that includes, labor, farming, manufacturing, lumber, and other ordinary jobs. The tribe

also engages in business development of its own. The tribe now operates several gaming facilities, several “travel plazas” which are convenience stores with fuel and gaming, “smoke shops” with discount tobacco products, and several other smaller operations including pre-fabricated housing manufacturing.

Since 1985, all Choctaw health care facilities have been managed by the tribe under the auspices of the Indian Self-Determination Act (Indian Health Service, 2000). There is a contract between the Oklahoma City Area Office of the Indian Health Service and the Health Service Authority of the Choctaw Nation. Federal funds are provided for tribal use each year and technical assistance is provided by Indian Health Service personnel. Physicians and other health care professionals may be either commissioned officers of the Public Health Service or direct employees of the Choctaw tribe. Currently, the majority of providers are direct employees of the Choctaw Nation, and many are members of the tribe.

The Choctaw Nation of Oklahoma is the first tribe in the United States to build its own hospital. The Choctaw Health Services Authority manages the hospital at Talihina, Oklahoma, and four health centers located in the towns of McAlester, Hugo, Poteau, and Broken Bow. The Broken Bow Health Center has two staff physicians to service 10,800 outpatient visits annually while support staff care for an additional 5,000. The Hugo Health Center and McAlester Health Center each have one physician and one physician’s assistant. They manage 11,000 outpatient visits a year. Information about staff and outpatient visits at Poteau was not available at the time of this writing.

The hospital and the clinics annually log about 48,000 patient visits. The patient seeking services must be a member of any federally recognized tribe and, must reside in the Choctaw Nation Health Service Area. Tribal facilities cannot provide a full range of health care, and it may be required that the patient be treated elsewhere. Unfortunately, prejudice remains toward Choctaws. For some, the prospect of obtaining needed services in the White community is considered undesirable and may result in a demeaning experience. Nonetheless, non-tribal care is an extremely important element of the health care delivery system although care must be authorized through the Contract Health Service Program. Costs remaining after Medicare, Medicaid, VA, Worker’s Compensation, Title XIX, and/or group health insurance is used, is paid by the tribe.

Diabetes mellitus II (adult onset) is a particular problem for most tribes, and the Oklahoma Choctaw are no exception. The American Diabetes Association states diabetics should receive their care from a physician-coordinated team. Such teams include, but are not limited to, physicians, nurses, dieticians, and mental health professionals with expertise in diabetes (American Diabetes Association, 1998). The Diabetes Clinic at the Choctaw Nation Hospital provides high-risk diabetic patients with a comprehensive multidisciplinary program. Staff includes physicians, nurses, a podiatrist, a nutritionist, certified diabetes educators, and mental health practitioners.

The Choctaw Nation also has numerous other health and social services. These include emergency medical service, drug and alcohol testing, substance abuse recovery program, mail order pharmacy, eyeglasses, dentures, and hearing aid clinics. Also, other services include child care assistance, day care, food distribution, Head Start programs, Indian Child Welfare programs, low income home energy assistance, nutrition services for elders (55+), vocational rehabilitation, and Women, Infant, and Children (WIC) programs.

Living conditions vary widely among the Choctaw, from one-bedroom homes in need of repair with a wood stove, cold water, and outhouse, to three-bedroom centrally heated homes with contemporary furnishings. Many elders reside in small “Indian homes,” which have running hot and cold water and adequate plumbing. These “Indian homes” are federally subsidized housing provided under strict eligibility requirements. Living rooms sometimes doubled as sleeping quarters for extended family (Faiman-Silva, 1997). The Choctaw nation is committed, however, to providing support to elders in order to improve living conditions. Aid includes the availability of affordable rental housing, Indian Housing, the tribally funded Housing Improvement Program, and the Bureau of Indian Affairs Housing Improvement Program. Renovations may be done with tribal assistance. Heat assistance is also available.

MEDICAL PRACTITIONERS

Since about 1955 when the Indian Health Service (IHS) was established, most tribes have had allopathic physicians providing basic primary care at modest clinics and hospitals on tribal lands. In recent years, many tribes have

elected to take over the cost of operating their own health care facilities independent of the Indian Health Service. Yet, the ability to do so is uneven across tribes and leaves some with excellent services and some with suboptimal care. The IHS itself estimates that it can meet only half of the needed primary care for tribes.

Other types of health care providers are numerous. These include licensed nurses, physician assistants, psychologists, social service staff, nutritionists, and podiatrists. Podiatric service is connected to the high rate of diabetes mellitus and consequent foot trauma. Nutritional counseling is also available through programs of the Women, Infant, Children early nutrition and child care program of the Federal government.

In addition to physicians and other biomedically trained staff, an important part of health provision is done by tribal Community Health Representatives (CHRs). These CHRs are paraprofessionals that are members of the tribe for whom they provide services. They receive training from an Indian Health Service program. Their functions are to conduct disease screening (e.g., hypertension, diabetes), deliver health education (e.g., diet, exercise, safety), conduct in-home visitation, broker information/resources, and provide transportation to health care services. The number of CHRs for the Oklahoma Choctaw is about thirty and these are mainly women. Their value as part of an ongoing health promotion program for family members of all ages is extremely high.

Each CHR travels many thousands of miles per year because of the predominately rural nature of the Choctaw Nation. The Indian Health Service provides a four-door, medium sized car for each CHR. This vehicle is used to go to clients' homes, no matter how remote, and to transport clients to the tribal clinics and hospital. CHRs also have required in-service education to maintain expertise on the topics germane to their paraprofessional role. On a regular basis, the CHRs will conduct health fairs which are done in communities large and small. The purpose of CHR tribal health fairs is to bring the health education, screening, and resource information sharing to a community-level population base.

CHRs are evenly distributed geographically across the Choctaw Nation based on population. The land base comprises ten and one-half counties of the State of Oklahoma. Each of the ten counties has a tribal "Field Office" which is the place for many activities such as senior meals, speakers, and other social functions. Also, the Field Offices serve as office space for the Women,

Infant, and Children programs, CHRs, and workers in other programs. The CHRs generally live in the area that they serve. In towns that are larger than most of the rural towns, there may be two CHRs working. However, most of the counties have one CHR. Their case loads range from about 30 to 60 clients per month.

The "cultural distribution" of the CHR is not absolutely fixed, but has a trend toward having a CHR who is fluent in Choctaw in the regions where more people are most comfortable speaking Choctaw. In these areas are found those with the strongest cultural identification with the old ways and some elders who are monolingual Choctaw speakers. Since CHRs are educators and recipients of information related to their clients' personal health and family related matters, having CHRs whose cultural identification and language skills are most similar to the client base is seen as helpful.

Outside the establishment provider groups is the traditional healer. This person is the "*Chattah alikchi*," or "Choctaw doctor," in today's idiom. The *alikchi* occupies the role of the spiritual healer and probably, in some instances, is close to the definition of shaman. Originally, it did not mean "doctor" in the contemporary sense that a doctor is a physician who treats biomedical disease based on allopathic theory. *Alikchi* is a morpheme that means "supernaturally connected." It was applied to a person, male or female, who had specific supernatural connections via training as a child by the "little people." These people are considered to be inhabitants of the local woods and have supernatural capabilities. Many Choctaw people believe that these entities are still present. The "little people" were said to capture a child at play, take them to their home in the woods, and train them to be *alikchi*. Their skills would be applied only as an adult.

The notion of healer is conceptualized today in three separate categories. First, is the *Chattah alikchi* who is specifically a Choctaw person with supernatural healing capacity. There are vague references indicating that *Chattah alikchi* can use their power to do harm as well as good. Second, there is the category of *alikchi* meaning a Native American person who may be Choctaw but could be a member of another neighboring tribe such as the Creek or Chickasaw. Sometimes, however, the designation of *alikchi* is applied to someone more culturally removed from Choctaws, such as a Comanche person in southwestern Oklahoma. The distinctive features for inclusion in this category are; being Native American, and having an accepted capacity to heal based on tribal

ethnomedical constructs. Third, *alikchi* is used in Choctaw language discourse to refer to allopathically trained, non-Native American physicians who are encountered in the tribal health services or surrounding community. In this usage, *alikchi* is synonymous with “doctor,” as used by the non-Native American population.

In contemporary Oklahoma Choctaw life, *Chattah alikchi* occupy a somewhat vague position in terms of contemporary practice. From data collected about degrees of cultural identification by one of the authors (LCH), 14 of 30 elder interviewees acknowledged the existence of *Chattah alikchi*. However, only eight discussed using *Chattah alikchi* themselves. Moreover, information of the specific whereabouts of *Chattah alikchi* was not forthcoming. In summary, the fully practicing *Chattah alikchi* may be rare in practice, but common in cultural consciousness.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

The Oklahoma Choctaw have experienced generations of contemporary American education and life experience. Most of the Choctaw population are subscribers to the biomedical model and are participants in it via the health care services provided by the Indian Health Service or the tribal health care operations staffed by conventionally trained personnel. However, medical pluralism is present as indicated by the use of culturally derived healers, as reported herein.

The contemporary Oklahoma Choctaws have a cultural history imbued with multiple explanatory models for health and disease. Although many of the “old ways” are shielded from outsiders, there are reported instances of practices derived from disease-object intrusion theory. For example, a report of shoulder pain was treated with superficial skin incisions over the site of pain, direct application of the mouth to the incisions, sucking of the incision site, and showing the disease-object (a “spider-like” mass) to the patient. Also, a type of “soul loss” is known to the tribal members, although no current reports of an instance of this have been reported. An entity known as “*impashilup*” (literally, “eater [of the] spirit”) would enter the body and consume the soul. Prevention was to abstain from destructive or morose thoughts. Cure is not currently known.

Medicine bags (*baht inkwish*, literally, “bag” “medicine”) made of animal skin and containing plant and mineral material considered to have “medicine” were widely used in the past, and, many Choctaw people have their own medicine bags today. They are used to ward off problems and give “medicine” (i.e., protective power) to the holder.

Although historically the use of communal sweat lodges was not found within the Oklahoma Choctaw culture (sweat lodges for one person were common), the use of communal sweat lodges has increased within the Choctaw Nation, as well as in other parts of Indian Country, in the post-World War II era. The sweat lodges have been especially useful in the treatment of drug and alcohol abuse, incorporating traditional healing with accepted counseling modalities.

Diabetes mellitus afflicts one out of every five American Indians. Yet, according to the Diabetes Quality Improvement Project, in 1996, the Indian Health Service received \$1,578 per capita to care for its population compared with \$3,920 per capita expended for the U.S. civilian population (Acton et al., 2001). Moreover, the rate and degree of severity of the disease within the American Indian population is higher than that of the rate and severity within the general U.S. population. Additionally, American Indian diabetics are four times more likely than their White counterparts to experience an amputation as a consequence of diabetes and six times more likely to experience kidney failure. In Oklahoma, where the Choctaws are one of the largest tribes of 37 federally recognized tribes, 24% of Oklahoma Indians have diabetic retinopathy (American Diabetes Association, 2002).

Improving diabetic health status among Oklahoma Choctaw could well be possible. Recent insights about the cultural dynamics of Oklahoma Choctaw diabetic health behavior constitute a crucially important component for the biocultural appreciation of the disease (Henderson, 2002). Sixty subjects (30 diabetics and 30 health care providers) were interviewed. All subjects were classified as either identifying strongly with Choctaw culture or identifying strongly with White culture. Subjects that identified strongly with the “old Choctaw ways” were *less* likely to understand the biology of the disease and to see the disease and its sequelae as an expected part of one’s life. However, Choctaws subjects who had a strong cultural identification with the larger White community were more likely to know the basic biology of the disease and to comply with medical treatments and advice. Moreover,

the majority of health care provider subjects that treated these patients did not consider the Choctaw patient's cultural identification position relevant to their clinical work. However, the few health care providers who are themselves Choctaw and who identified strongly with Choctaw culture recognized the relevance of cultural differences to treatment practices within the Choctaw community. The result is that while diabetes is one disease, there are at least four variant models for diabetes operating in the community.

The four models, based on this sample, first include those Choctaws that strongly identified with the "old Choctaw ways." This explanatory model normalized the symptoms of the disease, made compliance an undesirable connection to the White establishment, and rendered disease sequelae such as amputation and renal insufficiency expected life course events for "Indian" diabetics. Second, those Choctaws that strongly identified with mainstream American White society had an explanatory model of diabetes that is similar to "Whites" and were more likely to comply with interventionists' recommendations. Third, the dominant explanatory model of the providers was one which recognized that there were Choctaws that follow the "old ways" and those that do not, but believe that these two positions are not relevant to their practice, treatment, or intervention efforts. Last, those providers who were Choctaw and identified strongly with the "old Choctaw ways," considered the cultural identification position of Choctaw diabetics very significant in the development of treatment approaches for them. Accounting for these multiple models of diabetes in intervention and prevention efforts could greatly improve diabetic health status.

SEXUALITY AND REPRODUCTION

Partner selection mainly follows the larger American society practices. However, there is extant an admonition to preserve Choctaw ancestry as fully as possible. This promotes a pressure to court and marry only members of the tribe. Secondly, there is acceptance of marriage with a member of another tribe. Nonetheless, it is common for Choctaws to marry members of the majority population.

Children are desired, but do not constitute a type of kinship wealth. They are generally well cared-for largely in the context of a nuclear family setting. However, there is some greater sense of corporate child care across family

kindred groups than in the local White society. This is most observable when families have maintained their former allotment lands and live in clustered home sites. Such home sites typically have houses grouped together with about 20–75 yards separating them. These clustered home sites have produced good-natured jokes about those families that refer to them living on the "rez." This is considered a humorous analog to tribes that do live on Federal reservation land, unlike the Oklahoma Choctaw.

HEALTH THROUGH THE LIFE CYCLE

The items below represent main trends in overt behavior. Cultural heterogeneity allows for many conceptual and behavioral variations that may be linked to the earlier Choctaw practices but that are privately held or selectively revealed.

Pregnancy and Birth

The exposure to American educational institutions and the biomedical model via the Indian Health Service has lead to a Choctaw model of pregnancy and birth that is largely based on contemporary American patterns. Today, virtually all births occur in hospitals whether it is the tribal hospital or in a non-Indian local hospital. However, before the last decade, prenatal care was not easily available due to many barriers, such as rural distances to care, transportation limitations, financial limitations, and cultural barriers. It was also not uncommon for women in labor who could not reach the tribal hospital to go to a non-Indian hospital parking lot, stay in the car throughout labor, and when delivery was imminent, present themselves at the emergency room. In so doing, they were assured of receiving obstetrical care, albeit on an emergency basis.

Elder women today tell of labor and delivery in the early Choctaw hospital built in 1916. Women of that era did use indigenous herbal teas to ease and speed labor. These were brought by family members to the hospital, kept in a jar under the bed, and used by the patient. Also, the indigenously preferred position of delivery was probably a squatting position based on reports of women who would get in a squatting position in the hospital bed. However, these reports conclude with the expectant mother being wheeled from the ward to a delivery room where the patient was placed in the supine position.

Infancy

The exposure to American educational institutions and the biomedical model via the Indian Health Service has led to a Choctaw model of infancy that is largely based on contemporary American patterns. However, there is sufficient concern for some mother–infant pairs regarding nutrition and parenting that a strong Women–Infant–Children program is available throughout the tribal area. Mothers will come to one of ten “Field Offices” operated by the Choctaw Nation. These Field Offices typically are brick buildings with about 1,000 square feet of space. They have a common room for meals and meetings as well as offices for project coordinators who administer nutrition projects, family resources (e.g., parenting, domestic abuse) assistance, and Community Health Representatives. The infants can be brought to these locations for basic anthropometric measurements to screen for developmental indicators. The mothers also receive health education information from the staff and by print materials. They can also obtain nutritional supplements for the infant.

Childhood

All children receive education in the local public schools. There are Head Start programs that are well attended and to which tribally owned buses transport the children from remote rural locations. However, there is a problem with proper childhood nutrition that many believe results in adult onset diabetes mellitus, and an increasing concern about a rising incidence of Type II diabetes in childhood. The Choctaw Nation is currently expanding its diabetes education base to include elementary school children because primary prevention strategies are of utmost importance to diabetes control.

Adolescence

Choctaw adolescents attend local public middle and high schools where they are exposed to a typical American curriculum regarding the sciences and health. There is a significant problem with smoking rates that is compounded by Oklahoma’s dubious distinction as the state with the highest use of tobacco products. Moreover, there is some cultural impetus for tobacco use that relates to tobacco as a sacred substance. Many advertisements in American Indian newspapers advocate “Traditional Use, Not Abuse.” However, adolescent tobacco use remains high.

There is also an increasing prevalence of obesity in this age group. Consequently, Type II diabetes is as much a health concern for adolescents as it is for adults. There are new programs for adolescents that emphasize diet and exercise. Also, cultural messages that relate to the early days of American Indian life in which there was no obesity or diabetes are becoming more common. The current epidemic of obesity and diabetes is blamed on the “white man,” or “civilization.”

Adulthood

Nutrition, exercise, and substance abuse are the main health issues of adulthood. The health care program of the tribe has aggressively responded to these in the last several years. As with other non-Indian programs responding to these matters, it has proven difficult to have a total success with these health problems.

Substance abuse is a problem of sufficient magnitude that special programs have been developed. A special inpatient facility has been operated by the tribe for years and serves members of all tribes. This includes alcohol abuse as well as other substances. One component of the substance abuse program integrates the use of sweat lodges with the more conventional treatment protocols. It is considered to offer spiritual, mental, and physical purification.

The Choctaw Nation hospital has made strides to respond to adult onset diabetes (Type II) by operating a Diabetes Wellness Center. This center is staffed by endocrinologists, diabetes educators, specially trained nurses, and podiatrists. The center takes a family model approach to intervention and conducts family education for the prevention and treatment of diabetes.

Aged

Elderhood has many facets to it. First, “elder” may be a social status conferred to adults considered helpful, socially powerful, and having qualities of leadership regardless of age. Second, “elder” may also be used to indicate a person who is old regardless of social status. Last, “elderlies” is sometimes used to refer to all the old people in a tribe. In general, anyone who is considered old is accorded respect. Those who are both “old” and “elders” (i.e., the social status) receive even more respect.

Like many elders, Choctaw elders experience multiple jeopardy. They are members of a minority group (by

government definition), many are poverty-stricken, and are in poor health compared to their general population counterparts. The Indian Health Service designates those persons age 55 and older as elders. American Indian elders are living longer, due to improved public health, but they are “sicker longer” with chronic disease when compared to the general population. Indian Health Service data indicate that elders are more disabled and experience health declines at an earlier age than their White counterparts.

Assistance for Choctaws elders is also available by the provision of hearing aids, eyeglasses, dentures, canes, wheelchairs, and other disability-related equipment to those who cannot afford to purchase them. Through the U.S. Department of Agriculture, the Choctaw Nation has a food distribution program which serves over 5,000 people per month throughout the 10 counties. In addition to this program, the Nutrition and Supportive Services Programs provide meals, information and referral, transportation, and arts and crafts to Indian Senior Citizens 55 years of age or older. The program provides one meal a week at the local community centers.

Dying and Death

The influence of general American society has led to a contemporary view of dying and death that is very similar to those of the Christian church. However, there are some Choctaw people whose multi-culturalism is seen relative to death and spiritual matters. For example, some people will not walk near the cemetery of their own “Indian Church” after the sun sets because *shilup* (i.e., ghosts) come out then. An Indian Church is a remotely located church that is partly Christian and, yet, retains some Choctaw-specific beliefs. Most Indian Churches have adjacent cemeteries. For burial, a back-hoe from the county is brought out to dig the grave. Also, in addition to Christian beliefs and rituals, some will burn white sage, tobacco, and cedar and “smudge” the body prior to closing the casket lid. Then, they will smudge themselves as a rite of purification.

CHANGING HEALTH PATTERNS

Increased longevity results in the manifestation of diseases and conditions that are age associated, and typically, are chronic, incurable, and debilitating. One of

these is late life onset cognitive dysfunction due to organic brain disease (e.g., Alzheimer’s disease and vascular dementia). However, a recent genetic study suggests that Choctaws may be less likely to develop Alzheimer’s disease than Anglo-Europeans (Henderson et al., 2002). The Apolipoprotein E4 gene is associated with developing Alzheimer’s disease. From a sample of 70 people with Certificate of Degree of Indian Blood confirmation of “full blood” status, the frequency of this allele is less than 50% of White controls. However, there is speculation that vascular dementia may be more prevalent due to antecedent risk factors that are high prevalence conditions in this and other tribes (e.g., smoking, diabetes, obesity, hypertension, and alcohol abuse) (Henderson, 1994).

Linguistically, there are no Choctaw morphemes coding for the disease known in English as “Alzheimer’s Disease” (Henderson & Henderson, 2002). The closest terminological connection is “*imanokfila kanea*” (intellect lost). Other candidate morphemes, such as, “*tasembo*” (crazy) fail since they can apply to non-humans as well (e.g., dog, horse). Also, from a cultural construction of disease perspective, there are families in the Choctaw tribe in which the hallucinatory symptoms of dementia are interpreted as the person communicating with the supernatural world in preparation for death (Henderson & Henderson, 2002). As one person said of her grandmother who suffers from dementia, “She sees people we don’t see.” The granddaughter does *not* say that her grandmother “sees people that aren’t there.” The afflicted person simultaneously exhibits special capacity, reveals details about the vaguely understood “other side,” and brings a bit of mystical awe to the family. This view departs greatly from the usual medical model of pathology and consequent symptomatology due to brain cell death. Additionally, this “supernormal” construct of dementia offers an expanded window into the extensive range of interpretive models applicable to perceptible states of health and disease in the context of culture.

Roma of the United States and Europe

Anne Hartley Sutherland

ALTERNATIVE NAMES

The Roma name is one that has become common currency today, replacing the designation Gypsy which has negative connotations. Since many Roma use the term Gypsy with outsiders, and there are contexts in which Gypsy is the broader term, its use is still applicable in certain contexts and certainly appears in the literature as well as Internet search engines. In Europe and the British Isles, terms such as Romanies, Travelers or Tinkers are also used. Many different groups form the Roma population based on a common sense of belonging although they may have very different characteristics and use different names.

LOCATION AND LINGUISTIC AFFILIATION

Roma can be found in significant numbers in the United States, Europe, Russia, Middle East, North Africa, India, Pakistan, and Central Asia. Some have migrated to Australia, Hawaii, and Alaska, but as far as we know they have not reached Japan, China, or Southeast Asia. The Roma are generally believed to have originated in Northern India, but they dispersed about 1,000 years ago and have lived in other places since. Today they are located in cities and towns.

The Roma speak Romanes which is a Sanskrit based language, that belongs to the Indo-Aryan branch of Indo-European languages. Because the Roma have lived in so many places over a long period of time, Romanes contains approximately 60% loan words. The closest language to Romanes is Hindustani. All Roma speak a second or third language from the country in which they live or have traveled.

OVERVIEW OF THE CULTURE

There is no census data on the Roma in the United States, but estimates of the Roma population range between 100,000 and 300,000 members of various diverse groups (Vlach Roma, Boyash, Irish Travelers, Hungarian Roma, etc.) living in all parts of the United States. The population of Roma in Europe is estimated between 4 and 10 million, with the largest numbers concentrated in Central European and Balkan countries (as much as 5% of the population). Not all Roma are Vlach-speaking Roma, but the designation of Roma has been given a more general meaning by intellectuals among the Roma to apply to all groups who self-identify as Gypsy. There are a number of diverse Roma groups. Not all of them speak the same dialect or language or have the same cultural practices.

Different groups have taken up different occupations, including music, metal work, buying and selling horses or cars, fortune-telling (primarily women), and selling craft items. Middle-class Roma have entered the professions, but this is still a small group. Most Roma work for themselves or are occupied in menial jobs.

The Roma migrated into Eastern and Western Europe through Persia en route from India over a period of approximately 1,000 years. Theories about the origins of the Roma in India have been based on linguistic and cultural information, but recent studies in genetics indicate that the Roma indeed originated with a small group of founders splitting from a single ethnic population in the Indian subcontinent (Gresham et al., 2001). Since leaving India, Roma have always lived within another culture or country as a minority and pariah group. They have been the subjects of extreme discrimination and persecution throughout history, especially in Western and Central Europe where they were enslaved in the Middle Ages. Between 500,000 and 600,000 European Roma perished under the Nazis in World War II. In the 19th century they migrated to North and South America where they continue to be a nomadic or semi-nomadic group. In the United States where discrimination is less severe than in Central Europe and the Balkans, they still suffer negative stereotypes. Police, for example, typically view the Roma as a criminal class rather than a culture.

Roma trace descent through both parents but take on patrilineal names and have a patrilocal marriage preference. They live in a large, close, patrilocal descent group called a *vitsa*. Authority in the *vitsa* is based on age with both older women and men having the highest status. Men are powerfully situated in the system of juridical authority, and women in the complex system of religious, spiritual, and medical authority. The lowest status kinship category is the daughter-in-law or *bori*. She is expected to serve her in-laws, take on a primary role as provider and wage earner for the extended family, as well as provide children for the grandparents. Roma have no religious specialists other than older women, but they use religious specialists from local churches to conduct baptisms. In the United States their own religion is punctuated by certain rituals including the baptism of a 6-week-old child, marriage, the *pomana* (death ritual), *slava* (saint's day feast) and some American holidays such as Easter and Thanksgiving (Sutherland, 1986).

Roma in the United States generally live in urban areas, usually on main streets and in the poorer parts

of towns. They are not as easily recognizable to the American population as they are in Europe where they stand out more. In America they often prefer to represent themselves as a member of another ethnic group than Roma since it abates the stereotyping and discrimination against them. However, the women often wear long colorful skirts and low cut sleeveless blouses with a scarf on their head if they are married. One of their survival mechanisms is to keep to themselves and avoid contact with non-Roma except in work related circumstances.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

The Roma are not a healthy population. Life expectancy is up to 10 years less than in the non-Roma population, and infant mortality is up to four times higher (Braham, 1993). High levels of poverty, overcrowding and unemployment, and low levels of education are contributing factors. Their medical condition is in fact quite serious. In one study of 58 Roma in the Boston area, Thomas (1985) found that 73% exhibited hypertension, 46% diabetes, 80% hypertriglyceridemia, 67% hypercholesterolemia, 39% occlusive vascular disease, and 20% chronic renal insufficiency. Their diet is extremely high in animal fat, and their lives are very sedentary. Thomas also found that 84% were obese and 86% smoked cigarettes. All of these factors combined with high cholesterol levels, hypertension, and perhaps a genetic predisposition, result in the life expectancy of a Roma in the United States to be between 48 and 55 years (Thomas, 1987). Since births are often not registered and age at death is difficult to determine, life expectancy statistics are not exact in accuracy. However, during my fieldwork, of the eight deaths that took place, the oldest was 50 and the average age was 40 (Sutherland, 1992b). A study in Sweden noted a higher incidence of asthma and chronic bronchitis among Roma than the control group. A U.K. study also documented high incidences of obesity, heart disease, and diabetes (Lehti & Mattson, 2001). Globally their nutrition and access to clean water is poor as is their access to adequate income, housing, and education. In Russia and Central Europe, as well as in the Balkans, their health condition is seriously deteriorating.

MEDICAL PRACTITIONERS

The Roma in the United States seek medical help both from American doctors and their own *drabnari*, literally meaning older women who have knowledge of medicines. They are very assertive in seeking medical care from the medical system. Many are on welfare and have medicaid cards and therefore have access to good medical care. They have an unusual ability, given that most are illiterate, to understand our complex medical system and to get attention from medical personnel (Sutherland, 1992a). On the other hand, their insufficient knowledge of biology and medicine as well as their rudimentary vocabulary in English puts them at risk. They often do not practice preventative medicine or understand the full implications of doctors' instructions. While they may demand specific famous doctors or treatment they have heard about, they ignore preventative and long-term treatment. They have been known to share pills with each other, request specific colored pills and prefer older, physically bigger doctors over younger, thinner ones (Sutherland, 1992a,b). When a family member is sick, large numbers of relatives congregate at the hospital, sometimes camp on hospital grounds, and create confusion among medical personnel. However, they respect authority and are eager to learn about the best treatments and are supported by a huge network of relatives. One study in the United States concluded that Roma receive better medical care than other urban minorities because they are so effective at utilizing medical services (Salloway, 1973). These generalizations are not applicable to Balkan and Eastern European Roma where the discrimination is so much more severe, and where many Roma are denied access to medical care.

Some older women are medical practitioners for diseases they consider under the purview of their own group. These women may supervise treatments for the patient in addition to those ordered by the doctor. Their treatments deal with diseases they classify as "Gypsy diseases" which include convulsions based on possession by the Devil (the cure is the Devil's own dung or *Asafetida*); infection by a spirit called *Mamioro* which means "little grandmother" (the cure is her vomit prepared into tablets). Older women acting as midwives also attend childbirth to help the mother have an easier birth (a *Selaginella* plant, called St. Mary's Hand, is placed in water to open the womb—also at the deathbed to make sure the spirit leaves the room) (Sutherland, 1992a).

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

The Roma view health and illness in the larger context of social order. Good health and good fortune (many children, money) are consequences of individual diligence in following purity rules. Conversely illness, bad luck, and impurity are also closely associated with being ritually unclean (*marime*). To be ritually clean, the Roma must follow a large number of rules about washing, eating, separation of parts of the body, separation of male and female, and separation from the polluting influences of non-Roma who do not follow these rules (Sutherland, 1986). They make a distinction between illnesses caused by contact with non-Roma and their own "Gypsy illnesses." For the former they go to the American medical system, and for the later they consult their own *drabarni*. Gypsy illnesses include those caused by *Mamioro*, a spirit who visits places that are unclean and brings illness, *tosca*, a disease they translate as "nerves" is caused by the devil, as are convulsions which are a sign that the devil has entered the body of the individual. Other illnesses and bad luck are caused by *mule*, the ghosts or spirits of dead relatives. *Mule* are not necessarily harmful, but relatives of the dead who do not properly observe *pomani* (death rituals) could be made ill by them. Mental illness is rare, although virtually every Roma person I knew who was tested by a psychiatrist was diagnosed with borderline personality disorder, that is, in relation to the American view of a healthy personality (Sutherland, 1986). The cure for mental illness is for a person to follow the purity rules and other social customs such as getting married. All *drabarni* carry a bag of medicines that may include *Asafetida*, *johai* (literally meaning, ghost) which are baked pieces of the vomit of *Mamioro* (most likely is a slime mold called *Fuligo septica*) and other herbal medicines such as a fungus called "the spoon," a special herb called *drarnego*, garlic, black pepper, gold coins, and pieces of the aprons of ancestors who were *drabnari*. *Johai* is the most valuable medicine a *drabnari* carries in her medicine bag. It cures fear of ghosts, hemorrhages, influenza, pneumonia, cholera, and epileptic convulsions and is administered in addition to medicines prescribed by a doctor (Sutherland, 1992a).

SEXUALITY AND REPRODUCTION

Roma attitudes toward sex and sexuality include separation of the sexes before marriage (even close relatives), and rules about sex and sexuality based on notions of purity. Bodily substances emanating from the lower body are polluting, including sexual fluids, menstrual blood, blood from childbirth, urine, and fecal matter. These substances must be separated in touching and washing from the upper body and particularly the head which must be kept pure. Thus sex can make a person impure and liable to illness if practiced wrongly. People who engage in sexual intercourse may also abstain from all animal products on Fridays as a cleansing act. Impurity may also adversely affect fecundity which is generally welcome, children being highly valued. Roma may practice contraception or have their tubes tied when they reach the limit of family size they desire. Fecundity increases a woman's status; infertility lowers it. Oral sex is considered the most polluting act one could perform, but its prohibition also has the effect of making it the most titillating.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

Most Roma go to the hospital to give birth but neglect the important period of pre-natal care because they do not want to undergo an internal examination by an obstetrician. If a *romni* midwife delivers the baby she cleans the umbilical cord with ashes, and an amulet prepared by the *drabarni* is sewn into the baby's clothes for protection. A hospital birth will usually include a mother or older woman as an assistant rather than the father who stays outside the birth room for cleanliness reasons. An important reason that women have chosen hospital births over a *romni* midwife is to leave all polluting substances from the birth in the hospital and lessen the period of separation and isolation after birth. This period is now about 9 days instead of the traditional 6 weeks. The incidence of miscarriages and infant mortality is high. In a 1967 sample of 400 American Roma, infant mortality was 25% of all reported past pregnancies and births. Since hospital births have risen since then, infant mortality is presumed to be lower now (Sutherland, 1992b) although still higher than the control population.

A recent study (Nemenyi, 1999) of 80 Hungarian Roma women has shown that different Roma groups have different attitudes toward family planning. The Vlach (Roma) group, the most "traditional" in customs have large numbers of children by choice and practice family planning (both contraception and abortion). The Boyash practice no family planning, but the Romungro (musicians) and urban Budapest "Gypsies" have smaller families by choice with the highest level of consciousness of family planning of any Roma group. However, the Romungro and urban Roma start giving birth at a very young age. One of the most interesting conclusions of this study is that the Hungarian health care workers seemed to view all Roma women as "wild," assuming that their higher fertility was due to lack of family planning. Nemenyi also noted that the poor health conditions of the mothers and their shorter life expectancy in relation to the Hungarian population, contributed to a higher incidence of premature births in connection with early, frequent, and late deliveries and a higher amount of dystrophy, mental and physical disabilities.

Infancy

In the first 6 weeks, an infant is viewed as highly vulnerable. At birth the baby is tightly swaddled and handled only by the mother. If the mother nurses, she is told to avoid certain foods considered to produce colic (green vegetables and tomatoes). Many women choose to bottle-feed. In the first weeks of life the mother and baby are isolated from all other family members, and the windows and door to her room are kept shut to keep out a spirit of death that may come to harm the baby. Another danger to the baby is the evil eye which causes the baby to fuss and become ill. The giver of the evil eye is then asked to make a cross with spittle on the forehead of the baby to counter it. The dangers of infancy are ameliorated when the baby is baptized at about 6 weeks of age. If a baby dies, it is considered *prikaza* (a polluting misfortune) for the parents who must avoid the body of the baby (Sutherland, 1992a, 1996).

Childhood

A child is protected from illness when he or she is baptized and considered free of pollution from birth substances. Children are much loved and enjoy freedom from the restricting rules of cleanliness. They are not

susceptible to becoming defiled and are not expected to understand feelings of shame. Children, for example, may eat food prepared by non-Roma, food that adolescents must reject lest they become defiled by it. The entire extended family cares for children. They are not left alone and are included in adult social activities. They are allowed to eat sugar and fat and may develop tooth decay early. Children are indulged and allowed to run free with their cousins and only told to stop being noisy and boisterous if they bother the adults (Sutherland, 1992a, 1996).

Adolescence

A major change occurs at adolescence for both boys and girls. Adolescents are introduced to the notion of personal shame. Their bodies and their behavior are suddenly judged in terms of their control of polluting substances (menstrual blood, semen) and shameful actions (sexual contact). Girls in particular have to keep clean and observe the washing, dressing, cooking, and eating codes of women. Women's clothes are washed separately from those of men and children, and they cannot cook food for others during menstruation unless they avoid touching menstrual blood. Some girls fast during menstruation (Sutherland, 1986). Adolescents are expected to behave much like adults and to marry as early as possible. Those who experiment with drugs or sex are considered to have a social or mental problem for which marriage is a cure. Alcohol and smoking are not discouraged.

Adulthood

Married women are expected to support their husband's family and their own children. Men's income can be spent on themselves or their children. Women must serve food to their in-laws and show respect to men by not passing in front of them (unless they have a baby in their arms) or allowing their skirts to touch men. They must show modesty by wearing more traditional Roma clothes, and, if married, a head scarf (*diklo*). Adult women and men soon develop health problems such as obesity, diabetes, high cholesterol, and hypertension leading to an untimely death in many cases. At menopause or when they cease sexual relations, men and women become pure again and the cleanliness rules are eased. To encourage good health, they eat pepper, salt, vinegar, garlic, and onions (Sutherland, 1992a).

The Aged

Old people are highly regarded for their knowledge and special status as pure because menstruation and sexual relations are assumed to have ceased. The aged are politically powerful and exert a great deal of influence over the younger members of the extended family group. They are consulted on everything including arranging the marriages of their offspring and all political decisions by the group. Usually a younger person will not agree to medical procedures without the approval of their oldest relatives who often arrange the medical treatment and act as a mediator with the doctors. In the hospital an older authority figure must be involved in all decisions, and the older women may also treat the patient. The aged are surrounded by their family and cared for at home until death. They may not travel much because of illnesses, but they are at the center of all social and political life. Showing proper respect for the old is the best way of ensuring that their spirit will not carry a grudge to the grave and plague the relatives left behind. Even before a person dies their good deeds begin to take on a mythological stance, and the bad deeds are never mentioned (Sutherland, 1986).

Dying and Death

The period of dying and death constitute a personal crisis as well as a social crisis. When Roma become seriously ill, the entire community is galvanized, and doctors, hospital staff, reporters, social workers, and the police are made aware of a great happening. The Roma flock into town, camp on hospital grounds, and gather in large numbers. Dying in old age when one has prepared for death is a crisis for the *vitsa*, but it is accepted as natural. The ideal death is a "great death" for which one has prepared and that can be shared with large numbers of relatives and friends. The death of a young person, on the other hand, is an enormous tragedy and is thought to have happened because of some moral uncleanness. The relatives are so grief-stricken and fearful, they may become wild and threatening, especially to doctors. Relatives scratch their faces until they draw blood, beat themselves on the chest and head, and wail or shout plaintively to the deceased.

A person who is dying is never left alone. Relatives keep a constant vigil with the dying person to make sure they do not die with a grudge or curse on their lips, to assure that the spirit is released out an open window at the moment of death so it can roam free and leave the relatives

left behind, or to frighten death away if they see him approaching the room. The last words of the dying are very important. When the person dies, embalming is considered good to remove the blood from the body. Relatives sit with the body day and night usually in the funeral parlor.

Relatives who are in mourning abstain from washing, shaving, combing hair, or changing clothes for 3 days, at the end of which they can wash and the body is buried. A *pomana* (death feast) is held 9 days, 6 weeks, 6 months and a year after death. The *pomana* may be held in a hall or at the end of the year at the gravesite. The spirit of the dead person (*mulo*) is present at each *pomana* and is set a place to eat and drink. Relatives generally try to avoid the spirit except at the *pomana* when it is important to show the deceased that they are receiving the proper respect.

CHANGING HEALTH PATTERNS

Published literature on the health of the Roma is sparse, and there is a need for more study of their health needs and conditions (Hajioff & McKee, 2000). Recent genetic medical research has identified nine Mendelian disorders in Roma populations caused by mutations including muscular dystrophy, galactokinase deficiency, primarily congenital glaucoma, congenital myasthenia, congenital cataracts, facial dysmorphism neuropathy syndrome, and hereditary motor and sensory neuropathies (Kalaydjieva et al., 2001).

Today the Roma in Europe and the United States are increasingly transnational. In the last 25 years in Europe, and since the fall of communism, Roma have either joined the middle class or become increasingly marginalized at the bottom of the social scale where their health conditions have seriously deteriorated. This altering of the traditional social structures in a demographically young population, in addition to the loss of traditional jobs (scrap dealing and traveling sales) combined with the obstruction they meet in trying to find new ways of making a living, mean that all too often the sale of drugs or prostitution is a primary source of income. Until recently drug use by Roma had been unknown. The rise in drug use has been accompanied by the appearance of HIV infection (Sastipen Network).

Poor health, overcrowded living conditions, lack of employment, and little access to health care have created serious health problems. A number of alarming trends in health have been noted in the European Roma community. One study in Spain reported a nine times greater prevalence

of antibodies to hepatitis A in Roma children than in the non-Roma population (Cilla, Perez-Trallero, Marimon, Erdozain, & Gutierrez, 1995). Another Spanish study showed that Roma children are at particularly high risk for lead poisoning (Redondo, 1995). In Romania the Roma have one of the highest fertility rates in the region, but infant mortality is also higher than in the population at large. Life expectancy is significantly lower as well. Romani children have a higher rate of vitamin deficiency, malnutrition, anemia, dystrophy, and rickets than the non-Romani in Romania. Romania has the most AIDS-infected children in Europe due to the use of unsterilized needles, and the Romani community has also been dramatically affected. The number of cases of TB and AIDS has been growing at an alarming rate. Over half of the children in one Romani neighborhood were HIV positive according to interviews with one group of doctors (Zoon, 2001, pp. 79–80). In Bulgaria, doctors working in Romani neighborhoods identified widespread cardiovascular conditions, and kidney, liver, gastric and intestinal diseases. In one neighborhood 40 of 70 children tested positive for TB. The last reported cases of polio in Bulgaria were among Romani children (90 cases) and half were disabled by the disease. Romani children seem to have significantly low immunization coverage (Zoon, 2001, p. 90). In Macedonia the Roma infant mortality rate is twice the national average, and infants have extremely high incidences of diarrhea (52% of the women answered “yes” when asked if their infants had diarrhea in the last month) and respiratory diseases (Zoon, 2001, p. 102).

Samoa

James R. Bindon

LOCATION AND LINGUISTIC AFFILIATION

The Samoan Archipelago comprises nine volcanic islands from 13° to 15° south and 168° to 173° west. Since 1900, the islands have been divided into eastern and western moieties. The five islands in the east; Ta'u, Ofu, Olosega (the Manu'a Islands), Tutuila, and Aunu'u form the Territory of American Samoa, while the four islands to the west; Upolu, Savai'i, Manono, and Apolima make up the Independent State of Samoa (ISS). The largest population concentrations are in the Pago Pago Bay Area on Tutuila in American Samoa, and Apia on Upolu in ISS. Prior to colonial influence, there were two polities in the archipelago, separating the Manu'a Islands from the six islands to the west. All of the Samoan Islands are high volcanic islands with peaks up to 6,000 ft on Savai'i and partially encircling reef structures with nearshore lagoons.

The Samoan language falls within the Polynesian Group of the Austronesian language family. There are no significant dialect variations of Samoan, but there are important distinctions in the phonology from region to region within the islands. Samoan has a relatively elaborate lexical division between common words used for

everyday conversation (Shore, 1982) and respect or chiefly vocabulary used both for speaking to chiefs (*matai*) and between non-chiefly individuals to denote formality and politeness. Within the chiefly vocabulary, there are also alternate words used for and by chiefs (*ali'i*) and talking chiefs (*tulafale*). English is the most common second language and Samoans in American Samoa are highly bilingual in English.

OVERVIEW OF THE CULTURE

Population

Demographers agree that there were no reliable estimates of population in the Samoan Islands until the 1920s. Reports of missionaries and administrators during the 19th century vary widely in quality, and supply widely varying population counts. Commodore Wilkes based his 1839 estimate of the population on reports from local missionaries to come up with a total of about 57,000. This early figure is viewed as the least reliable of the 19th century. The first reasonably reliable census yielded a total of about 34,000 in 1853. The discrepancy between these two censuses led to speculation about severe depopulation after European contact. However, most demographers

maintain that the population of the islands was relatively stable between about 34,000 and 39,000 throughout the 19th century. This stability was the result of the typical pre-transition patterns of high fertility coupled with periodic high mortality. The 20th century saw the impact of the demographic transition on the population of the islands. Entering the century with a population of about 40,000, continued high fertility coupled with reduced mortality due to improved medical care led to a 600% increase in population by the turn of the century. The estimated population of the archipelago for July 2001 was about 250,000, with 179,058 in ISS (CIA, 2001b) and 67,084 in American Samoa (CIA, 2001a). In addition, as many as 100,000 Samoans live abroad, mainly in the United States, New Zealand, and Australia.

History

Voyagers of the Lapita culture settled in the Fiji-Tonga-Samoa area between about 1500 and 1000 BC. Contacts between Samoa, Tonga, and Fiji were maintained throughout prehistory and, later, relations were maintained with other Polynesian groups including Tokelau, Wallis, and Futuna. Significant European contact and acculturation began in 1830 when John Williams of the London Missionary Society (LMS) arrived and established his church through fortuitous political circumstances.

There was conflict for colonial control between Germany, Great Britain, and the United States until 1900 when the four islands in the west became a German colony and the five islands in the east were claimed as the Territory of American Samoa by the United States. As a result of the League of Nations actions during World War I, New Zealand assumed administration of the German colony from 1914 to 1962. Independence from New Zealand as a constitutional monarchy came in 1962 with the founding of the Independent State of Western Samoa, later changed to the Independent State of Samoa (commonly Samoa) in 1997. The eastern islands remain a United States territory, administered by the Office of Insular Affairs, U.S. Department of the Interior. The territory elected its first Samoan governor in 1977.

Economy

The traditional economy of the archipelago was based on root and tree crop farming supplemented by fishing. The economic development of the two Samoas

(ISS, American Samoa) differed dramatically throughout the 20th century as American Samoa received substantially more developmental aid from the U.S. government than Western Samoa did from New Zealand. Family remittances from overseas remain a substantial part of the economy throughout the islands. Agricultural products, featuring coconut cream, coconut oil, and copra, are responsible for 90% of the exports from ISS, and 65% of the employment is in agriculture with another 30% in service, and 5% in industry (CIA, 2001b). About 50% of adult males and 20% of adult females are in the wage economy in ISS. The economy of American Samoa is tightly intertwined with that of the United States, with tuna canned at the local cannery forming the primary export. Unemployment was 16% in 1993, with the government accounting for 33% of the jobs, tuna canneries 33%, and a variety of other industries making up the final third of jobs in American Samoa (CIA, 2001a).

Social Organization

The fundamental unit of social organization in Samoa is the *aiga* which can mean the household, the nuclear family, or the extended family. As an extended family, each *aiga* is headed by a title holder or *matai*. Traditionally each *aiga* had a specific compound with several related families living under its *matai*. Communities or villages (*nu'u*) consist of several *aiga* with long-term associations. *Nu'u* are governed by councils or *fono* in which all *matai* have a voice. The *matai* titles are divided into two general types, chiefs or *ali'i* and talking chiefs or *tulafale*, and ranked within each of these divisions from lowest to highest. The *nu'u* are independent political units but they group together into regional alliances for some purposes. This community level of organization is still important in the ISS and American Samoa, although residence has become increasingly based on the nuclear family rather than the *aiga*.

Religion

There is little remnant of traditional religion other than generalized beliefs in ancestral spirits (*aitu*). Today Samoans are overwhelmingly Christian. In ISS 99.7% of the population adheres to Christianity, about half of which belongs to the LMS derived Christian Congregationalist Church of Samoa (CCCS). The rest are Roman Catholics, Methodists, Latter-Day Saints, and Seventh-Day

Adventists (CIA, 2001b). In American Samoa the CCCS accounts for about 50% of the population, the Roman Catholic Church about another 20%, and other Protestant and non-Christian denominations about 30% (CIA, 2001a).

THE CONTEXT OF HEALTH

Health Indicators

Many 19th-century sojourners remarked on the general good health of the Samoan population (MacPherson & MacPherson, 1990). The well being of the Samoans has been attributed to a hospitable environment, an excellent vegetable- and marine-based diet, limited opportunity for infectious disease exposure from outsiders, and a high standard of personal hygiene, including frequent bathing. This good health notwithstanding, the early visitors to Samoa heard of an epidemic illness introduced by “sailing gods” long before the arrival of Europeans. This epidemic is said by one observer to resemble cholera. Other than this relatively isolated prehistoric episode, Samoans appear to have enjoyed a long, stable period of good health prior to European exposure in the 19th century. Kramer (1903/1995), because of his medical training and extended stay in Samoa, provides the best early description of medical conditions. He notes the absence of malaria and comments on the occasional presence of leprosy, the frequent occurrence of respiratory ailments (much of which he classifies as consumption or tuberculosis), and the widespread incidence of elephantiasis (filariasis), which he estimates as afflicting 5% to 10% of the population. Many other 19th-century visitors commented on the presence of elephantiasis which manifests as extreme swelling of the legs, scrotum, or breasts. While the high visibility of this disease (it was not uncommon to see Samoans with the signature swollen legs and ankles in the 1970s) accounts for some of the remarks, it is clear that this was a significant pre- or early-contact disease.

A seminal event separating the health history of ISS and American Samoa occurred in 1918. An epidemic outbreak of influenza (the Spanish flu pandemic) arrived in Apia aboard the New Zealand ship *Talune* in November 1918. The official death rate in ISS was recorded as 22% (20% among Samoans, 33% among part-Samoans, and 2% among Europeans) although the impact was much greater as many deaths occurred in the

succeeding year and the toll on the native leadership was particularly high. Seventy miles away, in American Samoa, there was no evidence of the flu. Death records for 1918 and 1919 from American Samoa show no increase in the number of deaths, no alteration in the age structure of mortality, and no cases attributed to flu. The Samoans blamed the New Zealand administrator for failing to quarantine the islands as had been done in American Samoa where the *Talune* was not allowed to dock. This incident colored much of the later New Zealand administration of the western islands.

Today health differs in the two Samoas based in part on differences in the resources available to American Samoa from the United States. The health care system, water treatment, and general sanitation in American Samoa have been ahead of those of their neighbors to the west for more than 50 years. As a result, American Samoa progressed through the epidemiological transition before Samoa. Health indicators for ISS are on par with the worst found in Polynesia, although health conditions are substantially better than in many developing areas (see Table 1). On the basis of life expectancy and infant mortality American Samoa is among the healthiest of Polynesian groups. Throughout the Samoan archipelago, the most common cause of hospital admission is respiratory disease, frequently flu or pneumonia. Tuberculosis, leprosy, and viral hepatitis are also present in significant numbers.

Chronic and obesity-related diseases became more frequent causes of death in both Samoas throughout the

Table 1. Health Characteristics of the Independent State of Samoa and American Samoa

Characteristic	ISS	American Samoa
2001 estimated life expectancy at birth, years	69.5	75.3
1995 crude birth rate/1,000 pop.	4.6	4.1
2001 estimated Infant Mortality/1000 births	31.8	10.4
1995 Mortality	deaths/100,000	Rank
Circulatory diseases	42	#1
Neoplasms	23	#3
Respiratory diseases	18	#2
Perinatal conditions	13	—
Infections and parasitic diseases	13	—

20th century, with circulatory diseases being the number one cause of death by 1995. Modernizing influences of engagement in the world economy in the second half of the 20th century brought about significant changes in diet, especially in American Samoa where the shift from subsistence agriculture to wage labor and purchased foods was most dramatic (Bindon, 1988). Changing economic conditions also altered patterns of activity, as wage employment for both men and women generally involves less demanding activities than prior to contact, resulting in massive obesity and its sequelae (Bindon, 1995). There appears to be a genetic predisposition to diabetes among Samoans with a diabetes prevalence of 3–12% in ISS and 27% in American Samoa (Bindon & Baker, 1997). The high diabetes rate in American Samoa shows up in the mortality statistics primarily through the complications that result in increased deaths from kidney and cardiovascular diseases (see Table 1).

Health Infrastructure

Prior to contact there was a limited set of personal practices and healers (*fofo*) available for the relatively few native health problems. Most medical consultation occurred within the village context where different healers were responsible for specific conditions. By the 1860s, there were trained physicians (*foma'i*) in Apia, brought in by the LMS and German companies. The German Navy established a hospital in Apia in the 1890s, but there was no Western medical attention paid to the eastern islands until 1900 (Gray, 1960). As the U.S. Navy began administration of American Samoa, plans were made for a dispensary near Pago Pago which turned into the local hospital and served until it was replaced by the current L.B.J. Tropical Medical Center in Faga'alu in the 1970s. In ISS, the genesis of the public health system of outreach dates to the experience with the Spanish flu. The New Zealand administration established women's committees (*komiti tumama*) in the villages to promote health and hygiene. By the 1940s there was a well established system of primary health care available throughout ISS, and many village hospitals were built.

MEDICAL PRACTITIONERS

Prior to contact individuals offered their own prayers for ailments or they consulted one of the healers or *fofo* near

Table 2. 1996 Healthcare Workforce in the Independent State of Samoa and American Samoa

	ISS		American Samoa	
	Number	Per 10,000	Number	Per 10,000
Doctors	57	3.44	16	2.90

their village. Missionaries brought a limited medical knowledge starting in the early 19th century and Western physicians and nurses began to arrive later in the 19th century. Throughout the 20th century increasing numbers of Western practitioners took part in health care in the Samoan Islands. Physicians, nurses, midwives, dentists, pharmacists, and an array of technicians currently populate the healthcare workforce (see Table 2). The training of most of the biomedical practitioners takes place overseas in the Fiji schools of medicine and dentistry as well as in schools of medicine and public health in New Zealand, the United States and Australia. Most nurses are trained locally although some are sent overseas for additional training. *Fofō* continue to train through apprenticeships and practice in most villages.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

Precontact paradigm

Prior to the arrival of Europeans, Samoans attributed illness to the displeasure of the gods or to the work of spirits (*aitu*). Stair, who visited Samoa in the 1840s, classified the gods into four categories, the third of which was the *aitu* who were responsible for much of the mischief and illness that befell Samoans (Stair, 1897). These beliefs resulted in treatments that focused on identifying the act that caused the displeasure or the *aitu* responsible for the malady and prescribing behaviors to assuage the god or *aitu*. There are many prayers that are

aimed at keeping various gods happy and preventing illness, such as this from George Turner who was an LMS missionary in Samoa in the 1840s and 1850s:

In [one] family [the god Tuiali'i] was prayed to for life and health before the evening meal; an offering of a blazing fire was essential to the success of the prayer, which ran as follows: "This is our fire to you, it burns bright; other fires are dim and going out; send these families to the lower regions, but give us life and health." (Turner, 1884, p. 75)

Other prayers and offerings were made once a specific god or *aitu* was identified as being responsible for an illness:

In a case of sickness, a cup of kava [*ava*, beverage made from the root of *Piper methysticum*] was made and poured on the ground outside the house as a drink-offering, and the god [Salevao] called by name to come and accept of it and heal the sick. (Turner, 1884, p. 51)

In some cases the families could not approach the god directly for intercession, and instead they had to commission a priest or work through other human agents, as noted by Turner:

At one place in Savai'i Salevao had a temple in which a priest constantly resided. The sick were taken there and laid down with offerings of fine mats. The priest went out and stroked the diseased part, and recovery was supposed to follow. (Turner, 1884, p. 49)

and

In another place [Taisumalie] was incarnate in an old man who acted as the doctor of the family. ... His principal remedy was to rub the affected part with oil, and then shout out at the top of his voice five times the word Taisumalie, and five times also call him to come and heal. This being done, the patient was dismissed to wait recovery. On recovery the family had a feast over it, poured out on the ground a cup of kava to the god, thanked for healing and health, and prayed that he might continue to turn his *back* towards them for protection, and set his *face* against all the enemies of the family. (Turner, 1884, p. 59, emphasis in the original)

In these ways, Samoans sought to cope with the ailments they encountered prior to contact.

Stair is not alone among 19th-century visitors in referring disdainfully to the limited native medical system of Samoa, comparing it unfavorably to that of Tonga and commenting that, "their remedies were few, and for the most part unreliable" (Stair, 1897, p. 164). MacPherson and MacPherson (1990) argue that the impoverished indigenous medical system of Samoa became elaborated upon contact with Europeans due in part to the introduction of new illnesses and in part to borrowing of practices from the missionaries and traders who gained more prominence

in Samoa during the 19th century. By the time Kramer visited the islands in the 1890s, much of the original health belief system about *aitu* had been obliterated by the missionaries and the Samoans had over 50 years of experience in dealing with diseases and treatments introduced by Europeans.

Contemporary paradigm

MacPherson and MacPherson (1990, p. 79) characterize the contemporary Samoan paradigm as "two sets of medical belief and practice [existing] alongside one another in... an arrangement aptly described... as a 'collage'." That is, the biomedical and indigenous systems are both used to satisfy the medical needs of the population. Part of this coexistence may have resulted from the public health training of individuals who were already recognized as *fofō* within their villages. As the western medical establishment increased in scope throughout the 20th century, Samoans came to rely on biomedically trained physicians for *ma'i palagi* (European illness) and on *fofō* for *ma'i samoa* (Samoan illness). In American Samoa, where the establishment of medical care by the Naval administration was seen as beneficial and the epidemic of 1918 was avoided, traditional medicine has been less integrated into the overall medical paradigm. As a result, the tension between the systems is greater as noted by Holmes and Holmes in their quotation of the following letter from a medical center member published in the *Samoa News* of November 17, 1988:

The most disturbing preventable problem has been the use in children of local Samoan bush medicine. By this I mean the plant and herbal medicines given by *taulesea* [*taulasea*, polite term for healer] or *fofō*. In the past year, we saw at least six children die after being given "Samoan medicine" by mouth from a *fofō*. The picture was not a pretty one. The children initially had mild cases of the "flu." They were then given "Samoan medicine" and soon developed seizures, kidney failure and increased acid in the blood. Despite intensive care at the hospital, these children died within three days. ... Many of the medicines given by a *fofō* are probably safe for children, but some are poisons and will quickly kill a child. In the first half of 1988, more children died in American Samoa from being given "Samoan medicine" than died from any other cause. (In Holmes & Holmes, 1992, p. 132)

In Samoa, as elsewhere, idiosyncrasies are certain to abound within the lay view of the biomedical paradigm, such as the attribution of diabetes to eating too much sugar. This may derive in part from a misapprehension of the Samoan term for diabetes (*suka* or *ma'i suka*). With

regard to obesity, one of the first claims an acculturated Samoan will make is that, "I eat too much taro," possibly because of the full feeling that taro gives. In fact, both obesity and diabetes would benefit from a diet with more taro and less of the high fat, low fiber foods that have become common during the 20th century. Both conditions would benefit even more from cultivating the taro that is eaten, thus increasing the physical activity of the individual.

Mental Health

Few cultures have had as much written about mental health as have the Samoans, beginning with Mead's characterization of a people with few neuroses and little maladjustment (Mead, 1928) and accelerating to a fever pitch with Freeman's depiction of aggressive and suicidal Samoans (Freeman, 1983). Several volumes have since dealt with this controversy (see Caton, 1990; Holmes, 1987; Orans, 1996). Neither extreme viewpoint is likely to have much merit and a better characterization of Samoan mental health would lie somewhere between the two. A psychiatrist working in American Samoa in the 1970s hypothesized that the underreporting of mental illness by biomedical standards in American Samoa was a result of the social system, which provides a means of "curing" emotional disorder by family group process and ritual, by making the disorder less disruptive, and by absolving the affected individual of personal guilt (Walters, 1977). Thus, much of what would be diagnosed and treated as deviant under the biomedical paradigm is informally handled within Samoan families.

SEXUALITY AND REPRODUCTION

Sexual attitudes and practices in Samoa have been shaped in part by the open walled houses and the general openness of the village setting. Premarital sex is strongly discouraged for women, an attitude that continues to be supported by the church in Samoa and enforced by a woman's brothers. Abortion was practiced in cases where the girl was afraid of her family or ashamed and pressure on the abdomen was the primary method used (Turner, 1884).

In ISS and American Samoa, relatively high fertility rates have been maintained from pre-contact times. A poster aimed at promoting birth planning in the Ob/Gyn clinic at the LBJ Tropical Medical Center in

American Samoa in the 1970s said "You space your coconuts, why not your children." Fertility continues to be high. The WHO (1999a; 1999b) provides total fertility rates of 4.76 for ISS in 1991 and 4.5 for American Samoa in 1995. Harbison (1986) described a differential effect of education on women in ISS and American Samoa. In ISS, education did not show a depressing effect on fertility. Harbison speculated that because education was provided within the village context, it tended not to shift attitudes on fertility and ideal family size, and since there was little opportunity for employment, education did not tend to remove women from their families. In American Samoa, wage jobs were available, especially for educated females, and attitudes about the cost of additional children and ideal family size were changed as a result of women's experience in schools and the work place (Harbison, 1986).

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

During pregnancy, Stair (1897) tells us a woman would permit her hair to grow long to mark her condition and to assure a healthy child. After 2 or 3 months, food would be brought by the husband's *'aiga*. A few months later the husband's family would present a gift of pigs called *o le popo* (of the child). The number of pigs would vary according to the rank of the husband, up to fifty pigs for the wife of a very important chief. One final gift of food called *o le taro fanaunga* (the taro of birth) was brought to the mother and then all of the gifts were divided up according to political connections of the wife's family (Stair, 1897). Turner (1884) describes rituals surrounding the birth of a child as follows:

[The woman's] father was generally present ... and either he or her husband prayed to the household god, and promised to find any offering he might require, if he would only preserve mother and child in safety. ... "O Moso, be propitious; let this my daughter be preserved alive! Be compassionate to us; save my daughter, and we will do anything you wish as our redemption price." (Turner, 1884, p. 78)

He says that if the child was a boy the umbilical cord was cut on a club to help him be brave in war; if it was a girl her cord was cut on the *tapa* (bark-cloth) making board so that she would be useful to the family. Infanticide was unknown in old Samoa according to Turner.

Today most Samoans attend pre-natal clinics and give birth in the local dispensary or hospital with family

in attendance or nearby, or at home with the assistance of a midwife. Birth weights of American Samoan infants averaged 3,250 g in the 1980s, a very high value, perhaps reflecting the high rate of diabetes in the population (Bindon & Zansky, 1986). Birth weights were somewhat lower in Western Samoa, but they were still in the mid-range of birth weights on a worldwide basis. Samoans are less likely than most populations to be at risk for low birthweight (less than 2,500 g).

Infancy

After children were born they were lovingly cared for. For the first 3 days, attention was paid to shaping the head by laying the child on its back and surrounding the head with flat stones. The hand was used to press the forehead and the nose to produce the desired shape (Turner, 1884). The mother's milk was examined by a woman every day for up to a week to determine if it were ready for the infant. During this time the infant was fed on the juice of the coconut, after which breast-feeding and supplementation with pre-masticated vegetables were started (Stair, 1897).

Contemporary infants are primarily breast-fed, but this varies between American Samoa and ISS. In American Samoa, where employment opportunities are better, women tend to wean their infants early to return to work. In ISS, breast-feeding is likely to continue longer. In both areas, infants grow very rapidly during the first 6 months of life after which time the infants in ISS, especially from remote rural areas, tend to slow in rate of growth (Bindon & Zansky, 1986). Bindon and Cabrera-Mereb (1990) found infants in American Samoa to be quite healthy, with respiratory complaints being the most common illness. They also found that exclusively breast-fed infants tended to be healthier at 3 through 9 months than infants who were at least partially bottle-fed.

Childhood

Stair (1897) describes child rearing as alternating between overly severe punishment for minor infractions and over-indulgence. Holmes and Holmes (1992) also note severe punishment in Manu'a in 1954. Similar discipline continues to be the norm, and is the source of some difficulties with child welfare organizations outside the islands. By 3 or 4, the gender roles are being shaped among the children and girls begin to assume household roles. By 5 or 6 a young girl may be baby-sitting and

caring for her next younger sibling. Boys have more freedom during early childhood, although they may have to feed the chickens, fetch water, and accompany their mother in gathering food on the reef. By 7 or 8, both boys and girls have assumed an active role in the gender-appropriate tasks of the household. An exception to this training may occur in a family where a mother has no young daughters and cannot adopt a young girl to help with the housework. In such a case, a son may be recruited by the mother to fill the role of a young girl in helping the mother manage the household. In such cases, when the boy continues to adopt the female gender role into adolescence and perhaps adulthood, the name *fa'afafine* is applied. A *fa'afafine* may marry and have children but continue to play a female role in the family and the village. Since the institution of formalized schooling, the patterns of training and household assistance by children have been dramatically altered. Pre-school child care is more likely to be done by the elderly while school-age siblings are in class, and everyone shares in the household chores once done by the children.

Adolescence

Male circumcision is the norm in Samoa. At about 9 or 10, two boys arrange to go to a specialist to perform the surgery. They bring him a gift of food and *tapa*. The operation involves a single longitudinal incision on the foreskin which peels back and after healing looks as if the foreskin has been removed (Holmes & Holmes, 1992). There is no other ceremony associated with this milestone. No such female operations are conducted.

A young man joins the *aumaga* (society of untitled men) with the sponsorship of his *matai* at around 14 or 15 or, today, after he graduates from school. The *aumaga* serves the village at the direction of the *fono*. Adolescent girls used to join the *aualuma* (unmarried women) and sleep in a separate house serving as a court to the *taupou* (village princess). Today the group comes together only on special ceremonial occasions, frequently for dancing and singing.

Adulthood

Turner (1884) says that adulthood was marked for men by tattooing. Males spend their adulthood seeking a *matai* title and their wives support this attempt as their status is also enhanced. Today upward mobility through

educational and occupational advancement increase a candidate's chances of gaining a title. This upward mobility has not been without added health cost. Bindon (1997) reported on an analysis of lifestyle and blood pressure in American Samoa that indicated attempts to present a higher material culture status than can be afforded caused a stress response in Samoan men, but not women, increasing the men's blood pressures. Women who were working outside their home had lower blood pressures, but husbands of women working outside the home had higher blood pressures. Some of the strongest impacts of modernization among Samoans have been exerted as a result of trying to adopt a Western material life style with insufficient resources.

The Aged

Old age has traditionally been identified in Samoa as the best time of life. The elderly, over about age 50, are treated with respect, they have minimal demands on their time and energy, and one can rely on the support of one's children and relatives. Many of these attitudes persist today, although times are changing. Since the 1970s, homes for the aged have been opened in both ISS and American Samoa, a result of the emigration of younger Samoans and the occasional failure of family resources to provide for the elderly who remain in the islands (Holmes & Holmes, 1992). A number of elderly Samoans suffer the deprivations of diabetes, blindness being one of the most visible symptoms.

Dying and Death

The dying were traditionally looked after at home where friends and family could easily visit to pay respect. If wounded in battle or taken sick away from home, every effort would be made to return home prior to death. Today, Samoans who are terminally ill prefer to spend their time at home with their family rather than staying in one of the hospital or dispensary facilities. Local nurses assist with this desire by stopping in on the ill at home.

At death, while the body is being prepared by female relatives, word is sent to relatives in other villages. Family begin to arrive bearing gifts of fine mats (*afuelo*, woven of pandanus fiber) and *tapa*. After the funeral the gifts will be given to the female relative in charge of body preparation and she may make a further division to reinforce

political ties. If the deceased is an important chief, the display of wealth may be great (Holmes & Holmes, 1992). Today, in addition to the fine mats and barkcloth, cash and purchased goods may also form part of the funerary wealth. A *matai* from the deceased's family will call on family members to make contributions (*fa'alavelave*) to support the funeral and burial.

Burial takes place on the family homestead with the erection of a small mound of volcanic rocks in the form of a monument to the deceased. The interment of individuals on family land was an important part of pre-missionary religion with the belief that they joined the ranks of the *aitu* that oversaw the health and well-being of the family. Today the burial also takes place on family land but the mounds are likely to be constructed of concrete and incorporate Christian icons.

Saraguros

Ruthbeth Finerman

ALTERNATIVE NAMES

The word “Saraguro” translates from the Quichua language as “Land of Corn.” The indigenous community self-identifies as Saraguros, *indígenas*, or more rarely, as *runas* (“people”). Non-indigenous residents may speak of Saraguros with the pejorative *indio* or *chinita*. Saraguros occasionally make derogatory reference to acculturated individuals as *leichos* or *gente acomodado*.

LOCATION AND LINGUISTIC AFFILIATION

Most Saraguros continue to reside in Loja Province, in Ecuador’s southern Andes. A majority populates intermontane valleys surrounding the township of Saraguro (3.7°S, 79.3°W, elevation 640 m to 910 m). In addition to the town, the region comprises croplands, managed pastures, residences, and scattered *altiplano* woodlands and *paramo* grasslands. In recent generations, intense competition for land encouraged migration to exploit farm and pasture lands in the Yacuambi Valley on the eastern foothills of the Andes, and wage labor opportunities in major metropolitan centers. In the late 1990s, Ecuador’s

economy collapsed, spurring hundreds of Saraguros to migrate to Spain for work as farmhands.

Virtually all elderly and most adult Saraguros speak both Spanish and Quichua, a southern Ecuadorian highland dialect of the Quechuan language (Harrison, 1989). Younger generations are less likely to speak Quichua, and few youths are proficient in their native tongue. Nevertheless, Saraguros retain a strong identity as *indígenas* and possess close cultural and political affiliations with all other Quichua speakers.

OVERVIEW OF THE CULTURE

Demographics and History

Although census data are unreliable, Saraguros are estimated to number at least 20,000. Historically, the region remained independent until Incan domination in the late 15th century AD. At that time, Saraguro town was founded as a *tambo* or way station between Cuenca and Loja. While their origins remain uncertain, most Saraguros accept the view that their current population was founded through the intermarriage of forced migrants (*mitimaes*) and local Cañari or Palta (Macas, 1995).

European rule began by the 1530s, but lands remained in the possession of indigenous Saraguros. With construction of the PanAmerican Highway in the 1940s, non-Indians took control over most of the town center, but Saraguros maintain land claims in town and most of the surrounding countryside. Although contact with a dominant outside culture has influenced aspects of their culture, the indigenous community sustains a fairly strong sense of tradition and identity, and a basic distrust of external forces.

Production

Like most Andean peasants, Saraguros are agropastoralists (Gade, 1999; Wilson, 1999). Bullock-pulled plows are used to plant maize, potatoes, beans, wheat, and barley. Cattle herding yields major capital, and families also raise sheep, guinea pigs, swine, chickens, and rabbits. Wool from sheep is handspun and woven to fashion traditional Colonial-period garments. Crafts, including beadwork, embroidery, and weavings are also manufactured for personal use and for sale.

Kinship, Marriage, and Family

Descent here is reckoned bilaterally and egocentrically, although patronyms take precedence in official records. While monogamous, divorce and abandonment can occur. Most voice a preference for neolocality, yet small extended households predominate. There is no clan or lineage affiliation, but they express solidarity within *barrios*, politically linked neighborhoods that support communal lands and labor cooperatives. There is also a clear inclination toward *barrio* endogamy. Still, Saraguros possess a strong sense of household autonomy, making *barrio* alliances relatively unstable.

Social Organization

Strong differences in wealth and status exist among Saraguros, and between indigenous and non-indigenous residents (Belote, 1978). Status also differs somewhat by gender, as males enjoy a higher public profile. However, Saraguro women can garner recognition by sponsoring religious festivals and, as in other parts of Ecuador, they wield ample power over household resources, decision-making, and family comportment, particularly as they

relate to health (Finerman, 1995; Wayland, 2001; Weismantel, 1988).

Religion

While evangelical movements have made some inroads in the region, Catholic doctrine dominates religious life. Yet, as in much of the Andes (Allen, 1997; Dover, Seibold, & McDowell, 1992; MacCormack, 1991), Saraguro beliefs and practices retain many elements of pre-Conquest cosmology, including animistic reverence for the sun, moon, wind, rivers, and rainbows. Such spirits are also linked to personalistic illnesses.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

Health Profile

Reliable data are unavailable, but Ecuadorian health officials agree that Saraguro morbidity and mortality well exceed national rates. As in many Andean nations, rates of infant mortality for the richest and poorest provinces vary by as much as 200%. One survey found that more than 40% of Saraguros reported at least one health complaint during the prior two months (Kroeger & Barbira-Freedmann, 1992, pp. 251–252).

Newborns in Saraguro are slightly more vulnerable than average to post-partum infection. Infants and children experience frequent if not chronic parasitic infection, diarrhea and dehydration, and acute respiratory infection, although infectious disease rates began to fall after 1960 and most dramatically after about 1980, as a result of intensified immunization campaigns (UNICEF, 1995). Adults are subject to work-related injury, and health workers report that a sizeable proportion (up to 30% in some *barrios*) carry tuberculosis. Many adults also suffer complications from alcohol abuse. Malnutrition is less common, as most Saraguros sustain a balanced diet and active lifestyle. Yet, the PanAmerican Highway has eased access to high calorie but nutritionally inferior processed foods (e.g., sugar, white rice, noodles), alcohol, and tobacco, posing greater risk of obesity, hypertension and diabetes, particularly in pregnancy. The incidence of other so-called “diseases of development” such as cancer, heart disease, and sexually transmitted diseases has also grown.

The indigenous population is also vulnerable to a range of traditional or culture-specific illnesses (Argüello & Sanhuenza, 1996; McKee & Argüello, 1988), such as nerves (*nervios*), envy (*envidia*), fright (*susto*), evil airs (*mal aire*), evil eye (*mal ojo*), soul loss (*espanto*), and witchcraft (*brujeria*). With the exception of *nervios*, children and elders are the most common victims of such disorders.

Environmental Factors

The natural ecosystem presents a mixed bag of health risks and benefits. The high altitude and cold temperatures produce several deaths each year from hypothermia. The climatic phenomenon *El Niño* produces devastating rains that wipe out crops and wash out roads, cutting off access to medical care. Wildlife—mainly venomous snakes and spiders—poses some threat, particularly since most children and older adults walk barefoot. Domesticated animals expose their owners to zoonoses including tuberculosis, rabies, flea and tick infestations, and a host of parasitic diseases. Nevertheless, the rich ecosystem also supports a diverse food supply and a vast array of medicinal plant species that are routinely exploited for health promotion in Saraguro and throughout the Andes (Bastien, 1987; Naranjo & Escaleras, 1995; Wilson, 1999).

Household ecology also yields risks, although these have shifted over time. Most old homes have dirt floors, and kin tend to share beds in one room, facilitating contact with contaminants and the spread of communicable disease. Recent home renovations and new homes invariably boast plank flooring and separate sleeping quarters, yet these upgrades mainly reflect the crowding of large extended families into a single home. Prior to 1990, most Saraguros cooked on open hearths fueled by firewood, risking burns and respiratory irritation. However, depletion of firewood supplies has since forced a shift to use of cooking gas. This has reduced hearth fire hazards, but poses a danger should gas cylinders rupture and explode. During the same period, most homes gained access to water pipelines, but the unpurified water continues to spread disease. The community also lacks effective sewage and waste disposal, but many homes now feature outdoor latrines and showers, slightly reducing waste levels indoors. Still, some Saraguros continue to collect urine in the home (for use in dye vats), and most residents come into contact with solid waste and contaminated soil and water when cultivating fields.

Social Factors

Saraguros associate social and economic productivity with health, thus disability, inactivity, or unemployment is considered both unhealthy and antisocial. Pressure to remain productive has fostered migration, particularly of unemployed males, forcing many women and young children to take charge over households, crops, and herds. Worse still, the migrants frequently return from the lowlands and cities carrying a host of new diseases (e.g., malaria, cholera) that spread through the community.

Interpersonal harmony is also viewed as fundamental to health, and some illnesses are attributed to anger, envy, despair, or discord. Thus, social cohesion is characterized as essential to well-being, and gossip stands as a powerful social control mechanism. Women here are concerned to avoid gossip should their children appear ill or malnourished and they take special pride when told that their children look robust. These women retain the primary social role in managing family health, and skillful healers gain substantial power in both the household and community (Finerman, 1995). Females are socialized into the family healer role during childhood, when they begin to assist their own mothers in preparing remedies for younger siblings. As they age and establish their own families, women continue to consult their mothers and female friends for health care advice.

Political and Economic Factors

Throughout most of their history, Saraguros remained at the social, political, and economic periphery of the state. However, the PanAmerican Highway expanded contact, and the adoption of cattle husbandry increased dependence on the national economy. In the final decades of the 20th century, depleted oil reserves reduced the nation's wealth, sustained *El Niño* rains devastated roads and infrastructure, and pervasive political corruption and massive international debt all combined to lead Ecuador into financial ruin. Saraguros, previously immune from economic downturns, were gravely impacted as banks, schools, and hospitals closed, the national currency (the *Sucre*) was abandoned, prices for pharmaceuticals and essential goods soared, and commercial ventures failed. As the crisis intensified, health levels began to deteriorate. While reliable statistics are not available, government officials claim that mortality among infants, children, and elders has begun to rise, and domestic abuse reports have increased.

MEDICAL PRACTITIONERS

Indigenous Saraguro curing specialists include herbalists, midwives, and shamans. Herbalists provide medicinal plant preparations and advice on diet for a range of ailments. Midwives advise women on fertility, prenatal and postpartum care, and may assist in labor and delivery, employing massage, baths, herbal remedies, and dietary guidance. *Curanderos* specialize in intractable conditions, particularly illnesses suspected of being caused by supernatural agents. Nevertheless, Saraguros make minimal use of these practitioners, treating almost all illnesses with home remedies (*remedios casseros*). Not surprisingly, only a few of these specialists practice here, and those who do are more likely to be patronized by non-indigenous town residents.

In addition to traditional curers, the town supports a few private physicians and dentists, and a hospital staffed by medical and nursing interns and community health workers. Several private pharmacies also operate, typically selling products without prescription. But, as with traditional healers, Saraguros have proven unlikely to consult biomedical providers unless all home treatment efforts are exhausted.

Home-based health care combines preventive activities involving hygiene, dress, dietary laws, and personal comportment, plus an extensive repertoire of herbal remedies. Women view their healing role as a natural extension of their duties in bathing, clothing, feeding, and generally nurturing kin. They invariably argue that they are the first to spot the signs of illness (e.g., appetite or sleep loss, pain, lethargy) and they usually possess years of healing experience. Most also reason that other practitioners could never match a mother's concern for her own family's welfare.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

Etiology

Saraguro views of illness concern the actions of both naturalistic and personalistic agents. One of the most pervasive beliefs here and throughout Latin America is that of humoral opposition (Foster, 1998). Specifically,

“heat” and “cold” appear as ubiquitous elements, found in individuals, animals, plants, foods, seasons, and emotional states. A balanced state assures health, while an excess or deficiency yields illness and symptoms of heat (e.g., fevers, blisters, infection) or signs of cold (e.g., chills, cough, diarrhea).

Naturalistic etiologies here also reflect a view of the outside world as inherently dangerous (Finerman, 1987). Illness is considered most likely to occur when eating or socializing away from home, and especially when traveling a great distance (although this belief holds more strongly for women than for men). The introduction of germ theory merely reinforced opinions of the outdoors as infested with toxins, contaminants, and microscopic *bichos* or “bugs.” Saraguros invariably complain that cheese, milk, and similar foods prepared by other families are inferior or “dirty” (*sucio*); food prepared in the town is particularly tainted. Consequently, little of the food served at local communal festivals is consumed on the spot; most is taken home and re-cooked to eliminate impurities. When offered refreshment, guests routinely hear the phrase, *Quizás no le hace mal* (“Maybe this will do you no harm”) and respond with *Dios se lo pague* (“God will repay you”), a refrain that both reassures and warns the host.

Intense natural emotions can also cause harm (Tousignant, 1988). For example, adult Saraguro women suffer a high prevalence of *nervios* (“nerves”), a physical collapse resembling depression, which they usually blame on *pura sufrimiento*: “pure misery.” *Nervios* is also common for women overwhelmed by the strain of family illness. While disabling, the condition offers relief from the stress of family care and affords a degree of control over kin (Finerman, 1988). Such ailments also reveal how conditions of mind and body are linked in Saraguro culture. Mental illness is not generally recognized here; instead, both physiological and psychological distress find expression in physical form.

In addition to these naturalistic etiologies, Saraguros retain several pre-conquest animistic beliefs about dangerous supernatural forces including sacred lagoons, winds, rainbows, rivers, the earth, moon, and sun. While few expressly describe these agents in anthropomorphic terms, they manifest their concerns in folktales and codes of conduct. For instance, many recount legends or personal accounts where mountaintop lagoons rise from their banks, seeking to abduct women. They use medicinal plant bundles to “sweep away” malevolent

winds, and avoid rivers where the rainbow is said to impregnate female bathers. During feasts, hosts may spill small offerings of alcohol as a gift to the earth mother (*pacha mama*), and many cease planting during a new moon to avoid crop failure. Saraguros also wear distinctive hats while outdoors, to show respect for the sun and thus avoid its “vengeance.” Of note, younger generations increasingly ignore these traditions, especially the precaution of wearing hats. Few minors have even heard of once common illnesses like *baño de agua* (“water fright illness”). Such youths leave elders fretful about the health and well-being of their families and community.

Despite a decline in some animistic beliefs, nearly all Saraguros retain conviction in the power of other human beings to cause harm through envy, evil eye, or witchcraft. Mothers here usually swaddle infants and carry them on their backs hidden under shawls, to protect them from envious gazes. Young children wear red bandanas, jewelry, or clothing to ward off witches. Even small animals (especially kittens) may be safeguarded with a red collar. Nonhumans (e.g., snakes, dogs) are also said to cause magical fright or soul loss sickness, although episodes here are relatively rare.

Treatment

As noted, Saraguros usually rely on their mothers or wives to manage health, despite access to various professional curers. This “popular” or informal sector of family-based care predominates cross-culturally (Kleinman, 1980); in southern Ecuador Saraguros enjoy a degree of fame for their expertise in herbal medicine.

Indigenous women here possess curing knowledge that is at once highly complex and syncretic, blending traditional curing elements with biomedicine. The richness of their knowledge derives from a lifetime of experience in treating sick kin and from continual expansion of their curing arsenal. Saraguro women routinely consult their own mothers and female friends for advice, and they gain fresh curing insights from health specialists. Women usually accompany spouses and children to practitioners, and providers tend to direct treatment instructions to these women. In the process, they learn new concepts and therapies that help them upgrade their curing routines. By contrast, specialists such as *curanderos*, midwives, and physicians almost never share insights among one

another; indeed, they usually express scorn for different medical systems.

Family care in this population incorporates both preventive and primary care. Illness prevention is accomplished mainly through attention to dress, hygiene, and diet. Infants and children are clothed in layers to bundle them against malevolent winds and humoral disorders. As noted, children may also be dressed in red to guard against witchcraft. Hygiene acts to cleanse away contaminants, eliminate humoral excess, and thwart sorcery. Thus, medicinal plants may be added to bath water to both clean skin and prevent evil airs, while hairs lost during combing are meticulously gathered into bundles and burned to keep them out of the hands of witches. Meals include a mix of nutrients and medicinal plants, designed to ensure nutritional and humoral equilibrium. Some foods are also utilized as remedies. For example, humorally “hot” foods such as chilis, raw sugar (*panela*), and beef can alleviate ailments like extreme cold (*recaida*), while “cold” foods such as milk, white sugar, and chicken help to reverse ailments such as extreme heat (*gangrena*). Several foods are also expressly prescribed or prohibited during various stages of the reproductive cycle. For instance, avocado consumption is taboo for menstruating girls, as it is considered toxic at such times.

A majority of treatments are administered as herbal teas (*aguaita* or *infusión*), however many remedies also take the form of a vapor bath (*baño vapor*), spray (*sopla*), flotation (*flotación*), rub (*sobado*), poultice (*cataplasma*), or plaster (*escayola*). Saraguro women take pride in their mastery of medicinal plant lore. They can name dozens or even hundreds of plants in free lists, and describe plant growth habits, uses for different plant parts, processing techniques, and applications. Women cultivate many of the more vital domesticated medicinal plants in kitchen gardens (*huertas*), located next to or near the house. These gardens vary in size and complexity, depending on several factors. Often, the largest and most complex gardens are cultivated by women with many children, many years of curing experience, and the wealth and labor pool necessary to support garden maintenance. Such gardens can contain hundreds of varieties of medicinal plants. Even young brides and elderly women tend medicinal plant gardens, although these are likely to be smaller and less diverse. Women add to their reserves by gathering hundreds of medicinal plants that grow wild in the region’s diverse ecosystems (Naranjo & Escaleras, 1995).

SEXUALITY AND REPRODUCTION

Sexual Activity

Despite strong affiliation with Catholicism, Saraguros demonstrate only weak adherence to religious mores regarding sex. In particular, premarital sex is only mildly discouraged, and births outside wedlock are both common and readily accepted. Indeed, such births are a positive indicator of a female's fecundity and can enhance her prospects for marriage, though aspirations decrease with subsequent pregnancies. Extramarital affairs incur slightly more social disapproval, yet most residents profess tolerance, particularly in cases of absent spouses (e.g., wives of migrant workers, or abandoned spouses). Homosexuality is criticized, but almost never discussed. Greater censure is reserved for incest, which is called immoral and unhealthy. Local folklore claims that incestuous couples gradually transform into dogs, manifesting new canine attributes after each transgression. For the most part, however, locals regard sex as both normal and healthy, but also a private matter. Women follow select rules of sexual decorum; in particular, they cover their mouths when smiling and laughing, as showing teeth is vulgar. However, men and women are equally fond of sexual jokes and innuendo.

Fertility

In the indigenous community, the social transition from childhood to adulthood is not marked by initiation into sexual activity or, in the case of females, by menarche. Instead, childbirth is the main marker of maturity. Females retain the title "girl" (*niña*) or "child" (*hija*) even after marriage, until their first birth. Males also lose the moniker *niño* or *hijo* only after they have children. Childbearing is significant in most peasant societies; offspring are critical to expand a family's labor pool and provide care for aging parents; households also procure support through fictive kin networks (Mitchell, 1991, pp. 47–51).

Fertility itself is a sign of good health and humoral equilibrium. A woman who readily conceives and bears children is robust and "warm"; infertility and miscarriage may arise from various problems, including a "cold" metabolism, witchcraft, and envy. Barren women are also considered prone to weakness (*debilidad*) and heart failure.

Saraguro understandings of conception shifted in recent generations. Accounts from the 1960s cite

preformationist views. At that time, locals claimed that males were preformed in sperm and implanted in the womb, while females generated inside the mother. By the 1970s they had abandoned such notions, as more youths learned biology in school. After that point, conception was explained as the fusion of egg and sperm, while the womb was characterized as a "basket" that carries the fetus.

Fertility Control

Ideal family size also evolved over the last half of the 20th century. Historically, Saraguro couples hoped to have many children to expand production and care for their aging parents. Yet, by the 1950s competition for land intensified and youths deserted Saraguro in search of acreage and wages. More couples also found that larger families could not afford to educate all of their children. By the 1970s, family planning campaigns began to actively promote the benefits of smaller families. Today, families with just one son and one daughter are the ideal. Even so, Saraguros face multiple barriers to effective contraception.

Church representatives in Saraguro condemn birth control, and many men fear that contraception facilitates adultery by women. Such antagonisms make discussion of the topic both sensitive and infrequent. Yet, most in the indigenous community regard pregnancy prevention as a woman's privilege, and as her burden. A majority of women rely on herbal teas to prevent or terminate a pregnancy, though such preparations are unreliable. Occasionally, women seeking abortion consult *curanderos*, or travel to larger cities to purchase contraception. Few see local physicians or druggists, fearing gossip. A small number have taken drastic steps to induce miscarriage, pounding their belly, falling down hillsides, or ingesting irritants such as wood ashes. Still, few attempt to terminate unwanted pregnancies; almost all reconcile themselves to the condition as "God's will" (*lo que Dios quiere*). Nevertheless, they frequently bemoan their large families and extol the good fortune of women with few children.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

As noted, pregnancy usually occasions happiness or, at worst, forbearance. In any event, Saraguros describe the

condition as fraught with danger. Thus, they strive to diagnose pregnancy early, to ensure a successful outcome (Finerman, 1988). Pregnancy signs cited most frequently include interrupted menses and/or morning sickness. Some report other indicators such as a darkening of the nipples and changes in appetite, sleep, or energy levels. A few claim to detect pregnancy through the presence of white solids in expectorate or urine.

Once recognized, Saraguros take protective measures. Usually, the expectant mother is encouraged to fulfill food cravings; these are credited to the fetus, which may kick or harm its mother if frustrated. Exceptions to such indulgence are extremely "hot" or "cold" foods, which might exert additive or antagonistic effects on the hot state of pregnancy and induce illness. Women may also reduce workloads and avoid activities that shake the body (e.g., work at sewing machines or weaving looms, as well as sexual activity), as these could prematurely "wake the child." Emotional disturbances, including domestic arguments, accidents, shock, and envy are also harmful. Pregnant women are also warned to avoid cemeteries (e.g., funerals, All Soul's Day mass) as they readily succumb to sickness from evil airs (*aire grande*) around graves.

Across Latin America there is great variation in the use of birth attendants (Bolton & Bolton, 1978; Cosminsky, 1976). In Saraguro, indigenous women almost always give birth at home, alone or assisted by their spouses. Primiparous (first time) mothers are somewhat more inclined to seek additional assistance from female relatives or midwives. Hospital deliveries are rare; most result from protracted labor or other complications.

During accouchement, Saraguro women may soak in an herbal bath or drink medicinal plant teas to aid labor; eating is permissible, but few do so. Women rest in any position that feels comfortable, but avoid sudden movement. Husbands provide massage to reduce pain. Women usually deliver in a vertical squat position supported by spouses or female attendants, if present. The umbilical cord is cut immediately upon delivery; some claim that this practice prevents the womb from "reclaiming" the infant. Women may then smoke tobacco or datura, to encourage placental rejection. Customarily, the placenta is buried at the entrance to a home, without prayer or special ceremony.

Childbirth is followed by a 40-day post-partum confinement (*la quarenta*). This term of lying-in protects the debilitated mother and newborn from evil airs and

other illnesses. During this stage, both take a series of herbal baths on prescribed days. Mothers wrap their abdomen with poultices made from various fats and medicinal plants, to aid recovery, and nourish the womb. New mothers also adhere to a strict traditional diet. They continue to avoid foods with extreme humoral qualities, especially cold foods, claiming these sicken a mother as her metabolism cools after the heat of pregnancy. They also eschew foods like citrus that might "cut off" lactation.

Infancy

Indigenous parents profess no gender preference among offspring. Both sexes retain their parents' names, and both can inherit. Twin births seem to cause no concern, but are extremely rare in this population. It is possible that, in the past, such births precipitated higher maternal mortality, leaving a population that is genetically less prone to multiple pregnancy. Birth defects and deformities do incite shame and are interpreted as a punishment from God. However, the child faces minimal risk for active or passive infanticide, since religious doctrine effectively prohibits such recourse. Still, a few families have hidden such offspring at home, so that their disgrace is less public.

Saraguros rightly regard newborns as especially vulnerable to illness and death; fears are understandable given that, prior to the 1960s, infant mortality at times reached 40%. Waves of measles, chicken pox, and whooping cough decimated families before immunization campaigns intensified. Infants still face substantial risk of diarrhea and dehydration, respiratory infection, and communicable disease, and are considered highly prone to evil airs, magical fright, soul loss, envy sickness, and witchcraft.

Here and elsewhere in Latin America, infants and children who die before their First Communion are said to become angels or *angelitos* (Lillo, 1942). The dead child is adorned with a paper crown and wings, and seated on a decorated altar in their home. Their death is marked by an extended period of feasting and dancing; the tradition helps parents to better cope with the loss of a child.

While such deaths are celebrated, Saraguros take pains to forestall the loss of offspring. Newborns are kept in virtual isolation for the first 40 days of life. Saraguro mothers breast-feed infants on demand, rather than on a schedule. Mothers customarily breast-feed for one year, or until the mother becomes pregnant again.

Solids (mostly cereals) are introduced gradually, usually beginning around 6 months of age. Infants wear little clothing while indoors and can defecate freely, but they are kept clean, warm, and protected. As they grow they are free to explore the home, under the watchful eyes of their mother or older siblings. Infants enjoy attention from multiple caretakers, including parents, siblings, and extended kin. By the age of five, most children here begin to help carry and tend younger siblings.

Baptism represents a crucial religious rite and supernatural safeguard against illness, but the ritual cannot take place until some months after birth. In Ecuador, infants must complete a preliminary course of immunizations before they can be baptized. Local community health workers usually assist by making house calls to finish the vaccination series. Infants must also be strong enough to leave the safety of home. Therefore, most parents arrange baptism after the infant is at least 6 months old and celebrate the occasion with only a private family feast.

When taken outdoors, an infant is dressed in layers of clothing and red cord, swaddled, and carried on the caretaker's back under one or (more often) two shawls. Some mothers explain that swaddling helps the infant grow straight, while others claim the child is more comfortable and sleeps more readily when bound. However, the practice also curbs movement under shawls that might attract unwelcome attention, thereby protecting infants from witchcraft and envy.

Childhood

The transition from infancy to childhood in Saraguro is gradual, marked mainly by enhanced mobility, communication, and autonomy. Once offspring begin to walk, talk, and play independently, they are given more responsibilities and tasks. By five years of age children begin to help with younger siblings, keep watch over sheep and cattle, and fetch items for their mothers. Daughters assist mothers in meal preparation, sibling care, housework, and preparation of medicinal remedies. Parents rarely discipline offspring, although they may threaten spankings or a thrashing with nettles. More often, parents simply assign more chores, reasoning that work keeps children too busy to cause trouble.

In Saraguro, children must be fully vaccinated to register for school. Nonetheless, sickness rates increase for students, as contagious and parasitic diseases spread and children suffer more accidental injury. Parents also

fear that offspring will fall ill from foods prepared at school or purchased in town. Over time, though, children come to be viewed as relatively safe from illness, including personalistic conditions like evil airs, envy, and magical fright. Risk seems to decline around the time children complete the Catholic rites of Confirmation and First Communion.

Adolescence

Puberty and adolescence receive almost no recognition in this population. Typically, daughters quietly inform their mothers of the onset of menarche, but they receive little instruction and face few restrictions other than minor dietary taboos (e.g., consumption of avocado) and perhaps admonishment to avoid pregnancy. Adolescent sons garner still less attention, but may gain greater freedom; young Saraguro males frequently stay out all night attending fiestas or drinking with male companions. Such behavior risks few penalties other than mild parental rebuke. Youths are said to face few health risks, other than unplanned pregnancy or injury precipitated by intoxication.

Adulthood

Most Saraguro adults describe their lifestyle as exceptionally healthy (*sano*), comprising vigorous labor, and a balanced diet. Nevertheless, a majority report chronic, albeit minor complaints like muscle aches, fatigue, and eye strain, plus a range of acute respiratory and intestinal disorders. Other common concerns include pregnancy, physical trauma (usually related to work or alcohol intoxication), alcoholism, animal bites, and tuberculosis. Adults claim to suffer fewer traditional ailments like magical fright and soul loss, yet *nervios* is pervasive among adults (especially women), and *mal aire* strikes most adults who take cattle to pastures in the windy and wet high elevation *paramos*.

The Aged

Aging, like other social transitions, is a subtle process in this population. This is largely because there is no designated age for "retirement" or "social security" benefits; Most Saraguros remain economically productive throughout their lives, and provide supplemental aid with family care and curing expertise. Also, Saraguros show few signs of aging; hair tends to remain black until

extreme old age, and years of sun and wind exposure reduce skin elasticity early in life, making aging or decline difficult to detect. Often, the sole mark of maturity is a subtle change in mode of address. Over the years, Saraguro men gain the title *Taita* or *Taiti*, and women come to be called *Mama*. These Quichua terms, meaning father and mother, are titles of respect used by all Saraguros, not merely kin. It is unclear precisely when and why the title is added to one's Christian name, but it correlates with advanced age and a high level of social recognition.

While elders are treated with deference, aging here is accompanied by a decline in overall health. Muscle pain and respiratory and digestive disorders common among adults advance into persistent or even debilitating conditions. The aged also manifest high rates of arthritis, visual impairment, wasting, more cases of active tuberculosis, and traditional syndromes, especially *mal aire*, and *nervios*. Extended kin are expected to offer care, but elders sometimes complain that relatives are of little help; a few have no surviving kin to look after them. After Ecuador's financial crash in the 1990s, many elders were abandoned, as kin left the community in search of work. In such instances, elders have turned to fictive kin, friends, and neighbors for health care and other assistance.

Death

Saraguros exhibit both respect for and fear of the dead. With the exception of children honored as *angelitos*, the deceased seem to be regarded in vaguely malevolent terms. Survivors are loath to speak of the dead by their Christian name; more often, the deceased is referred to obliquely as *el cadver* or *el difunto*. Mourners view corpses as corrupted flesh that pollutes the home and threatens "corpse sickness" (*aire grande*), which can rob the living of their souls and even their lives. Consequently, indigenous funerary customs venerate the memory of the dead, but also operate to protect the health and well-being of the family and community.

Soon after death, the body is bathed, dressed for burial, and laid out at home. A rosary is placed in the hands, and candles encircle the bier. Mourners "accompany" the corpse on an all-night vigil and pray for their soul. As the night progresses, attendants may consume alcohol to toast the dead and pass the hours. The coffin is then carried to church for funeral mass, and then up a hill to the local cemetery. At graveside, mourners remove their hats

(but hold these over their heads out of respect for the sun) and recite final prayers. Saraguros assert that open graves emit dangerous airs and the essence of ghosts. Thus, mourners (especially those who handled the corpse, held vigil, or prepared the grave) return home immediately after the ceremony and bathe to remove any residue of death. Most also pour cologne in their hands and cup it to their face, rubbing it in and inhaling deeply as a treatment for supernatural illness.

Soon after mass and burial, family and friends strip the home of all possessions; these are carried to a local river, where all goods (e.g., clothing, bedding, and even furniture) are meticulously washed to purge the residue of death. The walls and floor of the house are also scrubbed, and doors and windows are left open for several hours to expel any lingering malevolent airs or spirits.

Rites may be interrupted if cause of death is in doubt (Finerman, 1984). Until recently, physicians performed autopsies in the cemetery just prior to burial, in full view of the mourners. Since proper instruments and lab analysis were not available onsite, results were unreliable at best. Worse still, this act delayed burial for hours and subjected mourners to the sight of a loved one's dissection (for which kin were billed). Today, bodies are usually autopsied at the hospital, then released for vigil, mass, and interment.

CHANGING HEALTH PATTERNS

In many respects, it is a mistake to characterize any health system as "traditional," because medical systems undergo constant transformation (Finerman, 1989). For Saraguros, contemporary beliefs and practices form a syncretic fusion of pre-conquest doctrines (e.g., animistic views of the sun, rainbows, rivers, and winds), Colonial theories (e.g., humoral equilibrium), and contemporary biomedicine (e.g., pharmaceuticals). Indigenous women here do not distinguish between these; all are selectively added or rejected on the basis of perceived efficacy. No matter the source (i.e., kin, friends, health specialists, or public education campaigns), new concepts that better explain illness causation, and innovative procedures that more effectively diagnose or cure, are readily incorporated into family care. Thus, explanatory models like humoral opposition or germ theory, and diagnostic labels like "parasites" are welcomed, as these explain how sickness can arise from agents too small to see. Similarly,

new medications like anti-parasitic purgatives can yield dramatic results. Nevertheless, innovations are rejected if they contradict accepted tenets or render poor results. Consequently, doctors have failed to dissuade mothers from treating kin and to rely instead on hospitals, since such facilities rate as inferior to the experience and compassion mothers can offer.

Saraguro is experiencing other transitions that shape health, for better or worse. As noted, the collapse of Ecuador's roads, infrastructure and economy have devastated its citizens. At present, most Saraguros find themselves in debt, lowering quality of life, and risking increased malnutrition, morbidity, and mortality. Hundreds have migrated, robbing the community of many of its youngest and most productive members, and leaving many children and elders abandoned.

Despite such setbacks, agencies have stepped up support for aid and development. Programs include live-stock vaccination, nutrition supplements, child immunization, and community health (Barreto, Barrera, Unda, & Carri, 1996). Alcoholics Anonymous has established chapters in a few *barrios*, helping Saraguros recover their productivity. Day care centers have opened, freeing women to expand economic activity (though centers struggle with funding cuts). Some *barrios* participate in new cooperative economic ventures (e.g., weaving mills, trout farms, greenhouses for cash crops, and incipient ecotourism) selling wares in and beyond the community. Such programs help offset some current threats to health. More critically, they represent an investment in the future, offering the best prospect for the continued wellbeing of Saraguros and their culture.

Shipibo

Warren M. Hern

ALTERNATIVE NAMES

Shipibo, Conibo, Chama.

LOCATION AND LINGUISTIC AFFILIATION

The Shipibo are located in the upper Peruvian Amazon. Their communities are found principally along the banks of the Ucayali River and its tributaries from Atalaya to Requena or on lakes off the main course of the river. The coordinates of the area are approximately 6° to 9° South and 75° West. Upstream on the Ucayali from the town of Pucallpa, the Shipibo are known locally as the Conibo, although the language spoken and the culture shared by the Shipibo/Conibo are essentially the same. The entire group will be referred to here as “Shipibo.”

Shipibo is one of the Panoan languages of the Amazon. Panoan speakers tend to be concentrated around the upper Ucayali drainage basin in eastern Peru and western Brazil.

The word “Shipibo” is not generally used by the Shipibo to describe themselves. They tend to use the word “jonibo” (person [pl.]) in reference to themselves and the word “nahuabo” (foreigner/stranger/not-person [pl.]) in reference to others who are not Shipibo. The term “Shipibo” has been used by members of other tribes to refer to the group under discussion because of their custom of capturing and maintaining as pets specimens of the pygmy marmoset (*Cebuella pygmaea*), the smallest known primate, which is indigenous to the eastern Peruvian Amazon. In Panoan languages, this animal is called a “shipi.” The suffix “bo” indicates plural.

The term, “Chama,” is considered by the Shipibo to be a highly derogatory term that is used by the Peruvian mestizo population to portray the Shipibo as a subhuman underclass. The term is found in some early anthropological literature.

OVERVIEW OF THE CULTURE

The Shipibo are thought to have occupied the upper Peruvian Amazon area for about 1,000 years. They have principally and traditionally inhabited small settlements on the banks of oxbow lakes (“cochas”) and small tributaries of the Ucayali, although there have been both riverine and interfluvial groups. The latter groups, living away from large rivers, maintained a cultural ecology adapted more to the forest with wild game as protein sources. The predominant riverine groups, on the other hand, depend on fish as a primary but not exclusive protein source.

The Shipibo have long had a highly developed ceramic tradition, and their contemporary pottery is internationally known for its beauty and craftsmanship. Pots are used for cooking, eating, and ceremonial purposes, and sometimes for decoration.

The Shipibo women are also accomplished weavers, using a native cultivated cotton for making yarn and thread. They use a backstrap loom for large bolts of cloth that may be 10–15 m long and require the weaver to secure the distal end of the longitudinal threads to a tree. Small exquisitely decorative pieces such as bracelets and anklets are woven in the same manner with tiny looms.

The geometric and repeating patterns used by the Shipibo are distinctive and are painted or engraved on

pottery, cloth, faces, oars and clubs, and anything that might retain the figures.

Until the last few decades, the Shipibo economy has largely been one of subsistence supported by fishing, hunting, gathering, cultivation of high carbohydrate plants such as yucca (at least two varieties of manioc, *Manihot esculenta* sp.), plantain, and a large purple sweet potato (Bergman, 1980). More recently, rice and corn have been sown and cultivated for the market as well as for consumption. Chiclayo (black-eyed pea) is sown and cultivated on the exposed river beaches in the dry season.

Traditional Shipibo family patterns tend to be matrilineal and matrilineal, although this appears to alternate from generation to generation (Abelove, 1978; Eakin, Lauriault, & Boonstra, 1980; Hern, 1992b). Sororal polygyny was widely practiced in the past but is now much less common. Levirate and sororate are practiced: the brother of a man who has died accepts his deceased brother's wife as a second wife. She is often the sister of her new husband's first wife.

Cross-cousin marriages were the preferred marital arrangements in the past, particularly in polygynous families.

A typical Shipibo village consists of a single matrilineal extended family containing five or six nuclear families and representing as many as four generations. A specific example is a study community of 48 persons in which the oldest couple, parents of several daughters, have a household that includes several grandchildren in addition to the original couple. The most prominent man in the community is the husband of three of the couple's daughters, each of whom has her own hearth and household where her children reside. As a woman's daughters come of age, the woman's household may be joined by a young man who is a suitor or husband to one or more of her daughters. A son of hers is likely to leave the community to find a wife elsewhere.

Larger Shipibo communities appear to be the result principally of missionary activity in 19th and early 20th century (Myers, 1990). Catholic then Protestant missionaries induced aggregation of various family groups into small communities that were more susceptible to proselytization for religious purposes.

Missionaries describe some encounters with the Shipibo as extremely dangerous (Samanez Y Ocampo, 1980). This was particularly true for more isolated groups such as the Pisquibo: Shipibo who lived along the banks of the Pisquibo river, a tributary of the Ucayali. Shipibo are

depicted in various accounts as ruthless in the treatment of their enemies, especially the Cacataibo, or Cashibo as they are called by the Shipibo. In the early 20th century, Europeans and Peruvian nationals seeking to exploit the rubber and timber resources contracted with the Shipibo to drive the Cacataibo out of the areas of economic interest. The Cacataibo were driven deep into the forest and the Shipibo are now afraid to penetrate into the territory of the allegedly ferocious Cacataibo. Also during the rubber boom and during the late 1930s, some Shipibo were taken as slaves from the Ucayali region to other parts of the Amazon.

The traditional leader (*curaca*) of a Shipibo community is the male head of a large extended family, with an informal but permanent status until death, old age, or disability requires him to accede to a younger man. Currently, the Shipibo choose a village chief on a rotating basis and elect officials to conform with the national governmental structure. These leaders generally consist of an chief "jefe de la comunidad," or *curaca* (traditional), a *teniente gobernador*, official representative to the district government, and *agente municipal*. These are not traditional Shipibo designations, but the community process by which leaders are currently chosen resonates with traditional Shipibo methods of dealing with issues that affect the community. Community assemblies are attended by both men and women, and while male leadership predominates, women express their opinions vigorously and often prevail.

Traditional Shipibo religious views and cosmology are animistic. Spirits reside in various living things, specifically certain trees and animals, and in the stars. Fresh water dolphins are of particular interest and are not killed because of their intelligence and capacity to inflict harm on humans. The best published description of Shipibo cosmology is *The Cosmic Zygote* by Peter Roe (Roe, 1982).

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

The Shipibo have survived culturally and demographically through hundreds of years of European colonization and missionary activity at the same time that other tribes such as the Cocama have lost their identities and languages

within the Shipibo culture area. The Shipibo have apparently absorbed other groups such as the Setebo. The population numbers of the Shipibo during precolonial times is not known, but there is evidence that they, like all indigenous Amazonians, experienced catastrophic population losses following European contact due to the introduction of exogenous diseases, armed conflict with European settlers, slavery, and intertribal warfare.

In the mid-1960s, there were approximately 100 Shipibo settlements from Atalaya to Requena, including those found on Ucayali tributaries and interior lakes, comprising a total population of approximately 15,000. In the mid-1980s, there were 125 identifiable Shipibo settlements. The present Shipibo population is estimated to be about 40,000–45,000 in 150 or more settlements, and many Shipibo have moved permanently to larger Mestizo towns such as Pucallpa, which was originally a central Shipibo settlement.

In a baseline health study of the Shipibo village of Paococha in 1969, Hern (1971, 1977) found a population growth rate of 4.9% per year in a carefully defined population of 538. The annual birth rate was 69.3 per thousand, and the death rate was 20.4 per thousand. The difference ($69.3/1000 - 20.4/1000$ or $0.0693 - 0.0204$) yields the excess of births over deaths ($48.9/1000$ population = 0.0489) or 4.89% per year. This extremely high population growth rate means that the population doubles approximately every 14.3 years.

In this group, the Total Fertility Rate, which is the sum of age-specific birth rates, was 9.935, which means that the average woman had an average of 10 live births during her reproductive years. This and other measures of fertility showed the Shipibo to have the highest fertility ever recorded in a human group.

It is immediately apparent that this rate of population growth is recent since it would only have taken 90 years for a village the size of Paococha to have supplied the entire contemporary (15,000) Shipibo population, whereas this was only one village. In another perspective, the population growth rate of the Amazon population over the past 10,000 years or so is estimated at approximately 0.1% up until the time of European contact, and Myers estimates that there may have been as many as 10 million indigenous residents of the entire Amazon at the time of European contact (Myers, 1988).

This means that, following a massive population crash during the 16th–19th and early 20th century time span, the Shipibo experienced a rapid population

recovery with population growth rates that exceeded pre-contact rates. In fact, it appears that the most rapid population growth of the Shipibo population occurred in the years immediately following World War II.

At the same time, there has been an aggressive immigration of other Peruvians into the upper Peruvian Amazon. The town of Pucallpa, which was principally a Shipibo settlement in the mid- to late 19th century, contained a Peruvian Mestizo–Criollo population of about 3,500 in 1944. The Trans-Andean “highway” reached Pucallpa at about that time, and immigration from the Andes and the Peruvian coastal cities began, as did increased commercial activities in logging, petroleum exploration, fishing, cattle ranching, and agriculture. The Shipibo were increasingly exposed to sources of rapid cultural change, and they also found themselves competing increasingly with other groups and immigrant populations for the same resources.

Rapid cultural change in the region was enhanced by the establishment in the late 1940s of the Summer Institute of Linguistics, an evangelical Christian group dedicated to translating the Bible into native languages. Their base was built on the shore of Lake Yarínacocha and included a landing strip for the use of the missionary planes as well as establishing a fleet of float planes capable of landing on the waterways and lakes. The missionaries also provided excellent medical care, both preventive and therapeutic, to all indigenous groups with whom they had contact.

Another important influence on both cultural change and the health of the Shipibo was the establishment in 1960 of the Hospital Amazonico (Albert Schweitzer) by Dr. Theodor Binder, a German physician who was dedicated to helping the indigenous people of the Peruvian Amazon. The hospital, located on a high bank overlooking Yarínacocha and near the village of Puerto Callao, was several kilometers upstream from the Summer Institute of Linguistics. This area was separated from Pucallpa by approximately five kilometers of canopy rain forest and an overgrown cacao plantation.

Dr. Binder found the Shipibo in the 1950s to be suffering from a wide variety of infectious and parasitic diseases, with tuberculosis as a major epidemic which was killing many adults. He established the hospital to treat the Shipibo and other indigenous people for free. He also employed Shipibo men in the agriculture and animal husbandry projects that provided the hospital staff and patients with food.

Extensive and intensive contact between the Shipibo and Dr. Binder, along with the rest of his hospital staff and support operation, has been a major source of cultural change for the Shipibo as well as major contribution to their improved health during that time. Shipibo families came from outlying villages to reside at the campsite near the hospital while family members received prolonged treatment for diseases such as tuberculosis and leishmaniasis. More recently, they lived in modest housing constructed by the hospital administration. This contact resulted in exposure to health education but also to European customs and a Spanish-language environment. These families then have taken some of their adopted customs, material culture, and language influences back to the home villages.

Yet another source of cultural change at the village level was the introduction of Western-style schools. These were primarily elementary schools sponsored by missionary groups such as the Seventh-Day Adventists or bilingual schools established by the Summer Institute of Linguistics. Some educational materials included reading and arithmetic, but the curriculum had a heavy emphasis on religious indoctrination and marching around the village plaza or soccer field in a goose-step military fashion. Later, these schools were replaced in all villages by government-sponsored bilingual schools with education levels through high school in some villages. The goose-step, which seems antithetical to the languid cultural ethos of the Shipibo, continues to be the prescribed mode of marching.

The health of the Shipibo has waxed and waned during the past 50 years depending on the availability of vaccination programs, local epidemics, the sporadic availability of altruistic young doctors and nurses, and climatic conditions. A smallpox epidemic swept through the upper Amazon in 1964, killing thousands of indigenous people in hundreds of villages of various tribes. Some local vaccination efforts carried out by missionaries and individuals such as myself protected certain groups from decimation. Both before and after 1964, epidemics of various other contagious diseases such as chickenpox, measles, whooping cough, and polio affected people throughout the region. An epidemic of measles in the upper Pisqui River in the early 1970s killed dozens of Shipibo children before a young German physician, Andreas Kaper, went into the remotest Pisqui villages with vaccine.

Prior to large recent population increases throughout the upper Peruvian Amazon, the Shipibo lived in the

presence of spectacularly abundant food sources (Bergman, 1980). A few hours' fishing resulted in more than enough for a large family. Hunting wild game on high ground during the seasonal flood season often resulted in kills of deer, wild boar, tapir, monkeys, large birds, large rodents, and land turtles that provided excellent sources of protein. Gathered and cultivated fruit and vegetables resulted in a highly varied diet rich in vitamins and fiber. General levels of nutrition were excellent.

As regional population levels have increased, the Ucayali fishery has been subjected to great pressure. The town of Pucallpa, which had a population of approximately 3,500 in 1944, was estimated in 2002 to exceed 300,000 in its metropolitan population. The Ucayali is no longer merely the richest freshwater fishery in the world supplying small amounts of fish protein to a few Shipibo settlements living in a subsistence economy. Commercial fishing enterprises use large refrigerator ships with huge drift nets to capture all fish and other organisms 200 km downstream from Pucallpa. The catch not consumed by Pucallpa's growing population is shipped by land to towns on the flanks and high plains of the Andes.

The consequences of the decline in the Ucayali fishery for the Shipibo as well as the complexity of the ecosystem have been dramatic. Whereas a small group of men could leave the village before dawn and return by noon with several canoes full of fish, enough to feed a large extended family in several households for days, a pair of brothers may fish all day now to return at dusk with only a basin full of small fish—enough to feed a nuclear family for one day. The crash in the fish population has been most dramatic during the “mijano”—the upstream fish migration during the dry season months of July and August. In the past, abundant fish caught during this time could be salted, sun-dried, and preserved for weeks or months.

The decline in the fishery has been accompanied by other important changes in the ecology of the Ucayali. Extensive deforestation has resulted in severe changes in the forest climate and river flows. Slash-and-burn agriculture no longer affects small, isolated plots. Large tracts are purposely burned for ranching or cultivation, and large tracts are burned unintentionally and uncontrollably when the forest is exceptionally dry. The desiccation of the forest has accompanied dramatic drops in dry-season rainfall and river levels as local daytime temperatures increase with deforestation. Heavy rains in the wet season are no longer held in the canopy rainforest and its

groundcover. Rapid runoff, erosion, and flooding produce extensive and prolonged inundation downstream that destroys all cultivated crops, domestic animals kept for food, and some forests not adapted to flooding. Wild game is driven deep into the interfluvial forest areas. Fish are hard to find. Nutrition suffers from lack of protein, carbohydrates, and fresh vegetables and fruit that are sources of vitamins. Poisonous spiders, snakes, and scorpions join the household. It is hard to find firewood. Hygiene is next to impossible, and there is no place to bury the dead.

In the dry season, lower water levels mean stagnant, contaminated water in ponds near villages, a higher incidence of gastrointestinal diseases, especially in children, and widespread respiratory diseases due to severe air pollution. Dust storms from the exposed beaches are more common, and this combines with severe smoke density from burning slash in large plots and burning sawdust at sawmills to produce air that is often unfit to breathe.

The exact impact of these large system changes on overall Shipibo health is difficult to determine with certainty, but it appears that nutritional levels have decreased as a result of intermittent deficiencies in both protein and vitamins. Increasing dependence on a cash economy results in the sale of certain high food value items and produce for money used to purchase lower food value items such as sugar, cooking oil, and polished rice. The physical development of children is now less dependent on traditional activities such as hunting game, paddling canoes, carrying game and produce, and wrestling. Exercise is more dependent on school sports and programmed activities. Soccer is intensely popular and provides excellent cardiovascular exercise but not strength conditioning.

A study of Shipibo infants and children by Hodge and Dufour (1991) showed a tendency in 1984 to lower than normal development and diminished growth rates, especially after the age of 9 months. The authors suggested that mild to moderate protein deficiency malnutrition might be responsible for these growth disturbances. No time-comparison studies of Shipibo child development have been published, but recent unpublished field studies suggest that child development is showing no improvement and may be diminishing.

A study comparing the relative parasite burdens and hemoglobin levels in two radically different Shipibo environments found that people living in the upper

reaches of the Pisqui River have much higher burdens of hookworm (*Ancylostoma* sp.), among other things, and lower hemoglobin levels, than Shipibo living on the banks of the Ucayali River (Hern, 1995, unpublished manuscript). In the upper Pisqui, the soil is composed primarily of poorly drained dense, sticky clay, whereas the soil along the Ucayali is principally river sand that is well-drained and quite dry most of the time. Hookworm larvae that penetrate bare feet survive much better in the poorly drained clay soil environment, where it is also somewhat more difficult to dig latrines.

MEDICAL PRACTITIONERS

Several kinds of traditional medical practitioners are recognized among the Shipibo, although the highest and most authentic status is accorded the *muraia*, or “seer.” The *muraia* is usually a man who, in addition to his normal activities of fishing, hunting, and tending his chakra, practices the traditional Shipibo healing arts. A principal component of the *muraia*’s method of combating illness is *oni*, otherwise known widely as *aya huasca*, or “dead man’s vine.” *Oni* is the Shipibo preparation of *banisteria caapi*, a hallucinogenic drug known and used in different forms throughout the Amazon. It is derived from a certain vine that is harvested, cut up into small pieces, and boiled for 8–10 h in order to decoct the alkaloid that is the active hallucinogen. The practitioner takes large gulps of this liquid while entering a healing session (*jonibensuate*) with one or more patients. The songs he sings under the influence of the *oni* help him go into the underworld to fight off the *yushin*, or evil spirit trying to kill both the patient and the *muraia*, and help him summon the *ani yushin*, or great spirit. The *ani yushin* tells the *muraia* which songs (“*huihua*”) to sing to heal the patient and where to look for the right herbal remedies.

In addition to singing the healing songs (“*jonibensuatehuihua*”), the *muraia* talks to the patient, sounding very much like a Western psychotherapist, blows smoke over the patient’s body, and rustles bundles of dried plants over the affected area. These sessions go on for hours.

Another medical practitioner may be a “*curiosa*,” (Spanish term), or birth attendant who is not trained formally as a midwife. Another Spanish term for such a person is “*parteira*,” or someone who attends “*partos*” (births). The Shipibo do not seem to have a word of their

own for this activity or defined role except as someone who helps with “*bacque picotash*” (birth). This can be just about any adult woman with birth experience herself or who has attended births in the past. Each woman helps her daughters and granddaughters, in particular, and a woman with many daughters and granddaughters may develop an earned reputation as someone with great experience in attending births.

Other practitioners may be informally recognized as men who have special knowledge or experience at setting bones. But orthopedic manipulation and setting fractured bones happens in broad daylight surrounded by the curious as distinguished from the true healing session conducted by the *muraia*, which is sparsely attended and happens very late at night into the early morning hours.

To some extent, all Shipibo are medical practitioners because, at least in the old days, such knowledge of herbal and folk remedies was available to everyone (Arevalo, 1994; Foller, 1990). The exception is the *muraia*, who has both special powers that are earned and ascribed.

For his part, the *muraia* becomes an expert practitioner by fasting, taking the *oni* over long periods of time, learning the sacred songs and when to sing them, and obtaining and controlling the pure vision possible only under the influence of *oni* that is precisely prepared.

In recent decades, a new kind of modern practitioner has appeared, the *sanitario*, or medical corpsman. Some *sanitarios* are well-trained Shipibo men who have relatively good diagnostic and therapeutic skills. Some non-Shipibo *sanitarios* sent by the Peruvian government have variable skills, but none of the *sanitarios* have had much to work with in the way of medical supplies, vaccines, or instruments.

The *sanitarios* sometimes play critical roles in the prevention and management of epidemic disease as in the case of the cholera epidemics of the 1990s and in vaccination programs. But missteps occur as new technologies are applied. In one instance, a poorly trained Shipibo *sanitario* decided to perform a needle aspiration of an abscess that he perceived in the umbilicus of an elderly woman, who had a little occasional discomfort in the bulging spot. She subsequently developed diffuse abdominal tenderness, which was diagnosed as peritonitis by a Western medical practitioner. The umbilical bulge was a herniation of a loop of small bowel that had been punctured by the *sanitario*'s needle.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

The Shipibo are practical people who live in a complex, dynamic, and potentially hazardous environment in which injuries and death can and often do occur quickly. Traumatic injuries such as snakebite, puncture wounds, fractures, burns, lacerations, sting ray wounds, bites by carnivorous fish and alligators, insect stings, accidental gunshot, and allergic contact with known poisonous plants are obvious sources of suffering and death for the Shipibo. They have innumerable herbal remedies (*rao*) for these injuries, and some of them work amazingly well. The Shipibo are generally, it seems, incredibly resistant to a wide variety of pathogens that would fell the average person of European descent almost instantly.

The Shipibo have a certain working knowledge of what Europeans would call comparative anatomy and physiology since they dissect animals of all kinds in the process of food preparation. They know, for example, that there are embryos and fetuses in the uteri of various female animals that they kill such as tapirs, wild boars, and monkeys and that these features are not found in male animals.

On the other hand, internal illnesses and conditions without obvious origins such as fevers, paralysis, birth defects, and difficult deliveries are traditionally ascribed to conditions in the spirit world. In particular, the condition of *cupia* is widely attributed as a cause for various ailments, and the term for experiencing a variety of *cupia* is *cutipado*. The first term may be an original Shipibo word, but the latter is the grammatically Spanish past participle of the verb, *cutipar*, which may be a Spanish adaptation of a Shipibo concept. It is a widely used expression throughout the Peruvian Amazon. In any case, *cutipado* roughly corresponds to “bewitched” in English, and *cupia* is a kind of instant explanation for an otherwise inscrutable condition or illness experience. A child who is albino or who is exceptionally light-skinned, but normal in all other respects, may be said to be *cutipado*. This characterization is also a useful deflection of potentially inconvenient questions about why the individual looks so different from his or her siblings or cousins.

If, for example, a woman is pregnant, there are certain foods she may or may not eat and certain acts she

may not commit at certain times such as sexual intercourse. If she violates these restrictions, she may experience *cupia* or said to be *cutipado*, (Alvarez, 1990) a part of which is the process of being visited by and having sexual intercourse with a river porpoise or dolphin during the night. This state becomes the obvious post-hoc explanation for a difficult delivery, a stillbirth, delivery of a deformed child, death of the woman during childbirth, hemorrhage following childbirth, lack of breast milk, etc.

If a man kills a cayman (*Caiman sclerops*, variety of alligator found on the Ucayali), dolphin, or certain other animals, or if he cuts down a tree such as a lupuna that is sacred, he also may be *cutipado*, which is the obvious explanation for his prolonged inexplicable illness in which he experiences severe abdominal pain, headache, malaise, convulsions, or jaundice and dies an agonizing death. It could also be that he simply offended someone, who arranged for him to be *cutipado*.

A young woman who is *cutipado* may experience a dissociative, hysterical episode during which she is obviously out of control, having seizures, screaming, shaking, clenching her teeth, sweating, moaning, and beyond any social interaction. These episodes, which are uncommon, may go on for long periods of time up to an hour. In such a case, she has clearly been *cutipado* by an enemy, perhaps a social or sexual rival, with the help of someone who practices *brujeria* (Spanish for witchcraft). The person who practices black magic (*magica negra*) casts a spell (*cupia*) on the person who then experiences the dissociative state, which does not in any way resemble what is known in Western medicine as an epileptic seizure. I have observed these behaviors (with similar explanations) in other indigenous societies in Latin America.

SEXUALITY AND REPRODUCTION

The Shipibo like sex and are sometimes quite open about it, particularly in joking relationships. They love obscene and intimate sexual humor, especially when there is a cover of darkness to obscure the speaker (even though everyone knows from the voice who is speaking). Whether it is under the influence of Christian missionaries or reflects traditional Shipibo custom, sexuality is not flaunted or openly recognized during the day and in the midst of communal activities. Young people court and disappear into the bush. Although there is no formal

marriage ceremony, young couples who are recognized as “newlyweds” are indulged as they spend long hours under the mosquito net together, even during the day. The young man is then likely to be ribbed mercilessly by his age-mates about his consequent alleged weakness and incapacity for any useful work. Most sexual activity, however, seems to occur in a more furtive fashion as husbands and wives bathe together in the river at dusk and meet secretly in a remote section of the *chacra*, or garden, distant from the village. It is customary for whole families to sleep under one mosquito net. Sexual activity between spouses occurs during the night under the family mosquito net when the children are asleep.

Shipibo women have a wide variety of herbal remedies that are thought to control reproduction. The general category of these remedies is *to-otirao* (pregnancy = *tooti*, and medicine = *rao* or “rau”). A kind of *tootirao* is taken in order to become pregnant.

Remedies to prevent pregnancy are more common. The most commonly known *tootimarao* (*ma* = negative) is *tootimahuaste*. *Tootimahuaste* is a grass-like plant (probably a sedge) that grows on the shores of a lake (*huaste* = herb). It is pounded and the juice squeezed into a cup of hot water. This tea is taken the first three days of two successive menstrual periods. This is alleged to result in permanent sterility.

Tootirao works by making the *baquenanutu* (uterus) moist, lush, and receptive to the seed of the man. *Tootimarao* works in the opposite way: by making the inside of the *baquenanutu* hard, dry, and unreceptive to the male’s seed.

Failing to observe the prescribed pregnant woman’s diet or behavior restrictions may result in *cupia* and a complicated pregnancy in which the woman dies, suffers a stillbirth, or gives birth to a deformed baby.

In spite of the widespread knowledge and use of herbal contraceptives (Hern, 1976), fertility has been exceptionally high among Shipibo women. A possible explanation for this paradox is that the prescribed dietary/behavior regimen that accompanies the use of herbal contraceptives includes sexual abstinence. In epidemiology, a lack of pregnancy under these circumstances of herbal contraceptive use would be called a “secondary non-causal association.”

Women living in monogamous, as distinguished from polygynous relationships, find it hard to observe a period of sexual abstinence. A later study of the relationships between polygyny and fertility showed that

polygynous women had longer birth intervals and fewer pregnancies. Further, the measured community fertility rate had a straight-line negative relationship to the level of polygyny practiced in a particular village. The less polygyny, the higher the community fertility rate, and vice versa (Hern, 1988, 1990, 1992a, 1992b).

In a traditional family, sororal polygyny (in which all co-wives are sisters) is the preferred and prevailing family structure. In this setting, women are able to observe post-partum sexual abstinence for longer periods of time than women who are in monogamous unions. Births are fewer with more time between them. This has a positive effect on the health of both mothers and children.

The change from polygyny to monogamy began with the first contact with Christian missionaries. Polygyny is still severely criticized by Christian missionaries, and in one well-known instance, a disapproving official Peruvian census taker would not count members of polygynous families. The extremely high fertility and high rates of population growth that have been found in Shipibo communities are at least partly due to cultural change with a disruption of patterns that dampened fertility.

Although the Shipibo treat children with a great deal of gentle affection, they do not express any desire for more than two or three children. The rare woman who is infertile or subfecund is regarded as unfortunate, but not tragically so. Such women and their partners readily adopt children from other households, and the children have two homes and families, almost always harmonious.

The Shipibo express vague concern and unease about population growth as they see it directly affecting their daily lives. There are a bewildering number of children needing school classrooms and teachers, more each year, and there are increasingly scarce resources. But they do not see how they can influence events, especially the growth and intrusion of large population groups from outside the village. *Estaremos aplastado por los nahuabo*—"We will be squashed (and wiped out) by the (non-Shipibo)."

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

Young Shipibo women learn about pregnancy and birth from close observation of their mothers, sisters, aunts, and cousins. Traditionally, the young woman has her first

menarche at the age of 12 or 13. She has her first sexual experience and perhaps a permanent partner at 13 or 14, and has her first baby by age 15.

One type of herbal contraceptive is called *navashuaste*, which is taken by young women in order to postpone pregnancy instead of causing permanent sterility, the effect sought by taking *tootimahuaste*. There is no evidence that the use of *navashuaste* for this purpose is successful.

When a woman is pregnant, she must observe certain dietary laws and taboos that restrict activity and foods. She must not be subjected to a frightening experience such as encountering a snake or other wild animal.

Spontaneous abortions occur, but they are uncommon and accepted as a matter of fact. The term for a spontaneous abortion is *bacquencahuana* (literally "baby falls out"). Twins are rare but do occur. Induced abortion is almost unknown.

Birth occurs in the woman's home, and she is usually attended by her mother and/or close female relatives in the same age range as the woman's mother. A young woman may be surrounded by all the women neighbors in the case of a difficult delivery. Freely offered folk advice from this gathering of interested spectators is accompanied during labor contractions by a frantic chorus of "Push! . . . Push! . . . Push!"

After delivery, the placenta is usually buried under the woman's house.

Infancy

Newborn infants are not given a name until one or more months of age. The Shipibo name (*janecon*, "true name") is given first, although a Spanish name with paternal and maternal surnames may be given for birth registry. The reason for the delay in naming is the recognition of a high probability of neonatal death.

Newborn infants are traditionally painted with *huito*, a black vegetable dye (*Genipa* sp.), with their faces painted in a typical geometric Shipibo design. The explanation for the face painting is that the design wards off the *yushin*, or evil spirit that causes illness and death. It also looks nice. There is no distinction between painting a thing or person with designs to protect it from evil spirits or just for fun.

Shipibo children are engulfed in love from their first moments and are highly indulged by both parents. Children are breast-fed for at least 6 months, and complete weaning may not occur for several years.

Infants are carried on the hip in a shawl tied around the mother's neck as she goes about her various chores. Very young infants sleep during the day in a covered hammock that is watched by a grandparent, sibling, or other relative who may be sitting nearby performing such tasks as weaving and potting.

In the past, a multiple birth resulted in one twin being killed by suffocation, as was the case of a severely deformed infant. This practice appears to have been abandoned, especially for twins.

All children receive close supervision and attention from a variety of adults, but particularly the child's mother and the mother's immediate relatives. This is true for both healthy and sick infants. The child of a woman who has deficient or no breast milk is nursed by a female relative who is lactating.

When infants are weaned, they are given increasing amounts of stewed ripe mashed plantains, a preparation that has the consistency of liquid oatmeal. Unfortunately, the mother may add raw river water that is heavily contaminated with human feces to this otherwise healthful preparation. As an obvious result, between 10–40% of children in some villages die of gastrointestinal ailments before they reach one year of age.

Childhood

Young children up to the age of 10–12 are given great freedom to play with their peers and to explore the area around the house and village. They frequently accompany their parents or other adults on excursions such as going to the garden to cultivate or gather food, or, in the case of boys, to hunt and fish with their fathers.

Shipibo children begin learning the complex family relationships including kinship terms and avoidance patterns at a very early age (Abelove, 1978). A Shipibo child's social success is highly correlated with its mother's pattern of interactions with others.

Child abandonment is almost unknown. It is inconceivable to the Shipibo. "Only mestizos abandon their children." Discipline is gentle and consists principally of quiet talking and persuasion. Once in a while, a parent will spank a young child. A parent may gently scold or, rarely, have an angry exchange with an ill-behaved older child, but it does not appear that the physical abuse of children occurs among the Shipibo.

Sick children are given round-the-clock nursing care, and those with chronic illnesses are given special

support, such as having someone specifically assigned to help that impaired person.

Adolescence

Although traditional patterns are changing rapidly with the introduction of formal schools through the high school level, Shipibo adolescents still assume many adult responsibilities that include subsistence activities and mating. Informal trial marriages occur with an adolescent couple cohabiting in the girl's parents' house, and these are generally regarded as temporary arrangements. If the girl becomes pregnant, however, a more stable relationship is likely to emerge.

Adulthood

In the absence of formal Western schools, Shipibo girls entered permanent sexual relationships at the age of 13 or 14 and immediately began having children. They were considered adults from that point on. Currently, girls are encouraged to attend school at least through grade school and beyond if possible. Sexual encounters occur, but adolescent cohabitation in the traditional patterns occurs much less than it did before the introduction of schools.

Once a nuclear family is established, the young husband builds a house for his own family, typically in the family compound or immediately adjacent to the home of the woman's parents. A separate structure containing the hearth and eating area is usually a few meters from the house. In the case of polygynous marriages, each woman may have her own house and hearth.

People over 40 years of age are considered "old" since life expectancy is under 50 for women and not much past 50 for men.

The Aged

People who are very old—those who reach the age of 70 or 80—are treated with great respect and veneration. An elderly adult woman suffering from tuberculosis, for example, is given her own hut next to the main family house, and young children are assigned to help her in every way. Her food is brought to her and she is accompanied to the lake or river for bathing.

Tuberculosis is a major killer of mature and elderly adults among the Shipibo—those who have the most knowledge of the ancient traditions, songs, and secrets of

the forest. An inordinate number of Shipibo women die from cervical cancer.

Although autopsy studies are not possible, it appears that some adults die from the effects of migration of certain ingested parasites to vital organs such as the brain and liver.

As death approaches a very sick person, family members, mostly women, gather around the person who is *isin* (sick) and offer whatever support they can. This is especially true for a very elderly person with many progeny and other relatives. When the person expires, the gathered kin begin wailing a melancholy falsetto falling scale in a minor key spanning about an octave. This pattern is repeated over and over, with the high notes sometimes sustained to express the intense grief. It is a penetrating and unmistakable sound that carries far, especially over large expanses of water, and it communicates the loss to all within hearing range.

The deceased is typically laid out on a table, if a child, or on a mat on the ground under the kitchen roof. Candles are sometimes placed at the head and feet, a custom that may be Catholic in origin. Friends come to pay their respects, sit quietly for awhile, perhaps wailing, then leave, offering a few words of consolation to the survivors.

Adults are placed in an old canoe, which is covered with sawn boards, and the body is buried in the village cemetery. Infants and children are placed either in a child's canoe or in half of an adult canoe. Everyone takes turns throwing dirt onto the casket as the grave is filled.

Funerary jars uncovered by erosion at an ancient settlement that surely predated European contact indicates that deceased individuals were buried in very large pots at that time.

The custom of close contact with those who are ill, including the sharing of drinking and eating vessels, contributed to high Shipibo mortality during a cholera epidemic on the Pisqui and Ucayali in 1990–91. Whole families died within hours of each other.

When an adult man dies, his house is burned down with all his possessions. His widow crops her hair and dresses in black for one year. The possessions of a woman who dies are burned, but not the house in which she lived.

At the end of one year, a funeral wake is held and marks the end of the mourning period.

The Shipibo have a proverb that helps them cope with constant death and loss among their families and friends: *Huinata jahuequi moa shinantima*—"We no

longer think about the things that are so sad they make us cry."

Sotho

Nancy Romero-Daza and David Himmelgreen

ALTERNATIVE NAMES

Basotho, Basuto, Southern-Sotho.

LOCATION AND LINGUISTIC AFFILIATION

The Sotho inhabit the southernmost region of Africa and are found across the international lines of three countries: South Africa, Botswana, and Lesotho. The Sotho constitute about 1% of the general population in Botswana and 16% of the total population in South Africa (Ikuska, nd). In both these countries, the Sotho are scattered around the territory and are not geographically distinguishable from other ethnic groups. On the other hand, there is a considerable concentration of Sotho in Lesotho, where they comprise 99.7% of the national population (Central Intelligence Agency, nd). Because of the close correspondence of ethnic and political boundaries, our discussion of cultural characteristics and their relation to health will be drawn from populations living in Lesotho. The Sotho are native speakers of Sesotho, one of the Bantu languages. Sesotho is closely related to other major languages spoken in southern Africa including Setswana (spoken in Botswana and South Africa), Sepedi (spoken in northern South Africa), and Silozi (spoken in Western Zambia) (Ambrose, 1976).

OVERVIEW OF THE CULTURE

Basotho society is patrilineal and patrilocal and politically organized as a chiefdom. Descent is traced exclusively through the father's lineage, as is the allocation of property rights (Gay, 1982). Upon marriage, women move to the husband's village, where they and their children reside for the rest of the woman's married life, usually in extended-family compounds. The Basotho people trace their ethnic origins back to the Bakoena clan, a group of cattle-owning agriculturalists who inhabited

the Witwatersrand area of the Transvaal in present day South Africa as early as the 5th century (Ambrose, 1976). In the 19th century, several Sotho-speaking groups that were fleeing the Zulu chief Shaka came together under the protection and leadership of Moshosho, who would become the founder and first king of Lesotho. During the Lifaqane wars between 1820 and 1830, Moshosho and his people were forced to retreat to the Thaba-Bosiu mountainous fortress in the Maluti mountains (Schwager, 1986). From there, they continued fending off various attackers such as the Amangwane in 1828, the Batlakoa in 1829, and the Amandebele in 1831. Starting in the mid-1830s and continuing through the mid-1860s conflict over land rights between the Basotho and Boers from the Cape Colony in South Africa resulted in the loss of the most fertile lands and the relegation of the Basotho to the most arid and infertile mountain regions. In March 1868, Basutoland became a British protectorate, and in 1966 it gained its independence from Great Britain.

Although an independent entity, the Kingdom of Lesotho remains economically dependent on its all-encompassing neighbor, South Africa. At present, only about 10% of the land is arable and agriculture contributes about 4% of the Gross National Product (GNP). There are some flourishing industries such as textiles, clothing, and mohair wool, and some natural resources such as water, which is exported to South Africa. Nevertheless, the country's main source of revenue is migrant labor to the South African mines (Romero-Daza & Himmelgreen, 1998). Participation of Basotho men in the South African mining industry dates back to the 1860s when the first diamond mines were opened in the Cape Colony (Gay et al., 1991; Murray, 1981). During the last decade there has been a very significant reduction in the number of Basotho men engaged in migrant labor in South Africa. For example, between 1997 and 1999 the number of Basotho miners was reduced to almost half due to the declining price of gold on the international market (Global Policy Network, 2001).

The present-day Basotho population in Lesotho is predominantly Christian. The main denominations include

the Roman Catholic Church, the Lesotho Evangelical Church, the Anglican Church, the Methodist Church, and several independent churches (Ambrose, 1976). However, many traditional beliefs and practices, especially those relating to ancestor worship are still prevalent among the Basotho. The ancestors, those relatives who have died, are considered to be guardians of their living relatives, and to afford protection, good health, and prosperity. However, if they are not honored in the appropriate way, or if they are neglected, they are likely to cause misfortune and illness (Sheddick, 1953).

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

By the year 2000, the total population of Lesotho was estimated at around 2,033,000 inhabitants, with a population growth of 1.9% between 1999 and 2000 (WHO, 2002). Life expectancy at birth was calculated at 42 years, with no noticeable differences by gender. As of May 2002, infant mortality was estimated at 72 per 1,000 live births, and mortality for children under five at 99 per 1,000 live-births (WHO, 2002). However, accurate figures are very difficult to obtain. In fact, UNICEF reports considerably higher rates for both these indicators, 92 per 1,000 and 133 per 1,000 respectively as of February 2002 (UNICEF, 2002).

Lesotho's mountainous terrain and its location outside the tropics provide a relatively salubrious environment. As a result, many of the tropical diseases such as malaria and schistosomiasis that are commonly found in other parts of Africa are not common in Lesotho (Gish, 1982; Ministry of Planning, 1991). Rather, the main problems that affect the health of the population are directly related to widespread poverty and the lack of basic sanitation. Among these are diarrheal disease, typhoid, and dermatological infections such as bacterial skin sepsis, fungal infections, and scabies, which affect the population at large and especially young children (Ministry of Planning, 1991). Only about 62% of the total population have access to safe water sources, while the rest, especially those in mountainous areas, use unprotected springs and wells which, if contaminated with fecal matter or other waste, could become a major source of infection for many Basotho (WHO, 2002).

The marked seasonal differences found in Lesotho are closely associated with the health of infants and children. For example, the hot humid summer months are the prime time for diarrheal disease. The effects of diarrhea are compounded by the rise of malnutrition that results from the low availability of foods during this time of the year, which corresponds with the pre-harvest period. During the dry and cold winter months, when food is plentiful, the incidence of diarrhea decreases, but respiratory infections rise significantly (Himmelgreen, 1994). At present, it is estimated that about 16% of Basotho children under 5 suffer from acute malnutrition (WHO, 2002). For adults there are also seasonal differences in nutritional status, especially in the highlands and for households that rely mostly on their own agricultural production. For example, Huss-Ashmore and Goodman (1988) found a seasonal weight fluctuation of 4 kg (7%) among women living the Mokhotlong District, in the Northeastern Maluti mountains. In a later study, Himmelgreen and Romero-Daza (1994) also found seasonal differences among women from Mokhotlong but these differences were not as marked as the earlier study. However, women who relied on subsistence agriculture lost more weight seasonally than did women who purchased most of their food. Today, as many developing countries, Lesotho is also faced with increasing rates of overweight and obesity, partly as a result of rapid modernization and the increased consumption of sugars and fat. The traditional diet of the Basotho tends to be highly monotonous and consists mainly of maize meal ("papa") and wild vegetables ("moroho"). Consumption of animal protein is generally limited to that provided by eggs, while the much more expensive sources such as red meat are consumed much less frequently (Himmelgreen, 1994).

An issue of central importance for the overall health of the Basotho is the rapid spread of Sexually Transmitted Infections (STIs), including HIV/AIDS. Between 1983 and 1993, STIs were the second most common outpatient condition seen in Lesotho clinics and hospitals (Family Health International, 2001). It is estimated that about 24,000 Basotho are currently living with HIV, reflecting an infection rate of 24% among adults, one of the highest in the world. Over half of these cases (54%) are found among women. So far, the epidemic has left an estimated 17,000 orphans among Basotho children (Family Health International, 2001). Central among the factors that have contributed to the rapid explosion of the AIDS pandemic is the system of labor migration of men into South Africa

(Romero-Daza, 1994b; Romero-Daza & Himmelgreen, 1998). The widespread poverty that fuels the prostitution industry in South Africa, coupled with lack of preventive and curative services for underlying STIs, results in increasing rates of infection for both women and men. Once infected, miners spread the virus to their wives and other sexual partners when they return to their home countries, and from them to their unborn children.

In Lesotho both traditional and biomedical systems of care co-exist. The country has been divided into 18 Health Service Areas (HASs), each of which includes a hospital, at least one clinic for outpatient care, health centers run by a nurse clinician with the support of village health workers and traditional birth attendants, and village health posts which are visited by medical teams on a monthly basis (Ministry of Planning, 1991). However, the provision of biomedical services to the Basotho is restricted by overall low budgets, limited infrastructure, and shortage of personnel, and is especially deficient in isolated rural areas. According to estimates by the World Health Organization, as of 1995 there were 5.4 physicians, 60.1 nurses, 47 midwives, and 0.5 dentists per 100,000 inhabitants (WHO, 2002). Traditional medicine provides a major source of health care for the Basotho, especially those living in places where biomedical facilities are inadequate. The practice of traditional medicine is regulated and overseen by the Universal Medicinemen and Herbalist Council established in 1978. This body is responsible for the registration and licensing of traditional medicine practitioners, and promotes the development of new skills among practitioners (WHO, 2001). It is not possible to get an exact number of Basotho traditional healers still practicing in Lesotho, since many of them are not officially registered with the Council. As of 1991, there were 9,579 registered healers and an estimated 23,000 unregistered practitioners (Gay & Hall, 1994).

MEDICAL PRACTITIONERS

Basotho traditional healers can be categorized depending on the healing methods they use and the type of training received. Two of the major categories include herbalists and Bible readers (Romero-Daza, 1994a). Herbalists specialize in the treatment of diseases through the use of herbs and roots, while Bible readers usually belong to a specific church and treat their patients almost exclusively with blessed water and prayers. Depending on the

severity of the disorder, some Bible readers mix their water with ashes obtained from animal bones or with specific types of soil. Bible readers usually diagnose through the use of biblical passages, by the "laying of the hands," or by praying over and examining water collected by the patient from a river or brook. Herbalists usually diagnose by casting bones, dice, or shells, and interpreting the way in which such objects fall on the ground. Regardless of healing or diagnostic differences, the call to become a healer follows a similar pattern. Usually the person becomes very sick (physically and/or mentally), and is said to have "moea" (literally wind, spirit), which is an indisputable sign of his/her call to be a traditional healer. The disease period is characterized by "thoasa," recurrent dreams in which the person's ancestors instruct the individual on their wishes and guide him/her to look for a tutor to teach the apprentice about traditional medicine (Romero-Daza, 1994a). The role of the traditional healers often extends beyond the treatment of physical and mental disorders, and covers the solution of interpersonal difficulties that may affect the harmony among family or village members. This role fits well with the overall Sotho conceptualization of "health" as a balance among physical, psychological, social, and spiritual aspects of life.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

While the biomedical paradigm is readily accepted by most of the Basotho, traditional beliefs regarding the cause of illness and disease are still commonly found among this population. Prominent among these is the belief that diseases are caused by the breach of taboo. For example, a person who has sexual relations while still mourning the death of his/her spouse may be afflicted by "mashoa" or "mahae" which roughly correspond to genital warts. According to traditional beliefs, as the body of the deceased decomposes, so do the sexual organs of the surviving spouse (Hall & Malahleha, 1989). Another common cause of disease is the use of witchcraft. For example, a person can cause another to become sick by placing a special magical substance (usually water containing powerful medicines) on the path to be traveled by his/her enemy (Romero-Daza, 1994a). Finally, disease

can be caused when ancestors have been neglected by their living relatives, or when spirits such as the “thokolosi” enter the body. One of the main results of witchcraft or of spirit possession is the manifestation of mental health problems that can only be cured with traditional therapies. However, mental problems are not always considered negative. Quite often, a person who presents what would be classified as mental health symptoms (e.g., hearing voices, having hallucinations) is believed to have been chosen by their ancestors to become a traditional healer. In such cases, the ancestors communicate their desires and specific instructions through visions and dreams. Once the person becomes a healer, he/she may continue to communicate with the ancestors, thus continuing to strengthen his/her curative powers.

Regardless of the cause of disease, the placation of the ancestors’ wrath is one of the main methods of treatment for the great majority of problems. Traditional Basotho culture prescribes the slaughtering of animals and the performance of specific rituals in honor of the ancestors. Other curative methods include the widespread use of medicinal plants both by traditional healers and by lay people. An important healing practice that might become significant in the spread of HIV is that of “scarification,” in which traditional healers make small incisions on the patient’s skin, and use their mouth to extract the disease-causing object from the patient’s body (Romero-Daza, 1994a, 1994b). Given the great number of patients seen by traditional healers, many of whom may be HIV positive, the use of contaminated blades may provide an effective medium for the transmission of the virus from person to person (Romero-Daza & Himmelgreen, 1998).

SEXUALITY AND REPRODUCTION

Fertility rates among the Basotho tend to be lower than among other African populations, and were estimated at 4.6 in 2000 (WHO, 2002). Possible reasons for such low rates are the constant absence of men engaged in migrant labor in South Africa, the practice of extended breastfeeding, and the existence of postpartum sex taboos. In addition, the high rate of sexually transmitted infections and of maternal malnutrition may also decrease pregnancy rates and increase spontaneous abortions (Ministry of Planning, 1991). The rate of contraceptive use has

been estimated at 23% (UNICEF, 2002). Nevertheless, Basotho greatly value children of both sexes and strive to have large families. Children provide a source of support for elderly parents, a source of labor for domestic, agricultural, and pastoralist activities, and a great source of prestige. Having children affords women the status of full womanhood (this is represented linguistically by the honorifics *M’e* (mother) and *Ausi* (sister) used to address women who have children and those who are childless, respectively). Moreover, infertility was considered a just cause for divorce. Traditionally, remedies for infertility included the use of special herbs provided by healers who specialized in the treatment of the condition, and the practice of carrying specially made dolls on the women’s back, as if they were children (Ministry of Planning, 1991). If the combination of these two methods was ineffective, the woman’s husband was allowed to take a second wife. However, any children born of that union would be considered to belong to the first wife (Ministry of Planning, 1991). At present, infertility is still regarded as a serious problem that needs to be treated by either Western or traditional doctors. Even among traditional healers there is a growing understanding of the fact that men, and not only women, can suffer from fertility problems, and need to be equally evaluated.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

A Basotho woman’s first pregnancy is considered of great importance since fertility is an indication of harmony between the living and their ancestors, and pregnancy signifies the continuation of the father’s lineage, and the establishment of the couple as a new family (Gay, 1980). The pregnant woman is expected to follow a diet that is rich in nutritious grains, and to avoid the consumption of fish, which is believed to cause health problems to the unborn child. Traditionally, Basotho women return to their paternal home around the seventh month of pregnancy and remain there for up to three months after the birth of their child. This transition from their husband’s to their own group is marked by special rituals and feasts in which the two families participate (Gay, 1980).

Traditional Basotho considered spontaneous abortions, major abnormalities in infants and fetuses, and the death of young children to be the result of witchcraft

(Ministry of Planning, 1991; Sechefo, nd). To protect against such problems, a pregnant woman was required to remain in her house, avoid going out at night, and avoid walking in places where people could have placed harmful medicines. Women in labor were supposed to cover their breast with a special skin to ward off evil spirits that could harm her or her baby (Ministry of Planning, 1991). Placentas were traditionally placed in earthen pots and buried in the early morning or at night. Only women who had helped the mother during her pregnancy or labor were allowed to perform the burial rituals (Sechefo, nd). While most of these practices have disappeared, some are still common in the most remote rural areas of the country.

Infancy

During the first two or three months after the birth of a baby, mother and infant are secluded in a house whose entrance is marked with reeds projecting from the thatch right above the door. These reeds serve to warn strangers as well as men who are not immediate relatives to stay away (Gay, 1980). It is believed that this protects the new baby from evil that can be caused by the “bad conduct” of adults (Sechefo, nd). The new mother must remain inside as much as possible, but if she needs to come out, she must cover herself with a special blanket or shawl. Both mother and child receive direct care from the mother’s female relatives, thus exposing the baby from the beginning of its life to direct interaction with many “mothers.” Special ceremonies to end childbirth pollution are conducted when the baby loses the remains of the umbilical cord. These include the shaving of the baby’s head and the washing of clothing and bedding. At this point, the baby’s father is allowed for the first time to enter the house where his wife and child are (Gay, 1980).

Among Basotho, there is a strict taboo against sexual relations during the post-partum period and especially during the breast-feeding period, which may extend for up to two years. Engaging in sexual activity during the lactation period is believed to result in the contamination of the breast milk by the semen, which causes serious health problems to the infant (Romero-Daza, 1994a). “Senyeha” as the disease is called, is characterized by rapid weight loss, severe diarrhea, loss of appetite, and failure to thrive, and may be fatal to the infant. Weaning informally marks the end of the period of infancy, and signals that the mother is ready to resume sexual activity (Gay, 1980).

Childhood

The beginning of the weaning period, when the child is around two years of age, coincides with the expansion of the number of caretakers a child has. At this time, the child begins to spend much more time under the care of other female relatives, including very young girls, and starts the active process of socialization into the prescribed gender roles. Young girls spend most of their time in the family compound and begin contributing to domestic chores such as the collection of dry dung to be used for fire, or the collection of wild vegetables. Young boys, on the other hand, spend most of their time taking care of the animals. In fact, with the absence of adult men for most of the year, even very young boys often spend extended periods of time away from their homes while taking care of the family’s animals. This early division of labor translates onto marked differences in school attendance. Unlike girls in many other developing countries, Basotho girls have a higher school attendance rates and higher overall literacy rates than do boys (Ministry of Planning, 1991).

Although minor corporal punishment as a disciplinary measure is not uncommon among the Basotho, the culture rejects the use of excessive force that may result in injuries (Ministry of Planning, 1991). Among Basotho children, the most common health problems are waterborne diseases such as diarrhea and typhoid, nutritional deficiencies such as kwashiorkor and marasmus, acute respiratory infections, and skin problems such as scabies and fungal infections (Gish, 1982; Himmelgreen, 1994; Ministry of Planning, 1991; WHO, 2002). Rates of HIV infection among Basotho children are increasing rapidly. With prevalence rates among pregnant women reaching up to 24%, many HIV positive children are being born. Even those who are not infected are experiencing the indirect consequences of the epidemic, as they often lose one or both of their parents to the epidemic. More and more, orphaned children are being forced to take the responsibility for younger siblings if they do not have grandparents or other relatives who can support them when their parents die.

Adolescence

In Basotho society, the end of childhood is traditionally marked by participation in initiation schools. Although the practice is diminishing in frequency, it still constitutes a

major rite of passage for many young Basotho. During initiation school, groups of adolescents spend a period of up to several months in isolated areas of the country. During this time, which is surrounded by secrecy, teenagers learn about their traditions, their culture, and about what it means to be Basotho. At the end of the initiation school, boys are circumcised, and special ceremonial feasts are conducted to mark their entrance into adulthood and their new status as full members of the group. Young girls are not required to undergo any genital operation.

Basotho discourage the practice of premarital sex and encourage marriage at an early age. Traditionally, there existed taboos to regulate the sexuality of adolescents. For example, young women were not allowed to eat eggs, since these were believed to increase the adolescent girls' sexual needs and to make them more fertile than necessary. Nevertheless, premarital sex is on the rise, as is the number of children born out of wedlock (Ministry of Planning, 1991). Teenagers are also exhibiting increasing numbers of Sexually Transmitted Infections, and of HIV/AIDS. As of 1993, teens accounted for 9.4% of all individuals seeking outpatient care for STIs in public hospitals and clinics (Family Health International, 1997). One factor that contributes to the spread of STIs and undermines the efficiency of prevention programs is the cultural tradition that prohibits the open discussion of sexual matters before marriage (Romero-Daza, 1994a, 1994b).

Adulthood

The most common health problems among Basotho adults include high blood pressure, alcoholism, respiratory tract diseases, cardiovascular disease, skin conditions, STI (especially gonorrhea, syphilis, and AIDS), and injuries (Gay & Hall, 1994; Schumacher et al., 1990). Among women, reproductive problems and STIs including gonorrhea, syphilis, trichomonal vaginalis, and candida moniliasis account for most outpatient visits to health facilities throughout the country (Gay & Hall, 1994). Women accounted for more than half of the HIV infection cases in the country as of 2000 (Family Health International, 2001). The rate of infection for pregnant women who seek prenatal care has been increasing considerably in both urban and rural areas of the country, and ranges from 12.3% in the isolated mountainous areas of Mokhotlong to 42.2% in the capital city of Maseru (Family Health International, 2001).

Among men, the major causes of morbidity and mortality are associated with their occupation as miners.

For example, mining accidents are a major cause of injury, disability, and death among Basotho males. Likewise, the high prevalence of tuberculosis may be directly related to the overcrowding and overall poor sanitary conditions of the living quarters commonly found in the mining compounds. The high rate of sexually transmitted infections is directly associated with sexual relations with prostitutes and the low use of condoms. In addition, alcoholism is a very serious problem among adult Basotho. In 1993 it was considered the second most serious disease affecting the population at large (Gay & Hall, 1994). Alcoholism has been associated with very high rates of automobile accidents and interpersonal violence. The easy availability of liquor, including the homemade traditional "joala" beer and the general social acceptance of drinking contribute to the problem.

Domestic violence also constitutes an important cause of morbidity and mortality among modern day Basotho. Actual rates are difficult to determine because many cases of domestic violence are never reported to the authorities. However, admission and treatment records from hospitals, clinics, and other health care facilities report high rates of violence-related injuries, especially among women of reproductive age (Gay, 1980).

The Aged

Among the Basotho, the elderly are afforded special status and respect as pillars of the society. Traditionally, children and grandchildren offer a source of material and social support for their elders. However, as in many places in Africa, with the explosion of the AIDS pandemic, the traditional roles are rapidly changing, and the elderly are being forced to care for their younger relatives. Specifically, as adults of reproductive age become ill, their parents become the main care providers, who are also burdened with the responsibility of finding financial resources for the treatment of the diseased. As the younger generation dies, the elderly find themselves being responsible for the upbringing of any of their young grandchildren left orphaned (Romero-Daza & Himmelgreen, 1998).

Dying and Death

Basotho consider the death of an older person as a normal part of the life cycle and as a transition to the world of the ancestors. However, the death of young people, and especially of children is often believed to be the result of either

witchcraft or of the failure to perform the necessary rituals or to fulfill obligations to the ancestors (Ministry of Planning, 1991). In the past, the death of a young woman at childbirth was especially alarming since it represented an omen of misfortune for the whole family. In such a case, the surviving child was considered to be highly vulnerable and was afforded special protection by his/her relatives throughout his/her life (Ministry of Planning, 1991). Also worrisome were any sudden deaths or those caused by lightning, which were believed to be the result of witchcraft. Regardless of the cause of death, the body was buried immediately following death, usually during the night. Only adults were allowed to participate in funerals, and there was a strict taboo against mentioning the name of the dead person, especially during the mourning period. Special ceremonies were performed immediately following the funeral. These included the cutting of the hair for all close relatives of the dead person, and the wearing of the "thapo" or mourning veil (Schefo, nd). The official mourning period lasted about one to two months for relatives other than the spouse of the deceased. The end of mourning was marked by the slaughtering of an ox in honor of the ancestors. Failure to do so could result in physical or mental problems for the surviving family. At present, many changes have occurred, including the common practice of holding wakes. However, prohibitions and taboos regarding widows remain unchanged. A widow is supposed to spend about one week after the funeral lying or sitting in the room where her husband's body was kept. After the funeral she is supposed to wear only black clothes, is not allowed to wear any new clothes, is not allowed to go out of her house after dark, and is forbidden from having sexual relations. After one year, the woman is supposed to return to her own family's home where her brothers perform a special ceremony to officially mark the end of the mourning period. The widow is expected to come back to her late husband's home where she remains the head of the household. The traditional practice of levirate by which a widow would become the wife of her late husband's brother has almost completely disappeared, as more and more widows choose to live by themselves or even to remarry (Gay, 1980).

LOCATION AND LINGUISTIC AFFILIATION

The Sudan, Africa's largest country in area, is a territory of incredible historical and political importance. It covers an area of about 2.5 million km² or almost one tenth of the total area of Africa. The country is located in the northeastern part of Africa and extends from latitude 3° to 23° north and from longitude 22° to 39° east. The Sudan shares borders with nine countries: Egypt, Libya, Central African Republic, Chad, Zaire, Kenya, Uganda, Ethiopia, and Eritrea. The country is on the whole a mammoth plain, divided by mountain ranges such as Jebel Marra in western Sudan and Mount Kinyeti Imatong, bordering Uganda. The Blue and White Niles come together in Khartoum forming the River Nile, which flows northwards through Egypt to the Mediterranean Sea.

The Sudanese land and its location at the crossroads of Africa have influenced the course of its politics and history, and the Sudanese people have ardently developed multifaceted identities across it. The characteristics of the land have influenced the life and social organization of its inhabitants, defining in a dramatic way the socioeconomic and political organization of people across this vast territory. As a result of the geographical and historical heritage

of the land, the Sudan straddles Africa and the Middle East, thus consolidating its place in history as a meeting point of Arab and sub-Saharan worlds.

The Sudan is the place of birth of more than five hundred cultural and linguistic groups, all with distinctive outlooks on life, culture, cosmology, faith traditions, and experiential knowledge. Arabic is the lingua franca in addition to English, which is the main language of instruction in southern Sudan. A northern Sudanese Christian minority, the Copts, also speaks Arabic. In addition, numerous linguistic groups and dialects are spoken throughout the country.

Diversity rather than conformity remains a distinguishing quality of cultural and religious Sudanese life. For example, Arabized Sudanese cultures predominate in regions where Islam is the major religion (70% of the entire population). The branch of Islam practiced by Sudanese Muslims is known as Sunni. This tradition is distinguished by the pervasiveness of religious orders or brotherhoods, each placing its unique demands on its followers. What they have in common with the Muslim population worldwide, however, are the Five Pillars, which are constitutive of universal Islam. These pillars include the profession of the faith, daily prayer, almsgiving, fasting in the holy month of Ramadan, and fulfilling the pilgrimage to Mecca. In communities where Islam is the major religion, it is noticeable that it has adapted itself to preexisting beliefs and local cultural understandings. northern Sudan is, to a great extent, arabized in cultural

traits, identity, and political alignment. Historians of the Sudan attribute the twin processes of Arabization and Islamization to immigrants coming to the Sudan from the Arabian Peninsula across the Red Sea, Egypt, and the Maghreb. A complex mix of conquest, migration, religious conversion, and miscegenation define the identity of the northern Sudanese as Arab. According to Ali Mazrui two parallel processes of social transformation swept the country in the course of Arab expansionism, “one linguistic and cultural, by which the people of the land acquired Arabic as their language and certain Islamic cultural conceptions and became connected with the Arab tribal system; and the other racial, by which the incoming Arab stock was absorbed in varying degrees, so that today a modicum of Arab blood flows in their veins” (Mazrui, 1973, p. 47).

According to Mudathir Abdel Rahim: “(Arab immigrants’) readiness to mix, coupled with the matriarchal system of the Nubians on the one hand, and the Arabian patriarchal organization of the family and the tribe on the other, had the effect not only of facilitating the assimilation of the immigrants and the spreading of their culture and religion, but also of giving them the reins of power and political leadership in the host society” (Abdel Rahim, 1973, p. 31).

Southern Sudan, conversely, is home to countless ethnic groups, ranging from the Nilotics such as the Nuer, the Dinka, and the Shilluk; the Nilo-Hamites such as the Latuka; and the Sudanic comprising the Jur, Moru, and Azande. The Christian people of the Sudan’s south and the Nuba Mountains are predominantly Roman Catholic and Anglican. In addition to Islam and Christianity, indigenous beliefs and religions are followed with equal devoutness and fervor. Indigenous beliefs are specific to particular ethnic groups. According to the Sudan country study report “the beliefs and practices of indigenous religions in Sudan are not systematized, in that the people do not generally attempt to put together in coherent fashion, the doctrines that they hold and the rituals they practice.”

OVERVIEW OF THE CULTURE

In spite of the cultural complexity of the Sudan, the people of the Sudan are frequently classified into binary social categories on the basis of geography (north versus south), ethnicity (Arabs versus Africans), and religion

(Muslim versus Christian). Nevertheless, an impressive array of ethno-linguistic and religious groups inhabits this vast territory, and they do not necessarily fall into this opposition. They are *Hadandwa, Mahas, Nuer, Danagla, Dinka, Shiluk, Nuba, Rubatab, Rikabia, Shayqia, Murle, Kababish, Manasir, Azande, Jaleen, Bori, Shuli, Joar, Anwak, Latuka, and Beja*, among other groups.

The variety of Sudanese cultural life has been imaginatively portrayed in the ethnographic literature. From the southern part of the country, Evans Pritchard brought the lives of the Nuer and the Azande peoples to international attention. In the Nuba Mountains in the west, James Faris enriched our knowledge about the intersections of politics and aesthetics in this region through his ingenious analysis of the Nuba personal art. Here, we learn a great deal of how bodily adornment, is employed as an effective means for articulating important social relations and self-expression in Nuba society (Faris, 1972).

The extraordinary variation in Sudanese cultural life, notwithstanding, some commonalities exist in some fundamental aspects pertaining to social organization. On the whole, patriarchal authority, patrilineal descent, and patrilocal residence distinguish the Sudan. Territorial endogamy remains the preferred type of marriage unions. Invariably, all Sudanese peoples accord considerable deference and loyalties to extended families and collectivities.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

Health care delivery systems throughout the Sudan are acutely under pressure. The high occurrence of devastating diseases has increased considerably in recent years as a result of economic, social, and environmental factors. Moreover, the pervasive political and economic volatility in the country had weighed heavily on the health and security of individuals and communities. Life expectancy is 53 years; infant mortality rate is estimated at 7.8% while literacy rate is 43%. The civil war, which has been raging since 1955, has taken an enormous toll on the population, which struggles against the effects of chronic malnutrition and contagious diseases. Health care in the Southern States is severely lacking. Exceptionally susceptible are the 1.25 million children and adolescents that

constitute part of the Sudan's internally displaced people. According to United Nations Humanitarian Operations in Sudan, food shortage affected the health of war victims considerably. The report stated "Food insecurity in the Sudan in 2000 has been a result of continued general insecurity; population displacements, drought and floods, as well as the high prevalence of disease due to poor health and sanitation. In some areas where rainfall patterns were ideal for cultivation, insecurity drove people from their homes and fields" (2000, p. 14). In addition to the deleterious impact of the civil war, during 1984/85 the Sudan experienced one of the most devastating environmental disasters. Severe drought and desertification and crop failure in western Sudan led to a mass exodus to the capital city of Khartoum as well as to other parts of the country. Today, massive numbers of farmers and their families find their way to Khartoum's camps for the internally displaced persons along with their southern counterparts.

To remedy these serious problems, some measures such as consolidation of efficient health coordination structure, rehabilitation of all health facilities, provision of drugs and equipment, and staff training, particularly in the area of child and maternal health were recommended (UN Report, 2000, p. 16).

MEDICAL PRACTITIONERS

Medical practitioners in the Sudan include physicians, physician assistants, midwives, nurses, traditional birth attendants, traditional healers, *zar sheiks* and *sheikhas* (the Sheikhas are the women who officiate in *zar* or spirit possession ceremonies), and diviners among others. Modern medicine in the Sudan was officially introduced by the Anglo-Egyptian regime (1898–1956), a process that was thoroughly chronicled by historian Heather Bell (1999). During the colonial period, different sectors of Sudan's health care were developed including the introduction of modern midwifery training. Reliance on biomedical versus traditional healers varies vastly by education, residence, and gender differences. For instance urban dwellers are more likely to go to hospitals as opposed to rural populations who rely heavily on traditional or folk cures. Also significant are gender differences, where women seek the advice of religious leaders or *zar sheikhas* more than their male counterparts who often dismiss the importance of folk healing.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

Illness, physical or psychological, is subject to scrupulous theorization. Consequently, ways of dealing with illness are not confined to biomedicine. Instead, reliance on traditional healing is especially obvious. In fact, throughout Sudanese provinces and villages, traditional healing is the single mode of curing that is readily available for the community. According to Sudanese gynecologist Osman Modawi, modern medicine is commonly thought of as the last resort (1982). The term "traditional medicine" encompasses a variety of methods of protecting and restoring health that existed before the appearance of modern medicine. On the whole, traditional medicine refers to acupuncture, traditional birth attendants, mental healers, and herbal medicine (WHO Fact Sheet, 1999).

In the Sudan, one of the most important theories of illness is derived from the overwhelming belief in the power of the evil spirits. The spirits are thought to inflict injury as well as undermine one's health through the notion of *Ammal*, or the foul act. *Ammal* is typically inflicted through witchcraft causing substantial impairment and damage. Treatment is at all times sought through the counsel of shamans or witch doctors who alone have the God-given gift of counteracting the callous act. The shaman, who listens carefully to the symptoms of illness, performs a series of steps to identify types of spirits and methods for the cure. The Azande for instance, believe that witchcraft can be inherited and that a person can be a witch, causing others impairment, without realizing his/her power. Because of this threat, effective resources of diagnosing witchcraft are very important. One method is through the use by oracles, of *benge*, a poison, which is fed to little chickens. The chicken's death or survival provides the oracle's answer. Azande also use *benge* as proof to substantiate one's guilt before a court of law (Evans Pritchard, 1976). Notwithstanding the changing cultural life of Azande people and their forced displacement as a result of war, their beliefs on illness and adversity continue to hold witchcraft as the most important threat to someone's health and well-being. In an interview I conducted with Thomas, a 43-year-old Azande, who resides in ElSalam camp for the internally displaced, he stressed that "Kuguor still run rampant. People cannot forget everything about their lives at home before they came to this place."

Diseases, which are attributed to evil spirits in many Sudanese communities, are classified as *zar* or spirit possession. In the words of British anthropologist Susan Kenyon: “Zar is both category of spirit and the cult associated with possession by those spirits. Such possession can cause problems or illness, usually a form of mental illness, *marud nufsi* as the Sudanese describe it, and these are referred to as *zar*” (1991, p. 185). *Zar* spirits are generally appeased and kept at bay through ritual ceremonies including animal sacrifice, drumming, and dancing. The types of healers who officiate in these ceremonies are called *shaikhas*, generally women who are well-versed in the world of the spirits and can act as interlocutors between the spirits and the patient whom they possess.

Another powerful branch of traditional healing is known as *El-tibb, El-nabawi*, or “prophetic medicine”. In Khartoum today large numbers of clinics are scattered all over the capital city. In May 2002 I interviewed Hajj Hassan, a man whose knowledge in this field is superb. In the words of Hajj Hassan, human beings should realize the complicated link between mind and body. Prophetic medicine does not target physical ill health as an isolated phenomenon. Instead through Quranic verses, the patient receives considerable mental consolation and calmness. He articulates the underlying principle of the proliferation of Prophetic medicine as follows: It is well known that the belief of people in God plays a greater role in their recovery, regardless of the seriousness of the disease. So, the religion of Islam inspires the person who is ill to make his way through the verses of the Quran and the instructions of the Prophet. For example Prophet Mohammad described to his followers the necessity of taking honey everyday for various illnesses. He, peace be upon him, described for those suffering from high blood pressure (*elfisada*) to let blood out of their veins. He emphasized the benefits of herbs like ginger and peppercorns etc. In addition, there are a number of verses that when read regularly can bring serenity and peace of mind for patients. That is why people believe that the Quran can provide ways of dealing with their anxieties, not readily available in modern medicine.

The connection of mind and body in Sudanese theories of illness is made with crystal clarity in situations where patients seek the opinion of modern medicine and traditional healing simultaneously. This procedure is not at all infrequent or rare. The mother of a 37-year-old woman who suffered from clinical depression told me, that the psychiatrist who treated her daughter used a

combination of modern procedures with elements from prophetic medicine with impressive results.

SEXUALITY AND REPRODUCTION

Sexuality

Attitudes toward sexuality and reproduction are positioned at the heart of significant cultural and religious beliefs amongst the Sudanese. Open discussion of matters pertaining to sexuality is extremely proscribed by these beliefs. To a great extent, this interdiction is intimately linked to how society views sexuality in the first place. Largely seen as an ominous threat that looms largely over one’s purity and morality if left unchecked, social and physical regulation is aggressively pursued. This view is of special relevance to female sexuality. One of the most important vehicles for dulling women’s sexuality is achieved through female circumcision.

The origins of this practice are very mystifying and obscure. In exploring its ideology, we find varied oral accounts describing mythological rather than documented origins. Although the majority attributed the diffusion of the practice to pharaonic Egypt, some analysts argued that the custom might have originated from the Red Sea People who introduced it to neighboring peoples. Writers such as Abdalla Eltayeb (1964), a noted Sudanese linguist, see female circumcision as a legacy of the Arabization of the Sudanese people. What is important to remember is that female circumcision is not a universal practice in the Sudan, which is not surprising because the peoples and cultures of the country are very heterogeneous. According to Sudan Demographic & Health Survey the prevalence of the practice is as follows: northern Sudan, 98.7%, eastern Sudan, 86.5%, western Sudan, 95.5%. Because of the important link between female circumcision and sexuality, it is necessary to elaborate its ideological underpinnings. Understanding ideology is a step toward understanding strategies for its eradication. Indeed, Habermas (1971) argues that the only knowledge that can orient action is knowledge that frees itself from mere human interests and is based on ideas. The reasons for female circumcision and the age at which it is performed differ across Sudan by regional, ethnic, and class differences. As far as the operations among northerners are concerned, they have been practiced for a variety of cosmetic, religious, medical, and

social reasons. For instance, people justify their support of the practice by arguing that it preserves virginity, enhances femininity, and increases purity and cleanliness. There is also variation in its prevalence, in the exact types of the practice, and in the rituals associated with it. The practice includes the following types: clitoridectomy, excision, and infibulation.

In spite of the cultural importance of this practice, it has been met with strong opposition since British colonial rule (1898–1956). In fact the practice became illegal in 1946, when the British colonial administration passed a law making female circumcision a crime punishable by imprisonment and fines. From the time of independence in 1956 until the end of the 1970s, new plans were formulated to stop the practice. Attention now focused on those social and cultural aspects of the practice that accounted for its endurance in the Sudan. More recently, several organizations, including the Sudan National Committee for Traditional Practices Affecting the Health of Women and Children, The Red Crescent, and the Mutawinat Group have identified the practice as an act of violence, and have devised research strategies, and adopted a variety of approaches to eradicate female circumcision. The most notable of these plans, include community outreach through the use of mass media, audio-visual aids, and publications. Another approach aims to incorporate efforts to end the practice into existing programs concerned with public health, family planning, anti-violence programs, maternal and childcare, midwifery training, and nutrition.

Fertility

Fertility and fecundity figure prominently in the cultural constructions of gender identities and conceptions of womanhood and manhood amongst the Sudanese. Conversely, fear of infertility prompts individuals and communities to invent effective measures to counteract the prospects of childlessness. In the Nuba Mountains, Modawi (1982, p. 81) described the effort of one community of dealing with infertility: “In the Nuba Mountains there is a small hill which looks like the male genital organs. Infertile women visit this hill to perform certain rituals to treat their infertility. In some of the other rituals a toy boy with prominent genitalia and made of hina is thrown into water. It is also thought that eating the male genitals of animals corrects infertility. The scarcer the animal, such as crocodile, the more potent the cure.”

In other parts of the country, important rituals are fervently pursued to guarantee that a woman who enters into a marriage union is able to contribute to the productivity of the community as a whole. One of the most joyous occasions for the public recognition of fertility is the *jirtig* ceremony. It is believed that this rite prevents evil spirits from undercutting the woman’s ability to bear children, thus acquiring a quasi-religious quality and significance. A bride who does not take part in the *jirtig*, Sudanese say, will become infertile, for her reproductive organs are filled with evil spirits. The *jirtig* is redolent with symbolism and cultural meaning, and the values it celebrates are deemed essential to the life of the married couple, whether at home or abroad. During this ceremony, the *jirtig* bed is placed in the middle of the front yard of the house where tens of people gather to witness the ceremony. The bed is covered with a red velvet bedspread, which symbolizes fertility. The bride is also dressed in red, while the groom wears the traditional robe-like outfit, with a red band tied around his forehead. The ritual concludes with a procession to the Nile for blessing and good fortune. These rituals however are overwhelmingly female-oriented. In fact in several cases, it is almost impossible for a man to acknowledge infertility, which is more often than not equated with lack of virility and masculinity.

Apart from cultural notions about fertility and reproduction, fertility levels have declined sharply in the Sudan from an average of six children per woman to five children (Sudan Demographic & Health Survey, 1991). There is a great variation in fertility levels in light of educational attainment, socioeconomic backgrounds, and residential patterns. The great majority of Sudanese women are well aware of the various methods of family planning and contraception use (Swar Eldahab, 1996). Significant hurdles that mitigate against their involvement in family planning, however, loom large. In Dar Elsalam, Khartoum, I interviewed a group of women about their views on birth control. There was a significant consensus about the impact of their own economic situation on their ability to limit family size “Contraceptives are very expensive. We came here from Dar Fur when we used to have our farming land and we lost it because of the drought. We attended the talk of a group of health workers about birth control. They told us about pills and condoms. These items are very expensive. We cannot afford birth control pills. So, even if we want to have a small family, we cannot because of our financial situation.” This sentiment

echoes those of thousands of women who are constrained by poverty and inability to secure better lives for themselves and for their offspring.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

Cultural understandings about conception and birth are shaped by the notion that giving birth is not purely a result of sexual intercourse between men and women. One of the most compelling explanations of this view was discussed in Francis Deng's ethnography of the Dinka of the Sudan in which he argues: "(Conception) is the creation of God and the blessing of the ancestral spirits. The cooperation of the father, the mother, and the spirits in the venture is verbally conceptualized. The word *ahiet* means, 'to beget' and 'give birth'. Dinka view of conception does not distinguish between the role of man and woman. They copulate to 'beget' jointly and 'give birth' while God intercedes to 'create' and the ancestors assist in protecting the creation from malevolent powers of destruction" (1972, p. 30). In other parts of Sudan children are considered to be wealth in and of themselves. To secure the health of the pregnant mother and her unborn child, Sudanese prescribe a variety of foods and herbs believed to be beneficial for the blood and for breast-feeding after delivery. In the Sudan many practices associated with breast-feeding are considered very beneficial. According to Shazali "Most mothers especially in rural areas, believe that mother's milk is best for the infant and are psychologically prepared to breast-feed" (1982, p. 103). In some situations however, local beliefs interfere with feeding such as the notions that boys should not be fed at sunset, because it is considered to be a bad omen and a threat to their intelligence (Shazali, 1982).

Infancy

In the Sudan infants are most warmly welcomed through an exciting assortment of rituals and rites celebrating their arrival in the world. One of these celebratory occasions is the *Simaya*, or the naming ceremony. In northern Sudan, and elsewhere this ritual has attracted the attention of anthropologists for its zestfully symbolic content. The symbolism of this ceremony is brilliantly captured by Fadwa El-Guindi, who argued, "A function of such a

ritual is to emphasize and impress beyond the shadow of a doubt that one-passé of the life-cycle has been left behind and to announce and stress that henceforth he or she is in another phase. Another aspect is to make sure that the individual has received communion with the deepest cultural ideals" (1996, p. 3). The *simaya* solemnizes the naming of the child as an important rite of passage and a source of blessings (*baraka*) and good omens. Generally, anywhere from one to two weeks after the birth of a child, a sacrificial lamb is slaughtered for the ritual naming of the newborn. It is celebrated with feasts, drumming, remembrance ceremonies, and concerts and marks the rite of passage from birth to initiation into the wider community. Equally emblematic, are occasions celebrated all over southern Sudan where names signify important aspects of social organization (Deng, 1972). Infants are cared for by parents, grandparents, family members, neighbors, and hired help, who also provide invaluable help with the daily household tasks. Most infants are breast-fed for at least two years, a factor that seems to mitigate some of the problems of malnutrition and childhood diseases.

Mothers and infants are often believed to be the most vulnerable people to health problems and to the attacks of evil spirits. To deal with their inbuilt vulnerability, mother and child are obliged to remain indoors for 40 days. A Sudanese woman told the unusual story of her being visited by a ghost-like creature three days after giving birth "I will never forget the incident that happened to me shortly after the birth of my first son, who is now 41 years old. I was lying down, sleeping in the middle of the night when I was awakened by an unusual noise, almost like very heavy breathing. I opened my eyes and saw a Caucasian woman dressed in a nurse's uniform sitting in a chair across from me. I was horrified. I started to call my cousin who was sleeping outside in the hosh: "Fathia, Fathia, come quickly." The woman started to call Fathia with a masculine, hoarse voice. Fathia came running and she turned on the light; the woman disappeared. But Fathia said she had heard the strange voice calling her name. "From that moment on, we had to read the Quran and put amulets on my son's arm to protect him. My neighbors told me that this woman wanted to steal my infant and put another deformed one in his place but Allah protected both of us." To a large extent these complex beliefs have a significant role to play in attitudes toward the health and sickness of infants. Official reports however, demonstrated that lack of safe water,

undernourishment, insufficient sanitation, and poor hygiene are considered the most significant causes of high infant mortality and morbidity in Sudan.

Childhood

Children are seen as a source of security and spiritual immortality (Deng, 1972). Childhood is also a phase in which intensive efforts at gender bending and conditioning gets underway. For example, in many parts of the Sudan Sudanese boys and girls are circumcised during this period. Rites of passages that signify the acquisition of new identities are also observed during this time. However, children, like the rest of the Sudanese population are experiencing insurmountable problems relating to health, political conflict, economic insecurity, and social unrest. This situation is particularly clear in a UNICEF report (2001) on the situation of children in Sudan. The report provides detailed analysis of the impact of the civil war, internal displacement, landmines, economic exploitation, and abductions, on children. Contagious diseases and illnesses that infringe upon children's health in the Sudan are wide-ranging, including malaria, diarrheal and acute respiratory infections. Lack of drugs and inadequate medical care combine to affect the health of Sudanese children dramatically.

Adolescence

In the Sudan, the onset of adolescence is managed through culturally proscribed means and strategies. In fact, the socioeconomic circumstances prompt many parents and caregivers to entrust adolescents with responsibilities and obligations that are far beyond their years. Hence, social maturity is not measured by one's age as such, but by their productivity and contribution to the family's economics.

Adulthood

Achieving an adult status in the Sudan is contingent upon fulfillment of crucial steps in the social ladder such as marriage, attainment of employment, and property ownership. Adulthood, however, does not presuppose total individuality or independence from extended family networks. It is very common for adult children—married or unmarried—to continue to reside with their parents.

The Aged

Compassion and empathy toward the elderly population is one of the most important values for Sudanese people irrespective of region, ethnicity, or religion. Children and grandchildren view their relationship to aging parents as one of obligation and debt. Hardly ever do aging family members get sent to nursing homes.

Aging does not only mean a longed-for release from physical work, but it also means greater authority especially for post-menopausal women. Age frees women considerably from some of the most arduous tasks and societal expectations that they had had to adhere to during their reproductive years. It follows that menopause is looked at as a phase in life that is increasingly empowering, and is rarely discussed as a medical problem. A woman in her fifties recalled that when her mother was experiencing menopause and had all the symptoms associated with the condition such as hot flashes, her physician never explained to her that she was experiencing menopause. She added that in the Sudan "women never talk about menopause." This observation is corroborated by the fact that literature on fertility in the Sudan has rarely touched on attitudes toward menopause.

Dying and Death

The miscellany of Sudanese cultural worldviews and ideologies are manifestly reflected in how they deal with the question of death and dying. In the Sudan beliefs about death and dying are to a great extent molded by the deeply entrenched faith in *El-qaddaa' wa El-Qaddar* (God's will and fate). Death presents an opportunity for communities to come together to express their support and solidarity for the deceased person's surviving kin. In most parts of the Sudan, mourning rituals extend to 40 days during which the family of the deceased continue to receive tens of mourners a day.

CHANGING HEALTH PATTERNS

AIDS rates have escalated in the past few years due to a number of factors ranging from use of unsterilized syringes, unprotected sex, poor health in general. There is no comprehensive governmental policy regarding the mitigation of the escalating rate of the disease.

Thai

Chris Lyttleton

ALTERNATIVE NAMES

Siamese, replaced in 1939.

LOCATION AND LINGUISTIC AFFILIATION

The Thai live within the Southeast Asian nation-state of the Kingdom of Thailand which consists of five regions characterized by distinct landforms: the northern ranges and plateaus, the central fertile plains, the southeast coastal seaboard, the arid northeast plateau, and the Southern humid plateau. The Thai live in all regions but predominately in the central plains. The Thai are one of many *Tai*-speaking peoples inhabiting mainland southeast Asia. Thai is the official national language (often called Central Thai) and is gradually replacing other *Tai* dialects in regional parts of Thailand.

OVERVIEW OF THE CULTURE

The *Tai* peoples moved down from Southern China roughly a thousand years ago to populate most of the central portion of the Indochinese peninsula. Over many centuries, a Thai culture, civilization, and identity has emerged as a product of interaction between the *Tai* and prior inhabitants such as the Mons and Khmers.

The population of Thailand was 62.31 million in 2001. The Thai (Siamese) are the majority population living within the Thai borders and number more than 30 million. Other *Tai* ethnic groups also live within the Kingdom of Thailand, the most prominent being the ethnic Lao (*Isan*) with just over 20 million, however due to the impact of national administrative and development policies, ethnic differences are slowly being dissolved and Thai culture is becoming dominant throughout the country. Although the following summary of social, cultural, and economic

aspects of health is focused on the Thai, statistical data (cited from MOPH, 1999 unless noted otherwise) is gathered at the national level and therefore includes other minority populations who nowadays regard themselves as politically Thai. Most national surveys identify all *Tai*-speaking peoples as Thai if they live within national borders—it is thus common to see reports that cite more than 80% of Thailand's population as ethnically Thai.

The Siamese emerged as a dominant regional identity during the 13th and 14th centuries when Khmer authority was defeated and the independent *Tai* Kingdom of Sukhothai was established in and around the central plains. By the 16th century a characteristically Siamese culture became associated with the styles, tastes, and values of the new court based at Ayutthaya that slowly distinguished itself from neighboring *Tai* kingdoms in the north and east (Wyatt, 1982). In the 18th century the capital of Siam was moved to its present day site in Bangkok and by early 1800 had extended the rule of Siam to cover much of mainland Southeast Asia.

Thailand is the only nation in Southeast Asia that was not colonized as successive Siamese monarchs preserved their right to independent rule with great political acumen. The current borders were formally established in 1896 when the French took control over all Siamese/Lao territories east of the Mekong River. In 1932, King Rama VII accepted that the country would be best served by a democratic government and a constitutional monarchy. In 1939, Prime Minister Phibun changed the name of Siam to Thailand to emphasize Thai characteristics of national identity (rather than the economically dominant Chinese) and as a gesture of solidarity with other *Tai*-speaking peoples within national borders. Since then there have been frequent changes of governments (53 cabinets) and military coups (11), however, a new constitution was promulgated in 1997 that enshrines far more rigorous controls on the electoral process. It is widely considered the “first constitution of the people.”

Since the 1960s, the Thai have rapidly transformed from being a largely subsistent and agrarian, primarily rice-growing, population into an export-oriented industrialized society. They are now a highly urbanized and modernized society that, at the same time, still utilizes social and cultural understandings from pre-modernist ideologies and belief systems. The combination creates a complex mix of behaviors that influence illness and healing practices. From the early 1980s until the late 1990s, Thailand had one of the fastest growing economies in the

world fostering rapid social and economic development. By 1996, 97.5% of the 70,000 villages nationwide had electricity, by 1997, 98.27% of households had sanitary latrines and by 1998, 95.47% of households had access to clean drinking water. A major impact of this economic transition has been the expansion of the urban sector. Rapid industrialization has promoted large-scale internal migration—more than 40 million Thai live in rural villages but a huge percent spend extended periods working in cities or larger agricultural provinces with serious impacts on the cohesion of the family unit. Bangkok has grown from 1.5 million in 1960 to over 9 million in the 1990s (Osborne, 1995). A further consequence is a growing disparity in income. By 1990, Greater Bangkok had 1,404 slum settlements housing over 1.2 million people (Pasuk & Baker, 1996). From 1960–90 the proportionate contribution of agriculture to the GDP dropped from 40% to 12% even though it still employed roughly 60% of the populace (Medhi, 1992). While overall poverty levels have declined, the gap between rich and poor has increased and the vast majority of those below the poverty line are farmers. In 1997, the “bubble” economy crashed and high levels of unemployment sent many urban workers back to their rural homes, average incomes dropped, poverty incidence increased, and health expenditure declined (Tangcharoensathien et al., 2000). In 2000, poverty incidence ranged from 0.3% in Bangkok to 50% in the poorest provinces, with a national average of 14.2% (UNDP, 2003).

Almost all Thai are Theravada Buddhists.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

Thailand's population growth rate dropped from 3.2% in 1970 to 1.16% in 1997. It is projected to decrease to 0.53% by 2020. Between 1964 and 1996, life expectancy rose from 55.9 to 69.97 years for males and from 62 to 74.99 years for females. It is projected that Thailand's annual birth rate will be approximately 15–16 per 1,000 population for some years to come or approximately 900,000–1,000,000 births per year (Pramote, 1998). The crude death rate in 1998 was 5–6 per 1,000. It is expected to rise over the coming years as the population's age structure changes. The infant mortality rate (deaths per 1,000 live births) has dropped from 84.3 in 1964 to 26.1

in 1996; however, the rate in urban areas is consistently lower than in the rural sector. The rate of low-birth weight infants (less than 2,500 g) dropped from 9.3% in 1991 to 7.9% in 1996 but it rose again to reach 8.9% in 1998. Maternal mortality rates dropped significantly from 374.3 (per 100,000 live births) in 1962 to only 10.6 in 1997. Many vector-driven disease threats to health have been reduced. The widespread immunization program has caused vaccine preventable diseases to decline dramatically. For example, tetanus, measles, diphtheria, and poliomyelitis have all decreased to low incidence. Leprosy has been eradicated and encephalitis nearly so. Malaria incidence and mortality have also dropped markedly (from 200,000 cases in 1991 to 100,000 cases in 1996) except in border areas with large refugee populations where incidence has recently increased primarily due to parasite drug resistance.

Despite such overall improvements, social changes affecting the everyday lifestyles of most Thai have led to a changing profile of health and illness. Main causes of death nowadays are heart disease, accidents, cancer, and AIDS. Non-communicable diseases such as cardio-pulmonary vascular disease and cancer have become the leading causes of morbidity and mortality over the past 30 years; their prevalence generally attributed to changes in lifestyle and dietary habits. Heart disease prevalence rates (per 100,000 population) increased from 56.5 in 1985 to 168 in 1997, while the cancer rate rose from 53.8 in 1987 to 60.4 in 1997. During the same period, lung cancer prevalence rates rose from 3.96 to 14.2 related to both smoking (currently 38.9% of males over 11 smoke) and air pollution. Alcohol and drug use (both licit and illicit) is also considered to be on the rise. Liver disease rates have increased from 4.3 to 12.3 between 1977 and 1997. Alcohol is also linked to a high prevalence of road accidents.

Accidental death is currently the second highest cause of death for the Thai. The vast majority occurs as a result of traffic accidents, although drowning accounts for death rates between 4.4 and 6.7 (per 100,000). Traffic accidents have declined slightly since the economic crash, causing 11,000–13,000 deaths in 1997–98. The main cause of road fatalities is head injuries incurred in motorcycle accidents, despite a 1992 law making crash helmets mandatory.

HIV/AIDS (and associated tuberculosis) is the most rapidly rising cause of ill health and mortality in Thailand. Since 1984 when the first case was detected, it is estimated that just over 1 million Thai have been infected with HIV (nearly 2% of the adult population) and by 2000 more than 200,000 had died from AIDS. In

provinces hardest hit by HIV infection there is a projected life expectancy decrease of 10–13 years for young boys and 5 years for young girls (Van Griensven et al., 1998). In 2003, the UNDP listed the life expectancy of the Thai as 68.9 years—a drop of 1.4 years because of AIDS. Acute respiratory diseases have remained important health problems with little overall improvement. Dengue hemorrhagic fevers are persistent threats with periodic outbreaks and no signs of consistent decline. In short, the Thai now face not only the burden of a huge caseload of HIV infected people, and non-communicable chronic and degenerative diseases but also the emergence of new health threats for instance, drug abuse, occupational hazards, and environmental pollution.

The changing complexion of the health status of the Thai can be directly linked to the social and economic changes of the past 40 years. Thailand's rapid industrialization occurred primarily at the expense of the agricultural sector through the provision of an agricultural tax and encouragement of a mobile workforce. Thai farmers are still the world's largest rice exporters, but they face increasing problems from debt required to stay technologically competitive and from diseases related to a reliance on pesticides. Data collected throughout the 1990s shows that 16–21% of farmers has abnormally high cholinesterase levels (pesticide poisoning). Mean-while in the cities, occupational diseases directly linked to the industrial sector have emerged—incidence of silicosis, byssinosis (cotton dust disease), and lead poisoning have increased dramatically. Many studies show that health levels in Bangkok are severely compromised by toxic air and water pollutants. For example, it is reported that in Bangkok 27.4% of children had an average lead content in their blood higher than 10 mcg/dl (the level above which it is regarded as dangerous to the brain and nervous system).

More generally, we can link increased vulnerability (both voluntary and involuntary) to 'lifestyle' diseases with changes in the social and cultural life of the Thai. Forty years ago Thailand was 80% rural; for the newer generations traditional village based life has evolved to one oriented to migration and urban wage labor. In addition to a changed family structures, social values are now more deeply embedded in materialism and consumer consciousness than before. In the absence of adequate controls (as government policies do not immediately replace traditional community sanctions), rapid modernization has led to a wide array of health damaging behavior, ranging from workplace risks and stress to vulnerability directly linked

to forms of material purchase (e.g., road accidents, drug abuse, and risk of sexually transmitted diseases through commercial sex).

As a case in point, since the economic crash, mental illness has received greater attention. Rates of psychoneurosis, hypertension, and stress disorders have been steadily on the rise over the past 15 years, as have rates of suicide (up from 6 per 100,000 in 1978 to 11.7 in 1998). Initially it was felt this was a product of competition spurred by the rapidly growing economy but recent increases are associated with unemployment, retrenchment, and financial difficulties as well as the emotional and physical burdens of widespread HIV/AIDS. Stress relief clinics have recently been opened in 125 public and private hospitals.

Changing consumption practices promote an evolution in nutritional status. The overall development of the economy has improved certain aspects of diet: protein energy malnutrition (from eating mainly rice), anemia, and vitamin A deficiency have diminished to almost negligible levels (although the economic crash has caused cuts in the school lunches program and some families are unable to adequately feed their children resulting in the recent increase in low birth weight levels). Iodine deficiency (goiter) is down to a national average of 2.6%. In contrast, the marked shift to packaged and pre-cooked food has caused new nutritional disorders such as high blood cholesterol. Nutritional surveys in 1986 and 1995 showed increased obesity in all Thai age groups—in the 40–49 age group obesity rose from 19.1% to 40.2%. Greater levels of everyday consumption also lead to inappropriate use of pharmaceuticals, particularly antibiotics and analgesics. The Thai have one of the highest per capita drug consumption levels in the world (pharmaceuticals have numerous outlets including village grocery stores). In 1998, 28.5% of national health expenditure was for the purchase of drugs.

Health Infrastructure

Health services infrastructures in Thailand include government, non-government organizations (NGOs), and private sector clinics and institutions. Over the past 30 years the government has allocated slightly less than 5% of its annual budget to the Ministry of Public Health (MOPH). Since the onset of the Five-Year Development Plans in the early 1960s, the highly bureaucratized network of State health facilities has been extended across

the country. Gradually patterns of health-seeking behavior have shifted away from self-medication and traditional remedies towards predominant patronage of government services although until the economic crash there was a parallel trend towards private clinics and hospitals where finances permitted. The first three Development Plans (1960–76) concentrated on the expansion of health facilities and trained staff to all provinces. The 4th Plan recognized the ongoing difficulties in the rural areas and proposed more institutional resources, hospitals in all districts and health centers in every sub-district. These goals were implemented in the Fifth Five-Year Plan (1982–86), along with one key change. Bottom-up planning from the village and sub-district level was encouraged to attack poverty and ill health more effectively. Integrating health care with a wider level of rural development, the Thai Government vigorously promoted essential elements of Primary Health Care (PHC) in the villages: health education, nutrition, mother and child health (including family planning), safe water supply and sanitation, immunization, prevention and control of locally endemic diseases, and provision of essential drugs.

As a core aspect of PHC philosophy, local participation in health management has been encouraged through the recruitment of Village Health Workers and Communicators. By 1990, virtually all villages in Thailand had some members trained to assume the liaison role between public health initiatives channeled through the sub-district health centers and their village community. The 6th and 7th Plans (1987–96) aimed to improve public participation towards achieving key WHO benchmarks of reduced mortality and morbidity. Health insurance schemes were begun during this period and the poor issued with health cards that allowed free consultations and care at government facilities. In face of enduring economic difficulties, the Government has recently replaced this with a more efficient and equitable “30 Baht” (U.S. 75 cents) scheme that guarantees subsidized medical treatment for all below certain income levels.

Despite widespread provision of services, analysis of health shows that achievements have not always been forthcoming in all sectors. The lip service given to fundamental social development fuelled by PHC programs is sometimes no more than the manipulation of statistics. This shrouds the enduring factors that promote ill health in a wide array of sectors, as the poverty figures from rural Thailand and the emergence of new forms of morbidity attest. Severe shortages of trained medics in some

rural areas were exacerbated by the economic crash, when budget cuts caused medical staff to seek work in the private sector. Against this backdrop, NGOs throughout Thailand have made attempts to generate more fundamental changes to social and political systems including health. The increased recognition of civil society organizations as a fundamental foundation of a secure social environment has led to the proliferation of alternative health movements and organizations. Historically such groups have included religious and ethnic welfare organizations. Following the 5th Plan, NGOs received more active support from the Government and a recent survey listed 513 organizations whose activities are related to health promotion. In 2000, 126 organizations applied for MOPH support including advocacy groups, AIDS networks, alternative and traditional medicine groups, consumer's forums, village volunteers groups and so forth (Amara et al., 2001).

MEDICAL PRACTITIONERS

The Thai practice pluralistic preventive and curative strategies engaging a range of health practitioners. The medical system in Thailand was oriented to traditional Thai health regimens until the late 18th century. Over the past 100 years, Western medical practice has become dominant in terms of government support and local patronage. Health practitioners trained in (cosmopolitan) biomedicine are therefore the most prominent in Thai society.

In 1998, there were 19,500 practicing doctors (a ratio of 1 : 3,136 people, with a disproportionate number in the urban sector). Between 1971 and 1995, the percent of these doctors working in the public sector declined from 93.3% to 76.3% reflecting a move into the more financially rewarding private hospital sector (in 1998 there were 957 public and 473 private hospitals, some of which have become famous worldwide for cosmetic surgery). Since the economic crash this trend has been reversed. In 1998, there were 56,366 professional nurses (1 : 1,073) with the vast majority (roughly 90%) working in the public sector.

A large number of government doctors (and sometimes nurses in rural areas) also run private clinics during out-of-work hours. Here they offer a range of services from general practice to specialist medical services. It is estimated that as high as 69% of practicing specialists have not been certified by the Thai Medical Council. The medical doctors (and nurses) are able to increase their

income not simply from their diagnostic services but also from pharmaceutical sales.

Community health workers at sub-district health centers form a crucial link between state policy and village level communities—they initiate government health programs at the village level providing technical support and supervision. In 1999, there were 9,689 health centers covering every sub-district in Thailand, staffed by 39,438 health workers who have received a 2-year tertiary training course in public health. Staff are equipped to handle minor ailments, monitor maternal and child health, and are licensed to prescribe commonplace pharmaceuticals and contraceptives. They supervise Village Health Volunteers who assist with the dissemination of public health knowledge and the distribution of certain pharmaceuticals and health provisions such as painkillers and condoms. The volunteers also monitor the health status of the villagers and report back to the sub-district health centers. They administer certain village organizations, such as drug cooperatives, rice banks, and health card funds.

Pharmacists are another key link in the Western style bureaucratic management of health. Many Thai self-medicate and pharmacists often provide diagnostic services for particular ailments, selling most pharmaceuticals without a prescription. A common (although lessening) practice in rural areas is the sale of combination therapies. This entails the dispensing of a number of pharmaceutical drugs in one package. Occasionally rural pharmacists will compile and then sell these packages to village stores. At times they include dangerous combinations of stimulants and depressants (Lyttleton, 1996).

Other health practitioners conduct therapies outside of the biomedical framework. After years of marginalization, traditional forms of Thai medical practice are undergoing resurgence as biomedical models are seen as not being the answer to all ills. Although fast disappearing, some villages still have elderly members who practice traditional arts of massage and prescribe herbal medicine therapies. In place of informal training Thai traditional massage is increasingly taught in national institutes, which receive both government and international support. Thai massage is widely practiced throughout the country, albeit with varying degrees of expertise. Traditional herbal medicine is also a form of local knowledge that has received government and foreign support. Traditional Thai medical institutes both train doctors and study plant forms and their efficacy in treating illness. Since the rapid increase in AIDS-related illnesses it is common for

HIV/AIDS support groups to both cultivate and prescribe local herbal remedies. International agencies are presently including a number of Thai plants known for their retroviral activity in their drug trials. Village midwives form a third group of alternative practitioners receiving official recognition although after the rapid economic development most village women give birth in local hospitals.

A further group of health practitioners receive no legitimization from government circles, however they form an important component of multiple health seeking strategies. Firstly, there is a large group of healers who utilize spiritual assistance. This is more common in rural areas although some well known 'divine' healers have large urban followings. These healers are usually of two types, those that rely on Buddhist or Hindu modalities of sacred power, and those that communicate with the host of animist spirits that are believed to be ever-present in everyday surroundings. Healing entails divination of causality and prescription of remedial action. Secondly, there are those that illegally practice forms of Western medicine. It is common in more remote rural areas for "injection doctors" to perform injections for villagers. This involves diagnosis, prescription and injection of pharmaceuticals, saline, and/or vitamins. Backyard abortion doctors are also found in both rural and urban areas. A small number use traditional techniques of severe massage intended to snap the fetus's neck along with herbal effusions to induce miscarriage.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

Strongly influenced by the Ayurvedic system of medicine in India, traditional Thai medicine classifies forty-two bodily elements into four groups—fire, wind, water and earth. Disease comes from changes in the balance of elements of fire, wind, and water—earth is very stable and seldom causes disease—and correspondingly illness is classified as a disease of either bile, wind, or mucus (Mulholland, 1979). Historic Thai medical texts report wind illness as the most common affliction which, following the Indian humoral theories of medicine, denotes any illness affecting the quality or faculties of movement, including such diseases as leprosy or epilepsy. In practice, it is highly likely that over the centuries a synthesis

has occurred between imported Indian medical systems and indigenous beliefs in causes of ill health that include soul loss as the cause of a wide array of ailments. Traditional Thai medical practice is best considered as a continuum from oral folk medicine practiced at the village level and more closely linked to animistic beliefs through to more official elite versions associated with text-based Indian theories of disease (Bamber, nd).

In traditional Thai medicine, diagnosis involves careful consideration of environmental, behavioral, and physiological characteristics. Treatment is determined after considering symptoms, place of birth, age of patient, and time of year and primarily uses medicines concocted from a wide range of plants and occasionally animal and mineral substances (1,500 drug remedies are listed in handbooks). Massage and use of spells can also be enlisted to effect a cure depending on the extent to which malevolent spirits are believed to be involved. Towards the end of the 19th century, the adoption of Western medicine was spearheaded by the Royal Family's interest in "modernizing" indigenous medical practices at a time when cholera epidemics were widespread. The association of Western medicine with scientific knowledge, modernity, and royal patronage led to its rapid domination of the traditional Thai medical practice. It has been described as elitist (in terms of class and status), capitalist, drug oriented, urban centered, and assertive of its dominance over other health practices by means of subordination or exclusion (Cohen, 1989). Biomedicine is almost invariably the first option in seeking medical assistance. A majority of Thai self-medicate as first choice for minor ailments using pharmaceuticals although a recent study shows that self-medication has dropped as socioeconomic status has improved (Komatra et al., 2000). If medical expertise is required, private clinics are usually preferred over government health services (just as commercial pharmaceuticals are preferred over government-issue) although this will depend on practical issues of distance and cost.

Even though biomedicine dominates as a paradigm for diagnosis and treatment, many Thai still employ pluralistic explanatory models and therapeutic strategies. Magico-religious beliefs remain complementary components of health-seeking behavior. They provide answers to "why" an illness has taken place. In a social order strongly predicated on a belief in *karma* as a causal ontology, current situations are frequently interpreted as emerging from prior events. While Western etiology is almost universally accepted as explaining morbidity, spirit doctors might also

be consulted to determine whether malevolent spirits were involved in its onset. Buddhist, Hindu, and animist beliefs commonly intersect in the prescribed rites and remedies. Recalling a lost soul is a crucial element both in preventive and healing rites. Persistent diseases or those without a clear pathogen, such as forms of mental illness, are still commonly treated by a divine or “spirit” doctor who will either divine, incarnate, or do battle with, the inflicting forces. Although belief in spirits is declining in favor of pharmaceutical treatment for most diseases, a Buddhist and Hindu background confers legitimacy on traditional Thai medicine that ensures a widespread faith in Thai herbal remedies. These are still widely sold and consumed.

SEXUALITY AND REPRODUCTION

Sexuality for the Thai has often been described as a “fluid” arena where what goes on in private is of less concern than the maintenance of public appearances. This has particular relevance to same-sex practices. Similarly, debates concerning Thai sexuality often draw on the tolerance shown for cross-gender displays and whether the widespread presence of *kathoeys* (transgenders/transsexuals) constitutes an ontological third sex/gender. Despite an arguable lack of fixity in sex/gender identities, normative models of gender and sexuality still strongly shape the sexual and reproductive lives of the Thai.

Gender ideologies, based on predominant bilateral kinship patterns and Buddhist beliefs in the innate karmic superiority of the male, structure ideas about appropriate sexuality. By and large, Thai men are socialized to believe they have a “naturally” greater sex drive that requires consistent relief. Many men therefore have multiple and regular sexual interactions both prior and external to marriage most commonly within the context of commercial sex. As adolescents, male same-sex behavior carries no stigma if the male maintains his role as penetrator. Thai women, on the other hand, are taught to be more conservative and express sexuality solely within the bounds of marriage. These social values are changing rapidly with modernization and young Thai women are more sexually active than ever before. Gender roles have never entirely subordinated women—the Thai have one of the highest levels of female participation in the workforce (over 45% of total workforce) and within the household they have active economic and decision-making capacities including family size. Remnants of the widespread belief that female

sexuality is dangerous and polluting still find contemporary manifestation particularly in early HIV/AIDS campaigning that targeted female prostitutes as the cause of its spread.

A direct result of both the prevalence of commercial sex interactions and the liberalization of youth’s sexual mores, sexual health is a pressing issue for the health of many Thai. By the late 1980s, sexual transmission had become the major vector of HIV spread and by the late 1990s accounted for 82.6% of AIDS cases. Increasingly women are becoming infected, mostly from their husbands. By the end of 1999 UNAIDS calculated that of the 740,000 adults living with HIV/AIDS, 305,000 or 41.2% are women. In 2000, it was estimated that roughly 50% of new infections in Thailand would be women infected by their husbands or sex partners, 25% through injection drug use, and 20% among sex workers and their clients (World Bank, 2000). Due to effective campaigning, patronage of prostitution has plummeted throughout Thailand. But in its place there has emerged a more complex and ambiguous arena of negotiated relationships in which casual sex takes place. What is of current concern is that condom use frequently does not accompany sexual interactions that take place outside of institutionalized commercial sex raising the threat of continued HIV spread, particularly in light of burgeoning permissiveness and drug use amongst many Thai youth.

The inability of women to insist on condom use, within or outside marriage, highlights ongoing forms of sexual vulnerability. Over the past 30 years Thai women had actively embraced contraception as a means of limiting the family size but this seldom included condom use (average family size has dropped from 5.6 members in 1960 to 4.4 in 1990 and is expected to reach 3.4 in 2015). Easy access to a wide range of contraceptive measures without social or religious stigma coupled with extensive health promotion advocating the benefits of smaller families is behind the high prevalence of contraceptive use. At present, Thailand’s total fertility rate, which was as high as six 30–40 years ago, has declined to only 1.9 in 1996. By 1987, 70.5% contraceptive prevalence nationwide had been achieved rising to 72.2% by 1996. The oral contraceptive is the most popular, followed by female sterilization and injectable hormonal contraceptives. These three account for 85% of contraceptive use. Male methods of family planning are almost negligible. Vasectomy is cited by 2.0% of married women of reproductive age and condoms by 1.8% as their methods of contraception (Gray & Sureporn, 1999).

Declining fertility is also linked to delayed age of marriage and increasing percentage of women who remain unmarried (reaching 14% in 1990 for women between 30–34 years of age). This trend is a product of higher educational levels for women, higher levels of employment in the highly modernized occupational sector, increased urban migration and gender-specific acceptability for men to marry spouses of lower socioeconomic status (Guest & Tan, 1994). For women of higher socioeconomic status being unmarried carries no particular stigma, whereas more pressure is placed on rural women to marry even if the spouse is not a focus of affection.

Between 8% and 12% of women seeking gynecological care in government hospitals are found to be infertile. Adoption is not common amongst the Thai due to beliefs that an orphan has little karmic merit. In the past, particularly in rural communities, divorce has been regarded as a relatively straightforward occurrence (officially, it has increased from 8.3% in 1987 to 20.8% in 1998 although many rural marriages are not registered). In some instances, inability to have children may be an instigating factor in marital separation but I am unaware of any survey of its prevalence.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

Biomedicine has taken complete control over the management of pregnancy and birth—subdistrict health clinics provide antenatal care and women give birth in district or municipal hospitals. Cesarean births account for over 50% of all deliveries partly due to the desire to choose an auspicious birth date. For many Thai, marriage is less important than pregnancy in marking female transition into responsible adulthood although these days pregnancy is increasingly postponed as the married couple works to gain some material foundations. Unmarried parenthood is not widespread and if marriage is not feasible, unwanted pregnancies commonly end in abortions (54% of abortions are performed on women under 25 years old). Following biomedical models, miscarriages are understood in physiological terms however rites restoring potential or actual soul-loss are often performed. Both male and female children are valued—males for the karmic merit they can bring the family (particularly through ordination into the Buddhist monkhood) and females for their practical household assistance.

Infancy

Traditional postpartum confinement rites wherein the mother would lie by a fire in her house for 5 to 9 days, have largely disappeared. Coupled with specific food restrictions geared to restoring humoral balance, this was believed to restore and strengthen her body and soul and complete a first-time mother's transition into mature womanhood (Hanks, 1963, p. 71). Such practices have been dispersed by changing beliefs as to the nature of recuperation, practical issues such as lack of fireplaces in modern houses, lack of time, and the recommendations of doctors who discourage it especially after Cesareans and/or tubal ligations.

Lying by the fire was based on beliefs that females are soft natured/souled and spiritually vulnerable after birth. Such beliefs also apply to the child, and ritual specialists still typically perform soul protection ceremonies shortly after the child is born.

Breast-feeding has declined in favor of bottle and formula feeding in sync with the large presence of many young mothers in the workforce. Public health campaigns have recently advocated breast-feeding as the most desirable option for new mothers. Infants and young children are typically cared for by extended family members and older siblings, as it is common that both parents work. National rates of young children (ages 3–5) enrolled in nurseries and pre-school childcare rose from 39.3% in 1992 to 79.5% in 1998. On the other hand, child abandonment has also increased. A survey of abandoned infants at 40 health facilities showed a rising rate from 90/100,000 to 120/100,000 in 1998.

Childhood

In the past young rural Thai boys and girls would begin to work the fields at around the age of 11 or 12. From some parts of Thailand, teenage girls were sent into the sex industry shortly after reaching puberty. These days such practices are illegal and prosecuted as child abuse. Six years of state-sponsored secondary school education has recently become available nationwide ensuring a later entry into the workforce. Gender roles still strongly influence models of socialization with male qualities believed to be best nurtured through avoidance of strict discipline whereas girls are required to carefully observe parental rules. In early childhood, it is not uncommon for the young boy's genitals to be an item of attention (joking and tickling), young girls on the other hand are generally taught to be modest and compliant from an early age. Pneumonia is

the main cause of death in children under five, although its incidence has dropped from 5.2% in 1995 to 2.73% in 1997.

Adolescence

The major health problems of youth (10–19 yrs—20% of population) are linked to social behaviors including substance abuse, teenage pregnancy, sexually related health problems (STDs), and mental health issues such as violence and suicide. Maternal mortality is highest in the 15–19 age group often resulting from unsafe and illegal abortions. Thai adolescents face large risks from STDs, in particular HIV/AIDS—47% of STD patients are between the ages of 15 and 24—and in the first decade of HIV spread from 1984 to 1996 single females under 24 years of age were the highest risk group for infection, largely through commercial sex (Pimpawun et al., 2000). Nowadays, for many Thai “safe sex” is as much an issue of *who* one has sex with as it is of using a condom or not. As sexual relations between Thai adolescents take place more commonly, and condom use is not prevalent as these relations are seen as safe because they are not commercial sex. Genital operations, the insertion of small round objects (pearls) under the foreskin, are found amongst a small number of Thai males but it is unclear whether this contributes to the spread of disease. Substance abuse, in particular of methamphetamines (ATS), has also increased dramatically amongst Thai youth. Over 6 months in 1995/96 a nationwide survey conducted a urine analysis of 118,375 students from primary through university level. Of the 79,671 secondary students sampled, 1.1% tested positive to methamphetamine use and 3.8% of the 17,082 vocational students tested positive (Vichai et al., 2001).

Adulthood

As the majority of pathogen-based diseases decline, social factors also contribute to the morbidity and mortality of Thai adults. Many of these can be linked to rising levels of stress. It is not only the youth who are susceptible to substance abuse. One survey reports that more than 300,000 Thai labourers (20%) in Bangkok use methamphetamines as a response to stringent quota demands incurred by the 1997 economic crash. The overall number treated for ATS abuse has risen from a paltry 97 in 1990 to 12,518 in 1999 (UNDCP, 2001). Domestic abuse is widespread. In a recent study (Kritiya et al., 2001) conducted with over 2,000 women in Bangkok and a Northern Province, 44% reported experiencing sexual or other forms of violent abuse from their partner (22% within the 12 months). Male

suicide rates are currently 2.8 times higher than that of females and rank 6th in terms of years-of-life lost to premature deaths (AIDS is the highest for both men and women). AIDS also contributes to the socio-economic burdens felt throughout Thailand at the turn of the millennium. Many thousands of HIV-infected Thai women are widows who, having nursed their husbands, are left without economic resources to take care of themselves and their children. Hundreds of support groups throughout the country have come together to provide moral and social support for those affected by HIV and to date their membership is largely women.

The Aged

In accordance with Buddhist ideology the elderly generally have high status within the household; in rural areas they have traditionally resided with the youngest daughter and her husband. Home care is typical for most manageable forms of illness. The most common diseases of the elderly are muscular, tendon and skeletal disorders, followed by peptic ulcers, hypertension, and heart disease. Primary causes of mortality are cardio-pulmonary disease, cancer, diabetes, liver, and kidney disease. A 1995 survey (Chantaphen, 1995) of both rural and urban elderly showed 82.8% of those between 50 and 59 still worked which dropped to 42% for those 60 and over. The most common diagnosed ailment was back pain and 29.1% had been hospitalized in the previous year. Forty-two percent exercised regularly and 57% meditated daily. Illiteracy is high amongst this group and self-medication, especially analgesics and vitamins, by far the most common form of health-seeking treatment.

Dying and Death

Where possible, it is considered preferable for dying to take place at home rather than in a medical institution. Terminal patients are often sent home from hospitals in their last stages of life. The dead are cremated and Buddhist rites take place at the local temple and the deceased's residence to ensure smooth passage to the next life and to protect kin from potential malevolence associated with the dead spirit. The remains of the bones will sometimes be stored in receptacles within the temple walls. Although less common these days, distinction between normal and abnormal death is made that corresponds to “natural” versus unexpected, violent or accidental forms of death that prevent the completion of a life cycle. Bodies of those who have suffered an abnormal death will be buried for several years—the

remains are subsequently exhumed and cremated—to prevent similar misfortune befalling kin. These beliefs are no longer widespread. There is usually no change to the living arrangements of the remaining spouse with the existing kin.

Tongans

Barbara Burns McGrath

ALTERNATIVE NAMES

Tongans originate from the Kingdom of Tonga, formerly known as “The Friendly Islands.” Due to out-migration, there are more Tongans living overseas than within the country, primarily settling in New Zealand, Australia, and the United States. Outside of Tonga, Tongans are included under the more general category of Polynesian or Pacific Islander.

LOCATION AND LINGUISTIC AFFILIATION

The Kingdom of Tonga is made up of 170 small islands, approximately 40 of which are inhabited. These are spread over 700,000 sq km of the South Pacific about two third the way from Hawai'i to New Zealand. They are characterized as high islands formed by geologically recent volcanic activity, and low coral limestone atolls. The climate is sub-tropical with temperate weather and

high humidity. Rainfall is moderate and regular so that most crops are planted and harvested throughout the year. Cyclones and hurricanes occur every few years, and can result in extensive damage to buildings and crops. Tongan is in the Proto-Polynesian branch of the Austronesian language family. Tongan and English are the main languages spoken. The literacy rate in Tonga is 98%.

OVERVIEW OF THE CULTURE

Tonga is a relatively homogenous society (most of its population of approximately 105,000 are Polynesian) with a highly stratified social structure headed by the monarch at the national level, and by chiefs and chiefly lineages at the local level (Marcus, 1978). The first ruler, Tu'i Tonga reigned during the late 9th century. He was the son of Tangaloa, the god of the sky, and Va'epopua, an earthly mother. Succeeding holders of the title of Tu'i Tonga descend from Tangaloa and form the top of the pyramid-shaped social organization, the base of which is made up of commoners. In 1643, the Dutch explorer Abel Tasman noted the long-established peace and stability of the islands, which he felt were due to the system of reciprocal relations that existed between the chiefs and commoners. In 1845, Tupou I united the islands that were ruled by a number of competing chiefdoms (Campbell, 2001; Lātūkefu, 1974).

Much of the early history of Tonga is recorded in oral tradition with genealogies providing a chronology of events. They continue to be used to evaluate rank, seniority, and status, and are called upon to mediate disputes involving land allocation and title succession (Herda, 1990). Poetry and dance are another means used to record both culture and history. These often link events to specific localities of the Tongan landscape emphasizing the connection between the people and their environment. This ecology-centered concept of culture and history (*tala-e-fonua*) is being explored by contemporary Tongan scholars to examine past events from a new perspective (Hau'ofa, 2000; Mahina, 1993).

Despite a long history of European contact, Tonga is the only island group in the Pacific to avoid colonization. It became a constitutional monarchy in 1875 and a British protectorate in 1900. Tonga acquired its independence in 1970 and became a member of the Commonwealth of Nations. The government reflects the hierarchical social structure with decisions being made primarily by the monarch (King Taufa'ahau Tupou IV), the nobility, and a

few prominent representatives of the commoners. Calls for constitutional change and government reform began in the 1970s and 1980s and coincided with increased efforts at economic development in Tonga. The 1987 general election is considered a turning point in modern political history with the addition of new representatives who then spawned a pro-democracy movement (Campbell, 1994). This political movement is challenging traditional assumptions about power and rank, and subsequently having far reaching consequences in the country beyond the political system.

Missionary influence, beginning in 19th century, was very successful with the result that today Tonga is a strongly Christian nation. The major religions are Free Wesleyan Church of Tonga, Catholic, Free Church of Tonga, Anglican, and Seventh-Day Adventists. More recently, The Church of the Latter-Day Saints has been growing in popularity with 46,000 members, giving Tonga the distinction of having the highest percentage of Mormons of any country in the World.

The economy is based on the cultivation of tropical and semitropical crops including squash, coconuts, bananas, and vanilla beans. Agricultural exports make up two third of total exports. Demand for imported food (primarily from New Zealand) and manufactured goods and products that are unavailable locally have resulted in a sizeable trade deficit. Overseas aid and remittances from Tongans living abroad are critical aspects of the economy, and in turn have great influence on the affairs within the country.

The *'api* or household is the basic unit of the society. *Kainga* is another important unit, and describes extended family, or in some cases, those persons loyal to a particular chief (James, 1990). Mutual support with formalized obligations and privileges are realized within *kāinga* social relations. Considerations of rank and status affect daily life and are organized along a strict hierarchy. Although the father is the head of the household (*'ulomotua*), sisters have higher status than brothers, with the father's eldest sister (*mehekitanga*) having great power within a family (Rogers, 1977). Other factors such as birth order, age, and mother's personal rank determine an individual's rank in relation to another person. Both religion and kinship determine the rank of chiefs (Campbell, 2001). Prestige that was dependent on birthright and rank in the past is now also available to those who are able to achieve individual success such as with an advanced college degree, a job with high status, or personal wealth.

Adoption and fosterage among kin is very common and parents who give up their children (perhaps to a childless relative) are looked upon as generous. Migration has had a more recent effect on adoption practices in Tonga with children living overseas being sent back to Tonga to live with relatives for varying lengths of time (Gailey, 1992; James, 1991). It may be a temporary solution until the parents have established a stable home, or an arrangement for children to live with relatives for a few years as a way to ensure that they learn Tongan ways and proper behavior. In other cases, if the child is doing poorly or in trouble with the law in the new home, he or she is sent back to Tonga in hopes that the family, often the grandparents, can exert some control over the child.

Tongans are highly mobile and have a long history of travel, both sea-faring voyages and for more permanent settlement. Today there is a pattern of kin based migration resulting in a very transnational population of Tongans. These diaspora communities have an impact on affairs in Tonga because, in addition to sustaining the economy through their remittances, they are a conduit for new ideas and practices from the outside. Because of the Internet, communication among all the diaspora communities and Tonga is very free flowing. Most of the web sites have chat rooms where dialogue and gossip can occur.

In Tonga, as in most places around the world, globalization is viewed with mixed feelings. There is popular appreciation and pride for the fact that certain cultural values and traditions are key to Tongan identity (love, respect, sharing, etc.). This is accompanied by explicit efforts to retain these aspects of the culture, and reflected in slogans or tourist marketing schemes that proclaim Tonga as the most traditional island in Polynesia. At the same time, participation in a global economy and having access to some of the benefits (material and nonmaterial) of modernization are also desired (ease of travel, health care, etc.). Some changes are being welcomed, but there are also unintended consequences that are cause for concern (alcoholism, suicide, unemployment).

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

The health care system of Tonga may be characterized as a medical pluralism with coexisting paradigms. It

includes more than one medical ideology and more than one system of services so that an individual has a choice of receiving care from a traditional Tongan healer (*faito'o fakatonga*), or a physician or registered nurse who has been trained and who practices within the biomedical tradition. There is a range in attitudes toward biomedicine and traditional practices with some families relying on a single system. Most however, use both approaches when treating illness or seeking health. Health is not simply the absence of disease, but also includes having a good life, being lucky or fortunate, and being satisfied that you are fulfilling duties to God, your country, and family. Health includes all of these states, and illness strikes when any one is out of balance.

William Mariner is a popular source of information regarding healing practices of early Tonga (Mariner & Martin, 1981). In 1806 he was aboard an English ship that was attacked and burned. Mariner's life was spared and during his four years in Tonga he recorded his observations of healing practices, including the skill used in performing operations, such as removing an arrow point lodged in a man's lung, and in setting broken bones. Historical accounts, together with interviews conducted in the first part of this century (Beaglehole & Beaglehole, 1941; Bott, Salote, & Tavi, 1982; Collocott, 1923; Ferdon, 1987; Gifford, 1929) create a picture of healing among the chiefly class in early Tonga with the supernatural at the center of the medical paradigm. In order for a cure to be successful, the god or the spirit of a deceased ancestor who was causing the trouble had to be appeased. This was done with sacrifice and invocation. Tongans had a reputation with the other islanders in the Pacific as being also knowledgeable about herbs and internal remedies (Macpherson & Macpherson, 1990). In 1990, it was estimated that there were over 200 healers practicing on the main island of Tongatapu.

The more recent history of biomedicine is intimately tied to the history of Christianity in Tonga, as it is in much of the Pacific. Missionaries quickly learned that villagers who would not attend church for a sermon, traveled great distances for medicines, and the dispensary was soon part of the mission structure (Lātūkefu, 1974). Although it is unlikely that missionary medical treatments of the time were any more effective than what was being practiced, they did offer an alternative (Shineberg, 1978).

Today there are two hospitals in Tonga with outpatient departments, dozens of public health clinics, and a few private physicians who practice primarily in the capital,

Nuku'alofa. Health care that is provided at a government facility is free for all citizens and administered by the Ministry of Health. Patients are often referred to New Zealand for medical care that is unavailable in Tonga. The leading causes of death are cardiovascular, neoplasm, diabetes and related conditions, respiratory, and hypertensive conditions. Life expectancy is 68 years.

MEDICAL PRACTITIONERS

Health care providers in Tonga may be divided roughly into two types: traditional healers (*faito'o fakatonga*) who prescribe herbal cures, set bones, and use therapeutic massage, and biomedical practitioners (physicians and registered nurses) who are located in the hospitals and clinics.

Traditional Healers

Both men and women can be healers, though there appear to be more women. Entry into the profession varies, but most individuals are young adults when they begin to practice. Recruitment is informal with a tendency to choose a relative. The person who is selected may be one who showed an early interest or aptitude, or one the healer decides is appropriate to receive the skill. When it is time for a healer to retire, he or she will transfer the knowledge and skill to the successor. This ritual has a name, *fanofano*, but may be as simple as saying a few words, "I give you my *faito'o*." Other healers learn of their ability by accident or are told about it in a dream. If they are able to effect cures in people previously labeled as incurable, they are described as having *mana*. Healers live ordinary lives, receiving minimal material benefits. They receive gifts from patients, but these are more tokens of gratitude than payment. These can be as small as a few cigarettes or as valuable as woven mats or bark cloth for a particularly impressive cure. During the treatment, *kava* or food is often shared. Because the healer is merely the *vaka* ("vessel") for the healing power of God, abuse of this divine gift will result in the healer losing the ability to cure. The sins of greed or pride put the healer at risk for possession by the very spirit being fought (Cowling, 1990).

Healers tend to be specialists, not general practitioners, and those who claim to have cure-alls have little credibility (Parsons, 1985). As in the past, infusions

and poultices made from herbs, leaves and bark are prescribed. New ones are always being added to the pharmacopeia, and in 1992, a botanist collected information on 77 that are commonly known for their curative properties (Whistler, 1992). The art of massage is practiced throughout Polynesia for a variety of external and internal ailments. Other specialties include pediatrics, midwifery, setting bones, and treating spirit possession.

Biomedical Practitioners

Following the influenza epidemic of 1918 that took the lives of 8% of the population, Queen Sālote established a Department of Health with free medical care for all. Most practitioners studied medicine in Fiji, and later in Samoa (Wood-Ellem, 2001). Today there are approximately 70 physicians, most of whom trained in Fiji, New Zealand, or Australia, and 340 nurses (Young Leslie, personal communication, 2002). Nurses attend the nursing school in Tonga for their basic education and study abroad for advanced training.

The oldest and largest hospital is on the main island of Tongatapu with 200 beds, running at 50–60% occupancy. The average adult duration of stay is 10.1 days. The reasons for hospitalization match the recorded leading causes of mortality in Tonga: diseases of the circulatory system, neoplasm, intestinal infectious disease, respiratory disease, and digestive disease.

When a person is admitted to the hospital, it is assumed that a relative will be available for personal care such as bathing and feeding. The caretakers of the patients create an informal system within the institution. Physicians and nurses receive respect as individuals who have gifts for healing, however, many people view the hospital with a mixture of relief and fear. Relief that Tonga now has a modern facility to care for its citizens, and fear because it seems that everyone who is admitted dies there. The hospital is referred to as *fale mahaki*, house of sickness. The medical response to the fear of death is that statistics do not confirm this perception, but what does happen is that people wait so long before coming in that it is too late to save them, and the mortality rates are higher than they need be. For their part, health care workers express ambivalence toward traditional practice. One would be hard-pressed to find an individual who has not experienced the therapeutic effects of massage when skillfully administered, but traditional methods are also described as dangerous, and should not be

used in conjunction with biomedical therapeutics. Their use may also hinder a person from seeking medical care. This problem is being addressed in a very interesting public education campaign currently underway that is attempting to assist traditional healers make a differential diagnosis between spirit possession and schizophrenia in order to avoid the harmful delay of medical treatment for major psychotic disorders (Puloka, 1999).

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

The concepts of *mana* and *tapu* are central to an understanding of health and illness. *Mana* refers to the degree to which objects and persons are endowed with supernatural powers. Having *mana* offers some protection against misfortune and bad luck, and it is the force that allows healers to act as a vessel for the healing power of God. *Tapu* is also a complex concept that combines a number of distinct notions (Radcliffe-Brown, 1952). *Tapu* is sacred, and describes a connection with the gods. It also describes those things that are forbidden or prohibited (the English word “taboo” is derived from this Tongan term). It is in this sense that the early Tongan chiefs and objects touched by them were *tapu*. These two dimensions of social control also have cosmic consequences, so that breaking a *tapu* or misusing *mana* may result in misfortune through the agency of spirits (Levy, 1973; Shore, 1989).

Illness is talked about in a number of different ways. One system distinguishes Western illnesses from indigenous ones. Conditions thought to be introduced by Europeans, or at least best treated with Western therapies, are *mahaki faka Palangi* (“European sickness”). The category *mahaki fakatonga* includes everything else (Parsons, 1985). Another classification that is used describes those misfortunes caused by “natural” events as *mahaki pe* or *puke pe* (“just sick”), as opposed to problems caused by spirits. The latter are *mahaki* (or *puke*) *faka tevolo* (McGrath, 2000).

The word *tevolo* is a complex term, most often glossed as “devil,” but more accurately refers to ancestral and nameless spirits (the older term for *tevolo* is *fa’ahikehe*, “other side” (Ka’ili, personal communication, 2002). *Puke faka tevolo* implies supernatural agency. The

cause of an illness is an action or behavior by the person, or someone in the family, that is offensive or disrespectful to God, an ancestral spirit, a chief, or to a superior on earth who is in a higher social position. In addition, failure to fulfill one’s responsibility to family or church is implicated in cases of misfortune. Breaking a *tapu* leaves one open to punishment until forgiveness is requested and granted. In some cases even though forgiveness is given, the punishment will be a lethal illness. This does not negate the importance of correcting the wrong. If forgiveness is not granted, the punishment will be passed on to descendants and they will suffer for many generations. Spirit-caused illness is most often a result of improper behavior, but spirits also play tricks on people or act mischievously (McGrath, 2003). The actions of *tevolo*, and the way people use them, demonstrate their ambiguity and instrumentality. This allows for humorous explanations of the intentions of *tevolo* and offers the potential for human interpretation and deception (Poltorak, 2002). Sociopolitical purposes may also be served by *tevolo*. Mageo (1998) notes that in the Pacific, discourse on possession has a countercolonial aspect to it, as well being oppositional vis-à-vis Christianity.

While spirit-caused illness is not as common an ailment as in the past, every community has a healer who knows what to do, a *faito’o faka tevolo*. The treatment must not only cure the symptoms (with methods such as massage or herbal poultices), but deal with the cause of the trouble by first identifying the offended spirit, and then by righting the wrong. Prayers to God are often added to the therapy. A special case of spirit possession is *āvanga*, which seems to occur most often with young unmarried women. The person may act in ways that are considered socially improper, exhibit altered mental status, unusual strength, and increased sensory awareness (Gordon, 1996). Treatment provided by the *faito’o faka’āvanga* includes medicines as well as a discussion with the family concerning the cause.

There are certain conditions that are clearly spirit-caused, and going to a doctor will do little good, just as there are a number of conditions that can only be treated in the hospital (e.g., automobile accidents, tuberculosis). However, even in these situations, if the primary therapy is not progressing, there is some room for flexibility by adding alternative treatments as adjuncts. There is also movement between systems (going to see a healer or a physician) with the most common type of conditions, those described as *puke pe*. This category is used with a

wide variety of conditions that are self-limiting or seem to respond in a predictable manner to treatment.

There are a number of traditional interventions available when a person is *puke pe*. Massage is frequently used for a range of ailments, both internal and external. It can be done gently with the tips of the fingers, superficially with the whole hand, or deeply for underlying muscles. Bone fracture reduction is also done with massage. Some healers work with dry hands, other use water or coconut oil (“Tongan oil”) as a lubricant. Tongan oil may also be used as the medium for herbal medicines. The plant parts used in healing are the leaves, leaf buds or young leaves, the inner bark or trees, and the root or rhizomes of ferns and ginger (Whistler, 1992). These are crushed and placed in a bottle of Tongan oil, or boiled in water, to drink, or to place on the skin as a poultice.

Disease categorization is of interest, but does not necessarily dictate treatment. There are a number of options available to a person who is sick, and illness is usually accompanied by much discussion with the result that diagnosis is most frequently made retrospectively—what treatment worked defines the condition. Decisions about where to go for care then are based primarily on pragmatic factors. Even though the ideologies of biomedicine and traditional healing are very different, it is often practical considerations that determine where care will be sought. Family and friends’ influence are important, as are past experiences with illness, and accessibility to care providers.

The official (government) position supports modern biomedicine, and encourages the best students to enter medical and nursing schools. There are also strong proponents in Tonga of the value of traditional methods, especially if they are used in a complementary manner with biomedical approaches. There has been a call for rigorous study of herbs so they can be standardized (Bloomfield, 1986; Finau, 1981) Tongan medicine is a common topic in the local newspaper, with interest in its survival. A concern is that many of the healers are getting old and their children seem uninterested in following in their footsteps.

Tonga, like other Pacific Island nations, is facing serious health problems as a result of changing diet and activity levels (Englberger, Halavatau, Yasuda, & Yamazaki, 1999; Evans, Sinclair, Fusimalohi, & Liava’a, 2001; Sinoue, 2000). The effects of “modernization” or “Western lifestyle” with a high-calorie diet and low physical activity lead to obesity-related conditions such as

diabetes and cardiovascular disease (Crews & MacKeen, 1982). This is true in Tonga, where diabetes is so common, a Diabetes Centre was established in 1993 to focus and intensify efforts to prevent and treat the disease (Vivili, ‘Eseta, Finau, & Lutui, 1999) and among Tongans living overseas who (along with other Polynesians) suffer disproportionately high rates of type 2 diabetes (Bathgate, Donnell, Mitikulena et al., 1994; Collins et al., 1994; Simmons, 1997).

Research from New Zealand suggests knowledge about the need for dietary change is widespread, but the changed behavior is difficult to achieve. In Polynesian cultures, the value of food is in its ability to preserve traditions and help develop the community’s unique identity. Its social value is perceived to be greater than the health value, with certain foods having higher social values than others (i.e., imported food, or meat with high fat content) (Small, 1997). Food continues to be an important way social relations are managed between kin and neighbors as evidenced in the everyday greeting, “ha’u tau kai” come let us eat (Young Leslie, 2004).

Large bodies are a reflection of *mana* in the case of chiefs, but in general reflect personal and familial rank and power. Cultural role expectations also contribute to the high rates of obesity in women (39%). Value is placed on a large and motionless body so that women should remain still, indeed to stay seated whenever possible. Their prototypic forms of labor, such as beating tapa, weaving pandanus mats, washing clothes, and caring for children, is done sitting down. Schoolgirls participate in active sports, but for many, this stops as soon as they leave school and must begin to behave like proper adults (Tupoulahi, 1990; Young Leslie, 2004). Typically, men’s lives include more physical activity such as working in the gardens or fishing. As more families engage in wage labor in the city, adopt a more sedentary lifestyle, and shift their diets to more convenient and available “fast foods,” it can be assumed that diseases related to obesity will increase. Stress is thought to be another consequence of changing lifestyle. A study in Samoa using biomarkers to measure stress suggests that those adolescents who experience social status incongruity as a result of culture change also experience greater stress (McDade, 2002). A similar pattern may be assumed to exist in Tonga with nontraditional, Western ways of living often being at odds with long-standing practices, thus posing challenges for individuals who wish to participate in both (Foliaki, 1999).

SEXUALITY AND REPRODUCTION

Gender relations in Tonga follow the pattern of much of Polynesia where women enjoy high status, yet men have greater power (Schoeffel, 1978; Tongamoa, 1988). Women are *fahu*, they have specific rights and certain privileges over their brother's children, maternal uncles and their children (Moengangongo, 1988). This status is usually exercised at social occasions, such as weddings or funerals. While sisters exercise a controlling power (*mana*) over their brothers, and are thus honored and served by them, as wives they are expected to serve their husbands and submit to their authority. Women's sexuality is viewed as under the control of her father and brothers, who keep a close eye on the young women of the family.

The topic of sexuality and reproductive health are considered to be very private, and it is *tapu* to talk about these things when brothers and sisters (biologic or classificatory) are together. When there is discussion about sex, it tends to be in the form of humor using metaphor and double entendre.

Gender liminal men in Tonga, or *faka leiti*, and their counterparts throughout Polynesia have a long tradition and are variously accepted into their communities. Besnier defines *faka leiti* by their characteristics: the demeanor exhibits stereotypically feminine qualities; many cross-dress and engage in sexual activity with "straight" men; they are associated with domestic spheres of activity; and work in activities associated with women such as mat weaving, tapa cloth beating, keeping house, or work in the hotel or entertainment industry (Besnier, 1996). A form of transsexualism, *faka leiti*, resists easy generalization and is undergoing change as a result of globalization and increasing transnationalism. The influence of Western gay culture is a topic of discussion within the community. There is very little known about these gender identity issues among women.

Chiefly marriages in the past were arranged for politically strategic purposes. Social relations continue to be important considerations when choosing a partner, particularly the qualities of the potential in-law family. Although not all couples include their families in their plans to marry, most decisions are made after all sides have given their approval. Once this is obtained, the parents and other important relatives meet to discuss the wedding arrangements, including the exchange of gifts. If the couple chooses to elope, the marriage can still be acknowledged by attending the church services the

following Sunday wearing ritual fine mats. Most marriages occur when the couple are in their 20s, and they often live, at least temporarily, with parents of one side or the other. A young wife who lives with her husband's family faces challenges as she is of lower status than her affines, especially her husband's sisters.

Having children is very important and fertility is valued as an expression of femininity. Although infertility is cause for concern, adopting a child can moderate the social stigma. Fertility rates vary, with some rural families having six or more children; in the city two or three children is more common. Overall the fertility rate is gradually decreasing. The government and a few of the churches promote family planning, but because of feelings of modesty about sexuality, and personal religious beliefs, few couples use contraceptives. Children are viewed as future providers for the family, and blessings from God, so there is pressure to have a large family. This presents a conflict for the increasing number of families with both parents working outside the home.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

Pregnancy is considered a special and potentially dangerous time. A pregnant woman is taught by other women about the multiple prohibitions (*tapu*) she must observe to ensure the health of her baby. She is told that her behavior, what she eats, her relationships with others, and even how she moves her body all influence the physical and mental being of the baby inside (Morton, 1996). The mother breaking a *tapu* may be offered as the explanation for a miscarriage, stillbirth, a physical deformity, or mental or behavioral problems of the child.

Prenatal care is available at government public health clinics in the villages, and by midwives (*mā'uli*). The majority of births (over 80%) occur in the hospital attended by nurse-midwives and physicians (Morton, 2002). Some women deliver their babies at home by choice; others do so because they are unable to travel the distance to get to a hospital or because they miscalculate the dates and find themselves in labor on an outer island.

Infancy

Traditional practices, such as burying the placenta near the home, are followed to a varying degree throughout

the islands. The Tongan term for placenta, land, and grave are the same, *fonua*, signifying the cyclical nature of life, and a connection between person and place (Mahina, 1999). After childbirth, the mother and infant return home for a period of rest and seclusion. Ideally, female relatives will appear and provide help for the household. The Christening, which occurs at three months, marks the end of the seclusion, acknowledges the child's membership within the *kāinga*, and is accompanied by gift exchanges. Naming the child is an honor often given to a person of rank or a relative of high status, such as the *mehekitanga*.

During the first few years of life, the baby receives almost constant attention from both men and women of the household, and sleeps next to the mother at night (Spillius [Bott], 1960). Breast-feeding is the norm, and lasts until the baby is about 8 months old. Babies are frequently massaged with scented or herbed coconut oil to prevent ailments or deformities, or to treat fussiness or fever. This massage is done by the mother or other female relatives. Massage of the skull soon after birth is done by a *faito'o* to ensure the fontanel closes properly. The first birthday is cause for great celebration with an elaborate feast attended by the *kāinga*, the minister, and neighbors in the village.

Childhood

Most of the following data on childhood and adolescence in Tonga are from Helen Morton (1996). Children, both boys and girls, are highly valued and bring meaning to life and to social institutions such as marriage. Early childhood is marked by love and affection from indulgent adults. It is the responsibility of the mother to teach her children to act properly, but as the child grows, all adults of the community, as well as older sibling and relatives, act in parental ways. As they get older, boys have more freedom to wander, whereas girls are expected to stay at home and do chores, be better behaved, and act more responsibly.

Adolescence

The whole span of childhood and adolescence is regarded as a time for molding behavior to become a fully adult person. The importance of kinship relations and the values of love (*'ofa*), respect (*faka'apa'apa*), and obedience (*talangofua*) are described by many Tongans as the key to

their cultural identity and inform proper behavior. These exert a powerful influence on children and are reinforced not only in the home, but also in the church and at school. Transgressions are viewed as bringing shame on the whole family. Physical punishment is a common form of discipline with children explaining their parents do it out of love. This issue poses problems for migrant communities where the distinction between discipline and abuse is not necessary shared (McGrath, 2002).

There are no initiation rites to mark a girl's passage to womanhood. Male circumcision is done as a boy enters puberty, either at the health clinic, hospital, or performed by an elder male.

Dying and Death

Death ideally occurs in the home, with the person surrounded by close family members. Although there is no formal stage of terminal illness, there are different terms to describe the seriousness of an illness. If a sickness that initially is described as *puke pe* or *puke faka tevolo* is resistant to cure and progresses, the person is then *puke lahi*, or very sick. Typically, he or she will remain in bed, or on a mat on the floor. A piece of bark-cloth or fabric may be hung up to separate the space where the person lies from the rest of the house. Children are not allowed to play nearby or make loud noises. During this time when recovery is not expected, last advice, *tala tuku*, is given. Not all families have this tradition, but parents are likely to make this their last formal act with their children. *Tau'aki* describes a more serious state, usually marked by loss of consciousness, with death occurring within hours or at most, days. This is a special time with sanctions against improper behavior imposed by the family. Only specific relatives are allowed near the dying person. *Tapu* prohibitions must be respected and a sister will not be close to her brother, and vice versa. They will remain on the other side of the cloth divider. Personal care is performed by females, usually daughters and other female relatives, who are of the same or higher rank as the individual. Expressions of strong emotions are to be avoided around the time of *tau'aki*. It is thought that it will be more difficult for the person to leave if those around are very sad or having a hard time. Similarly, physical contact such as touching also makes it difficult for the spirit of the person to leave when its time has come to depart. After death, the body will be washed with water, the skin rubbed with coconut oil, powder, and

perfume. The body is dressed and preparations are made for the funeral.

Funeral rituals are very elaborate, and a point of pride among Tongans. Pulotu, the Tongan afterworld, was the focus of funeral rituals before widespread conversion to Christianity, and although heaven has replaced this image in many respects, there continue to be frequent references to it in song and poetry, suggesting that the image of Pulotu may not be far from the minds of many present at funerals (Filihia, 2001). Aspects of status and rank which are less important in everyday life become central at a funeral (Kaeppler, 1993). These are also times to reaffirm Tongan traditions and pass them on to the next generation. Principles of rank are enacted with those attending the funeral placed according to their relationship to the deceased. Those higher are *fahu* and have certain rights and obligations, those lower are *liongi*, and are expected to take care of other tasks. The rituals begin with the 'āpō, or wake, in the home. Everyone who has a connection to the person will come by to pay respects. While some relatives are inside the house keeping watch over the body and welcoming mourners, the relatives who are *liongi* are outside preparing and serving food and drinks. The main activity outside is the gift exchange. *Koloa*, literally wealth or valuables, are ritually presented. These may include very finely woven mats (some of which are named) and bark cloth (Filihia, 2001). These will be re-distributed during the following days. The burial in the cemetery occurs within three days.

Graves in Tonga are very distinctive with shaped mounds of white sand that are then decorated by women. These decorations, or art forms, respond quickly to cultural change and prevailing taste so that now in addition to more traditional crushed coral and woven flowers one finds beer bottles or plastic syringes carefully arranged on the grave (Teilat-Fisk, 1990).

After the burial, the head of the household invites the entire community to a feast and announces how long the mourning period is to be. The time of mourning is marked by special clothing, *ta'ovala putu*, a mat wrapped around the waist, and prohibitions against sporting games, dances, music, and beating *tapa* in the village. Ten days of village mourning was the norm in the past, now one or three days is more common. There have been other changes in funeral rituals: the body may remain in the hospital morgue to wait for overseas relatives to arrive; coffins (rather than wrapping the body in *tapa*) are being used; and while funerals are still important social

occasions to strength kinship ties, often those of the nuclear family are often emphasized over ties with the extended *kāinga*.

CHANGING HEALTH PATTERNS

A caution must be raised concerning the nature of this description of the Tongan culture and health care. Generalizations about beliefs and practices have the potential to smooth out all difference and present a picture of an essential Tonga that is unchanging and without variation. This is not the intent, nor is it an accurate representation of Tonga or of Tongans. One of the tenets of medical anthropology is that the body is a site for social action, so that healing becomes a useful way to examine cultural transformations. In Tonga, as everywhere, all individuals do not experience the culture in the same manner. Knowledge and behavior around health and illness are dynamic and reflect the diversity that exists based on gender, class, education level, and so forth. Research and analysis of these issues, as well as the influence of political, economic, and social change on health is currently underway by a number of Tongan scholars whose works will make important contributions to the literature based on their deep understandings of the culture.

Trobriand

Jay Bouton Crain, Allan Clifford Darrah, and Linus Silipolakapulapola Digim'Rina

ALTERNATIVE NAMES

Bweyowa, Kiriwinia, Kilivila, Bowoya, Trobrianders, Trobriand Islanders.

(Murua) on the Woodlark and Marshall Bennet Islands, and (3) Kilivila on the Luscancy Islands and Trobriand Islands (Kiriwina, Vakuta, Kitava, Kaile'una, Kuaiwa, and Munuwata).

LOCATION AND LINGUISTIC AFFILIATION

The Trobriand Islands are located in the Massim region of Melanesia 120 miles north of the eastern tip of New Guinea (approximately Latitude: 8.30S, Longitude: 151E). The Trobriand archipelago, consisting of some 22 flat and partially raised coral atolls, sits at the intersection of the Coral and Solomon Seas and is politically situated within the Milne Bay Province of the Republic of Papua New Guinea. The population is centered in the larger islands of Kiriwina (Bowoya), Vakuta, Kaile'una, and Kitava. Bowoya's population, exceeding 26,000, is located in some 60 villages (Lepani, 2001; see also Weiner, 1987). The language of the Trobriands is Kilivila (Kiriwinan). Lawton (1993) lists 11 dialects. Five of these are spoken on Bowoya proper, three on each of the remaining large islands, and the last three in culturally related Luscancy Island (Simsimla) and the Marshall Bennet group (Iwa, Gawa, and Egum Atoll). Milke (1965) suggests putting Kilivila in the Oceanic subgroup of Austronesian. Senft (1986) treats Kilivila as a language family within the Austronesian "Papua-Tip-Cluster" defined by Capell (1976) and identifies three languages: (1) Budibud (Nada) on the Laughlan Islands, (2) Muyuw

OVERVIEW OF THE CULTURE

Trobriand cultural institutions share the forms of cultural practice which are characteristic of many Melanesian societies: religious concepts focus on the processes of growth and decay; male sorcery involves powers of life and death; magic controls food production; rank is asserted pro forma, but in reality is contingent on elaborate exchanges during birth, mortuary, and harvesting rites and, to a lesser extent, in association with kula exchanges (Young, 1983). Men are defined by their success in gardening and exchanges of yams and kula shells while women are distinguished through mortuary exchanges of skirts and leaf bundles (Weiner, 1976). Trobrianders are also defined by a system of rank tied to the alimentary history of their direct matrilineal ancestors, transmitted through mother's milk (Montague, personal communication). Differences in rank are articulated through violations of food prohibitions that adversely affect magic stored in the stomach.

Trobriand social life has been described as being organized around sub-clans (*dala*) each of which is assigned to one of four clans (*kumila*). Malinowski (1929) and to some extent, those who have followed,

treated Trobriand kinship as exclusively matrilineal, viewing fathers as merely affines. Recently Montague (2001) has argued that Trobriand kinship has bilateral characteristics and that Trobrianders define their relationships in terms of dietary history and exchanges. However, bilateral relations attain their meanings only within the generation or lifetime of the individuals concerned, but not beyond it; matrilineal descent (*dala* principles) takes over in between generations in order to regulate new sets of relations once again.

Bweyowa subsistence is based on agriculture and fishing. The main crops are yams, sweet potatoes, taro, bananas, and coconuts. A food surplus is produced in normal years; however periodic droughts, attributed to the magic of Tabalu chiefs, result in famine (Digim'Rina, 1998). Young's observations that Goodenough Islanders' preoccupation with food dominates their symbolic idioms and cannot be completely explained by ecological exigencies, also holds for Trobrianders (Young, 1986). Trobrianders have gone to inordinate lengths to make food the measure of all things, particularly health and well-being.

Evidence for the initial occupation of the Massim, in the form of pottery deposits, suggests widespread settlement by Austronesian speakers about 2,000 BP (before present) (Bickler, 1998). Recent evidence dates the occupation of Kiriwina to about 900 years ago (Burenhult, 2002). Inter-island group trade in the form of *kula* may date from around 500 BP (Egloff, 1978). In 1793 French explorer Bruny D'Entrecasteux named the group after his lieutenant, Denis de Trobriand and in the century that followed there were occasional visits by traders and whalers. By 1894 pearl traders and Wesleyan Missionaries were living permanently on Boyowa (Campbell, 1984). Australian colonial officials set up a government station at Losuia in 1904. One year later a hospital was built in response to reports that there had been a serious population decline due to the spread of venereal diseases (Black, 1957).¹ In 1936–37, a mission and primary school were set up by the Sacred Heart Catholic Mission. During the Pacific War, Australian and American forces were stationed at two airstrips constructed on Boyowa. Local government and various business ventures were established in the 1950s and a high school in the 1980s. National independence and inclusion into Milne Bay Province took place in the 1970s (Young, 1983).

Bronislaw Malinowski's pioneering and widely influential works on Trobriand society made the

islander's lives accessible to readers around the world. Trobriand society has been the focus of considerable ethnographic field research and the descriptions and analyses derived from these studies have themselves been the subject of voluminous debate and re-analysis. Each generation of scholars have brought to the Trobriand materials the insights and biases of their own training.² The corpus of Trobriand literature is enormous and, in an appropriate analogy for a work in medical anthropology, it resembles nothing less than the thick chart of a chronic patient: a series of not clearly connected narratives written at different times by different clinicians, ostensibly about the same person. What follows is a synthesis of this huge literature that focuses on the visual aspects of health.³ However we recognize that such a synthesis is just that, synthetic.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

The islands have undergone sustained population growth. Pösch and Pöschl estimate that between 1913 and 1985, the population of Boyowa grew exponentially (Pöschl & Pöschl, 1985). They also report that pregnancy in younger girls is increasing in frequency and that family size is expanding (1985; see also Lepani, 2001). Darrah and Crain (personal communication) found the population still expanding in 2001.

The scarcity of arable land has led to a reduction in the yam planting cycle from seven to three years. Pöschl and Pöschl report an increase in deficiency diseases and malnutrition even in years with a good harvest. They also found tuberculosis in malnourished children and underweight adults and suggest that enteric diseases were to be found in larger villages with poor sanitation and inadequate water supplies (Pöschl & Pöschl, 1985). Lepani (2001) reports that malaria, skin disease, and pneumonia are the leading causes of morbidity, while perinatal conditions, meningitis, malaria, and tuberculosis are leading causes of mortality. However, Montague (1985) notes that the risk assessment for the effects of malaria, made by people in Kaduwaga, tends to be lower than those of health officers. Annual sprayings of DDT to control mosquitoes are opposed locally and available malaria drugs are used for treatment rather than prevention. Montague

also found no evidence of children frequently being ill from malaria.

Diet and Health

Food consumption is central to Bweyowa thought about society and the body. Eating articulates social divisions of rank (Malinowski, 1929), kinship (Montague, 2001), age, states of being, and definitions of self. Pre-colonial Trobrianders contrasted themselves with neighboring cannibals. Tudava, the great culture hero, eliminated cannibalism substituting yams for humans and lessened the effect of garden magic to make room for individual achievement. This magic provides a lattice of inferences that yam and human life cycles mirror each other (Brindley, 1984; see also Darrah, 1972). Today Trobrianders raise and exchange yams, which are metaphorical humans.

Malinowski's Trobrianders assumed that people ate for pleasure rather than to sustain the body (1929, 1935). However, Malinowski also notes famine was thought to produce a variety of illnesses which could lead to death (1929). Montague reports that death ultimately results from consumption of food that has lost its nourishment due to adulteration by a sorcerer (1989). Humans require a steady intake of yams or taro (*kaula* or *kauna*) to build their bodies and confer the hardiness essential to withstand sorcery (Montague, 1989). Trobrianders, particularly during mourning, stress the obligatory side of ingestion making it a moral duty to eat food provided by others. Annual gifts of yams, totaling more than half a man's production, result in people being food-dependent.

A powerful expression of the obligation to "eat for others" was the former reciprocal obligation of the *kopoi* relationship where fathers pre-masticated food for their infants, and were repaid after death when son's symbolically ate from their father's bodies and vomited. This exchange should be viewed in the context of food prohibitions. Sons are responsible for their father's well-being and go to great lengths to show that they did not cause their deaths. A son refrained from eating his father's totems so that the father would not get sick when the son used his food utensils (Seligman, 1910). Alternately, fathers also had to maintain their children's food taboos.

Coupled with the obligation to eat with appreciation and share prohibitions is a public reticence to eat at all. Restraint in eating, particularly *kaula*, is a civic virtue. The intent of harvest magic was to control people's appetites so that yams rotted in storehouses rather than stomachs.

The famous Trobriand magic of prosperity [*vilamalia*] worked directly on people's appetites (Malinowski, 1935). Obesity, which is evidence of the failure of magic to restrain appetite, as well as a sign of selfishness, is not desirable. Nutrition surveys have generally found the Trobriand diet to be a healthy one (Hipsley & Clements, 1950; see also Lindeberg et al., 1994).

Wives maintain their husbands' food taboos to protect the magic stored in their husbands' stomachs (Montague, 1974). Foods, mentioned in magical formula and/or which share defining characteristics with the magic's intent, are avoided to preserve the effectiveness of spells (Munn, 1986). Violation of a food taboo would be to "eat one's ancestor" (Munn, 1986). Spells list the ancestors who held the magic in their own bellies. "Eating one's ancestors" is to ingest and then eliminate the ancestor laden spells; magic should be ingested and then brought back up.⁴

MEDICAL PRACTITIONERS

The literature makes no note of specialized traditional positions or offices for medical practitioners. However, there are individuals in each village who have knowledge of curative spells and magic-producing materials. Malinowski noted that magic to prevent dangers in childbirth, to cause abortion, treat genital discharge, swellings of the limbs, and toothache was controlled by women, but men also possess spells to control various aspects of reproduction (Malinowski, 1929).

Noting that Trobrianders lack a tradition of local midwives, Pöschl and Pöschl (1985) called for the training of female birth attendants. Lepani (2001) indicates that 126 women have been trained as Village Birth Attendants. There is also a health center in Losuia and more than a dozen local aid posts, with the actual count of functioning sites varying due to staffing problems.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

Classifications of Illness

Bweyowa notions of the body, the beginning and ending of life, the nature of disease, and the various stages of life

involve a complex assemblage of assertions and practices that are not easily, nor perhaps properly, separable from other aspects of life. Linking these, and used here as a guide through a brief discussion of Bweyowa views of biology, are local notions of agency elaborated through overlapping classificatory schemes involving properties of color (white/red/black), hot/cold, hard/soft, shiny/dull, wrapped/unwrapped, and mobile/anchored.

Agency and Illness. As in other areas of Melanesia, the body is mediated through a complex web of social relationships; its condition is enhanced, sustained, or endangered through a carefully monitored series of social and economic exchanges (Knauff, 1999). Bweyowa attribute most illness to four kinds of agency: *bwaga'u* (sorcerers), *mulukwausi* (witches), *tauva'u* (malignant spirits), and *gaga* (offenses against customary exogamy rules). Secondary forms of agency include *kosi*, a spiritual essence of recently deceased sorcerers, and *tokwai*, tree spirits who work in conjunction with sorcerers.

Sorcery. Illness (*silami*) results from the introduction of magically treated objects into the body. Vectors include tobacco, food betel, smoke, and charmed stones (Malinowski, 1929). The object is wrapped to preserve the magic's force. Feeling heavy, the recipient retires to his/her home to heal over the family hearth. In the dead of night the sorcerer attempts to intensify the illness by depositing herbs in the protective fire. The third, projective, phase of sorcery employs metaphors of spearing, stabbing, or otherwise piercing the body with a magical implement.

Tauva'u. Epidemics are attributed to the agency of *tauva'u*, spirits with the power to assume the shape of men, as well as crabs, snakes, and lizards, all of whom emerged from underground, in the mythic past, with the ability to rejuvenate by sloughing their integuments. A *tauva'u* taught sorcery to a man who then killed his benefactor. *Tauva'u* come to the Trobriands from the south, at the change of seasons, a time when people become ill from eating the first, unhealthy, "black" yams of the new garden. The yams are made unwholesome by Kitavan magic, which banishes evil influences, via the trade winds blowing toward the Trobriands (Malinowski, 1935). The invisible *tauva'u* kill people in epidemic proportions by striking each with a club. Not only are *tauva'u* the source of sorcery but they also are responsible

for teaching witches, their consorts, how to kill people (Malinowski, 1929).

Flying Witches. Witches remove internal organs, particularly those associated with ingestion and speech, and eat them causing sudden death. Most witches live on other islands, but Trobrianders identify some local women as witches and are quick to include them in food distributions when a relative is close to giving birth. The actions of witches, including their rituals of parturition, are the inverse of proper Trobriand women. Witches are greedy for food, and eat raw meat. Witches are strongly associated with fire, heat, and hyper-sexuality. At night their inner spirit, *sans* clothes and skin, takes the shape of a flying animal and moves through the sky emanating fire.

Prohibitions. Breaches of exogamy [*suvaso*] result in skin disease, swelling, and wasting. The body swells, the skin turns white, and breaks out into sores. A small snake-like creature appears and moves about in the body causing symptoms of swelling and wasting (Malinowski, 1929).

Theories of Illness

The natural state of a person is health. Theoretically people die from old age; however, usually one of the above agencies is blamed. Weiner has argued that magic comes to the forefront, not because of risk, as Malinowski suggested, but rather when the outcome of an exchange is imperative. In Weiner's view, magic is about controlling men through exchanges rather than control of nature; control over natural forces, such as the wind and rain, is proof that one has the power to dominate others (Weiner, 1987). Weiner's starting point is different from that of Weber, who places the source of meaning in the crises of illness. Weiner's perspective does not focus on misfortune or its remediation, and tends to ignore revenge, the other half of reciprocity. It is also a top-down view of society given that magic is such a limited resource, a prerogative of rank, while suffering is the great common denominator.

Both illness and senescence are associated with blackening and also with heat/fire. Malinowski observed that magic which affects health comes in paired sets of spells, called *vivisa* for therapeutic magic and *silami* for magic of affliction (Malinowski, 1916). A sorcerer without the perceived capacity to heal would be deemed incompetent. *Vivisa* refers to the defensive or healing

portion of magical formulae. It means to untie the knot of offensive magic which has the patient tied up in illness. The *-visi* suffix is also associated with peeling with the hands and to cool by fanning. Transformations of the skin are closely connected to health and therapeutics. The process of aging, visualized as darkening skin, results from accretions of black magic; *vivisa* and beauty magic reverse this process.

The general term for illness is *katoula* (e.g., *to-katoula*, "sick person," *eweya katoula*, "he caught an illness," *I kapilakeigu kala katoula*, "he gave me his sickness") (Baldwin, 1937). Specific Bweyowa disease categories include *kaivatokula* (wasting disease), *diega*, *bwawa*, *pwawa* (elephantiasis of the leg, arm, testicles, respectively), *kweyagola* (disease of the bones; rheumatism; tertiary yaws), *popoma* (disease causing swollen belly), *silaipwasa* (disease of stricture of the bowels), *lelia* (swellings; plague), *tobudawa* (abscess), and *silami* (incurable internal abscess) (Baldwin, 1937).

Fires of Life. *Momova* is life, and *mova* is life/alive; humans are *tomomova* [*to-* prefix for man]. *Yomova* and *yomovi*, literally "to cause life," means to heal. *Tokatumova* means healer. Scoditti (1996) translates *momova* as vital force. *Mo-* or *mwa-* are prefixes which impart maleness or humanity while Lawton notes that *-va* is a gentle, intimate action done with fire. *Mova* can be glossed as human fire. On the other hand, *mata* is both death and a dormant fire; *kimati* is both "to kill someone" and "extinguish a fire." The life as flame metaphor is elaborated through analogies between fire making and intercourse. The traditional form of starting a fire was rubbing a small pointed stick, on another stick, fire plough fashion (Silas, 1926; see also Fortune, 1932). The rubbing stick was called *kaikwila*; *kai* means wooden and *kwila* is penis. On neighboring Dobu, the fire stick is called *kekusi*, and the act of rubbing is *kusi* or *usi*, terms for the penis. Sexual intercourse is sometimes spoken of as "...we copulate and it flames up" (Fortune, 1932).

Fire originated through human reproduction. Malinowski (1929) provides a myth about the origins of fire in which a woman gives birth to fire, followed by the sun and moon. She conceals fire in her vagina bringing it out only to secretly cook her food. Intercourse produces heat that, at birth, ignites into the flame of life. Rituals that attempt to regulate the problematics of reproduction draw upon the quotidian acts of cooking. Trobrianders metaphorize alimentation as reproduction. Elements from

the culinary domain are used to build scenarios for the manipulation of analogous aspects of reproduction thereby reinforcing the assumption that life is a fire.

Treatment of Illness

Bloodletting is an important therapeutic practice in the Massim (Baldwin, 1937; see also Munn, 1986; Senft, 1986; Villeminot, 1967). Blood, produced by eating heavy *kaula*, is itself heavy, and its removal has the effect of lightening a person in terms of both color and weight. Gawan dancers are bled to lighten themselves. In the Trobriands, cuts or scratches are made with a sharp stone in order to remove blood or relieve pain, headaches, lassitude, chills, hematoma, and bruises (Villeminot, 1967). Bruises which produce a discoloration, likened to those suffered by pigs when clubbed to death, are lacerated to remove the blackness. Blood, once released from the body, is dangerous to matrilineal kin, but can be a gift that can establish exchange relationships. Gawan fathers put blood on their children to inaugurate exchanges of betel and other edibles with them (Munn, 1986).

SEXUALITY AND REPRODUCTION

Malinowski's (1929) discussion of the sexual freedom enjoyed by young Trobrianders has led to a distortion of Trobriand sexual ideologies and practices. The popular appellation of "Isles of Love," and the mind-set which is attracted by this term, ignores the extensive limits to sexual expression which were also documented by Malinowski. Prior to marriage, adolescents enjoy great latitude so long as their actions are private and within the confines of exogamy as well as peer pressures to restrict their choices to local candidates. It is commonly believed that sexually transmitted diseases are usually contracted from individuals from outside the local community (Lepani, 2001).

Marriage, which is bound by strong expectations of monogamy, does not legitimize sexual relations; on the contrary, marriage requires the couple to maintain a public fiction that intimacy is nonexistent. It is a grave insult for someone to suggest to a married person's face that he or she is sexually active with their spouse. The Trobriand ideology of asexual reproduction furthers this fiction; otherwise children would be public evidence of their parent's private actions. However, Malinowski (1929)

also observed that, during the harvest season, there were occasions when the strict norms of marital monogamy were relaxed. This was also a time when young people engaged in organized public competitions and dances, which were expected to lead to liaisons. Bellamy reported a large increase in births occurred 9 months following the harvest season (Black, 1957).

Instead of sex, marriage legitimizes alimentary behaviors. The first, trial phase of marriage, is marked by the couple sharing food in public, an activity that lasts for only the first year of marriage. During this period the couple consume food prepared by others as the bride is taught by a woman from the husband's home, how to maintain his dietary restrictions. Phase two begins at the end of the first year when the wife is given her own hearth; after this time, the couple will separately eat her cooking. Divorce is signaled by either party throwing the hearth stones out of their house (Montague, 2001).

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

It has been frequently reported, and contested, that Trobrianders believe that human conception is asexual, yet is also clear that intercourse plays a part in reproduction (Malinowski, 1929; see also Austen, 1934–35; Leach, 1966, 1968; Montague, 1971, 1973; Powell, 1968; Spiro, 1968, 1972, 1973; Weiner, 1976). Montague (personal communication) reports that the “hammering” of intercourse closes the cervix, staunching the menstrual flow and thereby facilitates pregnancy.⁵ Fertility is also aided by attachment to a particular partner. Conception occurs when a *waiwaia* [spirit child] is deposited on a woman's head by a deceased relative (Austen, 1934–35). Shortly after the *waiwaia* is deposited, an embryo [*veguvegu*] is brought into existence [*ebubuli*] (Austen, 1934–35). Blood and water from the uterus move to the woman's head, collects the *veguvegu*, and descends again, causing dizziness, headaches, and vomiting. At about 3 months, the *veguvegu* turns into a rat-like object rolled up in a mat like membrane.

Malinowski (1929) reports that *waiwaia* are reincarnations of ancestral spirits, created when rejuvenation, under the influence of magic, reverses spirits back to their pre-embryonic state. In 1918, Billy Hancock, Malinowski's expatriate friend in the Trobriand Islands,

advised Malinowski that Trobrianders did not believe in reincarnation, having said so only to agree with Malinowski (Stocking, 1977). Montague (1971), Austen (1945), Campbell (personal communication), and Digim'Rina (personal communication) all report beliefs in reincarnation.

If we examine *ebubuli* we find a variety of usages for its root *bubula*, the noun form. It is the initial state in carving, when order is imposed (Senft, 1986). It also means to shine, and to adorn. *Bububula* refers to the process of creation and manufacturing (Lawton, 1993). In his transcription of the great creation myth of Tudava, Malinowski records a passage describing Tudava's creation of fine gardens with the phrase '*valu i-bubuli*, the countryside was made bright' (Malinowski, 1935, Vol. 2). *Ebubuli* is a construct of Trobriand ideas of order and the initial stage of a transformation. The highly valued condition of brightness is linked to transformations of age, beauty, and health. One of the more compelling themes in Trobriand ritual is the use of magic to contravene the visual effects of aging, brought about by black magic, by restoring lightness and a beautiful bright sheen to the body's surface.

Special ceremonies are performed to make a pregnant woman beautiful and white. She is given a special bath, her father's sisters perform beauty magic over her, and her skin is covered with coconut oil. She is covered with a special white cloak and avoids the sun and thoughts about sex, for both would darken her skin. In the third trimester she resides with her own family who protect her with armed guards. At delivery she is placed over a fire to cause her blood to liquefy. Magic is performed to prevent sorcerers from darkening her skin, cooling her reproductive organs, and sabotaging her passage toward an uncomplicated delivery. Montague (1985) noted that a woman was ideally secluded after delivery for up to six months, so that her skin would match the white color of her child's.

In the *veguvegu*, or nascent embryo stage of existence, the symbolic focus is a house cricket called *vegu*. The salient qualities of the *vegu* are its long sensuous feelers, a very beautiful, luscious abdomen, and a sun sensitive skin that causes this nocturnal creature to wrap itself in a leaf (Malnic, 1998). Used to attract birds, *vegu* also means bait. The characteristics of the *vegu* are dramatized in the rituals that transform a *prima para* into a mother. The equally vulnerable parturient, who also attracts flying predators (i.e., witches) must cloak herself from the sun and wait patiently in her house.

Infancy

Children are generally welcome additions to the family, however, both Austen (1934–35) and Lepani (2001) indicate that abortions, by both herbal and mechanical means, are also an option. Lepani also reports that pregnancy often results in marriage, an outcome that is far more frequent these days than 30 years ago. Powell (1980) mentions the use of traditional forms of contraceptives, called *kaikariga* [*kai-* is a prefix for wood and *kariga* is death].

Bellamy (Black, 1957), Assistant Resident Magistrate and doctor in the Trobriands, from 1906 to 1915, reports that female infanticide may have been practiced; however, Malinowski rejected this possibility (1929). Montague (1985) reports that Kaduwagans deny practicing infanticide even though it is within a mother's rights up until she has fed her child. A newborn, prior to its first meal, is the property of the woman who did the work of growing it, just as yams are the property of the man who raised them. A genetrix can elect to feed a neonate, give the child to someone else to feed, or the infant can just disappear, without ever entering the kinship system. Once the neonate has been fed, it is human rather than property, and its kinship ties, which follow milk rather than blood, are to the person whose dietary history it shares (Montague, 2001). All newborns have the same kind of undifferentiated blood. It is only when a child drinks milk, which incorporates the nurse's unique dietary history, that it becomes related through these shared differentiations. Weiner notes that wet nurses are given axe blades [*beku*] as repayment for their milk and to reclaim the infant for its natal *dala*.⁶

From the third month of her pregnancy through the first month after parturition, a *prima para* must eat hard dry foods [*kaula*], which produce blood and milk. If she eats soft and wet foods, the baby will suffer from a nonspecific disease called *gwemata* (Pöschl & Pöschl, 1985). *Gwemata* means cold and damp (Baldwin, 1937). As late as the 1970s, women were encouraged to refrain from conjugal relations until their children entered the toddler stage in order to protect the quality of their milk. During postpartum seclusion, a major concern is to protect the mother's milk by keeping it warm. Cold or reheated foods are also avoided to prevent damaging fluctuations to the mother's internal temperature. Women also cover their heads at night out of fear that they will lose body heat, thereby cooling their milk (Montague, 1985).

Mothers nurse their infants for periods reported to be in excess of one year or up until the child starts walking. Colostrum may or may not be given. A 1980 Milne Bay weight-by-age nutrition study raised concerns about the diet and feeding practices for children from weaning up until 24 months of age (Nutrition Monitoring Group, 1980). The report found that a starchy diet, low in protein and high-energy foods, combined with a low frequency of food consumption made it difficult for young children to ingest amounts adequate to their energy and nutrient needs. Montague (1985) suggests Trobrianders exaggerate their dependence on *kauna* and underreport their consumption of other foods. In any case, Trobrianders of her acquaintance were far more concerned about emergency health care than issues related to child nutrition. In the Trobriand view it is good for babies to be plump but from the toddler stage on the preference is for thinness coupled with sturdy muscle development and high energy.

Any ambiguity surrounding the father's part in conception does not spill over onto his role as nurturer. Fathers have intense physical and emotional contact with their children starting several months after birth (Weiner, 1976). Fathers feed and care for their children even before their abrupt weaning. After this juncture, the child sleeps with its father until age 10 or until it is adopted by a family member. Powell (1969) suggests that young Trobriand children do not lack for support or guidance when their parents are absent.

Childhood

Children enjoy considerable independence. Malinowski (1929) reports that parents are more likely to request favors of their children, sometimes accompanied by threats, than they are to give them commands. They rely on the child's sense of fairness and obligation, which is instilled at a very early age. By age four, the child moves into the village play group and increasingly avoids parental discipline and oversight in a process of emancipation which Malinowski (1929) judged to be gradual and pleasant. At a point roughly coinciding with menarche, young girls are given a short red skirt symbolic of their capacity to evoke desire from others.

Adolescence

As a child ages it is expected to explore its sexuality and may receive adult approval and encouragement in

this quest. First sexual encounters reportedly occur between the ages of 11 and 16 years and are associated with the onset of puberty (Lepani, 2001). It is commonly believed that the enlargement of a girl's breasts and her menarche result from her being sexual active. Young women have great freedom in choosing their partners but if they have too many partners they run the risk of being labeled "tasteless." Young people who do not go out at night may be categorized by peers and adults as worthless. As girls age, they look for longer, monogamous relationships in preparation for marriage. These steady attachments are thought to enhance the chances of pregnancy, which reportedly occurs at an increasingly earlier age, resulting in growing numbers of unwed mothers (Lepani, 2001). Lepani suggests that the freedom of adolescence, combined with beliefs that liaisons within the community are safe, and expanding contact with people outside the local group, put Trobriand youth at an increasing risk for sexually transmitted diseases. Adolescence is a period devoted to honing skills of seduction, which employ decorations and magic provided by the father's family. Weiner (1976) notes that adults persuade others with magic and exchanges while the young must rely on their beauty augmented by magic. Mothers and aunts (both paternal and maternal) take an interest in their daughters'/nieces' relationships, which they monitor through the gifts provided by the girl's suitors (Lepani, 2001). Fathers, like mother's brothers, are properly not concerned with their daughters'/nieces' courtship.

In line with the general association of red with adolescence, the letting of blood provided an idiom through which Trobriand girls could communicate about their relationships with a particular boy. A girl could publicly express her interest by wounding a boy at a special harvest competition. During the foreplay, which would ensue, the couple would bite each other's lips to mingle their blood. Sometimes a girl would cut her lover's breast or upper arms as an indication of her commitment to him (Malinowski, 1929). This "red" period of the life cycle ends with marriage when the girl receives a white skirt with the expectation that pregnancy will follow, her menstrual flow cease, and her skin will be bleached through the rituals surrounding parturition.

Adulthood

The emphases on white symbolism, in *prima para* rituals, is best viewed in the broader context of Trobriand

efforts to control time with beliefs and practices focusing on the chromatics of ontology. Campbell (1984) reports that white is associated with newness, cleanness, purity, immaturity, innocence, but not with semen or milk. It is with experience and history that the skin ages and darkens. As people age their bodies turn from the white of infancy to the sexually active red of youth followed by progressively darkening hues as they gain experience, acquire magic, and are affected by the magic of others. White, black, and red have both positive and negative aspects (Tambiah, 1968, 1983). On the positive side a youth's "red" glossy exterior is highly desirable and allows him/her to influence others. The *prima para* is at the point of exiting the red stage of her development cycle and in entering the black stage of maturity.

Young people lack social maturity and the ability to make important exchanges. Mature adults, who have darkened as the result of magic, must use magic to compel others to succumb to their own wills (Campbell, 1984). At maturity, the jet-black hair of youth turns white, a reversal of the body's progression. White hair, like dark skin, signifies knowledge of life, and either draws fear and respect or ridicule depending on the individual's conduct. Hair, the site of conception, may be a harbinger of reincarnation when it whitens.

Transforming Liquids. Magic that reverses or speeds the effects of time, whether a complete rejuvenation or less potent beauty magic, follows a common pattern. The person is bathed, exfoliated with leaves to remove the accreted darkening layers of magic, and then anointed [*putuma* or *vaputuma*] with coconut oil, to give the skin a youthful sheen (Lawton, 1993; see also Senft, 1986). Tuma Island is not only the residence of the dead but also a place of perpetual youth because the spirits who reside there are able to return to a youthful red stage of existence by bathing in a special brackish spring called *Sopiwina*. *Sopiwina* is water used to wash off unwanted smells such as meat or fish, or to remove dirt. *Sopi* is water. Malinowski (1929) tells us that *wina* is an old form of *wila* [cunnus]. *Sopiwina* may be evocative of the transformative power of semen. Bathing is also associated with pregnancy; bathing in the lagoon can lead to impregnation by the *waiwaia* floating on the water.

Weiner's account of the bathing process in Tuma differs significantly from Malinowski's: "...the wrinkled skin is sloughed off and [the *baloma*'s]...life continues as before. When this occurs, however, a ...*waiwaia*...is

created" (1987, p. 54). In Weiner's version, the *waiwaia* is a by-product of rejuvenation and is either an entirely new entity or something that has broken off from an ancestor spirit, perhaps the sloughed blackened skin.

Dying and Death

Visual aspects of a child's identity are usually regarded as acquired from its father and his sisters as a result of close contact and applications of beauty magic. Baldwin (1945) records a passage that suggests that the dead endow the living with aspects of their appearance; he was told that a dying woman would "endow with her beauty [*bubula*] the child that was coming."⁷ Shining beauty, *bubula*, the color and brightness of the skin, is a gift from one generation to the next. When persons die their major affines, in a reversal of beauty magic, blacken their bodies, cut their hair, wear old dark clothes, and forfeit their names. Just as there is a close association between the whiteness of *prima para* and embryo, there is also a close and analogous association between the blackness of deceased and the chief mourner, and to a lesser extent the deceased's other close affines (Weiner, 1987). The principal mourner is confined indoors, thus avoiding the sun but is made black rather than white. The *prima para*'s diet is restricted to dry *kaula* [yams and taro] while the principal mourner avoids *kaula* and consumes wet foods. Cooked over a fire, and shielded from the sun, a *prima para* is made white, dry, and shining, so that her embryo will be white, beautiful, and strong. Mourners are denied fire, their transition into the damp blackness of death and decomposition mirror the condition of the deceased.

Beauty Magic. Weiner indicates that the gifts of *wageva* beauty magic, performed by the father's sisters [*tabu*], for a man's children, are linked to the yams he gives them. Children without fathers experience shame because their mother's kin cannot perform this essential rite for them. The ritual, referred to as *talilisi*, which means to wipe away, requires the *tabu* to dress in mourning skirts when administering this magic to young people (Weiner, 1976). Like mourning services, the *talilisa* is linked to the yam prestations from a man to his sisters but mourning and *talilisa* are alike in other ways. *Talilisi* is a compound of *tali*, to bid farewell and *lisi*, to lower or knock down or push away. *Lisaladabu* is payment for the mourners having shaved their heads, darkened their bodies, and otherwise

given up their beauty, acts which are repayments triggered by the deceased gifts of yams. *Dabu* is heaviness and *lisaladabu* is "pushing away heaviness." *Lisaladabu* removes the heaviness of grief and the need to act under the heavy strictures of taboo but some of this heaviness is transferred to the individual who did not perform well in the competitive exchanges. Kasaipwalova notes that those who have done well in the exchanges will feel good and light while those who have not will feel heavy (Malnic, 1998).

But *lisaladabu* is not just about skirts, it is also very much about bundles (*nununiga*), which are metaphorical breasts (*nunu*) (Weiner, 1987). The visual representation of the heaviness of grief is the black skins of the mourners and their dark attire. To be light at a time of grief would be tantamount to claiming responsibility for the death. Instead kinswomen set about the task of creating thousands of bundles, the distribution of which, if successful, will remove their own heaviness, and which will pay others for assuming heavy tasks. Appropriately the creation of bundles involves a transformation from black to white which mirrors the hoped for change from heavy to light. After a death occurs, the women of the *dala* are conspicuously busy creating pseudo breasts, symbols of youth and whiteness, by a process that peels away the dark surface to reveal a white interior. The meaning of bundles lies, in part, in the details of their manufacture. The removal of the dark integument to expose a white interior is the very transformation that takes place in Tuma when a *baloma* sheds its darkened, aged skin to be reborn white and young again. White breasts are associated with nursing while black breasts mark the end of nursing; women will paint their breasts black to deter a child from nursing (Schiefenhövel & Schiefenhövel, 1996). In making and distributing symbolic breasts, women of the *dala* manipulate the chromatics of their cyclical model of ontology, to nurture the transfer of the *baloma* from life in this world to life in Tuma.

Ignorance speaks when those in the know are silent. Malinowski wrote his future wife of his reluctance to say anything about *kula* due to the fact that any Trobriander might know a great deal more than he (Wayne, 1995). As members of the initial culture to "benefit" from first-hand, in-depth, descriptions of their institutions, Trobrianders have, for the most part, silently suffered more than their share of mis-conceptualizations at the hands of anthropologists casting them in the role of definitive, and thus static, "other." Malinowski's descriptions of the great complexity of their society helped dispel

ethnocentric notions of primitive simplicity but in revealing his “discovery” of an underlying order, and thereby testifying to his own understanding, he also inaugurated the facile process of essentialization which masks the great diversity of their often closely held opinions. Montague, who achieved a singular vantage of intimacy, was told by Trobrianders, who are generally careful to avoid offence, that they go along with the “tourist’s” view of their reality (personal communication). We therefore offer the above discussion of the esoteric, “withheld other,” situated in the highly private context suffering, as invitation for those who know to speak.

NOTES

1. Montague has collected oral histories that indicate that there was a severe population decline during the early 19th century due to post-contact diseases (personal communication).
2. *The major ethnographers of the Trobriand and related Massim cultures include:* C. G. Seligman, Bronislaw Malinowski, Henry Powell, Annette Weiner, Shirley Campbell, Ann Chowning (Fergusson), Debbora Battaglia (Port Moresby and Sabarl), Fredrick Damon (Woodlark Island), Linus Digm’Rina (Trobrianders and Fergusson), Reo Fortune (Fergusson and Dobu), Edwin Hutchins, Susanne Kuehling (Dobu), Jerry Leach, Maria Lepowsky (Sudest), Luciana Lussu, Martha Macintyre, Susan Montague, Nancy Munn (Gawa), Giancarlo Scoditti, Carl Thune (Normanby), Karin Grossman, Stuart Berde (Panaeiti), and Michael Young.
Medically trained observers include: R. L. Bellamy, R. H. Black, R. Pöschl and U. Pöschl, Wolf Schiefenhövel, and S. Lindeburg.
Other relevant views of Trobriand life have been written by: Tom’Tavala, John Kasaiपालova, Chief Naributal, Juta Malnic (photographer and author), Leo Austen (Magistrate), Rev. Ralph Lawton (missionary-linguist), Father Bernard Baldwin (missionary), Kenneth Costigan (architect), and Ellis Silas (artist).
3. This work employed the DEPTH Database, a compilation of 8,000 pages of digital texts on Massim cultures, which is a greatly expanded version of the HRAF Trobriand Collection (www.csus.edu/anth/trobriand/depth). The authors wish to acknowledge the assistance of Caroline Gardner, Andy Connelly, Erin Caddy, and Sebastian Barbosa of the DEPTH team.
4. For magic to live in the belly, it must continually be retrieved by sub-vocalization; thus, spells recorded by anthropologists are no longer active. The usual expression for a man who has completely learned all of his father’s magical knowledge would be “Your father (his name) died empty handed, you have completely taken all of his stomach’s contents.” This is a direct reference to the man’s magical knowledge and its transmission, whilst adding praise for the competence of the heir.
5. Digm’Rina notes that even though the benefits of “hammering” have been frequently cited in the literature, the idea is foreign to him.
6. It should be noted that Weiner (1976) views *dala* as a kinship category equivalent to a matrilineage, with membership being determined by shared blood. Montague, on the other hand, says that people are grouped into a *dala* based on shared mental capabilities which are determined by an individual’s dietary history.
7. People are said to resemble their fathers rather than their mothers or other matrilineal kin. It is a grave insult to say that blood relatives resemble each other. In this passage, beauty refers to the brother’s daughter.

Tuareg

Susan J. Rasmussen

ALTERNATIVE NAMES

Kel Tamajaq (“People who speak Tamajaq”); Kel Tagelmust (“People of the Veil”); Targui; Touareg; and also names designating groups from the different regions and confederations, for example, Kel Air (“People of the Air region”); Kel Ewey (“People of the Bull”, a political confederation), descent groups or clans (“Kel Nabarro”; “Kel Tafidet”), and the pre-colonial social strata, for example, Imajeghen (designating the aristocracy); Inaden (smith-artisans); and Imghad (tributaries).

LOCATION AND LINGUISTIC AFFILIATION

Most Tuareg today live in Saharan and Sahelian regions of West and North Africa: in the present-day countries of Mali, Niger, Burkina Faso, Algeria, and Libya. They are believed to have originated in the central Saharan Fezzan region of Libya. Some Tuareg from Mali and Niger have fled from recent drought and war, to refugee communities in Mauritania. In addition, many men travel extensively on caravan trade to Nigeria and labor migration to Nigeria and other countries, where they reside long term. Language spoken: a Berber language, Tamajaq (alternative spelling: Tamacheq), with several regional dialects: for example, Tamahaq in the Ahaggar Mountain region of southern Algeria and Tayrt in the Air Mountain region of northern Niger.

OVERVIEW OF THE CULTURE

Estimated population: between approximately 750,000 and one million (Decalo, 1996; Rasmussen, 2001).

History

A number of sources—oral traditions recorded by Rodd (1926), Bernus (1981), and Nicolaisen & Nicolaisen (1997), Saharan rock art, and Arab chronicles—relate the early origins and migrations of various Tuareg

confederations. As early as the 7th century AD, there were extensive migrations of pastoral Berber peoples, including two important groups related to many contemporary Tuareg: the Lemta and the Zarawa. Invasions of the Beni Hilal and Beni Sulaym Arabs into Tuareg regions of Tripolitania and Fezzan pushed the Tuareg more southward toward the Air Mountain region of present-day Niger. By the 14th century, the Tuareg had become prominent as stock-breeders and caravanners on Saharan and Sahelian trading routes that led to the salt, gold, ivory, and slave markets in North Africa, the Middle East, and Europe. Later, however, caravans declined when much trans-Saharan trade was diverted to the West African coast, and 19th-century European exploration and military expeditions in the Sahara and along the Niger River led to the incorporation of the region into French West Africa by the early 20th century (Claudot-Hawad, 1993; Decalo, 1996; Porch, 1984; Rasmussen, 2001).

Economy and Occupations

French colonial domination, as well as recurrent droughts and intermittent conflict with central state governments of the independent nations where Tuareg reside, have profoundly affected local subsistence. The French colonial administrators disrupted many local systems of adaptation and the natural ecological balance of the Sahara and Sahel. In some regions, they destroyed traditional irrigation and well systems, replacing them with artesian springs which attracted mosquitoes, and installed gasoline-powered pumps which altered the distances between herds, pasture, and water. Colonial policies imposed limitations on the trans-Saharan caravan trade, taxed subject populations, and encouraged sedentarization and the growing of cash crops which were hard on the soil and displaced many populations farther into the pastoral nomadic zone. Some Tuareg, in particular nobles, initially resisted secular schools as threats to local culture and magnets for census and taxation counts. The traditional aristocracy at first sent the children of their slaves to these schools. Consequently, until recently Tuareg of noble

origins tended to be underrepresented in the new occupations of the governmental and urban infrastructures. Recently, however, attitudes toward education have been more favorable.

Most Tuareg today practice a mixed economy of livestock herding, oasis gardening, caravan and other itinerant trading expeditions, and labor migration. A series of recurrent droughts, however, has diminished the livestock of many herders, pressuring them toward greater sedentarization and more intensive gardening. In addition, there are more specialized artisan activities traditionally performed by smiths, an endogamous, hereditary occupational social stratum. Recently, some Tuareg have also become active in tourism.

Social and Political Conditions

Pre-colonial Tuareg society was organized into hereditary, hierarchical, specialized occupational groups or social strata who were also, in principle, endogamous: at the top of the social pyramid were nobles (called *imajeghen*), who controlled large livestock, managed the caravan trade, and collected tribute from peoples of varying degrees of tributary (*imghad*) and servile (*ighawalen* and *iklan*) status, and practiced mutual client-patron rights and obligations with their attached smith/artisan (*inaden*) families. These relationships featured some pollution beliefs, for example, belief in the activation of destructive powers by smiths upon nobles' neglect of obligations toward them. In addition, Islamic scholars (*ineslemen*, also popularly called "marabouts") served as scribes, ritual specialists, legal councils, and Quranic healers. Despite its marked stratification, this social organization has always been characterized by considerable flexibility and negotiability (Keenan, 1976; Nicolaisen, 1997; Rasmussen, 1999). Leaders in the recent nationalist/separatist Tuareg rebellion have called for wider identification beyond kinship and social stratum, on the basis of the Tamajaq language, its Tifinagh script, and Tuareg cultural identity. In many rural areas today, the most intact relationship is between persons of noble origins and smith/artisans: the latter continue to act as political go-betweens, assist at arranging noble marriages, perform praise-songs, serve food and tea at noble weddings, manufacture jewelry and household tools for noble patron families, and dress nobles' hair, in exchange for remuneration. Nowadays, however, many nobles are impoverished and experience difficulty fulfilling their obligations

toward smiths. Tuareg political structure included local drum chiefs who headed noble clans or lineages, who elected the sultan (*amenukal*) or their larger regional confederation. In many groups, the drum chief office was inherited through matrilineal descent, although personal qualities of the chief were also important. Under the domination of first, the French colonial administration and later, the central governments of independent nation-states, Tuareg political leaders experienced modifications in their powers. Some chiefs' powers were diminished, others' were increased (Claudot-Hawad, 1993). In rural communities, elders and Islamic scholars adjudicate local-level dispute cases.

Family and Kinship

Most communities are predominantly semi-nomadic nowadays, and many household compounds are enclosed by either a fence or adobe wall, and contain adobe mud houses, usually owned by men, and the more traditional nomadic tent, owned by married women. In most Tuareg groups, descent is now bilateral: vestiges of ancient matrilineal institutions have become submerged within patrilineal institutions introduced upon conversion to Islam (Claudot-Hawad, 1993; Murphy, 1967; Nicoliasen, 1997). Many clans trace their descent to founding female ancestors/culture heroines. In some groups, succession to the chiefship passes from maternal uncle to sister's son. In many groups, there are prominent symbols of matrilineal and pre-Islamic cosmology alongside those of patrilineal and Islam in rites of passage and healing rituals. There are alternative forms of property transmission, in pre-inheritance gifts called "living milk" (*akh ihuderan*), in which some property (herds, date palms) is reserved for sisters, daughters, and nieces. This is intended to compensate women for Quranic inheritance (*takachit*), in which brothers receive twice the amount sisters receive. While living milk property once constituted women's primary source of economic independence, its future is now uncertain since the advent of nation-state laws and Quranic rulings which tend to favor patrilineal inheritance and droughts which have diminished many women's livestock herds.

Religion

The local "pre-Islamic" or "popular Islamic" belief system interweaves with more "official" Islamic beliefs and practices. Tuareg converted to Islam under the influence of Sufism and Almoravid marabouts between the 7th and

11th centuries; (Norris, 1975, 1990). Some Tuareg initially resisted Islam, and many Arab explorers disapproved of them for some “laxness” in Islamic observances, in particular for not secluding women, who among Tuareg may travel, receive visitors, and interact freely with unrelated men. In many groups, Islamic scholars are very respected and play important roles in ritual, healing, and politics. Offerings of dates and stones are made to tombs of marabouts and ancient ruins of the People of the Night or the People of the Past (*Kel Nad* or *Kel Arou*). During daytime many people pray at these tombs and occasionally consult them in divination. At night they are believed to be haunted by evil spirits. There are spirit pantheons integrating Islamic and local cultural cosmologies: for example, spirits called *djinn* (mentioned in the Quran) and spirits called the People of Solitude or the Wild (*Kel Essuf*) figure prominently in local folktales, rituals, and healing. Persons may become possessed by these spirits, and undergo special rituals to cure them. There are frequent practices to ward off evil spirits, malevolent humans such as thieves, and other misfortunes such as birth defects: for example, use of amulets made by both smith/artisans and Islamic scholars/marabouts, and observance of many ritual restrictions or “taboos.” There are diverse “witchcraft”-like powers or forces, each designated by a distinct Tamajaq term, believed to operate upon violation of various “taboos,” for example, those of jealousy or covetousness upon greedy consumption of (often scarce) food, or upon too ostentatious display of possessions (Rasmussen, 1998a, 2001). Additional cultural values in moral conduct, such as *takarakit* or shame/reserve, and *imojagh* or dignity, are also significant as constraints in interpersonal relations and limitations on conduct: too-openly boasting, for example, invites catastrophe. Many taboos, therefore, serve as “leveling mechanisms,” limiting accumulation of wealth or power and moderating consumption by any single individual or social stratum. Ideally, they serve to restrain undisciplined or selfish conduct in an environment that requires, ideally at least, balanced reciprocity, sharing of resources, and mutual aid.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

Most Tuareg still live in rural communities, in the Sahara desert and in the Sahel savanna areas along its fringe. Except in the mountain massifs (Air in Niger, Ahaggar

in Algeria, and Adragh n Ifoghas in Mali), which offer somewhat milder conditions, the climate is among the harshest in the world. It is subject to a very short and unpredictable rainy season (approximately July–August), recurrent droughts, and temperature extremes: for example, temperatures in the Sahara may reach 130°F in the hot season (April–July), and may plunge to freezing (32°F) at night during the cold season (December–March), when there are also high winds sometimes reaching 80 miles an hour, and sandstorms, locally called the Harmattan. In the northern regions of Mali and Niger above the agricultural line, the soils require daily irrigation.

Many diseases and environmental dangers are regional and season-specific. Malaria mosquitoes, while less prevalent in the desert regions than further South, pose a threat in the desert near oases gardens and standing pools of water. Local pests such as scorpions are ubiquitous in the rainy season. During the cold dry Harmattan season, conjunctivitis, streptococci, and meningitis are common. Intestinal parasites and wound infections tend to occur more rarely than they do in the forest zones.

Tuareg diets vary according to degree of sedentarization and urbanization, and have changed over the past half-century. In more nomadic camps, the principal foods consumed are millet and dates from caravan trading, and, when rains and pasture are sufficient, dairy products such as milk and cheese from goats, sheep, and occasionally camels. Meat tends to be eaten only at festivals, religious holidays, and rites of passage. In semi-sedentarized villages and on oases, in addition to these more traditional items, grains (maize, wheat, barley) and vegetables (potatoes, onions, tomatoes) and a few fruits (usually citrus) are consumed. Additional products obtained less regularly from trade and, more recently, food relief aid agencies and some small shops, include macaroni, manioc flour, rice, peanuts, and beans. Since the early 1990s, millet has become more expensive because of droughts in regions of Niger and Mali where it is grown; thus an important cereal source of high-protein has been somewhat more difficult to obtain, in some cases now supplemented or replaced by store-bought manioc or refined flour. If this trend continues, it has ominous implications for local nutrition. In urban areas, the diet reflects more multi-ethnic influences: for example, rice is a status food, and if funds permit, it is eaten not solely at festivals (as in the countryside), but more often, nearly on a daily basis. In some towns with large livestock markets, meat is consumed much more frequently than in the countryside,

in sauces over rice, millet, or maize. In the towns, many dishes from the countryside—for example, the nutritious beverage made of millet, dates, and goat-cheese and several wheat dishes—while valued by urban Tuareg, are more seldom prepared since some ingredients are more difficult to obtain.

According to many elderly persons, food was scarcer and less varied in the past, yet healthier. It was necessary to move about more often in order to find food (in nomadism and some hunting and gathering). They indicated that, although foods today are more abundant since one can find many sold in shops, such processed foods are more expensive and less nutritious. In the past, many people ate wild plants and grasses nowadays consumed only as herbal medicines. Periodic droughts threaten many herbal medicinal plants and trees, which traditionally constitute a rich local pharmacopoeia, particularly in more mountainous regions. Some foods are famine foods: for example, the core of the doum palm and thorns of various species of trees, pounded and grilled.

Most countries where Tuareg reside today are poor. For example, Niger has one of the lowest per capita incomes in the world, estimated at US\$260 in 1987 (World Bank, *World development report*, 1989, p. 14). This income has declined in the past decade from World Bank-imposed economic austerity measures. Life expectancy in many countries where Tuareg reside is low; in Niger, for example, this was estimated at 45 years in 1987, and the infant mortality rate was estimated to be 135 deaths per 1,000 live births (World Bank, *World development report*, 1989, p. 226). More recently, infant mortality was estimated at 123 per 1,000 births (U.S. Department of State, *Background notes, Niger*, July 1994). The central government budget in 1994 was estimated at US\$291.4 million (adjusted for devaluation in 1993 of the French West Africa C.F.A.). The 1994 investment budget (capital and development expenditures) was at \$190 million (U.S. Department of State, *Background notes, Niger*, July 1994).

Private medical insurance and other benefits are not available to the vast majority of patients in many countries where Tuareg reside. Governments do not reimburse hospitals directly for the care of their employees, so the programs for government employees are in effect exemptions from payment. Throughout Niger, for example, public facilities administered by the Ministry of Public Health provide most of the biomedical health-care. There are two tiers of prices: private sector patients pay higher fees than public sector patients for private hospital rooms, diagnostic

exams, and surgical procedures (Weaver, Wong, Sako, Simon, & Lee, 1994, p. 566). Only a small percentage of the population is employed by large companies and receive insurance benefits from them (Rasmussen, 2001, p. 13).

MEDICAL PRACTITIONERS

Types of traditional medical practitioners in Tuareg society include herbalists; bone-setters; Islamic scholars or marabouts; diviners; and spirit possession ritual exorcism specialists. Some of these specializations overlap, many practitioners refer patients to each other, and many patients consult more than one practitioner for a given illness. Herbalists are predominantly though not exclusively women; many are called “medicine women” (*tinesmege-len*). Many inherit their profession in clans and apprentice with an older female relative. These practitioners do diagnostic, healing, and referral work and cure mostly stomach afflictions with leaves, barks, and roots and also, sometimes, with medicines purchased in markets or brought into the region by trade. They diagnose through massage with special focus upon the stomach. Herbalists also practice some psycho-social, particularly marital, counseling and, along with Islamic scholars/marabouts, are often consulted to treat women’s fertility problems. Many herbal medicine women emphasize their complementary, rather than competitive relationship to Islamic scholars/marabouts in healing, describing these healers as being “like husband and wife,” and referring some patients to marabouts (Rasmussen, 1998b). Some herbal medicine women perform non-Quranic divination, through dreaming; this specialty is called *asawad*, denoting “to look or see,” and its practitioners called *imaswaden* (sing. *amaswad* or *amanai*, fem. *tamaswad* or *tamanai*) (Rasmussen, 2001). Some herbalists also know bone-setting, while other practitioners set bones, but do not practice herbal medicine: they are called *imadasen* (sing. *amadas*, fem. *tamadas*). Other non-Quranic diviners are called by the Hausa-derived term *bokaye* (sing. *boka*); these diviners tend to be male and practice more often in the towns, whereas the herbalist/diviners tend to be female and practice more often in the countryside. *Bokaye* diviners work with plants as well, but supplement them with scents (usually perfumes, but also some herbal medicines inhaled through the nose) and other ritual paraphernalia such as cowrie shells. They are believed to work with a tutelary spirit, in a pact with the *Kel Essuf*

spirits of the Wild, whom they must propitiate at intervals with sacrifices (Nicolaisen, 1961, 1997). Their position among the Tuareg is ambiguous, and some residents express ambivalence toward them, suggesting that this specialty originated from outside Tuareg society, perhaps from the neighboring Hausa people (Rasmussen, 2001). Islamic scholars or marabouts (*ineslemen*) are active in healing organic and non-organic illnesses, many of which are defined as caused by spirits. They also do psycho-social counseling. Marabouts cure with the Quran, which has special verses that cure diverse illnesses. Marabouts make amulets from these verses, to be worn around the neck or against the skin. Many men and some women see marabouts, although the latter sometimes feel intimidated by them, or find them unsympathetic and undergo alternate cures, seeing additional healers when their illnesses do not respond to marabouts' healing, explained locally as caused by spirits who do not respond to Quranic verses. In such cases, patients are referred to other healers, such as exorcism specialists who preside over a musical spirit possession ceremony called *tende n goumaten*, featuring drumming and singing believed to "please" and placate certain non-Quranic spirits alternately called *goumaten* or *Kel Essuf*, which predominantly afflict women (Rasmussen, 1995). These practitioners consist of musicians, who are often relatives and close friends of the possessed: namely, a female chorus who perform songs addressing the spirits and also containing critical social commentary; a woman who strikes the *asakalabo*, a calabash floating in water; and a drummer, usually a smith/artisan man or a woman of any social origin, who strikes the *tende* drum, constructed from a mortar with goat-hide stretched across its top.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

Despite some influence of hospitals and clinics, particularly in the towns, Tuareg cultural understandings concerning illness, particularly in the countryside, include many alternatives to the biomedical paradigm. Fundamental to the local paradigm is a continuum, rather than rigid opposition, between body and mind and between organic and non-organic illnesses. Much Tuareg medicine features counteractive theories of balance and harmony,

for example, "hot" versus "cold" states of the body and diseases caused by imbalance of these forces. These states are gender-linked; for example, women should ideally be cool, and men should ideally be warm, but these states should not become too pronounced or intensified, for example, a man can become too hot and ill (Figueiredo in Claudot-Hawad, 1996, pp. 113–137). Too intense cold or heat, or conversely, accumulation of the opposite of the ideally-dominant quality brings illness, and requires a cure. These conditions of "hot/cold" and associated afflictions are sometimes literal, sometimes non-literal or metaphorical in connotations, for example, "hot" illnesses (*tuksi*) are believed to be caused by too much heat, from "hot" foods (dates, tomatoes), sunlight, or moon-beams (these latter may cause illness from direct contact, as in sun-stroke, or, alternately, by sitting on warm mats or from their reflections inside doorways). *Tuksi* may also result from anger and other strong sentiments. These require counteractive treatments with herbal medicines, ritual precautions, or dietary remedies (such as "cold" foods, e.g., millet). Many of these illnesses include stomach ailments. "Cold" illnesses (*tessmat*) are the counterpart of "hot" illnesses. These include urinary tract problems and STDs. Treatment is sought from herbalists, who often prescribe plant remedies and ritual bathing (Rasmussen, 1998b). Other diseases may be caused by the wind and aromas; covering the bodily orifices is important to prevent them.

There are additional conditions that defy neat classification into organic and non-organic, and have only approximate, rather than exact, translations into the English language and Euro-American established biomedical paradigms: for example, *anoughou* refers to a condition caused by a sudden change in routine with subsequent deprivation of the usual nourishment or habit; *tamazai* refers to a condition approximating depression, in which one suffers from a long-term hidden wish or resentment that cannot be directly expressed. This latter relates to important Tuareg cultural values that discourage direct or explicit speech and encourage indirect expression by allusion. Sometimes, many residents believe, this condition results from unrequited love or other love problems (*tarama*). It often provokes *goumaten* spirit possession. A stomach ailment called *karambaza*, usually diarrhea, is believed to be caused by the mystic ritual powers of smith/artisans (*tezma* or *ettama*), activated automatically when they are refused a present or denied a request. *Karambaza* attacks children or livestock of the offending party, often a noble patron. Its remedies involve seeing an

herbalist, and also gathering up the sand in the smith/artisans' footprints and throwing it into the fire.

Other illnesses may result from negative gossip (*togerchet*) by anyone, behind one's back (Casajus, 2000; Rasmussen, 2002). More lethal is an affliction believed to be caused by sorcery, called *ark echaghel* (literally denoting "bad work"). This is practiced surreptitiously and considered very dangerous and anti-social, for it requires the assistance of a marabout who is willing to misuse his powers destructively (Nicolaisen, 1961; Rasmussen, 2002). Sorcery almost always causes the death of the targeted victim. It is often transmitted through contamination of food, burying of harmful amulets beneath the ground where one walks, or through contact with the victims' clothing or other possessions or bodily fluids. Sometimes, an animal such as a dog may be sent to harm the intended victim.

Prominent in theories of health and illness among the Tuareg are concepts of the body and soul. The head (*eghef*) is considered the place where spirits reside, once they have entered the liver (*tessa*) and stomach (*tedis*). The stomach is also the symbol of the matriline, whereas the back (*aghuri*) is the symbol of the patriline. If herbal medicine women diagnose spirits "dancing" in a patient's stomach, they refer the patient to a marabout, who treats the patient in seclusion with counseling and the Quran, often also divining with the Quran and various cabalistic formulas. The liver is considered the seat of sentiments such as anger and love, and is the place where non-Quranic spirits often enter; these require the *tende n goumaten* spirit possession ritual, whose public curing with music and a large, diverse audience who encourage the possessed person in trance in her dancing, constitute an effective form of group therapy. Sometimes, patients see diverse healers in succession for the same ailment, for example, *bokaye* non-Quranic diviners after seeing herbalists and marabouts. *Bokaye* treat non-organic illness through non-Quranic divination methods; they diagnose with scents and oils. The soul (*iman*, also denoting life and breath), is believed to leave the body during sleep and walk about. Upon death, the soul may be contacted through dreams or through offerings to graves. The heart (*ewel*) is connected to sentiments such as generosity and compassion, and is closely associated with the soul and the liver in psycho-social and non-organic connotations; many non-organic illnesses such as spirit possession are referred to as "illnesses of the heart and soul."

SEXUALITY AND REPRODUCTION

Tuareg differ from some of their neighbors in the marked degree of free social interaction between the sexes, and in the generally high prestige and economic independence of Tuareg women. Unrelated men and women may visit each other, flirt, and conduct courtship. Conversation between the sexes is considered extremely important. Women may travel, visit, and receive male visitors before and following marriage (Murphy, 1964, 1967). Women may initiate divorce, and own the tent and inherit and manage livestock.

There is some variation among the different Tuareg confederations concerning pre- and extramarital sexual mores. In some groups, women and men may conduct pre- and extramarital affairs freely; in others, particularly among the more devoutly Muslim clans of Islamic scholars/marabouts and in some chiefly families, there is a tendency to frown on this. Illegitimate children bring shame to the mother, and are often hidden and raised in distant regions.

Most women in semi-nomadic rural communities bear approximately six to eight children. There are indications that with increased sedentarization, many families prefer more children to assist with oasis gardening. Precise statistics from large samples are not available, but many local residents indicate that in the past, nomadic lifestyles discouraged having many children and there were efforts to space children. Although Tuareg women's status is not solely dependent upon childbearing, and Tuareg recognize that men as well as women may be responsible for childlessness, nowadays wives feel greater pressure than in the past to bear children, and fear that husbands may contract polygynous marriages if they are infertile.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

Local beliefs surrounding reproduction include the idea, expressed in local slang, that during menstruation, a woman's eggs (pl. *chikikaten*) are "broken"; at other times, they are whole. Some beliefs appear gender-based; for example, men describe women as being like "containers" or "leather sacks" during pregnancy; whereas women describe female reproductive physiology as centered on the stomach (*tedis*) and womb, called *ehan n barar* ("the child's tent"), and tend to place greater

emphasis upon love as important in conception. The male is believed to transmit “heat” (*tarraf*) during conception. Iblis, the Devil, is considered to be the ultimate source of reproductive force.

Women must protect themselves from malevolent spirits believed to cause birth defects and infant mortality. During menstruation, there are ritual restrictions against praying, touching Islamic amulets, handling animal hides, and dressing hair. These measures are believed to protect *al baraka* in living things, and by extension, the yet-to-be born child (Rasmussen, 1991). Conception should not occur outside the tent under the moonlight, nor before the end of the week-long wedding. At childbirth, the earth opens up and threatens the woman in labor (Worley, 1992, pp. 54–64). In rural communities, babies are born within the mother’s tent, with elderly female relatives attending. A baby should not be left in a doorway (at a crossroads); this action is believed to cause mental disabilities. New mothers are secluded for 40 days following birth, to protect them from jealous spirits threatening mother and child. A knife (metal is believed to ward off spirits) is stuck in the sand near the mother’s bed, and Quranic amulets are prominently displayed. There are also ritual practices to promote fertility, for example, animal sacrifice followed by the married couple’s consumption of specified foods: the animal’s lungs, fresh rather than dried (symbol of life and breath), and eggs with Quranic verses written in vegetal ink.

Infancy

In the countryside, infant mortality is approximately 60%. Spirits are believed to sometimes mistake babies for goat-hide water-bags, and pull them back into the spirit world. Efforts are made to keep newborns in the world of humans. The firstborn male wears a tuft of hair on top of the head “in order to be pulled by the Prophet up into paradise” in the event of death. If a baby is stillborn, no condolence or nameday rituals are held; if a baby dies after crying, a condolence ritual is held as for deceased adults. Babies are often called “stranger” until they are 1 week old, then are given several names, Quranic by the father and marabout, and non-Quranic by the maternal grandmother, at the nameday ritual. The marabout writes Quranic verses in vegetal ink for the baby’s mother to drink, to protect from malevolent spirits and humans. Special names are given to babies when a previously-born sibling died, in order to distract the spirits, for

example, Tekle (denoting slave). Twins are regarded as somewhat demanding of scarce resources, but efforts are made not to make them angry. Mothers are supposed to treat each twin in identical ways: for example, they are given alliterative names (e.g., Alhassane and Alhouseini), are breast-fed at the same time, and arranged in the same sleeping positions. Babies are breast-fed for approximately two years. They sleep with their mother, and parents practice a postpartum sexual taboo for approximately two years; a child born before this time is considered shameful, and some birth defects are attributed to a lapse in practicing this taboo. There is no transitional baby food; small children are encouraged to eat adult food. Small children are toilet-trained gradually and casually: mothers encourage them to go far from the household to relieve themselves, with other children.

Childhood

Children are encouraged to assist with adult chores. In some regions, toddlers are given chickens to raise as pets to practice for future herding of their parents’ livestock. Small children are encouraged to explore their physical environment freely, and corporal punishment is rare, although adults in rural communities keep a watchful eye on children’s activities. Toddlers begin to wear protective religious amulets around weaning age. At around eight years, young girls begin to assist their mothers in cooking and fetching water. At this age, boys traditionally start to accompany their fathers on caravan trading expeditions, help in the oasis gardens, and smith/artisan boys begin apprenticeships at the forge with an older male relative. Children of both sexes herd livestock. Nowadays, more girls and boys of diverse social origins go to both Quranic and secular schools.

Adolescence

Despite children’s full participation in adult tasks, Tuareg recognize adolescence as a distinct phase, and a Tamajaq term designates an adolescent: *ekabkab* (fem. *tekabkab*). Local concepts of the life course are, nonetheless, not strictly linear, chronological, or biological, but rather these phases are socially and ritually defined (Rasmussen, 1997). For example, females are considered to “become women” at marriage, rather than upon menstruation; males are considered marriageable upon taking up the men’s face-veil, at approximately 18–20 years of age. Adolescents of either sex, but particularly women, are believed to be vulnerable to jealousy of spirits and humans at life transitions.

Adulthood and Middle-Age

Women and men among Tuareg are considered full social adults upon becoming parents; children are extremely important to mature, adult status. Informal adoption is often practiced in cases of childlessness, but rituals promoting fertility convey the importance of having children, and eventually, children-in-law (Rasmussen, 1997). Sons-in-law contribute important economic resources to their affinal household through bridewealth and groom-service. There is an extreme respect/reserve relationship between a man and his parents-in-law, particularly the mother-in-law. Thus, while Tuareg women generally enjoy high social prestige and some economic independence throughout life, these ideally increase upon their children's, particularly daughters' marriages.

There is equal access to medical care, both traditional and established bio-medical, for Tuareg men and women throughout life; the problem of unequal care principally affects Tuareg generally, regardless of gender, and arises from the predicament of most Tuareg as a marginalized group within the nation-state, from the geographic inaccessibility of rural communities, and general poverty of those nation-states where most Tuareg reside.

The Aged

Aged persons are ideally respected. Children are supposed to care for ailing parents. Elderly persons of either sex reside next door to children, and participate prominently in Islamic and pre-Islamic rituals. Many elderly persons continue to work (herding, caravanning, and gardening) as long as their health and energy permit, although more arduous labor (fetching well water and firewood) is usually performed by younger relatives.

Physical problems of older women are attributed to aging processes in general, rather than specifically from the cessation of menstruation (Rasmussen, 2000, pp. 91–116). Herbal medical specialists and other women report few symptoms associated with the “menopause” model in western established bio-medicine. Post-childbearing women's ritual and social roles apparently compensate for any perceived physical problems, and many such problems merge with other age-related problems in local medicine.

Dying and Death

Mortuary beliefs and practices interweave local Tuareg and Islamic cosmologies and rituals. Dead souls are believed to

wander in the vicinity of graves, and some communication with them is possible through dreams and divination. Funerals (called *iwichken* or *iban*) are held within 3 days of death, and consist principally of condolences at the home of relatives, during which special foods are served and the marabout comforts the bereaved, ritually spitting in a goblet in order to “calm” them. The body is prepared for burial by elderly same-sex living persons: it is washed, wrapped in a white shroud, and carried to the cemetery, accompanied by chanting from the Quran. Men and marabouts officiate at the burial. Two lines are formed in order to allow the angel of death to pass through. Thereafter, the name of the deceased is not mentioned. Graves are not individually marked, although stones are piled higher on tombs of prominent marabouts and chiefs, and offerings made to them. In keeping with Islamic beliefs, marabouts emphasize judgment day following death, when angels measure the relative weights of bad and good deeds of the deceased in life. While ancestor cults among Tuareg appear less elaborated than in some other African societies, there are commemorative rituals (*takote*) for deceased at intervals following death, which feature animal sacrifice, alms-giving, feasts, and reading from the Quran.

CHANGING HEALTH PATTERNS

Many rural Tuareg initially feared hospitals because they appeared implicated in colonial and post-colonial schemes to dominate and control: for example, many medicine distributions were accompanied by census counts, taxation records, and political speeches. Some viewed hospital and clinic staffs as unsympathetic and hostile to local culture (Rasmussen, 1994, 2001). More recently, many Tuareg are less fearful of hospitals and clinics due to their staffing, since the Peace Pact of 1995, with more local and Tamajaq-speaking personnel. Nevertheless, most rural people still go to traditional local medical practitioners before clinics and hospitals because of difficult access to hospitals, located only in the major towns—and travel there is often difficult. Prescription medicines are irregularly stocked and expensive. Some pills are now sold at cheaper prices at vending tables on the street; these are, however, often dangerous, uncontrolled, and unlabeled. Recently, in the wake of economic austerity and privatization policies initiated by the International Monetary Fund and the World Bank, private practitioners have sprung up in capital cities, but most rural residents cannot afford their fees.

Wape

William E. Mitchell

ALTERNATIVE NAMES

Wapei, Wapi.

LOCATION AND LINGUISTIC AFFILIATION

The Wape live on the large island of New Guinea located just north of Australia. Their country, Papua New Guinea,

occupies the eastern half of the island; Sandaun Province, where the Wape reside, is situated in its northwest corner bordering Irian Jaya and is one of the country's poorest and the least developed. "Wape" is a term given by Westerners to the culturally similar Olo speakers. It is derived from the Olo word *metane wape*, which denotes a human in contrast to a spirit. Olo is one of the 47 languages of the Torricelli Phylum that is provisionally divided into 7 stocks and 13 families. Olo is classified

within the Wapei Family, 23,378 speakers, and the Wapei-Palei Stock, 31,770 speakers (Foley, 1986; Laycock, 1975; McGregor & McGregor, 1982).

Most of the men, many children, and an increasing number of the women speak Tok Pisin (Melanesian Pidgin), the *lingua franca* (Mihalic, 1971). Tok Pisin is a post-contact language, the vocabulary of which is 80% English origin (Foley, 1986). Tok Pisin and English are the country's two official languages. English is the language of instruction of the village primary schools, but as attendance is not compulsory, only a minority of the Wape are fluent.

OVERVIEW OF THE CULTURE

The approximately 10,000 Wape live in the rain forests of the Torricelli Mountains located between New Guinea's north coast and the sprawling swamps of the Sepik River to the south. The average yearly rainfall is 264.16 cm. They occupy 55 villages between 396 and 853 m above sea level with a population density of approximately 50 people per square mile. Germany claimed the Wape area in 1885 but there is no evidence that they had any direct contact with the people. After World War I, the area became part of a mandated territory under the aegis of the League of Nations and administered by Australia. The first government patrols probably entered the Wape area from the coast in the early 1920s, but no stations were established. In 1926, when the first scientist, zoologist E. A. Briggs (1928, 1929) from the University of Sydney explored the area, it had received only a few visits from labor recruiters and prospectors.

Foreigners, including Brigg's student and explorer-writer A. J. Marshall as well as gold and oil prospectors, continued sporadic incursions into the area during the 1930s and with few exceptions were received peacefully. In 1935, a disastrous earthquake ripped through the Wape area taking an unknown number of lives. It destroyed houses and gardens, and created landslides that dammed rivers and streams (Marshall, 1938). During World War II, both the Allies and Japanese sent patrols into the area impressing local men as carriers. The Allies also used local labor to build a small military airstrip near Lumi village in the heart of the Wape area. Some Wape men went to work as laborers for the Allies at their base on the coast near Aitape. When dysentery broke out on the coast in 1944, many men fled back to

their villages carrying the disease with them and the resulting epidemic took many lives. After World War II, in 1946, the eastern half of New Guinea became a trust territory of the United Nations under Australian administration. In 1947, two Franciscan priests from the coastal Aitape mission opened a mission station by the abandoned airstrip in Lumi and the mission remains active today. In 1948, the government established a patrol post nearby and a small hospital was built soon afterwards. In 1973, the territory was given internal self-government status and in 1975, gained full independence as Papua New Guinea.

Christian Brethren missionaries have been active in the area since 1951 and in the 1980s an indigenous evangelical church began winning some adherents. Although many Wape are nominal Christians, most continue to follow the rituals of their ancestors. Throughout the years of foreign contact, the government and missions have introduced numerous economic schemes for the Wape (Taru, 1977). None have enjoyed much success and the Wape remain subsistence farmers practicing slash and burn agriculture with limited access to money. To obtain money to buy coveted imported commodities, Wape men formerly worked as indentured laborers in other parts of the country. With this work no longer available and no town in the immediate area, there is an increase in the number of families moving to the coastal towns to find work. Unlike large parts of the highlands of Papua New Guinea where tribal warfare is still practiced, the Wape live at peace with each other and neighboring groups. In the past as at present, villages have no internal government except that of kinship although they participate in regional council, provincial, and parliamentary elections.

Villages traditionally were situated on ridges for easier protection and, as today, population is usually several hundred people. In the village center is a dirt plaza where children play and community rituals are performed. Wape houses are made of forest materials but where they formerly had a single earthen floor room, today they are more often built on stilts with several rooms serving different domestic functions in the Western fashion. Parents, today as traditionally, live together with their children in their own home. At puberty, sons move into a separate dwelling with other youths and unmarried men. Some villages still have a separate men's ceremonial house where ritual objects are stored and rituals are enacted. Wape do not enter each other's homes unless they are close kin, but most

dwellings have a front verandah or an area beneath a raised house where neighbors and relatives gather to visit.

Dwellings have no electricity, telephone, or plumbing, and access to most villages is by narrow footpaths. In the 1980s, the government built a rough dirt road connecting the Wape to the coastal town of Wewak, but the heavy rains, scarcity of transport, and occasional blockades by landowners seeking toll along the route makes its use problematical. Regarding work, women cook, fetch water, and firewood, make string bags, process sago, and forage. Men hunt, prepare gardens, cut down the sago palms, and make tools and ritual objects. Men and women both participate in childcare, weeding, and harvesting.

The most important social and economic unit in Wape society is the patrilineage whose members usually live contiguously in a single village along with several other patrilineages. At birth a child becomes a member of her or his father's patrilineage and remains so until death. Patrilineages are composed of several patrilineages from a number of villages. Clan ties provide access to others in times of hardship but the proviso to assist is not as stringent as among patrilineage mates. Inheritance of land and food trees is patrilineal. Marriage with a member of one's patrilineage and patrilineage is forbidden, but it is sometimes violated among patrilineage members. Today, women usually marry by choice and the groom's family pays bridewealth in the form of money to her patrilineage. A woman goes to live with her husband at marriage and, in the unlikely event of divorce, she returns to her village while the children should, but do not always, stay in their father's village. Plural marriage is permitted but uncommon.

One of the most striking aspects of village life is its placidness, a feature also observed by early visitors to the area (Marshall, 1938). Physical aggression is disapproved and seldom occurs and while verbal aggression is allowed, it too occurs infrequently. The customary response to an aggressive act is simply to turn away and ignore it. Men and woman live relatively harmoniously together and spousal abuse is unusual (Mitchell, 1999). Male ethos is egalitarian and the elaborate and pervasive reciprocal exchange system of pig meat, sago, and valuables among relatives in different villages mitigates against the accumulation of individual wealth (Mitchell, 1978). The gambling dice game *satu* is played by many men and is another important way of leveling wealth (Mitchell, 1988).

Wape traditional religion is animistic, with beliefs in ghosts, demons, witches, and sorcery that are intimately involved with ideas about health, sickness, and healing.

Unlike many New Guinea societies that center their ritual and ceremonial life around harvests or male initiation, the Wape center theirs on healing.

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL AND POLITICAL FACTORS

The Wape live in very broken forested country with generally thin and poor soils subject to landslides by the heavy rains, and the many steeply banked streams and rivers, which bisect the forest, contain few fish. The men are avid hunters but population density and the introduction of the shotgun (Mitchell, 1973) has depleted the wild game, for example, pigs and cassowaries. Because of the crime problem in some parts of Papua New Guinea since Independence, shot guns, always limited to one or two in a village, are now difficult to obtain and there are reports that wild game is increasing in number. As the Wape area is economically undeveloped, the people have restricted access to money for the purchase of food commodities such as tinned fish or rice from a local trade store. Some villagers keep a pig or two who, foraging for themselves, are fed just enough to prevent them from becoming feral. As pigs are raised primarily for ceremonial exchanges, the meat is distributed only periodically and is not an enduring source of protein. Men to the south occasionally bring smoked fish and pig into the area, but its availability is also random and undependable.

Most of what villagers eat is raised in their unfenced slash and burn gardens, for example, bananas, coconuts, sweet potatoes, taro, breadfruit, and *Gnetum gnemon* tree leaves, or processed from sago palms planted in swampy areas. As a result their diet consists primarily of sago starch, a notoriously poor nutrient, augmented with garden produce. With the absence of important amounts of fish and game in the diet, vegetables are their main source of protein. Consequently, the Wape diet has a negative effect on their health and maturation resulting, in part, in low birth weights, delayed growth, and malnutrition.

The introduction of health services by the missions and government in the 1940s was an important accomplishment of the colonial era. However, after Independence many of the expatriate health workers returned home severely shrinking the country's health resources. Unfortunately, the local training of replacement workers

continues to lag. As a Third World country with limited economic resources, Papua New Guinea currently concentrates its health expenditures in the towns where the new indigenous elite live. The comparatively isolated Wape suffer accordingly with limited access to health as well as other services. Although a service may exist on governmental paper, staff and supplies are frequently inadequate to meet urgent rural needs.

MEDICAL PRACTITIONERS

Indigenous

The Wape recognize three types of part-time indigenous practitioners who diagnose and/or treat sicknesses, none of which use trance or an altered state of consciousness (Mitchell, 1990). A *numoin* (Olo), the most feared and powerful, is a male shaman-witch who receives his healing prowess by magically killing persons whose ghosts give him his healing powers. In Tok Pisin he is called a *sangumaman* and is found in other parts of New Guinea as well as among some of the Australian aborigines. A *sangumaman* supposedly can fly and make himself invisible and his services are used only when a person is seriously ill. If the patient recovers, the *sangumaman* receives the credit. If not, further treatment is sought. Today there are few, if any, *sangumaman* practitioners among the Wape, but the less contacted groups to the south still have them and they are sometimes resorted to.

A *wobif* (Olo) does not have the supernatural powers of a *sangumaman* and is not feared by villagers. He learns his healing skills from another *wobif* and is given a small fee or gift for his services. The third type of practitioner is a *glasman* (Tok Pisin) whose skills were brought into the area by men returning from contract labor work on the coastal plantations. He is solely a diagnostician and does not offer treatment. As a clairvoyant he determines the cause of the illness by looking "into" his patient and asking questions. Having specified the cause on the basis of an indigenous differential diagnosis he then prescribes an appropriate treatment that may include consulting a *wobif* or *sangumaman*. He too receives a small fee or gift for his services.

Introduced

The grassroots practitioner of modern medicine is the aide post orderly or *doktaboi* (Tok Pisin). These men have

training in first aid procedures, hygiene, and the treatment of common illnesses and injuries including acute respiratory and alimentary tract infections, malaria, common skin diseases, burns, and wounds. Aid posts are found in strategically located villages and are the most important medical service in terms of the number of patients served. If a health problem is beyond the aid post orderly's competence, he refers the patient to the small regional hospital situated in the midst of Wape territory. The hospital wards are coed except for one reserved for mothers and babies. As patients must provide their own food, they are usually accompanied by relatives who cook for them. Hospital orderlies provide basic patient care and are supervised by several nurses and the medical officer. Some of the most frequent presenting cases include acute upper respiratory tract infections, malnutrition, skin infections, birth confinements, malaria, anemia, gastroenteritis, tropical ulcers, and wounds. Only minor surgery is performed. If transport can be arranged, major surgery cases and other cases demanding sophisticated medical skills and technology are taken out to the coastal hospital in Wewak.

At one time nurses regularly held maternal and child health clinics in each village but staffing shortages have made these more episodic. The work of these clinics is to examine pregnant and nursing mothers as well as infants and small children, give immunization shots, and provide instruction on diet and hygiene. When the clinics are active, the hospital census of childhood malnutrition cases increases.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

Although many Wape have a rudimentary understanding of the biomedical theory of sickness in terms of, for example, a penicillin injection's attack on invading bacteria, it is seldom persuasive. It is the theories of their own culture intimately conveyed in myth, ceremonial, and everyday events that offer a more satisfying understanding of sickness and dying. The Wape believe in a complex set of unseen spirit forces that affect them in both positive and negative ways (Mitchell, 1987; Waisi, 1982). While these can, for example, cause an earthquake or inflict illness and death, with the proper rituals they can enhance life as well.

The spirit forces most frequently causing illness are ghosts and demons. Each patrilineage owns tracts of land wherein reside the dreaded ghosts of recently dead relatives who will attack their closest kin as well as others. Also in residence are ancestral ghosts who can bring sickness to trespassing individuals or to those in conflict with their descendants. Finally, there are the vengeful and unpredictable demons residing in places of unusual or strange appearance like a waterfall, landslide, or still pond. Any of these forces may cause sickness or injury by entering into an individual and seizing a vital organ, shooting foreign objects into the body or, for example, may cause an injurious fall when climbing a coconut tree. Such attacks may be of the malevolent force's own volition or at the direction of a member of the related patrilineage. Some of these forces also may be appealed to for help, for example, the *mani* demon when hunting or a long dead father's ghost is asked to protect the home while the family is visiting kin in another village.

An attack by a *sangumaman* is the most feared cause of illness; once a person is assaulted and made ill, rectification is considered rare. A *sangumaman* may attack on his own volition or is hired to attack one's personal enemy. Although the details of the form of the assault vary with the informant, the procedure is roughly as follows. The victim is attacked and rendered unconscious by choking after which small incisions are made in the skin and bits of flesh removed. These are later put in little packets for sale to facilitate hunting. The wounds are magically closed without scaring and the victim is brought back to consciousness. Confused and dazed, the victim is told to return to her village, that she will have no memory of the attack and will die after a specified number of days. Consequently, any person returning to the village in a dazed or feverish state is considered a possible victim of *sangumaman*.

Sorcery is another cause of illness. Many villagers know spells for affecting the physical and emotional life of others. To bring sickness or death, a spell is performed with a bit of the victim's exuviae. For this reason most individuals are careful about when and where they defecate and take care to destroy their hair and fingernail cuttings.

In the treatment of illness, the Wape have recourse to a variety of therapists and therapies including their own pharmacopoeia consisting mostly of plants. For a persisting malady they are likely to try a number of therapies before they return to health or die. Self-treatment is usually the first form of treatment intervention. For a headache, a tight band may be tied around the forehead;

an aching leg may be superficially cut to let out the hot blood; a boil may receive a leaf poultice or, if ripe, lanced. Judged by the premises of Wape culture these actions, like those by biomedical practitioners, are palliative, not curative, in nature. They treat the noxious symptoms but in etiological terms do not treat the *cause* of the symptoms. If self-treatment does not help and the suffering increases, the afflicted person will probably seek the diagnostic cultural skills of a *sangumaman*, *wobif*, or *glasman*.

A *sangumaman* is adept at the magical removal of small objects, for example, stones, thorns, and slivers of bamboo, that a forest demon or another *sangumaman* allegedly shoots into their victim causing sickness. After probing his patient's body to locate the offending object, he magically removes it, sometimes shows it to his patient, and is paid a small fee. The treatment specialty of the *wobif* is the use of massage to mend skeletal breaks caused by malevolent spirits and magically sucking from the body bad blood and bits of taboo food eaten by the victim that caused the illness.

The cause of an illness is frequently attributed to one of the taboo demons living in the forest, rivers, and streams. As a particular demon is related to a patrilineage's land, the afflicted person must go to one of the lineage mates who know the demon's secret name and ask to be exorcised. Such requests are never refused. These exorcisms are a common occurrence in the village and often one of the first therapies attempted. The exorcism is informal and simple. Lightly brushing the afflicted area with some ginger leaves, the exorcist inaudibly appeals to the demon by his secret name to leave his victim in peace. Embarrassed by the chastisement, the spirit readily departs. Of course if the illness worsens, then the diagnosis was wrong and a new diagnosis must be made and another treatment tried.

Some of these demons, for example, *niyl*, *poril*, and *mani*, are the center of curing societies whose exclusively male membership cuts across lineage lines. Men initiated into a society learn the requisite secret name and are responsible for performing exorcisms and carrying the demon's mask in a curing festival. The *niyl* curing festival is the largest and is months in preparation. Its climax features a parade of the sacred masks, all-night traditional dancing, and a dawn exorcism rite. All of these activities are intimately articulated with the Wape's elaborate exchange system. Although a curing festival is held to exorcise specific victims, others previously afflicted by the demon also may participate. Rubbing their skin against the sweaty body of a mask carrier, they receive

a kind of booster immunization shot as an inoculation against future attacks.

The Wape tolerate erratic and strange behavior in fellow villagers as long as it is not threatening or, if aggressive, episodic in nature. Some men, but not women, are especially prone to episodes of threatening manic behavior. If the behavior becomes chronic, a man will be forced to leave the village and made to live in the forest where his actions are not a constant threat to village tranquility. Whether an individual is benignly mad or berserk, the cause is the same; possession by a demon or ghost, an event sometimes precipitated by the chewing of betel nut. A person exhibiting crazy behavior is not blamed for her or his crazy actions but, being possessed, is perceived as similar to a horse controlling its rider.

There are a number of ways to cure a person from her or his madness. The most common is to exorcise the demon or ghost by appealing for it to leave its victim as previously described. If this is unsuccessful, two other treatments are intended to drive the spirit out. A possessed man acting aggressively is grabbed from behind and, as he is held, other men rub and beat his body with a special type of ginger plant to force the invasive spirit out of him. The other treatment is performed when a victim is not agitated and can cooperate with the treatment. The victim goes to a bamboo grove with family members and, lying down, is completely wrapped in several dried palm flower sheaths. The bamboo is lighted and explodes in loud reports whereby the victim breaks loose from his confinement and, running away, the offending spirit runs away too.

Villagers view the two therapeutic systems, one indigenous and the other introduced, as complementary, not competing and may utilize both when ill or injured. The indigenous one offers culturally compelling explanations of illness and related treatments. While the introduced biomedical system's explanation of illness is exotic and conceptually irrelevant, nevertheless it provides some powerful forms of therapy they gladly take advantage of.

SEXUALITY AND REPRODUCTION

Sexual intercourse between a man and a woman is not a carefree activity. Like childbirth and menstruation, it is associated with female sexuality and is ritually polluting. A woman's vaginal area, especially when she is menstruating, is contaminating to men. During her period she eats

and sleeps by a separate fire in the back of the house and, if her husband eats her food, his hunting will be luckless. A husband who wishes to continue to hunt will prepare the family's food. Sexual intercourse may occur in the house or in the forest but not in the gardens; a demon angered with smelling the sexual secretions could ruin the plants. For the same reason a menstruating woman cannot go into the forest or a demon would make her sick. Her period over, she washes her vaginal area and resumes her regular activities.

If a man intends to maintain his strength and health, sexual intercourse must be carefully regulated. If he has intercourse too frequently—about every four days is appropriate—he will lose weight, his skin will droop in folds like an old man's, and he will become soft like an overripe banana. Semen is conceived as energizing; by its discharge into a woman, a man becomes weaker with its loss as she gains strength. Although today some Wape are aware of the scientific explanation of conception, the traditional belief is that it takes many acts of intercourse to create a baby. Regarding family size, there is no special desire to have a large family. Many couples are content with two or three children because finding sufficient food for a large family, including the meat children cry for, is a losing battle.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

According to one study, Wape women have an average of 4.1 live births with 2.7 remaining alive (Wark & Malcolm, 1969). A newly pregnant woman wishing to abort the fetus can perform magical spells to expel it. A pregnant woman continues her regular tasks best she can until parturition. Birth usually occurs in her house while attended by one or two female kin. Delivery is in a squatting position and after the baby is cleaned, the umbilical cord and placenta are buried in or near the house. If there are complications during the birth, the husband, kin, and friends gather and various exorcisms are performed and indigenous practitioners consulted. In an intractable case, she might be transported or carried to the area's hospital (J. Mitchell, 1973). Within a day or two after birth, she appears publicly with the baby carried in a sling.

A wife and husband should refrain from intercourse from the time she is pregnant until their new baby can walk, usually about 18 months. An admittedly difficult

ideal to achieve, if they violate the taboo, the child may be too weak to stand up.

Infancy

The mean weight of the Wape baby at birth, 2.40 kg, is one of the lowest on record (Malcolm, 1973). Malaria is holoendemic and one of the main causes of high infant mortality. From birth until about a year old, an infant subsists on its mother's milk and pre-masticated sago paste. Nursing babies usually double their birth weight within 3 months and treble it just over a year. From between about 8 months and 1 year, infants may be offered pre-masticated taro and a green shoot when seasonally available. However green vegetables in the form of boiled *Gnetum gnemon* leaves are not offered until a child is walking and completely toilet trained, about 2 years old. As a result, by the age of 6 months, a baby is most likely deficient in both caloric and protein intake. After a year, more solids are occasionally added to the diet including sago grubs and breadfruit providing additional protein. As the Wape also have little access to meat, and fresh fish is taboo to babies, malnutrition is not an uncommon problem among babies and toddlers.

Although a mother has the main responsibility for her infant, the father will remain in the village with the baby in a sling on his body when his wife is in the forest making sago flour. If a baby cries to nurse, it is not unusual for a father to offer his own breast as a pacifier. Other children and relatives also carry the baby from time to time; until it can crawl it is in almost constant physical contact with one attentive caregiver or another. Weaning is a gradual process with the toddler returning occasionally to the breast until it is dry.

Childhood

Unless there is a school in the village or close by, children are left much on their own to play with their age mates in the central plaza or shadow the activities of their parents. Boys, more than girls, go into the forest and forage for small game and other food. Children sleep in the same house as their parents and take their meals there too. Dining is a private family affair. Overt signs of malnutrition are not as common among children as they are among toddlers and infants. Parents are affectionate to both their male and female children and to viciously strike or whip a child is almost unheard of.

When a toddler does not get its way, he may lie on the ground and kick and scream but the response is to ignore him. A sibling may be posted nearby to keep the child from hurting himself but he is left to cry it out, learning at an early age that tempestuous behavior has no rewards. Children are susceptible to the usual childhood diseases, especially upper respiratory tract infections; some younger children appear to have a constant cold, and mucous smeared noses are common. Just as infants are unusually small, children in comparison to their European cohorts are too. At some point while still a child, every Wape boy and girl is taken to a river for a ritual washing by the mother's brother to assure its growth. The mother's brothers, by cultural definition a succoring person, performs the ritual during a *niyl* curing festival.

Adolescence

Chronic undernutrition appears to be a factor in the comparatively late onset of secondary sexual characteristics. One study (Wark & Malcolm, 1969) notes the onset of menarche in girls at 18.4 years. The onset of puberty in boys including the lowering of the voice is correspondingly delayed in comparison to European populations. Unlike some New Guinea societies, the Wape have no special ceremonies marking puberty. While toddlers and younger children play together, adolescent boys and girls tend to separate into gender-determined groups. Girls take an important role in helping their mothers in the family's food quest, but the small birds and animals obtained by boys are usually reserved for themselves.

Adulthood

Premature aging has been observed in many New Guinea societies and the Wape are no exception. Measurements of adults show a marked decline in height with age from 2 to 3 cm and there is a concomitant loss of weight. The average age of death for both men and women is the mid-forties. With physical maturity coming late and death coming early, Wape adulthood is of limited duration for many.

The Aged

There are few aged in Wape society. It is an exception for an adolescent to have grandparents. An old person usually lives with her or his son's family. The elderly help

with looking after babies in ways that their health and strength permit. Unlike others who move actively in and out of the village, the aged, thin and fragile, are more likely to spend most of their time in the village. Their knowledge about the past is valued by adults who consult them, for example, regarding past exchanges, kinship relations, and ownership of land and food trees.

Dying and Death

Most individuals die in the village under the care of their immediate family members. As death is not considered natural but due to a malevolent cause, various indigenous diagnoses and treatments are attempted until a person is near death. Recourse to the aide post's therapies are utilized but unless a patient is strong enough to walk to the hospital, it is usually considered too costly to have him or her transported by a group of carriers. The almost obsessive last minute attempts at treatments in some cases may be attributed to the family's affection for the patient as well as an attempt to insure against the predations of a vengeful ghost. At death, a person's spirit departs the body via the anus and becomes a dangerous homicidal ghost. Only in time is it becalmed and joins the patrilineage's ancestral ghosts and demons deep in the forest.

CHANGING HEALTH PATTERNS

A general point about Wape culture is that it is defensively oriented. Ever on the defense against a world of hostile spirits, the Wape have centered their ceremonial life around pacifying malevolent ghosts and demons who strike them down with sickness and death. A deeply religious and conservative people concerned with culture stability and continuity, they have dedicated much of their intellectual, affective, and behavioral energy to the social elaboration of a therapeutic system that features curing practitioners, male curing societies, and curing rites and festivals with extensive social and economic intervillage ties. This passionate concern with health and curing is probably one of the main reasons for the Wape's easy adoption of the biomedical therapies introduced by the government and missions in the 1940s. These new secular therapies do not challenge their own ritual ones in terms of explaining sickness and death but, perceived as effective palliatives, significantly augment their therapeutic armamentarium.

Whereas sickness may be alarmingly disruptive in some societies, the Wape, by placing it at the core of their culture have, as it were, turned sickness on its head and organized a way of life around it. This may, however, be changing. Recent reports allege that some villages are abandoning their curing festivals. What this purports for the future of Wape health patterns, only further research can reveal.

Yanomamö

Jennifer Kuzara and Raymond Hames

ALTERNATIVE NAMES

Yanomami, Waika, Waica, Guaica, Shori, Yanoama, Yanomama, Shiriana, Xiriana, Shidishana, and Guajaribo. The names Sanema, Sanumá, and Sanima are auto denominations of Yanomamö people to the north and east of the main tribal distribution. They are culturally and genetically very closely related to the larger Yanomamö groups and their dialect is partially intelligible.

The name Yanomamö means person, individual, or human. Alternative names such as Shamatari or Waica (Waika) are relative terms used by some Yanomamö to refer to other Yanomamö living to the south or north, respectively.

LOCATION AND LINGUISTIC AFFILIATION

The Yanomamö are located in the extreme southeastern corner of the Venezuelan state of Amazonas and in the northern portions of the Brazilian states of Roraima and Amazonas. In Venezuela, the northern extension of the Yanomamö is delimited to the north by headwaters of Erebató and Caura rivers, east along the Parima Mountains, and west along the Padamo and Mavaca in a direct line to the Brazilian border. In Brazil, they concentrate themselves in the headwaters of the Demini, Catrimani, Araca, Padauari, Uraricoera, Parima, and Mucajai rivers. In Brazil and Venezuela there are about 20,000 Yanomamö in 200–250 villages, covering an area of approximately 192,000 sq km. Dense tropical forest covers most of the land but sparse savannas may be found in higher elevations. The topography is flat to gently rolling with elevations ranging from 250 to 1,200 m.

The Yanomamö language has not been confidently associated with any other South American language group. Linguists have attempted to provisionally place the language in Macro-Chibchan (Greenberg, 1960), Carib (Migliazza, 1972), or Panoan (Speilman, 1979). Migliazza divides Yanomamö into four major dialectical groups known as Sanema (3,262 speakers), Yanam (856 speakers), Yanomam (5,331 speakers), and Yanomamö (11,752 speakers). The last two dialects, accounting for 81% of the total, are mutually intelligible while the others may not be.

OVERVIEW OF THE CULTURE

The Yanomamö are horticultural people with a strong dependence on foraging (Hames, 1989; Lizot, 1977). Hunting is still accomplished with bow and arrow and swidden cultivation of plantains and bananas (manioc in some places) is central to the subsistence economy. Except for villages associated with missions, no locally produced goods are traded with outsiders. Although steel goods such as machetes and axes are common, they have had little impact on subsistence other than to make it more efficient (Hames, 1979).

Village size ranges from about 40 to more than 250 with a mode of between 60 and 100 (Chagnon, 1997; Early & Peters, 2000). Where raiding is intense, villages tend to be large, and where raid is relatively uncommon, they are smaller (Chagnon, 1997). Villages tend to be located about a day's walk apart and in areas between major rivers. Over the last 30 years some villages have begun to concentrate near missions on large rivers. All villagers inhabit a circular communal lean-to (*shabono*),

and in higher elevations fully enclosed communal houses are built. These houses begin to deteriorate within 2–3 years. As the thatch and structural members deteriorate, the house becomes infested with cockroaches, crickets, sand fleas (*Tungans penetrans*) (Hagen, Hames, Craig, Lauer, & Price, 2001), and fecal and soil-born parasites. Sand fleas can be a serious health problem for children, especially orphans. This unsanitary and vexatious situation is resolved by building a new communal structure nearby.

Yanomamö social organization could be characterized as tribal and egalitarian (*sensu*; Service, 1975). The headman and the shaman are the only two socially differentiated roles and, in some villages, there may be more than one headman. Descent is patrilineal and residence is patrilocal. Lineages are local, of shallow genealogical depth, and lineage members do not own communal property. The major role of lineages is in dispute settlement, vengeance and the regulation of marriage. Each village is an independent political entity. Weak and ephemeral alliances between several villages are frequently established for mutual defense and aggression. In some areas, warfare is chronic while in others it is episodic and rare.

Most Yanomamö live in simple nuclear families. Anywhere from 20% to 25% of all families are polygynous (Hames, 1996). Polyandry is not uncommon in some areas comprising 2% of all marriages (Early & Peters, 2000). Each household owns one or more garden and is responsible for realizing its subsistence requirements. Sharing of food resources is common but families tend to restrict their reciprocity to only a few other families (Hames, 1999).

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

Disease patterns among the Yanomamö are affected by a variety of physical and social environmental factors that are only now beginning to be understood. Malaria appears to be endemic throughout much of their territory but there appears to be considerable variation in the species of *Plasmodium* involved and in the intensity and prevalence of infection. Other diseases may be dependent on geography; for example, higher elevations appear to have greater incidences of river blindness (*Onchocerciasis*). Contact by

non-Yanomamö is by far the most serious health problem faced by the Yanomamö. Influenza, measles, and hepatitis have been introduced by nonnative peoples who visit the area, or, in the case of gold miners in Brazil, have illegally invaded Yanomamö land.

Patterns of Disease

There has been a considerable amount of biomedical and epidemiological research done on the Yanomamö since 1966 that we cannot hope to effectively detail here. Elsewhere (Hames & Kuzara, in press) we present a much more complete review of this research, especially as it relates to the complexities of disease processes, origins, interactions, epidemiology, genetic susceptibilities, and the role of contact and acculturation. The pattern of diseases that affects the Yanomamö has been changing rapidly since first contact with Europeans and others.

It is difficult to know with certainty what the disease pressures acting on the Yanomamö prior to contact would have been; it is likely that many of the infectious diseases affecting the Yanomamö today were absent before the last century. Presently, in addition to introduced infectious diseases, the Yanomamö suffer widely from macroparasite infections. The humoral immune defenses that are most effective against macroparasites preclude the T-cell driven immune defenses that would be of most aid against many introduced diseases, such as tuberculosis. Thus, the matrix of both diseases to which the Yanomamö have been exposed since before their first contact, exacerbated by the conditions of sedentism in which many Yanomamö now find themselves, and those to which they are newly exposed, is complex. Because first contact occurred so recently, many diseases which have been introduced can be traced to their original source or point of introduction. Others, however, seem to have preceded actual contact with Europeans, either through contacts between the Yanomamö and other Amerindians of the area, or through infected animal vectors.

One of the most serious parasitic diseases now afflicting the Yanomamö is malaria, a serious infection that can result in high fevers, hemolytic anemia, and potentially dangerous enlargement of the spleen and liver. Of the two species of *Plasmodium*, *P. vivax* is the most common species, while *P. falciparum* results in the most severe infection. In Yanomamö territories, *P. falciparum* accounts for most infections (68.6%, Torres, Magris, Villegas, Torres, & Dominguez, 2000; 57.1%, Mato, 1998).

The patterns of the distribution and prevalence of *P. falciparum* among the Yanomamö seem to be much different than in other regions, even in Venezuela itself: the average Venezuelan distribution of infections in 1992 showed that 76% were *P. vivax* and only 24% *P. falciparum*. Additionally, a study by Laserson et al. (1999a) showed that two entire Yanomamö villages were infected with a single genotype of *P. falciparum*, suggesting that the epidemic in these villages was introduced by a single carrier.

Malaria is related to several long-term health problems: hepatomegaly (enlargement of the liver) and splenomegaly (enlargement of the spleen). Both conditions can be severe and sometimes chronic, and may result in portal hypertension and eventual cirrhosis. Malaria can also result in acute hemolytic anemia, as infected blood cells are killed by the exiting parasites or by the immune system. Anemia, including hemolytic anemia, has been shown to affect nearly the entire population of Yanomamö, and may have severe health consequences for these people (Torres et al., 1988).

In one study of the Yanomamö villages of Ocamo and Mavaca (Torres, Noya, Mondolfi, Peceno, & Botto, 1988), however, 44% of individuals were subject to some degree of splenomegaly. In some cases a syndrome known as hyperreactive malarial splenomegaly (HMS) results in those who have suffered repeated infection. In the same study, 23% of malaria cases resulted in the syndrome. In some of these, subjects' spleens occupied up to two thirds of their abdominal cavities.

One explanation for this may be related to the previously mentioned characteristic of Yanomamö immune reactions that seems to favor humoral rather than T-cell driven immune responses. Research has shown a link between a decreased number of T-lymphocytes and the development of HMS in other study populations. Related overproduction of IgM seems to be implicated in the development of HMS.

Torres et al. (2000) established a link between HMS and hemolysis in the Ocamo and Mavaca villages in Venezuela. In the year prior to the study, 38 of the 550 inhabitants of Ocamo and Mavaca had to be evacuated for emergency transfusions because of severe hemolytic anemia. In the study, 26 patients exhibiting severe hemolysis were studied, all of whom fulfilled the diagnostic criteria for HMS. The condition seems to be related to a cold agglutinin-mediated autoimmune response, one of the B-cell mediated immune responses. Whatever the cause

of the syndrome, it seems to have a higher prevalence among the Yanomamö than among many other populations living with endemic and hyperendemic malaria, and the health consequences, in the form of hemolysis and anemia, can be severe.

Onchocerciasis, also known as river blindness, is caused by a parasitic infection with filarial worms of the genus *Onchocerca*, often *O. volvulus*. The parasite was introduced to the Americas via European and African immigrants, and may not have affected the Yanomamö prior to contact. Studies have shown the disease to be endemic to varying degrees among the Yanomamö of Brazil (Grillet et al., 2001; Rassi, Laurda, & Giuaimaraes, 1976), from a prevalence of 240 cases per 1,000 in one village to 606 cases per 1,000 in another.

The prevalence of onchocerciasis seems to be greater at greater altitudes, thus highland Yanomamö may be more at risk than lowland. In a study of biting rates of three species of black fly (the vectors), the biting rates of two species increased with altitude (Grillet et al., 2001). This may be related to the fact that the larval stage of the fly requires fast-flowing, highly oxygenated water, which is more likely to be found at higher altitudes.

While onchocerciasis is not fatal, it can be severely disfiguring and debilitating. Blindness and disorders of lymphoid tissue are potential results. The most adverse consequences of this infection are caused by the inflammatory immune response to the microfilariae by the host, rather than the infection itself. This can sometimes involve intense itching, cracking and thickening of the skin, related bacterial infection, and eventual fibrosis. Inflammation of lymph nodes can also ensue, resulting in a condition known as hanging groin. Of 75 Yanomamö subjects who had tested positive in skin biopsies, only 17 had palpable nodules (Rassi et al., 1976). Lymphatic involvement was not found in any of the Yanomamö subjects of this study. In the study conducted by Rassi et al. (1976), vision problems were only found in two Yanomamö subjects.

Yanomamö are widely infected with various macroparasites, with varying degrees of pathogenicity. Lawrence et al. (1980) conducted a study surveying several types of parasite in two newly contacted Yanomamö villages, as well as in three native, though non-Yanomamö, villages of the same region that are in the process of acculturation.

One of the main routes through which parasites such as nematode worms are spread is oral-fecal contact. Among swidden agriculturalists such as the Yanomamö,

periodic relocation is common, which helps to mitigate the effects of a lack of sanitary means of defecation, which generally takes place outside, but near, the village or *shabono*. When populations become more sedentary, such as in areas near missions, parasites can build up in the soil and infection can thus become more prevalent, more severe, or both, if the settlement does not also include some form of sanitation, such as designated pit latrines.

Ascaris lumbricoides, among the more common intestinal helminthes infecting the Yanomamö, is passed through ingestion of feces. The primary complication, particularly in children, is intestinal obstruction. The two Yanomamö villages had infection rates of 90% and 100%, higher than in the acculturating villages.

The Yanomamö villages had hookworm infection rates of 76% and 80%. Hookworm enters a new host through the skin, particularly that of bare feet. The primary complication of infection with hookworm is iron-deficiency anemia, through the loss of blood; no information was available on the prevalence specifically of this type of anemia among the Yanomamö; considering the prevalence of other types of anemia, as well as the prevalence of hookworm infection, this should be the subject of future investigations into Yanomamö health.

Infection rates of *Trichuris trichiura*, also a nemathelminth, in the Yanomamö villages were 66% and 92%. *T. trichiura*, like *A. lumbricoides*, requires a period of incubation in the soil before eggs are infectious. Once ingested, they reside in the intestine and can cause diarrhea and abdominal pain, and potentially rectal prolapse.

Strongyloides stercoralis, a roundworm, involves infection through the skin. In some individuals, particularly those who are immunosuppressed, fever, abdominal pain and even shock may occur. The prevalence of this infection was 4–12% in the two Yanomamö villages, similar to acculturating villages.

Several species of amebic parasites were surveyed in the same study. Two parasites had higher infection rates in Yanomamö villages than in acculturating villages. *Entamoeba histolytica*, the parasite that is responsible for amebic dysentery and tropical liver abscess, had a prevalence of 28% in one village and 78% in another. *Chilomastix mesnili*, which can cause diarrhea, was more prevalent among the Yanomamö, almost half of whom in one village were infected.

Escherichia coli was nearly ubiquitous in the Yanomamö villages, although it is most often non-pathogenic. *E. hartmanni* was far less common than other

microparasites and did not differ from the acculturating villages. Other generally nonpathogenic parasites were studied. *Endolimax nana* and *Iodamoeba buschlii* were both more than twice as prevalent among Yanomamö as among non-Yanomamö.

Giardia lamblia, infection with which can cause severe symptoms, such as diarrhea, vomiting, and weight loss that may last for several months, was not present in one Yanomamö village, and present among 5% of the population of the other, but infected about a quarter of the residents of acculturating villages. The low rates among the Yanomamö are surprising, considering that much of the fresh water of the Americas is infected with this parasite. *G. lamblia* infected about a quarter of the population of the acculturating villages, meaning that this may be a health concern for the Yanomamö in the future. While not generally fatal, the severity of the symptoms and especially the duration of the infection make it an important concern.

One must be careful in interpreting these results; in acculturating villages, 14 different species of intestinal parasites were found, while only 11 species were found in Yanomamö villages. However, in the Yanomamö villages, a higher average number of species were found per person, ranging from 4.2 to 6.8. In acculturating villages, the average number of species per person was much lower, from 1.3 to 6.0. Whether this fact points to the health of the Yanomamö as being more precarious than that of Amerindian groups who are farther along on the road to acculturation is dependent on two things: the severity of each individual infection and the pathogenicity of each species.

It is possible that Yanomamö are better able to deal with certain parasitic infections than some other groups. Many of these infections are dangerous, not because of the parasite itself, but because of the body's reaction to the parasite during some stage of its development in the body. Allergic reactions, for example, are the primary cause for the most severe symptoms of onchocerciasis. These reactions, ranging from mild itch to shock, are caused by an overabundance of immunoglobulin E (IgE). Some studies have suggested, however, that South American Indians can have levels of IgE higher than many Europeans would be able to cope with. Indians living with such high levels of IgE show no signs of ill-health as a result, however, which may make for a reduced negative reaction to the presence of certain parasites in the body.

In addition to parasites, viruses present a great health risk to the Yanomamö. Particularly threatening are the hepatitis viruses, as well as the polyoma viruses and the measles virus. Hepatitis B (HBV) and hepatitis Delta (HDV) may both be found among the Yanomamö. The severity of the health risks of these viruses varies, but the primary threat is the damage done to the liver, which can be very serious, and often fatal, in chronic cases.

HBV is the most common form of the virus among the Yanomamö. In general, this virus can be asymptomatic or associated with mild liver disease and jaundice, and the body's defenses can overcome it in a few months. After this, the infected person becomes immune, and can no longer transmit the infection. In about 10% of adult cases, and 30% of cases in children, however, the disease is not overcome. Chronic HBV lasts through the person's lifetime, potentially causing jaundice, cirrhosis, ascites (abdominal distention and discomfort), and eventual hepatic failure. The chronically infected person may transmit the infection, primarily through blood contact, as well as through contact with saliva and sexual secretions. HDV, first described in 1977, is more acute and often fatal, particularly in individuals who already carry HBV, even those who were previously asymptomatic.

A 1986 study (Torres & Mandolfi, 1991) of Ocamo and Mavaca villages showed that of samples assayed, only 16.2% of the population had not been infected and 53.7% had developed immunity to HBV. A full 30.3% showed current infection with HBV, meaning that they were either chronic or newly infected. As the virus was introduced 18 years prior, and the prevalence of infection was so high, it is likely that many of these were chronic cases. These rates seem abnormally high, since generally only 10% of adult infections are chronic. However, 39.7% of those infected with HBV also tested positive for HDV, which can greatly exacerbate the HBV infection. This may explain why the rates of chronic HBV were so much higher than average.

In the same study, an examination of serum samples that had been collected in 1975 and preserved, 52.7% showed infection with HBV. This rate is likely so high because this was near the time of the first introduction of the disease, by a missionary in 1968 who had been infected and had been known to reuse needles in the administration of vitamin complexes to himself and to the Yanomamö of the area. In this case, a full 96.5% of the samples showed that the individual had been exposed to HBV at some point. Although only six samples were

tested for HDV, all six of them were positive for the presence of anti-delta antigens, showing that this particularly severe form of hepatitis was present among the Yanomamö prior even to its description in the medical literature. However, these results may not be representative of the entire population, as the samples from 1975 were collected from individuals who showed some sign of liver disease.

Hepatitis poses a severe health risk for the Yanomamö who engage in many practices that make the wide and rapid spread of this blood- and saliva-borne disease likely. Breast-feeding, which can last 2–3 years, the pre-mastication of children's food, the sharing of instruments used to pierce the body, the sharing of chewed tobacco, and the early onset of sexual activity are only some of the examples of this.

Venereal disease has been present among the Yanomamö since the 1960s, and gained greater prevalence since then (Peters, 1998, p. 247). HIV is also a concern, as Boa Vista, one of the larger settlements in close proximity to the Yanomamö, has one of the highest rates of HIV in Brazil.

Another kind of virus with long-term effects that is now a concern for the Yanomamö is the polyoma virus. Working in the field in 1969, James Neel and Arthur Bloom showed high rates among the Yanomamö of cytogenetic damage similar to that caused by SV40, the simian polyoma virus. The polyoma virus is a type of papova virus, or DNA tumor virus, a class of viruses which have been implicated in carcinogenesis. These viruses can also produce kidney, neurological, and lymphoid disease. A study by Major and Neel (1998) showed that among individuals from 33 villages, 43.06% had significant titers of antibody to JCV polyoma virus, and 40.65% had significant titers of antibody to BKV polyoma virus. The distribution and heterogeneity suggested that the viruses were of recent introduction to the Yanomamö, and that there were probably two points of entry of the virus into the group, with introduction from the eastern (Brazilian) portion of their territory more significant than that from the western (Venezuelan) side. Other studies have shown unexpected chromosomal damage among the Yanomamö (Neel, 1971). The Yanomamö were chosen for a study of chromosomal damage as an example of a population who had been exposed to minimum levels of toxic agents in the environment. The results were surprising, showing that compared to the controls (members of the expedition) and a group of Japanese examined in a similar study,

the Yanomamö had very high rates of chromosomal damage. Particularly surprising was the number of dicentric chromosomes, in some cases several in a single cell, a condition which is exceedingly rare. The reasons for this have not been discovered, but may be related to congenital defect, the presence of a virus or other pathogen, or possibly an environmental agent such as one of the hallucinogenic plant preparations used by the adult males of the group (although this latter possibility is less likely, as similar damage was shown among female Yanomamö, who are prohibited from using these preparations).

Measles, although generally not fatal among urban peoples, is a severe health risk to the Yanomamö. A serological study conducted in 1966 and 1967 (Neel, Centralwall, Chagnon, & Casey, 1970) showed that all but a handful of Yanomamö had not before been exposed to measles; in only two villages of 18 did a significant number of individuals test positive, one of which was located near a mission and had been known to have experienced an epidemic. In the other village, none of the positive responders was younger than 28 years, suggesting that this village had sustained an epidemic of measles prior to contacts with people of European descent.

As a consequence of this discovery, Neel secured measles vaccine and was about to begin a vaccine campaign when he learned of the outbreak of measles in Brazil and Venezuela. He quickly entered the field, treated the infected and vaccinated a cordon around those who had not contracted measles.

Again, although measles is generally not fatal in western populations, fatality rates in non-western populations can be quite high. The primary complications are bronchopneumonia and a high febrile response, as well as encephalitis in severe cases. In this epidemic, at least 36% of those suffering from measles were estimated to have developed pneumonia as well, and it is thought to be the primary cause of death associated with the disease.

The other complicating factor in the spread of a disease such as measles among naïve populations is the incapacitation of the population. Measles incurs an acute febrile response, as well as prostration and dehydration. Adequate water, nutrition, and care are essential to recovery. When an entire village is stricken, however, there is often no caretaker available; hunting and garden work are suspended, breastfeeding is suspended by ill mothers. It is important to note that Neel and others believe that the complete breakdown of the economic and care system

among New World peoples is largely responsible for the devastating effects of Old World diseases on these populations (Neel et al., 1970). In this epidemic, most villages were visited by a government team or missionaries, and antibiotics were supplied to help prevent secondary infections. For some, especially distant, villages, treatment was provided late in the epidemic, however. Neel et al. (1970) estimate that of about 170 cases, 29, or 17.7%, proved fatal. This number, while disheartening, would certainly have been staggering had the team not been able to vaccinate so many. This would likely have been the case had Neel not predicted the fact that the Yanomamö were likely naïve to measles and tested them for resistance, and then worked to procure vaccine. It also shows what a devastating effect such an outbreak could potentially have had if health care workers had not been vigilant.

Finally, tuberculosis must be considered a significant threat to the health of the Yanomamö. The disease may be treated with some success; however, drug resistant strains have developed with an associated 80% mortality. More effective than treatment is vaccination with bacille Calmette-Guerin (BCG), a live attenuated *Mycobacterium bovis* vaccine. Sousa et al. (1997) examined individuals from five villages. Serum samples were taken and tuberculin skin tests were administered. Subjects were also examined for BCG scars and they were found in 76% of the sample. The results were somewhat surprising. Prevalence of active tuberculosis was high, at 6.5%. Reactivity to the skin test was found among only 42% of Yanomamö who had received the BCG vaccine just 3 years earlier. The control group, European Brazilian army recruits, had a reactivity of 72% after having received the vaccine a full 18 years previously.

While analysis of T-cell response in this study was not possible, this study suggested that the Yanomamö had a reduced T-cell responsiveness to the disease, with an elevated humoral response. This is based in part on the low reactivity to the tuberculin skin test. Also noted was the fact that among the Yanomamö, production of antibodies, particularly IgM, but also IgG, was elevated in comparison with the control group.

Most disturbing in this study was the fact that of 28 new cases of tuberculosis, 82% occurred in individuals who had received BCG vaccine 3 years earlier. This incidence is higher than that seen in many other populations, and should be of concern, considering that the prevalence of tuberculosis is 100 times higher among Brazilian

Yanomamö than the average for Amazonas State, Brazil. If the vaccine is less effective for the Yanomamö, other types of treatments will need to be readily available, and health care workers will need to be especially vigilant in detecting tuberculosis early, if the 50% mortality associated with the untreated disease is to be avoided.

Diet and Nutrition

Aside from the effects of the infections described above, the general health of the Yanomamö is good. In terms of diet and by many standard measures of cardiac and circulatory health, they fit an ideal profile. The traditional diet of the Yanomamö consists primarily of manioc and plantains, supplemented with wild fruits, fish, game, and insects. Except near missions, domestic animals and their products are not consumed by the Yanomamö, and there is very limited access to processed or refined sugars and grains (Lizot, 1977). The resulting diet, similar to that of some other isolated groups, is low in fat and sugar, and high in protein, fiber, and complex carbohydrates.

The effects on their health of this diet, as well as a lifestyle necessarily including a great deal of physical activity, are evidenced in a variety of measures. Mancilha-Carvalho and Douglas Crews (1990) measured anthropometric traits and serum lipids among a group of Yanomamö of the Surucucu area in Brazil. The study showed that total serum cholesterol levels among Yanomamö adult men were half that of American men, and among Yanomamö adult women, were two thirds that of American women. Mean levels among the Yanomamö for all age groups were 121.9 mg/dl for men and 142.5 mg/dl for women.

They also showed that both height and weight were lower among Yanomamö of both sexes than among Americans. Mean Body Mass Index (BMI) was 20.4 kg/m² for Yanomamö men, compared to 25.3 kg/m² for comparable samples of American men, and 21.3 kg/m² for Yanomamö women, compared to 25.0 kg/m² for comparable samples of American women. BMI, as well as lipid level, was higher for Yanomamö women than for Yanomamö men. This is likely due to the fact that about half of the women in the sample were either breastfeeding or pregnant at the time of the examination. Additionally, total serum cholesterol increased with age among the Yanomamö in this study. This must be interpreted with the consideration that the sample size for each age group was small, ranging from 1 to 17 individuals.

The increase was, however, statistically significant, suggesting that age-related increase in cholesterol is not solely a product of a high-cholesterol, Western-type diet.

A study of sodium metabolism (Oliver, Cohen, & Neel, 1975), close to the time of first contact for those studied, showed that the mean blood pressure for Yanomamö was low, from 93.2 to 108.4 systolic and 58.6 to 69.4 diastolic for men, and 95.7 to 105.7 systolic and 61.6 to 64.5 diastolic for women. In contrast to most Western and acculturating groups, the Yanomamö did not seem to experience any age-related increase in blood pressure. These results certainly implicate diet as a factor; likely the fact that the Yanomamö diet includes no significant source of sodium chloride. Urine excretions of sodium were also measured, and were quite low.

In this study, excretions of potassium, found in high quantities in plantains and bananas, were much higher for the Yanomamö than for the control group. Aldosterone excretions, for which potassium is an important stimulus, were also high. Yet plasma renin suppression was not affected. The authors suggest that given these results, sodium deficiency is a more important stimulus upon renin activity than potassium suppression.

Mortality among the Yanomamö remains high, in spite of this picture of overall physical well-being. This is largely a result of infectious and parasitic diseases, which accounts for about 70% of Yanomamö mortality. The second leading cause of death is physical violence, accounting for about 13% of Yanomamö mortality (a figure that varies greatly depending on area). Accidental trauma and degenerative disease account for 7% and 6%, respectively (Melancon, 1982). Thus it is obvious that while the resources available to the Yanomamö are adequate, infectious disease poses by far the greatest threat to Yanomamö health and life than any other factor, even warfare.

MEDICAL PRACTITIONERS

Shamans (*shabori*) are the major medical practitioners among the Yanomamö. Young men who wish to become shamans are apprenticed by an experienced shaman who is usually a senior agnate (Taylor, 1976). They are taught appropriate chants to call spirits (or *hekura*, who are causes and cures for illnesses and exist in the form of tiny humanoids) and supernatural lore. The training is demanding often lasting more than a year and during this

time, trainees are required to obey a series of taboos such as dietary restrictions and refraining from sex. In some villages, up to a quarter of all men may have done through shaman training but only a few distinguish themselves as consistent and effective healers.

A shaman may have dozens of *hekura* living in his body. All have animal counterparts, different personalities, and habits and may be male or female, with male *hekura* more powerful than the females. *Hekura* dwell inside the shaman's chest going about their daily activities until called upon.

Recent research among Brazilian Yanomamö suggests that contrary to previous observations on Yanomamö health practices, the Yanomamö use a wide variety of medicinal plants and that women were the main practitioners (Miliken & Albert, 1996). This research shows that male shamanic cures are typically followed by the use of medicinal plants administered by women. This same research reveals that the Yanomamö employ 113 medicinal plants, 11 of which are cultivated. Many of the plants used are also used by other Amazonian groups to treat many of the same illnesses. Knowledge of the uses of these plants is being rapidly lost through acculturation. It is possible that one of these plants (*Aspidosperma nitidum*) may have anti-malaria properties. Pharmacologists in Brazil are currently investigating this possibility.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

The Yanomamö believe that nearly all illness (and most misfortunes) are caused by either spirits (*hekura*) or the ghosts (*bore*) of deceased Yanomamö. The Yanomamö have a complex conception of the soul. One of these, the *möamo*, can be attacked or lured out of the body by *hekura* sent by a malevolent shaman (Chagnon, 1997, p. 113). If counter magic is not preformed by a curing shaman, death will ensue.

There are two kinds of spirits that can cause illness: *bore* or sprits of dead Yanomamö and *hekura*. A *bore* is that part of the soul that travels to a distant area of forest when a person dies. If a kinsman offended the deceased during his lifetime, the ghost may avenge himself by causing sickness. An important offense is an improper mortuary ceremony which includes, among other things, destruction of

the deceased's property and cremation. Alternatively, a warrior who kills an enemy is in danger from the ghost of the slain if he does not carefully follow the *unokaimou* ceremony to cleanse himself (Chagnon, 1997).

A much more common cause of illness is an attack by a *hekura* sent by an enemy shaman. Shamans have a variety of *hekura* at their disposal, which they send to destroy the souls of Yanomamö. Some are especially powerful and can only be counteracted by equally powerful shamans.

If someone falls ill, a shaman is called for a diagnosis. The shaman begins by taking hallucinogenic snuff so he may easily communicate with his *hekura*.

SEXUALITY AND REPRODUCTION

The Yanomamö are relatively permissive of premarital sex. Men aggressively seek sex with women whenever they have the opportunity and women acquiesce, sometimes, out of fear. Extramarital sex leads to fights among men over sexual rights to particular women. The most significant reproductive outcome of an illicit affair is abortion or infanticide (Peters, 1980). A strongly enforced postpartum sex taboo lasts for the 2-year duration of breast-feeding. The effectiveness of this taboo is reflected in the inter-birth intervals.

Ideas about Conception

If a woman fails to become pregnant, she is deemed to be at fault and is stigmatized (Peters, 2000). A shaman will be called to help a woman overcome this problem. In some cases, a shaman discovers that a man other than the woman's husband is using magic to cause her to be sterile or abort her fetuses. Women are expected to produce numerous children and to assiduously care for them. If twins are born, the weaker or the female is killed. The Yanomamö believe that a woman cannot adequately care for twins.

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

The Yanomamö believe that each act of sexual intercourse contributes to the formation of the fetus: a man makes the

child while a woman delivers it. In effect, the uterus is a passive receptacle for the formation of the fetus which grows with each contribution of semen. Consequently, as many men who contributed to the formation of the fetus are fractional fathers. This belief in "partible paternity" is not uncommon in Amazonia and elsewhere (Beckerman et al., 1998).

Abortion is common among the Yanomamö: one researcher estimates that by age 30 most women are likely to have had at least one abortion (Early & Peters, 2000). There are a number of reasons for abortion which include: the woman is too young to bear a child; a current child is nursing; or the husband believes that the child his wife is bearing is not his own. Abortion is both crude and probably dangerous for the mother. It is accomplished by direct pressure or blows to the uterus to damage the fetus or placenta.

Birth takes place immediately outside of the village where a woman is assisted by several other women, usually her mother or sisters. No men are allowed to be present. The expectant mother elevates her self by sitting on a log or other object while other women hold her from behind. The infant is allowed to fall onto a bed of fresh plantain leaves. After delivery the umbilicus is severed with a bamboo knife, the infant is inspected and washed by the assistants, and returned to the mother.

Infancy

Infanticide occurs for all the reasons listed above for abortion and, in addition, if the child has a congenital defect. Preferential female infanticide is widely reported for the Yanomamö. The Yanomamö show a decided preference for males (as in the case of twin births described above) and in many villages there is an infantile and juvenile sex ratio strongly skewed towards boys. To some extent, this skewing is a consequence of preferential female infanticide. Early and Peters (2000, pp. 210–212) in a careful analysis of infanticide for Brazilian Yanomamö show that 8% of all births results in infanticide and of these 32% are preferential female infanticides. However, in nearly all cases the decision to kill a child is made prior to birth.

During an infant's first 6 months of life, it is in the exclusive care of his mother or a close female relative when the mother is indisposed. During this time fathers are believed to lack the competence to care for infants. Mothers are expected to provide attentive care for the child and nurse on demand. Throughout most of the day

the infant is attached to the mother via a sling that runs diagonally from the mother's shoulder to her hip where the child is suspended. From this position the child has easy access to the breast. A Yanomamö infant travels with its mother as she journeys to forest or garden to collect food. If the infant is out of the sling, it is never more than a few feet from the mother. One of the most traumatic events a child faces is when it is weaned from the sling. Even though a child is able to walk, it expects to be carried when the mother takes it to the forest or garden. On the trail the mother sets the child down and encourages it to follow her. The child will follow for a short distance but ultimately refuses to walk and cries or throws a tantrum until the mother picks it up. Over a period of several days, the mother repeats the process until she ultimately refuses to carry the child and it now walks on its own.

Children nurse until they are about 3 years old or until a new child is born. Supplemental feeding begins at about 6 months with soft food such as plantains. During the period of breast-feeding, a mother should not have intercourse with her husband to prevent the birth of a new child who would deprive the infant of milk.

Childhood

During the first 3 years of life children are seldom disciplined. However, if discipline is meted out, it can be very severe. If the child cries or becomes upset, it is given the breast or its genitals are gently rubbed, or it is pacified in other ways. Between the ages of 4 and 8 children roam immediately about the village in mixed age and sex groups. However, during this time boys and girls begin to segregate in same-sex groups with boys having more freedom to range further from the village and the girls are encouraged to help their mothers or care for younger siblings.

Adolescence

During this period boys and girls begin to take on labor activities that ultimately mirror adults patterns. Girls begin this process much earlier. By the time they are 9 years of age, they help carry firewood, fetch water, and prepare food. By the time they are 12–13, they have mastered the rudiments of nearly all of a woman's tasks. Throughout this period they are expected to avoid boys and young men when they are bathing or otherwise out of sight of their parents. At the sign of their first menses,

they are confined to a small enclosure near their parents' hearth where they enter their puberty confinement. While in confinement they are subject to a variety of taboos and rituals that mark their transition to adulthood. When a girl emerges from confinement, she is recognized as a mature woman eligible for marriage. Frequently, she takes up residence with her betrothed.

There is no rite of passage ceremony that marks the transition from boyhood to manhood. During adolescence boys are expected to hone their hunting skills and assist their fathers in heavy work such as house construction and garden clearance. They tend to associate with other males of their age: they hunt and fish, seek female companionship, and visit other villages.

Adulthood

There are few Yanomamö women who do not bear the scars of their husband's violence. Women may be jabbed in the buttocks or thigh by arrow points, burned with firewood, or cracked across the head with firewood splitting the skin on the skull. Sometimes these injuries lead to significant disability or death. There are probably no Yanomamö men who do not bear injuries from dueling or warfare. Most injuries are on the head in the form of split skin. In fact, the men will shave their tonsure to show these dueling injuries. Death through violence accounts for 5–30% of all adult male mortality (Hames, 2001).

The Aged

The aged are treated well especially if they are surrounded by numerous kin and can still make economic contributions to families with whom they are associated. Common ailments include arthritis and old injuries that limit mobility.

Dying and Death

As mentioned above, the Yanomamö believe that nearly all deaths are supernaturally caused. They are products of *hekura* sent by long distance by enemy shamans to weaken and destroy the soul. Alternatively, death may be the result of the blowing of charms (*oka*) by enemy Yanomamö from the edges of the settlement. An inquest is usually made by a local shaman in an attempt to identify the likely source of the death magic.

Immediately after death, the body is placed on a scaffold in the forest where the bones are picked clean by

scavengers. After the flesh is removed, the bones are brought back to the village where they are ceremonially incinerated. Alternatively, the whole body may be cremated in the village. In either case, the bones are removed from the fire and crushed to powder, and stored in a gourd. Later, amid much ceremony, the bone ash is mixed into a puree of plantains and/or bananas and is consumed by close kin as a final mortuary rite. In many cases, the dead are mourned on a regular basis just after sunset. The mourners cry and sob while they speak of their sadness and bitterness at the loss of a loved one. Women often lead in these evening rituals and will smear their cheeks black with ashes to mark their mourning status. Mourning may last for years. Its duration and intensity is dependent on a complex of factors such as the deceased's social status (e.g., infants are mourned the least while prominent men are mourned the most), how deceased, and the cause of death.

CHANGING HEALTH PATTERNS

Centers for contact such as mission stations, government installations (frequently they are in the same place), and mining installations influence Yanomamö morbidity and mortality patterns. Chagnon (1997, pp. 241–254) claims a higher rate of mortality for Yanomamö villages at an intermediate distance from missions. Early and Peters (2000, pp. 187–188) cast reasonable doubt on this assertion. With regard to mission contact in Brazil, Early and Peters (2000, pp. 188–190) find no consistent variation in mortality patterns. Nevertheless, it is abundantly clear that HIV, measles, influenza, tuberculosis, and various forms of hepatitis have been introduced through contact with devastating consequences for the Yanomamö.

While the missions might be implicated in the introduction of potentially life-threatening diseases to the Yanomamö, as was the case with the introduction of hepatitis and measles, the missions do not constitute the only contact the Yanomamö have, especially in Brazil, where gold miners and even farmers living in relatively close proximity can present an even greater hazard to the Yanomamö. A case is cited by Peters (1998, pp. 245–246) of what is believed to be the first case of tuberculosis among the Yanomamö, which the individual likely contracted while in the employ of Brazilian farmers, in 1966. Beginning in 1973, the Perimetral Norte, a spur of the Transamazon Highway, was constructed through the

southern edge of the Brazilian Yanomamö region in the Catrimani area. Contact with road construction crews and travelers led to outbreaks of influenza and measles that killed between 30% and 50% of the people in three different villages in 1977 (Saffirio & Hames, 1983, p. 11).

There is little doubt that the invasion of gold miners beginning in 1980 has had and continues to have a devastating impact on the Yanomamö. Ramos (1995, pp. 278–279) documents huge increases in malaria, anemia, splenomegaly, respiratory infections, and tuberculosis in the Surucucu and Paapiú regions inhabited by the Yanomamö and invaded by gold miners.

John Peters (1998), a long-time missionary and ethnographer among the Yanomamö, describes the health care and facilities available to the Brazilian Yanomamö with whom he has worked. Missions and government health centers, such as *Fundação Nacional do Índio* (FUNAI) and *Fundação Nacional de Saude* (FNS) provide medical care for the Yanomamö. For the Brazilian Yanomamö at least, the *Casa do Índio* and *Casa da Hekula* in Boa Vista are available to meet many health needs, and hospital care is available in Boa Vista as well, in cases of dire emergency. The FNS makes transport available via airplane. Finally, the Comissão Pró Yanomami (CCPY) is an umbrella organization devoted to enhancing the quality of medical care and health monitoring (as well as assisting the Yanomamö politically) for the Yanomamö. Their web site at http://www.proyanomami.org.br/index_fl.htm is an important source of current information on the variety of health crises facing the Yanomamö.

Obviously, the availability of proper medications, such as tuberculosis treatments and antibiotics is crucial to maintain the health of the Yanomamö. Until 1995 these were available from FUNAI and FNS personnel, by missionaries, and by field nurses (Yanomamö trained to provide basic care). Currently, medications are available from FUNAI and FNS at specific centers.

Thus, some care and treatments are available to the Yanomamö; however, these remain problematic. Transportation to Boa Vista for emergency care may not be fast enough in many cases. Also, many Yanomamö continue to move often, or to spend a great deal of time away from their villages: ensuring that all receive treatment or vaccination is difficult. Better sanitation, facilities (e.g., latrines), and practices especially with sedentism becoming more common near mission posts, must be implemented if conditions are to improve.

Nonetheless, disease being the greatest threat to Yanomamö life and health, these conditions must be augmented by access to medical resources, such as

medicines and supplies, and vigilant health care, whether from missionaries, government posts or others, if these conditions are to be ameliorated for the Yanomamö.

Yoruba

Norma H. Wolff

Alternative Names

In the past the Yoruba have been identified by outsiders as the Anago, Olukumi, and Aku (Adediran, 1998). Major subgroups include the Egba, Egbado, Ekiti, Igbomina, Ijebu, Ijesa, Ife, Kabba, Ondo, Owo, and Oyo.

LOCATION AND LINGUISTIC AFFILIATION

The Yoruba are located in the tropical rain forest and guinea savanna zones of coastal West Africa, concentrated in southwestern Nigeria (Yorubaland) with smaller groupings in southeastern Benin, Togo, and Ghana. As a result of the diaspora, enclaves of Yoruba culture are evident in Cuba and Brazil. The Yoruba language, marked by dialect diversity, and in some cases unintelligibility between subgroups, is a tone language that is a member of the Kwa group of Niger–Congo languages.

OVERVIEW OF THE CULTURE

Twenty to twenty-five million people speaking dialects of the Yoruba language form one of the largest ethnic groups in Nigeria, making up about 20% of the population (Zeitlin & Babatunde, 1995). Yoruba culture emerged in a series of kingdoms and chiefdoms in the tropical forests of southwestern Nigeria between the 9th and 12th centuries AD. The forest environment, with wide biodiversity, an abundance of mineral resources, numerous north-south flowing rivers, and a climate conducive to year-round agriculture, encouraged surplus agriculture, leading to population growth, centralized political systems, large-scale craft production, and trade. The early concentration of populations into large indigenous towns which were political, economic, and residential centers prior to European contact set the Yoruba apart in sub-Saharan Africa.

The Yoruba are horticulturalists. Root crops, including a variety of yams, cocoyam, and cassava, are the most

important food crops. Maize, rice, millet, beans, plantains, bananas, and a wide variety of vegetables including tomatoes, onions, okra, peppers, and greens are also grown. Kola nuts are harvested for trade, and palm oil is processed for sale. Cocoa, introduced during the colonial period, is a major cash crop. Agricultural surpluses are the rule and have long been a staple of trade between rural and urban areas.

Despite the economic importance of farming, Yoruba take great pride in being town dwellers. Long before European contact, Yoruba towns were residential centers and the foci for economic redistribution, political administration, ritual activities, and the production of crafts. With the rise of long-distance trade, they became important links in the major trans-Saharan and Atlantic coastal trade routes of the region. A typical walled Yoruba city (*ilu*) is made up of multi-familied lineage compounds with a centrally placed palace of the king to whom descent groups acknowledge allegiance. The town is the core of a kingdom, and the palace provides a central focus for administrative, ritual, and economic activities with a major market in front. Beyond the walls of a city, farmlands, corporately owned by descent groups, extend 2–30 miles outward. Farmers live in town compounds and commute to their farms on a daily or seasonal basis. Temporary small hamlets (*aba*) spring up at farm outposts and sometimes develop into larger more permanent villages (*abule*). Villagers remain loyal to their city-bound king and retain links to the city compounds of their lineages.

Men were full-time farmers in the past. Other indigenous male occupations include long-distance trade and part-time crafts such as iron-smithing, weaving, woodcarving, and beadworking, combined with farming. Men's crafts are hereditary occupations associated with specific lineages. While women farm and raise vegetables, the ultimate female occupation is trader. Virtually all women take part in local trade and the controlled distribution of foodstuffs and trade goods at periodic markets. Women's craft skills include pottery manufacture, weaving, dyeing, and decorating textiles with resist designs.

Political organization of a Yoruba subgroup revolves around an *oba*, a king with divine attributes. The *oba* embodies the kingdom; his health is an indicator of the strength and stability of the polity. Decisions concerning the maintenance of peace and order in the town, such as quarrels between lineages, land disputes and other local altercations, are made by ward or town chiefs. Palace chiefs, backed by the *oba*, are ultimate decision-makers concerning public affairs and outside threats that endanger the kingdom. Public morality and the maintenance of social order is supported by members of ancestral cults such as *Egungun* and *Oro* who take active roles in applying supernatural sanctions to encourage proper social behaviors and punish wrongdoing. Today, national and state sanctions overlay indigenous practices.

The concept of family begins with membership in a lineage that traces ancestry back to a known male ancestor five or six generations in the past. While individual social mobility is possible, lineage membership determines boundaries of possible achievement. Religious choice, rights to land and property, occupation and access to political office, in large part, are a prerogative of lineage membership. Living male descendants of a named progenitor, their wives and children and unmarried female descendants live together in a walled compound named for the ancestor. Today, with a changed social and economic climate, individuals feel more free to reside outside the family compound, but lineage loyalties remain strong, and visits and extended stays at family compounds are typical. Within the lineage, the polygynous family is the ideal. Beyond family, the Yoruba are group-oriented, and non-kin associations based on economic cooperation, occupation, age, and religion are common.

Religious belief reflects an ongoing relationship with the rain forest environment. *Olorun* (*Olodumare*), the supreme deity, created a multitude of lesser *orisha* (deities) who control the forces of nature and culture, including *Osanyin*, the deity of medicine. For each deity, there are ritual paraphernalia, taboos, praise names, symbols, sacrificial foods, and texts for worship and supplication. In contemporary "Yorubaland," indigenous belief is retained in varying degrees. Most Yoruba are Muslims or Christians. Islam is seen as more compatible by many, because polygyny is allowable and Islamic medicine shares characteristics with the Yoruba religio-medical system. Christianity's promotion of Western education has brought vast changes in Yoruba life and culture. However, Christian

syncretic churches combine indigenous and Western beliefs and practices.

Social interactions are governed by two important Yoruba precepts: seniority and good character. Respect for age and seniority plays a part in every social interaction. From the palace to family compounds people are ranked by age and birth order with elders given positions of responsibility. Beyond the family, status accrues with lineage affiliation, individual industriousness, wealth, and achievement of honored positions such as chieftaincies. Personal character (*iwa*) is of extreme importance. To have good character one must honor and respect the elderly, show generosity and kindness, engage in selfless service to others, be truthful and moral, and show hospitality to all, especially strangers.

Contemporary Yoruba life and belief are shaped by multiple forces. Islam and Christianity influence belief, and Western-style education, industrialization, and modernization affect every aspect of life. With the introduction of universal primary education in the mid-1950s, awareness grew of opportunities to make one's own life decisions, enter new professions, and practice new health strategies. Today the Yoruba are identified as the most urbanized and industrialized ethnic group of sub-Saharan Africa. Nine Yoruba cities are estimated to have populations of over 100,000. With more than 50% of Nigeria's light manufacturing located in Yorubaland, the Yoruba have one of the highest population densities of sub-Saharan Africa and face some of the highest environmental pollution threats in the world (Adediran, 1998; Zeitlin & Babatunde, 1995).

THE CONTEXT OF HEALTH: ENVIRONMENTAL, ECONOMIC, SOCIAL, AND POLITICAL FACTORS

Environmental Factors

The Yoruba live in a tropical ecosystem where diseases, illnesses, and parasites are endemic. These include malaria, cholera, skin diseases, unspecific fevers, and guinea worm. Historically, global diseases such as smallpox and influenza took their toll. In a 1980 United Nations Report for Nigeria, infectious diseases, combined with malnutrition, accounted for about 70% of illnesses, with the leading causes of death being malaria,

dysentery, pneumonia, measles, tuberculosis, gastroenteritis, and gonorrhoea. Water-borne diseases such as cholera, diarrhoea, and other enteric infections are common due to the lack of reliable water supplies. Piped water is available only in urban areas. Villages depend on streams, wells, and rainwater stored in pots and drums for their water. Such water is often polluted. Another major factor in determining health status is diet. Ecological conditions are such that the major crops raised are high carbohydrate foods. They include cassava, yam, and maize. Protein sources are scarce and expensive to acquire. Children are fed a high carbohydrate diet, particularly *eko* or *ogi* (cornmeal pap). Malnutrition based on inadequate consumption of proteins and enteric infections caused by bad water and contaminated food, stored and cooked under unsanitary conditions, are common (Iyun, 1994). Aspects of the built environment also contribute to health problems. Particularly in the urban areas, overcrowding and inadequate public services contribute to deplorable sanitation and outbreaks of diseases in low income neighborhoods.

It is estimated that half of Nigeria's children die before the age of 6 from such causes as measles, gastroenteritis, malaria, tetanus, meningitis, pneumonia, diarrhoea, whooping cough, polio and tuberculosis (Osunwole, 1997; Oyeneye, 1991). In parts of Yorubaland, infant mortality rates remain high, 78 out of 1,000 children dying before the age of 3 (Folasade, 2000). The most common nonfatal chronic diseases are malaria and guinea worm infestation. In 1987, the World Health Organization estimated that Nigeria had the highest number of guinea worm cases (140 million) in the world. Complications of guinea worm infestation are the major cause of work and school absenteeism. At the end of the 20th century, epidemics of infectious diseases included cholera, yellow fever, cerebrospinal meningitis, and AIDS, as well as continuing chronic infections of malaria, guinea worm, and high rates of malnutrition (Metz, 1992). A newer trend that is affecting higher income groups is the prevalence of noninfectious social-stress diseases. Hypertension is a leading cause of illness of Yoruba adults over the age of 30 treated in hospitals in Ibadan, Yorubaland's largest city, with males over the age of 45 bearing the greatest risks of developing cardiac disease (Iyun, 1994, 1995). Upper income males are most likely to suffer from hypertension and myocarditis, while women run the risk of rheumatic and pulmonary heart disease (Iyun, 1995). The increase in heart disease in urban Westernized Africans has been

attributed to changes in lifestyle associated with pursuit of the modern lifestyle. Risk factors leading to hypertension include dietary changes such as increases in alcohol and salt intake, smoking, physical inactivity, obesity, and continual psychological stress (Akinkugbe, 1995; Iyun, 1994, 1995). A four decade study revealed that 1 in every 10–15 Nigerian adults is hypertensive, leading to strokes, heart and kidney failure and visual impairment (Akinkugbe, 1995).

The Introduction and Impact of Biomedicine

Dual medical systems, indigenous and Western, have competed in Nigeria since European colonization. Yorubaland was a primary target for the establishment of Christianity in West Africa. European and American missionaries introduced biomedical care in the 19th century, and the British colonial government continued to develop modern healthcare facilities in the 20th century. In 1948, the British established Nigeria's first medical school as part of the University College of Ibadan, with a modern teaching hospital opening in 1957. By the time the British left Nigeria in 1960 they had laid the foundations for modern medical services with over 3,000 hospitals, all concentrated in urban areas (Falola, 1999). Following independence in 1960, a first priority of the new government was to control endemic diseases and improve medical care services, particularly building hospitals. However, in the early 1970s, it was felt that most of the Nigerian population still relied on traditional medicine; those who accepted modern medicine were the urban educated (Foreign Area Studies [FAS], 1972). In 1975, the Nigeria Primary Health Care program was established to control communicable diseases, improve environmental hygiene, deliver preventive and curative care to at-risk populations such as the elderly and handicapped, and provide family planning and mother-child health services. Problems persisted. In 1980, over 85% of the doctors in Nigeria trained in Western medicine were concentrated in urban areas, and only about 35% of Nigeria's population had access to modern health-care services (Oyeneye, 1991; Warren, Egunjobi, & Wahab, 1996). In the 1980s, Nigeria's first population policy was implemented (Riedmann, 1993), and a Primary Health Care program was launched to serve all urban and rural Nigerians. The goal was to increase health-care personnel, collect reliable health data, make essential drugs

available to all, improve nutrition, promote health education, develop a family health program, promote family planning, introduce improved therapy for childhood diarrheal diseases, and implement vaccination campaigns against major childhood diseases (Metz, 1992). In the early 1990s, challenges remained, including continuing disparities between rural–urban availability of health-care facilities and personnel. These problems persist in the 21st century due to continuing economic tensions and lack of foreign exchange limiting the availability of medical supplies, drugs, and equipment.

MEDICAL PRACTITIONERS

Yorubas have a wide variety of options in seeking health care. Choices are determined by the nature and history of the illness and the availability of services. Treatment often starts in the family with herbal remedies made with recipes passed through generations or after consulting locally printed indigenous medical formula books (Maclean, 1971). Indigenous practitioners who tap nature's unseen powers to treat a full range of human misfortunes and illnesses are often the next recourse. *Onisegun* are herbalist-healers who heal illness and combat misfortune. *Oloogun* are more likely to both cure and cause illness and misfortune (Wolff, 1979, 2000). When supernatural causation of illness is suspected, the close ties between the medical and religious systems draw the afflicted to *babalawo*, divination priest-healers of Ifa, or *olorisa*, priests of deities. Additional specialists include midwives, bone setters, circumcisers who cut tribal marks and incisions for medicines placed under the skins, and specialists in the treatment of mental illnesses.

Gender is not a problem to practicing indigenous medicine. Women practitioners (*iya isegun*) specialize in women's and children's health, as well as treatment of conditions such as asthma, diabetes, jaundice, hypertension, and fractures (Osunwole, 1997). As midwives, female practitioners manage childbirth and gynecological problems that affect fertility. Women favor female healers because of the bonds of similar experience and their expertise on children's diseases, including whooping cough, measles, neo-natal tetanus, tuberculosis, and polio. Women do not treat mental illnesses and other conditions that necessitate using powerful supernaturally charged medicines for fear that exposure to such forces causes

infertility or birthing of deformed children by the practitioner. Because of the importance placed on women treating women in indigenous context, there is a modern focus on training Traditional Birth Attendants (TBAs) who combine indigenous and biomedical practices to oversee pregnancies and act as educators on women's and children's health. TBAs provide both pre- and postnatal care and take an active role in Primary Health Care programs including family planning and safe mother programs. They give advice on curing infertility, preventing unwanted pregnancies, and consult with pregnant women on diet, activity levels, and sexual relations during pregnancy. As midwives, they provide indigenous herbal therapies to speed birth, stop postpartum bleeding and stimulate breast milk, as well as perform childbirth rituals (Osunwole, 1997; Oyeneye, 1991).

In the urban areas, health-care options are evidence of the contemporary indigenous and biomedical mix. Clinics and hospitals provide access to biomedical specialists, including doctors with a wide range of specialties, nurses, interns, midwives, and other medical workers. On the streets and in the markets, every sort of pharmaceutical drug is for sale, specialists offer indigenous medicinal ingredients including plants, animal parts, and minerals; peddlers hawk patent medicines and home remedies, and injectionists provide shots for every ailment. Contemporary religious beliefs also play a part in urban healing practices. Christian faith healers of the syncretic churches, such as Aladura, cure and drive out harmful spirits with prayers and holy water. Muslim scholar-healers cure with Islamic medicines and charms and the power of the holy word.

Biomedical doctors in Yorubaland have found that cooperation with indigenous healers is feasible, cost-effective, and welcomed by patients, particularly in the rural areas. Blending indigenous with scientific medical practices makes them more acceptable and sustainable in the Yoruba worldview. Adeoye Lambo, a Western-trained Yoruba psychiatrist who served as the head of the World Health Organization, was a pioneer in this effort. As director of Aro Psychiatric Hospital in southwestern Nigeria, Lambo found that Yoruba mental patients recovered more quickly when indigenous practitioners were involved in their treatment. He developed the therapeutic village approach where the mentally ill and their relatives live together in a nearby settlement where the patient receives treatment from both hospital and indigenous practitioners.

CLASSIFICATION OF ILLNESS, THEORIES OF ILLNESS, AND TREATMENT OF ILLNESS

The Yoruba take a holistic approach to health or *alafia* (lit. “peace”), a philosophy of life, health, and death tied to the indigenous religion. *Alafia* encompasses physical, social, emotional, psychological, and spiritual well-being in the total environmental setting (Ademuwagun, 1978). Physical health (*ilera*), a prerequisite to achieving life goals, is negatively impacted by *aisan*, minor illnesses, such as fevers, headaches, diarrhoea, and vomiting that interfere with daily activities, and *arun*, which includes serious pathological conditions, communicable diseases such as smallpox and venereal diseases, infirmities, chronic tiredness, debilitating mental illnesses, and unexplained misfortunes (Ademuwagun, 1978; Warren, Egunjobi, & Wahab, 1997a).

The indigenous medical system takes into account both natural and supernatural causation of illness and misfortune (Awolalu, 1979; Odebiyi, 1989). It is a “personalistic medical system” where causation includes super-sensory forces directed toward afflicted individuals in acts of “active purposeful intervention” by human or nonhuman beings (Foster, 1976). Giving offense to potentially dangerous human beings such as witches (*aje*) or sorcerers (*osho*) and to entities such as evil spirits (*anjonu*), deities (*orisha*), and ancestors (*egungun*) is an ever-present danger. The belief that misfortunes of all kinds result from power attacks directed by malevolent beings is firmly entrenched in Yoruba thought. Every stage of life is fraught with possibilities of supernatural intervention that negatively affect advancement. Medicines or *oogun* are designed to combat these forces.

Oogun takes tangible or intangible form to either cure, cause, or counter illness and misfortune. In medicines, *ashe*, a potent universal power that the creator god put into all nature, is focused and energized for good or evil purposes through the combination of ingredients, preparation procedures, and incantations or words (Abiodun, 1994). To make medicine is to transform the raw materials of nature such as leaves, roots, fruits, woods, bird and animal parts, minerals and soils, and sometimes artifacts, into power objects according to specific formulas. The potential danger in the powers incorporated into medicines necessitates taboos and precautions in the making. *Osanyin*, the deity of medicine, is

often appealed to for success. Sexual abstinence and the banning of women from the area during preparation may be necessary because of the perceived polluting effect of females (Buckley, 1985; Wolff, 2000).

While there are dialectal differences, a complex lexicon identifies medical conditions, symptoms, and treatments. Distinctions are made between diseases by sex, age, location in or on the body, natural or spiritual causation, and harshness of effect (Warren, Osunwole, & Wolff, 1997b). There is also a sense of hot and cold illnesses and the need to balance the body with foods and medicines of the opposite nature. The hot diseases (*arun gbona*), usually characterized by high fevers, include epidemic diseases such as cholera, yellow fever, and smallpox, as well as severe mental illnesses; they may be caused by deities and are considered serious and difficult to cure. Cold diseases (*arun tutu*) are less serious, associated with natural causation such as exposure to cold, and may manifest themselves as pains and aches in the body and mucous discharges (Odebiyi, 1989).

Abnormal behavior and states of personality disintegration that are identified as psychoses or neuroses in the West are recognized. *Were* labels chronic psychoses and persons manifesting symptoms of schizophrenia, where the afflicted poses no threat to the social order. It is the most common condition treated by indigenous and biomedical practitioners. *Were alaso* (“were who wear clothes”) refers to less severe cases where the personality is intact. *Were agba* (“elderly were”) labels conditions such as Alzheimer’s disease and senile dementia. *Were d’ile* (“were of the lineage”) refers to hereditary psychosis. Withdrawal into paranoid uncommunicative psychosis is known as *dindinrin*. Yorubas are generally tolerant of the mentally ill who are allowed to roam if they are not violent. Severe mental illness, characterized by violent acute psychotic episodes involving mania, catatonic excitement, or agitated delirium, is called *isin-win*. Neuroses are also recognized and labeled; they are thought of as physical diseases. Persons diagnosed with *ori ode* (“hunter’s head”) have sensations of burning or insects crawling in their brains, coupled with vision problems, dizziness, trembling, and insomnia. Organic and hysterical paralysis (*aluro*, *egba*, *ategun*), posturing and tics (*aiyiperi*), and epilepsy (*warapa*) are also distinguished (Prince, 1961).

Medicines are categorized by function, techniques used in preparation, and the physical form of the resultant products (e.g., Buckley, 1985; Verger, 1995; Warren et al.,

1997b). Types commonly identified include *agunmu* (pounded medicines), where ingredients are pounded to a pulp, dried, and ground to powder to eat or mix in a drink; *oogun jijo or etu* (burnt medicines) made by charring ingredients in a dry pot and grinding them to powder to ingest dry or add to liquids to drink or rub into skin incisions (*gbere*); *agbo* (infusions) prepared by steeping fresh ingredients to ingest or rub on body; and *oshe* (black soap) made by pounding burnt or fresh ingredients into palm kernel oil soap used to wash. Charms (*onde*) are a popular form of medicine. The most requested charms are *awure* that bring power, wealth, and good luck in life's ventures (Verger, 1995). *Afose* are charms that cause misfortune to enemies if placed in their proximity. Medicines can also be nonmaterial. The importance placed on the efficacy of words is exhibited in incantations (*ofa*) and curses (*epe*) that call directly upon the powers of nature, spirits, deities, witches, and wizards for a desired effect. A particularly malevolent spirit (*shigidi*) is summoned by sorcerers to attack people as they sleep (Wolff, 2000). The prescription and proscription of medicinal foods (*aseje*) is another medicine category (Buckley, 1985; Odebiyi, 1989). Some food proscriptions are widely held. Sweets, in particular, are considered to cause health problems and discomfort caused by worms. In a commonsense cure, healers forbid the eating of vegetables when patients have dysentery or gastroenteritis, because eating vegetables as roughage is affective in the treatment of constipation. The magical principle of similarity is applied when okra and other slimy foods are banned during treatment of infected wounds or skin lesions of measles and smallpox. Thermally hot food and alcoholic beverages are prescribed to alter body balances to combat cold diseases. Food and behavior proscriptions are also associated with avoiding offence to deities. For example, *Soponna*, the deity of smallpox, may punish people for roasting and eating melon seeds in the dry season or whistling in the hot part of the day.

In treatment, practitioners take natural and supernatural causation into consideration. They observe patients by examining their skin, eyes, and afflicted body parts and may look at blood, urine, and stool samples. Before arriving at a diagnosis, there are questions about social relationships between patient, relatives, and neighbors to determine the likelihood of supernatural attack. Once causation is ascertained, the healer prepares an appropriate medicine. Healers have many remedies for any one condition that are tried serially until a cure is affected.

When stubborn conditions do not respond to treatment, divination may be performed to determine ultimate causes and treatment is adjusted. A common finding is that the ill person or someone close to the patient has broken a taboo associated with a deity. Dealing with such transgressions can involve sacrifices and joining cults dedicated to the deity.

SEXUALITY AND REPRODUCTION

Traditional Yoruba attitudes favor "excessive fertility" (Olusanya, 1969) in a society that stresses ancestry and descent. The economic importance of children's labor in horticultural farming practices, a desire for lineage continuity, and economic and emotional security for parents in old age, coupled with high child mortality rates, have favored a high birth rate. A Yoruba proverb asserts that a man's wealth is counted in terms of money, wives, and children. This strong desire for children shapes Yoruba sexuality and promotes men's desire to control women's fertility. While Yoruba women enjoy a surprising amount of economic independence, their lives still center upon childbearing. In a typical village surveyed in the mid-1990s, Total Fertility Rates averaged over 8 births per woman and the overall fertility rate of 6.5 is among the world's highest (Lawoyin & Onadeko, 1997; Riedmann, 1993). Education has modified but not eliminated the desire for large families. In a study of fertility attitudes of Nigerian university students in the United States, ideal family size was five to six children (Adebayo & Adamchak, 1991). Today, among university-trained Yoruba, four children per monogamous family is common. It is generally held that men are the decision-makers about how many children a wife should bear. However, when women wield significant economic power, men may have to negotiate their own preferences regarding family size. With literacy and the increased sense of self worth associated with education, coupled with lower infant mortality rates, women are more outspoken about reproductive goals.

By the late 1980s Nigeria's official policy was to encourage four children per woman, and biomedical contraceptives became increasingly available. Pills, condoms, spermicides, injections, diaphragms, and IUDs are widely available in urban and rural areas. However, attempts to introduce birth control technology such as IUDs have met with resistance from men (Renne, 1993).

Both illiterate and educated men consider that women using contraceptives without the consent of their husbands contradicts male authority and is morally wrong; their wives might be unfaithful if given access to such technology. In 1992, 43% of married Yoruba women were using some form of modern birth control (1993). Because women who use contraceptives risk detection from a disapproving husband, they often depend on patent medicine abortifacients or abortion at clinics or alternatively leave their husbands if they do not want more children. A man who wants more children may take another wife or threaten to do so; if he wants fewer children, he can abstain from sexual relations, withhold financial support, or refuse paternity for an unwanted child (Olusanya, 1969; Renne, 1993).

Abstinence is the major form of birth control, and men practice coitus interruptus or withdrawal (*adaye*). Postpartum abstinence for 2–4 years until a child is weaned is an indigenous form of birth control. During this period, the prohibition against sexual intercourse is reinforced by the prevailing belief that such activity spoils the breast milk and causes life-threatening infant diarrhea (Olusanya, 1969). The practice regulates the number of children a woman bears in a lifetime, but does not limit a man's desire for a large family of children in a polygynous society. The period of abstinence has declined as educated working women seek to complete their families by an earlier age (Osunwole, 1997). Additional indigenous birth control methods used by women include wearing magic iron rings (*oruka irin*) and amulets (*onde, igbada*) or drinking extremely salty water immediately after intercourse. Women employ abortifacients. For example, in the first month of pregnancy, women may drink a mixture of potash and lime juice to terminate a pregnancy or insert herbal suppositories into the vagina (Olusanya, 1969).

Yoruba attitudes toward infertile individuals are harsh, with blame usually placed on women. The social disapproval directed toward barren women is indicated in the term of reference *agon*, from the verb *gon* meaning "to despise" or "hold in contempt" (Abraham, 1958). Initially, a woman who does not conceive after marriage is treated with indigenous medicines and given advice on sexual relations by midwives (Oyeneye, 1991). If barrenness persists, it is thought to be either preordained, a condition of destiny (*iponri*), or due to supernatural intervention. Deities and ancestors may have been neglected or offended so that sacrifices must be made. If a

woman remains barren despite treatment, she may be pointed out as a witch so imbued with evil that her own body is corrupted (Wolff, 1979).

HEALTH THROUGH THE LIFE CYCLE

Pregnancy and Birth

The Yoruba believe that pregnancy and birth are natural phenomena that create no health problems unless taboos are broken or witchcraft, sorcery, or other forms of spiritual attack occur. To avoid such incidents pregnant women observe behavioral and dietary prescriptions and prohibitions to ensure the safety of mother and foetus (Maclean, 1971; Odebiyi & Togonu-Bickersteth, 1987). The cooperation of deities, particularly when they have been appealed to for children, is sought through appeasement rituals, sacrifices, and the consumption or avoidance of special foods (Odebiyi, 1989; Osunwole, 1997). Beliefs about the properties of foods also determine diet. Expectant mothers consume starchy foods while avoiding nutritional foods such as milk which is thought to create large babies that are difficult to birth (Odebiyi, 1989). Postpartum depression is recognized, and if severe symptoms emerge it is identified as *abisinwin*, a supernaturally caused mental illness to be treated by indigenous healers (Prince, 1961).

When a child is born, precautions are taken to ensure an easy delivery and the future welfare of the child. Men are not normally present. The husband's presence is thought to delay the delivery. Both male and female practitioners can act as indigenous birth attendants, but male specialists are called only when complications develop, particularly those requiring spiritual interventions. Traditionally umbilical cords are ritually buried in the family compound to link the child to the father's lineage and to protect the mother from future barrenness. To prevent infertility in the child's adulthood, no word is spoken until it cries. The newborn is held by the feet and shaken three times to ensure that it will be brave and not have spasms; its head is touched to the ground so that future accidental falls will not result in injuries (Bascom, 1969; Osunwole, 1997).

Children born with striking physical traits or birth circumstances, such as twins and triplets, those born with the umbilical cord wrapped round the neck, an unruptured caul, extra fingers or toes, or abundant curly hair, are given

special names and treatment. Multiple births are common. The Yoruba have the highest rate of fraternal twinning (4.4% of all births) in the world (Leroy, Olaleye-Oruene, Koeppen-Schomerus, & Bryan, 2002). Twins are both desired and feared as they have special powers. In the past twin infanticide was practiced, but it was replaced by elaborate ritual activities that harness the powers, particularly when a twin dies (Renne & Bastian, 2001).

It is still common for children to be born in lineage compounds. In urban areas only about 40% of women use modern health institutions at delivery (Oyeneye, 1991). A reason many women prefer home delivery is that modern health workers discard umbilical cords. Harmful effects of home birthing are unsanitary conditions and remedies administered during the birthing. Maternal mortality is primarily due to malnutrition, contemporary shortness of pregnancy intervals, and absence of adequate obstetric services.

Infancy

Male and female circumcision is performed a few days after birth, although the Egba and Ijebu sub-groups do not practice female excision (Caldwell, Orubuloye, & Caldwell, 1997). Men report that circumcision enhances sexual performance and reproductive potential, as well as reduces the female libido and promiscuity. Women support the practice of female circumcision by claiming that it makes child delivery easier (Osunwole, 1997). There is also a belief that the clitoris tip is charged with dangerous power that can kill the birthing child if it touches its head (Caldwell et al., 1997). It is only recently with global campaigns condemning female circumcision that Yoruba women identified the practice as an act of male domination to reduce female sexuality. In a 1997 survey, male circumcision remained universal while female circumcision, still prevalent in the rural areas (98%), had slightly declined in the urban areas (94%). Education, religion, and socioeconomic status were significant factors in the decline. Only 87% of girls born to mothers with secondary school education were circumcised. Christians were less likely than Muslims to circumcise females, and there was a decrease in families where fathers were in professional, managerial, or clerical occupations. The most significant change has been the medicalization of circumcision beginning in the 1970s. With involvement by biomedical professionals, circumcision-related deaths are rarely reported, and there has been a

major shift from excision to clitoridectomy in female circumcisions (Caldwell et al., 1997).

Infants are carried on the mother's back and breastfed on demand. From birth breastmilk is supplemented with herbal infusions (*agbo*) thought to guard against a variety of ailments and ward off evil influences. Solid food in the form of cornstarch pap is introduced as early as 2 months. While seen as health-enhancing, these practices increase the likelihood of death-threatening diarrhea and other illnesses. Malnutrition is also a strong possibility if breast-feeding is not continued, because pap is a poor source of protein and kwashiorkor may develop (Davies-Adetugbo, 1997). In addition, the tonic purgatives (*agbo*) given to infant early each morning in the first 6 months and to older children whenever they fall sick may be detrimental to health as ingredients, including cow urine, are variable and unregulated (Maclean, 1971).

Some infants are singled out for special treatment. Tied to high infant mortality rates is the belief in *abiku* ("born-to-die") children, troublesome spirits that die before adulthood and return again and again to the same mother. Such children are treated with special medicines and given names such as Malomo ("Do not go again") (Maclean, 1971).

Childhood

There are many safeguards to ensure the health of children and protect them from evil influences and accidents. Home remedies are used to treat minor illnesses and indigenous and biomedical healers are consulted for more serious ailments. From birth, children wear charms and have imposed food proscriptions associated with attracting the favor of deities. However, children born with physical and mental defects are stigmatized. Congenital malformations in children are perceived as supernatural punishment for the parents and can be grounds for a husband to desert his wife (Odebiyi & Togonubickersteth, 1987). There is little tolerance for individuals with physical abnormalities, despite the indigenous belief that they are favored children of Obatala (Orisha-nla), the "sculptor-divinity" who shapes children in the womb. Albinos (*afin*), dwarfs (*irara*), hunchbacks (*abuke*), cripples (*aro*), and the dumb (*odi*), for example, are sacred to Obatala (Awolalu, 1979). In the real world, handicapped children are ridiculed and avoided and often exhibit withdrawal behavior. For example, in studies of attitudes toward deaf children, no efforts were made at home

to communicate with them, they were not taken out socially, and they were disciplined more harshly than normal siblings. Attempts at curing deafness and other handicaps focuses on placating witches or offended deities (Odebiyi & Togonu-Bickersteth, 1987).

Adolescence

While there are no elaborate prolonged puberty rituals, the importance of women's childbearing role is marked by special ceremonies with sacrifices to the deities to thank them when a girl reaches menarche (Togonu-Bickersteth, 1988).

Adulthood

The Yoruba have no ritual acknowledgment of adulthood. Adulthood is recognized by taking on the expected male and female roles defined by the division of labor. Men take up economic activities, such as farming and craft production, and women become childbearers and rearers. It is marriage and parenthood that fully identify individuals as adults. Men marry between ages 25 and 30 and women between 17 and 25. An integral part of marriage negotiations between families is investigations to reveal any family history of undesirable characteristics such as the presence of leprosy, insanity, epilepsy, barrenness, birth anomalies, or social digressions. It is expected that the bride be in good health and be able to bear strong healthy children. While expectations of virginity have altered in contemporary context, the unquestioned health of wife and future children is imperative (Eades, 1980; Olusanya, 1969).

The Aged

Yoruba old age occurs when the person can no longer effectively carry out primary gender roles associated with the division of labor. For men, the critical sign is decreased stamina, so that active farming and labor become difficult and economic productivity dwindles. The critical indicator for women is menopause when childbearing ceases. Three major factors contribute to a sense of well-being and happiness in old age. These are having good health, responsible children nearby, and sufficient money. Security for the elderly comes from within the family where adult children, particularly sons, provide for aged parent's economic and emotional needs.

Without such support, old age is a period of sadness and dependancy upon distant relatives or strangers (Togonu-Bickersteth, 1988). Urbanization, industrialization, migration, and rural change have altered the context of aging. With national and local inflation and recurring economic crises, adult children have more difficulty in meeting their obligations, and the number of elderly destitutes has grown, specifically in urban areas (Togonu-Bickersteth, 1988). In a study of 706 urban women aged 55–102, it was found that 70% continued to work to meet their sustenance needs and suffered a higher rate of depression than rural elderly women (Udegbe, 1995).

Dying and Death

At death, funeral rites and burial are guided by the circumstances of death. Age at death, reputation, status, and the predominant religion of the family all play a part (Adelowo, 1988). In the case of elders, the funeral and burial is a time for descendants and relatives to come together and celebrate the good life, with the funeral used by the family as an opportunity to display affluence and filial status. It is common for burial to be postponed until funds can be collected for the feasting.

Rites are carried out to move the spirit away from the living world but enable it to return as ancestor, or through reincarnation, in the future. The first child of the right gender born after a death is named either Babatunde ("father returns") or Iyabo ("mother returns"). The corpse is buried under the floor of the house or outside the door in the lineage compound. The often unmarked grave site becomes a focal point where the ancestral spirit can be summoned by pouring libations and calling out praise names (*oriki*) of the deceased to encourage the spirit to return to the household of the living when help is needed. It was only with the adoption of Christianity and Islam that designated burial grounds were established.

The bodies of those whose deaths are considered unnatural are treated differently (Adelowo, 1988). There is no mourning allowable at the death of abiku ("born-to-die") children. The corpses of infants and abiku children who die young or in an untimely fashion, lepers, hunchbacks, albinos, pregnant women, persons killed by lightning, those who hang themselves and others who die unnatural deaths are buried in the bush outside town or in special sacred groves. Suspected witches and wizards may be denied burial, and their bodies are thrown into bush areas inhabited by wicked spirits.

CHANGING HEALTH PATTERNS

The Yoruba are one of the most studied ethnic groups of sub-Saharan Africa. International and national research projects have provided continuing information on health status, the prevalence of diseases, fertility, and the interface of biomedicine with indigenous cultural belief. A current focus of research is AIDS. The presence of AIDS in Nigeria was officially announced in 1987. In 1990, it was estimated to affect less than 1% of the population (Metz, 1992). In early 2002, it was estimated by the Federal Ministry of Health of Nigeria that the HIV population in Nigeria was over three million (National HIV/Syphilis Seroprevalence Survey).

ENCYCLOPEDIA OF MEDICAL ANTHROPOLOGY

Health and Illness in the World's Cultures

VOLUME 1 • TOPICS

EDITED BY CAROL R. EMBER AND MELVIN EMBER

Published in conjunction with the Human Relations Area Files at Yale University, New Haven, Connecticut

Medical practitioners and the ordinary citizen are becoming more aware that we need to understand cultural variation in medical belief and practice. The more we know how health and disease are managed in different cultures, the more we can recognize what is "culture bound" in our own medical belief and practice. Currently, there is no reference work that describes the cultural practices relevant to health in the world's cultures and provides an overview of important topics in medical anthropology.

The encyclopedia is organized into two main sections: Topics and Cultures. The Topics section covers general topics relating to medical anthropology such as medical systems; political, economic and social issues; sexuality, reproduction and the life cycle; and health conditions and diseases. The Cultures section covers over 50 cultures from around the world and describes their health practices in detail, following a standard format to facilitate comparisons.

Since medical anthropology is such a diverse course of study, combining both the medical and the social worlds, the *Encyclopedia of Medical Anthropology* has many audiences. It can be used both to gain a general understanding of medical anthropology and to find out about particular cultures and topics. For researchers interested in comparing cultures, this work provides information that can guide the selection of particular cultures for further study. For those interested in international studies, the bibliographies in each entry can lead one quickly to the relevant social science literature as well as provide a state-of-the-art assessment of knowledge about medical cultures around

the world. For curriculum developers and teachers seeking to internationalize the curriculum, this work is a basic reference and educational resource as well as a directory to other materials. For government officials, it is a repository of information not likely to be available in any other single publication; in many cases, the information provided here is not available at all elsewhere.

This major reference work will be an essential part of any institution's library and belongs in the library of anyone interested in a cross-cultural perspective on health and illness.
