Because the concentration of triterpenes in centella varies between 1.1% and 8%, it is difficult to calculate an appropriate dosage when simply using the crude plant material. However, because most samples yield a concentration between 2.2% and 3.4%, approximately 2 to 4 g/day of crude plant material would contain an appropriate quantity of triterpenes, although it is unknown if this correlates with the clinical efficacy of the standardized extracts.

Daily dosages of the various forms of centella are as follows:

- Standardized extract (40% asiaticoside, 29%–30% asiatic acid, 29%–30% madecassic acid, and 1%–2% madecassoside): 60 to 180 mg/day
- Crude dried plant leaves: 2 to 4 g/day
- Tincture (1:5): 10 to 20 mL/day
- Fluid extract (1:1): 2 to 4 mL/day

TOXICOLOGY

C. asiatica and its extracts are well tolerated, especially orally.[1,2] There is one report of three case histories of women (61, 52, and 49 years old) who developed jaundice after taking *C. asiatica* for 30, 20, and 60 days, respectively.[55] However, there was little description or validation of the product in question. Nonetheless, the hepatic lesions were quite significant on biopsy (granulomatous hepatitis with marked necrosis and apoptosis, chronic hepatitis with cirrhotic transformation and intense necroinflammatory activity, and granulomatous hepatitis). All patients improved with *C. asiatica* discontinuation and ursodeoxycholic acid 10 mg/kg per day.

The topical application of a salve containing centella was reported to cause contact dermatitis, although quite infrequently.[1]

Although the oral administration of asiaticoside at a dose of 1 g/kg body weight was not proved toxic in toxicology studies, the toxic dose of asiaticoside by intramuscular application to mice and rabbits was reported as 40 to 50 mg/kg body weight.[1]

Asiaticoside was implicated as a possible skin carcinogen when repeated applications were used in an experimental animal model.[56] Teratologic studies using the extract in rabbits proved negative.[23]

DRUG INTERACTIONS

There are no known drug interactions at this time.

Chinese Prepared Medicines

Mark Harrison Nolting, ND, EAMP

OUTLINE

INTRODUCTION

Chinese herbal medicine (CHM) is considered a key part of traditional Chinese medicine (TCM). TCM providers have spread across the world over the past 30 years in increasing numbers. As a result, those experienced in CHM have set up practices, become educators, established herb stores, and in some cases established growing operations and developed TCM trading companies.

This chapter focuses on one very popular and widely used segment of CHM: the Chinese prepared medicines (CPMs). These preparations were referred to as patent medicines for hundreds of years, then more properly as prepared medicines, and as the regulatory oversight of such products evolved (at least in the United States and Europe), as herbal supplements. The landscape of these "over-the-counter" (OTC) medicines (or supplements) is changing because of regulation, economics (large global profits), adulterants, endangered and extinct species, and basic supply and demand. Chinese "patent" medicines were exported from China to the tune of $160 million U.S. dollars in 2009, a growing number partly a result of the increased effort by the Chinese government to promote TCM globally.[1] The total value of exported traditional Chinese medicines in 2017 was $3.64 billion. Of that total, CPM exports had climbed to $250 million. That is just more than an 11% rise from 2016 and way up from the $160 million in 2009. The famous Tong Ren Tang TCM pharmacy company at the end of 2017 increased its international outlets to 140 in 27 different countries.[2] There was a sense in China (among some in the government) that the Chinese had lost ground over the years in the trading of herbal medicines and in the marketing of their traditional medicine. As the global herb market rapidly develops, China finds itself accounting for an increasing share of the market.[3]

East Asian medicine (EAM) is defined as a "medical system that arose in East Asia deriving from the traditional concepts of Qi and Yin-Yang Theory. EAM has developed various interventions such as acupuncture and moxibustion, massage and physical manipulation, diet therapy, herbal medicine, meditation and exercise."[4,5] Although acupuncture is the global face of Chinese or EAM, CHM is the therapeutic core. The "new face" of EAM is the hope, among Asian governments, "that high-volume screening and rigorous clinical trials will unlock the secrets of ancient herbal remedies and that the results will pass muster with Western scientists."[6]

The CHM (*Zhong-Yao* in Chinese pin-yin) pharmacy has evolved over many hundreds of years and is massive in scope and application, as the following "snapshot" of usage in China indicates:
Listed medicinal plants: 11,146
Animal drugs: 1581
Mineral drugs: 80
Processed remedies: 50
Clinically "proven" folk medicines: 5000
Traditional formulas: 84,464[7]

CHM is widely practiced across the world. In the United States, CHM is widely taught in most acupuncture school curriculums. However, for the most part, many students among the 62 (as of 2018) accredited schools in the country concentrate on acupuncture, with CHM as a secondary study,[8] but not all by any means. In California specifically, CHM is a major part of the study, licensure, and practice of acupuncturists.[8]

CPM is the OTC medicine of the traditional Chinese pharmacy, which includes thousands of various preparations of classic and conventional Chinese herbal formulas. Much of this medicine has been in constant use for hundreds, even thousands, of years, often maintaining original formulations.

One example is a frequently sold CPM called Jie Geng Wan (*Platycodon* root pills).[9] The source of this respiratory system medicine is the *Jing Kui Yao Lue Fang Lun* ("Synopsis of the Golden Chamber"), written by Zhang Zhong Jing in 219 A.D.[10] Zhu, writing in his highly useful and informative *Clinical Handbook of Chinese Prepared Medicines,* explained the following:

> *The overtaxed Sung-dynasty merchant, as well as the frazzled Ming mother, appreciated the simple convenience and economy of a well-prepared herbal pill, powder, or syrup as much as does his or her modern counterpart.*
>
> *Yan Bian Lian, the phrase commonly used when referring to these Zhong Cheng Yao ["Chinese Ready-to-Be-Taken Medicines"], may best express fundamental reason-for-being of ready-to-take medicaments in any tradition: "Effectiveness, Convenience, Economy."*[11]

Secret family (or company) recipes called patent medicines were first produced in the Song Dynasty (960–1234 AD) and were dispensed by government agencies, such as the Imperial Benevolent Prescriptions

of the Taiping Period.[12] Few true patent medicines exist anymore in the Chinese pharmacy. Many of these medicines have become part of the public domain, making it more appropriate to refer to them collectively as CPMs.

> *Keeping Chinese medicine formulae as trade secrets has led to some losses of knowledge and experience accumulated over generations. Drugs as well as dietary supplements are subject to regulations and disclosure requirements; it has become increasingly difficult for Chinese medicine (CM) practitioners to keep their prescriptions and treatment methods as trade secrets. In 1993 the Chinese government issued the Regulations on the Protection of Traditional Chinese Medicines which, to this date, provides administrative protection to certain prescriptions and manufacturing processes.*[13]

Unfortunately, there are too many dubious CPMs in the worldwide market that have been adulterated in various ways, some containing Western prescriptive medicines, toxic elements, and endangered species often hidden from the unsuspecting consumer.[14] In their quest for safe, natural, and effective medicine, consumers may find serious, unexpected medical consequences. This is an issue that deserves scrutiny by consumers, practitioners, and regulators alike. As with most natural products, CPM quality and purity are left to the discretion of the companies themselves.

Typical images of the U.S. "Wild West" include cowboys, American Indians, farms, and the frontier life. However, there was another, lesser-known presence in the West: the lives of Chinese immigrants. Many came to America seeking life on the "Gold Mountain," the view of America that had been created in China during the 1800s. According to Paul Buell, writing in his *Chinese Medicine on the Golden Mountain* book:

> *When in the midnineteenth century Chinese immigrants began to arrive in America, all kinds of traditional medical practitioners came with them; well-practiced Chinese medicine was often superior to contemporary western practice.*[15]

The immigrants, mostly men, left their families to mine for gold. Many ended up working as miners or other laborers. They brought with them their traditional form of Chinese medicine and their traditional herbal medicine, which included various forms of CPM. CHM is a highly evolved system of traditional medicine that draws from a *materia medica* composed of thousands of individual herbs (herbs in TCM include plant, mineral, and animal).[11,16] CPMs would generally be considered an adjunct to CHM in most practices because they are convenient and good alternatives to the strong, bitter-tasting decoctions often used in practice. Many practitioners, particularly in the West, prefer to use granulated Chinese herbs or powdered herbs.

Global Market

The market for CPMs is huge. More than 5000 "licensed patent medicines" are estimated to exist in China.[17] According to *China Today,* exports of CHMs worldwide reached $20 billion in 2002. About 5% of this amount was China's share, and prepared medicines comprised less than one-third of this. In China, the famous Tong Ren Tang factory, which exports the most CPMs in China, earned $14.5 million.[18] This amount continued to steadily rise into 2018.

Outside of the enormous "inside China market," the growing interest in and use of natural medicine worldwide are driving the consumption of prepared medicines rapidly upward. As mentioned previously, this growth has sparked abuse and problems with product labeling and safety that the entire profession is working to counteract.

Although Chinese medicine and pharmacy began to spread outside of China's borders nearly 2000 years ago, it is only in the past 30 years that interest has grown in North America. Much of this is a result of former President Richard Nixon's trip to the People's Republic of China in the early 1970s and subsequent reporters' visits and articles, especially those of James Reston of the *New York Times.* The growth of acupuncture and oriental medical practices, such as herbal medicine, in the United States has been steady since that time.

The traditional loose herb recipes used in CHM are cooked and made into medicinal soups, which are often bitter and difficult for the American palate. The Chinese solution to this dilemma was to increase the use of raw licorice in the formula and to offer sugar wafers to the patient to help offset the bitter taste, although most Chinese welcome a bitter taste as a normal part of Asian cuisine. The prepared medicines offer an alternative to traditional preparations. A number of companies, particularly in Taiwan and California, have begun to popularize the manufacture and sale of powder and tincture formulas in the single herb form to help "bridge" the traditional form and the prepared, more palatable, forms of medicine. This allows the practitioner to still use the traditional approach—that of mixing and adjusting the formulas tailored to the patient's individual diagnosis. Prepared formulas are fixed, of course, and do not allow any adjustments in the ingredients.

Before the mid-1970s, the U.S. Food and Drug Administration (FDA) restricted the import and sale of traditional medicines by ethnic groups. New legislation and court rulings since then have lifted these restrictions, which, coupled with the explosion of acupuncture on the American health scene, has opened the door to the spread of prepared medicines.[19]

Now, because of this rapid growth in the sale and use of prepared medicines, problems with adulterants and false labeling are increasing, especially in California, where a multiagency herbal medicine task force involving numerous California and federal government agencies was formed in response. The California Department of Health Services documents state that "most imported Asian patent medicines do not fully comply with California laws."[19] Although some of these violations are potentially dangerous and may involve toxic ingredients and the inclusion of endangered species, many involve labeling issues, which can often be sorted out by revising the labeling at the company of origin.

FORMULATIONS AND PREPARATIONS

CPMs are prepared in numerous different forms. As far back as 200 BC, Chinese pharmaceuticals had a surprising level of sophistication. Pills were bound together using a wide variety of animal and human substances.[20] Box 65.1 lists 15 of the most common dose forms of CPM. In China, prepared medicines are produced at factories located throughout the country. Reputation and awards are important to these mainland Chinese operations. Factories such as the Chongqing Tong Jun Ge Medicine Works in the Sichuan province, built in 1908, are proud of their products. This factory produces more than 200 medicines in 14 therapeutic categories.[20]

Roadside and rooftop billboards across China extol the benefits of "famous" CPMs and display the awards various formulas have received over the years. Longevity is an important virtue attributed to specific herbs and formulas in Asian medicine. Ginseng, in all its many species and preparations, is the most revered and used herb in China. The pursuit of longevity is central to its popularity, aside from the fact that it is a highly useful and effective herb. An interesting side note is that the American species of ginseng, *Panax quinquefolius,* is exported in great quantities to China, only to be repackaged and exported back to Western markets. American ginseng is considered a milder, more "supportive" ginseng in action, making it more suitable for the elderly and weak.

BOX 65.1 Common Dose Forms of Chinese Prepared Medicines

- Pills (honey, water, glue, extract)
- Paste
- Concentrated
- Powders
- Granules
- Pellet
- Tablets
- Syrup
- Mixtures
- Dripping pills
- Capsule
- Hard
- Soft extract
- Enteric
- Wine
- Tinctures
- Liquid extracts
- Plasters (adhesive)
- Ointments
- Medicinal distillates
- Tea
- Injections
- Suppositories
- Lozenges

Modified from the Pharmacopeia Commission of PRC. *Pharmacopeia of the People's Republic of China* (English edition), Vol. 1. Beijing: Chemical Industry Press; 1997:A3–A14; Chen JK, Chen TT. *Chinese Herbal Formulas and Applications. Pharmacological Effects & Clinical Research.* City of Industry, CA: Art of Medicine Press, Inc., 2009:16–18.

Ginsengs are part of the tonic herb family, a major classification that does not exist in the conventional Western pharmacy. The most famous factory for herbal medicine products in China is the Tong Ren Tang Pharmacy in Beijing. The Tong Ren Tang Pharmacy, first established in 1669, has been operated by the same family for more than 317 years. Prepared medicines produced in this factory have generally been held in the highest reputation in China, where the factory has supplied medicines to Chinese royalty over several centuries. The drug control acts implemented by the Chinese government in the 1970s and 1980s have helped further guarantee quality control of prepared medicines in China, and companies such as the Tong Ren Tang pride themselves on following these standards.[11] As noted earlier in this chapter, Tong Ren Tang has rapidly expanded its operations into many other countries. Indeed, the company is planning oversees factories and growing operations.

ADULTERANTS, ENDANGERED SPECIES, AND STANDARDS

The issue of adulterants and endangered species has increasingly threatened the reputation of CPM as safe and effective. The massive historical and growing contemporary usage of these products in Asia and the world often obscures these quality and ethical realities. The use of tiger bone, rhino horn, bear gallbladder, and seahorse are realities in a system of medicine that spans the centuries. Raising the consciousness of practitioners who grew up in that culture is the task of education to reshape that culture. Trafficking of illegal products is tied to big money, and separation between this practice and the legitimate market can be challenging. Western pharmaceuticals find their way into "herbal" products as "secret" ingredients that boost the effectiveness of the actions. Government control in the countries of origin is one thing, but controlling this globally, given widespread corruption and conflicting priorities, is a difficult task. The fundamental question remains: "Is the product purchased today in the Asian supermarket or local health food store free of adulterants and endangered species?"

Many prepared medicines made outside mainland China lack the same quality controls as the factories within China. Factories and sellers within China can be visited and found to have good-quality products determined to be safe and free of adulterants. In 1975 an herbal-based preparation called Toukuwan was manufactured in Hong Kong by the Nan-Lien Pharmaceutical Company and widely promoted in the United States as a treatment for rheumatism and arthritis. The FDA banned the importation of Toukuwan after it discovered four drugs, including valium, in the Chuifong preparation. Various prescription drugs have also been discovered in other prepared medicines. The *Journal of the American Medical Association* also reported four cases of agranulocytosis caused by prepared medicines in 1975, before the FDA ban. The Chuifong product has continued to appear under various names, such as "miracle herb," since 1975.[21,22] Caution must be used when purchasing and prescribing prepared herbal medicines, and we recommend using only well-known and reputable manufacturers.

If consumers are in doubt, we recommend using products produced at American, Canadian, or Australian companies, which typically are subject to far more quality control standards than those in Asia, and we suggest always consulting practitioners who research the origins of the various products they use and recommend.

In May 1994, Traffic USA and the World Wildlife Fund published "Prescription for Extinction: Endangered Species and Patented Oriental Medicines in Trade."[23] This report gave insight into the vast number of endangered species being used in natural medicine. The report indicated which products and traditional formulas contained endangered or threatened species, according to Appendices I, II, and III of the Convention on International Trade in Endangered Species (CITES) of Wild Fauna and Flora.[24]

Lu,[25] writing in the *China Daily,* described new European regulations in 2004 regarding the importation of CHMs into the European market. He stated the following:

> *The directive regulates that manufacturers who export herbal medicines to the EU market must get the union's GMP (Good Manufacturing Product) certificate, products quality must comply with EU pharmacopoeia, and importers should have import licenses.… But generally speaking, the directive, which for the first time grants TCM legal status as medicines, will benefit Chinese medicine makers to explore the European market in the future. Currently, most of the TCM products exported to the EU market are under the category of food, native produce, health products, or pharmaceutical ingredients, instead of medicine. Industry experts said that when one TCM product is registered as traditional herbal medicine in the EU, it indicates great market potentials. First, the market value of TCM will be greatly lifted compared to being sold as food or pharmaceutical ingredients. Second, the legal status as medicine would allow TCM to join EU countries' hospitalization insurance system. And EU's recognition of TCM will help reduce possible unfair treatment of Chinese medicines from other countries. Meanwhile, domestic makers should strengthen research and development, dismiss some ingredients which are unacceptable to western people, and develop products to cater for the huge European market.*

Hong Kong, long a stronghold of TCM despite a restrictive anti-TCM atmosphere under British rule, has upgraded its standards for Chinese herbs. The Chinese Medicine Council of Hong Kong was formed in 1999 to protect public health and consumers' rights and to ensure the professional standard of Chinese medicine practitioners and the trade of Chinese medicines. On the council's website, Shaw[17,26] discussed the trailblazing approach Australia took to create standards for the practice and sale of CHMs:

> *In that country [Australia], products were either "listed" or "registered." Listed products were of certified quality and were required to have supporting evidence of safety from the literature. No claims regarding efficacy could be made. Registered products equated to those with a license in the UK.*

Shaw also referred to the 1996 report "Towards a Safer Choice," which resulted from a review of the practice of TCM in Australia. The report concluded that regulation of CHMs and acupuncture practitioners was necessary and led to the Chinese Medicine Regulation Act of 1999, which set out statutory regulation for such practitioners in the state of Victoria. The intention was that regulation would eventually be brought in on a national scale. Shaw emphasized that this was being done for the benefit of the public, not practitioners.

Summing up, Shaw listed five elements for improving the safety of CHMs:

- Research into efficacy and safety
- Training of practitioners
- Quality herbs
- Adverse effect monitoring
- Appropriate regulation

Also on the council's website is a valuable list of safety concerns raised by Anderson[21] of the Hong Kong Medicines Control Agency, listed as follows:

- Lack of adequate authentication
- Intentional or accidental substitution
- Use of toxic substances and heavy metals (e.g., arsenic disulphide)
- Use of toxic animal materials (e.g., Bufo secretions)
- Use of synthetic drugs (e.g., corticosteroids, nonsteroidal anti-inflammatory drugs)
- Inadequate or inaccurate labeling

DISPENSARY GUIDE

CPM serves a number of different therapeutic purposes in and out of the practitioner's office. First and foremost, it is best prescribed within the principles of prescribing of traditional CHMs. For example, formulas for clearing heat or dispelling dampness require some understanding of the philosophy underlying these principles. If CHMs are just prescribed cookbook style, then individual patient reactions cannot be understood and tracked properly, and the full effect of the formulas will not be appreciated.

Secondly, CPM can augment and support traditional decoction-style prescribing. Thirdly, CPM is most valuable in acute prescribing and generally lends itself to OTC use. OTC use is best with input from trained Chinese medicine practitioners. In the case of Yin Chiao, described in the following, this widely used effective formula is most often prescribed at the onset of colds. Then there is the formula called Chuan Xin Lian (*Andrographis* anti-inflammatory tablets), which has tremendous effectiveness in inhibiting common bacterial infections, almost an "herbal antibiotic."[11] A final example of useful CPM in acute prescribing is the famous formula called Yunnan Baiyao. This is the most important CPM one should have at hand (according to general usage), at home and on the road. It is an emergency medicine stated as useful in all cases of injury. The signature of Yunnan Baiyao as traditionally dispensed involves little bottles of yellow powder with a tiny red "emergency" pill that is said to help revive critically injured individuals. Yang and Liang[27] described it as follows:

> *Yunnan Baiyao, literally meaning Yunnan White medicine, smells like a walk through an exotic forest. That's a clue to its composition: a dozen or so herbs from the southwestern flora-abundant province of Yunnan—but exactly which herbs remains a state secret. Successfully used for more than 80 years, Yunnan Baiyao, now available in several forms, is a veritable cure all and an essential, trusty family medicine in China.*

Because of the questionable standards of prepared medicines manufactured in Asia and generally outside China, it is suggested that practitioners scrutinize the labels of products from unknown sources or avoid them all together. With correct labeling, ingredients of prepared medicines should be obvious to anyone who can read Latin or Chinese herbal names.

In recent years, prepared medicine companies have become well established in the United States. Several high-quality manufacturers are now producing more suitable formulas. These tinctures, powders, and capsules are usually based on well-documented classic formulas.

Cimicifuga racemosa (Black Cohosh)

Michael T. Murray, ND, and *John Nowicki, ND*

OUTLINE

Cimicifuga racemosa (family: *Ranunculaceae*)
Common names: black cohosh, macrotys, rattleweed, black snake root

GENERAL DESCRIPTION

Cimicifuga racemosa is a perennial herb native to North America that grows on hillsides and in woods at higher elevations from Maine and Ontario to Wisconsin, Georgia, and Missouri. The large, creeping rhizome produces stems up to 9 feet high. The ovate or oblong leaflets are 1 to 6 inches long and 4 inches wide, whereas the smaller leaflets are ternate, then pinnate, and sometimes even further divided. Small, white, fetid flowers grow in long racemes from May to August (Fig. 66.1). The rhizome is the portion of the plant used for medicinal purposes.

CHEMICAL COMPOSITION

C. racemosa contains at least three important natural product groups that contribute to its pharmacology: cycloartane triterpene glycosides, such as actein and 26-deoxyactein; phenylpropanoid esters; and phenolic compounds, such as caffeic acid derivatives, including ferulic acid and isoferulic acid (Figs. 66.2 and 66.3).[1–3] Early reports showed that it also contained the phytoestrogen flavonoid formononetin, but more recent analysis demonstrated that this compound was not contained in either the crude herb or standardized extracts. At this point, despite extensive chemical, biological, and clinical studies, neither the active constituents nor the exact mode of action of black cohosh have been determined.[4] Currently, the standardization of cimicifuga preparations is based on the content of triterpene glycosides, calculated as 26-deoxyactein. Other important triterpene glycosides include actein and cimicifugoside (aglycone cimegenol).

HISTORY AND FOLK USE

The generic name *cimicifuga* comes from the Latin *cimex,* a bug, and *fugo,* "to drive away," alluding to its use as a vermifuge. Native Americans used cimicifuga rhizomes for the relief of pain during menses and childbirth, as well as snakebite. The rhizome of *C. racemosa* was listed in the National Formulary from 1936 to 1950 and in the U.S. Pharmacopeia from 1820 to 1936. Eclectic physicians in the early part of the 20th century used cimicifuga in gynecological disorders, as well as rheumatoid and myalgic pain.

Although use in the United States declined dramatically from 1950 to 1995, cimicifuga preparations were used extensively in Europe during this same period, primarily as a natural alternative to hormone replacement therapy (HRT) during menopause. This popularity was based on substantial empiric and clinical evidence.

PHARMACOLOGY

The primary pharmacological effects of cimicifuga appear to revolve around its ability to affect endocrine regulatory mechanisms.[5–8] In the past, this activity was thought to be related to various phytoestrogenic components of cimicifuga, with formononetin perhaps being the most significant.[9] However, this line of reasoning has been questioned by the lack of formononetin in clinically studied cimicifuga extracts, as well as equivocal reports on phytoestrogen activity. The current thinking is that certain cimicifuga components exert selective estrogen receptor modulator (SERM) activity with no action in the uterus but that beneficial effects do occur in the hypothalamo-pituitary unit and in the bone.[5,10,11]

Cimicifuga's primary effect on endocrine regulatory mechanisms appears to be the result of complex synergistic actions of its key ingredients. Evidence suggests that these compounds act on both the hypothalamus and vasomotor centers to produce significant clinical benefits in menopause. For example, one study to determine the endocrinological actions of cimicifuga extract involved treating 110 women with either cimicifuga extract (supplying a total daily dose of 8 mg of 27-deoxyactein) or placebo.[8] After 2 months of treatment, luteinizing hormone (LH) decreased by 20% in the cimicifuga group compared with the placebo group. Unlike estrogens, cimicifuga does not affect the release of prolactin and follicle-stimulating hormone. Researchers then divided the extract into three distinct types of active compounds based on their ability to reduce LH secretion in ovariectomized rats and to compete in vitro with 17-β-estradiol for estrogen receptor binding sites:

- Constituents that did not bind to estrogen receptors but did suppress LH secretion
- Constituents able to bind to estrogen receptor sites and to inhibit LH secretion
- Compounds that did bind to estrogen receptors but that did not inhibit LH secretion

The authors concluded that "the LH suppressive effect of *C. racemosa* extracts observed in menopausal women and ovariectomized rats is caused by at least three different synergistically acting compounds."

One of cimicifuga's key pharmacological effects is inhibition of the secretion of LH by the pituitary gland. This effect is accomplished equally by components that do and do not bind to estrogen receptors. If cimicifuga was simply mimicking the effects of estrogen, it would certainly alter the secretion of other pituitary hormones just like estrogen, but it does not. It appears that enhancement of dopaminergic activity is the responsible mechanism for some of these central effects on menopausal symptoms.[5,12]

Cimicifuga extracts also appear to exert some beneficial effects in preventing bone loss. In an experiment carried out on ovariectomized rats, cimicifuga extract increased the expression of collagen I and osteocalcin. Similarly, other animal studies demonstrated that cimicifuga extract significantly reduced the urinary parameters of increased bone metabolism and bone loss. The effects in these animal models were similar to raloxifene, a well-confirmed SERM.

Importantly, although early studies reported a direct estrogenic effect with cimicifuga, the current perspective is that ethanol and isopropanol extracts of black cohosh do not contain formononetin or other estrogenic flavonoids and therefore do not bind to the estrogen receptor, upregulate estrogen-dependent genes, or stimulate the growth of estrogen-dependent tumors in in vitro and animal models.[5,13,14] Black cohosh (8% triterpene glycosides) was shown to induce a concentration-dependent decrease in both estrogen receptor alpha (ERα) and progesterone receptor (PR-A/B) protein levels, supporting the potential of black cohosh as a preventative measure against breast cancer initiation and progression.[15]

A systematic review conducted on black cohosh use in women with or at risk of breast cancer concluded that evidence does not support an association between black cohosh and increased risk of breast cancer.[16] Interestingly, of the studies reviewed, two studies reported significant reductions in the risk of primary breast cancer among postmenopausal women (adjusted odds ratio = 0.47, 95% confidence interval; 0.27–0.82), and risk of recurrence (adjusted hazard ratio = 0.75, 95% confidence interval; 0.63–0.89). Seventeen trials showed no significant effect on circulating hormone levels or proliferation in estrogen-responsive tissues.

CLINICAL APPLICATIONS

C. racemosa extracts are by far the most widely used and thoroughly studied natural alternatives to HRT in menopause. Clinical studies showed that cimicifuga extracts relieved not only hot flashes but also depression and vaginal atrophy.[5,17–25]

Although evidence indicates that cimicifuga may provide benefit in other gynecological complaints, such as premenstrual syndrome, amenorrhea (both primary and secondary), dysmenorrhea, polymenorrhea, uterine fibroids, and fibrocystic breast disease, its primary clinical application is menopause.[24–27]

Menopause

In one of the first clinical studies, a large open study involving 131 doctors and 629 female patients, cimicifuga extract (two tablets twice a day, providing a daily dose of 4 mg 27-deoxyactein) produced clear improvement of menopausal symptoms in more than 80% of patients within 6 to 8 weeks.[20] As shown in Table 66.1, both physical and psychological symptoms improved. Most patients reported noticeable benefits within 4 weeks after the onset of cimicifuga therapy. After 6 to 8 weeks, complete resolution of symptoms was achieved in a large percentage of patients. Cimicifuga was well tolerated; there was no discontinuation of therapy, and only 7% of patients reported mild transitory stomach complaints.

In one of the first double-blind studies, 60 patients were given cimicifuga extract (two tablets twice a day providing a daily dose of 4 mg 27-deoxyactein), conjugated estrogens (0.625 mg/day), or diazepam (2 mg/day) for 12 weeks.[21] Results from standard indexes of menopausal symptoms indicated a clear advantage of cimicifuga extract over both drugs. Cimicifuga's effect on relieving depressive mood and anxiety associated with menopause was far superior to either diazepam or conjugated estrogens (Table 66.2).

TABLE 66.1 Cimicifuga in the Treatment of Menopause

Symptom	Percentage No Longer Present	Percentage Improved	Total Percentage Improved
Hot flashes	43.3	43.3	86.6
Profuse perspiration	49.9	38.6	88.5
Headache	45.7	36.2	81.9
Vertigo	51.6	35.2	86.8
Heart palpitation	54.6	35.2	90.4
Ringing in the ears	54.8	38.1	92.9
Nervousness/ irritability	42.4	43.2	85.6
Sleep disturbances	46.1	30.7	76.8
Depressive moods	46.0	36.5	82.5

TABLE 66.2 Effect on Kupperman Menopausal Index of Cimicifuga Compared With Conjugated Estrogens and Diazepam

Treatment Group	Beginning	At 12 Wk
Cimicifuga	35	14
Conjugated estrogens	35	16
Diazepam	35	20

One of the most used assessments in clinical studies in menopause is the Kupperman Menopausal Index. This quantitative assessment of menopausal symptoms is achieved by grading severity: severe = 3, moderate = 2, mild = 1, not present = 0. The symptoms assessed include the following:

- Hot flashes
- Depressive moods
- Profuse perspiration
- Feelings of vertigo
- Sleep disturbances
- Loss of concentration
- Headache
- Joint pain
- Nervousness/irritability
- Heart palpitation

The results of the Kupperman Menopausal Index from this trial clearly demonstrated cimicifuga extract's superiority over conjugated estrogens and diazepam, especially when safety and side effects were taken into consideration.

In another early double-blind study, 80 patients were given cimicifuga extract (two tablets twice a day, providing a daily dose of 4 mg 27-deoxyactein), conjugated estrogens (0.625 mg/day), or placebo for 12 weeks.[22] Cimicifuga produced better results in the Kupperman Menopausal Index, the Hamilton anxiety test, and the vaginal lining than estrogens or placebo. The number of hot flashes experienced each day dropped from an average of five to less than one in the cimicifuga group. In comparison, the estrogen group only dropped from 5 to 3.5. Even more impressive was the effect of cimicifuga on the vaginal lining. Although both conjugated estrogens and the placebo produced little effect, a dramatic increase in the number of superficial cells was noted in the cimicifuga group.

In a double-blind study of 110 women, cimicifuga extract (two tablets twice a day, providing a daily dose of 4 mg 27-deoxyactein) was shown to exert significant improvements in menopausal symptoms.[8] In addition to providing relief of hot flashes, cimicifuga once again demonstrated impressive results on the vaginal lining, as confirmed by vaginal smear.

In one study, 60 women less than 40 years old who had hysterectomies leaving at least one intact ovary received one of the following: cimicifuga extract (two tablets twice a day, providing a daily dose of 4 mg 27-deoxyactein), estriol (1 mg/day), conjugated estrogens (1.25 mg/day), or estrogen–progestin combination (Trisequens, one tablet a day).[23] Although the hormone therapies produced better results as determined by a modified Kupperman Menopausal Index, cimicifuga still displayed significant effects in relieving the symptoms of surgical menopause. These results indicated that cimicifuga could be a suitable alternative to estrogens in women having partial, and possibly even complete, hysterectomies.

In a double-blind study, cimicifuga extract was evaluated for its effect on menopausal symptoms, bone metabolism, and on the endometrium compared with those of conjugated estrogen and placebo.[24] The 62 postmenopausal women were treated with either black cohosh extract (40 mg/day), 0.6 mg conjugated estrogen, or matching placebo for 3 months. Results indicated that the black cohosh extract was equipotent to conjugated estrogen and superior to placebo in reducing menopausal complaints. Both black cohosh extract and conjugated estrogen produced beneficial effects on bone metabolism, but the black cohosh extract had no effect on endometrial thickness, which was significantly increased by conjugated estrogen. Vaginal superficial cells were increased with cimicifuga and conjugated estrogen treatment. These results seemed to confirm that cimicifuga extracts contain substances with SERM activity (i.e., with desired effects in the brain/hypothalamus, bone, and vagina, but without exerting uterotropic effects).

Women being treated with tamoxifen most often experience symptoms similar to menopause. To examine the effect of cimicifuga extract on hot flashes caused by tamoxifen adjuvant therapy in young premenopausal breast cancer survivors, 136 breast cancer survivors (ages 35–52 years) who had been treated with segmental or total mastectomy, radiation therapy, and adjuvant chemotherapy were randomly assigned to receive tamoxifen 20 mg/day orally or tamoxifen plus black cohosh extract (20 mg/day).[25] The duration of treatment was 5 years for tamoxifen, according to international standards for adjuvant therapies, and 12 months for the black cohosh extract. Follow-up included clinical assessment every 2 months; the primary goal was to record the number and intensity of hot flashes. Results indicated that almost half of the patients getting the black cohosh extract were free of hot flashes. Only 24.4% of patients taking black cohosh extract experienced severe hot flashes compared with 73.9% of the women taking tamoxifen alone. An isopropanolic extract of black cohosh was reviewed in a prospective observational study carried out in 50 patients with breast cancer with tamoxifen treatment. Patients were treated with one to four tablets (2.5 mg each) for 6 months and recorded their complaints before therapy and after 1, 3, and 6 months of therapy.[28] There was a statistically significant improvement in hot flashes, sweating, sleep problems, and anxiety, with 90% of participants reporting the tolerability of the black cohosh extract as good or very good.

A 2007 randomized, double-blind, controlled 3-month study was done in China, enrolling 244 menopausal women.[29] Women were assigned to either an isopropanolic extract of black cohosh containing 40 mg/day or 2.5 mg/day tibolone. There was a significant trend (57.08%) in the finding that women given Remifemin responded better than tibolone in terms of efficacy–risk balance, and black cohosh was clearly superior to tibolone if the safety profile for abnormal bleeding, endometrial thickening, breast pain, vaginal discharge, and edema was followed. Studies indicated that black cohosh might produce beneficial effects on bone metabolism by stimulating osteoblasts and may also have a weak effect on maturation of vaginal cells.[30,31]

Five studies showed no effect on menopausal symptoms with black cohosh use, including no effect on cognitive function.[32–36] Possible reasons included the use of an alcoholic extract versus an isopropanolic extract or the confounding health issues of the women studied.

Studies also evaluated the combination of black cohosh and St. John's wort. In one study, the mean Menopause Rating Scale score decreased 50% in the treatment group and 19.6% in the placebo group.[37] The Hamilton Depression Rating Scale score decreased 41.8% in the treatment group and 12.7% in the placebo group. In both measures, the results in the group using the St. John's wort and black cohosh were significantly superior to that of the placebo group.

Another black cohosh/St. John's wort trial was carried out in perimenopausal or postmenopausal Korean women.[38] Healthy perimenopausal women with typical climacteric symptoms and not on HRT for at least the previous 3 months were given a 264-mg tablet containing 0.364 mL of extract from black cohosh equivalent to 1 mg terpene glycosides and 84 mg of St. John's wort extract with 0.25 mg hypericin. Forty-two women in the treatment group and 35 women in the placebo group completed the study. Mean Kupperman index scores at 4 and 12 weeks were significantly lower in the treatment group ($P \leq 0.002$). At the end of the study, the average decrease in the Kupperman index score was 20 points in the treatment group and only 8.2 points in the placebo group ($P < 0.001$). Vaginal dryness and low libido were two symptoms that did not improve, but the average hot flash score was significantly lower in the black cohosh/St. John's wort group.

Despite some studies demonstrating no benefit of black cohosh, a meta-analysis of all nine placebo-controlled studies published until 2013 confirmed the reliable efficacy of *C. racemosa*–based medicinal products for menopausal symptoms.[39] The collective findings in black cohosh studies and long-term clinical anecdotal evidence on black cohosh indicate that it is most effective for menopause symptoms of day time or night time hot flashes, mood swings, sleep disorders, and body aches.

DOSAGE

The dosage of cimicifuga is based on its content of 27-deoxyactein, which serves as an important biochemical marker to indicate therapeutic effect. The dose of the cimicifuga extract used in the majority of clinical studies was 40 mg of black cohosh isopropanolic extract supplying 2 mg of 27-deoxyacteine twice daily. Approximate dosage recommendations using other (nonstandardized) forms of *C. racemosa* are as follows:

- Powdered rhizome: 1 to 2 g
- Tincture (1:5): 4 to 6 mL
- Fluid extract (1:1): 3 to 4 mL (1 tsp)
- Solid (dry powdered) extract (4:1): 250 to 500 mg

The German Commission E recommended that treatment with cimicifuga should be limited to 6 months (which is also the standard recommendation for HRT). However, this recommendation was made before detailed toxicology studies. Based on currently available data, cimicifuga is appropriate for long-term continued use.

TOXICOLOGY

The standardized extract of *C. racemosa* providing 1 mg of 27-deoxyactein in 40 mg of extract per tablet has been used in Germany since 1956 and has a remarkable safety record. A comprehensive review including preclinical and clinical research in estrogen-sensitive populations, including women at risk for breast cancer and breast cancer survivors, as well as human cell lines most relevant to breast cancer, confirmed this safety record. No serious side effects have ever been reported.[40] Cimicifuga offers a suitable natural alternative to HRT for menopause, especially when HRT is contraindicated (e.g., in women with a history of cancer, unexplained uterine bleeding, liver and gallbladder disease, pancreatitis, endometriosis, uterine fibroids, and fibrocystic breast disease).

Because cimicifuga extract shows some, albeit weak, estrogenic activity, researchers sought to determine Remifemin's effect on an established breast tumor cell line whose growth in vitro depends on the presence of estrogens. The results from these experiments showed no stimulatory effects, but rather inhibitory effects as well as an ability to promote apoptosis in these cells.[41,42] Furthermore, combining black cohosh with tamoxifen was shown to potentiate the inhibitory effects of tamoxifen.

In 2008 the Expert Committee of the U.S. Pharmacopeia's Council of Experts did an updated review of safety information for black cohosh.[43] Regulatory agencies in Australia, Canada, and Europe released statements and guidelines regarding the potential association between black cohosh products and hepatotoxicity. The committee analyzed human clinical case reports, adverse event reports, animal and toxicological data, historical uses, and regulatory status. Thirty reports on the use of black cohosh and possible liver damage were analyzed. All the reports of liver damage were considered to be possibly caused by black cohosh, and none were probable or certain. None of the animal toxicological or pharmacokinetic information revealed adverse information about black cohosh. The committee determined that the link between black cohosh and reports of liver damage was weak and "not of certain causality." They cited incomplete case information, unknown products, confounding variables (e.g., alcohol use

or concurrent medications), preexisting risk factors for liver damage, and no animal data or pharmacological data pointing to a mechanism of action that would cause a concern. Results of two meta-analyses of black cohosh confirmed these conclusions, finding no evidence of liver toxicity.[44,45] Despite these limitations, the increase in reports between 2002 and the present resulted in the committee's recommendation that black cohosh products should have a label with a cautionary statement, which is a change from the Expert Committee's previous decision.[43]

In 2012 black cohosh was nominated to the National Toxicology Program (NTP) for general testing by both the National Cancer Institute and National Institute of Environmental Health Sciences due to its widespread use and lack of human or animal studies in the published literature demonstrating its safety. In the study, female rodents (mice and rats) were given 0, 15 (rats only), 62.5 (mice only), 125, 250, 500, or 1000 mg/kg/day of black cohosh extract (BCE) by gavage for 90 days.[46] BCE induced dose-dependent hematological changes consistent with a nonregenerative macrocytic anemia and increased frequencies of peripheral micronucleated red blood cells indicative of chromosomal and hematological changes in both species. Both the chromosomal damage and hematological effects were more severe in mice than rats. Although this study provided the first comprehensive assessment of the subchronic toxicity of BCE in rodents, direct extrapolation of the results to humans is difficult because BCE preparations are variable natural mixtures of chemicals, with the potentially harmful compound(s) still unknown, and the dose used was significantly higher than a human subject would ingest. The lowest external dose that had an effect (62.5 mg/kg/day) was 125 times the recommended amount for daily human consumption (40 mg or ~0.5 mg/kg/day for a 70 kg human). Another research group conducted a study to investigate the potential of a functional cobalamin or folate deficiency as a possible explanation for the hematological changes observed in the NTP BCE subchronic toxicity study.[47] Female mice were exposed to 1000 mg/kg BCE for 92 days. The study confirmed the previous findings from the NTP study, in that exposure to BCE caused a decrease in the red blood cell count with an increase in MCV and MCH. In addition, although folate and cobalamin levels were unchanged, two biomarkers that are used for diagnosis or confirmation of folate and cobalamin deficiencies, homocysteine and MMA, were both elevated. The authors concluded that these findings suggested a BCE-induced functional deficiency of cobalamin, and possibly folate.

DRUG INTERACTIONS

As discussed previously, there is concern that black cohosh might harm the liver. Taking black cohosh along with medication that might also harm the liver requires proper monitoring.

Citicoline (CDP-Choline)

Alexander G. Schauss, PhD

OUTLINE

INTRODUCTION

Citicoline (cytidine-5′-diphosphocholine; CDP-choline) is an endogenous mononucleotide, composed of ribose, cytosine, pyrophosphate, and choline, and an essential precursor for the synthesis of neuronal plasma membrane phospholipids, important as a rate-limiting step in phosphatidylcholine synthesis (Fig. 67.1). Citicoline can also be an exogenous source for the synthesis of acetylcholine, a key neurotransmitter, and is a member of the group of molecules that play important roles in cellular metabolism, such as nucleotides that form the basic structural units found in nucleic acids.[1]

Kennedy and colleagues first identified citicoline in 1955[2] and synthesized it in 1956. Since then it has been studied extensively in Europe, Japan, and the United States.

There are two forms of citicoline available as either a dietary supplement ingredient or as a pharmacotherapeutic: citicoline sodium and citicoline free-base. Whereas citicoline free-base has been available as a dietary supplement in the United States for three decades, citicoline sodium is primarily used in other countries as a drug or para-drug for the treatment of neurological disorders. Citicoline is also available for intravenous use and as a topical in solution, for use as eye drops.

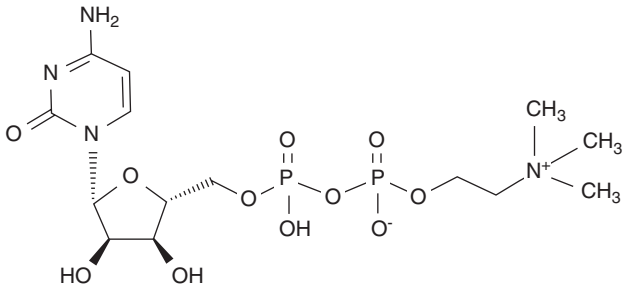

Fig. 67.1 Structure of citicoline.

Citicoline Versus Choline

Choline is a component of the diet and is produced in the brain, albeit in small amounts (Fig. 67.2). Because of its low endogenous production, it is considered an essential nutrient and classified with the B-vitamin complex. It plays several essential roles in human physiology, including enhancement of structural integrity and signaling for cell membranes; supporting acetylcholine synthesis; and the synthesis of betaine, a methyl donor.[3]

When taken orally, citicoline is hydrolyzed in the intestinal tract and in the circulation to form choline and cytidine, which is the nucleoside of cytosine. Citicoline provides the brain with a source of choline and cytidine, which are efficiently used in the Kennedy cycle to generate phospholipids. Although choline on its own is preferentially used for the synthesis of acetylcholine, cytidine is highly efficiently used in the brain for the synthesis of various nucleotides. Studies in neuronal cell lines showed that cytidine administration increased the incorporation of choline into membrane phosphatidylcholine.[4]

In terms of safety, choline is a substance with a low level of toxicological concern. Administering choline with cytidine, in the form of citicoline, lowers the toxicity index by twentyfold.[5] Furthermore, citicoline administration is significantly different from the administration of choline in cases of cerebral ischemia caused by stroke and other

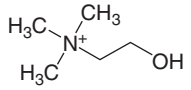

Fig. 67.2 Structure of choline.

conditions. Citicoline's therapeutic effects in such conditions stem from its ability to:

1. increase the synthesis of phosphatidylcholine, the primary component of neuronal membranes. Beyond phosphatidylcholine action in maintaining phospholipid metabolism, one of its mechanisms of action is to restore and preserve the structure/function integrity of neuronal membranes after an acute ischemic stroke or brain damage from traumatic head injuries;
2. enhance acetylcholine synthesis, thereby ameliorating the symptoms resulting from ischemic loss of cholinergic neurons;
3. promote the synthesis of several other membrane phospholipids, including phosphatidylethanolamine and phosphatidylserine, to contribute to the repair and regeneration of axons and synapses;
4. serve as agonists at nicotinic acetylcholine receptors, which play a critical role in maintaining normal cognition; and
5. prevent the accumulation of free fatty acids and generation of free radicals at the site of ischemia, thereby preventing the initiation of a proinflammatory cascade of events. However, as will be discussed in this chapter, citicoline has also been studied for its effects on eye health and visual function, substance abuse, infectious diseases, and metabolic diseases.

BIOAVAILABILITY/PHARMACOKINETICS

The pharmacokinetics of an oral dose of ^{14}C-labeled citicoline has been studied in humans. Administration of a single 300-mg dose to healthy adults was shown to have nearly complete absorption, with less than 1% of the labeled compound found in feces after a 5-day collection period. Absorption of citicoline gave rise to two chromatographic peaks in concentrations of radioactivity in plasma, the first at 1 hour and the second, larger peak at 24 hours after dosing. The main route of excretion was found to be via respiratory carbon dioxide, with significant excretion also occurring through urine. After 5 days, 16% of the administered dose was recovered, suggesting that the remainder was incorporated into tissues or was available for biosynthetic and biodegradative pathways.[6] Fig. 67.3 reports the metabolic pathways of citicoline.

A pharmacokinetic study in rats using ^{14}C-methyl-labeled citicoline confirmed almost complete absorption with oral administration, with calculated oral bioavailability being approximately 92% of that obtained from intravenous (IV) dosing. The absorption was categorized as slow and complete with sustained blood levels, the highest being at around 5.5 hours after administration. Radioactive labeling found citicoline and its metabolites widely distributed throughout tissues, including distribution of metabolites to the brain, confirming their ability to participate in the synthesis of phospholipids.[7]

A confirmatory study, again using radiolabeled citicoline in rats, found 62.8% of total radioactivity was distributed in brain tissue as phospholipids, including phosphatidylcholine and sphingomyelin. These results suggested that metabolites of orally administered citicoline were available in the brain for resynthesis of endogenous citicoline.[8] Although only a small percentage of the total citicoline dose crosses the blood–brain barrier as choline and cytidine, the utilization of these precursors in brain tissue for phospholipid biosynthesis is extremely efficient.[4]

A rapid liquid chromatography-electrospray ionization-tandem mass spectrometry (LC-ESI-MS/MS) method has been developed and validated for the pharmacokinetic investigation of choline, the active metabolite of citicoline in human plasma.[9] The method was effectively applied for evaluation in a study of the pharmacokinetic parameters and bioequivalence of citicoline administered to 12 healthy male volunteers.

MECHANISM OF ACTION

Much remains to be learned of citicoline's mechanisms of actions and biotransformation.[10] Much of the evidence shows that citicoline is sequentially hydrolyzed and dephosphorylated to uridine (in humans) and choline.

Citicoline has several important mechanisms of action, leading to a broad range of beneficial effects on neurological function. In cerebral ischemia, citicoline primarily acts by increasing the synthesis of phosphatidylcholine, the primary neuronal membrane phospholipid, and enhancing the production of acetylcholine. Oral citicoline administration increases plasma levels of choline and cytidine, which are building blocks used to restore neuronal membrane integrity.[5] These effects, in addition to apoptosis inhibition, neuroplasticity potentiation, acetylcholine (Ach) and phospholipid synthesis, contribute to our understanding of the mechanism of action that has demonstrated beneficial effects both in degenerative and vascular cognitive decline.

Interestingly, citicoline seems to have differential effects on phosphatidylcholine synthesis in younger versus older adults. Phosphatidylcholine is an essential compound for cell membrane integrity and repair. It is normally reduced in brain cell membranes as a result of aging. A study using protein magnetic resonance spectroscopy to measure brain concentrations of cytosolic choline-containing compounds before and after a single oral dose of citicoline found that the choline resonance in the brain of younger individuals increased,

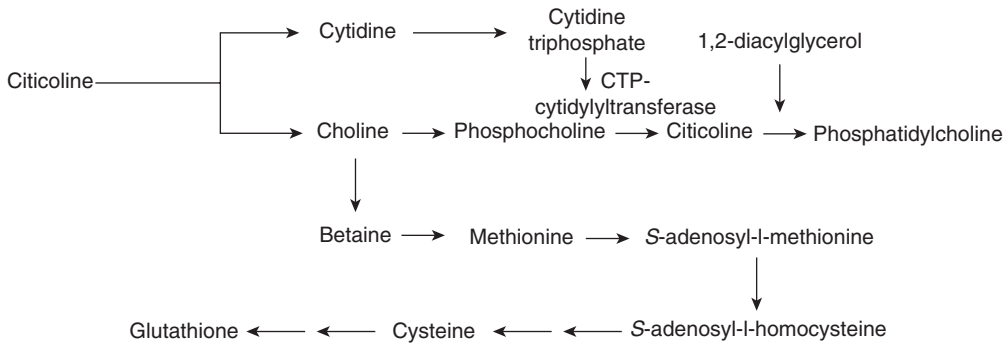

Fig. 67.3 Metabolic pathways of citicoline. (From ResearchGate. The role of citicoline in cognitive impairment: Pharmacological characteristics, possible advantages, and doubts for an old drug with new perspectives. <https://www.researchgate.net/Citicolines-metabolic-pathways-Abbreviation-CTP-cytidine-triphosphate_fig2_280776646>. Accessed August 22, 2018.)

whereas it decreased in older subjects. It was presumed that the cytidine component of citicoline enhanced the incorporation of brain choline into neural cell membrane phosphatidylcholine in older subjects, resulting in the decrease.[11]

The ability of citicoline to stimulate brain phospholipid synthesis in humans was further supported by studies showing that healthy subjects consuming 500 mg/day orally of citicoline for 6 weeks had increased levels of phosphodiesters in brain tissue, such as glycerophosphocholine and glycerophosphoethanolamine, as assessed by phosphorus magnetic resonance spectroscopy. These findings supported citicoline's ability to increase phosphatidylcholine synthesis.[12] Findings from a study of healthy middle-aged adults confirmed these results but suggested that the increase in phosphorus metabolites attributed to citicoline intake was regionally specific, with the frontal lobe being the preferred site of deposition, ultimately enhancing frontal lobe energetics and improving phospholipid membrane turnover. This area of the brain contributes to memory function by supporting vigilance, attention, and working memory capacity and by reducing mental fatigue. Because citicoline's effect was most prominent in this brain region, this is a likely explanation for its clinical benefit of improved cognitive function.[13]

Citicoline may further benefit patients experiencing ischemia by decreasing the accumulation of free fatty acids at the site of the lesion, which occurs as a result of neuronal cell damage and death. Soon after initiation of ischemia, there is a significant increase in proinflammatory arachidonic acid, glycerols, and free fatty acids, caused by the breakdown of neuronal membranes. Toxic metabolites, prostaglandins, thromboxanes, and free radicals, can accumulate, leading to further damage. Animal studies showed that intracerebral administration of citicoline before the induction of ischemia reduced the increase in free fatty acids, arachidonic acid, and other toxic metabolites, attenuating free radical damage and restoring membrane function.[5]

Some evidence points to the ability of citicoline to normalize neurotransmitter release patterns. In conditions of cerebral hypoxia, which exist in ischemia, norepinephrine release may decrease, whereas the release of dopamine may increase. In several animal models, citicoline was shown to inhibit the impairment of neurotransmitter release in hypoxic conditions. Furthermore, citicoline administration to rats kept in a chronic hypoxic state reduced behavioral deteriorations and increased survival time. Additional studies found that citicoline was able to increase the dilation of blood vessels in animals with cerebral microcirculation injury, significantly increasing cerebral blood flow.[4]

Citicoline shows neural restorative effects, presumably via action on the dopaminergic system of the central nervous system. Rats with substantia nigra lesions were shown to regenerate nerve cells after treatment with citicoline, indicating its protective effect in this region. Further studies found that citicoline administration to rats increased striatal dopamine synthesis. Several other investigations in animal models yielded evidence of citicoline's ability to enhance dopaminergic synthetic pathways.[4] This was a result of the activation of tyrosine hydroxylase and inhibition of dopamine reuptake, which is related to citicoline's activity on phospholipid synthetic pathways. Citicoline is also known to have effects on serotonin and norepinephrine.[14] Studies in rats showed that citicoline improved learning and memory capacity and enhanced motor performance and coordination in aged rats. These findings provided further evidence for citicoline's cholinergic activity.[15]

Studies have suggested that citicoline enhances the preservation of an inner mitochondrial membrane component known as cardiolipin, which is important for the preservation of mitochondrial function. Citicoline facilitates the preservation of sphingomyelin, which promotes signal transduction in nerve cells. Citicoline exhibits direct antioxidant effects; research has shown that it has an ability to stimulate glutathione synthesis and the activity of the enzyme glutathione reductase. Furthermore, citicoline attenuates lipid peroxidation. These downstream effects may be attributable to citicoline's larger function of attenuating the activation of phospholipase A_2, thus reducing inflammation in neural tissues and in general.[16] Citicoline was shown to have direct free radical suppressive effects, as seen in animal models of transient cerebral ischemia, in which citicoline had a suppressive effect on hydroxyl radical generation.[17]

Citicoline may significantly affect brain-remodeling activity. In an animal model, citicoline treatment significantly increased the length and branch points of dendrites, which led to increased efficiency of sensory information processing.[18] This mechanism of action could potentially account for a significant portion of citicoline's neurorestorative functions.

Diminished auditory sensory gating and associated cognitive deficits in schizophrenia have been studied relative to treatment with citicoline. In a randomized, placebo-controlled, double-blind design involving oral administration of 500 and 1000 mg of citicoline to 24 healthy volunteers assessed for auditory gating and for executive function, improvements were seen at the low dose.[19] The effectiveness of the lower dose of 500 mg was confirmed in a second study of schizophrenic patients using a randomized, placebo-controlled, double-blind design. In this study the orally administered dose was 500, 1000, and 2000 mg. As was found in the study of healthy subjects, the 500-mg dose was found to have a demonstrated treatment effect in increasing the suppression of P50 event-related potential (ERP) consistent with an α-7 nAChR mechanism.[20]

Choline is a selective α7-nAChR agonist. Twenty-four healthy male volunteers (mean age, 21.3 ± 0.99 years) were recruited to participate in a randomized, placebo-controlled, double-blind, crossover clinical trial to determine whether citicoline single dose administration of either 500 or 1000 mg would increase sensory gating and cognition. Citicoline exhibited changes in electroencephalographic (EEG) oscillations similar to those reported with nicotinic agonists and was observed to improve gating (1000 mg) and suppression of the S2 P50 response (500 and 1000 mg), with the effect being selective for individuals with low gating (suppression) levels.[21] These results have implications for cognitive treatments focused on specific functional roles such as coding of sensory information and cognitive disorders related to cortical and thalamic structural pathologies at sites with the highest α7-nAChR expression, seen in schizophrenia. The crossover trial also used EEG recordings to elucidate citicoline's mechanisms of action 4 hours after a single administration of either dose. Citicoline enhancement in the brain was found to facilitate multiple mechanisms, among which is its ability to facilitate nicotinic cholinergic activity (i.e., altered expression of the α-7 nicotinic acetylcholine receptors [nAChR]).[21]

To evaluate citicoline induction of an oscillatory response profile associated with nicotinic stimulation, a resting-state EEG is acquired to test the hypothesis. This kind of study was carried out in a pilot randomized, double-blind, placebo-controlled trial with 24 subjects, which showed that citicoline enhanced cognitive function.[19]

CLINICAL APPLICATION

Learning and Memory

Experiments in animals and humans provided evidence of citicoline's ability to promote important cognitive processes, including learning ability and memory functions. Clinical studies evaluating citicoline administration for cognitive enhancement have been conducted for several decades. A review of trials using citicoline as a treatment for senile alterations of memory in 1991 found significant benefits

in patients with cerebral insufficiency and chronic cerebrovascular disease.[22]

A randomized, double-blinded, placebo-controlled study was undertaken to assess the effects of citicoline supplementation on verbal memory function in 95 healthy subjects aged 50 to 85 years (47 women and 48 men) who were administered citicoline (500 mg orally twice daily) or placebo for 3 months. The study subjects were well educated (mean, 14.3 years of education). Baseline testing included a logical memory assessment test, which was used to classify those with relatively inefficient memories. At the end of the initial study, 32 individuals (16 from the citicoline group and 16 from the placebo group) from this pool were recruited to participate in a follow-up crossover study. The initial study found that citicoline improved delayed recall for only those with relatively inefficient memory at the beginning of the trial. In the follow-up crossover study, the dose of citicoline was increased to 2000 mg/day. In this subgroup, the higher dose of citicoline improved immediate and delayed logical memory.[23]

An open-label crossover trial consisting of 24 elderly individuals without dementia but with demonstrable memory impairment (assessed by comparison with 24 healthy young control subjects), showed that oral citicoline (500, 1000, or 300 mg/day combined with nimodipine [90 mg/day]) significantly improved memory performance compared with the no-treatment periods, as evidenced by reduced error scores on word recall tasks, immediate object recall, and delayed object recall.[24]

Attention

Attention and mental alertness play an important role in supporting cognitive function and performance. Attention is the cognitive process of selectively concentrating on discrete information. Paying attention is the first step in the learning process, especially the ability to focus attention at the right time on what is important and simultaneously ignoring irrelevant information occurring at the same time. Animal studies have shown that citicoline can enhance learning and memory.[25,26]

In a study using proton magnetic resonance spectroscopy to measure in vivo brain chemistry, investigators found that 3 hours after a single oral dose of citicoline was given to participants, plasma choline levels increased in younger and older adults. These results are particularly important to older adults because in this study, the investigators found that intracellular cytidine levels increased after the administration of citicoline, leading to increased incorporation of choline already present in the brain into membrane phosphatidylcholine.[11]

Citicoline may benefit healthy individuals by improving attentional ability. To test this hypothesis, a randomized, double-blind, placebo-controlled trial was carried out in 40- to 60-year old healthy females. Subjects were given either 250 or 500 mg/day for 28 days, or placebo. The groups receiving citicoline exhibited improved cognitive attentional performance by committing significantly fewer commission errors on the Conners' Continuous Performance Test II (CPT-II) compared with the placebo group.[27] A similar study was performed in healthy male individuals ranging from 13 to 18 years of age, in which either 250 or 500 mg/day of citicoline was administered, or placebo, for 28 days. Significant improvements in attentional task and motor function were measured.[28]

In a study by Bruce and colleagues, when citicoline was combined with caffeine to create a citicoline-caffeine based beverage, a generalized improvement in the ability to accommodate new and relevant information within working memory and sustained attention was seen, in addition to overall enhanced brain activitation.[29] The 8 ounces (227 g) of the beverage, containing 35 mg of caffeine and 250 mg of citicoline, or an identical placebo beverage without the caffeine-citicoline blend, was randomly given to 60 healthy adult participants (33 women and 27 men; $M = 24.2$) enrolled in a randomized, double-blind, placebo-controlled trial. Both measures of electrical brain activity using EEG 30 minutes after consuming the beverage and neuropsychological measures were used to measure electrical brain activity and neuropsychological performance changes in working memory, attention, behavioral inhibition, and executive functioning.

The observed increase in electrical brain activity seen in the Bruce study is in agreement with another study of a different beverage containing citicoline performed by the same lead author. In this study, 250 mg of citicoline was combined with lycopene, caffeine, and vitamin E.[30] Ten healthy adults (five women and five men; aged 25–32, $M = 28.1$) participated in a double-blind, placebo-controlled, crossover trial. Subjects undertook a noninvasive EEG that measured concomitant changes in ERPs in response to a range of cognitive tasks. The experimental activation tasks were designed to reflect the brain's core adaptive competencies and underlying neural networks. Thirty minutes after consuming 8 ounces of the beverage, EEG and ERP indices were significantly modified compared with the brains of the placebo group.

Alzheimer's Disease and Dementia

Citicoline supplementation has been well studied in Alzheimer's disease and vascular dementia. A study of 19 patients (mean age, 66.21 ± 1.48 years) given oral citicoline at a dosage of 1000 mg/day for 30 days found significant improvements in cognitive function in the subgroup of patients with early-onset Alzheimer's disease and a trend toward increased cognitive function in the overall group, as assessed by brain electrical mapping. Brain spectral data readings provided an indication that the brains of early-onset Alzheimer's patients showed greater damage than those of late-onset Alzheimer's patients, whereas both groups had the same degree of cognitive impairment. It was postulated that the therapeutic effects of citicoline might be mediated by an enhancement of cholinergic neural transmission, activation of repair mechanisms to rejuvenate neuronal membranes, a regulatory effect on parameters associated with blood flow and circulation, and the regulation of several immunological responses, which, if left unchecked, would lead to potential neuronal dysfunction and cell death.[31]

In further studies, oral administration of citicoline (1000 mg/day) to 20 patients (age range 57–78 years) with early- or late-onset Alzheimer's disease resulted in improvements in mental function, particularly in the early-onset group. This 1-month treatment with citicoline resulted in an increased blood-flow velocity from baseline measures (assessed by transcranial Doppler ultrasound) in the middle cerebral artery, which has been found to decrease with age, possibly resulting in neuropathologic changes. Citicoline's cholinergic effects and influence on cytokine production might also partially account for its benefits.[32]

Researchers investigated the regulatory effects of citicoline on blood histamine levels. Alterations in the histamine system are present in Alzheimer's disease, and high levels have been found in several central nervous system regions, cerebrospinal fluid, and serum. Histamine may also participate in the aging process, with histamine-related changes reported in several different tissues, including the central nervous system. In one study, 14 individuals with Alzheimer's disease (7 early onset, 7 late onset) were administered citicoline (1000 mg/day for 30 days). Blood histamine measurements were taken at baseline, at 2 hours after administration of the first dose, and after 30 days of treatment with citicoline. All participants experienced an acute reduction in blood histamine levels; after 30 days, early-onset Alzheimer's patients saw a decrease in blood levels of histamine of about 55% compared with baseline, whereas late-onset individuals saw a 45% decrease.

Early-onset patients clearly had higher baseline levels of histamine than late-onset patients. Reducing endogenous histamine excesses may support cognitive function because excessive histamine levels have been implicated in etiopathogenic events in Alzheimer's disease.[33]

The effects of citicoline administration (1000 mg/day orally for 3 months) were assessed in a trial in patients with senile dementia (Alzheimer's disease and multiinfarct dementia) to elucidate whether the nutrient was able to restore immune function and improve mental parameters. The study consisted of four groups: control subjects (n = 8), early-onset Alzheimer's subjects (n = 11), late-onset Alzheimer's subjects (n = 7), and multiinfarct dementia subjects (n = 10). After 3 months of treatment, citicoline supplementation improved mental performance in all groups (including controls), as assessed by several standard assessment tools (including the Mini-Mental State Examination and the Hamilton Rating Scale for Depression). Patients with early-onset Alzheimer's showed increased levels of interleukin-1β at baseline. Citicoline administration normalized these levels in the early-onset Alzheimer's group. The researchers concluded that citicoline showed benefit in senile dementia patients as a restorative and palliative treatment, improving vascular risk factors, stabilizing immune function, and improving mental performance.[34] Further studies corroborated these effects of citicoline.[35]

Citicoline was further studied in a double-blinded, placebo-controlled randomized trial in 30 patients with apolipoprotein-E (Apo-E) genotyped Alzheimer's disease. All 30 participants were categorized as having mild to moderate dementia. Citicoline (1000 mg/day orally) or placebo was administered daily for 12 weeks, and its efficacy was further evaluated on the basis of each of the individuals' Apo-E genotype. The development of certain symptoms of Alzheimer's disease is correlated with differing Apo-E genotypes. The results of the study showed that clinical interview-based impression of change scores worsened significantly in the placebo group, whereas a clear trend toward improvement in the citicoline group was observed. In those individuals bearing the ε4 allele of the Apo-E (Apo-E4), citicoline was found to induce significant improvements on the cognitive function subscale of the Alzheimer's Disease Assessment Scale. Furthermore, statistically significant improvements in Alzheimer's Disease Assessment Scale scores were found with citicoline administration in the subset of Apo-E4 patients with mild cognitive deterioration (as assessed by Geriatric Depression Scale scores of less than 5). An overall increase in cerebral blood flow velocity was also seen with citicoline compared with placebo, whereas beneficial changes were further noted in brain bioelectrical activity.[36] Recently two clinical studies were published on the effect of citicoline coadministered with cholinesterase inhibitors. In a retrospective, multicenter case-control study in Italy, involving 448 consecutive patients aged 65 years old or older affected with Alzheimer's disease, 197 patients were treated with an AChEI and 251 were treated with an AchEI + citicoline 1000 mg/day given orally. Patients treated with citicoline plus an AChEI showed a statistically significant increase in Mini-Mental State Examination (MMSE) and slowing disease progression.[37] The CITIRIVAD study was a retrospective case-control study on 174 consecutive outpatients aged 65 years or older affected with Alzheimer's disease (AD) or mixed dementia (MD). Of the 174 patients, 92 had been treated with rivastigmine + citicoline 1000 mg/day given orally; 82 patients had been treated with rivastigmine. Data show the effectiveness of combined administration versus the AchEI alone, mainly in slowing disease progression and consequently in disease management, both in AD and in MD.[38]

In a number of studies, coadministration of citicoline with prescription drugs has been proposed to lead to a greater increase in intrasynaptic levels of Ach than when either is given alone. Such a demonstration was reported in a retrospective multicenter case-control study of 448 patients aged 65 years of age or older with AD, of which 197 patients were treated with acetylcholinesterase inhibitors (AChEIs) and 251 were given AChEIs and 1000 mg/day of citicoline orally. Multiple functional cognitive assessments showed significant improvements of the combined administration after 3 and 9 months compared with AChEIs alone.[37] Similar results were reported in the CITIRIVAD study, a retrospective case-control study on 174 patients aged 65 years or older affected with AD or MD (mean age, 83.3 ± 4.5 yrs). In this study, 92 patients were treated with rivastigmine (an acetylcholinesterase inhibitor) and 1000 mg/day of citicoline, and 82 patients were treated with the ACHEIs alone. In both groups, a rivastigmine patch at the highest tolerated dosage had been used by the patients for at least 6 months. Multiple functional tests for cognition were administered to assess changes in both groups. The study found that the combination was well tolerated and that combined administration was effective in slowing disease progression and improving disease management.[38]

Parkinson's Disease

Citicoline may also benefit individuals with Parkinson's disease. Citicoline was administered by intramuscular (IM) injection to 20 patients (aged 52–76 years) at a dosage of 1000 mg/day for 15 days, followed by 500 mg/day for an additional 15-day period. (All of these patients received levodopa alone or in combination with other drugs before and during the trial.) The patients had improved scores on the Columbia Rating Scale (one of several validated and reliable rating tools for disability in Parkinson's[39]) by 7.3%, and also had measurable improvements in rigidity, time to walk 10 meters, time to turn over, and handwriting test scores. Results from a self-assessment revealed that symptomatology was improved in 15 of the 20 patients, including improvements in speech, gait, posture, tremor, agility, and slowness of movements. Five patients showed minor improvements in dyskinesia; however, this was otherwise unaffected by citicoline treatment.[40]

Additionally, citicoline has a levodopa-sparing effect and an ability to increase dopamine synthesis. In one trial, 85 Parkinson's disease patients were randomly assigned to two groups: patients received either their usual dose of levodopa (mean 381 mg/day) or half their usual dose (mean 196 mg/day). Both groups were simultaneously administered 1200 mg citicoline (400 mg orally three times daily); it was found that the group consuming half of their usual levodopa dose plus citicoline had significant improvements at week 6 (which was the end of the fourth week of citicoline administration) on the Webster Rating Scale, a measure of neurological and clinical symptoms. This trial indicated that citicoline has the ability to compensate for the reduction of levodopa dosage, potentially contributing to a reduction in side effects associated with long-term levodopa usage.[41]

A similar trial was performed in 30 individuals with Parkinson's disease in which the participants were treated with levodopa and concomitantly received 500 mg of citicoline by IM injection daily for 30 days. Significant improvements in neurological signs were noted (including moderate improvements in facial expression and digital skill and marked improvements in the ability to rise from a seated position, posture, and gait) in addition to improvement in certain electrophysiologic parameters. An increase in dyskinesia was noted as a side effect in this group. In the second phase of the trial, the levodopa dosage was reduced by one-third. This decrease restored the incidence of dyskinesia to pretreatment levels, whereas the therapeutic response remained stable.[42]

An additional double-blinded, placebo-controlled, crossover design trial, in which citicoline (500 mg/day IM) or placebo was administered to 30 Parkinson's disease patients already on levodopa and a dopa decarboxylase inhibitor found that citicoline induced improvements in bradykinesia. There was a 26.97% improvement from baseline on the

Webster Rating Scale. This improvement was highly statistically significant compared with baseline and compared with placebo. Significant improvements in rigidity were also noted with citicoline treatment, whereas no such improvement occurred with placebo.[43]

Stroke and Cerebral Ischemia

Stroke is one of the leading causes of physical disability and contributor to vascular cognitive impairment and vascular dementia that can significantly affect a patient's quality of life. Multiple trials have shown positive benefits after citicoline administration in patients who have suffered a stroke because of cerebrovascular ischemia.[44]

In one study, investigators conducted a multicenter, double-blinded, placebo-controlled trial to evaluate the efficacy of oral citicoline administration in patients who experienced an acute cerebral infarction. The study consisted of 272 patients with a confirmed diagnosis of cerebral infarction and a mild to moderately impaired level of consciousness. Patients were randomly assigned to receive either 1000 mg/day of citicoline administered intravenously or a placebo for 14 days. When these acute stroke patients were assessed at days 7 and 14, citicoline treatment resulted in significant improvements in the level of consciousness and neurological status.[45]

In a second multicenter, randomized trial conducted in the United States (the US Citicoline Stroke Treatment Study), positive results were reported for patients who experienced an acute stroke. Treatment was initiated within 24 hours of stroke onset with citicoline for 6 weeks, and patients were assigned to one of three dose groups that were administered either 500, 1000, or 2000 mg/day, then compared with a placebo group. The Barthel Index, an ordinal scale that assesses functional independence in stroke patients, was used as the primary outcome measure to assess functional improvement. In the 500-mg/day citicoline group, the odds ratio for improvement was 2.0, and in the 2000-mg/day group, the ratio was 2.1, signifying that individuals in these groups were twice as likely to achieve higher Barthel scores than those in the placebo group. Overall, the results showed that either 500 or 2000 mg/day of citicoline significantly improved functional recovery after 6 weeks of treatment compared with placebo by the 12th week of follow-up. Interestingly, the group taking 1000 mg/day of citicoline did not show a comparable benefit. This was puzzling in that the baseline characteristics of each group were essentially identical, except for weight, which was higher in this group than in the other treatment groups. The authors postulated this might have played a role in the outcome, suggesting that a high dose may be needed for patients with a body-mass index (BMI) greater than 30.[46]

In a third multicenter, randomized, placebo-controlled trial in acute stroke patients, patients were given citicoline for 6 weeks and assessed according to the National Institute of Health (NIH) Stroke Scale. No benefit was seen in terms of recovery, likely because of several significant confounding factors that affected the analysis, such as populating the placebo arm of the study with more patients with milder strokes.[47]

A larger Phase III, multicenter, randomized, placebo-controlled clinical trial was organized to assess the effectiveness of 2000 mg/day of citicoline taken for 6 weeks to determine whether this dosage would facilitate an accelerated rate of stroke recovery. This study featured recruitment from 118 stroke centers representing 899 patients randomized to receive either citicoline or placebo. Unlike earlier trials that assessed the efficacy of citicoline in moderate-stroke patients, this study recruited participants with NIH Stroke Scale scores of 8 or higher, characterized as having experienced a severe stroke. The major end point of this trial was a comparison of the proportion of individuals with an improvement of 7 or more points on the NIH Stroke Scale by week 12. Although no significant differences were noted between groups using the NIH Stroke Scale, a benefit was seen for citicoline on the Barthel Index at 6 weeks; a significantly higher proportion of those in the citicoline group returned to baseline function by then.[48]

An international, randomized, multicenter, placebo-controlled study, the International Citicoline Trial on Acute Stroke (ICTUS) trial, aimed to determine whether neurovascular protection and repair would improve the recovery of patients who experienced an acute ischemic stroke and received citicoline treatment. In this study, 2298 patients were randomly assigned to receive either citicoline or placebo within 24 hours after the onset of symptoms, after which they were given 1000 mg of citicoline every 12 hours intravenously in first 3 days after the stroke and orally thereafter for a total of 6 weeks. Of the patients, 1148 were assigned to the citicoline group versus 1150 placed in the placebo group. An analysis of the results found that global recovery was similar for both groups (odds ratio 1.03; 95% confidence interval [CI] 0.86–1.25; $p = 0.364$), and no significant differences were reported for adverse events.[49] A subsequent critique of the study pointed out that patients in the ICTUS trial were older by 4 years on average, had more severe strokes, and were more frequently treated with intravenous administration of tissue plasminogen activator to dissolve the clot to improve blood flow, along with heterogeneity among previous trials the ICTUS study compared itself to that could be a function of methodological and clinical differences and random error.[49] In an updated meta-analysis of the ICTUS trial, the authors showed an overall significant effect of citicoline (odds ratio 1.14; 95% CI 1.00–1.30) and a significant heterogeneity of effects ($p = 0.0029$) between previous studies and the ICTUS trial.[50]

Hazama and colleagues conducted a double-blinded, placebo-controlled trial in 1980 to assess the effect of citicoline administration as an adjunct to regular rehabilitation in post-stroke recovery from hemiplegia (paralysis of one side of the body).[51] In their study, citicoline was administered once daily for 8 weeks to patients continuing rehabilitation and assigned to one of three groups: a citicoline high-dose group (1000 mg/day IV), a citicoline low-dose group (250 mg/day IV), or placebo (isotonic saline). Upper and lower limb joint range of motion was assessed at intervals throughout the study, as were subjective symptoms, neurological signs, and mental symptoms. Significant improvements were noted in functional recovery in the upper limb in all groups, with dose-dependent improvements noted in both of the citicoline groups, which were significantly superior to placebo by week 8. No significant differences were noted between groups in the lower limb, although both citicoline groups showed a slightly higher rate of improvement compared with the placebo.[51]

Citicoline was evaluated in a randomized, placebo-controlled study consisting of 92 patients with chronic cerebrovascular conditions. Patients received 1000 mg/day of citicoline intramuscularly or a placebo for two treatment cycles of 4 weeks, each with a 1-week interval between cycles. The study outcome showed that citicoline significantly improved attention ability, as seen by the decreased number of wrong responses on the Toulouse-Piéron Test for nonverbal stimuli. Furthermore, a constant and progressive improvement was noted with citicoline treatment on memory tests and emotional and behavioral assessments.[52]

Citicoline treatment of patients with hemorrhagic, nontraumatic cerebral infarction was found to enhance the recovery of muscular strength associated with recovery. A double-blind, randomized trial conducted with 32 study subjects assigned to receive either 250 mg of citicoline IV twice daily or a placebo for 14 days showed that compared with baseline, muscular strength in the citicoline group increased significantly more so than in patients receiving placebo.[53]

It is noteworthy to mention the editorial that appeared in 2006 in the *Journal of Neurological Sciences* that declared citicoline to be the first

clinically effective neuroprotective agent in acute ischemic strokes.[54] The editorial recommended that citicoline be the agent of choice in trials of combination therapy for stroke with thrombolytic agents because of its safety profile and experimentally demonstrated efficacy in promoting recovery from ischemic conditions. This editorial followed by a year the review by the Cochrane Collaboration that analyzed the outcomes from clinical trials using citicoline in the treatment of cognitive and behavioral symptoms resulting from chronic cerebral conditions in the elderly, which concluded that citicoline showed benefits for improved memory function and behavior in elderly individuals with chronic cerebral disorders.[55]

To assess the value of citicoline administration over longer periods of time, two open-label, randomized, parallel studies were performed that compared citicoline with conventional treatments for the treatment of ischemic stroke patients was undertaken. In the first study, subjects were selected 6 weeks after suffering a stroke and recruited for an open-label, randomized, parallel study into one of two arms that either received 1000 mg/day of citicoline for 12 months or a control group that did not receive the supplement. All subjects underwent a series of neuropsychological tests and evaluations at months 1, 6 and 12. Of 347 subjects, 172 received citicoline, and 175 served as controls. Cognitive function improved at 6 and 12 months after the stroke in both groups. In comparison with controls, the patients receiving citicoline showed improvements in attention-executive functions ($p = 0.007$) and temporal orientation ($p = 0.045$) at the 12-month follow-up.[56] This study demonstrated that citicoline treatment for at least 12 months after an acute ischemic stroke is potentially effective and safe in preventing longer-term cognitive impairment in that citicoline treatment resulted in significant improvement in attention, executive function, and temporal orientation.

In the second open-label, randomized, parallel trial, patients were selected 6 weeks after they suffered a stroke and randomized into parallel arms. A series of neuropsychological examinations was performed at month 1, month 6, year 1, and year 2 after the stroke. Subjects in the study consisted of 163 patients who had suffered their first stroke. The mean age of subjects was 67.5 ± 10.5 years; 50.9% were females. After 2 years, long-term citicoline use was associated with a greater quality of life and significantly improved cognitive status compared with patients receiving conventional treatments.[57]

For patients with subjective memory complaints and neuroradiological evidence of vascular lesions, a 9-month study was performed in 349 subjects (79.9 ± 7.8 years) to assess the effectiveness and safety of 500 mg of citicoline given twice a day to 265 individuals with mild vascular cognitive impairment or a control group of 84 nonsupplemented patients (78.9 ± 7.01). Individuals recruited for the study with probable Alzheimer's disease were excluded. The study found that citicoline was effective and well tolerated.[58] Whereas the control group experienced a decline in scores over the 9-month period on the MMSE, used extensively to measure cognitive impairment, the citicoline group essentially remained unchanged over time, except for an insignificant increase of 0.5 points on the test.

In summary, the evidence in support of citicoline in the treatment of stroke continues unabated, as discussed by Martynov and Gusev in the *Journal of Experimental Pharmacology.*[59] In a review in the *Journal of Stroke and Cerebrovascular Diseases,* a similar conclusion stated, "Citicoline is the only drug that in a number of difference clinical stroke trials that continuously had some neuroprotective benefit," given its safety and beneficial effect in expediting the recovery of patients after experiencing an acute ischemic stroke.[60] Nevertheless, administration of tissue plasminogen activators (tPAs) remains the preferred method of treatment for patients experiencing an acute ischemic stroke, and conventional medicine remains sufficiently unimpressed with the experimental evidence of the benefits of citicoline to recommend its use concomitant with tPAs and other therapeutic agents. Unfortunately, this attitude comes from reliance on several cumulative meta-analyses that dilute the evidence for citicoline's benefits by mixing studies that are heterogeneous in dosage, administration, inclusion criteria, and outcome measures.[61,62] Nevertheless, the totality of evidence, when examining each study on citicoline's treatment effect in stroke and cerebral ischemic patients, supports the use of citicoline for its neuroregenerative potential benefit in preventing post-stroke cognitive impairment.

Traumatic Head Injuries

Traumatic head injuries are a major cause of long-term disability that may surpass many diseases as the major cause of death and neurobehavioral disability.

Research into the beneficial effects of citicoline for the treatment of traumatic head injuries and concussions has been ongoing for several years. Injuries to the head can result in decreased production of cell membrane phospholipids, resulting in an accumulation of intracellular water that leads to edema and possible deterioration of the hematoencephalic barrier. Citicoline can have therapeutic benefits in these conditions because it is a precursor for the synthesis of neuronal membrane phospholipids.

A single-blinded randomized study assessing the administration of 1000 mg of intravenous citicoline given every 6 hours for 2 days, followed by 1000 mg every 8 hours thereafter on the third and fourth days, in addition to conventional therapy, was undertaken in 216 patients with severe or moderate head injuries. The study found citicoline to be superior to conventional therapy alone for 3 months after injury as assessed by the Glasgow Outcome Scale, along with a trend toward shortening hospital stays for severe head injury patients while at the same time improving motor, cognitive, and mental symptoms.[63] The authors cited earlier research on citicoline in treating moderate to severe head injuries, which showed that citicoline increased the chances of recovery to a nondependent condition (including the ability to walk and perform activities of daily living) in improving quality of life. Citicoline also improved levels of consciousness assessed at 60 days after injury in traumatic coma patients while reducing the percentage of patients showing focal neurological signs at 60 and 90 days postinjury.[63]

In a study comparing 67 patients diagnosed with traumatic brain injury who received citicoline administration compared with 67 matched patients who did not, patients receiving citicoline experienced significantly reduced rates of intensive care unit mortality (5% vs. 24%, $p < 0.01$), in-hospital mortality (9% vs. 24%, $p = 0.035$), 6-month mortality (13% vs. 28%, $p = 0.031$), and observed versus expected mortality (0.42 vs. 0.84).[64]

Citicoline therapy may also help alleviate postconcussional symptoms, frequently associated with emotional disturbance of clinical proportions.[65] In one randomized trial with 14 young adults ($M = 25$ yr in citicoline group; $M = 20$ yr in placebo group) with mild to moderate head injuries, participants were administered 1 g of citicoline orally or a placebo. Assessments included tests of memory function, fluency, and attention. Although results at 1 month did not reach statistical significance, the group given citicoline trended toward higher improvement in several categories at follow-up, including improvements in recognition memory, and a decrease in the incidence of headaches, dizziness, and tinnitus.[66]

A review article examining trials of citicoline for the treatment of traumatic head injuries, including in children as young as age 5, espoused the benefits of citicoline therapy for improving neurological signs and symptoms, increasing the level of consciousness, enhancing

recuperation, and facilitating electroencephalographic improvements. The review highlighted several trials related to traumatic coma patients treated with citicoline, which led to better recovery of motor function and walking ability compared with placebo. The overall results of these trials indicate that citicoline treatment reduced the duration of coma and the incidence and severity of mental and motor deficits associated with traumatic head injuries. Citicoline was also shown to be safe and well tolerated in patient populations of several age ranges with various types of traumatic head injuries.[67]

To determine the possible benefit of citicoline in patients with severe traumatic brain injury, a double-blind, randomized clinical trial was conducted in 58 subjects with a diagnosis of diffuse axonal injury to the head that had a score of 8 or greater on the Glasgow Coma Scale (GCS). Although mean GSC levels improved in both groups, the difference bordered on insignificant ($p < 0.05$). Noteworthy was the increase in fetuin-A ($p = 0.012$), a negative-phase reactant, and matrix Gla-protein (MGP; $p = 0.046$), a calcification inhibitor, both of which are calcification modulators.[68] This outcome suggests that citicoline may have a protective effect against inflammation after vascular calcification secondary to traumatic brain injury by increasing serum levels of fetuin-A and MGP.

In the randomized, double-blind Citicoline Brain Injury Treatment Trial (CORBRIT), 1231 patients attending eight level I trauma centers were given either citicoline or a placebo to determine its neuroprotective properties to facilitate neurorepair after injury. Subjects were given either 2000 mg/day or placebo for 90 days. Functional and cognitive status were assessed, including the TBI-Clinical Trials Network Core Battery. Rates of improvement on the Glasgow Outcome Scale-Extended were similar for both groups, whereas other measures, such as the TBI Clinical Trials Network Core Battery (global odds ratio 0.98; 95% CI, 0.83–1.15) showed no difference between groups. The use of citicoline compared with placebo did not result in an improvement in functional or cognitive status.[69] Although the COBRIT study's outcome would not encourage the clinical use of citicoline in the treatment of patients with traumatic head injuries, it is important to keep in mind that there is insufficient evidence to support pharmacological treatments relying on drugs such as modafinil, atomoxetine, rivastigmine, and monoamine stabilizers; they have been found to be no more effective or better than placebo.[70] Hence, given the compelling evidence I support of citicoline's neuroprotective properties, consideration for its use is warranted for traumatic head injuries, especially when considering the evidence of its safety.

EYE HEALTH AND VISUAL FUNCTION

Several trials with citicoline showed beneficial effects on eye health, specifically in cases of amblyopia and glaucoma. Amblyopia, or lazy eye, is the leading cause of decreased visual acuity in children, resulting in poor depth perception. Glaucoma is a leading cause of blindness in U.S. adults and is a group of conditions resulting in damage to the optic nerve, usually as a result of elevated intraocular pressure.

Amblyopia

Amblyopia is a condition whose prevalence ranges between 1% to 5% of the population. The possibility that citicoline may be useful in the treatment of amblyopia is based on several studies that used citicoline in the treatment of this eye condition.[71]

In one study, 80 subjects were recruited to undergo amblyopia therapy with a Bangerter 0.8 filter or the filter with oral citicoline. Forty-eight of the subjects had exodeviation of the eyes, a type of strabismus in which the visual axes diverge, and 32 had esodeviation, characterized by a reduction in the vision of one or both eyes. Treatment with citicoline was administered daily, 5 days a week, for 12 months. After 1 year, those subjects who received citicoline along with the filter experienced a more rapid increase in visual acuity, along with reduced recovery time and improved visual acuity. This led the authors of the study to conclude that by combining the use of the filter with citicoline, both visual acuity and visual evoked potential latency improved, most likely because of enhanced transmission of the electric impulses from the retina to the visual cortex.[72]

An open trial and a pilot double-blinded follow-up study were conducted to assess the possible benefits of citicoline therapy in patients with amblyopia. The open trial consisted of 50 patients (mean age, 16.6 years) who were administered citicoline (1000 mg/day IM) for 15 days. The visual acuity of both eyes was tested 1 week after the initiation of treatment and continuing at weekly intervals for the first month, and then on a monthly basis for an additional 6 to 18 months. For the double-blinded portion of the study, 10 patients were divided into two groups: 1 group received citicoline (1000 mg/day IM), and the other group received placebo. Citicoline improved visual acuity in 92% of the patients in the open study. Improvements were noted in both the sound and amblyopic eyes and were highly statistically significant. In the double-blinded study, significant improvements were noted between groups, with the citicoline group showing enhanced visual acuity.[73]

Another trial of citicoline took place in 45 children with amblyopia aged 5 to 9 years old. Participants were divided into three treatment groups: group A received 500 mg of citicoline daily via IM injection for 10 days every 6 months; group B received the same dosage of citicoline as group A in combination with 1 hour of occlusion (of the sound eye) per day; and group C received daily occlusion therapy alone. Although visual acuity improved in all groups at the end of the treatment period, treatment with citicoline was found to enhance the effect of occlusion therapy. Visual acuity improved in 73% of participants in group A, 86.6% of group B, and 66.6% of group C.[74]

An open-label trial with oral citicoline (800–1200 mg/day of citicoline according to body weight for 30 days) plus partial occlusion therapy in 61 children (aged 5–10 years) found that citicoline contributed to stabilizing the gains obtained during the treatment period when assessed at the 60-day posttreatment follow-up visit. Those receiving occlusion therapy alone showed a decrease in visual acuity gains at the 60-day follow up, whereas those in the citicoline group maintained the gains achieved with occlusion therapy.[75]

A randomized controlled trial assessed the effectiveness of the addition of citicoline to patching in the treatment of amblyopia in the age group of 4 to 13 years. Patients received patching therapy until achieving a plateau. Thereafter, one group received citicoline plus patching while a second group continued on patching therapy. The primary outcome measurement was visual acuity on the logMAR chart, used to estimate visual acuity, after 12 months. The improvement in visual acuity with citicoline plus patching was significantly more than that with patching alone after 1 year of treatment.[76]

Citicoline likely influences improvements in visual acuity in amblyopic individuals by stimulating the availability of several neurotransmitters and neuromodulators. It also enhances the activity of endogenous dopamine while improving vascular aspects of neurological function.[77]

Glaucoma

Lulia and colleagues have reviewed the neuroprotective benefits of citicoline on glaucomatous disease and the retina,[78] and the review by Roberti and colleagues provides a critical summarization of the evidence for the use of citicoline in the treatment of glaucoma.[79] Included among the studies reviewed is a randomized, placebo-controlled,

clinical trial evaluating the effects of citicoline in 40 patients with open-angle glaucoma who received either daily IM injections containing 1000 mg of citicoline or placebo for 60 days. Citicoline significantly improved visual evoked potential (a measure of bioelectrical activity of the visual cortex in response to visual stimuli) and the pattern-electroretinographic (used to evaluate the functional integrity of the innermost retinal layers) parameters compared with placebo. Patients in the citicoline group were then divided into two age-matched groups after a 120-day washout period. In one of these groups, the washout period was extended for an additional 120 days, whereas the second group received a further 60-day treatment of citicoline. This second group showed further improvements in visual evoked potential and pattern-electroretinographic parameters, indicating citicoline's ability to enhance retinal function and visual cortical response in glaucoma patients.[80]

A double-blind RCT assessing the benefits of citicoline in glaucoma patients confirmed that administration of citicoline for 60 days (1000 mg/day IM) was superior to placebo and significantly improved retinal function and cortical bioelectrical responses. This particular trial included an analysis of 8 years of follow-up data.[81]

A review examining the potential mechanisms through which citicoline exerts its beneficial influence in glaucoma patients theorized that citicoline's ability to enhance the synthesis of phosphatidylcholine and other cell-membrane phospholipids could explain its observed improvements. Glaucoma is considered a neurodegenerative disease in which the pathology extends to retinal ganglion cells. The death of these cells is likely a result of apoptotic mechanisms. The enhancement of phosphatidylcholine synthesis as a result of citicoline intake countered the neuronal apoptotic mechanisms associated with glaucoma that conferred neuroprotection.[82]

The use of citicoline eye drops has also been investigated, starting with its encouraging effects on the vitreous and retina of animals,[83] after which human clinical trials did not take long to begin. In one trial that enrolled 34 patients, citicoline was found to delay the progression of glaucoma using a 1% and 2% administration of citicoline drops three times a day in the eye. In another trial, 53 patients were enrolled (47 completed the trial) with open-angle glaucoma (mean age 52.4 ± 4.72 years) and were treated with topical citicoline (3 drops/day) over a 2-month period and compared with 23 patients treated with beta-blocker monotherapy. Whereas the group treated with beta blockers showed no improvement, patients treated with citicoline drops experienced an improvement in both retinal bioelectrical response (increase of pattern electroretinogram) and bioelectrical activity of the visual cortex.[84] The conclusion of the investigators of both trials was that topical citicoline administered as drops in the eye had neuroprotective bioactivity.

That citicoline drops might significantly slow down the rate of progressive glaucoma was studied in 41 patients with a diagnosis of progressing glaucoma. The patients were given citicoline drops for 2 years, during which time visual field examinations were performed. After 2 years, the mean rate of progression was slowed and there was an increase in intraocular pressure, resulting in the investigators concluding that, "citicoline might significantly slow down glaucomatous rates of progression."[85] Frolov and colleagues administered the combined oral administration of 1000 or 500 mg/day of citicoline in patients with open-angle glaucoma with 10 days of intravenous citicoline. Following this treatment protocol, both dosage groups experienced improvements in visual function, perimetry, morphometric retinal tomography, and life quality. The authors believe the improvement seen in patients could be attributed to a decrease in apoptosis, supporting the evidence that citicoline is an ocular neuroprotective agent.[86]

Ischemic Optic Neuropathy

Nonarteritic ischemic neuropathy is an irreversible ischemic event associated with the intraocular optic nerve. The condition occurs acutely and painlessly, yet it induces a loss of visual acuity and visual field. In a pilot study designed to assess citicoline's effect on this condition, 26 patients with at least a 6-month history of nonarteritic ischemic optic neuropathy were divided into two groups: one received treatment consisting of oral citicoline (1600 mg/day) for 60 days, whereas the second group received no treatment. After the 60-day treatment cycle, there was a washout period of 120 days. After this, a second period of treatment with citicoline for 60 days was instituted in the original citicoline group. A third group of 14 age-matched healthy subjects provided control data. At the end of treatment, statistically significant improvements were noted in visual evoked potential, visual acuity, and pattern-electroretinographic parameters in the citicoline group compared with pretreatment values, whereas no such changes were observed in the untreated group of nonarteritic ischemic neuropathy subjects.[87]

Substance Abuse

Citicoline has been considered as an adjunct treatment for cocaine dependence by researchers in the field in recent years. The justification for its use stems from citicoline's ability to repair neuronal membranes, which are damaged by cocaine use, and its ability to increase central nervous system dopamine levels, attenuating cravings for cocaine and other abused substances.[88]

A small double-blinded, placebo-controlled trial in 14 subjects with a history of cocaine dependence found that oral citicoline (500 mg twice per day for 14 days) caused no adverse events and also attenuated some measures of cocaine craving and drug use.[89]

An additional experiment in eight healthy occasional cocaine users investigated the influence of citicoline pretreatment on cocaine-induced cardiovascular and behavioral effects and plasma levels of cocaine. The primary outcome measure was to determine the safety of coadministration of citicoline with cocaine. Because citicoline did not adversely affect cardiovascular end points associated with acute cocaine intake, the use of citicoline in this patient population was presumed safe. Although citicoline did not block the acute subjective effects of cocaine use, cocaine users experienced a higher incidence of major cerebrovascular events. Thus the authors speculated that citicoline could play a role in attenuating these undesirable consequences of cocaine use, although further studies are needed to investigate these potential benefits.[90] These studies have had mixed results to date. The possibility that citicoline could be used in the treatment of cocaine dependence was studied in 29 subjects in a randomized, double-blind, placebo-controlled trial. Cocaine-dependent outpatient participants were given either 500 mg twice daily of citicoline or placebo for 8 weeks. Citicoline had no effect on reducing cocaine craving or total use.[91] In contrast, a placebo-controlled study of 130 outpatients with bipolar 1 disorder (depressed or mixed mood state) and cocaine dependence found a significant reduction in cocaine dependence, which, however, diminished over time.[92] Also of interest was the study's completion rate, which favored the citicoline group (71% compared with 57% on placebo).

Methamphetamine dependence is a major public health problem. Because citicoline may decrease cocaine craving,[89,93] a preliminary study of citicoline treatment for methamphetamine dependence was conducted. Sixty participants with bipolar or unipolar depression and methamphetamine dependence participated in a randomized, double-blind, placebo-controlled trial. Subjects were given either 2000 mg/day of citicoline orally ($n = 28$) or a placebo ($n = 20$) for 12 weeks. Changes in mood state were assessed by several psychometric

instruments that found it had a measurable antidepressant effect.[94] However, despite a doubling of completion rates in the citicoline group, no differences were seen in drug use or other cognitive outcomes.

Individuals with bipolar disorder are at an increased risk for substance abuse, with cocaine use being particularly common in this condition. Both the disorder and cocaine use are associated with mood symptoms and cognitive deficits. Given these commonalities, a 12-week double-blinded randomized control trial was conducted to assess the effect of citicoline supplementation on 44 individuals with bipolar disorder and cocaine dependence. Citicoline resulted in an improvement in some aspects of declarative memory. However, no evidence for antidepressant properties was seen with the use of citicoline. There was also a significantly lower probability of a positive urine test for cocaine at the end of the study in the citicoline group.[95]

Although the legalization of medical marijuana is becoming widespread, along with the legalization of recreational marijuana in a number of states in the United States, there is concern that habitual use of marijuana can affect frontal/executive function in adolescents and young adults[96,97] and in long-term heavy users seeking treatment.[98] Because recreational marijuana use has been reported to be associated with a range of cognitive impairments and changes in brain structure and function, particularly after early-onset exposure (age 15 and earlier), a study was conducted to see if executive functioning, sustained attention, and impulse control would improve after 8 weeks of treatment with oral citicoline in a randomized, double-blind, placebo-controlled trial.[99] The study found that among 30 participants who received 2000 mg/day of citicoline or a placebo for 8 weeks, and who met eligibility criteria, of which 19 completed the study, those receiving citicoline demonstrated significantly lower levels of behavioral impulsivity, improved task accuracy on two measures of inhibitory function, and different patterns of brain activation patterns than those who received placebo. The later improvement in brain activation was based on a comparison of functional magnetic resonance imaging (fMRI) results of the anterior cingulate cortex, a region critical to inhibition processing. Other changes noted in the scans from baseline to 8 weeks of citicoline treatment included a shift from posterior/midcingulate to genual cingulate activation that corresponded with a reduction in total voxel cluster size. No activation in genual or near-genual regions was seen in the placebo group over the same time period.

Infectious Diseases

A recently published article highlighted the role citicoline might play as an adjunctive therapeutic agent for the treatment of disease arising from an infectious etiology. The pathology of infectious disease involves dysregulation of the host immune response. Although currently available treatments target the infectious agent, they do little to address the concurrent neurological abnormalities. These consequences, if unaddressed, lead to eventual mortality in a high percentage of cases. In the case of cerebral malaria, studies highlighted cytokine-induced endothelial inflammation and the compromised blood–brain barrier as major pathological factors leading to the associated neurological signs and symptoms. Ischemia is a large underlying mechanism for damage in sepsis and cerebral malaria. Because these underlying issues are similar to conditions such as stroke and myocardial infarction, it is likely that citicoline would benefit these patients as an adjunct treatment for sequelae of sepsis and cerebral malaria.[2]

Appetite Control and Satiety

Given citicoline's ability to enhance cognitive function, confer neuroprotection, and support neuroregenerative effects, and its action to support dopaminergic activity in the brain, researchers investigated the potential of citicoline administration for controlling appetite and promoting satiety. In this particular study, the effect of 2000 mg/day of oral citicoline given orally for 6 weeks was assessed by functional magnetic resonance imaging to elucidate cortico-limbic responses to images of various foods, along with subjective ratings of appetite and measures of weight. Sixteen healthy adults (age range of 40–57 years and a BMI range of 20.1–38.6 kg/m^2) were included in the study. Eight participants were assigned to the 500-mg/day citicoline group, and the other eight were assigned to 2000 mg/day. The results of this study indicated that self-assessment ratings for appetite declined significantly between visits in both groups, with the magnitude of decline in the high-dose group reaching statistical significance. No significant between-group differences were noted for the magnitude of weight change. The high-dose citicoline group also showed higher activation within the right lateral orbitofrontal cortex and left amygdala during visual perception of high-calorie foods than the low-dose group when assessed by fMRI. This might indicate that high-dose citicoline leads to appetite suppression and feelings of satiety by increasing the responsiveness of these regions to images of calorie-rich foods.[100]

Mental Health

Citicoline's influence on cognitive capacity and neurological health, including modulatory activity on neurotransmitter production and function, make it a logical choice to support mental health and cognitive functioning.

To evaluate the effect of citicoline administration in eight depressed patients, a randomized, double-blind, placebo-controlled trial was conducted to test its effectiveness as an adjuvant therapy in the treatment of major depression. In the study, patients were given 500 mg/day IM, as 300 mg at 8 AM and 200 mg at 5 PM, for 21 days or longer. On the day preceding the beginning of treatment, plasma growth hormone was measured, levels of which indicated reduced growth hormone secretion in these patients. Significant improvements were noted in seven of eight participants (treatment was discontinued in one participant because of a noted suicidal tendency) when assessed using the Hamilton Rating Scale for depression. Although the study was small, the results indicate the potential for significant benefit from citicoline therapy in depressed individuals.[101]

Another randomized, double-blind, placebo-controlled trial was assessed to determine whether 100 mg of citicoline taken twice a day for 6 weeks would alleviate depressive symptoms.[102] Fifty patients with major depressive disorder who were under treatment with citalopram were recruited for the study. Significantly greater improvement was observed in Hamilton Depression Rating Scale scores in the citicoline group compared with the placebo group over a 6-week period (p = 0.021). Citicoline was demonstrated to be an effective adjuvant to citalopram in the treatment of major depressive disorder.

In a preliminary study that examined the therapeutic effect of a combination of citicoline with galantamine for the treatment of schizophrenic patients, the results were encouraging. Evidence to date suggests that α7-nicotinic choline receptors have decreased functionality in schizophrenia. Because citicoline provides choline, a known α7-nicotinic choline-receptor agonist, and galantamine is a modulator of α7-nicotinic choline receptor function used to enhance the efficiency of choline binding to these receptors, it seemed reasonable to observe whether the combination would be of greater therapeutic value than either alone. To find out, a pilot study was conducted that included six schizophrenic patients given 2 g/day of citicoline in combination with 24 mg/day of galantamine daily in a 12-week open-label study. The combination proved to be well tolerated by all participants, with only minor transient side effects. No adverse cardiovascular events were reported. Five of the six participants had lower-than-baseline diastolic blood pressure readings at the end of the study, which was an unexpected benefit. Other improvements noted in five of six patients were

seen on the Clinical Global Impressions Inventory and the Positive and Negative Syndrome Scale. Total Positive and Negative Syndrome Scale scores and Clinical Global Impressions severity scale scores decreased over the study period, providing encouraging results suggesting that the combination therapy was potentially effective.[103]

Metabolic Diseases

Only recently has citicoline been the subject of investigations for its therapeutic potential in glucose management for patients with either type 1 or type 2 diabetes. Insulin-dependent diabetes mellitus is associated with a risk of potentially severe hypoglycemic episodes. The ability of citicoline to reduce neuronal death associated with such episodes has been demonstrated previously in animal studies.[104,105] An animal study showed that when citicoline is given by injection, it can significantly increase acetylcholine levels in the hippocampus after induction of severe hypoglycemia by insulin, suggesting that it could be used in the treatment of hypoglycemia-induced brain injuries.[106] In another animal study, the combination of S-Methylisothiourea (a selective iNOS inhibitor) and citicoline, alone or in combination, was investigated on neuropathic pain in the rat with type 2 diabetes mellitus because neuropathy is a common complication. Citicoline, and the combination, significantly attenuated the diabetic neuropathic pain associated with decreased nerve conduction velocity, mechanical and thermal hyperalgesia, and cold allodynia.[107]

TOXICOLOGY

Clinical investigations using citicoline revealed a favorable safety profile, with few reports of any major adverse events. The most common adverse reports were related to digestive disturbances. Citicoline has also been found to have a lack of significant adverse events in children, as evidenced by its use in clinical trials with pediatric subjects with amblyopia[74] and children with traumatic head injuries.[67]

Citicoline has undergone several toxicological evaluations in multiple animal species and has proven to have a high level of safety. Single-dose acute oral toxicity studies were performed in mice and rats, with a median lethal dose of 27.14 g/kg in mice and 18.5 g/kg in rats. Chronic oral toxicity tests in dogs (1.5 g/kg per day for 6 months) and subchronic intraperitoneal dosing studies in rats (1 g/kg per day for 12 weeks) showed no abnormal signs.[14]

An acute 14-day study and a 90-day subchronic toxicity evaluation of citicoline in rats revealed that the supplement was well tolerated. In the 14-day study, a single dose of 2000 mg/kg showed no abnormalities, and in the 90-day repeated oral dosing study, doses of 100, 350, and 1000 mg/kg per day resulted in no mortality in the animals. In male rats, slight increases in serum creatinine were noted in the two highest-dose groups, whereas in female rats, a dose-related increase in renal tubular mineralization was noted and attributed to an increase in phosphorus intake as a result of high citicoline consumption. Mineralization in female laboratory rats of all universally used strains is a common incidental finding as a result of a decreased calcium/phosphorus ratio in the diet. Because citicoline yields a significant amount of phosphorus—thus influencing the calcium/phosphorus ratio—this finding was not unexpected.[108]

A drug surveillance study was recently published examining the efficacy and safety of oral citicoline intake in acute ischemic stroke. The study of 4191 Korean patients confirmed a high level of safety for citicoline (500–4000 mg/day for 6 weeks or longer) with an incidence of 37 adverse events in 31 patients (only 0.73% of patients experienced adverse events). Adverse events in all but 1 of the 31 patients showed no relationship to citicoline administration. Thirty-two of the 37 (nearly 84%) patients reported events resolved over a mean of 9 days after onset. Furthermore, no dose-related effects of citicoline on the occurrence of adverse events were noted. The most frequent side effects included minor nervous system–related complaints ($n = 8$; numbness, headache, tingling sensations) followed by gastrointestinal symptoms ($n = 5$; abdominal discomfort, diarrhea).[109]

There remains limited information on the long-term use of citicoline in healthy individuals. What few transient side effects are reported in the literature have been minor and reportedly resolved over time. No reliable information to support the safety of citicoline supplementation in pregnant or breastfeeding women has been reported.

DOSAGE

Effective dosing of citicoline based on data from clinical trials ranges from 500 to 2000 mg/day. Based on evidence from trials in children as young as 5 years of age,[67,74] citicoline is safe for use in pediatric and adult populations. Oral doses of up to 1200 mg/day have been used in children.[75] Studies using oral, IM, and IV dosing of citicoline in children and adults, with minimal occurrence of adverse events, affirmed its high level of safety.

Because citicoline activates the biosynthesis of phospholipids in neuronal membranes and has neuroprotective effects during ischemia and hypoxia, the safety of oral administration of 500 mg of citicoline twice a day was of primary interest to investigators conducting the multicenter Italian studio di intervento nel decadimento vascolare lieve (IDEALE study) to assess the its effectiveness in 122 men and 143 women (mean age 79.9 ± 7.8 yrs) with mild vascular cognitive impairment. No adverse events were reported or recorded.[110]

DRUG INTERACTIONS

There are no reports of adverse drug interactions associated with the use of citicoline. Citicoline does have a levodopa-sparing effect of minimal clinical significance, given its potentiating benefits in reducing certain side effects associated with long-term levodopa or carbidopa use.[41–43]

CONCLUSIONS

Until recently, citicoline was only perceived to be a novel compound with a broad spectrum of benefits in conditions associated with neurological disorders and dysfunctions. This seemed reasonable in that citicoline acts at multiple levels to support and maintain neural health to support optimal cognitive function. It also promotes cholinergic and dopaminergic functions, supports phospholipid synthesis and its incorporation into cell membranes, and enhances antioxidant mechanisms in the body while suppressing the damaging effects of free radicals on neural tissue, facilitating anti-inflammatory activities, and facilitating the release of essential neurotransmitters. Given its widespread activity on neural tissue, citicoline should be considered a comprehensive therapeutic agent for supporting brain health.

Its broader clinical applications are growing beyond that of a neuroregenerative and neuroprotective agent. Citicoline treatment of conditions affecting the eye and visual functioning is an example of new therapeutic applications for this compound in ophthalmology. More research is needed on its potential to dampen the adverse effects of substances of abuse, such as cocaine and amphetamines. Recent interest in its attributes in treating metabolic diseases has just begun and awaits results. That citicoline is safe is supported by overwhelming evidence based on its use in dozens of controlled clinical trials, regardless of outcomes.

Coenzyme Q_{10}

Joseph Katzinger, ND, Laurie Mischley, ND, PhD, MPH,* and *Jason Allen*, ND, MPH*

OUTLINE

INTRODUCTION

Coenzyme Q_{10} (CoQ_{10}) is an endogenous proenzyme synthesized naturally in the human body.[1] Because of its ubiquitous presence in nature and its quinone structure, CoQ_{10} is also known as ubiquinone (Fig. 68.1). The two major physiological actions CoQ_{10} has been recognized for are (1) as a cofactor in the production of adenosine triphosphate (ATP), and (2) as an antioxidant. In addition to these two well-known actions, recent evidence suggests it also has other physiological effects, including (3) an influence on the expression of genes involved in cellular signaling and metabolism, and (4) a modulation of the mechanical and permeability of lipid membranes (similar to cholesterol), both of which may explain some of its therapeutic effects. For example, in some human trials supplementation has been shown to downregulate expression of oxidized low-density lipoprotein receptor 1 (LDLR), several interleukin genes, and tumor necrosis factor alpha (TNF-α), while upregulating peroxisome proliferator-activated receptor gamma (PPAR-γ) expression.[2,3] This may help explain the anti-inflammatory effect of CoQ_{10}; for example, a 2017 meta-analysis of 17 randomized controlled trials found significant reductions in C-reactive protein, IL-6, and TNF-α with CoQ_{10} supplementation.[4]

Because most cellular functions depend on an adequate supply of ATP, CoQ_{10} is essential for the health of virtually all human tissues and organs. Cellularly, the highest concentration of CoQ_{10} is found in the inner mitochondrial membrane, where it facilitates energy production, but CoQ_{10} is found in the cell membranes of many organelles, where it plays a role in membrane stability.[5] CoQ_{10} is the only endogenously synthesized lipid soluble antioxidant.[6] In its role in electron transport, the CoQ_{10} molecule continuously goes through an oxidation-reduction cycle. As it accepts electrons, it becomes reduced to ubiquinol. As it gives up electrons, it becomes oxidized to ubiquinone. In contrast to other antioxidants, this compound inhibits both the initiation and the propagation of lipid and protein oxidation. In its reduced form, ubiquinol, the CoQ_{10} molecule holds electrons rather loosely, so the CoQ_{10} molecule will quite easily give up one or both electrons and thus act as an antioxidant. It is especially protective against the oxidation of bases of mitochondrial DNA. In addition, ubiquinol is responsible for regenerating vitamin E from the α-tocopheroxyl radical and, thereby, interfering with the propagation step of lipid peroxidation.

Biosynthesis of CoQ_{10} starts from acetyl coenzyme A (CoA) and flows through a multistep process of the mevalonate pathway to produce farnesyl-PP, the direct precursor for not only CoQ_{10} but also cholesterol, dolichol, and isoprenylated proteins (Fig. 68.2). The long isoprenoid side-chain of CoQ_{10} is synthesized by transprenyltransferase, which condenses farnesyl-PP with several molecules of isopentenyl-PP, all in the trans configuration. The next step involves condensation of this polyisoprenoid side-chain with 4-hydroxybenzoate, catalyzed by polyprenyl-4-hydroxybenzoate transferase. Hydroxybenzoate is synthesized from tyrosine or phenylalanine. In addition to their presence in mitochondria, these initial two reactions also occur in the endoplasmic reticulum and peroxisomes, indicating multiple sites of synthesis in human cells. Nonetheless, numerous conditions are now known to arise in which the body's synthetic capacity is insufficient to meet CoQ_{10} requirements. Susceptibility to CoQ_{10} deficiency appears to be greatest in cells that are the most metabolically active, such as the brain and heart. Tissue deficiencies or subnormal serum levels of CoQ_{10} have been reported to occur in a wide range of medical conditions and decline with advancing age.[6]

A need for supplemental CoQ_{10} could theoretically result from the following:

- Impaired CoQ_{10} synthesis as a result of nutritional deficiencies
- A genetic or acquired defect in CoQ_{10} biosynthesis or utilization
- Increased tissue needs resulting from a particular illness
- The requirement to prevent the side effects of medical intervention

*Previous edition contributor

Because oral administration of CoQ_{10} can increase tissue levels, it is possible to correct CoQ_{10} deficiency and its associated metabolic consequences by supplementation.[7]

Coenzyme Q_{10} Deficiency

Inherited CoQ_{10} deficiency has been associated with five major clinical phenotypes: (1) encephalomyopathy, (2) severe infantile multisystemic disease, (3) cerebellar ataxia, (4) isolated myopathy, and (5) nephrotic syndrome. In a few patients, pathogenic mutations have been identified in genes involved in the biosynthesis of CoQ_{10} (primary deficiencies) or in genes not directly related to CoQ_{10} biosynthesis (secondary deficiencies). Respiratory chain defects, reactive oxygen species production, and apoptosis contribute to the pathogenesis of primary CoQ_{10} deficiencies.[8,9] Considered quite rare, as of 2018, only 200 patients belonging to 130 families have been described in the medical literature.[10] However, an analysis published in 2017 using large-scale gene sequencing data estimates as many as ~124,000 individuals are likely to be affected worldwide (~1500 in the United States), with a minimum of 1665 if limited to known pathogenic variants (192 in the U.S.).[11]

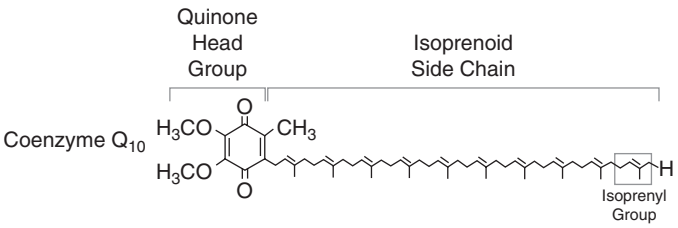

Fig. 68.1 Ubiquinone. (From Lee SQ, Tan TS, Kawamukai M, et al. Cellular factories for coenzyme Q_{10} production. Microb Cell Fact. 2017 Mar 2;16[1]:39. PMID: 28253886. Reproduced under the terms of the Creative Commons Attribution 4.0 International License [http://creativecommons.org/licenses/by/4.0/].)

Acquired CoQ_{10} deficiency is less well established. There are at least two major factors that lead to deficiency of CoQ_{10} in humans: reduced biosynthesis, and increased utilization or need by the body. The typical dietary intake of CoQ_{10} is 3 to 5 mg,[12] so dietary lack is probably not a significant contributor to CoQ_{10} deficiency. As mentioned previously, endogenous synthesis is a multistep process that can be affected by aging, disease status, and various medications. Some chronic disease conditions (cancer, heart disease, etc.) are associated not only with reduced biosynthesis but also increased demand for CoQ_{10}. Even a persistent food intolerance or allergy has been linked to an acquired CoQ_{10} deficiency, at least among children.[13] Additionally, a number of mitochondrial diseases may increase the degradation of CoQ_{10}, possibly by generating excessive reactive oxygen species as a result of a dysfunctional respiratory chain.[14]

Measurements of plasma CoQ_{10} levels have been used to detect deficiencies and are by far the most common clinical assessment of CoQ_{10} status.[15] Normal plasma levels are believed to range from 0.45 to 1.5 mcg/mL (or 0.46–1.78 μmol/L), with 93% to 100% being the reduced form, ubiquinol.[15,16] However, plasma measurement of CoQ_{10} has been criticized as having poor sensitivity (most patients with a primary CoQ_{10} deficiency still have normal plasma levels), and influenced by differences in plasma lipoprotein levels (which are CoQ_{10} carriers) and dietary intake.[17] Some studies use a functional assessment using an assay that measures the citric acid cycle (Krebs cycle) enzyme succinate

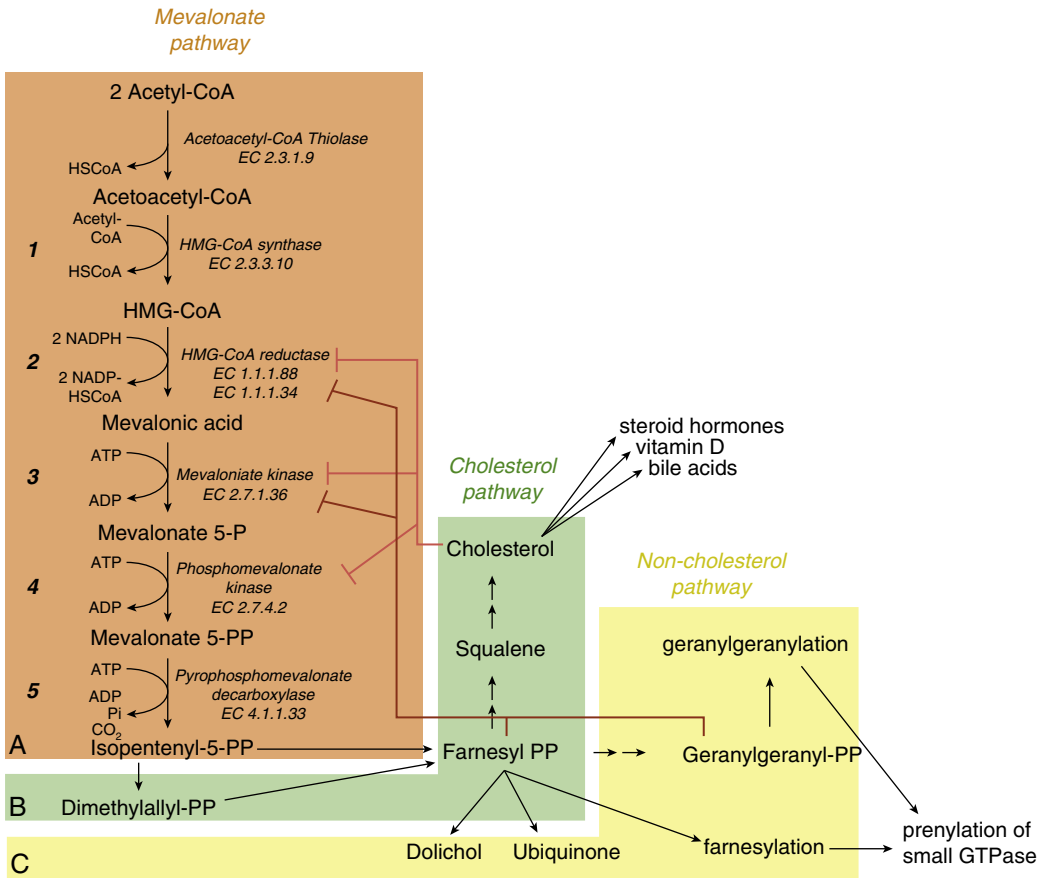

Fig. 68.2 Schematic representation of the mevalonate pathway. Divided into (a) The mevalonate pathway that produces mevalonate 5-PP and then isopentenyl 5-PP; (b) The cholesterol pathway that produces cholesterol, which in turn induces the formation of steroid hormones, vitamin D and bile acids; and (c) The non-cholesterol pathway important for the production of farnesyl-PP and geranylgeranyl-PP that induces respectively farnesylation and geranylgeranylation of small GTPase. (From Tricarico PM, Crovella S, Celsi F. Mevalonate pathway blockade, mitochondrial dysfunction and autophagy: a possible link. *Int J Mol Sci.* 2015;16(7):16067-84. PMID: 26184189. Reproduced from an open access article distributed under the terms and conditions of the Creative Commons Attribution license [http://creativecommons.org/licenses/by/4.0/]).

dehydrogenase-CoQ_{10} reductase.[18] CoQ_{10} acts as a critical coenzyme to this enzyme, so if the enzyme is fully saturated with CoQ_{10} in vivo, addition of exogenous CoQ_{10} does not increase enzyme activity. Nonetheless, muscle biopsy remains the best option for determining CoQ_{10} status in mitochondrial disorders, though additional methods for assessing CoQ_{10} status are also becoming available.[8,19,20] Leukocyte and skin fibroblasts, for example, appear to reasonably approximate muscle levels, though they are not widely available clinically, and urinary tract CoQ_{10} has emerged as a noninvasive technique for determining renal CoQ_{10} status.[21,22]

Coenzyme Q_{10} Absorption and Pharmacokinetics

After gastric emptying, CoQ_{10} is absorbed along with other lipids as chylomicron particles in the small intestine. The primary site of uptake of exogenous CoQ_{10} is the duodenum, followed by the colon, then the ileum, and then the jejunum. Absorption in the ileum and colon regions supports the possibility of an enterohepatic recirculation of CoQ_{10}. This possibility is further strengthened by the presence of a second peak in plasma levels about 24 hours after administration of either ubiquinone or ubiquinol. Absorption appears to be a complex process involving both active and passive mechanisms.

In the liver, CoQ_{10} is incorporated with lipoproteins and released into the blood. In plasma, CoQ_{10} is almost totally associated with lipoproteins, where it has greatest affinity for very low-density lipoprotein (VLDL) and LDL cholesterol. The CoQ_{10} is then distributed to peripheral tissues for uptake by cells and their mitochondria.

Commercial Forms and Dosage Considerations

Commercially CoQ_{10} is primarily produced via a yeast fermentation process using *Schizosaccharomyces pombe.* An alternate source of manufacturing is chemical synthesis using solanesol isolated from the tobacco plant.

A very important consideration in the clinical application of CoQ_{10} is its pharmacokinetics. CoQ_{10} as ubiquinone is a crystalline powder that is insoluble in water and has poor absorption characteristics as a result. Ubiquinol has greater solubility and has been promoted as having greater bioavailability that ubiquinone,[7,23] but there are limited data currently available and many questions remain to be answered, because ubiquinol is easily oxidized to ubiquinone and absorption studies to date have been suspect. Ubiquinone has an extensive history of use, particularly in oil-based soft-gelatin capsules. Several technologies are now used to enhance the bioavailability of ubiquinone, such as particle size reduction (nanonization) and solubility enhancement via use of emulsifying agents, carriers, and self-emulsifying systems.[24] For example, complexing ubiquinone to a soy peptide ($BioQ_{10}$ SA) has shown exceptional bioavailability because the soy peptide emulsifies the CoQ_{10} and helps usher it into the bloodstream.[25] Given the excellent absorption of this form of ubiquinone, the advantage of ubiquinol over regular ubiquinone appears to have more to do with its improved solubility than because it is in the ubiquinol form.

In light of the pharmacokinetic issues, proper clinical dosing is yet to be determined for CoQ_{10}. Therefore some have suggested that therapeutic targeting will likely be based on achieving specific plasma CoQ_{10} levels (e.g., more than 3.5 mg/mL) or tissue saturation.[15,26,27] Prescribing a set dosage, even a milligram per kilogram body weight dosage, at this time is a best guess scenario without confirmation by monitoring CoQ_{10} blood levels, given the differences noted in absorption rates among the different forms as well as the interindividual variability.

Numerous studies have now been conducted claiming enhanced absorption of one form or another.[7] However, there are shortcomings in most of these studies, and some of the studies appear to have been set up to show an advantage for commercial reasons. For example, ubiquinol is being promoted as the best absorbed form of CoQ_{10}, yet the published studies were set up in a curious fashion. In the one study examining ubiquinol absorption, the administration of the ubiquinol was always with a total of CoQ_{10} capsules that included the emulsification agents diglycerol monooleate, canola oil, soy lecithin, and beeswax, and although the study used a placebo, it did not compare ubiquinol with ubiquinone.[23] It is possible that ubiquinone might have fared just as well if emulsified as well as the ubiquinol in this study. Absorption studies showed that when CoQ_{10} was given with food, it was absorbed twice as fast and at least twofold greater than on an empty stomach.[28] It is believed that food-induced secretion of bile acids is responsible for the improved absorption.

What is known based on current absorption studies is that eventually a steady state is produced (usually after 3–4 weeks of constant dosing), and the absorption of CoQ_{10} may be limited in some individuals. Dosages that exceed an individual's absorptive capacity for CoQ_{10} may have minimal effect on efficacy and unnecessarily increase the cost of treatment. When single dosages of CoQ_{10} begin to exceed 300 mg, the percentage of CoQ_{10} absorbed declines. Plasma CoQ_{10} levels at a dosage of 900 mg/day (as ubiquinone in an oil suspension in a soft gel capsule) are not significantly greater than a 600 mg/day dosage. Divided dosages (e.g., two or three times a day) result in higher plasma levels compared with single dosages, especially at higher dosage levels.

Despite the challenges, based on existing data from published studies, an attempt can be made to calculate the approximate plasma levels of CoQ_{10} for different commercial forms at 100 and 300 mg doses for at least 30 days with several caveats. First, these are estimates only, based on a typical 75 kg body weight. Keep in mind that absorption of CoQ_{10} in any form is likely enhanced considerably if taken with a large meal that includes some fat. Lastly, considerable pharmacokinetic studies in humans have indicated significant interindividual variability in CoQ_{10} absorption, underscoring the need for monitoring CoQ_{10} plasma levels during clinical studies and perhaps clinical use of CoQ_{10} as well (Table 68.1).

TABLE 68.1 Coenzyme Q_{10} Plasma Levels

Dose and Form	Estimated Plasma Levels in Micrograms Per Milliliter
100 mg	
Ubiquinone powder in hard gelatin capsule	1.25
Ubiquinone suspended in oil in soft gelatin capsule with rice bran oil	1.8
Ubiquinone solubilized in soft gelatin capsule	2.25
Ubiquinone powder nanonized	2.25
Ubiquinone emulsified with soy peptide in soft or hard gelatin capsule	2.50
Ubiquinol in soft gel capsule	2.50
300 mg	
Ubiquinone powder in hard gelatin capsule	2.5
Ubiquinone suspended in oil in soft gelatin capsule with rice bran oil	3.5
Ubiquinone solubilized in soft gelatin capsule	5.0
Ubiquinone powder nanonized	5.0
Ubiquinone emulsified with soy peptide in soft or hard gelatin capsule	7.0
Ubiquinol in soft gel capsule	7.0

The optimal dose of CoQ_{10} for many clinical indications is not known, and plasma or target tissue levels of CoQ_{10} are likely the primary determinant of efficacy, rather than the dose.[26,29] Current opinion based on the scientific literature is that an acceptable therapeutic plasma target level of CoQ_{10} should be at least 2.5 mg/mL,[30] but levels higher than 3.5 mcg/mL may be necessary for optimum improvement in neurodegenerative diseases and myocardial function.[15,26,29] The usual starting dosage for CoQ_{10} is generally 100 to 200 mg/day. Where possible, the dosage of CoQ_{10} should be adjusted according to the response of the patient and, preferably, by monitoring plasma CoQ_{10} levels for 3 to 4 weeks of constant dosing, when steady-state plasma concentrations occur. Less is known about the ability of CoQ_{10} and the dose required to reach the central nervous system. Again, divided dosages result in higher plasma levels compared with single dosages (e.g., taking 100 mg twice a day produces higher plasma levels compared with taking 200 mg once a day).[31]

CLINICAL APPLICATIONS

Given the central role of CoQ_{10} in mitochondrial function and cellular antioxidant protection, its clinical applications are extensive. There are so many conditions where CoQ_{10} may offer benefit that there is no question that it should be considered a conditionally essential nutrient. The specific uses of CoQ_{10} are described in the following:

- General antioxidant
- Cardiovascular disease
- Cardiomyopathy
- Congestive heart failure
- Protection during cardiac surgery
- Hypertension
- Cancer
- Diabetes mellitus
- Male infertility
- Parkinson's disease
- Friedreich's ataxia
- Muscular dystrophy
- Immune function
- Acquired immunodeficiency syndrome (AIDS)
- Toxicant exposure
- Topical antiaging effects

General Antioxidant

Numerous studies have shown CoQ_{10} can reduce oxidative damage, DNA strand damage, LDL oxidation, and formation of lipid peroxides, thereby supporting its use as a general antioxidant.[5,32] In particular, CoQ_{10} is often used to counteract the reduced synthesis of CoQ_{10} associated with aging. After the age of 35 to 40 years, humans slowly begin to lose their ability to synthesize CoQ_{10}.[33] It has been proposed that the increase in age-associated diseases is due in part to decreased protection afforded by CoQ_{10} as both an antioxidant and a facilitator of energy production at a cellular level. Indeed, CoQ_{10} has been shown to activate the expression of the sirtuin and Pgc-1α genes, proposed as regulators of age and age-associated diseases, and linked to lower oxidative stress and upregulated glutathione production as well as mitochondrial biogenesis.[34]

Previous studies identified oxidative stress as a promoting factor for dry mouth (xerostomia) and the development of Sjögren's syndrome, a condition associated with significant dry mouth. Basically, oxidative damage leads to the inability of salivary cells to produce enough ATP to secrete sufficient amounts of water. CoQ_{10} exerts antioxidant effects, but its main action in relieving dry mouth may be by increasing energy (ATP) production, allowing the saliva-producing cells enough energy to secrete more saliva into the mouth. In one double-blind study, 66 patients, including 31 with dry mouth, were given either ubiquinol or ubiquinone orally at a dosage of 100 mg/day, or a placebo for 1 month.[35] Salivary secretion and salivary CoQ_{10} content were analyzed before and after treatment. Among the dry mouth patients treated with ubiquinone, salivary secretion increased significantly from 0.7 g/2 min before treatment to 1.2 g/2 min after 1 month of treatment. Among the patients treated with ubiquinol, salivary secretion also increased significantly from 0.8 g/2 min before treatment to 1.4 g/2 min after treatment. In normal subjects without dry mouth, salivary secretion increased with ubiquinone (from 4.9–5.7 g/2 min) at a statistically significant level, but did not differ significantly after treatment with ubiquinol (from 3.5–3.8 g/2 min). Either form of CoQ_{10} exhibited a marked increase in salivary CoQ_{10} concentration (ubiquinol more than ubiquionine in dry mouth, ubiquinone more than ubiquinol in normal subjects), suggesting that the observed increase in salivary secretion was attributable to the effect on salivary levels of CoQ_{10}.

Cardiovascular Disease—General Considerations

Enhancing myocardial function is an important, although frequently overlooked, component of the overall prevention and treatment of cardiovascular disease. CoQ_{10} plays a key role in energy production and is therefore essential for all energy-dependent processes, including heart muscle contraction. CoQ_{10} deficiency has been documented in patients with various types of cardiovascular disease. Whether a decline in CoQ_{10} levels is a cause or a consequence of heart disease is unclear. Cardiac cells are highly metabolically active, and thus have higher mitochondrial coenzyme requirements to maintain ATP production. In addition to its role in cellular energetics, exogenously administered CoQ_{10} acts as an antioxidant to inhibit LDL oxidation,[36] decreases proinflammatory cytokines interleukin-6 and tumor necrosis factor-α, and attenuates markers of oxidative and nitrative stress in a dose-dependent manner.[5]

CoQ_{10} deficiency is common in patients with various types of cardiovascular disease.[5,37] Approximately 75% of patients who had cardiac surgery were shown to be deficient in myocardial CoQ_{10}. Concentrations of CoQ_{10} declined progressively in both blood and myocardial tissue with increasing severity of heart disease.[38] Myocardial deficiencies of CoQ_{10} were also found in the majority of patients with aortic stenosis or insufficiency, mitral stenosis or insufficiency, diabetic cardiomyopathy, tetralogy of Fallot, atrial septal defects, and ventricular septal defects.[39] Deficiencies have now been documented in congestive heart failure, angina, coronary artery disease, cardiomyopathy, and hypertension.[40]

Cardiomyopathy

Cardiomyopathy can take several forms, but all are manifested by weakening of the heart muscle associated with inadequate heart pumping or other functional problems. The well-established role of CoQ_{10} as a facilitator of mitochondrial energy production lends strong rationale for a role of CoQ_{10} supplementation in all forms of cardiomyopathy.

A prospective, randomized, double-blind, placebo-controlled trial was conducted in 38 children with idiopathic dilated cardiomyopathy. After 6 months of supplementation, there was a statistically significant ($P = 0.011$) improvement in diastolic function, leading the authors to conclude that "administration of coenzyme Q_{10} is useful in ameliorating cardiac failure in patients with idiopathic dilated cardiomyopathy."[41]

In one study, 126 patients with dilated cardiomyopathy received 100 mg/day of CoQ_{10} for up to 66 months. After 6 months of treatment, the mean left ventricular ejection fraction (LVEF) increased from 41% to 59% ($P < 0.001$) and remained stable thereafter with

continued treatment. After 2 years, 84% of the patients were still alive, and at 5.5 years, 52% were alive.[42] These survival rates were considerably better than the published survival statistics of patients given conventional therapy (i.e., 2-year survival rate of 50% for symptomatic cardiomyopathy, and 1-year survival rate of 50% for decompensated cardiomyopathy).

In another study, 88 patients with cardiomyopathy received 100 mg/day of CoQ_{10} for 1 to 24 months. Significant improvements in at least two of three cardiac parameters (LVEF, cardiac output, and New York Heart Association [NYHA] class) were seen in 75% to 85% of the patients. Approximately 80% of the patients improved to a lower (i.e., more favorable) NYHA functional class.[30]

In a double-blind, crossover trial, 19 patients with cardiomyopathy received 100 mg/day of CoQ_{10} or a placebo, each for 12 weeks. Compared with placebo, CoQ_{10} treatment significantly increased cardiac stroke volume and LVEF. Eighteen patients reported improvement in activity while taking CoQ_{10}.[43] In 2014 the results of the Q-SYMBIO trial (Symptoms, Biomarker status [BNP], and Long-term Outcome) were published, a prospective, randomized, double-blind, placebo-controlled, multicenter trial of CoQ_{10} as an adjunctive treatment of chronic heart failure. With more than 400 participants enrolled, a 50% reduction in risk for a major adverse cardiovascular event within 2 years was found for those taking 100 mg CoQ_{10} three times per day versus placebo. Additionally, significant reductions in both cardiovascular mortality (9% vs. 16%) and all-cause mortality (10% vs. 18%) were seen with CoQ_{10} supplementation versus placebo, as were reductions in hospital stay and a significant improvement of NYHA class. Subgroup analysis found that those with dilated cardiomyopathy may have even greater benefits; when taking CoQ_{10} the hazard ratio for a major cardiovascular event for those without cardiomyopathy was 0.60 compared with placebo, but for those with dilated cardiomyopathy it was 0.28. Furthermore, the benefit attributed to CoQ_{10} was in addition to that associated with concurrent medications, including beta-blockers, angiotensin-converting enzyme inhibitors, or angiotensin receptor blockers.[44]

Congestive Heart Failure

The potential of CoQ_{10} as a treatment for congestive heart failure (CHF) was suggested as early as 1967 by Japanese researchers.[45] In 1976 these same investigators administered 30 mg/day of CoQ_{10} to 17 patients with CHF. All the patients improved, and 9 (53%) became asymptomatic after 4 weeks of treatment.[46] Numerous studies since have demonstrated that CoQ_{10} supplementation resulted in an improvement of stroke volume, LVEF, cardiac output, cardiac index, and end-diastolic volume index.[5,47,48]

In the largest multicenter trial completed to date, 2664 patients in NYHA classes II and III CHF received 50 to 150 mg/day of CoQ_{10} (78% of patients received 100 mg/day of CoQ_{10}). After 3 months of supplementation, the results showed a low incidence of side effects, and the following proportion of patients had improvements in clinical signs and symptoms[49]:

- Cyanosis, 71.8%
- Edema, 78.6%
- Pulmonary rales, 77.8%
- Enlargement of the liver area, 49.3%
- Jugular reflux, 71.81%
- Dyspnea, 54.7%
- Palpitations, 75.4%
- Sweating, 79.8%
- Subjective arrhythmia, 63.4%
- Insomnia, 60.8%
- Vertigo, 73.1%
- Nocturia, 53.6%

The results of these uncontrolled studies were confirmed in several double-blind trials. Some 641 patients with CHF (NYHA classes III or IV) were randomly assigned to receive placebo or CoQ_{10} (2 mg/kg per day) for 1 year while continuing conventional therapy. The number of patients requiring hospitalization during the study for worsening heart failure was 38% less in the CoQ_{10} group than in the placebo group ($P < 0.001$), and episodes of pulmonary edema were reduced by about 60% in the CoQ_{10} group compared with the placebo group ($P < 0.001$).[50]

These positive results with CoQ_{10}, however, have not been seen in all studies. In one double-blind study, 55 patients with CHF in NYHA classes III and IV, with ejection fractions less than 40%, and peak oxygen consumption less than 50% during standard therapy, were randomly assigned to receive CoQ_{10} (200 mg) or placebo. Analysis indicated that there were no changes in ejection fraction, peak oxygen consumption, and exercise duration in either group. Possible explanations for failure to achieve a therapeutic benefit in this study (and others) may be the result of CoQ_{10} not being strong enough to produce significant effects in more severe stages of CHF or the fact that blood levels of CoQ_{10} did not reach sufficient levels. Although the mean serum concentration of CoQ_{10} increased from 0.95 to 2.2 mcg/mL, in 19 of 22 patients on CoQ_{10}, blood levels were below the suggested threshold of 2.5 mcg/mL.[51]

A more recent study administered CoQ_{10} 100 mg three times a day for 4 weeks to 21 patients with CHF in a double-blind, placebo-controlled, crossover design. CoQ_{10} administration resulted in a threefold increase in plasma CoQ_{10} levels, improved left ventricular contractility, and subsequently enhanced functional capacity, without any side effects.[52]

The Q-SYMBIO trial, mentioned previously, was designed to address whether CoQ_{10} supplementation extends survival in patients with CHF.[53] As discussed previously, significant reductions in both cardiovascular and all-cause mortality were found, in addition to the benefit associated with conventional treatments. The Q-SYMBIO trial and other clinical trials were incorporated into a meta-analysis published in 2017. This analysis of 14 RCTs and more than 2000 patients found that the use of CoQ_{10} reduced mortality by 31% compared with placebo among those with heart failure (Fig. 68.3). Additionally, exercise capacity was increased with CoQ_{10} use, though no differences in the endpoints of left heart ejection fraction or NYHA classification were observed.[54]

An important consideration in patients with CHF in NYHA class IV is that they often fail to achieve adequate plasma CoQ_{10} levels (>2.5 mcg/mL) on supplemental ubiquinone at dosages up to 900 mg/day. In one study, 7 patients with subtherapeutic plasma CoQ_{10} levels (mean level, 1.6 mcg/mL, on an average dose of 450 mg of ubiquinone a day [150–600 mg/day]) were changed to an average of 580 mg/day of ubiquinol (450–900 mg/day) with follow-up plasma CoQ_{10} levels, clinical status, and ejection fraction measurements by echocardiography.[55] Mean plasma CoQ_{10} levels increased from 1.6 to 6.5 mcg/mL. Mean ejection fraction improved from 22% (10%–35%) to 39% (10%–60%) and NYHA class improved from a mean of class IV to a mean of class II (classes I to III). In this study, ubiquinol dramatically improved absorption in patients with severe heart failure, and the improvement in plasma CoQ_{10} levels was correlated with both clinical improvement and improvement in measurement of left ventricular function.

Protection During Cardiac Surgery

Cardiopulmonary bypass (CPB) is used in coronary artery bypass surgery, cardiac valve repair, and numerous other surgical procedures. CPB, although permitting life-saving surgical procedures, is known

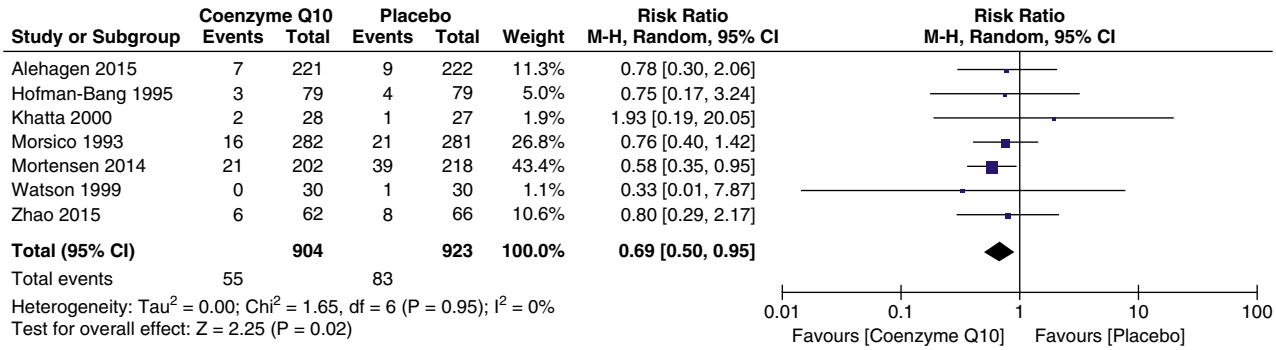

Fig. 68.3 Forest plot of mortality with CoQ_{10} supplementation for heart failure. (From Lei L, Liu Y. Efficacy of coenzyme Q_{10} in patients with cardiac failure: a meta-analysis of clinical trials. *BMC Cardiovasc Disord*. 2017 Jul 24;17[1]:196. PMID: 28738783. Reproduced under the terms of the Creative Commons Attribution 4.0 International License [http://creativecommons.org/licenses/by/4.0/].)

to induce oxidative stress. A prospective study of 30 individuals who underwent CPB randomized these patients to oral CoQ_{10} (150–180 mg/day) or placebo for 7 to 10 days preoperatively. The group that received CoQ_{10} had significantly fewer reperfusion arrythmias; lower requirements for inotropic agents, mediastinal drainage, and blood products; and shorter hospital stays compared with the control group.[56]

Postoperative low cardiac output is a major cause of early death after cardiac surgery. Fifty patients who underwent cardiac surgery for acquired valvular lesions were randomly assigned to receive 30 to 60 mg/day of CoQ_{10} for 6 days before surgery or to a control group that did not receive CoQ_{10}. Postoperatively, a state of severe low cardiac output developed in 48% of the patients in the control group, compared with only 12% of those in the CoQ_{10} group. These results suggested that preoperative administration of CoQ_{10} increased the tolerance of the heart to ischemia during aortic cross-clamping.[57]

A meta-analysis of eight clinical trials evaluating CoQ_{10} supplementation for patients undergoing cardiac surgery was published in 2015. CoQ_{10} supplementation was associated with a 53% reduced need for inotropic drugs (used to treat low cardiac output). Furthermore, supplementation was associated with a 95% reduction in the risk of developing a ventricular arrhythmia. No change in the cardiac index, length of hospital stay, or risk for atrial fibrillation was observed. Again, dosing may play an important role; in this meta-analysis, doses ranged from 30 mg to 600 mg per day, and in some cases CoQ_{10} was not given within 12 hours of surgery, whereas in others it was given orally for days or weeks before and after surgery, and via intravenous drip during surgery.[58]

Hypertension

The majority of studies exploring CoQ_{10} in the treatment of high blood pressure have been uncontrolled, or have used CoQ_{10} in combination with conventional antihypertensive medical treatments, making these studies difficult to interpret. In one study, 109 patients with essential hypertension received CoQ_{10} (average dose, 225 mg/day) in addition to their usual antihypertensive regimen. The dosage of CoQ_{10} was adjusted according to clinical response and blood CoQ_{10} levels (the aim was to attain blood levels >2 mg/mL). The need for antihypertensive medication declined gradually, and after a mean treatment period of 4.4 months, about half of the patients were able to discontinue between one and three drugs.[59] A review of studies on CoQ_{10} in the treatment of hypertension (12 clinical trials, 362 patients) concluded that in hypertensive patients, CoQ_{10} has the potential to lower systolic and diastolic blood pressure, without significant side effects. Among all included studies, decreases in systolic blood pressure ranged from 11 to 17 mm Hg and in diastolic blood pressure from 8 to 10 mm Hg.[60] In three of the 12 studies, CoQ_{10} was given in addition to existing antihypertensive medication, and in one of these, more than 50% of the patients were able to cease taking at least one antihypertensive medication during the trial. Large prospective and unbiased trials are needed, as concluded by a 2016 Cochrane review that found only two randomized trials sufficiently unbiased to be included in a meta-analysis and did not find a blood pressure–lowering effect of CoQ_{10}.[61] In a subsequent 2018 meta-analysis reviewing the effect of CoQ_{10} on blood pressure among participants with a metabolic disease (including diabetes, dyslipidemia, myocardial infarction, stroke, etc.), supplementation was associated with a statistically significant reduction in systolic blood pressure (standardized mean difference of −0.30; 95% CI −0.52, −0.08), on par with the effect of most antihypertensive medications.[62,63]

The mechanism for the antihypertensive action of CoQ_{10} is thought to be due to its counteracting vasoconstriction, resulting from either an impaired ability of the endothelium to induce nitric oxide–mediated relaxation of underlying smooth muscle, or via preservation of nitric oxide itself.[60]

Cancer

Because of its role in enhancing immune function, CoQ_{10} has been considered as a possible anticancer agent. In one study, 32 women with breast cancer, who were classified as "high risk" because of tumor spread to the axillary lymph nodes, received 90 mg/day of CoQ_{10}, along with vitamins C and E, β-carotene, and essential fatty acids. In six of these women, the tumor became smaller. During the 18-month treatment period, none of the patients died (the expected number of deaths was four), and none showed signs of further distant metastases. Six patients had an apparent partial remission. In addition, patients receiving CoQ_{10} required fewer painkillers.[64] In follow-up, a pilot study using this nutrient cocktail evaluated the survival of 40 patients with end-stage cancer over 9 years. Median survival of individuals receiving the CoQ_{10}-containing nutrient cocktail was 40% longer than median predicted survival using the calculated Kaplan-Meier curve.[65]

Anthracyclines are a class of drugs used in cancer chemotherapy for a wide range of tumors. The clinical value of these agents is limited by their cardiotoxicity, which is believed to be due to irreversible damage to heart cell mitochondria. These agents cause severe oxidative stress in cardiac inner mitochondrial membranes, resulting in damage to mitochondrial DNA and subsequent myocyte death.[66]

Research from the 1980s showed that cancer patients receiving doxorubicin (Adriamycin), a commonly used anthracycline, had lower myocardial levels of CoQ_{10} than did controls, and that the magnitude of CoQ_{10} depletion was directly related to the severity of cardiac

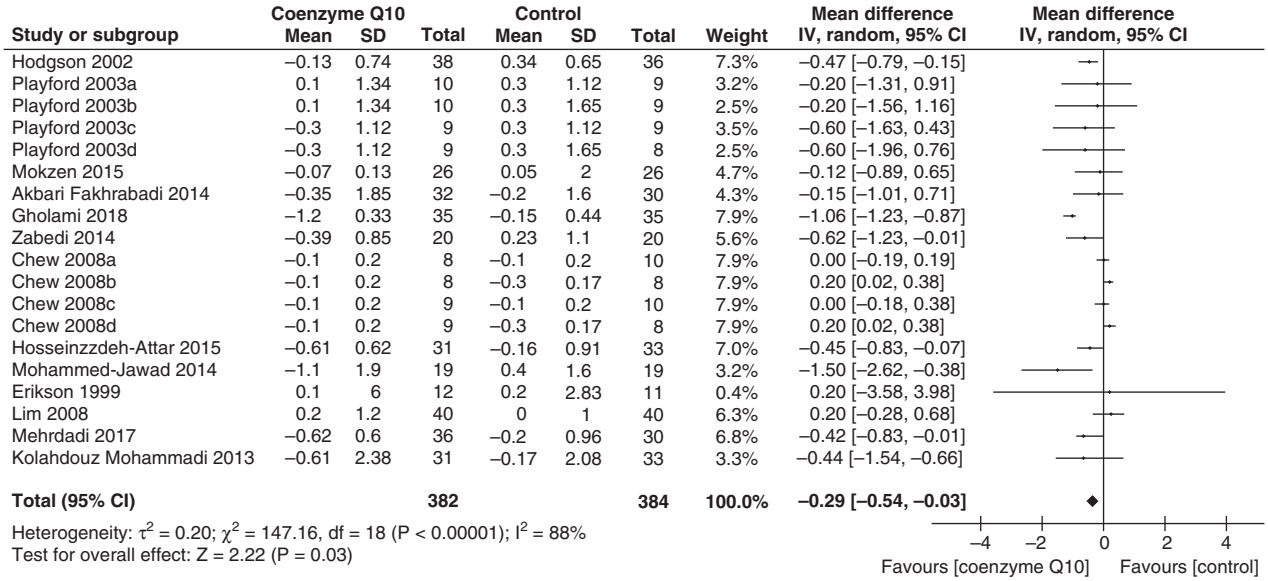

Fig. 68.4 Glycosylated hemoglobin with CoQ_{10} supplementation. (From Zhang SY, Yang KL, Zeng LT, et al. Effectiveness of coenzyme Q_{10} supplementation for type 2 diabetes mellitus: a systematic review and meta-analysis. *Int J Endocrinol*. 2018 Sep 16;2018:6484839. PMID: 30305810. Reproduced from an open access article distributed under the Creative Commons Attribution License.)

impairment.[67] To determine the effect of CoQ_{10} supplementation on doxorubicin cardiotoxicity, seven patients receiving doxorubicin were also given 100 mg/day of CoQ_{10}, beginning 3 to 5 days before doxorubicin was started. Another seven patients (control group) received doxorubicin without CoQ_{10}. Cardiac function deteriorated significantly in the control group, whereas patients given CoQ_{10} had little or no cardiotoxicity, although the cumulative dose of doxorubicin in the CoQ_{10} group was 50% greater than that in the control group.[68] These preliminary data, coupled with strong scientific rationale, suggest that CoQ_{10} supplementation should be considered for the prevention and treatment of anthracycline-induced cardiotoxicity.

Physical Performance

Because CoQ_{10} is involved in energy production and its concentration in muscle is correlated with performance, it is possible that supplementation may enhance aerobic capacity, muscle performance, and recovery.[69–71] In one study, six healthy sedentary men (mean age, 21.5 years) performed a bicycle ergometer test before and after taking CoQ_{10} (60 mg/day) for 4 to 8 weeks.[72] CoQ_{10} treatment improved certain performance parameters, including work capacity at submaximal heart rate, maximal workload, maximal oxygen consumption, and oxygen transport. These improvements ranged from 3% to 12% and were evident after about 4 weeks of supplementation. In a double-blind study in sedentary men, 100 mg/day of CoQ_{10} showed performance-enhancing effects during repeated bouts of supramaximal exercises.[73]

Although these studies suggest that administration of CoQ_{10} improves physical performance in sedentary individuals, other publications are conflicting. Larger studies are needed to confirm the performance-enhancing capacity of CoQ_{10}, and clarify any distinction between sedentary and athletic populations.[74] In a recent study that enrolled 21 male athletes, participants were given either placebo or 200 mg CoQ_{10} per day, for 30 days, before a single bout of intense exercise. Supplementation prevented the typical depletion of plasma CoQ_{10} levels, and reduced the cellular level of reactive oxygen species, though it did not alter any indexes of either physical performance or muscle damage.[75]

Diabetes Mellitus

Low tissue levels of CoQ_{10} have been consistently reported in diabetic patients, as well as a increased ratio of ubiquinone to ubiquinol.[76] There are several mechanisms by which CoQ_{10} may be of therapeutic value in diabetes.[77,78] Improved blood pressure and long-term glycemic control have been reported with CoQ_{10} supplementation (100 mg twice daily).[79] Enhancement of endothelial function may offer some protection against arteriopathies.[80] A study of 80 dyslipidemic type 2 diabetics found that CoQ_{10} (200 mg/day) in combination with fenofibrate (200 mg/day) significantly improved endothelial and nonendothelial forearm vasodilatory function.[81] This effect was not found with either therapy alone or in a placebo group. An accumulating body of research demonstrates a link between mitochondrial dysfunction and type 2 diabetes. The mitochondrial enhancement offered by supplemental CoQ_{10} appears to offer some therapeutic value against a defect in cellular energy production.[82,83]

In 2018 a systematic review and meta-analysis of CoQ_{10} use in diabetes was published, incorporating 13 randomized and controlled trials and 765 participants. CoQ_{10} was associated with a significant reduction in both hemoglobin A1c and fasting blood glucose levels (Fig. 68.4) but not with fasting insulin levels. It also was linked to a significant increase in HDL cholesterol and a reduction in triglyceride levels.[84]

Twenty-seven patients with ventricular premature beats (VPBs) and no evidence of organic heart disease received placebo for 3 to 4 weeks, followed by 60 mg/day of CoQ_{10} for 4 to 5 weeks. The reduction in VPBs was significantly greater after CoQ_{10} than after placebo. The beneficial effect of CoQ_{10} was seen primarily in diabetics, in whom the mean reduction in VPB frequency was 85.7%. A significant reduction in VPBs also occurred in 1 (11%) of 9 otherwise healthy patients and in 4 (36%) of 11 patients with hypertension.[85]

Male Infertility

Sperm dysfunction in infertile men has been associated with lipid peroxidation and decreased antioxidant defenses in spermatozoa.[86] A statistically significant correlation between CoQ_{10} levels and sperm count was found in 32 patients with a history of infertility.

Research suggested that sperm cells with low motility and abnormal morphology have low levels of CoQ_{10}.[87] Sperm cells with low CoQ_{10} concentrations might be less capable of quenching free radicals, and might also be compromised in their ability to produce ATP in these highly metabolically active cells. Some authors suggested using the reduced-to-oxidized CoQ_{10} ratio as a diagnostic test for asthenozoospermia.[88] In a 6-month, uncontrolled open trial, in which infertile men were supplemented orally with CoQ_{10}, sperm cells demonstrated a significant increase in motility, and both seminal plasma and sperm cell quantity of CoQ_{10} increased.[89] This was supported by other studies on both sperm motility and fertilization rates.[90,91] In 2013 a meta-analysis of 3 studies was published, which found that CoQ_{10} supplementation among men with infertility did not improve pregnancy rates (there were no data regarding live births), but it did improve both sperm motility and concentration.[92]

Parkinson's Disease

Excessive free radical production is largely responsible for dopaminergic cell death seen in Parkinson's disease (PD). Both as a cause and an effect of excessive oxidative stress, there is reduced activity of complex I of the mitochondrial electron transport chain. Given that CoQ_{10} is essential for the function of complex I and is also a powerful antioxidant, it holds therapeutic potential in the treatment of PD. Reduced levels of CoQ_{10} were demonstrated in the platelets of individuals with PD, and CoQ_{10} levels were strongly correlated with activity in complexes I and II/III. Clinically, it was demonstrated that oral CoQ_{10} increased complex I activity.[93]

A safety trial of CoQ_{10} supplementation in PD showed promising results.[29] All of the patients had the three primary features of PD—tremor, stiffness, and slowed movements—and were diagnosed with the disease within 5 years of the time they were enrolled. After initial screening and baseline blood tests, the patients were randomly divided into four groups. Three of the groups received CoQ_{10} at three different doses (300, 600, and 1200 mg/day), whereas a fourth group received a matching placebo for 16 months. The group that received the highest dose of CoQ_{10} (1200 mg/day) displayed a 44% reduction in PD progression compared with placebo. The groups that received 300 and 600 mg/day developed slightly less disability than the placebo group, but the effects were less than those in the group that received the highest dosage of CoQ_{10}. Average plasma levels were approximately 1.8, 2.1, and 4.5 mcg/mL, respectively, for the 300, 600, and 1200 mg dosages. These results indicated that the beneficial effects of CoQ_{10} in PD might require adequate plasma levels. It is important to point out in this study that CoQ_{10} was administered along with vitamin E at a dosage of 1200 international units (IU) per day. Because high dosages of vitamin E interfere with CoQ_{10} absorption,[12] it might have prevented higher levels of CoQ_{10} from being achieved. The researchers were aware of this issue but chose to include the vitamin E, given its apparent protective role against PD at the time (see Chapter 196 on Parkinson's Disease for more information).

Two recent studies cast doubt on the therapeutic efficacy of CoQ_{10} in PD. In a German study, a nanonized ubiquinone form of CoQ_{10} at a dosage of 100 mg three times daily or a matching placebo was given to 131 patients with PD for 3 months. Plasma levels of CoQ_{10} reached 4.6 mcg/mL in the treatment group, yet no effect on PD symptoms was shown. These results indicated that other factors might be responsible for determining the efficacy of CoQ_{10} in PD beyond achieving effective plasma levels. Two recent meta-analyses (published in 2016 and 2017) found that despite ample evidence of safety, there was no indication of a benefit from CoQ_{10} supplementation.[94,95]

On May 27, 2011 the National Institute of Neurological Diseases and Strokes (NINDS) stopped a Phase III study of CoQ_{10} for treatment of early-stage PD.[96] The study enrolled 600 patients with early PD at 67 sites throughout North America. Participants were randomized to receive one of the two dosing levels of active CoQ_{10} (1200 or 2400 mg/day) or matching placebo. All subjects also received vitamin E at a dosage of 1200 IU/day. Although CoQ_{10} was shown to be safe, results of an interim analysis showed that it was futile to complete the study because longer patient follow-up was not likely to demonstrate a statistically significant difference between active treatment and placebo. In 2014 the results of this Phase III trial were finally published, and no benefit was found.[97] Recently, a smaller study has suggested that when combined with creatine monohydrate, CoQ_{10} may slow the decline of cognitive function in Parkinson's patients.[98] Given the disappointing results from the Parkinson Study Group, it remains to be determined whether there is a role for CoQ_{10} in Parkinson's disease, either in combination with other therapies or for a subset of patients.

Friedreich's Ataxia

Friedreich's ataxia (FRDA) is a progressive neurological disease characterized by loss of myelin in the central nervous system. Evidence indicates that mitochondrial oxidative stress in FRDA may be responsible for the cardiomyocyte hypertrophy associated with this disease.[99] In a placebo-controlled trial, idebenone (a synthetic CoQ_{10} analog) significantly decreased heart hypertrophy (more than 20% decrease) in about 50% of study participants, with no adverse effects.[100,101]

A second study combined CoQ_{10} with vitamin E in an attempt to address two of the key features of FRDA—decreased mitochondrial respiratory chain function and increased oxidative stress. This therapy resulted in a rapid and sustained increase in the amount of energy generated by the diseased heart muscle, which returned to near-normal levels. The improvements in skeletal muscle energy generation paralleled those of the heart but were less substantial.[102]

A 2-year intervention study of CoQ_{10} with vitamin E in 50 FRDA patients demonstrated that low baseline levels of CoQ_{10} were the single best predictor of a positive clinical response.[103]

Muscular Dystrophy

The muscular dystrophies (MDs) are a group of hereditary diseases characterized by the progressive loss of muscle cells. In some types of MD, an impairment of mitochondrial function may contribute to the pathogenesis of the disease. Several studies demonstrated a deficiency of CoQ_{10} in muscle mitochondria of humans with MD.[38] In addition, serum CoQ_{10} levels were significantly ($P < 0.05$) inversely correlated with the degree of the genetic defect.[104] In addition to enhancing mitochondrial function, 90 days of CoQ_{10} supplementation resulted in markedly reduced inflammatory insult in animal models of MD.[105]

The first double-blind trial of CoQ_{10} in the treatment of individuals with MDs and neurogenic atrophies concluded, "Patients suffering from these muscle dystrophies and the like should be treated with vitamin CoQ_{10} indefinitely."[106] The same group conducted two studies on patients between 7 and 69 years of age who had MDs associated with cardiac diseases, including the Duchenne, Becker, and the limb-girdle dystrophies; myotonic dystrophy; Charcot-Marie-Tooth disease; and the Welander disease. Individuals were treated for 3 months with 100 mg/day CoQ_{10} or a matching placebo. In both trials, definite improvements in physical performance were recorded in the groups receiving CoQ_{10}. Cardiac function was monitored by technicians who were blinded to treatment group. In each case, they correctly identified the treatment group to which the patient had been assigned on the basis of improvement or lack of improvement in cardiac function.

In a smaller double-blind study, 100 mg of CoQ_{10} was given daily for 3 months to 12 patients with progressive MD. CoQ_{10} treatment resulted in significant improvements in cardiac output and stroke volume, as

well as increased physical well-being in 4 of 8 patients.[38] Subjective improvements included increased exercise tolerance, reduced leg pain, better control of leg function, and less fatigue. A small pilot trial of CoQ_{10} supplementation among participants with Duchenne muscular dystrophy receiving corticosteroid treatment also found benefit, with an 8.5% improvement in muscle strength among the CoQ_{10} group.[107]

Immune Function

A number of studies demonstrated immunomodulatory effects of CoQ_{10} or its analogs.[108–110] In a study of eight chronically ill patients, administration of 60 mg/day of CoQ_{10} was associated with significant increases in serum levels of immunoglobulin-G after 27 to 98 days of treatment.[111] In a cytokine analysis of white blood cells from 19 human volunteers, tumor necrosis factor-α levels were significantly decreased and interleukin-2 levels increased when incubated with CoQ_{10} in vitro.[112]

Acquired Immunodeficiency Syndrome

Because oxidative stress is believed to be involved in the pathogenesis of AIDS-related diseases, the antioxidant activity of CoQ_{10} may be of value for individuals with AIDS.[112,113]

Early studies suggested blood levels of CoQ_{10} were significantly lower in patients with AIDS and AIDS-related complex than in healthy controls, and that supplementation with CoQ_{10} improved ratios of lymphocytes.[114] Nucleoside reverse transcriptase inhibitor therapy, a mainstay of conventional human immunodeficiency virus management, has been associated with myopathy resulting from side effects on myocyte mitochondria. There is one report of CoQ_{10} alleviating this myopathy, thus permitting continuation of nucleoside reverse transcriptase inhibitor therapy.[115]

Toxicant Exposure

Many occupational and environmental toxicant exposures affect the mitochondrial respiratory chain.[116–120] Damage to the respiratory chain can decrease mitochondrial membrane potential, leading to upregulated apoptosis; CoQ_{10} demonstrated the ability to reduce this membrane-potential damage.[121,122] For example, chlorpyrifos, an organophosphorus pesticide associated with oxidative mitochondrial damage, may have some of its toxicity mitigated by CoQ_{10}.[123] It also appears that CoQ_{10} deficiency is associated with impaired detoxification via the sulfide oxidation pathway, as CoQ_{10} plays the role of an electron acceptor for the enzyme sulfide–quinone reductase (SQR).[124] This pathway is important for the detoxification of sulfide, which is endogenously produced via cysteine catabolism (Fig. 68.5). This pathway appears to be impaired among individuals with the nephrotic syndrome, for whom CoQ_{10} may be particularly important.[125] Although current diagnosis and treatment of environmentally related illnesses remain controversial, cytoprotection with CoQ_{10} may be an effective therapeutic method to reduce mitochondrial damage due to exposure to toxicants, both acute and chronic, and should be a focus of further research.[126]

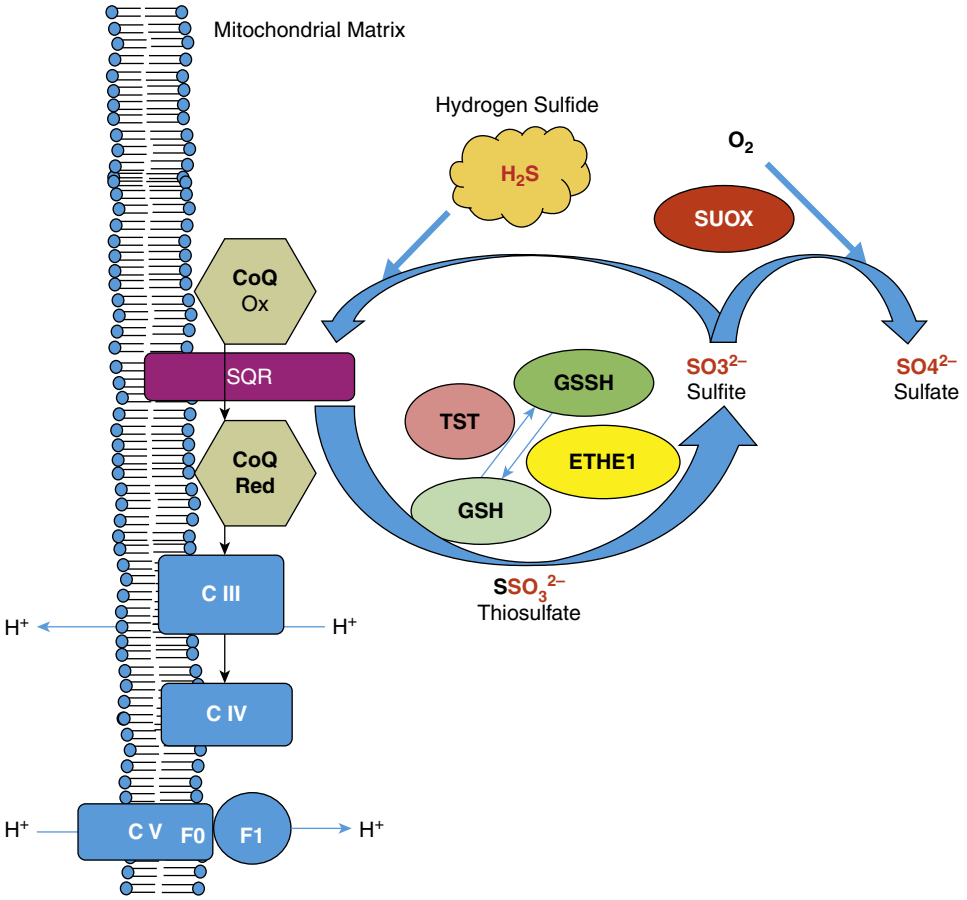

Fig. 68.5 Mitochondrial H2S oxidation pathway. SQR converts sulfide into thiosulfate by transferring two electrons from the H2S oxidation to ubiquinone (CoQ). Thiosulfate is then converted into sulfite by TST and ETHE1; this reaction requires a sulfur acceptor (glutathione, GSH). Excess of sulfite is converted into sulfate by SUOX. (From Ziosi M, Di Meo I, Kleiner G, et al. Coenzyme Q deficiency causes impairment of the sulfide oxidation pathway. *EMBO Mol Med.* 2017;9(1):96–111. PMID: 27856618. Reproduced from an open access article under the terms of the Creative Commons Attribution 4.0 License.)

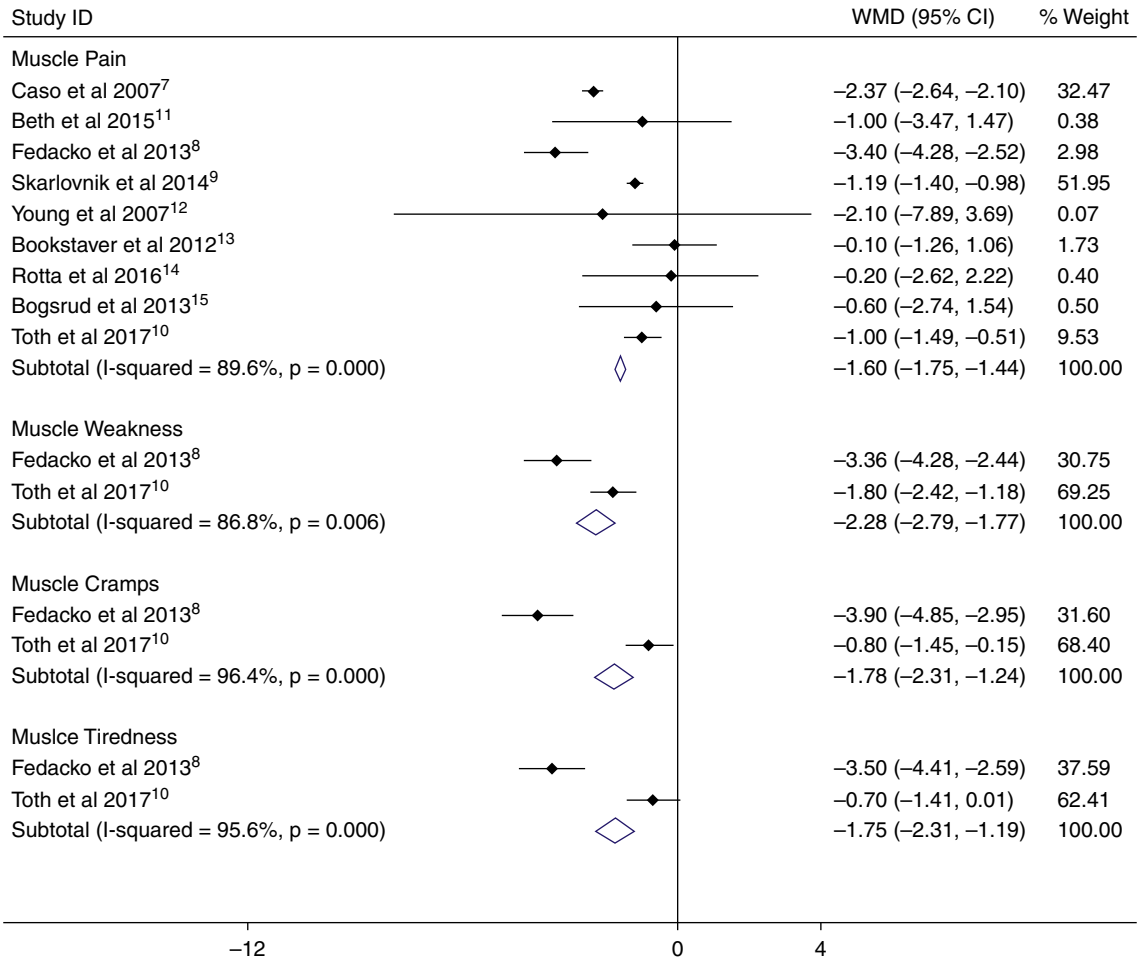

Fig. 68.6 Forest plot for statin-associated muscle symptoms: coenzyme Q_{10} versus placebo (fixed-effect model). CI indicates confidence interval; ID, identification; WMD, weighted mean difference. (From Qu H, Guo M, Chai H, et al. Effects of coenzyme Q10 on statin-induced myopathy: an updated meta-analysis of randomized controlled trials. *J Am Heart Assoc.* 2018;7(19):e009835. PMID: 30371340. Reproduced from an open access article under the terms of the Creative Commons Attribution–NonCommercial License.)

Topical Antiaging Effects

In recent years, makers of several over-the-counter skin creams have begun advertising the addition of CoQ_{10} as an ingredient capable of curbing the aging process. In a clinical trial, topical CoQ_{10} was able to protect against ultraviolet A–mediated oxidative stress, suppress the expression of collagenase, and cause a reduction in wrinkle depth.[33] Both ubiquinol and ubiquinone have been shown to increase in deeper epithelial layers (after topical application), and increase the skin's antioxidant capacity.[127]

Side Effects and Safety

CoQ_{10} appears to be safe and well tolerated in dosages up to 1200 mg/day in adults and up to 10 mg/kg body weight/day in children. Because safety during pregnancy and lactation has not been established, CoQ_{10} should not be used during these times unless the potential clinical benefit outweighs the risks. CoQ_{10} is contraindicated in cases of known hypersensitivity. In a series of 5143 patients treated with 30 mg/day of CoQ_{10}, the following incidence of side effects was reported[57]:

- Epigastric discomfort, 0.39%
- Loss of appetite, 0.23%
- Nausea, 0.16%
- Diarrhea, 0.12%

DRUG INTERACTIONS

Cholesterol-lowering statin drugs such as lovastatin, rosuvastatin, and pravastatin inhibit the enzyme 3-hydroxy-3-methylglutaryl CoA reductase, which is required for biosynthesis of both cholesterol and CoQ_{10}. Thus administration of these drugs might compromise CoQ_{10} status by decreasing its synthesis, and statin-associated myopathy has been hypothesized to be related to a depletion of CoQ_{10}. Although some trials demonstrated that statin therapy did reduce serum or muscle levels of CoQ_{10},[128,129] whether or not this CoQ_{10} depletion caused the myopathy remains controversial.[130] Given that statins are typically prescribed to lower cholesterol, with the intention being the prevention and treatment of cardiovascular disease, the concomitant use of CoQ_{10} seems well justified.

The question of whether or not CoQ_{10} therapy among statin users has additional benefit, however, may finally be answered after the results of two recent meta-analyses. In 2018 a meta-analysis of 12 randomized controlled trials of statin therapy found that statins were associated with decreased CoQ_{10} levels, regardless of the length of therapy, intensity, or type of statin.[131] That this decrease is consequential is well supported by a 2018 meta-analysis published in the *Journal of the American Heart Association;* this analysis of 12 randomized trials and 575 participants given CoQ_{10} or placebo (in addition to a statin) found that supplementation with CoQ_{10} significantly reduced muscle pain, muscle cramp, muscle tiredness, and muscle weakness, despite no reduction in plasma creatine kinase level (Fig. 68.6).[132]

The β-blockers propranolol and metoprolol were shown to inhibit CoQ_{10}-dependent enzymes.[133] The antihypertensive effect of these drugs might therefore be compromised in the long run by the development of CoQ_{10} deficiency. In one study, administration of 60 mg/day

of CoQ_{10} reduced the incidence of drug-induced malaise in patients receiving propranolol.[134]

A number of phenothiazines and tricyclic antidepressants were also shown to inhibit CoQ_{10}-dependent enzymes. It is therefore possible that CoQ_{10} deficiency might be a contributing factor to the cardiac side effects that are frequently seen with these drugs. In two clinical studies, supplementation with CoQ_{10} improved electrocardiographic changes in patients on psychotropic drugs.[135]

Several case reports describing potential interactions between CoQ_{10} and warfarin have been reported. CoQ_{10} is structurally related to menaquinone (vitamin K_2) and may have procoagulant effects.[136] In each of these patients, the international normalized ratio (INR), which had been stable and therapeutic, fell below the therapeutic range within 2 weeks of beginning CoQ_{10} supplementation (as low as 30 mg/day).[137] The INR returned to the therapeutic range after CoQ_{10} was discontinued. It is recommended that the INR be monitored closely if these agents are to be used concomitantly. However, in a double-blind trial, administration of 100 mg/day of CoQ_{10} for 4 weeks had no effect on the INR in 21 patients on long-term warfarin therapy.[138] Thus the sporadic case reports of an interaction between CoQ_{10} and warfarin might have been due to random fluctuations in INR values, rather than to CoQ_{10}.[15]

In a subchronic toxicity assessment, the no observed adverse effect level in rats was estimated to be 600 mg/kg per day for males and 200 mg/kg per day for females; in male and female dogs, the no observed adverse effect level was estimated to be more than 600 mg/kg per day.

Coleus forskohlii

Michael T. Murray, ND

OUTLINE

Coleus forskohlii (family: *Labiatae*)
Synonyms: *Coleus barbatus, Plectranthus barbatus, Plectranthus forskohlii*
Common name: coleus

GENERAL DESCRIPTION

Coleus forskohlii, a perennial, is a small member of the mint *(Labiatae)* family. It grows on sun-exposed, dry hill slopes between an altitude of 1000 and 6000 feet in subtropical, temperate climactic zones. Thus it is found in India, Nepal, Sri Lanka, and Thailand. Its Latin name comes from the word *coleos,* which means "sheath," and refers to the fused filaments that form a sheath around the stylus of the flower. The epithet *forskohlii* commemorates the Finnish botanist Forskal, who traveled extensively in Egypt and Arabia in the 18th century.

The radially spread rootstock is the portion of the plant that is used for medicinal purposes. The rootstock is also the source of a compound of unique biological importance, forskolin. No other species of *Coleus* contains forskolin.

CHEMICAL COMPOSITION

The primary chemical of clinical interest contained in *C. forskohlii* is the diterpene forskolin (Fig. 69.1). In 1974 forskolin was discovered during a large-scale screening of medicinal plants by the Indian Central Drug Research Institute. The screening revealed the presence of a hypotensive and spasmolytic component, which was initially named coleanol.[1] Additional investigation determined the exact chemical structure, and the name was changed to forskolin. From 1981 to 2010, forskolin was used in more than 15,000 in vitro and in vivo experimental studies designed to better understand the cellular processes governed by cyclic adenosine monophosphate (cAMP). Although most of these studies used this isolated constituent, there is evidence that other components within the plant extract may have biological activity, as well as enhance the absorption and action of forskolin.

HISTORY AND FOLK USE

C. forskohlii has a long history of use in Ayurvedic, Siddha, and Unani systems of medicine. Studies of the pharmacological activity of forskolin substantiate the traditional uses of *C. forskohlii* in such conditions as the following[1]:

- Cardiovascular disease
- Eczema
- Abdominal colic
- Respiratory disorders
- Painful urination
- Insomnia
- Convulsions

PHARMACOLOGY

As noted in a landmark experiment in 1981, the basic mechanism of action of forskolin is the activation of adenylate cyclase, which increases cAMP in cells.[2] cAMP is perhaps the most important cell-regulating compound. Once formed, it activates many other enzymes involved in diverse cellular functions.[3]

Under normal situations, cAMP is formed when an activating hormone (e.g., epinephrine) binds to a receptor site on the cell membrane and stimulates the activation of adenylate cyclase. This enzyme is found in all cellular membranes, and only the specificity of the receptor site determines which hormone will activate it in a particular cell. In contrast, forskolin appears to directly activate adenylate cyclase, bypassing hormonal transmembrane activation of adenylate cyclase.

The physiological and biochemical effects of a raised intracellular cAMP level include the following:

- Inhibition of platelet activation and degranulation
- Inhibition of mast cell degranulation and histamine release
- Increased force of contraction of heart muscle
- Relaxation of the arteries and other smooth muscles
- Increased insulin secretion
- Increased thyroid function

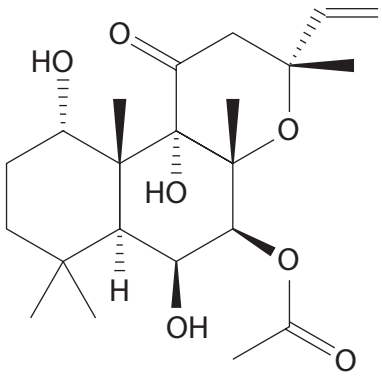

Fig. 69.1 Forskolin.

- Lipolysis

Forskolin possesses additional mechanisms of action independent of its ability to directly stimulate adenylate cyclase and cAMP-dependent physiological responses.[4] Specifically, forskolin was shown to inhibit a number of membrane transport proteins and channel proteins through a mechanism that did not involve the production of cAMP. The result was transmembrane signaling that resulted in activation of other cellular enzymes. Research is under way to determine the exact receptors to which forskolin binds.

Another action of forskolin is the inhibition of platelet-activating factor (PAF) by interfering with PAF binding to receptor sites.[5] PAF plays a central role in many inflammatory and allergic processes, including neutrophil activation, increased vascular permeability, smooth muscle contraction (e.g., bronchoconstriction), and reduction in coronary blood flow. Treatment of platelets with forskolin before PAF exposure results in a 30% to 40% decrease in PAF binding. This decrease in PAF binding caused by forskolin was concomitant with a decrease in the physiological responses of platelets induced by PAF. However, this forskolin-induced decrease in PAF binding was not a consequence of cAMP formation because the addition of a cAMP antagonist did not inhibit the action of forskolin. In addition, the inactive analog of forskolin, dideoxyforskolin, which does not activate adenyl cyclase, also reduced PAF binding to its receptor. Researchers speculated that the action of forskolin on PAF binding was due to a direct effect of this molecule and its analog on the PAF receptor itself or to components of the postreceptor signaling for PAF.

CLINICAL APPLICATIONS

The therapeutic ramifications of *C. forskohlii* based on the pharmacology of forskolin are immense. In many conditions, a decreased intracellular cAMP level is thought to be a major factor in the development of the disease process. *C. forskohlii* appears to be especially well indicated for the following:

- Atopic dermatitis
- Asthma
- Psoriasis
- Angina
- Hypertension
- Weight loss
- Glaucoma

Although *C. forskohlii* can be used alone, it may prove to be most useful when combined with other botanicals or measures, or both.

Inflammatory Conditions

Allergic conditions such as asthma and eczema are characterized by a relative decrease in cAMP in both the bronchial smooth muscle and the skin. As a result, mast cells degranulate and smooth muscle cells contract more readily. In addition, these allergic conditions are also characterized by excessive levels of PAF.

Asthma and Eczema

Current drug therapy for allergic conditions like asthma and eczema is largely designed to increase cAMP levels by using substances that either bind to receptors to stimulate adenylate cyclase (e.g., corticosteroids) or inhibit the enzyme phosphodiesterase, which breaks down cAMP once it is formed (e.g., methylxanthines). These actions are different than forskolin's ability to increase the production of cAMP via transmembrane activation of adenylate cyclase. The cAMP-elevating action of forskolin supports the use of *C. forskohlii* extracts alone or in combination with standard drug therapy in the treatment of virtually all allergic conditions.

C. forskohlii extracts may be particularly useful in asthma because increasing intracellular levels of cAMP results in relaxation of bronchial muscles and relief of respiratory symptoms. Forskolin was shown to have remarkable effects in relaxing constricted bronchial muscles in patients with asthma.[6–8] This type of smooth muscle is also found in the gastrointestinal tract, uterus, bladder, and arteries. Forskolin was shown to have tremendous antispasmodic action on these various smooth muscles. This antispasmodic action of forskolin supports the folk medicine use of *C. forskohlii* in the treatment of not only asthma but also intestinal colic, uterine cramps (menstrual cramps), painful urination, angina, and hypertension. In addition to forskolin's ability to relax smooth muscle, its other antiallergic activities, such as inhibiting the release of histamine and the synthesis of allergic compounds, are also beneficial in treating asthma.[9]

One double-blind clinical study sought to compare the antiasthmatic effects of forskolin with the drug fenoterol. Sixteen patients with asthma were studied using three different preparations:

- Single inhalation dose of fenoterol (as a dry-powder capsule [0.4 mg])
- Metered doses of fenoterol (0.4 mg)
- Forskolin dry-powder capsules (10 mg)

All three preparations led to a significant improvement in respiratory function and bronchodilation. However, although the fenoterol preparations caused tremors and decreased blood potassium levels, no such negative effects were seen with forskolin.

In another study, the bronchodilating effect (after 5 minutes) of forskolin was as good as that produced by fenoterol in 12 healthy volunteers (nonsmokers), as determined by whole-body plethysmography.[10] Both substances were administered by metered-dose inhalers. At the beginning (after 3 and 5 minutes) of the study, the protective effect of forskolin against inhaled acetylcholine was as good as that produced by fenoterol, whereas later on (after 15 and 30 minutes), fenoterol provided stronger protection.

Whether orally administered forskolin in the form of *C. forskohlii* extract would produce similar bronchodilatory effects is yet to be determined. However, based on the plant's historical use and additional mechanisms of action, it appears likely.

Psoriasis

Psoriasis is a common skin disorder that seems to be caused by a relative decrease in cAMP compared with cyclic guanosine monophosphate (cGMP). The result is a tremendous increase in cell division. Cells divide in psoriasis at a rate 1000 times greater than normal. Preliminary studies indicated that forskolin might be of great benefit in individuals with psoriasis via its ability to reestablish the normal balance between cAMP and cGMP.[1]

Cardiovascular Effects

The most useful clinical applications of *C. forskohlii* extracts that will emerge in the future will likely be for cardiovascular diseases such as hypertension, congestive heart failure, and angina. The cardiovascular effects of *C. forskohlii* and its components have been studied in great detail.[1,11,12] Its basic cardiovascular actions involve the lowering of blood pressure, along with improving the contractility of the heart. Again, this is related to increasing cAMP levels throughout the cardiovascular system, which results in relaxation of the arteries and increased force of contraction. The net effect is a significant improvement of cardiovascular function.

Hypertension and Cardiac Failure

Several clinical and animal studies supported the use of forskolin in hypertension and cardiac failure.[11–15] In one human study involving seven patients with dilated cardiomyopathy, forskolin was shown to improve left ventricular function primarily via reduction of preload and without raising metabolic costs.[13] This study confirmed earlier animal studies showing that forskolin increased the contractile force of heart muscle.[12]

In another human study, the hemodynamic effects of intravenous (3 mcg/kg per minute) forskolin given to patients with dilated cardiomyopathy were evaluated.[14] Although systemic vascular resistance and diastolic pressure decreased, forskolin had no effect on the cardiac index, ejection fraction, or myocardial oxygen consumption at this low dosage. However, when a small dosage of dobutamine was given along with the forskolin, an increase in all four parameters was observed. At a higher dosage (4 mcg/kg per minute), forskolin increased heart function by 19% and produced a 16% rise in heart rate. However, these changes were associated with symptomatic flush syndromes. These results indicated that forskolin might best be used in congestive heart failure in combination with other botanicals, such as *Crataegus* (see Chapter 71).

Forskolin was also shown to be a direct cerebral vasodilator, indicating that it might prove to be useful in cerebral vascular insufficiency and poststroke recovery.[15]

An additional mechanism of action particularly beneficial in a wide range of cardiovascular conditions is inhibition of platelet aggregation. In this area, the evidence indicated that the standardized *C. forskohlii* extract was superior to pure forskolin.[16] In an animal model evaluating in vivo inhibition of platelet aggregation, rats were divided into four groups: group 1 received *C. forskohlii* extract (480 mg/kg supplying 20 mg/kg of forskolin), group 2 received forskolin (20 mg/kg), group 3 received dipyridamole, and group 4 served as the controls. All treatments were given orally once daily. Adenosine diphosphate–induced platelet aggregation was measured on odd days 1 through 15. All three treatments produced significant inhibition of platelet aggregation. On day 15, the inhibitions were approximately 42% for group 1, 37% for group 2, and 52% for group 3. Hence, the extract of *C. forskohlii* produced greater inhibition than the pure forskolin.

Weight Loss Programs

Forskolin was shown to stimulate lipolysis, as well as inhibit the synthesis of fat in adipocytes.[17–20] Forskolin was also shown to counteract the age-related decreased response of fat cells to lipolytic hormones like epinephrine.[21] In one double-blind clinical investigation, oral ingestion of forskolin (250 mg of 10% forskolin extract twice a day) for a 12-week period was shown to favorably alter body composition while concurrently increasing bone mass and serum free testosterone levels in overweight and obese men.[22] However, a similar study in slightly overweight females showed little benefit over a placebo.[23] In the most recent double-blind study, there were no significant advantages with a *C. forskohlii* extract over the placebo in terms of weight loss or waist-to-hip ratio in the 12-week study, but results showed that supplementation with the extract in conjunction with a hypocaloric diet significantly improved insulin and insulin resistance and thus may produce greater effects over a longer period of time and be useful in the management of metabolic risk factors. Significant increases in high-density lipoprotein cholesterol (HDL-c) were observed in both groups after the 12-week intervention.[24]

Glaucoma

In clinical studies, forskolin was shown to greatly reduce intraocular pressure (IOP) when it was applied directly to the eyes.[24–27] This effect indicated that topical forskolin preparations might be of benefit in the treatment of glaucoma. Unlike current drug therapy, forskolin actually increased intraocular blood flow, had no side effects, and did not induce miosis. Oral administration might prove effective as well. In an open-label pilot study, 16 patients with glaucoma and stable IOP underwent treatment with different topical drugs and were given a supplement containing 15 mg of forskolin along with rutin (200 mg), thiamin (0.7 mg), and riboflavin (0.8 mg) for 40 days, which produced a further decrease in IOP by roughly 20% of the initial value.[28]

OTHER CLINICAL APPLICATIONS

C. forskohlii extracts concentrated and standardized for forskolin content may prove to be useful in a number of other clinical applications, including the following:

- Hypothyroidism
- Malabsorption and digestive disorders
- Depression
- Prevention of cancer metastases
- Immune system enhancement

Hypothyroidism

Forskolin was shown to increase thyroid hormone production, as well as to stimulate thyroid hormone release.[29]

Malabsorption and Digestive Disorders

Forskolin stimulated digestive secretions, including the release of hydrochloric acid, pepsin, amylase, and pancreatic enzymes.[30,31] Forskolin was shown to promote nutrient absorption in the small intestine.[32] *C. forskohlii* extracts might prove to be quite useful in treating dry mouth because forskolin was found to increase salivation.[33]

Depression

Forskolin was shown to exert antidepressant activity in animal studies.[34]

Cancer

The ability to increase cAMP is very relevant to cancer. Forskolin has shown a number of antitumor effects, including the induction of mesenchymal-to-epithelial transition, inhibition of cell growth and migration, and enhancement of sensitivity to conventional antitumor drugs in cancer cells. Forskolin was also shown to be a potent inhibitor of cancer metastasis in mice injected with malignant cells. As little as 82 mcg administered to mice inhibited metastasis by over 70%.[35]

Immune System Enhancement

Forskolin exhibited potent immune system enhancement (primarily through activation of macrophages and lymphocytes) in several models.[36–38]

DOSAGE

The recommended dosage should be based on the level of forskolin. Because the forskolin content of coleus root is typically only 0.2% to 0.3%, crude coleus products may not be sufficient to produce a pharmacological effect. The safety of the whole root at high dosages is not as well studied. It is best to use standardized extracts that have known forskolin content.

Daily dosages:

- Forskolin: 5 to 10 mg two to three times a day
- Standardized extract (10% forskolin): 250 mg one to two times a day
- Dried root: 2 to 5 g two to three times a day

TOXICOLOGY

The animal studies on forskolin indicated low toxicity. Inclusion of *C. forskohlii* extract in the diet at a 1% level is, however, associated with the inducement of fatty liver, presumably due to nonforskolin components stimulating the synthesis and accumulation of triglycerides within the liver.[39] Although this level of intake is unlikely in humans, it does indicate that screening for liver function is indicated with any long-term use.

The pharmacology of forskolin suggests it would be wise to restrict the use of *C. forskohlii* preparations in patients with low blood pressure and peptic ulcers.

DRUG INTERACTIONS

C. forskohlii preparations should be used cautiously in patients on prescription medications, especially antiasthmatics and antihypertensives, due to its ability to potentiate these and other drugs' effects.

Commiphora mukul (Mukul Myrrh Tree)

Michael T. Murray, ND

OUTLINE

Commiphora mukul (family: Burseraceae)
Common name: mukul myrrh tree

GENERAL DESCRIPTION

Commiphora mukul, a small, thorny tree that grows 4 to 6 feet tall, is native to Saudi Arabia and India. In its natural setting, the tree remains essentially free of foliage for most of the year. Its bark is ash colored and comes off in rough flakes, exposing the underbark, which also peels off. When injured, the tree exudes a yellowish gum resin that has a balsamic odor. This oleoresin is referred to as "gum guggul" or "guggulu." This resin is used for medicinal purposes. When tapped during the winter, the average tree yields 1.5 to 2 lb of resin.[1]

CHEMICAL COMPOSITION

Guggulu contains a mixture of diverse chemical constituents that can be separated into several fractions.[1] The first step in the fractionation process involves mixing guggulu with ethyl acetate to yield soluble and insoluble fractions. The insoluble fraction, containing the carbohydrate constituents, is regarded as toxic and is the major reason why extracts of the soluble portion are preferred to crude gum guggul for medical use. The insoluble portion has no demonstrable pharmacological activity other than toxicity.[1]

In contrast, the soluble portion possesses significant cholesterol-lowering and anti-inflammatory activity. The soluble portion can be further separated into base, acid, and neutral fractions. The neutral portion possesses almost all of the cholesterol-lowering activity, whereas the acid portion possesses the anti-inflammatory components.[1]

On further purification of the neutral portion, it was determined that the ketone fraction contains the most potent cholesterol-lowering components. The ketone fraction is composed of C_{21} or C_{27} steroids, with the major components being Z- and E-guggulsterone (Fig. 70.1). These compounds are considered the major active components of gum guggul and its extracts.[1]

For medicinal purposes, a standardized extract known as guggulipid, which is standardized to contain a minimum of 50 mg of guggulsterones per gram, is regarded as the most beneficial in terms of safety and effectiveness.[1,2] In addition to guggulsterones, guggulipid contains various diterpenes, sterols, esters, and fatty alcohols. These accessory components appear to exert a synergistic effect.[1,2]

HISTORY AND FOLK USE

Guggulu is a highly valued botanical medicine in the Indian system of medicine, Ayurveda. It is included in formulas for various health conditions, including rheumatoid arthritis and lipid disorders. The classic Ayurvedic medical text, the *Sushruta Samhita,* describes in detail the usefulness of guggul in the treatment of obesity and other disorders of fat metabolism, including "coating and obstruction of channels."[1,2]

Inspired by this description, researchers began examining, in well-designed scientific studies, the clinical effectiveness of gum guggul and its extracts in disorders of lipid metabolism—specifically, its ability to lower cholesterol and triglyceride levels and promote weight loss. This research resulted in the development of a natural cholesterol-lowering substance that is safer and more effective than many cholesterol-lowering drugs, including niacin. Guggulipid was granted approval in India for marketing as a lipid-lowering drug in 1986.[1,2]

PHARMACOLOGY

Lipid Disorders

Numerous studies in humans and animals showed that gum guggul (both crude and purified alcohol extract),[3–7] its petroleum ether extract (referred to as fraction A),[8–11] and guggulipid (standardized ethyl acetate extract)[12,13] all exert effective lipid-lowering activity. All lower both elevated cholesterol and triglyceride levels. The effect on cholesterol is particularly beneficial, as guggul lowers very low-density lipoprotein (VLDL) cholesterol and low-density lipoprotein (LDL) cholesterol, simultaneously elevating high-density lipoprotein (HDL) cholesterol, thus offering protection against heart disease as a result of atherosclerosis.

Guggul preparations appear most indicated in type IIb (increased LDL, VLDL, and triglycerides) and type IV (increased VLDL and triglycerides) hyperlipidemias. Preliminary human clinical trials using guggulipid found that cholesterol levels showed typical reductions of 14% to 27% in total cholesterol levels in a 4- to 12-week period, whereas triglyceride levels dropped from 22% to 30%.[12–14] However, a larger

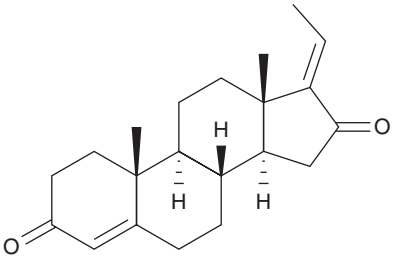

Fig. 70.1 Guggulsterone.

double-blind study did not show that either of two doses of a standardized guggul extract (guggulipid, containing 2.5% guggulsterones) lowered LDL cholesterol levels in healthy adults with hyperlipidemia.[15] Subjects received either standard-dose guggulipid (1000 mg), high-dose guggulipid (2000 mg), or matching placebo three times daily for 8 weeks. LDL cholesterol levels decreased by 5% in the placebo group. Both standard-dose guggulipid and high-dose guggulipid raised levels of LDL cholesterol by 4%, respectively. There were no significant changes in levels of total cholesterol, HDL cholesterol, triglycerides, or VLDL cholesterol in response to treatment with guggulipid in the intention-to-treat analysis. Although guggulipid was generally well tolerated, 6 participants treated with guggulipid developed a hypersensitivity rash compared with none in the placebo group. These results call into question the clinical effectiveness of guggulipid despite plausible mechanisms of action.

In vitro studies showed that the primary mechanism of action involves guggulsterones acting as an antagonist ligand for the farnesoid X receptor (FXR) and upregulating the bile salt export pump. As a result, guggulsterones promote the conversion of cholesterol to bile acids and increase the uptake of LDL cholesterol from the blood by the liver.[14,16–19] Another possible action of guggulsterones in affecting lipid levels is their ability to stimulate thyroid function.[20,21]

Despite these noted in vitro effects, more research is needed to clarify the clinical usefulness of guggul as a lipid-lowering agent. However, guggul may have other benefits against atherosclerosis beyond lowering lipid levels. Gum guggul and its extracts, including guggulipid, have been shown to prevent the formation of atherosclerosis and aid in the regression of preexisting atherosclerotic plaques in animals. This implies that they may have similar effects in humans.

Gum guggul and guggulipid were also shown to prevent heart damage by free radicals and to improve heart metabolism.[9,14] Gum guggul and its extracts have a mild effect in inhibiting platelet aggregation and promoting fibrinolysis, implying that it may also prevent the development of a stroke or embolism.[2,14]

Stock photo

Anti-Inflammatory Effects

The guggulsterone fraction of gum guggul was shown to exhibit significant anti-inflammatory action in experimental models of inflammation (e.g., raw paw edema and adjuvant arthritis method).[22–24] Its activity in models of acute inflammation is comparable to approximately one fifth that of hydrocortisone and equal to phenylbutazone and ibuprofen.[22] In models of chronic inflammation, it was shown to be more effective than hydrocortisone, phenylbutazone, and ibuprofen in reducing the severity of secondary lesions. The anti-inflammatory action is thought to be caused by inhibition of delayed hypersensitivity reactions.[23,24] Guggulsterones exert a number of anti-inflammatory effects, including inhibition of nuclear factor-κβ.[25]

The clinical application of these effects may include osteoarthritis. In an open trial of 30 patients with osteoarthritis of the knee, 500 mg of the concentrated extract three times daily produced significant improvements on the Western Ontario and McMaster University Osteoarthritis Index Total Score and subscales, visual analog scale, and 6-minute walk test. Western Ontario and McMaster University Osteoarthritis Index subscales were used as outcome measures.[26]

Anticancer Effects

Guggulsterone was shown to exert a wide range of anticancer effects, including an ability to modulate expression of proteins with antiapoptotic, cell survival, cell, angiogenic, and metastatic activities in tumor cells. As a result, evidence suggested that guggulsterone could suppress tumor initiation, promotion, and metastasis.[27] The clinical usefulness of these effects has not yet been determined.

DOSAGE

Although the crude oleoresin (gum guggul), alcohol extract, and petroleum ether extract all exert lipid-lowering and anti-inflammatory action, they are associated with side effects (e.g., skin rashes, diarrhea) at the doses required to produce a clinical effect. Interestingly, in classic Ayurvedic texts, the purification of crude guggul in Triphala kashaya is recommended to eliminate these side effects.[2]

Guggulipid, the standardized ethyl acetate extract of the gum guggul, demonstrated not only greater clinical efficacy but also much greater patient tolerance than crude or purified gum guggul. The dosage of guggulipid is based on its guggulsterone content. The typical dosage, 25 mg of guggulsterone three times per day, is an effective treatment for elevated cholesterol levels, elevated triglyceride levels, or both. For a 2.5% guggulsterone content extract, this translates to an effective dose of 1000 mg three times/day.

For comparison, the daily dosages of the other forms follow:

- Crude gum guggul—10 g
- Alcoholic extract—4.5 g
- Petroleum ether extract—1.5 g

TOXICOLOGY

The side effects of crude gum guggul and alcoholic and petroleum ether extracts were discussed previously. In clinical studies, guggulipid did not display any untoward side effects, nor did it adversely affect liver function, blood sugar control, kidney function, or hematologic parameters.[11–13]

Safety studies in rats, rabbits, and monkeys demonstrated guggulipid to be nontoxic.[14] It does not possess any embryotoxic or fetotoxic effects and is therefore considered safe to use in pregnancy. In mice, the oral and intraperitoneal mean lethal dose values were 1600 mg/kg.[1]

DRUG INTERACTIONS

Although there are no reported guggulipid–drug interactions, one in vitro study with hepatocytes showed that guggulipid could induce the expression of CYP3A enzyme activity, suggesting that guggulipid therapy should be used cautiously in patients taking prescription medications that are metabolized by CYP3A family members, including such drugs as statins, ketoconazole (Nizoral), itraconazole (Sporanox), fexofenadine (Allegra), triazolam (Halcion), and many others.[28] In addition, guggulsterones demonstrated agonist activity against the estrogen receptor α isoform and the progesterone receptor; therefore it should be used with caution with estrogen and/or progesterone preparations.

Crataegus oxyacantha (Hawthorn)

Michael T. Murray, ND

OUTLINE

Crataegus oxyacantha (family: *Rosacea*)
Synonym: *Crataegus laevigata*
Common names: hawthorn, may bush, whitethorn, haw

GENERAL DESCRIPTION

Crataegus oxyacantha is a spiny tree or shrub that is native to Europe. It may reach a height of 30 ft but is often grown as a hedge plant. Its common name, hawthorn, is a corruption of "hedgethorn" because it was used in Germany to divide plots of land. Its botanical name, *C. oxyacantha,* is from the Greek *kratos,* meaning "hardness (of the wood)"; *oxus,* meaning "sharp"; and *akantha*, meaning "a thorn." The fruit and blossoms are used medicinally.[1]

Other species of crataegus (e.g., *C. monogyna, C. pentagyna*) contain similar constituents and likely have identical pharmacological actions to *C. oxyacantha,* so they are suitable alternatives.[2,3]

CHEMICAL COMPOSITION

Hawthorn leaves, berries, and blossoms contain many biologically active flavonoid compounds, particularly anthocyanidins and proanthocyanidins (polymers of anthocyanidins, also known as biflavans or procyanidins; Fig. 71.1).[2–5] These flavonoids are responsible for the red to blue colors not only of hawthorn berries but also of blackberries, cherries, blueberries, grapes, and many flowers as well. These compounds are highly concentrated in hawthorn berry and flower extracts.

High-performance liquid chromatography and thin-layer chromatography (of crataegus extracts) demonstrated that extracts of the flowers are particularly rich in flavonoids (e.g., quercetin, quercetin-3-galactoside, vitexin, vitexin-4′-rhamnoside), procyanidins (Fig. 71.2), and oligomers of procyanidins (Fig. 71.3).[5,6]

In addition to flavonoids, crataegus extracts also contain the following[7]:

- Cardiotonic amines (e.g., phenylethylamine, o-methoxyphenylethylamine, tyramine, isobutylamine)
- Choline and acetylcholine
- Purine derivatives (e.g., adenosine, adenine, guanine, caffeic acid)
- Amygdalin
- Pectins
- Triterpene acids (ursolic, oleanolic, and crategolic acids)

HISTORY AND FOLK USE

Crataegus flowers and berries have been used primarily as cardiac tonics and mild diuretics in organic and functional heart disorders. They are also used for their astringent qualities to relieve sore throat pain.[1]

PHARMACOLOGY

The pharmacology of crataegus centers on its flavonoid components.[2–4] The proanthocyanidins in crataegus are largely responsible for its cardiovascular activities.

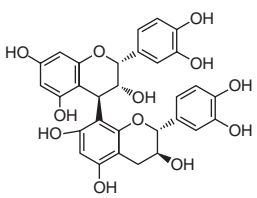

Fig. 71.1 Proanthocyanidin B2.

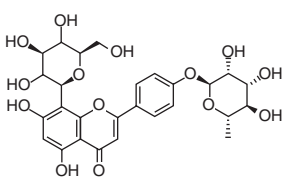

Fig. 71.2 Vitexin-4′-rhamnoside.

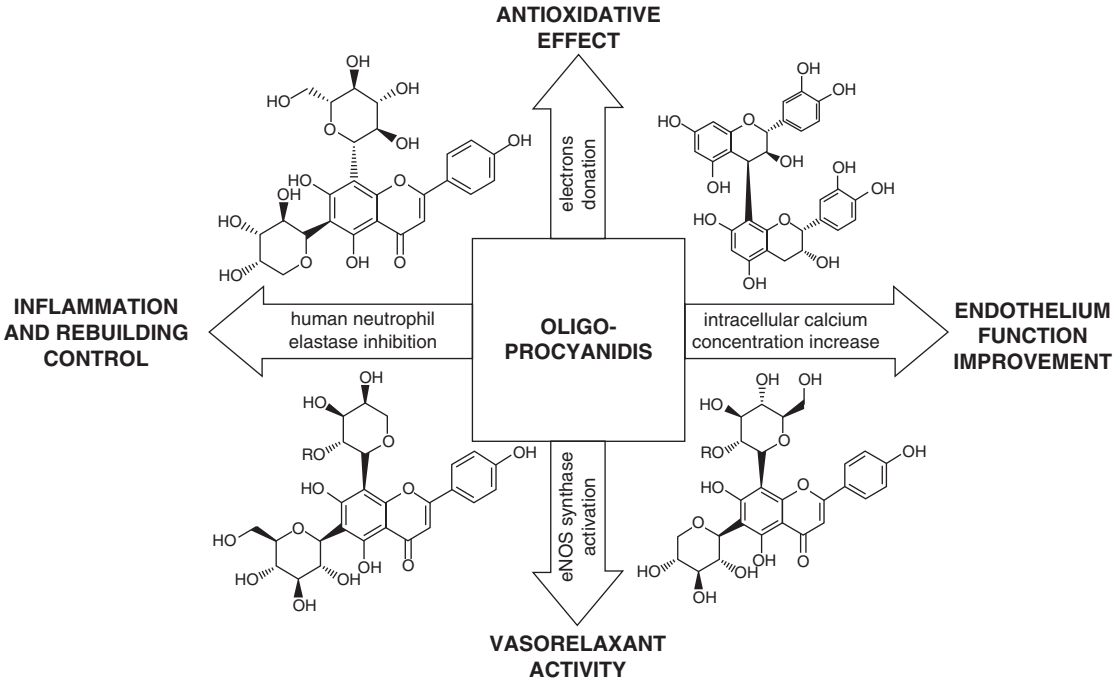

Fig. 71.3 Main mechanisms of action of oligopolycyanidins in *Crataegus*. (From Zorniak M, Szydlo B, Krzeminski TF. (2017). *Crataegus* special extract WS 1442: up-to-date review of experimental and clinical experiences. *J Physiol Pharmacol*. 2017;68[4]:521–526.)

Synergism with Vitamin C

As stated earlier, crataegus is particularly rich in anthocyanidins and proanthocyanidins. These flavonoids have strong "vitamin P" activity. Included in their effects are the abilities to increase intracellular vitamin C levels, stabilize vitamin C (by protecting it from oxidation), and decrease capillary permeability and fragility.[8,9]

Collagen-Stabilizing Action

Similar to other proanthocyanidin-rich extracts, crataegus possesses significant collagen-stabilizing action, including the following:

- Reinforcement of the natural cross-linking of collagen that forms the collagen matrix of connective tissue (e.g., ground substance, cartilage, tendon)
- Prevention of free radical damage because of potent antioxidant and free radical–scavenging action
- Inhibition of enzymatic cleavage by enzymes secreted by white blood cells during inflammation
- Prevention of the release and synthesis of compounds that promote inflammation, such as histamine, serine proteases, prostaglandins, and leukotrienes

Cardiovascular Effects

The beneficial effects of crataegus in the treatment of cardiovascular conditions appear to be a result of the following pharmacological actions:

- Improvement of the blood supply to the heart by dilating the coronary vessels[2,3,10–15]
- Improvement of the metabolic processes in the heart, which results in an increase in the force of contraction of the heart muscle and elimination of some types of rhythm disturbances[2,3,11,16–18]
- Inhibition of angiotensin-converting enzyme (ACE)[19]
- Decreased expression of microRNA-155, resulting in an increase in endothelial nitric oxide synthase (eNOS) expression and improved endothelial function.[42]
- Donation of electrons producing antioxidative free radical–scavenging effects
- Inhibition of human neutrophil elastase
- Increases intracellular calcium concentrations, protecting endothelial permeability dysfunction

The ability of crataegus to dilate coronary blood vessels has been repeatedly demonstrated in experimental studies. This effect appears to be a result of relaxation of vascular smooth muscle by a combination of direct effects on both the vascular endothelium and smooth muscle. In addition, various flavonoid components in crataegus have been shown to inhibit vasoconstriction by various substances, including hypophysin, histamine, and acetylcholine. In addition, procyanidins have been shown to inhibit ACE.[2,3,20]

Improvement in cardiac metabolism has been demonstrated in humans and animals that have received crataegus extracts.[2,3] The improvement is not only a result of increased blood and oxygen supply to the myocardium but also a result of flavonoid–enzyme interactions. Crataegus extracts and various flavonoid components have been shown to inhibit cyclic adenosine monophosphate phosphodiesterase (cAMP-PDE).[21] This results in increased levels of cAMP within the myocardium, leading to a positive inotropic effect (i.e., an increase in the force of contraction). This is particularly beneficial in cases of congestive heart failure (CHF; discussed in the section "Congestive Heart Failure").

The procyanidins of crataegus demonstrated a specific inhibition of ACE similar to the synthetic ACE inhibitors widely used in the treatment of hypertension.[20] The proanthocyanidins that appear to have the highest activity are proanthocyanidins B-5 3,3′-di-O-gallate and C-1 3,3′,3″-tri-O-gallate. It is not surprising that these proanthocyanidins are found in relatively high concentrations in hawthorn berries, flowers, and their extracts.[5,6]

Mitochondrial Effects

Many cardiovascular diseases (e.g., arrhythmias, heart failure, myocardial weakness) are associated with structural and functional

disturbances of the mitochondria. Because mitochondria produce 95% of the energy necessary for heart function, therapeutic agents that could influence mitochondrial dysfunction are of special importance. Considering the cardioprotective and cardiotonic effects of hawthorn, studies have been done to investigate the effect of crataegus fruit extracts (CE) on mitochondrial function. One animal study performed an oxygraphic investigation of the effect of CE (in concentration range from 70 ng/mL to 13.9 μg/mL of crataegus phenolic compounds [PC]) on isolated rat heart mitochondria.[22] At concentrations from 278 ng/mL to 13.9 μg/mL of PC, CE stimulated stage 2 respiration by 11% to 34% and decreased mitochondrial membrane potential by 1.2 to 4.4 mV, as well as H_2O_2 production. The highest CE concentration also slightly reduced the maximal adenosine diphosphate (ADP)-stimulated and uncoupled respiration, which may be because of inhibition of the mitochondrial respiratory chain between flavoprotein and cytochrome c. An additional animal study investigated the effect of CE on mitochondrial function during experimentally induced myocardial infarction in rats.[23] For 30 days, CE was administered orally at a dosage of 0.5 mL/100 g body weight. At the end of the 30 days, the animals were administered isoproterenol for 2 days at an interval of 24 hours. Pretreatment with CE maintained mitochondrial antioxidant status and prevented mitochondrial lipid peroxidative damage and a decrease in Krebs's cycle enzymes induced by isoproterenol. Although further studies are necessary, the promotion of mitochondrial function may be a significant mechanism of efficacy.

CLINICAL APPLICATIONS

The clinical use of crataegus revolves around its cardiovascular effects. Its use in atherosclerosis, hypertension, and CHF is discussed in the following subsections.

Atherosclerosis

Crataegus preparations, although in a supplement form, should be thought of as a necessary food in the prevention and treatment of atherosclerosis. Increasing the intake of flavonoid compounds by taking crataegus extracts has numerous health-promoting effects, including reducing cholesterol levels and decreasing the size of existing atherosclerotic plaques.[24] This effect is probably a result of collagen stabilization.

A decrease in the integrity of the collagen matrix of the artery results in cholesterol deposition. Many researchers believe that if the collagen matrix of the artery remains strong, atherosclerotic plaque will never develop. Crataegus flavonoids, by increasing the integrity of collagen structures, may offer significant protection against atherosclerosis. In addition, feeding proanthocyanidin extracts to animals resulted in the reversal of atherosclerotic lesions and decreased serum cholesterol levels.

Flavonoids contained in hawthorn extracts appear to offer significant prevention, and potential reversing effects, in the treatment of atherosclerotic processes, which are still the major causes of death in the United States.

Hypertension

Crataegus exerts a mild antihypertensive effect, which has been demonstrated in both experimental and clinical studies.[2] Its action in lowering blood pressure is unique in that it produces a number of diverse pharmacological effects. Specifically, it dilates the coronary vessels, inhibits ACE, acts as an inotropic agent, and possesses mild diuretic activity. Its clinical effects in lowering blood pressure, however, are generally mild.[19]

In one double-blind study evaluating crataegus hypotensive effects, 79 patients with type 2 diabetes were randomized to either crataegus extract (1200 mg/day) or placebo for 16 weeks. Hypotensive drugs were used by 71% of the study population, with a mean intake of 4.4 hypoglycemic and/or hypotensive drugs. Although there was no effect on systolic blood pressure, the diastolic blood pressure in the crataegus group dropped from a baseline of 85.6 to 83.0 mm Hg compared with the placebo group (baseline: 84.5 mm Hg; outcome: 85.0 mm Hg). No herb–drug interaction was found.[25]

The effects of crataegus generally require prolonged administration, and in many instances, it may take up to 2 weeks before adequate tissue concentrations are achieved. It should be kept in mind that because beta blockers lower blood pressure by reducing cardiac output, crataegus administration to patients on these drugs may produce a mild hypertensive response.

Congestive Heart Failure

Crataegus has a long history of use in the treatment of CHF, particularly in combination with digitalis or other herbs containing cardiac glycosides such as *Cereus grandiflorus,* also known as *Cactus grandiflorus,* and *Convallaria majalis.* It potentiates the action of the cardiac glycosides, presumably via its ability to inhibit cAMP-PDE and to interact with calcium channels.

Because of this enhancing effect, lower doses of cardiac glycosides can be used. In addition, magnesium has also been shown to augment digitalis action. For mild to moderate cases of CHF, crataegus extract used alone may be sufficient, but for moderate to severe CHF, it should be used in combination with other cardiac glycosides.

The effectiveness of crataegus in early or mild stages of CHF was repeatedly demonstrated in double-blind studies.[2,3,26–33] In a meta-analysis of 10 trials including 855 patients with chronic heart failure (New York Heart Association [NYHA] classes I to III), it was concluded that hawthorn extract provided significant benefit in symptom control and physiological outcomes as an adjunctive treatment for chronic heart failure. Exercise tolerance, the pressure–heart rate product, and symptoms (e.g., shortness of breath and fatigue) all improved significantly with hawthorn treatment compared with placebo.[34]

In one double-blind study, 30 patients with CHF (NYHA stage II) were assessed in a randomized, double-blind study.[29] Treatment consisted of a crataegus extract standardized to contain 15 mg procyanidin oligomers per 80-mg capsule. Treatment duration was 8 weeks, and the substance was administered at a dose of one capsule taken twice a day. The group receiving the crataegus extract showed a statistically significant advantage over placebo in terms of changes in heart function as determined by standard testing procedures. Systolic and diastolic blood pressures were also mildly reduced. Like all other studies with crataegus extracts, no adverse reactions occurred.

In another study, 78 patients with CHF (NYHA stage II) were given either 600 mg of extract standardized to contain 18.8% procyanidolic oligomers or placebo daily.[30] The parameter used to measure effectiveness was the patient's working capacity (W) on a bicycle ergometer. After 56 days of treatment, the crataegus group had a mean increase of 25 W compared with the placebo group's increase of only 5 W. In addition, the crataegus group also experienced a mild, but significant, reduction in systolic blood pressure (from 171–164 mm Hg) and heart rate (from 115–110 beats/min). There was no change in blood pressure or heart rate in the placebo group.

Crataegus provides a definite dose response. Individuals with more severe CHF require higher dosages to experience the most benefit. This comment is based on an important finding in a double-blind

study of 209 patients with NYHA class III CHF. Although those receiving 900 mg of a crataegus extract standardized to contain 18.8% procyanidolic oligomers demonstrated improvement in all parameters tested, those receiving 1800 mg showed even better results.[32] The failure of some studies to demonstrate a therapeutic benefit with crataegus extracts may reflect inadequate dosages being administered.[35–37]

DOSAGE

Clearly, the dosage depends on the type of preparation and source material. The amount of crataegus extract used in various clinical studies on CHF was equivalent to 30 to 169 mg of epicatechin or 3.5 to 19.8 mg of flavonoids, usually administered in two or three doses. Standardized extracts are preferred because the flavonoid content in crude preparations can vary tremendously. The dosages listed for the various crataegus formulas are for use three times a day:

- Berries or flowers (dried): 3 to 5 g or as infusion
- Tincture (1:5): 4 to 5 mL (alcohol may elicit pressor response in some individuals)
- Fluid extract (1:1): 1 to 2 mL
- Freeze-dried berries: 1 to 1.5 g
- Flower extract (standardized to contain 1.8% vitexin-4′-rhamnoside or 18% procyanidolic oligomers): 200 to 600 mg

TOXICOLOGY

Crataegus was shown to have low toxicity, with a mean lethal dose of 25 mg/kg.[38] In a human study in patients with CHF, dosages at levels 100 times the typical dosage did not produce any evidence of toxicity. Although some studies showed that proanthocyanidins might be carcinogenic, more careful evaluation indicated that the carcinogenicity was probably a result of nitrosamines found in the extracts used.[39] Purified proanthocyanidins were found to be nonmutagenic, according to the *Salmonella* mutagenicity assay system.

In total, 166 adverse events were reported in a review of 24 clinical studies and data from 5577 patients who received the daily dose (range, 160–1800 mg) and had 3 to 24 weeks of treatment with hawthorn monopreparations. Most of these adverse events were, in general, mild to moderate, with the most frequent adverse events being dizziness/vertigo, gastrointestinal complaints, headache, and heart palpitation.[40] Postmarketing surveillance studies reported only mild and infrequent side effects with crataegus extract. In a study of 1011 patients, 14 adverse events (1.4%) occurred after the administration of 900 mg of hawthorn extract for 24 weeks. In two patients, a causal relation with crataegus was suspected, but it was regarded by the treating doctors as unlikely. In another postmarketing surveillance study of 3664 patients who were treated with 900 mg of crataegus extract for 8 weeks, 48 patients (1.3%) reported adverse events, including hot flushes, stomach complaints, palpitations, dizziness, dyspnea, headache, and epistaxis. In 19 patients, this resulted in discontinuation of the treatment.[26]

DRUG INTERACTIONS

Hawthorn may potentiate or inhibit the actions of anticoagulants, antihypertensives, and cardiac glycosides. This concern is based primarily on theoretical grounds rather than clinical reports. Importantly, in a randomized crossover trial with eight healthy volunteers, hawthorn did not significantly alter the pharmacokinetic parameters for digoxin. This suggests that the combination of hawthorn and digoxin may be administered safely.[41]

Croton lechleri (Dragon's Blood)

Kathy Abascal, BS, JD, RH(AHG), and *Eric L. Yarnell, ND, RH(AHG)*

OUTLINE

Croton spp. (family: Euphorbiaceae)

Synonym: Many Croton species are identified as dragon's blood, including Croton lechleri, C. sordidus, C. urucurana, C. draco (C. draconoides, C. palanostigma), C. xalapensis, and C. erythrochilus.[1-4]

Common names: dragon's blood, sangre de drago, sangre de grado, Lora sangre (sp.), sangre de perro (sp.)

GENERAL DESCRIPTION

Dragon's blood comes from the species of Euphorbiaceae trees native to Bolivia, Brazil, Colombia, Ecuador, and Peru that produce a latex ranging in color from faint to deep red, and occasionally a slight orange.[1]

CHEMICAL COMPOSITION

The latex is used medicinally.[5] It consists primarily of proanthocyanidins (90%), including crofelemer, but also contains an important alkaloid, taspine, simple phenols, diterpenes, and phytosterols (Fig. 72.1 and Fig. 72.2).[5-8]

HISTORY AND FOLK USE

Dragon's blood is used widely by the indigenous peoples of the Amazon basin, and the Spaniards reported that it was used widely in the Amazon region in the 1600s.[5,7] The latex is applied topically to abrasions, cuts, scratches, blisters, bites, and stings. It is taken internally in dilute form for gastrointestinal distress (e.g., gastritis, gastric ulcer, intestinal infections and inflammation, diarrhea). It is used as a gargle for sore throat; a vaginal antiseptic; a hemostatic after childbirth; a topical hemostatic for severe cuts and lacerations; and an analgesic applied directly to molar toothaches.[2] It is also taken internally for wound healing. The latex is used for various respiratory infections (tonsillitis, pharyngitis, lung infections/pneumonia, influenza, and colds).

PHARMACOLOGY

Analgesic Effect

Dragon's blood balm (1% concentration)[9] had a significant analgesic effect compared with a placebo balm in a series of animal experiments.[3] Dragon's blood completely prevented hyperalgesia induced by a protease and blocked hyperalgesia induced by prostaglandin. Dragon's blood was analgesic even if the hyperalgesic stimuli were applied intradermally, suggesting that its active components can penetrate the skin. Dragon's blood inhibited the responses of mesenteric arteries to calcitonin generated peptide (a primary neurotransmitter of sensory afferent nerves) and attenuated the epithelial secretory response to capsaicin in guinea pigs, but not that of neurokinin-1 antagonist,

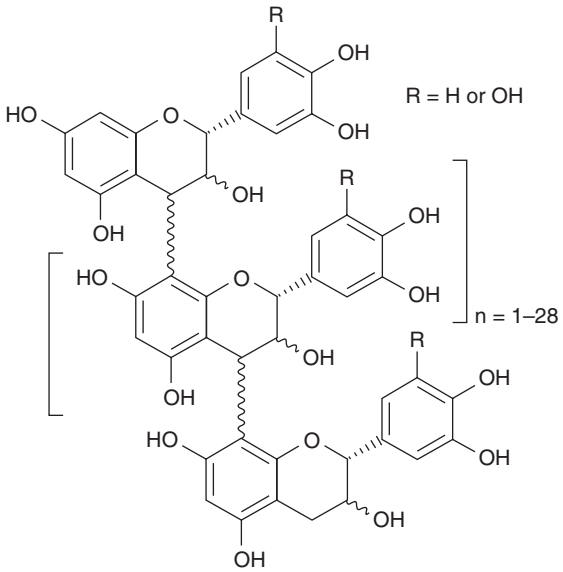

Fig. 72.1 Crofelemer.

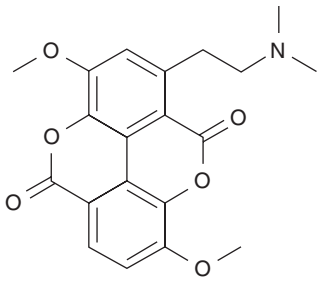

Fig. 72.2 Taspine.

suggesting a unique prejunctional and postjunctional effect on sensory afferent nerves. These pharmacological results tend to confirm the traditional uses of dragon's blood to relieve itching, pain, edema, redness, and discomfort.

Antidiarrheal Effect

Crofelemer is an extract of the proanthocyanidins and tannins from dragon's blood latex approved as a drug by the Food and Drug Administration (FDA) in 2012 (tradename Mytesi previously Fulyzac, originally studied as an investigational drug Provir or Virend or SP-303 hereinafter referred to as crofelemer). It is a first-in-class agent useful for different types of noninfectious secretory diarrhea as it prevents chloride and fluid secretion into the bowel by directly inhibiting two distinct chloride channels.

Crofelemer restored intestinal fluid accumulation to near-normal levels in mice administered cholera toxin.[10]

Antimicrobial Effect

Several phenolic compounds and diterpenes isolated from dragon's blood demonstrated potent activity against *Bacillus subtilis* and *Escherichia coli* in vitro.[11] Dragon's blood latex significantly inhibited growth of gram-positive and gram-negative organisms in vitro, including *Proteus vulgaris, E. coli,* and *Staphylococcus aureus.*[12]

Antiproliferative or Cytotoxic Effect, or Both

Dragon's blood latex and taspine were as effective as paclitaxel and vinblastine on human melanoma cells in vitro.[13] Taspine was cytotoxic against cervical cancer and hamster lung cells in vitro.[14] Dragon's blood induced apoptosis in human gastrointestinal cells in a dose-dependent manner, and cell proliferation decreased in all cells exposed to dragon's blood for 48 hours.[15] Overall, the effects were deemed similar to those observed with paclitaxel. Dragon's blood significantly reduced cancer cell adhesion, with more than 85% of cells remaining in suspension.

Taspine is also a topoisomerase inhibitor, but unlike other inhibitors such as doxorubicin and etoposide, taspine was cytotoxic to cells overexpressing drug efflux transporters and induced widespread apoptosis in spheroids in vitro and, to some extent, in vivo.[16] However, Dragon's blood showed no cytotoxicity and actually increased survival in 89% of acute leukemia cells.[17]

Ulcer Healing Effect

Dragon's blood administered at dilutions of 1:1000 and 1:10,000 in drinking water assisted the healing of ulcers in rats with acetic acid–induced gastric ulcers.[7] These doses were equivalent to doses used in traditional medicine for the treatment of gastric disorders. It healed ulcers comparably to a combination of penicillin and streptomycin and resulted in ulcers that were smaller, less inflamed, and with lower bacterial content. Whole dragon's blood latex was effective at lower doses than was crofelemer. The latex contains trace amounts of compounds that are 30 times more potent than penicillin.

Antiviral Effect

Various compounds in dragon's blood showed antiviral activity against influenza, parainfluenza, herpes simplex viruses (HSV) types I and II, and hepatitis A and B in vitro.[18] Crofelemer showed antiviral activity against respiratory syncytial virus (RSV) and inhibited viral penetration of the host cell.[19] Crofelemer also showed antiviral activity against two strains of HSV type 1, as well as a strain of HSV type 2 at a dose comparable to that of acyclovir.[20] The compound significantly reduced HSV lesion formation in the mouse vaginal model (applied topically in a 5%–10% preparation).

At aerosol doses of 0.5 to 9.4 mg/kg per day, crofelemer increased the survival of mice lethally infected with RSV.[21] At aerosol doses of 1.3 to 9.8 mg/kg, it reduced lung titers of RSV in infected rats. Crofelemer administered intraperitoneally also significantly reduced pulmonary RSV titers in infected rats with a minimum efficacious dose of 3 mg/kg.[22]

Crofelemer administered once daily for 8 days beginning before or after influenza A infection in mice reduced lung consolidation, but was lethally toxic at the dose of 30 mg/kg per day. The drug administered as an aerosol (2.5, 5, and 10 mg/mL) for 1 hour twice daily also reduced lung consolidation in animals. However, when administered before virus exposure, crofelemer treatment lengthened mean day to death, but did not inhibit lung virus titer.[23]

Wound-Healing Effect

In rats, crude dragon's blood rapidly stimulated wound contraction, formation of both a crust and new collagen along with quick and complete regeneration of the epithelial layer. The isolated polyphenol fraction stimulated contraction of the wound and formation of the crust but delayed wound repair and had no influence on the growth of new blood vessels.[24]

Dragon's blood precipitates proteins and other matrix elements, fostering accelerated wound healing with reduced pain, inflammation, and scarring.[3] Taspine showed a dose-related cicatrizant effect when administered in vivo to mice.[25]

CLINICAL APPLICATIONS

Analgesic

Ten pest control workers exposed to frequent insect bites applied either dragon's blood balm or placebo balm to bites and recorded the results over a 3-month period.[3] When workers had multiple simultaneous bites, they used both balms on different bites and compared the results. Dragon's blood latex offered rapid symptomatic relief in all cases and all applications. It was deemed far more effective than placebo by participants.

Diarrhea

Crofelemer is approved by the FDA for symptomatic relief of noninfectious diarrhea in adult patients with HIV/AIDS or antiretroviral therapy (ART). Approval was based on a multicenter trial that randomized 376 patients with HIV/AIDS on ART to take either oral crofelemer 125 mg twice daily or placebo.[26] Crofelemer significantly reduced secretory diarrhea compared with placebo.

No significant benefit in stool consistency was seen in a double-blind, randomized, placebo-controlled clinical trial in patients with diarrhea predominant irritable bowel syndrome (IBS; n = 242). The lack of benefit seen may possibly be a result of the diarrhea in IBS not being caused by a derangement of chloride secretion.[27]

Crofelemer 125 and 250 mg doses four times a day was effective in improving symptoms of acute-onset traveler's diarrhea in a multicenter, double-blind, randomized, placebo-controlled study of 184 adults. However, a 500-mg dose was no more effective than placebo, suggesting additional studies are needed.[28]

Clinical research on the benefit of crofelemer specifically in infectious diarrhea are largely lacking. A review of crofelemer in secretory diarrhea noted two foreign studies currently only available in abstract form. In one, a single 125-mg dose of crofelemer administered after rehydration and oral azithromycin significantly reduced watery stool output in the first 24 hours in patients with cholera compared with placebo in a preliminary trial of 100 adults.[29] In a second, 98 patients with acute diarrhea caused by various pathogens were treated with crofelemer (250 mg four times daily) or placebo for 2 days. Those taking crofelemer had better overall clinical success resolving watery stools in 48 hours but statistical details were lacking. (FN: *Ibid.*) Further clinical studies on the benefit of crofelemer in infectious diarrhea are definitely needed.

Herpes Simplex Viral Lesions

Virend (a topical formulation of crofelemer) showed a trend toward decreased lesion pain in a double-blind, placebo-controlled study of 45 HIV-positive patients with active-phase, culture-positive genital or perineal HSV lesions, or both. Virend was more active in patients with smaller lesion areas. Two patients experienced pain and burning after applying Virend, and one withdrew from the study for this reason. In another open-label study, 9 AIDS patients with HSV unresponsive to acyclovir were treated with crofelemer.[30] The drug showed a transient positive effect but failed to completely heal or stop virus shedding. Several patients complained that crofelemer caused pain or burning on application.

Stretch Marks

In an open trial of 10 women with stretch marks at hip level and 10 without, a cream combining *Punica granatum* (pomegranate) seed oil and dragon's blood latex extract was applied twice daily for 6 weeks.[31] The cream improved skin thickness, hydration, and elasticity, suggesting it might be helpful in preventing or improving stretch marks.

Wound Healing

Dragon's blood powder in a cream base applied twice daily significantly improved wound healing duration from the third day in a double-blind, placebo-controlled, randomized clinical trial of 60 patients undergoing skin tag repair (a total of 100 wounds).[32] The polyphenolic compounds create a protective layer on the wound surface, preventing microbial contamination and appear to shorten the inflammation process in wound healing.

DOSAGE

In traditional medicine, the internal dose is 3 to 20 drops mixed in a beverage, one to three times daily for up to 3 weeks.[2,7] The pure latex is applied topically as needed.

Although the usual study dose of crofelemer for diarrhea is 125 to 250 mg four times daily, the manufacturer Napa Pharmaceuticals recommends a 125-mg delayed release tablet twice daily (https://www.mytesi.com).

Doses of 125 and 250 mg of crofelemer, administered every 6 hours, were more effective at reducing the duration of traveler's diarrhea than the 500 mg dose.[33]

TOXICOLOGY

Dragon's blood, used topically or at low internal doses, is considered nontoxic.[34] Neither dragon's blood nor taspine showed carcinogenic or tumor-promoting effects in a 17-month long mouse study.[35] Taspine (<150 ng) was nontoxic to human foreskin fibroblasts.[21] It had no cell proliferative, carcinogenic, or tumor-promoting effects. 3′,4-0-Dimethycedrusin, isolated from dragon's blood, was nonproliferative and instead inhibited thymidine incorporation while protecting cells against degradation in a starvation medium.[15] In vitro, dragon's blood had a negligible effect on proliferation of endothelial cells and was not cytotoxic.[36] Crofelemer at doses of 16 to 18.7 mg/kg per day caused weight loss and decreased survival time in mice and rats.[21] Crofelemer injected intraperitoneally caused significant weight loss and death in rats at doses of 30 mg/kg per day. However, no toxicity was observed after oral administration of up to 270 mg/day of crofelemer.[22]

DRUG INTERACTIONS

Very little information is available about drug interactions with dragon's blood, but none has been reported in the existing clinical studies. However, crofelemer significantly worsened dacomitinib-induced diarrhea without altering blood levels of dacomitinib in rats.[37] Whether this would be a problem in humans should be investigated in a clinical trial.

Curcuma longa (Turmeric)

Michael T. Murray, ND

OUTLINE

Curcuma longa (family: *Zingiberaceae*)
Common names: turmeric, curcuma, Indian saffron

GENERAL DESCRIPTION

Curcuma longa, a perennial herb of the ginger family, is cultivated extensively in India, China, Indonesia, and other tropical countries. It has a thick rhizome from which arise large, oblong, and long-petioled leaves. The rhizome is the part used; it is usually cured (boiled, cleaned, and sun dried) and polished (Fig. 73.1).

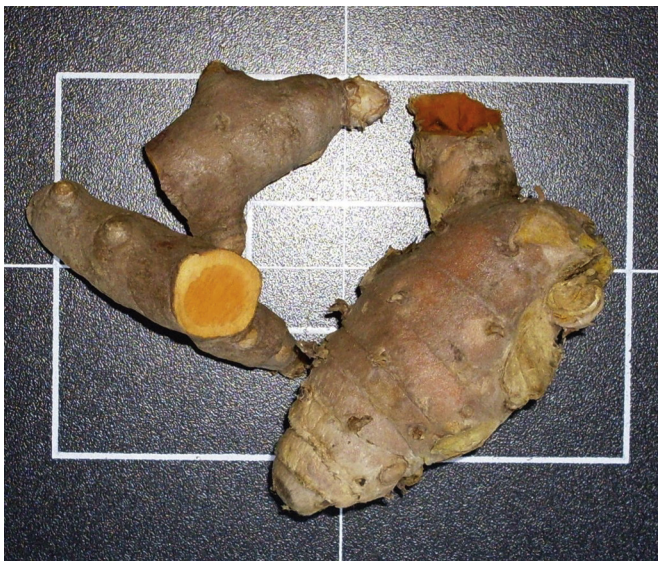

Fig. 73.1 *Curcuma longa* rhizome.

CHEMICAL COMPOSITION

Turmeric, like many spices, is full of many active phytochemicals. The key components of turmeric include the following[1]:

- Curcuminoids: 0.3% to 5.4%
- Volatile oils (e.g., turmerone, atlantone, zingiberene, etc.): 3% to 7%
- Resins (including terpenoids, triterpenoids, phenylpropenes, etc.): trace
- Alkaloids: trace
- Carbohydrates: 60% to 70%
- Fat: 5% to 10%
- Protein: 6% to 8%
- Fiber: 2% to 7%
- Vitamins: trace
- Minerals: trace
- Water: 6% to 13%

Fig. 73.2 shows the chemical structure of turmeric.

The reported consumption of turmeric in Indian and Asian cultures is in the range of 200 to 1000 mg/day, with consumption in urban areas being closer to the lower level (i.e., 200 mg/day), whereas in rural areas, the consumption is in the range of 600 to 1000 per day. Based on an average curcumin level of about 3%, even at 1000 mg of turmeric a day, the curcumin intake would be only 30 mg daily.

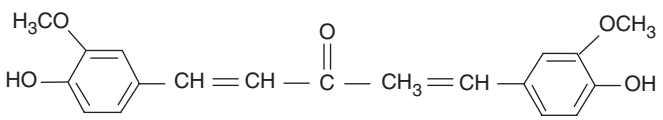

Fig. 73.2 Curcumin.

HISTORY AND FOLK USE

Turmeric is the major ingredient of curry powder and is also used in prepared mustard. It is extensively used in foods for both its color and flavor. In addition, turmeric is used in both the Chinese and Indian (Ayurvedic) systems of medicine as an anti-inflammatory agent and for the treatment of numerous conditions, including flatulence, jaundice, menstrual difficulties, bloody urine, hemorrhage, toothache, bruises, chest pain, and colic. Turmeric poultices are often applied locally to relieve inflammation and pain.

PHARMACOLOGY

Turmeric and its derivatives have undergone a great deal of pharmacological investigation.[1,2] Although a number of components demonstrate activity, curcumin and the volatile oil components are believed to be the most active components. Since 1990, more than 9000 scientific investigations on turmeric and curcumin have been published. Turmeric and curcumin-rich extracts have been shown to possess the following effects and many more:

- Antioxidant
- Anticarcinogenic
- Anti-inflammatory
- Antimicrobial
- Cardiovascular protective
- Hepatoprotective
- Gastrointestinal carminative and protectant
- Neuroprotective

These beneficial effects and actions, however, are largely based on in vitro or experimental models. There are significant pharmacokinetic issues with curcumin because it is poorly absorbed and rapidly metabolized and eliminated from the body. Pharmacokinetic studies in animals showed that 40% to 85% of an oral dose of curcumin passes through the gastrointestinal tract unchanged.[3,4] Several studies have looked at relatively high dosages of curcumin powder in humans. In one study, 24 healthy volunteers were administered escalating doses from 500 to 12,000 mg.[5] No curcumin was detected in the serum of participants administered 500, 1000, 2000, 4000, 6000, or 8000 mg. Table 73.1 shows the concentrations of curcumin in two subjects (one taking 10,000 mg and one taking 12,000 mg). No plasma concentrations of curcumin were detected in the remaining subjects at the 10,000- or 12,000-mg dose levels. Similar results were seen in other studies looking at dosages ranging from 3.6 to 12 g.

Another challenge with curcumin and other polyphenols is that they circulate bound to glucuronic acid. The theory is that when cells or mitochondria experience cellular stress or damage, they release glucuronidase. This enzyme subsequently liberates the curcumin, flavonoid, or other polyphenol to exert its effect locally or on a cellular basis.

Antioxidant Effects

Turmeric and curcumin exert significant antioxidant activity. Because of its bright yellow color and antioxidant properties, turmeric is often used to protect against lipid peroxidation in butter, margarine, cheese, and other food products. Although turmeric powder as well as both water- and fat-soluble extracts have been shown to be effective antioxidants in various in vitro and in vivo models, curcumin is the most potent component.[2] For active oxygen species, curcumin is slightly weaker than vitamin C but stronger than vitamin E and superoxide dismutase. Against hydroxyl radicals, curcumin offers greater effectiveness than these vitamins.[6] Not all of the antioxidant properties of turmeric are due to curcumin alone, because the aqueous extract of turmeric is more effective against superoxide than curcumin and is much stronger in inhibiting oxidative damage to DNA.[7,8] The antioxidant activities of curcumin may in part explain the anti-inflammatory, anticarcinogenic, and cardioprotective capacity of this spice. In vitro and in vivo studies have also shown this antioxidant action to be neuroprotective as well.[9]

TABLE 73.1 Serum Curcumin Levels for Two Subjects (in ng/mL)

Dose	Baseline	1 Hour	2 Hours	4 Hours
10 g	Approx. 6.0	30.4	39.5	50.5
12 g	Trace	29.7	57.6	51.2

Anticarcinogenic Effects

The antineoplastic effects of turmeric and curcumin have been demonstrated at all steps of carcinogenesis: initiation, promotion, and progression. In addition to inhibiting the development of cancer, several studies suggest that curcumin can also promote cancer regression. The protective effects of turmeric and its derivatives are only partially explained by its direct antioxidant and free radical–scavenging effects. It also inhibits nitrosamine formation, enhances the body's natural antioxidant system, increases the levels of glutathione and other nonprotein sulfhydryls, and acts directly on several enzymes and gene loci.

Curcumin's ability to protect against damage to DNA was demonstrated in a study in a community with a high content of groundwater arsenic.[10] Arsenic is extremely carcinogenic because it causes severe oxidative damage to DNA. Blood samples before curcumin supplementation showed severe DNA damage, with increased levels of free radicals and lipid peroxidation. Three months of curcumin intervention reduced the DNA damage, retarded free-radical formation and lipid peroxidation, and raised the level of antioxidant activity. In another study, cigarette smokers receiving turmeric demonstrated a significant reduction in the level of urinary-excreted mutagens—an indication of the ability of the body to rid itself of cancer-causing compounds via detoxification mechanisms (Fig. 73.3). For many reasons, curcumin is emerging as a very important agent in the battle against cancer.[11]

Data also suggest that curcumin causes cancer to regress. Some of curcumin's benefits come from its antioxidant activity, but it also:

- Inhibits the formation of cancer-causing nitrosamines
- Enhances the body's production of cancer-fighting compounds, such as glutathione
- Promotes the liver's proper detoxification of cancer-causing compounds
- Prevents overproduction of cyclooxygenase-2, an enzyme that may contribute to the development of tumors

In addition to these preventative actions, curcumin has also been shown to inhibit tumor growth in several ways:

- Inhibiting epidermal growth factor (EGF) receptor sites: EGF stimulates cells to proliferate by connecting to a receptor on the cell surface. About two thirds of all cancers produce an abundance of these receptors, which makes them highly sensitive to EGF. By reducing the number of EGF receptors, curcumin decreases the cell's tendency to proliferate.
- Inhibiting angiogenesis: Fibroblast growth factor is a protein that promotes the formation of new blood vessels to feed the growing tumor. Curcumin inhibits the production of this growth factor.
- Inhibiting nuclear factor-κβ (NF-κβ): This is a protein that many cancer cells produce to block the signals commanding them to stop proliferating.

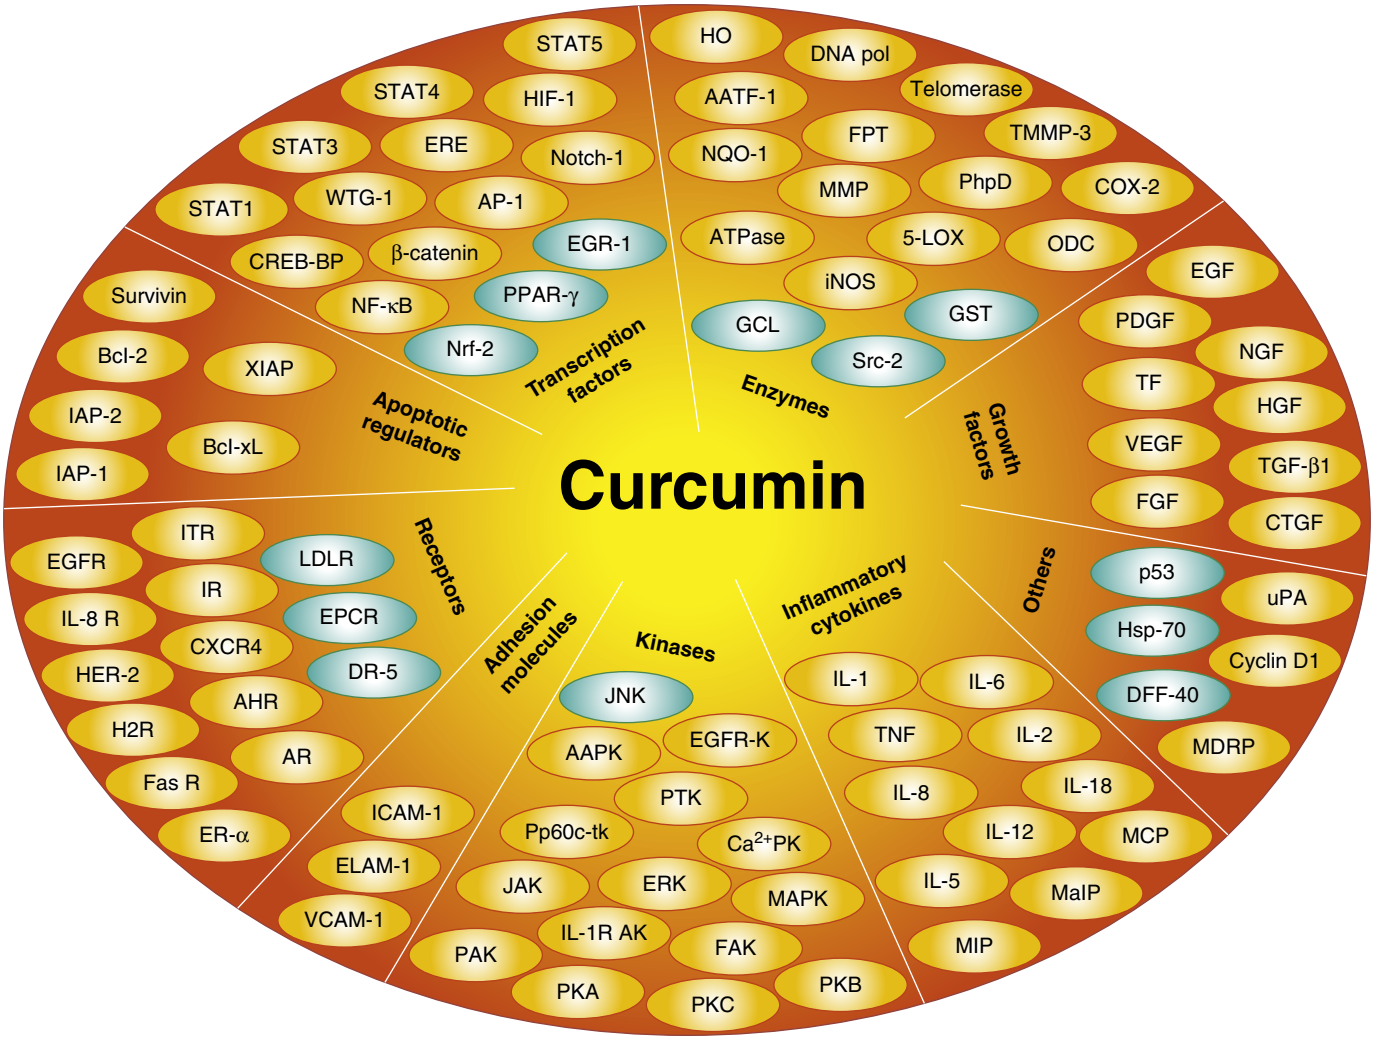

Fig. 73.3 Molecular targets of curcumin. 5–LOX, 5–lipoxygenase; AAPK, autophosphorylation–activated protein kinase; AATF–1, arylamine *N*–acetyltransferases–1; AHR, aryl hydrocarbon receptor; AP–1, activating protein–1; AR, androgen receptor; Bcl–2, beta–cell lymphoma protein 2; Bcl–xL, beta–cell lymphoma extra large; Ca2+PK, Ca2+–dependent protein kinase; CXCR4, chemokine (C–X–C motif) receptor 4; CREB–BP, CREB–binding protein; CTGF, connective tissue growth factor; DFF–40, DNA fragmentation factor 40–kd subunit; DR5, death receptor–5; ELAM–1, endothelial leukocyte adhesion molecule–1; EPCR, endothelial protein C–receptor; ERE, electrophile response element; ER–α, estrogen receptor–alpha; FAK, focal adhesion kinase; FPT, farnesyl protein transferase; FR, Fas receptor; GCL, glutamyl cysteine ligase; GST, gluthathione–S–transferase; H2R, histamine (2)–receptor; HER–2, human epidermal growth factor receptor–2; HGF, hepatocyte growth factor; HIF–1, hypoxia inducible factor–1; HO, haem oxygenase 1; HSP–70, heat–shock protein 70; IAP–1, inhibitory apoptosis protein–1; ICAM–1, intracellular adhesion molecule–1; iNOS, inducible NOS; IR, integrin receptor; MaIP, macrophage inflammatory protein; MCP, monocyte chemoattractant protein; MDRP, multi–drug resistance protein; MIP, migration inhibition protein; NGF, nerve growth factor; NQO–1, NAD(P)H:quinoneoxidoreductase–1; Nrf, nuclear factor 2–related factor; ODC, ornithine decarboxylase; PAK, protamine kinase; PhpD, phospholipase D; Pp60c–tk, pp60c–src tyrosine kinase; PTK, protein tyrosine kinase; Src–2, Src homology 2 domain–containing tyrosine phosphatase 2; STAT, signal transducer and activator of transcription; TF, tissue factor; TMMP–3, tissue inhibitor of metalloproteinase–3; uPA, urokinase–type plasminogen activator; VCAM–1, vascular cell adhesion molecule–1; WTG–1, Wilms' tumor gene 1.

- Increasing the expression of the nuclear p53 protein: This protein is essential for apoptosis, the normal process of cell "suicide."
- Inhibiting enzymes that promote cancer cell growth.

Anti-inflammatory Effects

The volatile-oil fraction of *C. longa* has been demonstrated to possess anti-inflammatory activity in various experimental models (e.g., Freund's adjuvant-induced arthritis, formaldehyde- and carrageenan-induced paw edema, and cotton pellet and granuloma pouch tests).[12,13] Its effects in these studies were comparable to cortisone and phenylbutazone. Even more potent in acute inflammation is curcumin. In animal models of acute inflammation, curcumin is as effective as cortisone or phenylbutazone, but it is only half as effective in chronic models.[14,15] However, although phenylbutazone and cortisone are associated with significant toxicity, curcumin displays virtually no toxicity (see later discussion under "Toxicology").

The rank in order of potency of curcumin analogs, cortisone, and phenylbutazone in carrageenan-induced paw edema is as follows: sodium curcuminate > tetrahydrocurcumin > curcumin > cortisone > phenylbutazone > triethylcurcumin.[15,16]

Based on in vitro studies, curcumin exhibits many direct anti-inflammatory effects, including the following[17]:

- Inhibition of leukotriene formation
- Inhibition of platelet aggregation
- Promotion of fibrinolysis
- Inhibition of neutrophil response to various stimuli involved in the inflammatory process
- Stabilization of lysosomal membranes
- Inhibition of NF-κB
- Inhibition of tumor necrosis factor

The blocking the activation of nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB) by curcumin is especially important.[18] Curcumin also inhibits tumor necrosis factor α (TNF-α), a major mediator of inflammation in most diseases, and this effect is regulated by the activation of a transcription factor, NF-κβ.[19]

Curcumin's counterirritant effect may also be a major factor in its topical anti-inflammatory action. Sodium curcuminate can be produced by mixing turmeric with slaked lime. This mixture, applied as a poultice, is an ancient household remedy for sprains, muscular pain, and inflamed joints. Capsaicin, a similar pungent principal from *Capsicum frutescens* (cayenne pepper), has been shown to be quite effective as a topical pain reliever in cases of postherpetic neuralgia and arthritis. Both capsaicin and curcumin deplete nerve endings of the neurotransmitter of pain, substance P.[20]

In addition to its direct anti-inflammatory effects, curcumin also appears to exert some indirect effects. In models of chronic inflammation, curcumin was much less active in adrenalectomized animals. Possible mechanisms of action include the following:

- Stimulating the release of adrenal corticosteroids
- "Sensitizing" or priming cortisol receptor sites, thereby potentiating cortisol action
- Increasing the half-life of endogenous cortisol through alteration of hepatic degradation

Cardiovascular Effects

The effects of turmeric and curcumin on the cardiovascular system include the prevention of oxidative damage to low-density lipoprotein cholesterol, inhibiting platelet aggregation, and reducing fibrinogen levels.[21–24] These effects are of great significance in preventing atherosclerosis and its complications.

In animal studies, adding as little as 0.1% curcumin to a high-cholesterol rat diet decreased cholesterol levels to one half of those found in rats fed cholesterol but no curcumin. Curcumin's cholesterol-lowering actions include interfering with intestinal cholesterol uptake; increasing the conversion of cholesterol into bile acids by increasing the activity of hepatic cholesterol-7-α-hydroxylase, the rate-limiting enzyme of bile acid synthesis; and increasing the excretion of bile acids via its choleretic effects.[24]

Effects on blood lipids from human studies are equivocal. In one small study, 10 healthy volunteers received 500 mg/day of curcumin for 7 days.[21] A significant decrease in the level of serum lipid peroxides of 33%, an increase in high-density lipoprotein cholesterol of 29%, and a decrease in total serum cholesterol of 11.63% were observed. However, two other studies failed to show any effect on blood lipids. One study used escalating doses (15, 30, and 60 mg three times daily),[25] and another used dosages of up to 4 g/day for 6 months, but these studies only raised the plasma curcumin concentration to 490 nmol/L.[26]

TABLE 73.2 Lowering Effects of the Treatment With a Curcuma Extract (Turmeric) on Abnormally High Plasma Fibrinogen Levels (Values in Milligrams per Deciliter Before and After a 15-Day Treatment)

Subject Number	Sex	Age (Years)	Before	After
1	M	68	809	241
2	M	31	476	272
3	M	64	584	290
4	F	54	351	282
5	F	59	480	268
6	F	62	690	240
7	F	69	490	272
8	F	66	402	251
Means ± SD			535.6 ± 151.4[a]	271.1 ± 31

[a]As shown by the analysis of variance test, the decrease had a statistical significance of α = 0.05.

Modified from Ramirez Bosca A, Soler A, Carrion-Gutierrez MA, et al. An hydroalcoholic extract of Curcuma longa lowers the abnormally high values of human-plasma fibrinogen. *Mech Ageing Dev.* 2000;114:207–210.

Curcumin's effect on fibrinogen and platelet aggregation, which are known predictors of future coronary heart disease, may be more significant than its effects on cholesterol. In a preliminary study of 30 apparently healthy volunteers, baseline levels of fibrinogen were recorded, and 8 subjects were found to have high plasma fibrinogen (above 350 ng/mL).[27] These subjects were given a hydroalcoholic extract of *C. longa* containing 20 mg of curcumin for 15 days. Impressively, curcumin administration decreased the fibrinogen levels to the range of 240 to 290 mg/dL (Table 73.2).

Turmeric's and curcumin's action on inhibiting platelet aggregation appears to be mediated by inhibiting the formation of thromboxanes (a promoter of aggregation) while simultaneously increasing prostacyclin (an inhibitor of aggregation).

Hepatic Effects

Curcumin exhibits hepatoprotection similar to that of glycyrrhizin and silymarin (see Chapters 96 and 123, respectively, for further discussion) against carbon tetrachloride and galactosamine-induced liver injury.[28] This protection is largely a result of its potent antioxidant activity. Similar results were seen with Javanese turmeric *(Curcuma xanthorrhiza)*. Mice given intraperitoneal injections of the hepatoxic drugs carbon tetrachloride (32 mg/kg) and acetaminophen (600 mg/kg) experienced significantly decreased liver damage, as measured by serum glutamate oxaloacetate and serum glutamate pyruvate transaminase, when treated with 100 mg/kg of turmeric.[29]

The antioxidant and hepatoprotective effects alone support turmeric's historical use in liver disorders; however, turmeric and curcumin also exert anti-inflammatory and choleretic effects. The increases of serum glutamate oxaloacetate and serum glutamate pyruvate transaminase commonly seen in experimental models of inflammation were prevented by curcumin. Curcumin is an active choleretic, increasing bile acid output by more than 100%. In addition to increasing biliary excretion of bile salts, cholesterol, and bilirubin, curcumin also increases the solubility of bile.[28] This suggests a benefit in the prevention and treatment of cholelithiasis.

Gastrointestinal Effects

Turmeric and its components exert a number of beneficial effects on the gastrointestinal system. Turmeric's long use as a carminative is supported in preclinical studies showing it to inhibit gas formation by *Clostridium perfringens* and in rats given diets rich in flatulence-producing foods. In addition, sodium curcuminate was shown to inhibit intestinal spasm, and another compound from turmeric, *p*-tolymethylcarbinol, was shown to increase the secretion of secretin, gastrin, bicarbonate, and pancreatic enzymes.[2]

As a component of curries and spicy foods, there is some concern that turmeric may be irritating to the stomach. However, several studies showed turmeric to be beneficial to gastric integrity. Turmeric and curcumin were shown to increase the mucin content of the stomach and exert gastroprotective effects against ulcer formation induced by stress, alcohol, indomethacin, pyloric ligation, and reserpine.[30] However, at high doses, curcumin or turmeric may be ulcerogenic (see later discussion on "Toxicology").

Antiaging and Neuroprotective Effects

As far as slowing down the aging process, in addition to the effects discussed previously, there is considerable evidence that curcumin protects against age-related brain damage, in particular, Alzheimer disease. Researchers began exploring this effect after noting that elderly (aged 70–79) residents of rural India, who eat large amounts of turmeric, were shown to have the lowest incidence of Alzheimer disease in the world, 4.4 times lower than that of Americans. In addition, researchers also demonstrated that curcumin was able to prevent the development of amyloid plaque and the neurofibrillary tangles that are the hallmark features of the brain lesions in mice specifically bred to develop the disease.[31,32]

Antimicrobial Effects

Alcohol extracts and the essential oil of *C. longa* were shown in one study to inhibit the growth of most organisms occurring in cholecystitis (i.e., *Sarcina, Gaffkya, Corynebacterium,* and *Clostridium*).[2] Other microorganisms that were inhibited include *Staphylococcus, Streptococcus, Bacillus, Entamoeba histolytica,* and several pathogenic fungi.[33] The concentrations used in these studies were relatively high: 0.5 to 5 mg/mL of the alcohol extract and essential oil and 5 to 100 mg/mL of curcumin.

CLINICAL APPLICATIONS

Turmeric and curcumin preparation have extensive potential clinical applications. The most popular uses of curcumin are for three primary purposes: (1) as a general antioxidant to prevent heart disease and slow down the aging process; (2) as a chemoprotector against cancer and as a treatment adjunct; and (3) to reduce inflammation, particularly in osteoarthritis and inflammatory bowel disease.

General Antioxidant and Prevention of Atherosclerosis

The benefits of curcumin as a general antioxidant and in the prevention of atherosclerosis and slowing down the aging process have been previously discussed. Curcumin's antioxidant activity may be particularly helpful in preventing exercise-induced oxidative damage as well as protecting against low-density lipoprotein cholesterol from becoming oxidized and damaging arteries. In addition, curcumin exerts other beneficial effects in preventing atherosclerosis, including possibly lowering cholesterol levels, preventing plaque formation, inhibiting platelet aggregation, and reducing fibrinogen levels (see previous discussion "Cardiovascular Effects").[24]

In regard to its effects as a general antioxidant, several clinical studies with forms of curcumin with enhanced absorption provide clinical support. For example, in one double-blind study, 40 patients with mild-to-moderate primary knee osteoarthritis were given Curcumin C3 Complex + Bioperine capsules (1500 mg of curcuminoids/day in 3 divided doses) or matched placebo capsules for a period of 6 weeks. Curcumin supplementation resulted in a significant elevation in serum SOD activities (mean change: 2.94 vs. –0.38; $p < 0.001$) and a significant reduction in MDA concentrations (mean change: –5.26 vs. –2.49; $p = 0.044$) in the curcuminoids compared with the placebo group. These changes in the serum activities of SOD and concentrations of GSH and MDA during the course of the trial were significantly correlated. Short-term supplementation with curcuminoids attenuates systemic oxidative stress in patients with osteoarthritis. These antioxidant effects may account for the reported therapeutic effects of curcuminoids in relieving osteoarthritis symptoms.[34]

Theracurmin was also shown to reduce oxidative stress in a double-blind clinical trial. It also increased the antioxidant capacity in response to acute endurance exercise. In the study, 10 male participants, ages 26.8 ± 2.0 years, completed three trials in a random order: (1) placebo (control), (2) single (only before exercise), and (3) double (before and immediately after exercise) curcumin supplementation trials. Each participant received oral administration of 90 mg of curcumin (from Theracurmin) or the placebo 2 hours before exercise and immediately after exercise. Each participant walked or ran at 65% of VO_2 max on a treadmill for 60 min. Blood samples were collected preexercise, immediately after exercise, and 2 hours after exercise. The concentrations of serum derivatives of reactive oxygen metabolites measured immediately after exercise were significantly higher than preexercise values in the placebo trial (308.8), but not in the single (259.9) or double (273.6) curcumin supplementation trials. Serum biological antioxidant potential concentrations measured immediately after exercise were significantly elevated in the single and double curcumin supplementation trials compared with preexercise values ($p < 0.05$). These findings indicate that curcumin supplementation can reduce exercise-induced oxidative stress by increasing blood antioxidant capacity. [35]

In another double-blind study, Theracurmin (150 mg curcumin) was shown to dramatically enhance the benefits of exercise on improving the health of the aorta and the entire arterial system. In the study, 45 postmenopausal women were randomly assigned to four interventions: placebo ingestion ($n = 11$), curcumin ingestion ($n = 11$), exercise training with placebo ingestion ($n = 11$), or exercise training with curcumin ingestion ($n = 12$). Very detailed assessments were used to evaluate cardiovascular function in all subjects. The aim of the study was to test the hypothesis that the regular endurance exercise combined with daily curcumin ingestion lowers the age-related increase in left ventricular (LV) afterload to a greater extent than either intervention alone in postmenopausal women. LV afterload is the tension against which the heart must contract to eject blood. Arterial stiffness, especially in the aorta, is the major determinant of LV afterload. The stiffer the artery due to atherosclerosis (hardening of the artery), the greater the LV afterload. Not surprisingly, an increase in LV is an independent risk for heart failure and death due to heart disease mortality. LV afterload tends to increase with advancing age. Regular physical exercise has been found to decrease the LV afterload to an extent, but in this study, the effect of exercise plus Theracurmin (equivalent to 5 capsules per day) reduced LV afterload, but neither therapy on its own was as effective. These results indicate that some of the cardiovascular benefits associated with exercise are greatly enhanced when exercise is combined with Theracurmin, and vice versa.[36]

In another evaluation in postmenopausal women, the effect of Theracurmin (150 mg curcumin) on vascular endothelial function was determined by using flow-mediated dilation as an indicator. In total,

32 postmenopausal women were assigned to three groups: control, exercise, and curcumin groups. The curcumin group ingested curcumin orally for 8 weeks. The exercise group underwent moderate aerobic exercise training for 8 weeks. Before and after each intervention, flow-mediated dilation was measured. Results indicated that curcumin ingestion was equal to aerobic exercise training in increasing flow-mediated dilation in postmenopausal women.[37]

The effects of curcumin (1.5 g per day) on risk factors for atherosclerosis were investigated in a 6-month randomized, double-blinded and placebo-controlled clinical trial that included subjects diagnosed with type 2 diabetes. The primary parameter assessed to measure atherosclerotic processes was pulse wave velocity (PWV), a well-accepted surrogate marker used for assessing atherosclerosis status. Results showed that curcumin intervention significantly reduced PWV, increased the level of serum adiponectin, and decreased the level of leptin. These results are associated with reduced levels of homeostasis-model-assessed insulin resistance, triglycerides, uric acid, visceral fat, and total body fat. In summary, a 6-month curcumin intervention in the type 2 diabetic population lowered the atherogenic risks. In addition, the extract helped improve relevant metabolic profiles in this high-risk population.[38]

Cancer Prevention and Treatment Adjunct

The anticancer effects of curcumin have been demonstrated in preclinical studies at all steps of cancer formation: initiation, promotion, and progression. Even dietary consumption of turmeric has been shown to exert some protective effects against cancer. In one human study, 16 long-term smokers were given 1.5 g of turmeric daily, whereas a group of 6 nonsmokers served as a control group.[39] At the end of the 30-day trial, the smokers receiving the turmeric demonstrated a significant reduction in the level of mutagens excreted in the urine. These results are quite significant because the level of urinary mutagens is thought to correlate with the systemic load of carcinogens and the efficacy of detoxification mechanisms. Due to widespread exposure to smoke, aromatic hydrocarbons, and other environmental carcinogens, the frequent use of turmeric as a spice appears warranted.

In one study, 62 patients with either ulcerating oral or cutaneous squamous-cell carcinomas who failed to respond to the standard treatments of surgery, radiation, and chemotherapy were given either an ethanol extract of turmeric (for oral cancers) or an ointment containing 0.5% curcumin in Vaseline.[40] The ointment or extract was applied topically three times daily. At the end of the 18-month study, the treatment was found to be effective in reducing the smell of the lesion (90%), itching and exudate (70%), pain (50%), and the size of the lesion (10%). Although these were not spectacular results, it must be pointed out that this patient population failed to respond to standard medical treatment.

Two studies have been conducted in patients with advanced pancreatic cancer given 8000 mg of regular curcumin daily. These studies showed some positive results.[41,42] For example, in one study of 26 patients with advanced pancreatic cancer, 8000 mg of curcumin produced clinically relevant biological activity in two patients. The failure to affect more patients in these studies is thought to be the result of poor absorption of curcumin. Formulations with much greater bioavailable curcumin may offer better results. For example, in one study, Theracurmin was given to 16 patients with advanced pancreatic cancer who were unresponsive to conventional chemotherapy.[43] This Phase 1 study sought to determine safety and dosage parameters. The patients produced no significant adverse effects even at relatively high dosage levels for Theracurmin (200 mg/day and 400 mg/day). The results showed that Theracurmin produced significant increases in the blood concentrations of curcumin in a dose-dependent fashion—the higher the dosage, the greater the increase in curcumin in the blood. Median plasma curcumin levels 2 hours after Theracurmin administration (representing peak levels) were as follows:

- 324 ng/mL at Level 1 (Theracurmin containing 200 mg of curcumin)
- 440 ng/mL at Level 2 (Theracurmin containing 400 mg of curcumin)

These values were significantly higher than the median values (85 ng/ mL) achieved in the authors' previous study using 8 g of conventional curcumin.

The big finding from the study was that Theracurmin produced a significant improvement in key quality-of-life (QOL) scores, such as the following:

- Fatigue
- Functional improvement (emotional, role, cognitive, physical, and social functions)
- Diarrhea
- Appetite loss

In addition, the median survival time (MST) was 132 days, and three patients (21%) survived more than 12 months. As a reminder, these patients were unresponsive to conventional cancer treatment, and with such advanced cancer, they were generally regarded as terminal with an average survival time of less than 2 months, so these results are quite promising.

General Inflammation

C. longa has been used in Ayurvedic medicine as a general anti-inflammatory. This use seems to be substantiated not only by the experimental studies described previously but also by clinical investigations in a variety of inflammatory conditions. In an early study, the postoperative inflammation model for evaluating nonsteroidal anti-inflammatory drugs (NSAIDs) was used, and it showed curcumin to exert comparable anti-inflammatory action to phenylbutazone.[44] However, although curcumin has an anti-inflammatory effect similar to phenylbutazone and various NSAIDs, it does not possess direct analgesic action. It is also important to point out that phenylbutazone and NSAIDs are associated with significant adverse effects, whereas curcumin is not.

As far as validation of systemic effects, there is a study that involved a rather interesting condition, chronic inflammation of the uvea—the front portion of the eye including the iris.[45] The study group consisted of 106 patients divided into three main groups of different uveitis origin: group 1 (autoimmune uveitis), group 2 (uveitis due to herpes), and group 3 (different causes of uveitis). The patients were given 1200 mg of Meriva for 1 year. In the previous year, there were a total of 275 relapses. In the 1-year treatment group with Meriva, there were only 36 relapses at the end of the 12-month follow-up, an 88% improvement. This study provides considerable evidence that curcumin can affect inflammation in a chronic inflammatory condition.

Again, the theory is that because curcumin circulates bound to glucuronic acid, when cells or mitochondria experience cellular stress or damage, they release glucuronidase. This enzyme subsequently liberates the curcumin to exert its effect locally or on a cellular basis.

Osteoarthritis

Curcumin exerts a number of mechanisms that address much of the underlying pathophysiology of osteoarthritis (OA). In addition to its antioxidant effects, in vitro studies demonstrated that curcumin exerts a number of beneficial effects through its ability to block the activation of the NF-κB system, such as suppressing the release of proteoglycans and metal metalloproteases and the expression of cyclooxygenase, prostaglandin E-2, and inflammatory cytokines in chondrocytes.[46]

Clinical studies also show some benefits in osteoarthritis. In one double-blind study, 40 patients with mild to moderate primary knee OA were given Curcumin C3 Complex + Bioperine capsules (1500 mg of curcuminoids/day in 3 divided doses) or matched placebo capsules for a period of 6 weeks. Treatment with curcuminoids was associated with significantly greater reductions in WOMAC ($p=0.001$), visual analog scale (VAS; $p<0.001$), and LPFI ($p=0.013$) scores compared with placebo. With respect to WOMAC subscales, there were significant improvements in the pain and physical function scores but not in the stiffness score.[47]

In a second analysis of this clinical trial, serum levels of interleukins 4 (IL-4) and 6 (IL-6), tumor necrosis factor-α (TNF-α), transforming growth factor-β (TGF-β), and high-sensitivity C-reactive protein (hs-CRP) and erythrocyte sedimentation rate (ESR) were determined at baseline as well as at the end of the trial. The results did not indicate any significant difference between the study groups, and the authors concluded: "Significant improvement in clinical symptoms of OA in curcuminoid-treated subjects cannot be attributed to the systemic anti-inflammatory effects of these phytochemicals."[48] Effects may be more localized at sites of inflammation, as described previously, although this preparation and more bioavailable forms of curcumin have shown systemic anti-inflammatory effects.

In the first double-blind study with curcumin in OA, 50 patients over 40 years old with knee osteoarthritis confirmed by x-ray took either 180 mg/day of curcumin (as Theracurmin) or a placebo daily for 8 weeks. Blood biochemistry analyses were performed before and after 8 weeks of each intervention to evaluate safety. The patients' knee symptoms were evaluated at 0, 2, 4, 6, and 8 weeks by the knee-scoring system of the Japanese Orthopedic Association and also the Japanese Knee Osteoarthritis Measure, the knee pain VAS, and the need for NSAIDs. The results showed that knee pain scores were significantly lower in the Theracurmin group than in the placebo group in those patients with moderate to severe symptoms. Theracurmin also lowered the use of celecoxib (Celebrex) much more significantly than placebo. Although 60% of the placebo group still relied on Celebrex for adequate pain relief at the 8-week mark, only 32% of the Theracurmin group still needed the NSAID, and there was a definite strong trend for eventual discontinuation. No major side effects were observed in the patients taking Theracurmin. This study is significant because it showed such a significant advantage over a placebo in a short-term study. Generally, in OA, this requires a much larger study group and much longer periods of time. Therefore, for Theracurmin to show such clear benefit in this relatively small, short-term study bodes well for people with OA gaining immediate and noticeable benefits with curcumin.[49]

Meriva has also been used with success in several studies.[50] In the first study, 50 patients were given 1000 mg Meriva (providing 200 mg of curcumin) for 3 months, after which symptom scores decreased by 58%, walking distance on the treadmill test was prolonged from 76 to 332 m, and the level of an inflammatory marker (C-reactive protein) in the blood decreased from 168 to 11.3 mg/L in the subpopulation with high C-reactive protein (CRP).[51] In another study, 100 patients with osteoarthritis were given the same dosage of Meriva for 8 months. Just as in the previous study, symptom scores, walking distance, and blood measurements of inflammation were all significantly improved.[52]

Rheumatoid Arthritis

Curcumin has been studied in rheumatoid arthritis (RA), with positive outcomes. For example, in one double-blind crossover clinical trial in patients with RA, curcumin (1200 mg/day) was compared with phenylbutazone (300 mg/day) (Fig. 73.4). The improvements in the

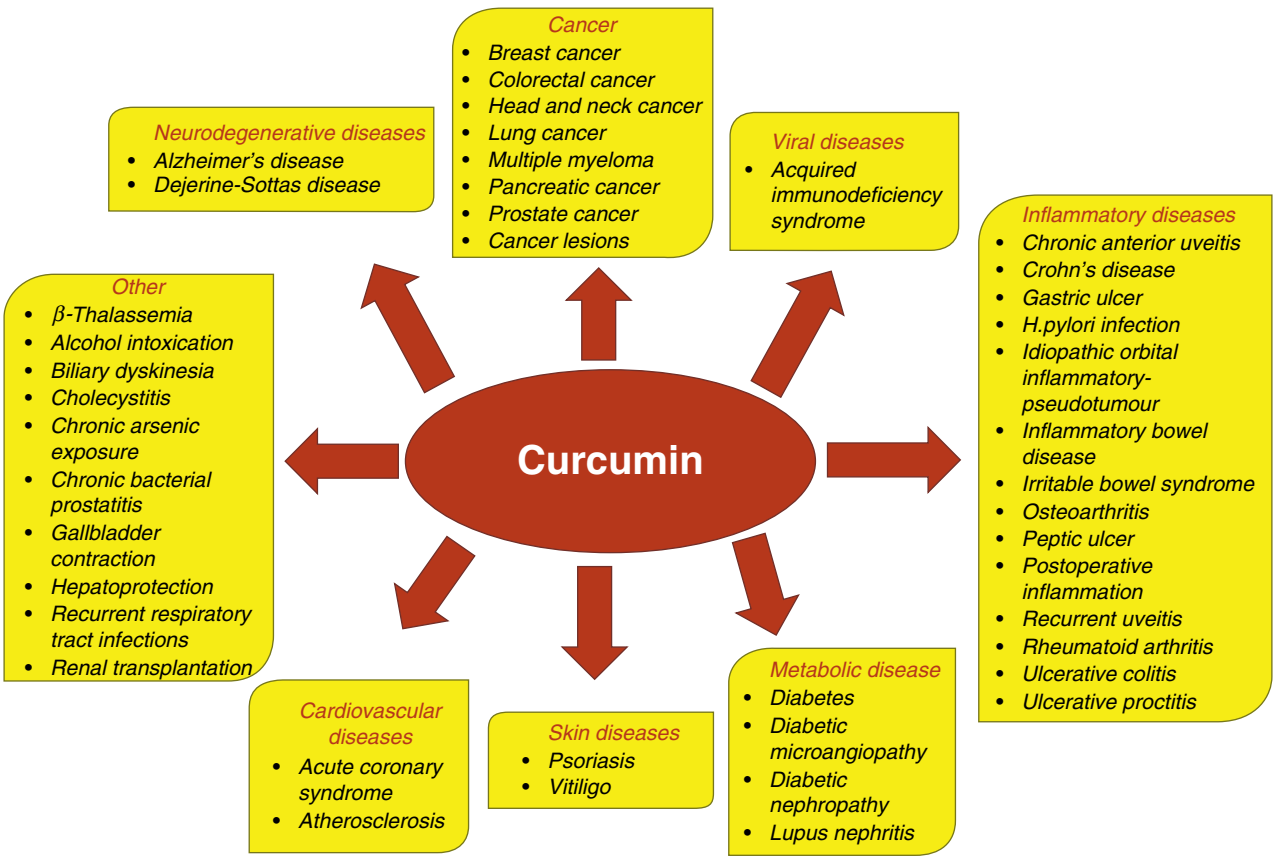

Fig. 73.4 Activity of curcumin against different human diseases based on clinical findings.

duration of morning stiffness, walking time, and joint swelling were comparable in both groups.[53]

In a more recent study in patients with active RA, 45 patients diagnosed with RA were randomized into three groups, with patients receiving regular, nonenhanced curcumin (500 mg) and diclofenac sodium (50 mg) alone or their combination. The primary end points were a reduction in Disease Activity Score (DAS) 28. The secondary end points included American College of Rheumatology (ACR) criteria for reduction in tenderness and swelling of joint scores. Patients in all three treatment groups showed statistically significant changes in their DAS scores. Interestingly, the curcumin group showed the highest percentage of improvement in overall DAS and ACR scores (ACR 20, 50, and 70), and these scores were significantly better than those of the patients in the diclofenac sodium group.[45]

Another small clinical trial used a more bioavailable form (Cureit). The 36 patients were divided into three groups, 250 mg curcumin, 500 mg curcumin, or a placebo twice daily. Significant changes in ESR, CPR, and rheumatoid factor (RF) values in patients receiving the study product compared with baseline and placebo. The results indicate that this novel curcumin in a turmeric matrix acts as an analgesic and anti-inflammatory agent for the management of RA at a dose as low as 250 mg twice daily, as evidenced by significant improvement in the ESR, CRP, VAS, RF, DAS, and ACR responses compared with placebo.[54]

Gastrointestinal Inflammation

Absorption of curcumin may not be as significant of a factor when dealing with gastrointestinal inflammation. There have been three randomized controlled trials in the treatment of ulcerative colitis that included a total of 142 patients. The use of curcumin along with mesalamine was associated with increased odds of clinical remission. Clinical improvement, endoscopic remission, and improvement rate also trended higher in the curcumin group compared with placebo.[55]

In one of the double-blind studies with ulcerative colitis, 43 patients received regular curcumin, 1 g after breakfast and 1 g after the evening meal, plus sulfasalazine or mesalamine, and 39 patients received placebo plus sulfasalazine or mesalamine for 6 months. Of the patients who received curcumin, 2 relapsed during 6 months of therapy (4.65%), whereas 8 of 39 patients (20.51%) in the placebo group relapsed. Furthermore, curcumin improved both the clinical signs and symptoms with ulcerative colitis via standard activity indexes.[56] In another study, 50 people with mild to moderate ulcerative colitis not responsive to mesalamine were given 1.5 g of curcumin twice a day (3 g per day of curcumin) or placebo for 1 month with continued mesalamine treatment. At week 4, 53.8% of those receiving curcumin went into remission, whereas none of the patients who received placebo achieved remission.[57] In another study, 1000 mg of curcumin taken twice daily in addition to mesalamine or sulfasalazine for 6 months helped maintain remission from ulcerative colitis compared with standard medications plus placebo.[58] But a lower dose (450 mg of curcumin daily) did not improve remission rates or improve mucosal healing compared with placebo in men and women with active ulcerative colitis taking mesalamine in another study.[59] This difference in response may be related to dosage.

In a study using an enhanced form of curcumin similar to Theracurmin, 56 men and women with mild to moderate ulcerative colitis found that 80 mg curcumin taken three times daily (240 mg per day) in addition to mesalamine for 1 month modestly decreased urgency of bowel movements and improved self-reported well-being, but did not decrease blood in the stool or colitis-related skin ulcers, compared with mesalamine alone.[60]

DOSAGE

On the basis of the evidence presented previously, it is clear that turmeric can be consumed liberally in the diet for its health-promoting effects. When specific medicinal effects are desired, due to the current understanding of curcumin pharmacokinetics, extracts of *C. longa* or curcumin are more feasible in achieving sufficient absorption.

Turmeric extracts, and more specifically curcumin preparations, are now major sellers in North America, with sales well above $300 million in 2018. The total global market for curcumin is growing as well and is expected to reach $1.3 billion by 2025. When natural products become commercially popular, it is not uncommon for synthetic versions to be introduced. That appears to have begun in early 2015. Plant-derived products can be distinguished from synthetic products by their content of an exceedingly small but accurately determinable amount of radioactivity. Plants assimilate carbon dioxide (CO_2) from the atmosphere, which contains a small quantity of radioactive CO_2. When made synthetically, the material has zero radioactivity. Any adulteration of an herbal extract, even partially, with synthetic equivalents can be detected accurately as to the relative ratios of each of the constituents.

The commercial landscape with curcumin has focused on improving bioavailability. Historically, turmeric and curcumin have been consumed in a lipid base, such as lecithin, fish oils, or essential fatty acids (with meals) or formulated in conjunction with Piperine or bromelain (on an empty stomach). A number of new methods now exist to enhance the absorption of curcumin. Table 73.3 provides several formulas reported to have enhanced bioavailability. These preparations deserve special mention because of their clinical investigations, most notably Meriva and Theracurmin. Meriva is produced by complexing curcuminoids with phosphatidylcholine to Phytosome.[49] Theracurmin is a surface-controlled particle dispersion within gum ghatti as the carrier.[61] It has an average particle size of curcumin of 0.19 μm compared with an average particle size of 22.75 μm in curcumin powder. This represents a reduction of over 100 times.

TABLE 73.3 Selected Formulations Reported to Improve Curcumin Bioavailability With Some Clinical Validation

Formulation	Manufacturer	Formulation Description
Biocurcumax (BCM-95)	Arjuna Natural Extracts Ltd. India (Dolcas Biotech)	Curcuminoid, essential oil of turmeric (45% ar-turmerone), and curcuminoids
Curcumin C3 Complex + Bioperine	Sabinsa, USA	Bioperine, and curcuminoids
Meriva	Indena SpA, Italy	Phytosome technology (curcumin, soy lecithin, microcrystalline cellulose, and 18%–20% curcuminoids)
Theracurmin	Theravalues Corp., Japan	Colloidal suspension of micronized curcumin (36% curcuminoids, 14.6% gum ghatti, 48.7% maltodextrin, 0.7% citrate)

Many brands/formulations will offer comparisons to curcumin. However, this practice is irrelevant given the poor oral absorption of curcumin. If the absorption of curcumin nears zero, how is any multiple of that number relevant clinically? Based on existing data from clinical studies, what is more important than comparing it to curcumin is the ability of a preparation to produce clinical results based on achieving targeted blood values. Here are the recommended targets:

- For general anti-inflammatory support, the therapeutic target is 50 to 100 ng/mL
- For more severe inflammation and in Alzheimer disease, the therapeutic target is 150 to 200 ng/mL
- For cancer and serious inflammatory conditions, the therapeutic target maybe 300 ng/mL or more

When evaluating absorption data from published human trials or the marketing claims from a manufacturer, the question comes down to what dosage of the preparation is required to produce the targeted blood levels listed here.

TOXICOLOGY

Toxicity has not been reported at standard dosage levels. The oral mean lethal dose levels for turmeric, its alcohol extracts, and curcumin have not been determined because 2.5 g/kg fed to mice, rats, guinea pigs, and monkeys and 3 g/kg sodium curcuminate fed to rats resulted in neither mortality nor chromosomal aberrations in teratology tests. At high doses, curcumin or turmeric may damage the gastrointestinal system because curcumin, with doses of 100 mg/kg body weight, was ulcerogenic in rats. Some studies found a sensitivity of mice to turmeric that resulted in hepatotoxicity. Curcumin toxicity has not been found in rats or other mammals, even at very high doses (5%–10% by weight of diet). Human studies suggest that curcumin is nontoxic to humans up to 8000 mg/day when taken by mouth for 3 months. Even the more bioavailable formulations of curcumin have been shown to be safe for humans.[62]

DRUG INTERACTIONS

Curcumin has several possible drug interactions, only a few of which have been confirmed. In one human study, 300 mg of curcumin reduced the absorption of the β-blocker talinolol by roughly 35%.[63]

In rabbits, pretreatment with curcumin resulted in increased plasma elimination half-life, thereby reducing the dosage of norfloxacin.[64]

In an experimental model, curcumin was shown to inhibit apoptosis produced by a number of chemotherapy agents, including camptothecin, mechlorethamine, and doxorubicin.[62]

Based upon in vitro studies, curcumin may inhibit the following drug-metabolizing enzymes: CYP3A4, CYP1A2, and CYP2A6.[65]

Curcumin was also shown to downregulate intestinal P-glycoprotein levels, thereby increasing the concentrations of Celiprolol and midazolam. This action may have significance for other drugs influenced by intestinal P-glycoprotein downregulation, including colchicine; various chemotherapy agents, including etoposide, doxorubicin, and vinblastine; digoxin; and immunosuppressive agents.[66]

Some theoretic concern has been raised that curcumin might increase the risk of bleeding of anticoagulant drugs due to its ability to decrease platelet aggregation.[67]

Dehydroepiandrosterone (DHEA)

Cory Szybala, ND, Mollie Parker Szybala, ND, MPH, Laurie Mischley, ND, PhD, MPH, Paul Nicolai*, ND,* and *Alan R. Gaby*, MD*

OUTLINE

INTRODUCTION

Dehydroepiandrosterone (DHEA) is a steroid hormone secreted primarily by the adrenal glands and, to a lesser extent, by the testes and ovaries, brain, and gastrointestinal tract (Fig. 74.1).[1,2] Circulating levels of DHEA and its ester, DHEA sulfate (DHEAS), are 20 times higher than those of any other adrenal steroid. In the past, no DHEA-specific receptors have been found. Thus this hormone has long been considered to only function as a reservoir from which the body could draw as a precursor for the formation of other hormones. Elucidating a physiological role for DHEA and possible clinical applications for DHEA are an ongoing topic of exploration in human medical research. This has paid off with new research showing direct neurotransmitter regulation, specifically the neurosteroids associated with neuronal excitability.[3]

Although DHEA was first identified in 1934, its clinical use did not achieve prominence until 1993 when French scientists claimed it was a "cure" for aging[4] based on the observation that human DHEA levels peak in the late 20s and decline steadily thereafter. Epidemiological evidence suggests that higher DHEA levels are associated with increased life expectancy[5] and enhanced well-being.[6–8] Persons with a steeper decline and greater variability in DHEAS levels over time have been shown to have a higher death rate, regardless of baseline DHEAS levels.[9] It has therefore been postulated that some of the manifestations of aging may be caused by a decline in DHEA production. DHEA has often been and continues to be used as part of an "antiaging" treatment program.

DHEA production varies profoundly throughout life. Levels begin to increase in children at 8 to 10 years of age (adrenarche) and peak in the second decade of life. Beginning in the early 30s, levels then progressively decline with age, approaching a plateau at approximately 65 to 70 years, until only 20% of peak levels remain.[6,7,10] This decline in DHEA production, often referred to as adrenopause, ultimately results in an 80% loss of total DHEA production compared with that of a young adult. Interestingly, this age-related decline does not occur with other adrenal hormones such as glucocorticoids or mineralocorticoids.[11] In addition to the normal decline associated with aging, other possible causes for a decline in DHEA production include inflammation, many illnesses, and both chronic and subchronic stress.[12]

DHEA BIOCHEMISTRY

DHEA and its sulfate, DHEAS, are the most abundant steroid hormones in the human body and can be found in blood, saliva, urine, and cerebrospinal fluid (CSF).[12] Most DHEAS synthesis occurs in the adrenals via the action of hydroxysteroid sulfotransferase, otherwise known as DHEA sulfotransferase. It is this sulfated form of DHEA that has the longest half-life and is found in the bloodstream in the highest amount, thus leading to the commonly accepted theory that DHEAS serves as a precursor or "buffer" reservoir of DHEA to be used for the intracellular synthesis of various estrogens and androgens throughout the human body. DHEA and DHEAS undergo continuous interconversion, via the sulfation and desulfation process, but because DHEAS represents approximately 80% of the total DHEA pool, has a longer half-life, and lacks the circadian fluctuation seen with DHEA, it is more reliably used in clinical laboratory assessment.[13,14]

Despite DHEA being the major secretory product of the human adrenals, an understanding of DHEA's many physiological roles remains elusive. That is until new research revealed the modulating effects of DHEA and DHEAS on the excitatory neurotransmitter system, as neurosteroids, by modulating the NMDA glutamate receptor, dopamine and serotonin signaling, and inhibition of GABA A receptor activity.[3] Still, assessing whether the many effects of DHEA are a direct result of the hormone, its metabolites, or a combination of the two has been difficult.[15] Although often chemically classified as a weak

androgen, little evidence of direct androgenic activity exists, so any androgenic activity is most likely mediated through its conversion to other more potent androgens. As a person ages and both ovarian and testicular production of hormones declines, this peripheral conversion of DHEA/DHEAS becomes increasingly more important as a source of these androgens.[12] In women, about two thirds of circulating testosterone is produced from peripheral conversion of ovarian and/or adrenal precursors. This percentage is higher in women who have had bilateral oophorectomy.[16]

The biosynthesis of all sex steroids in humans proceeds through DHEA.[17] As a steroid precursor, DHEA is converted to both estrogens and androgens, depending on the requirements of the target tissue. The majority of DHEA conversion to metabolites occurs within peripheral cells via the enzymes aromatase and steroid sulfatase (STS), both of which are present in the majority of human cells (Fig. 74.2).

The effect of endogenous DHEA in humans varies significantly depending on the individual's age, gender, menopausal status, and DHEA levels. On a cellular level, both the target tissue and intracellular enzyme availability shape the fate of the molecule.[18] This process, often referred to as intracrinology, allows for local action of the various hormonal metabolites of DHEA on target tissues such as the brain, bones, breasts, and ovaries without either a specific DHEA receptor or a significant increase in the circulating levels of these metabolites. A specific high-affinity DHEA receptor has not yet been discovered, and there is little evidence that DHEA is able to exert any physiological action without either modulating another receptor type or being converted into an active metabolite or another hormone, with the exception of its recently discovered direct effects on the neurotransmitter system.[3,19,20] In the brain, for example, endogenous DHEA's effects appear to be mediated via a combination of sex steroids, metabolites such as 7 α-hydroxy-DHEA, γ-aminobutyric acid, *N*-methyl-D-asparate, or other receptors.[12] In vitro studies demonstrated that DHEA has the ability to activate estrogen receptors in the prostate at reasonable physiological concentrations, as well as demonstrating an inhibitory effect of DHEA on androgen receptors at much higher concentrations.[19]

DHEA IMMUNOLOGY

Research has shown a significant immune modulation effect, including both immune stimulation and antiglucocorticoid effects.[21] Most of this information must be approached with caution in terms of a clinical perspective, however, due primarily to the fact that a preponderance of the data are from either in vitro studies or in vivo murine studies.

DHEA appears to have a significant regulatory effect on cytokine production in the form of increasing interleukin-2 (IL-2) secretion from TH-1 cells and decreasing production of IL-6 and IL-10 from TH-2 cells.[21] It has also been shown to significantly increase serum insulin-like growth factor-1 (IGF-1) and natural killer (NK) cell numbers in healthy age-advanced men with low DHEAS levels.[22] IL-6 stimulates hepatocytes to produce acute-phase reactants and B-lymphocytes to produce immunoglobulin. In rheumatoid arthritis, levels of IL-6 correlated strongly with both erythrocyte sedimentation rate and rheumatoid factor titers.[23] Both IL-6 and IL-10 were shown to be mediators of inflammatory- and age-related diseases, such as polymyalgia rheumatica, rheumatoid arthritis, inflammatory bowel disease, osteoporosis, and atherosclerosis. These same mediators are implicated as possible contributors to the pathophysiology of Alzheimer's disease, Parkinson's disease, and β-cell malignancies.[24]

It has been theorized that the increase in IL-6 production during the process of aging might be due in part to diminished DHEA secretion.[24] This theory is based on research demonstrating that serum DHEA levels correlated negatively with serum IL-6. Exogenously administered DHEA inhibits IL-6 secretion in a U-shaped fashion, with serum concentrations equaling that of healthy controls exerting the greatest effect.[24]

In one double-blind study, administration of 50 mg/day of DHEA to postmenopausal women produced a twofold increase in NK cell activity and a 6% decrease in the proportion of T-helper cells.[25] The significance of these changes is not entirely clear. Although the increase in NK cell activity might be expected to enhance immune surveillance against cancer and viral infections, the decline in T-helper cells could have adverse consequences. However, because DHEA is known to mediate T-cell responses,[26] the decline in T-helper cells could merely be a reflection of enhanced T-cell function.

DHEA was also shown to have a measurable positive effect in terms of mitigating the immune-suppressive effects of both endogenously produced and exogenously administered glucocorticoids.[21]

CLINICAL APPLICATIONS

Early studies hinted at a wide variety of beneficial effects in conditions such as primary and secondary adrenal insufficiency, mood and self-esteem, diabetes, obesity, decreased immune function, atherosclerosis, and many of the disorders typically associated with normal aging.[27] Although promising, the clinical utility of many DHEA studies may be limited in that they have been overly reliant on animal models, use inconsistent dosing protocols (in some cases doses unachievable in humans), and do not consider the rapid metabolism of DHEA, test subject comorbidities, or organ-specific differences.[28] Rodents have little endogenous DHEA, and their DHEA levels do not decrease with age. DHEA in rodent studies is often administered at supraphysiological doses, which may also make it difficult to determine the clinical relevance of using physiological doses of DHEA in humans. It is the intention of this chapter to base recommendations for the clinical use of DHEA on human studies to the greatest extent possible.

Adrenal Hypofunction/Addison's Disease

Despite the well-documented decline in DHEA levels seen in true adrenal hypofunction, adrenal hormone replacement protocols do not routinely recommend the administration of DHEA.[29–31] Even in the context of adequate glucocorticoid replacement, individuals with reduced adrenal function commonly report symptoms of depression and dysthymia, as well as a general reduction in overall quality of life. Several studies in patients with adrenal insufficiency demonstrated that DHEA replacement might result in an improvement in mood and fatigue, an increase in sexual satisfaction, and a better overall sense of well-being.[32–36]

Aging

Preliminary data suggest that DHEA might retard the aging process. For example, in a study of 75 healthy subjects, aged 90 to 106 years, men with the highest DHEAS levels had the highest level of functioning, as assessed by the Katz's scale of Activities of Daily Living (ADL).[37] Several other studies in elderly humans supported an inverse correlation between DHEA levels and the degree of dependence in activities of daily living and mobility. In one study, plasma DHEA levels were low in 80% of male nursing home residents who required total care, compared with 40% in other nursing home residents and 6% in independently living men of comparable age.[7,38]

In men older than 90 years of age, higher DHEAS levels were associated with a higher body mass index and waist-to-hip ratio, taken as indices of the body's energy (fat) reserves. In women older than 90 years of age, DHEAS levels were positively correlated with serum-free triiodothyronine and inversely with triglycerides.[37]

In an attempt to determine whether DHEA supplementation would counteract defects associated with aging, 280 healthy individuals between the ages of 60 and 79 years old were given 50 mg/day of DHEA or placebo for a year. In women older than 70 years of age, there was a reduction in the amount of bone loss and an increase in most libido parameters. Women also showed improvements of skin status, including greater hydration, epidermal thickness, sebum production, and pigmentation.[39]

Although DHEA levels do not appear to correlate significantly with cognitive function,[6,7,40] low serum DHEAS was associated with decreased psychological well-being and symptoms of depression.[7]

Depression

Elevated cortisol levels are well documented in depression, occurring in approximately 50% of cases.[41] Hypercortisolemia has also been shown to impair learning and memory in humans, and prolonged exposure to excess glucocorticoids leads to neuronal atrophy.[42,43] Therefore the neurocognitive deficits observed in depressive disorders may be partially attributable to glucocorticoid hypersecretion. DHEA possesses significant antiglucocorticoid activity,[44] and it may be via this mechanism that administration of DHEA reduces neurocognitive deficits in major depression.[45,46]

An extensive study of depression in adolescents showed approximately 30% had abnormally low DHEA levels,[47] and mean levels of DHEA in the saliva of depressed adults were lower than those in normal control subjects.[41] Improvements in cognition were observed after oral administration of DHEA to middle-aged and elderly depressed patients,[48] and the antidepressant actions of DHEA were demonstrated in several randomized controlled trials.[49,50–53] The ability of DHEA to affect depressive symptomatology seems to be most substantial where DHEA levels are low or in those with an elevated cortisol-to-DHEA ratio.

CSF DHEAS levels are highly correlated with serum levels,[7] and DHEA easily crosses the blood–brain barrier. Evidence also suggests the brain synthesizes DHEA from cholesterol.[54] The ability of DHEA to enhance mood may be related to its role in the central nervous system as a neurosteroid. DHEA supplementation was shown to increase levels of β-endorphins, bind *N*-methyl-D-asparate receptors, act as an antagonist of γ-aminobutyric acid receptors, regulate the excitatory neurotransmitter system, and protect against the deleterious effects of glucocorticoids.[3,49,50,55] In rats, DHEA was shown to increase hypothalamic serotonin levels.[56] These pharmacological properties might help explain the efficacy of DHEA in mood disorders.

New research looking at the effects of DHEA on mood disorders, particularly minor and major depression, has revealed a significant improvement of symptoms in just 3 weeks when subjects were supplementing with 90 mg/day of DHEA. In each study, few adverse events were reported, suggesting this readily available intervention might have clinical utility in some populations.[50–52,57]

Alzheimer's Disease

Unlike peripheral DHEA, which is predominantly converted to estrogens and testosterone, DHEA metabolism in the central nervous system appears to be somewhat unique.[58] A decreased concentration of plasma DHEAS in patients with Alzheimer's disease has been reported,[59–61] and low plasma DHEAS levels appears to be a risk factor for the development of Alzheimer's disease.[59] However, elevated brain tissue and CSF levels of this steroid also appeared to be a risk factor

for the development of Alzheimer's disease.[62] Reduced plasma DHEAS levels did not appear to be associated with the degree of cognitive decline or risk of mortality.[63]

Several small studies using DHEA in the treatment of Alzheimer's disease produced unimpressive results,[64–67] and it remains unclear as to whether different study designs might produce positive results. For instance, one proposed mechanism was that DHEA's antiglucocorticoid effects might offset hippocampal damage associated with elevated basal cortisol levels, and yet another looked at the inhibition of monoamine oxidase (MAO) and NMDA-induced nitric oxide (NO) production in the brain, suggesting an antioxidant effect.[64,65] Despite its unlikely role in cognitive improvement, there continues to be a substantial amount of enthusiasm for the potential role of DHEA as a neuroprotective agent.

Menopause

Practitioners of complementary and alternative medicine (CAM) often recommend including DHEA as part of a postmenopausal hormone therapy regimen to promote well-being, mental acuity, and enhance sexual function. A closer look at the current medical literature revealed that low sexual function in women was associated with low DHEAS more than any other androgen[68] and suggested several possible uses for DHEA in this population.

That said, any discussion pertaining to the use of DHEA in menopausal patients is likely handicapped by the fact that there is often great disparity between the way CAM practitioners prescribe DHEA and the way it is used in studies. CAM practitioners typically recommend smaller daily doses of 5 to 25 mg rather than the 50 mg/day (or more) that is often used in clinical research. Most clinical research also uses DHEA as the sole intervention, something most CAM practitioners would be unlikely to do with actual patients, as they would often employ some combination of estrogens, progesterone, DHEA, and testosterone, while attempting to help a patient improve their diet, exercise patterns, and other aspects of their lifestyle. One study that attempted to explore the use of DHEA in this type of combined manner demonstrated that oral dosing of DHEA at 10 mg/day for 12 months, either alone or in combination with estradiol and micronized progesterone, produced a significant rise in both androgens and β-endorphins, as well as a decrease in cortisol levels. Although intellectually promising and noteworthy, the researchers' decision to measure only biochemical outcomes instead of the physiological outcomes that are useful in clinical practice leaves much still to be determined.[11]

Topical application of 1% DHEA for 4 months resulted in an improvement in several parameters of skin health compared with topical application of the same formulation without the DHEA.[69]

Although evidence regarding the oral administration of DHEA does not tend to demonstrate consistent efficacy in terms of improving libido in postmenopausal women,[70,71] there is promising evidence regarding the use of vaginal DHEA for this purpose. Clinical trial data on DHEA vaginal suppositories demonstrated significant positive effects on libido, arousal, pleasure, and orgasm, as well as improvement in measures of vaginal atrophy, parabasal and superficial cells, pain at sexual activity (dyspareunia), and a lowering of vaginal pH. Also of potential clinical significance is the fact that 3 months of intravaginal DHEA administration did not affect endometrial histology and did not increase serum levels of estradiol, testosterone, or DHEA over those found in normal postmenopausal women.[72–76]

Osteoporosis

A possible relationship between DHEA deficiency and osteoporosis was suggested by a study of women with Addison's disease in whom the onset of menopause was followed by an unusually rapid rate of bone loss. This accelerated bone loss was associated with marked reductions in plasma concentrations of both DHEA and testosterone.[77] A study examining women aged 45 to 69 years determined that 55 of 105 women had low bone mineral density (BMD), and that the average serum DHEAS level was 60% lower in women with low BMD compared with those with normal bones. Also of note is the fact that, although there was no relationship between estrogen levels and BMD in this study, women with low DHEAS values were 40 times more likely to have osteoporosis than were women with normal DHEAS levels.[78] Another study of 29 postmenopausal women demonstrated significant positive correlation between bone mineral content in the distal radius and ulna and age-adjusted serum DHEA levels.[79] More recent studies continue to expand upon these findings by documenting the positive correlation between androgen levels and BMD in postmenopausal women who do not have Addison's disease, thus suggesting an essential role for DHEA, testosterone, or both, in the maintenance of bone mass in postmenopausal women. It appears that free testosterone levels are more significantly correlated with increased bone mass in the lumbar spine, whereas DHEAS levels tend to correlate with increased bone mass in the femoral neck, both notable areas of concern in terms of the prevention and treatment of osteoporosis.[75]

Although testosterone was shown to have receptor sites on osteoblasts, the lack of an analogous receptor for DHEA leaves the mechanism by which DHEA contributes to bone production and maintenance as a matter of some speculation. Possible theories include functioning as a precursor molecule for the formation of estradiol and various androgens in systemic circulation, a direct promotion of bone formation by increasing levels of IGF-1 while inhibiting skeletal catabolic IL-6,[80,81] or possibly an intracrine mechanism involving an interaction with vitamin D3 to enhance the conversion of DHEA to estrone in osteoblasts.[82]

Recommendations pertaining to the clinical use of DHEA for the prevention and treatment of osteoporosis are less clear due to mixed results in controlled trials and a lack of both long-term studies and good data in terms of fracture risk reduction. One double-blind, placebo-controlled study of 50 mg/day DHEA supplementation demonstrated improved bone turnover and decreased osteoclastic activity in women older than 70 years.[39] In another, treatment using transdermal DHEA cream for 1 year in postmenopausal women demonstrated significantly increased serum osteocalcin levels and BMD of the femur, while simultaneously demonstrating a decrease in bone alkaline phosphatase levels.[83] A recent randomized, placebo-controlled trial in 225 healthy adults age 55 to 85 years showed that oral dosing of 50 mg/day DHEA for a year increased lumbar spine BMD in women only. There was no effect on femoral neck or total body BMD in women and no significant changes in BMD were noted at any site in the men studied.[84] A study that selected exclusively men and women with lower levels of DHEA demonstrated a notably different result using the same 50 mg/day dose, in that BMD in the lumbar spine was improved in both men and women compared with placebo, as was hip BMD in women.[85] Unfortunately, neither of these studies looked at or directly mentioned fractures or fracture risk in their subjects, although there was one indirect mention of DHEA supplementation leading to increased serum IGF-1 levels and the positive correlation between lower IGF-1 levels and risk of hip fracture in postmenopausal women.[86]

Erectile Dysfunction

The Massachusetts Male Aging Study, conducted from 1987 to 1989, was the first to describe an inverse correlation between DHEAS levels and the incidence of erectile dysfunction. More than half of the men in this study had minimal, moderate, or complete impotence,[87] and the degree of impotence was directly correlated with lower serum DHEAS

levels. Follow-up research suggested that this was especially true for men younger than 60 years.[88] More recently, it has also been shown that men with higher levels of testosterone and DHEA and decreased levels of interleukin-6 (IL-6) reportedly perceived better general health, emotional support, intimacy, satisfaction with life, resilience, and a better relationship quality, all of which should be considered clinically in any CAM practice.[89]

One double-blind, placebo-controlled study demonstrated that oral DHEA supplementation at 50 mg/day for 6 months resulted in improvement in all five domains of the International Index of Erectile Function, which quantitatively describes an individual's ability to achieve or maintain an erection sufficient for satisfactory sexual performance.[90,91] Response was most substantial in individuals with hypertension or lack of an organic etiology for their condition.[90] There was no effect of DHEA treatment on serum prostate specific antigen, prolactin, testosterone, mean prostate volume, or mean postvoid residual urine volume.[91] A more recent placebo-controlled randomized trial of 50 mg DHEA twice a day demonstrated no benefit compared with either testosterone or placebo.[92]

Cardiovascular Disease

Administration of DHEA reduced the severity of atherosclerosis in cholesterol-fed rabbits.[60] In another rabbit model, low-dose DHEA mitigated the damaging biochemical and structural effects of a high-fat diet.[93] DHEAS was also shown to have digitalis-like activity, accounting for 62% to 100% of the total plasma digitalis-like factors in 11 healthy adults.[64] A study reviewing serum DHEA and DHEA supplementation found that DHEA has antiremodeling and vasorelaxant qualities.[94]

Mean plasma DHEAS levels are significantly lower in men with a history of heart disease than in men without such a history. One study found that in men with no history of heart disease at baseline, a low plasma DHEAS level (<140 mcg/dL) was associated with a more than threefold increase in the age-adjusted risk of death from cardiovascular disease.[95] Similar findings were reported by others,[96–100] although some investigators described only a modest protective effect of DHEA.[101,102]

The association between DHEAS and cardiovascular disease in women is less clear.[103] Cardiovascular death rates might actually be greatest in women with both low and high DHEAS compared with those with intermediate levels.[104,105] Although studies exploring the relationship between endogenous DHEA levels and cardiovascular risk factors have been encouraging in terms of demonstrating decreased carotid intima-media thickness[106] and less atherogenic lipid profiles,[107] recent randomized double-blind trials in hypoadrenal women did not demonstrate this benefit with the administration of oral DHEA. Several studies actually showed a tendency toward more atherogenic lipid profiles in terms of statistically significant decreases in the participant's high-density lipoprotein levels,[102,108] whereas another randomized, double-blind, placebo-controlled study of longer duration found no significant changes in the lipid values of postmenopausal women who took 50 mg/day of oral DHEA for an entire year.[109]

There appear to be numerous reasons to continue the study of DHEA administration for the prevention and treatment of cardiovascular disease, but there are currently few clinical data that support the routine use of DHEA, particularly when given the myriad of both pharmaceutical and complementary and alternative options that are available for this purpose.

Cancer

DHEA supplementation for cancer, although mostly positive, does have a few concerns, particularly in regards to breast cancer and potentially other hormone-related cancers.[110–113] There are premenopausal women with breast cancer that had significantly lower plasma levels of DHEA than age-matched controls without breast cancer, whereas postmenopausal women had significantly higher DHEA levels than age-matched controls.[114] In another study, women with DHEA levels in the highest tertile were 60% less likely to develop breast cancer than were women in the lowest tertile.[115] In a prospective case–control study, serum DHEA and DHEAS levels were significantly lower in individuals who subsequently developed bladder cancer than in those who did not.[116]

These findings suggest that DHEA has anticancer activity and that low DHEA levels may be a risk factor for cancer, except in postmenopausal women. However, it is obvious that further research is required before guidelines can be developed regarding DHEA therapy and cancer. The observation that some postmenopausal women with breast cancer have elevated DHEA levels, as well as the fact that DHEA is converted in part to estrogen and testosterone, should be cause for concern. It is unknown whether the anticancer effects of DHEA are stronger than the potential prostate cancer–promoting effects of additional testosterone or the breast cancer–promoting effects of additional estrogen. This is a complicated issue, because the metabolism of DHEA is usually "cross-gender" (i.e., women get an increase in testosterone whereas estrogen levels often do not change, and vice versa for men). Until these questions can be answered, DHEA therapy should be approached with caution in patients who have either been diagnosed with or who are at risk for developing hormone-dependent cancers.

Rheumatoid Arthritis

Although a 2009 case–control study demonstrated no significant correlation between serum DHEAS levels and the future likelihood of developing rheumatoid arthritis (RA), decreased serum DHEAS concentrations were demonstrated in patients with RA,[117–119] possibly due to increased aromatase activity in the synovial tissue and the subsequent conversion of DHEA into estrogens, which may in turn stimulate the inflammatory process in patients with RA.[120–122] From a clinical perspective, the real issue at hand continues to be whether these low DHEA levels are a consequence of RA rather than a predisposing factor to the disease and whether or not DHEA administration is beneficial in patients with RA.[118]

It is worth noting that several studies on RA demonstrated protective or even therapeutic effects of DHEA in rodents with experimentally induced arthritis.[123,124] One study noted a clear benefit from the administration of about 10 mg/day, an amount roughly equivalent to 2500 mg/day for a 75-kg human being.[124] Despite these potentially encouraging results and the fact that some practitioners have observed patients with RA who exhibited clinical improvement after treatment with DHEA, there are no controlled trials in humans demonstrating either a lack of efficacy or the same positive effects on disease activity that have been shown in murine models of RA.[125]

Systemic Lupus Erythematosus

Systemic lupus erythematosus (SLE) is a chronic inflammatory connective tissue disorder that occurs predominantly in women. A positive effect of DHEA administration in autoimmune conditions such as SLE is likely due to a decrease in the production of proinflammatory cytokines, such as IL-6, IL-10, and cytokine-mediated antibody, thus DHEA has the potential for a positive effect on the clinical manifestations of antibody-mediated diseases.[24,126,127]

Several studies demonstrated efficacy in patients with SLE when treated with 50 to 200 mg/day DHEA.[127–133] A double-blind, placebo-controlled trial of women with SLE demonstrated that the group receiving DHEA had a significant reduction in the number of disease

flares and serious lupus-related adverse events, as well as improvement in the person's global assessment.[132] However, a recent review of randomized controlled trials comparing DHEA with placebo in persons with SLE demonstrated little to no effect on measures of disease activity, but did demonstrate an improvement in quality-of-life measures.[134] It was also noted that DHEA-treated subjects reported twice the rate of androgenic side effects compared with those given placebo.[135]

Inflammatory Bowel Disease

DHEAS concentrations are decreased in patients with both Crohn's disease and ulcerative colitis (UC).[136] In one study, 200 mg/day DHEA was given orally for 56 days to 7 patients with active Crohn's disease and 13 patients with active UC, all of whom were refractory to conventional drugs. The treatment response rate was 85.7% (6 of 7) for Crohn's disease and 61.5% (8 of 13) for UC. No patient withdrew from the study because of side effects.[137]

The mechanism of action may result from the ability of DHEA to decrease mediators of inflammation. It was shown that DHEA inhibits the activation of nuclear factor-κβ and the secretion of IL-6 and IL-12.[24]

DOSAGE

Although DHEA appears to be safe, the long-term effects of moderate to high dosages are unknown. In the elderly, 50 mg/day will increase DHEA levels into the reference range of young adults.[6] Although some practitioners routinely prescribe 50 mg/day for healthy women and 100 mg/day for healthy men, such doses may be supraphysiological. Dosages of 5 to 25 mg/day for women and 10 to 50 mg/day for men appear to be safe.[35] Topical DHEA can be safely applied to the skin or inserted vaginally, at a dosage of 0.25% to 1%, for up to 3 to 4 months.[76,138] Patients with SLE or other autoimmune diseases sometimes need as much as 200 mg/day or more to obtain benefit. Large doses should be split into twice-daily dosing, usually morning and evening.

Studies show that orally administered DHEA is well absorbed,[139] and that once in circulation, DHEA readily penetrates the blood–brain barrier.[140,141]

TOXICITY

With some exceptions, both oral and topical administration of DHEA appears to be relatively safe for clinical use.[35] In one study, administration of 1600 mg/day for 28 days to healthy volunteers resulted in some degree of insulin resistance but no other significant side effects. A 2009 study giving postmenopausal women 50 mg/day of oral DHEA for a year demonstrated no significant effects on either insulin, glucose, or lipid values.[109] The same study also documented no significant difference in endometrial proliferation compared with placebo. In several SLE studies, 200 mg/day given for a number of months was generally well tolerated, with the exception of mild to moderate acne and occasional mild hirsutism. Another study reported intermittent nausea, perioral dermatitis, subjective feelings of aggressiveness, and intermittent hoarseness.[137] According to several reports, there is a possibility that cardiac arrhythmias and anxiety may be exacerbated by DHEA supplementation.[142,143] A positive association was reported between adrenal androgen levels and breast cancer risk in premenopausal women, particularly those over age 45.[144] Because DHEA is a known precursor to more potent sex hormones, its use should probably be avoided in individuals with hormone-sensitive cancers.

DRUG INTERACTIONS

Estrogen (oral contraceptive pills, hormone replacement therapy), free testosterone, and DHEA levels were reduced in women taking estrogen.[145]

All medications used to treat hormone-sensitive cancers including estrogen receptor downregulators (Fulvestrant) and aromatase inhibitors. These drugs are used to interrupt the growth of hormone-dependent cancers. Aromatase is the enzyme responsible for many of the conversions in the steroid pathway. When taken with DHEA, aromatase inhibitors may increase testosterone levels and reduce estrogen levels. More well-designed studies are needed to confirm this theory.[146]

DHEA may affect how insulin works in the body, and vice versa. Supplementation should be used with caution for those with conditions related to blood sugar dysregulation.[147]

Steroid sulfatase (STS) inhibitors are currently being developed for use in breast cancer therapy. STS controls the hydrolysis of DHEAS.[148]

DHEA may potentiate the action of thyroid hormones.[149]

Antidepressant medications, specifically those that increase serotonin levels. DHEA modulates the release of serotonin in hippocampal neurons and it is hypothesized that an increase in serotonin from supplementation may lead to serious side effects.[150]

SUMMARY

In conclusion, DHEA appears to have potential as a therapy for numerous conditions. However, much remains to be clarified in terms of human applications, so it would seem appropriate to treat this powerful hormone with caution and respect to maximize its benefits and minimize its risks.

Echinacea Species (Narrow-Leafed Purple Coneflower)

Michael T. Murray, ND

OUTLINE

Echinacea spp. (family: *Asteraceae*)
Echinacea angustifolia
Common names: narrow-leafed purple coneflower, black sampson, snakeroot
Echinacea purpurea
Common name: purple coneflower
Echinacea pallida
Common name: pale purple coneflower

GENERAL DESCRIPTION

Echinacea spp. are perennial herbs native to midwestern North America, from Saskatchewan to Texas. The genus derives its name from the Greek *echinos,* meaning "sea urchin." This refers to the prickly scales of the dried seed head portion of the flower. Nine species of echinacea have been taxonomically classified by McGregor on the basis of comparative anatomy and morphology (Table 75.1).[1]

Of the nine species, *Echinacea angustifolia, E. purpurea,* and *E. pallida* are the most commonly used clinically. *E. angustifolia,* with a typical height of up to 2 ft, is shorter than *E. purpurea* (1.5–5 ft) and *E. pallida* (1–3 ft). Another key to species identification is that *E. angustifolia* and *E. purpurea* have yellow pollen, whereas *E. pallida* is noticeably paler and has white pollen. The portions of the plant used for medicinal purposes include the aerial portion, the whole plant including the root, and the root itself. The taproot of *E. angustifolia* can reach a length of 3 to 4 ft.

E. angustifolia has thick, hairy, 1- to 3-inch-long leaves found at the base of a purple seed head shaped like a cone. The only exception to the family of "purple" coneflower is *Echinacea paradoxa,* which has a yellow flower.

CHEMICAL COMPOSITION

Analysis of *Echinacea* spp. has yielded a wide assortment of chemical constituents with pharmacological activities.[2,3] From a pharmacologic perspective, the important constituents of *Echinacea* spp. can be divided into seven categories:

- Polysaccharides
- Alkylamides
- Caffeic acid derivatives
- Flavonoids
- Essential oils
- Polyacetylenes
- Miscellaneous chemicals

In the case of echinacea, it appears that although individual immune-enhancing compounds produce significant effects when they are combined in meaningful amounts, there is an additive effect. The immune-enhancing components of echinacea work together in

TABLE 75.1 Taxonomic Formation of the Genus *Echinacea*

Species	Synonyms
Echinacea angustifolia	*Brauneria angustifolia*
E. atrorubens	*Rudbeckia atrorubens*
E. laevigata	*B. laevigata*
E. pallida	*R. pallida, B. pallida*
E. paradoxa	*B. paradoxa*
E. purpurea	*R. purpurea*
R. hispida	
R. serotina	
E. speciosa	*E. simulata*
E. intermedia	
E. sanguinea	
E. tennesseensis	*B. tennesseensis*

Modified from McGregor RL. The taxonomy of the genus *Echinacea (Compositae). Univ Kansas Sci Bull.* 1968;48:113–142.

a harmonious fashion to produce the phenomena of synergy. A key manner in which echinacea affects immune function is by enhancing the ability of macrophages to engulf and destroy particulate matter. The specific components of echinacea that possess this action are the polysaccharides, alkylamides, and cichoric acid. Although each component is effective alone, the greatest degree of enhancement was noted when the three active components were used in a specific ratio (0.25, 2.5, and 25 mg/mL).[4] This phenomenon of synergy was noted with a clear dose-dependent effect. In other words, the effects with the three actives were greater than any individual active and the higher the dosage, the greater the effect on enhancing macrophage function. A similar effect was noted in the ability of macrophages to detect the presence of foreign matter in the blood and signal the other components of the immune system to mount an attack via interleukin-1 (IL-1) and granulocyte colony-stimulating factor.

Because echinacea contains a wide assortment of chemical constituents with confirmed immune-enhancing effects, this is important for manufacturers to recognize to ensure sufficient levels of all these active compounds. Unfortunately, most echinacea products on the market do not specify the levels of active compounds because they have not been analyzed for them. In addition, when manufacturers do state the level of a particular marker compound, most consumers fail to realize that concentrating only for one particular active compound of echinacea results in the loss of other constituents and, as a result, all of the synergistic effects. For example, some manufacturers standardize for "total phenolic content" or the compound echinacoside.[5] Although these types of echinacea extracts were found to have some antioxidant properties, recent studies found them to have no effect on enhancing immune function in experimental animal studies.[6,7]

The growing understanding of the chemical composition of echinacea requires manufacturers to perform quality control tests not only on the finished product but also on the plant to ensure that it is being grown properly and harvested at the exact time for maximal levels of all active compounds. It is imperative that echinacea be treated properly after harvesting. In addition, studies indicate that a significant amount of the active ingredients are destroyed in the drying process. If the fresh plant material is not processed immediately, the content of several key components—especially cichoric acid and alkylamides—will be low (as much as 80% will be lost).[8–10] Chemical analysis of commercial echinacea preparations demonstrated tremendous variation in the levels of key compounds. For example, one analysis of various commercial echinacea products found that there was not only tremendous variation in the level of cichoric acid, with most products containing either none or little, but even within the same product, there was tremendous interbatch variation.[11]

Polysaccharides

A number of immunostimulatory and mild anti-inflammatory polysaccharides have been isolated from *Echinacea* spp.[2,3,12–15] Most notable are inulin, which is found in a high concentration (5.9%) in *E. angustifolia* root, and the high-molecular-weight (25,000–50,000) polysaccharides found in the aerial part of *E. purpurea.* These components possess significant immune-enhancing properties. Typically, the most potent immune-enhancing polysaccharides are the water-soluble, acidic, branched-chain heteroglycans composed of many types of sugars rather than the polyfructose content of inulin.

Alkylamides

Alkylamides typically exert a tingling sensation on the tongue, which is representative of their mild anesthetic effect. These compounds are found in highest concentrations in the roots. The roots of *E. angustifolia* contain higher concentrations (0.004%–0.039%) than *E. purpurea* (0.009%–0.151%) and *E. pallida* (0.001%).[16,17] Alkylamides are among the most active constituents of echinacea on macrophage function.[18] In a human pharmacokinetic study, alkylamides were detected in plasma 20 minutes after ingestion of an echinacea preparation and indicated that dosing at least three times a day was required to maintain plasma concentrations.[19]

Caffeic Acid Derivatives

Caffeic acid serves as the backbone for a number of important medicinal plant compounds in other plants and *Echinacea* spp. (Fig. 75.1). The first compound believed to be unique to *Echinacea* is echinacoside, a compound eventually shown to be composed of caffeic acid, a caffeic acid derivative (similar to catechol), glucose, and rhamnose, all attached to a central glucose molecule.[20] Echinacoside accumulates in the roots but is also found in smaller concentrations in the flowers. The roots *of E. angustifolia* contain 0.3% to 1.3%, whereas the roots of *E. pallida* contain a similar concentration of 0.4% to 1.7%.[12] It is assumed that *E. purpurea* has similar echinacoside levels as well.

Other caffeic acid derivatives important in the pharmacology of *Echinacea* include cichoric acid, chlorogenic acid, and cynarin.3 Cichoric acid was originally isolated from *E. purpurea* and is found in much higher concentrations in this species compared with *E. angustifolia* and *E. pallida.*[3,21] However, *E. angustifolia* and *E. pallida* have higher amounts of other types of caffeic acid derivatives. These differences are not thought to have much clinical significance; rather, they may prove to be valuable in quick chemical differentiation of species.

Flavonoids

The leaves and stems of *E. angustifolia* and *E. purpurea* have been shown to contain numerous flavonoids, with rutoside being the most abundant.[3] The total flavonoid content (calculated as quercetin) for *E. angustifolia* and *E. purpurea* was 0.48% and 0.38%, respectively.[3]

Essential Oils

The essential oil content varies among the three common species[22]:

- *E. angustifolia* root and leaves contain less than 0.1%.
- *E. purpurea* root contains 0.2%, and flowers and leaves contain 0.6%.
- *E. pallida* root contains up to 2%, and the leaves contain less than 1%.

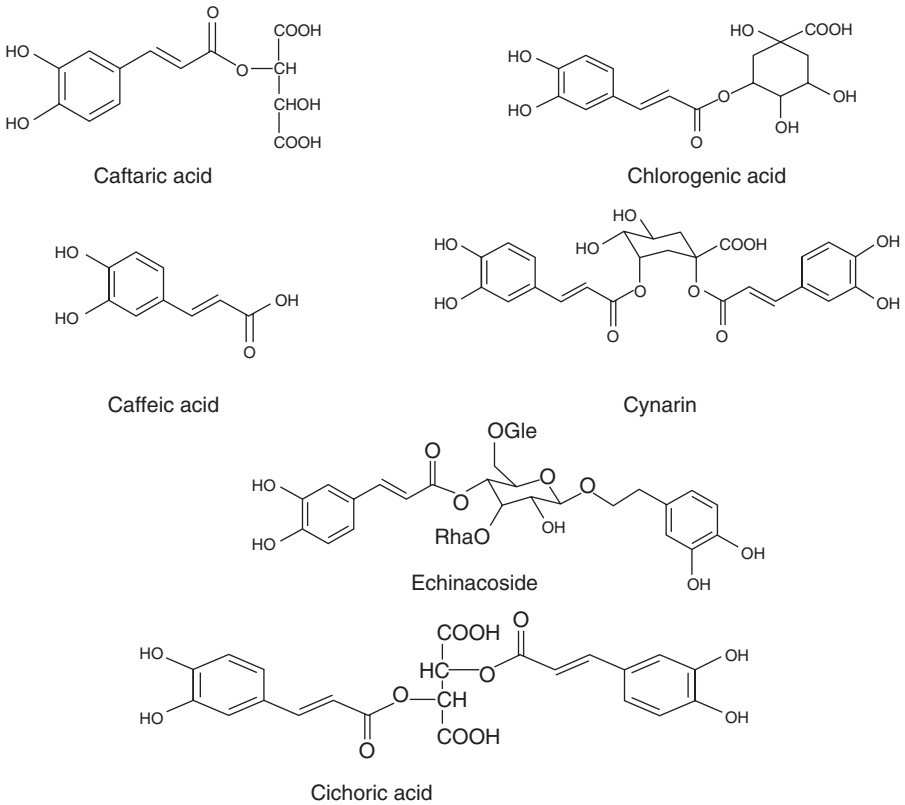

Fig. 75.1 Caffeic acid, Echinacoside, and other caffeic acid derivatives.

Interestingly, in one study, the essential oil content of *E. pallida* root was found to rise to 3.5% to 4% in April and May but fall to 1% to 1.5% for the rest of the year.[23] The major essential oil components are sesquiterpene derivatives, borneol, α-pinine, and related aromatic compounds.[3]

Polyacetylenes

A number of polyacetylenes have been identified from the roots of all three commercial species.[24] The difference in the type of polyacetylene and susceptibility to breakdown may help differentiate which species is best for commercial use. Because the polyacetylenes of *E. pallida* are quite susceptible to autoxidation, *E. angustifolia* may be better for commercial products.[25] Research showed that long-term storage greatly decreases the content of polyacetylenes to only trace levels at best. However, the polyacetylene derivatives of autoxidation of *E. pallida* are quite characteristic and useful in differentiating *E. pallida* from *E. angustifolia*.

MISCELLANEOUS

Undoubtedly, other constituents contribute to the pharmacology of echinacea. The occurrence of a "colorless alkaloid" was first reported by the great John Uri Lloyd in 1897 and substantiated recently by the isolation of the alkaloids tussilagine and isotussilagine.[26] Other compounds isolated from *Echinacea* spp. include the following[3]:

- Resins
- Glycoproteins
- Sterols
- Minerals
- Fatty acids

HISTORY AND FOLK USE

Echinacea was used extensively by the Native Americans living in areas where it grew. American Indians used echinacea against more illnesses than any other plant. The root was used externally for the healing of wounds, burns, abscesses, and insect bites; internally for infections, toothache, and joint pains; and as an antidote for rattlesnake bites.[27]

H.C.F. Meyer, a German lay healer, introduced a commercial product containing echinacea to Americans around 1870. He recommended "Meyer's blood purifier"[3] as a wonder cure for almost every conceivable malady, and there were numerous case reports of successful treatments for snakebites, typhus, diphtheria, and other infections.

E. angustifolia became a favorite with eclectic physicians because it was thought to be greater in activity than other species. Eclectics used it externally as a local antiseptic, stimulant, deodorant, and anesthetic and internally for "bad blood" (i.e., to correct "fluid deprivation with tendency to sepsis and malignancy").[28,29]

Although many physicians began to investigate and use echinacea as a serious medicine, in 1909 the Council on Pharmacy and Chemistry of the American Medical Association refused to recognize echinacea as an active drug, stating: "In view of the lack of any scientific scrutiny of the claims made for it, *Echinacea* is deemed unworthy of further consideration until more reliable evidence is presented in its favor." Despite this opposition, echinacea was included in the National Formulary of the United States and remained there until 1950.[3]

With the demise of the eclectic movement, the popularity of echinacea in the United States waned except among naturopathic physicians until around 1980, when it was rediscovered because of increased consumer interest in immune system disorders such as candidiasis, chronic fatigue syndrome, acquired immunodeficiency syndrome (AIDS), and cancer. Although interest in echinacea decreased in America between the 1930s and 1980s, European physicians continued research. Much

of this research was initiated by a 1932 study by Gerhard Madaus, who demonstrated immune-enhancing effects of a preparation from the fresh juice of the aerial portion of *E. purpurea.* This was followed by the development of a commercial product (Echinacin) and a great deal of scientific study. Thus *E. purpurea* began to be as respected as *E. angustifolia* among herbal practitioners in Europe.[3]

PHARMACOLOGY

The chemistry, pharmacology, and clinical applications of echinacea have been the subject of more than 300 scientific studies.[2,3,30] This section summarizes some of the pharmacologic information on *Echinacea,* with attention to the species used, part of the plant used, solvent used for extraction, and other relevant features. When no species delineation is made, the activity described is similar in all species.

Tissue Regeneration and Anti-inflammatory Properties

Echinacin (a commercial product consisting of the freshly pressed juice of *E. purpurea* stabilized in ethanol) and polysaccharide components of echinacea have been shown to promote tissue regeneration and reduce inflammation in experimental studies.[31] This effect is apparently largely because of inhibition of the enzyme hyaluronidase via formation of a polysaccharide complex with hyaluronic acid, thereby maintaining the structure and integrity of the collagen matrix in connective tissue and ground substance. In addition to increased hyaluronic acid stabilization, echinacea also stimulates fibroblast growth and the manufacture of glycosaminoglycans, a critical goal in wound healing. Echinacea exerts a mild, direct cortisone-like effect and enhances the secretion of adrenal cortex hormones.[3] The polysaccharide portion appears to be responsible for the direct anti-inflammatory effects, although the alkylamide fraction has also demonstrated some activity.[32]

Immunostimulatory Properties

Echinacea possesses a broad spectrum of effects on the immune system as a result of its content of a diverse range of active components affecting different aspects of immune function.[2,3] For example, inulin, the major component in the root of *E. angustifolia,* activates the alternative complement pathway and thus promotes chemotaxis of neutrophils, monocytes, and eosinophils; solubilization of immune complexes; neutralization of viruses; and bacteriolysis. Echinacea also increases the levels of properdin, the normal serum globulin that stimulates the alternative complement pathway.[2,3,33] Another nonspecific immune enhancement is echinacea's enhancement of serum leukocyte and granulocyte counts.[2,3,30–34]

The high-molecular-weight heteroglycan polysaccharide components of echinacea have profound immunostimulatory effects. The majority of these effects appear to be mediated by the binding of active echinacea polysaccharides to carbohydrate receptors on the cell surface of macrophages and T lymphocytes. However, some of the T-cell activation found in early studies is now thought to be a result of a contaminant protein. Later studies using a purer polysaccharide fraction did not show significant results.[3]

Echinacea promotes nonspecific T-cell activation (i.e., transformation, production of interferon, and secretion of lymphokines). The resultant effect is enhanced T-cell mitogenesis, macrophage phagocytosis, antibody binding, natural killer cell activity, and increased numbers of circulating neutrophils.[3,30]

Echinacea polysaccharides were also shown to enhance macrophage phagocytosis and to stimulate macrophages to produce increased amounts of tumor necrosis factor (TNF), interferon, and IL-1; destroy tumor cells in tissue culture; and inhibit *Candida albicans* infection in rats infected intravenously with a lethal dose (3×10^5 cells) of *C. albicans.*[3,34] The interactions with macrophages were most likely responsible for much of the immune system enhancement of echinacea polysaccharides.

In addition to the polysaccharides, lipophilic alkylamides and caffeic acid derivatives like cichoric acid are thought to contribute to the immunostimulatory aspects of echinacea, especially alcoholic extracts.[2,3,30] Although most research has been devoted to the water-soluble components such as polysaccharides, the lipophilic fraction yields the most potent enhancement of macrophage phagocytosis.[3,4]

The carbon clearance test is often used to measure systemic macrophage activation. The method involves measuring the rate of disappearance of carbon granules from the blood at varying intervals after administration of the test substance. Root extracts of echinacea administered orally tend to yield greater effects on phagocytic activity than the aerial portion, with *E. purpurea* greater than *E. angustifolia,* which is greater than *E. pallida.*[3]

Many studies used injectable preparations, but oral preparations are generally thought to yield similar or even better results, although direct comparisons are apparently not available. For example, intramuscular Echinacin administered to healthy males on 4 successive days was shown to increase granulocytic phagocytosis by nearly 50%, whereas the oral administration of an *E. purpurea* root extract at a dose of 30 drops three times a day to healthy males for 5 consecutive days resulted in an increase of 120%.[3] However, this difference might be because of the differing constituents of the forms used. The expressed juice of the aerial portion *E. purpurea,* as found in Echinacin, has lower concentrations of several of the phagocytosis-stimulating compounds characteristic to echinacea, including polysaccharides, alkylamides, and caffeic acid derivatives like cichoric acid, compared with the alcoholic extract.[3]

In general, echinacea appears to offer benefits for all infectious conditions. An exception to this statement may be AIDS. It is unclear at this time if echinacea should be recommended for AIDS. Although this condition is associated with widespread depression of the immune system, presumably because of the human immunodeficiency virus (HIC), stimulation of T-cell replication may also stimulate replication of the virus as well. In addition, echinacea was shown to lower T-helper cells and decrease the ratios of T-helper cells to suppressor cells.[2,3] Although there are anecdotal reports of echinacea's efficacy in HIV-infected individuals, more research is necessary.

Antiviral Properties

The juice of the aerial portion of *E. purpurea,* along with alcoholic and aqueous extracts of the roots, were shown to possess antiviral activity. Some of the viruses inhibited in cell cultures include influenza, herpes, and vesicular stomatitis viruses.[3,35] Although certain echinacea components (e.g., echinacoside, other caffeic acid derivatives, polysaccharides) might block virus receptors on the cell surface, the antiviral effects might also be a result of inhibition of hyaluronidases. The viral-inhibiting action of echinacea was significantly diminished when hyaluronidase was added to the cell cultures.[3] Many organisms secrete hyaluronidase, which increases connective tissue permeability and allows the organism to become more invasive.[36]

Clinically, the inhibition of hyaluronidase coupled with general immunostimulation of echinacea is probably more important than direct antiviral activity. The nonspecific antiviral action of echinacea enhances cytotoxic killing of virus-infected cells and the release of interferon. Interferons bind to cell surfaces, where they stimulate the synthesis of intracellular proteins that block the transcription of viral RNA.

Antibacterial Properties

The direct antibacterial activity of echinacea is quite mild. This is somewhat surprising because echinacea has a long history of effective use in both internal and external bacterial infections. Possibly, it possesses antiinfective properties that prevent bacterial adherence, although this has yet to be determined. Clearly, its clinical efficacy is because of its strong immune-potentiating actions.

Echinacea possesses mild antibacterial action due largely to echinacoside, the complex caffeic acid derivative, found in highest concentrations in the root of *E. angustifolia.* Echinacoside and caffeic acid were shown to have antibacterial action against *Staphylococcus aureus, Corynebacterium diphtheriae,* and *Proteus vulgaris.* Approximately 6.3 mg of echinacoside is equivalent to 10 Oxford units of penicillin.[3,20]

Antineoplastic Activity

Obviously, echinacea possesses indirect, antineoplastic activity via its general immuno-enhancing effects. Specifically important is its stimulation of macrophages to greater cytotoxic activity against tumor cells. (Z)-1,8-pentadecadiene, a lipid-soluble component found in the roots of *E. angustifolia* and *E. pallida,* was shown in vivo to possess significant direct antineoplastic activity.[37]

Endocannabinoid System

The alkamides of echinacea have been reported to have cannabinomimetic properties on both cannabinoid CB1 and CB2 receptors.[2] This effect is related to the structural similarity to the endogenous cannabinoid receptor ligand anandamide. In addition, these alkamides also inhibit the breakdown of anandamide. The clinical application of these effects on the ECS is in the treatment of anxiety and atopic dermatitis (both discussed later in the chapter).

CLINICAL APPLICATIONS

At present, although the results from clinical research are mixed, given the long history, safety, and confirmed immune-enhancing effects in experimental models, and the numerous clinical studies that showed positive results, the clinical applications of echinacea include the following:

- Treatment of the common cold and other viral respiratory tract infections
- Possible prevention of the common cold and viral respiratory tract infections
- Treatment of temporary immune deficiency and increased susceptibility to infections
  - Children attending daycare
  - Adults experiencing undue stress
  - Sport-induced immunodeficiency
- Supportive therapy to enhance the effectiveness of antibiotics in bacterial infections
- Chemotherapy and radiation-induced immune suppression
- Herpes simplex infections
- Anxiety
- Atopic dermatitis

Upper Respiratory Tract Infections

Mixed results from clinical studies with echinacea were most likely because of lack of or insufficient quantity of active compounds. The axiom for the effectiveness of any herbal product is its ability to deliver an effective dose of active compounds. If the product, by chance, had sufficient levels of active compounds, it would be effective. If not, it would likely be no more effective than a placebo. For example, in one double-blind study, 160 subjects were given either echinacea or placebo and then exposed to a common cold virus. Infection occurred in 44 (57%) and illness occurred in 36 (43%) of the echinacea- and placebo-treated subjects, respectively. However, the preparation contained no echinacosides or alkamides and contained only 0.16% cichoric acid.[38] In contrast, in a clinical trial using a well-defined echinacea extract containing alkamides, cichoric acid, and polysaccharides at concentrations of 0.25, 2.5, and 25 mg/mL, respectively, prepared from freshly harvested *E. purpurea* plants (commercially available as Echinilin or Echinamide), showed excellent results.[39] In this randomized, double-blind, placebo-controlled trial, 282 subjects, 18 to 65 years old, with a history of two or more colds in the previous year but otherwise in good health, were randomized to receive either echinacea extract or placebo. They were instructed to start the echinacea or placebo at the onset of the first symptom related to a cold, consuming 10 doses the first day and 4 doses per day on subsequent days for 7 days. The severity of symptoms (10-point scale: 0, minimum; 9, maximum) and dosing were recorded daily. A nurse examined the subjects on the mornings of days 3 and 8 of their cold. A total of 128 subjects contracted a common cold (59 echinacea, 69 placebo).

The total daily symptom scores were found to be 23.1% lower in the echinacea group than in the placebo group. Throughout the treatment, the response rate to treatments was greater in the echinacea group. This study indicated that early intervention with a standardized formulation of echinacea resulted in reduced symptom severity in subjects with naturally acquired upper respiratory tract infection.

Again, to highlight the issue of quality control and source of preparation, several studies with less well-defined echinacea products showed little benefit, especially in experimentally induced rhinovirus infections. In another double-blind study, 302 volunteers from four military institutions and one industrial plant in Germany were given either a placebo or alcohol-based tinctures from either *E. purpurea* or *E. angustifolia* dried root for 12 weeks.[40] The main outcome measure was time until the first upper respiratory tract infection. The secondary outcome measures were the number of participants with at least one infection, global assessment, and adverse effects. The time until occurrence of the first upper respiratory tract infection was 66 days in the *E. angustifolia* group, 69 days in the *E. purpurea* group, and 65 days in the placebo group. In the placebo group, 36.7% had an infection, whereas in the *E. angustifolia* group, it was 32%, and in the *E. purpurea* group, it was 29.3%. These results indicated that there was no significant benefit with either form of echinacea, although there was an approximately 20% reduced risk of infection in the echinacea groups. In addition, 70% of the *E. purpurea* and 78% of the *E. angustifolia* group felt they had benefited from treatment compared with 56% in the placebo group. The *E. angustifolia* group had a slightly higher percentage of subjects experiencing side effects (18%) compared with the *E. purpurea* (10%) and placebo (11%) groups.

In one of the most detailed clinical trials, 719 patients were assigned to 1 of 4 parallel groups: no pills, placebo pills (blinded), echinacea pills (blinded), or echinacea pills (unblinded, open-label). Echinacea groups received 8 tablets on the first day and 4 tablets per day on the subsequent 4 days, each containing the equivalent of 675 mg of alcoholic extract of *E. purpurea* root (of dried roots) and 600 mg of alcoholic extract *E. angustifolia* root; the placebo group received the same number of tablets. The primary end point was defined as the "area under the curve" for global severity with duration and severity. Severity was assessed by the Wisconsin Upper Respiratory Symptom Survey-21 questionnaire and the duration by the participants' impression of having a cold. The results showed only a statistically insignificant trend in reduction of the cold duration by half a day and a reduction of severity of approximately 10%.[41]

The result from this trial indicated that a major issue with some of the echinacea research might be the echinacea preparations used (i.e., weak ethanol-based tinctures derived from dried root). Clinical studies in upper respiratory tract infections done on extracts of fresh *E. purpurea* whole plant or aerial plant, especially in liquid form, are consistently positive compared with those using dried echinacea species extracts (or powdered herbs), especially in solid forms (tablets or capsules). It is possible that echinacea may exert direct local effects and that its contact with the oropharyngeal lymphatic tissue is extremely important in acute upper respiratory tract infection conditions. Reasonably large and well-designed, double-blind, placebo-controlled studies found that preparations of echinacea from the aerial portion of the plant produced modest effects in aborting, and reducing, the symptoms and duration of colds.[30,40,42]

In addition to the previously described study with a well-defined echinacea preparation from the aerial portion of *E. purpurea,* another study showed good results when 108 patients with the initial symptoms suggesting a cold received either EchinaGuard—an extract of the fresh-pressed juice of *E. purpurea*—at a dosage of 4 mL twice daily or placebo for 8 weeks.[43] The percentages of patients who remained healthy were 35.2% of the echinacea group and 25.9% of the placebo group. The length of time between infections was 40 days for the echinacea group and 25 days for the placebo group. When infections did occur in patients receiving echinacea, they were less severe and resolved more quickly. Patients showing evidence of a weakened immune system (CD4/CD8 ratio <1.5) benefited the most from echinacea.

The results from another trial were especially encouraging because it also suggested that echinacea could not only make colds shorter and less severe, but it could also sometimes stop a cold that was just starting.[44] In this study, 120 people were given a preparation from the fresh-pressed juice of *E. purpurea* or a placebo as soon as they started showing signs of getting a cold. Participants took either echinacea or placebo at a dosage of 20 drops every 2 hours for 1 day, then 20 drops 3 times a day for 9 more days. Fewer people in the echinacea group felt that their initial symptoms actually developed into "real" colds (40% of those taking echinacea vs. 60% taking the placebo actually became ill). Also, among those who did come down with "real" colds, improvement in the symptoms started sooner in the echinacea group (4 days instead of 8 days). Both results were statistically significant. However, echinacea's ability to shorten the duration of colds was more dramatic.

Not all studies of the fresh-pressed juice of *E. purpurea* or EchinaGuard showed positive effects in reducing the duration or severity, or both, of upper respiratory infections. For example, a study in children 2 to 11 years old was particularly disappointing because the results indicated that it was not only ineffective, but its use was also associated with an increased risk of rash.[45]

In another double-blind trial, 128 patients received 100 mg of the freeze-dried pressed juice from the aerial portion of *E. purpurea* or a placebo three times daily until cold symptoms were relieved or until the end of 14 days, whichever came first.[46] Symptoms (sneezing, nasal discharge, nasal congestion, headache, sore or scratchy throat, hoarseness, muscle aches, and cough) were scored subjectively by the patient and recorded daily in a diary. No statistically significant difference was observed between treatment groups for either total symptom scores or mean individual symptom scores. The time to resolution of symptoms was also not statistically different. The failure in this trial might have been a result of the previously mentioned lack of direct contact with the oropharyngeal lymphatic system.

Clearly, more research using well-characterized echinacea preparations at appropriate dosages is necessary in well-designed trials. Currently, the "gold standard" for evaluating cold remedies involves inoculating healthy individuals with rhinovirus. Although the concentration of viral assault is much greater than what one might encounter in the real world, any substance showing efficacy in this model is regarded as being highly efficacious. In one study, 48 healthy adults received the fresh-pressed juice of *E. purpurea* (EchinaGuard) or placebo, 2.5 mL 3 times per day, for 7 days before and 7 days after intranasal inoculation with rhinovirus (RV-39).[47] A total of 92% of echinacea recipients and 95% of placebo recipients were infected. However, colds developed in 58% of echinacea recipients compared with 82% of placebo recipients. Although administration of echinacea before and after exposure to rhinovirus did not decrease the rate of infection, it did appear to reduce the clinical development of a cold. However, because of the small sample size, statistical hypothesis testing had relatively poor power to detect statistically significant differences in the frequency and severity of illness. As mentioned previously, the only other experimental rhinovirus infection and echinacea study was seriously marred because the preparation used contained no active components.[38]

Candidiasis

Echinacea's effect against *C. albicans* noted in animal studies was confirmed in several human clinical studies.[3] A study featured in Table 75.2 demonstrated that Echinacin greatly accentuated the efficacy of a topical antimycotic agent (econazole nitrate), decreasing reoccurrence from 60.5% to 5% to 16.7%. The researchers used standardized skin tests to show that this enhancement was a result of echinacea's boosting of cell-mediated immunity.[48] Also of interest was the similarity in the efficacies of both the oral and injectable forms.

Wound Healing

Several uncontrolled clinical studies substantiated echinacea's wound-healing activities.[3,37,49,50] The largest (4598 patients) demonstrated that a salve of the juice of the aerial portion of *E. purpurea* had an 85% overall success rate in the treatment of inflammatory skin conditions, such as abscesses, folliculitis, wounds of all kinds, eczema, burns, herpes, and varicose ulcers of the leg.[3]

Arthritis

Echinacea's anti-inflammatory activity was shown in uncontrolled studies to be useful in rheumatoid arthritis. In one study, 15 drops of Echinacin three times daily resulted in a 21.8% decrease in inflammation. Although this improvement was less than cortisone (42%) and prednisone (49.2%), no side effects were associated with Echinacin, whereas both of these drugs have well-known side effects.[51]

TABLE 75.2 Treatment of Recurrent Candidiasis with Echinacin—Rate of Reoccurrence at 6 Months

Therapeutic Scheme	No. Of Patients	Recurrence Rate (%)
Topical antimycotic alone	43	60.5
Topical antimycotic + subcutaneous Echinacin	20	15
Topical antimycotic + intramuscular Echinacin	60	5
Topical antimycotic intravenous Echinacin	20	15
Topical antimycotic oral Echinacin	60	16.7

Modified from Coeugniet EG, Kuhnast R. Recurrent candidiasis: adjuvant immunotherapy with different formulations of echinacin. *Therapiewoche*. 1986;36:3352–3358.

Cancer

Several studies noted a stimulatory effect of echinacea on leukocyte counts in patients receiving radiation for cancer therapy.[49,52] A study using the commercial preparation Esberitox demonstrated that 85% of 55 patients showed a stabilization of leukocyte counts compared with the control group, which showed a steady decline in levels (starting at 6000 and decreasing to 2500 after 45 days).[49] This strongly supports the recommendation of echinacea to patients undergoing orthodox cancer treatments. In an open prospective study with matched historical controls, an injection of polysaccharide fraction isolated from the herb *E. purpurea* was shown to counteract the undesired effects of chemotherapy.[53] Fifteen patients with advanced gastric cancer, who underwent palliative chemotherapy with etoposide, leucovorin, and 5-fluorouracil, received daily intravenous injections of 2 mg of a polysaccharide fraction isolated from *E. purpurea* herb cell cultures for 10 days (beginning 3 days before chemotherapy). The median number of leukocytes 14 to 16 days after chemotherapy was 3630/mL in the patients who received echinacea polysaccharide compared with 2370/mL (870–3950) in the patients of the historical control group. These results suggest that echinacea might be effective in reducing chemotherapy-induced leukopenia.

Anxiety

The anxiolytic effects of echinacea alkamides were demonstrated in animal studies. In rats, an alkamide-rich preparation of *E. angustifolia* root decreased anxiety in the elevated plus-maze and ameliorated contextual conditioned fear models with no toxicity or adverse effects on behavior noted even when rats treated at dosages of 1000 and 3000 mg/kg. The extract was without effect in tests of locomotion (open-field), memory (object recognition), and rewarding potential (conditioned place preference) within a wide dose range. In human studies, 20 or 40 mg of the same *E. angustifolia* extract were administered for 1 week to volunteers scoring high on the State-Trait Anxiety Inventory (STAI). The dosage of 40 mg per day decreased STAI scores within 3 days in human subjects, an effect that remained stable for the duration of the treatment (7 days) and for the 2 weeks that followed treatment. The lower dose, 20 mg per day, did not affect anxiety significantly.[54]

Atopic Dermatitis

In the skin, the main physiological function of the ECS is to control the proliferation, differentiation, survival, and immune competence and/or tolerance of skin cells. Loss of ECS exacerbates allergic skin reactions, whereas enhanced ECS function leads to alleviation of these same symptoms. To prove the benefit of a topically applied alkamide-rich *E. purpurea* extract, an in vitro study was conducted on keratinocytes followed by an assessment of cutaneous tolerability, clinical efficacy, and the effects on stratum corneum structure and lipid in subjects suffering from atopic dermatitis.[55]

The study demonstrated a significant anti-inflammatory activity of the alkamide-rich extract, a low allergenic potential in the study of volunteers similar to placebo skin creams, no phototoxicity, and an ability to reduce the main dermatological symptoms associated with atopic dermatitis (erythema, edema/papules, weeping/crusts, excoriation, lichenification, dryness, pruritus) in a 3-month double-blind study involving 60 subjects with subacute or chronic atopic dermatitis. The improvements were sustained for up to 85 days.

An explanation of the long-standing improvements was offered in the clinical assessment of skin barrier function, levels of overall lipids, ceramide, and cholesterol. These were all significantly increased from baseline at day 15 following a twice-daily application of the alkamide-rich cream.

Snakebites

Echinacea has quite a reputation among naturopathic physicians and Native American healers for the treatment of snakebites. No controlled clinical studies of this use have been reported, but echinacea's inhibition of hyaluronidase might account for much of its reputed efficacy because most snake venoms permeate the system as a result of hyaluronidase in the venom breaking down the connective tissue of the ground substance.

COMMERCIAL PREPARATIONS

As evident from the previous discussion, determining which echinacea preparation is best is difficult. It is not only difficult to determine which species is most effective, but also the portion of the plant used and how it is prepared are serious issues. Dosage recommendations for all currently available forms follow, along with a few observations regarding the "preparations controversy."

Another problem that needs to be addressed is quality control. Since as early as 1904, many commercial sources of echinacea have contained adulterants and no echinacea. For example, it was estimated that because of supplier errors in collection, more than 50% (and possibly as high as 90% at times) of the echinacea sold in the United States from 1908 to 1991 was actually *Parthenium integrifolium,* or Missouri snakeroot.[54] Some suggested that this adulteration was because of confusion of the common names. Others pointed out that although the *P. integrifolium* plant looks quite different, "once the root is cut and sifted it has an uncanny resemblance to *E. angustifolia* or *E. pallida* roots, though it possesses its own characteristic flavor and fragrance."[56] From practical and clinical viewpoints, physicians should require adequate documentation from suppliers that they are, in fact, supplying echinacea and its species.

Species

Although studies have shown various echinacea species, or components found in higher concentrations in one species, to be more effective than others, each commercial species has its advantages and disadvantages. No "best" species can be recommended at this time because differing experimental models have yielded inconsistent results. Rather, the clinician must recognize the unique value of each species. Although *E. angustifolia* has long been considered the best species and to possess the greatest activity, some studies dispute this. For example, several studies showed *E. purpurea* to demonstrate greater enhancement of phagocytosis. In one study, an aqueous extract of *E. angustifolia* did not demonstrate any effect on phagocytic function in rats, whether it was administered orally, intraperitoneally, or intravenously.[57] Because *E. purpurea* is the easiest to grow commercially, it may become the most used in the United States, as it is in Europe.

Part of the Plant to Use

The portion of the plant that possesses the greatest immune-enhancing properties depends on the experimental model. The key points, as described earlier, are that various echinacea components exert immune-enhancing effects, and there is clearly a synergistic effect among these constituents.

Preparations

Echinacea products are available in many different forms:

- Crude plant in either ground or powdered form
- Freeze-dried
- Alcohol-based tinctures and liquid extracts
- Aqueous tinctures and liquid extracts
- Dry, powdered alcoholic or aqueous

It is popular to standardize hydro-/alcoholic extracts for echinacoside (for *E. angustifolia*) or cichoric acid (for *E. purpurea*). Although these extracts are thought by their proponents to be the most potent, it must be noted that other components have shown greater effects in some experimental models, and even 4 to 10× homeopathic preparations have been shown to produce activity.[32]

Solvents

Which solvent is best to use? Again, this question is extremely difficult to answer because both hydrophilic and lipophilic components have been shown to possess immune-enhancing activities. Even a small amount of ethanol results in the precipitation or breakdown of the immuno-active polysaccharides, suggesting that aqueous extracts may be best. However, an aqueous extract would leave behind valuable lipophilic immune-enhancing alkylamides and caffeic acid derivatives. To optimize an extract's immune-enhancing effects, many manufacturers use low-ethanol (10%–20%) hydro-/alcoholic mixtures or combine a low-ethanol extract with a high-ethanol extract. Both products typically contain both polar and lipophilic compounds.

Dosage

Box 75.1 lists dosages of echinacea as a general immune stimulant during infection. The question of whether echinacea should be used on a long-term or continual basis really depends on the need. In a healthy individual with no apparent depression of the immune system, continual administration is certainly not indicated. However, it appears that individuals with impaired immune function do benefit from long-term use. The usual recommendation with long-term use is 8 weeks on, followed by 1 week off, but there is no real basis for the week off.

Toxicology

When used at the recommended doses, there is no danger of toxicity because no studies have reported acute or chronic toxicity reactions caused by echinacea extracts. Echinacin, given intravenously, resulted in fever (0.5°C–1°C elevation in body temperature) on occasion. This was presumably a result of secretion of interferon-α and IL-1 by activated macrophages.[3]

The median lethal dose (LD_{50}) of intravenous Echinacin was determined to be 50 mL/kg body weight in mice and rats. The polysaccharides in *E. purpurea* (aerial portion) were shown to have an LD_{50} of 1000 to 2500 mg/kg when given peritoneally to mice. Long-term administration of Echinacin to rats at doses many times the human therapeutic doses gave no evidence of any toxic effects. Mutagenic tests have demonstrated no mutagenic activity.[2,3]

BOX 75.1 Dosages (Three Times/Day) as a General Immune Stimulant During Infection

Dried root (or as tea): 0.5 to 1 g
Freeze-dried plant: 325 to 650 mg
Juice of aerial portion of *Echinacea purpurea* stabilized in 22% ethanol: 2 to 3 mL (0.5–0.75 tsp)
Tincture (1:5): 2 to 4 mL (1–2 tsp)
Fluid extract (1:1): 1 to 2 mL (½-1 tsp)
Solid (dry-powdered) extract (6.5:1 or 3.5% echinacoside): 150 to 300 mg

Modern reviews of the safety and efficacy of *Echinacea* spp. found no toxicity in both adults and children in cases of both acute and long-term administration.[2,30,58–60] Given the number of echinacea doses consumed yearly (>10 million) and the number of adverse events (<100), echinacea appears extremely safe. Reported side effects are also uncommon and usually limited to minor gastrointestinal symptoms, increased urination, and mild allergic reactions. However, severe allergic reactions have occurred occasionally, some of them life threatening. Allergic reactions were often reported in people who were also allergic to other members of plants in the daisy *(Compositae)* family (e.g., daisy, ragweed, marigolds).

The German Commission E warns against using echinacea in cases of autoimmune disorders, such as multiple sclerosis, lupus, and rheumatoid arthritis. These warnings are theoretical because there is no evidence that echinacea use has actually harmed anyone with these diseases.

Echinacea appears to be safe even for pregnant or lactating women based on both animal studies and evaluation studies in women using echinacea during pregnancy showing no harmful effects.[61]

Drug Interactions

Echinacea preparations appear to have a low potential for drug interactions.[62] Currently, there are no verifiable reports of drug–herb interactions with any echinacea product. Theoretically, echinacea may interfere with drugs that are purposely used to suppress the immune system. These include cyclosporin, which is used in patients who have had organ transplants to prevent the immune system from rejecting the transplanted organ.

Eleutherococcus senticosus (Siberian Ginseng)

Michael T. Murray, ND

OUTLINE

Eleutherococcus or *Acanthopanax senticosus* (family: *Araliaceae*)
Common names: Siberian ginseng, touch-me-not, devil's shrub, eleuthero ginseng

GENERAL DESCRIPTION

Eleutherococcus senticosus (Siberian ginseng) is a shrub that grows 5 to 8.5 ft high. Its erect, spiny shoots, 1.5 to 2.5 inches in diameter, are covered with a light gray or brownish bark. The leaves are long petioled in a compound, palmate configuration. The five leaflets are elliptic and finely serrated at the margins on both sides, with scattered, minute spinules along the veins.[1]

Eleuthero grows abundantly in parts of Russia, the Far East, Korea, China, and Japan, north of latitude 38. Its distribution is much greater than that of *Panax ginseng* (see Chapter 110).[1]

The root is the most widely used component, with the highest concentration of biologically active substances occurring in the fall, just before defoliation. The leaves are also used medicinally, with their highest concentration of biologically active substances occurring in July, just before flowering.

CHEMICAL COMPOSITION

The initial phytochemical report on eleuthero was published in 1965 by members of the Institute of Biologically Active Substances in Vladivostok, Russia.[1] Seven compounds, termed eleutherosides A through G, were isolated from a physiologically active fraction of the methanol extract of eleuthero. The total eleutheroside content of the root ranges from 0.6% to 0.9%, and the content of the stems ranges from 0.6% to 1.5%. The ratio of the eleutherosides A through G obtained is approximately 8:30:10:12:4:2:1, respectively. Fig. 76.1 illustrates the structure of a key type of constituent. Table 76.1, modified from reviews of eleuthero, summarizes what is currently known about the components of *E. senticosus*.[1,2]

It is important to recognize that the ginsenosides characteristic of *Panax* sp. (American, Chinese, Korean, Japanese ginsengs) are not present in the roots of *E. senticosus*.

HISTORY AND FOLK USE

Ginseng plants, members of the family *Araliaceae*, including *E. senticosus*, are among the most ancient and esteemed of all medicinal herbs. Their use in Chinese herbal medicine dates back more than 4000 years.[1] References in ancient documents to members of the *Araliaceae* family are imprecise, giving rise to some confusion in modern interpretation. Nonetheless, in China, it has been long believed that the regular use of eleuthero increases longevity, improves general health and appetite, and restores memory.

The Russians have a separate history of eleuthero beginning in 1855 when a pair of Russian scientists, C. I. Maximovich and L. I. Shrenk, traveled from St. Petersburg to the Ussuri region of Russia on the Amur River. It was in this area that Maximovich observed a vast thicket of unusual plants, with leaves resembling horse chestnut and young shoots resembling ginseng. Unable to identify the plant, the two scientists brought back samples to St. Petersburg for classification. The plant was given the genus name of *Eleuthero,* or "free-berried shrub," and the species name of *senticosus,* which means "thorny" in Latin.

Not until the middle of the 20th century was eleuthero again "discovered," when Russian scientists began investigating substances that produce a "state of nonspecific resistance" in the body. Substances with this effect were termed *adaptogens.* In 1958 Brekhman described an adaptogen as follows[1,3]:

- It must be innocuous and cause minimal disorders in the physiological functions of an organism.
- It must have a nonspecific action (i.e., it should increase the resistance to adverse influences by a wide range of physical, chemical, and biochemical factors).
- It usually has a normalizing action regardless of the direction of the pathological state (alterative action).

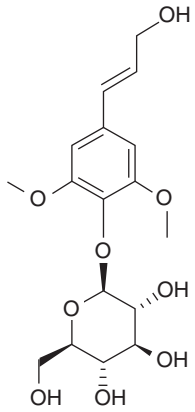

Fig. 76.1 Eleutheroside B.

TABLE 76.1 Compounds Found in *Eleutherococcus senticosus*

Compound	Type	Location
Eleutheroside A (daucosterol)	Sterol	Roots, stems
Eleutheroside B (syringin)	Phenylpropanoid	Roots, stems
Eleutheroside B_1 (isofraxidin-7–0-α-l-glucoside; also known as β-calycanthoside)	Coumarin	Roots
Eleutheroside B_2	Unknown	Roots
Eleutheroside B_3	Unknown	Roots
Eleutheroside B_4 [(–)-sesamin]	Lignan	Roots
Eleutheroside C (methyl-α-d-galactoside)	Sugar	Roots, stems
Eleutheroside D [(–)-Syringaresinol di-0-β-d-glucoside]	Lignan	Roots, stems
Eleutheroside E (different crystalline form of D; also known as acanthoside D)	Lignan	Roots, stems
Eleutheroside F	Unknown	Roots
Eleutheroside G	Unknown	Roots
Eleutheroside I (= mussenin B)	Triterpene	Leaves
Eleutheroside K	Triterpene	Leaves
Eleutheroside L	Triterpene	Leaves
Eleutheroside M (= hedera saponin B)	Triterpene	Leaves
Senticosides A–D (may be identical to eleutherosides I, K, L, and M)	Triterpene	Leaves
Vitamin E	Benzofuran	Roots
Beta-carotene	Carotenoid	Roots
Isofraxidin	Coumarin	Roots
Coumarin X	Coumarin	Roots
Complex mixture	Essential oil	Roots
Copper	Mineral	Roots
(–)-Syringaresinol	Lignan	Roots
Caffeic acid	Phenylpropanoid	Roots
Caffeic acid ethyl ester	Phenylpropanoid	Roots
Coniferyl aldehyde	Phenylpropanoid	Roots
Sinapyl alcohol	Phenylpropanoid	Roots
Beta-sitosterol	Sterol	Roots
Polysaccharides	Sugar	Roots, fruit
Galactose	Sugar	Roots
Glucose (α and β)	Sugar	Roots
Maltose (α and β)	Sugar	Roots
Sucrose	Sugar	Roots
Oleanolic acid	Triterpene	Roots

Modified from Davydov M, Krikorian AD. *Eleutherococcus senticosus* (Rupr. & Maxim.) Maxim. *(Araliaceae)* as an adaptogen: a closer look. *J Ethnopharmacol.* 2000;72:345–393.

Brekhman's research with adaptogens began with *P. ginseng* because this was the best-known natural adaptogen. After confirming the adaptogenic action of panax in human studies, Brekhman began searching for an alternative to this plant because of the difficulty and expense in obtaining panax. Initially, all six species of *Araliaceae* native to Russia were investigated, and eleuthero was found to be the most promising. Numerous studies (in vivo, in vitro, and human studies) have been conducted since the late 1950s, nearly all in the Soviet Union. They are not referenced here because they are not translated and not widely available. Instead, review articles and original articles in English are cited.[1–7]

PHARMACOLOGY

As mentioned earlier, several experimental and clinical studies demonstrated that eleuthero possesses adaptogenic properties (i.e., the ability to increase nonspecific body resistance to stress, fatigue, and disease). Additional experimental and clinical research supports additional therapeutic applications of *E. senticosus.*

Adaptogenic Activity

In experimental models, *E. senticosus* was found to do the following:

- Impede adrenal hypertrophy induced by adrenocorticotropic hormone and adrenal atrophy induced by cortisone
- Impede thyroid hypertrophy induced by thyroidin and thyroid gland atrophy induced by 6-methylthiouracil
- Reduce blood glucose levels in alimentary and adrenal hyperglycemia and increase glucose levels in insulin-induced hypoglycemia
- Reduce leukocytosis induced by the parenteral administration of milk and leukopenia induced by endotoxins
- Reduce erythrocytosis induced by cobaltous nitrate and erythropenia induced by phenylhydrazine

Adaptogenic activities are summarized in Table 76.2. Similar results were obtained with *P. ginseng* (see Chapter 110). In addition to adaptogenic activities, eleuthero, like panax, has been shown to do the following[1]:

- Increase resistance to infection in animals
- Reduce hepatic cholesterol biosynthesis
- Increase reproductive capacity and sperm counts in bulls
- Possess significant antioxidant activity
- Stimulate DNA synthesis and cellular repair enzymes

Stress Control

Another important action of adaptogens is the inhibition of the alarm phase of the stress reaction. Eleuthero was shown to increase the swimming time of rats, reduce activation of the adrenal cortex in response to stress (alarm-phase reaction), and prevent stress-induced thymic and lymphatic involution.[1–6]

Radiation Protection

Eleuthero has demonstrated both protective and therapeutic actions in animals exposed to both single and prolonged radiation. In one study, both *E. senticosus* and *P. ginseng* were found to double the life span of rats exposed to prolonged radiation (total doses of 1620–7000 rads).[7] When eleuthero was combined with antibiotics, the lifetime of irradiated rats (total dose of 3000 rads over 60 days) increased threefold. Eleuthero may therefore be of benefit in protecting against harmful radiation and as an adjunctive aid in radiation therapy in oncology.

Antiedema Effects

Proper lymphatic function is necessary for the transport of fluids, macromolecules, antigens, and immune cells out of the interstitium. Alterations in lymphatic function have long been associated

TABLE 76.2 Abnormalities Normalized by *Eleutherococcus senticosus*

Function	Normalization Action of *Eleutherococcus Senticosus*
Adrenal	Impedes hypertrophy induced by ACTH
	Impedes atrophy induced by cortisone
Thyroid	Impedes hypertrophy induced by thyroidin
	Impedes atrophy induced by 6-methylthiouracil
Kidney	Increases renal capacity in pyelonephritis
Blood pressure	Decreases high blood pressure through pressure improvement of atherosclerosis
	Increases pressure in hypotension
Blood glucose	Reduces alimentary and adrenal hyperglycemia glucose
	Increases blood sugar in insulin-induced hypoglycemia
Leukocyte	Reduces leukocytosis induced by the administration of milk
	Reduces leukopenia induced by endotoxins
Erythrocyte	Reduces erythrocytosis induced by cobaltous nitrate
	Reduces erythropenia induced by phenylhydrazine
Stress	Reduces activation of the adrenal cortex in response to stress
	Prevents stress-induced thymic and lymphatic involution
Radiation	Protects against radiation exposure
Cancer	Inhibits carcinogenesis from urethane, 6-methylthiouracil indole
Cholesterol	Reduces hepatic biosynthesis
DNA	Stimulates synthesis

ACTH, Adrenocorticotropic hormone.

with edema and inflammation, and certain inflammatory signals induce large increases in permeability by disrupting the integrity of the lymphatic endothelial barrier. Tie2 is an endothelial-specific receptor that, when activated, stabilizes lymphatic vessels. In vitro, E. *senticosus* and its component eleutheroside E induce phosphorylation of Tie2.[8] In addition, Siberian ginseng was found to stabilize lymphatic endothelial cells (LECs) by promoting the intercellular localization of vascular endothelial cadherin (an endothelial-specific cell–cell adhesion molecule) and induce the phosphorylation of endothelial nitric oxide synthase by LECs, effects mediated by the activation of Tie2. Researchers in this same study also investigated whether eleuthero powder improves edema in a two-way, randomized, crossover study in 50 healthy female volunteers. Compared with the control group, edema of the lower limbs was significantly attenuated at 2 and 4 hours after ingestion of Siberian ginseng powder.

Carcinogenesis Inhibition

Eleuthero preparations were shown to inhibit several cancer types in experimental studies in animals.[1,3] Some of the anticancer effects of eleuthero may be because of its immune-stimulating effects. In vitro, Siberian ginseng increased phagocytosis of *Candida albicans* by granulocytes and monocytes from healthy donors by 30% to 45%.[9,10] In vitro studies showed that whole ethanolic fluid extract of *E. senticosus* could induce and enhance the production of interleukin-1 and interleukin-6 but not interleukin-2.[11] A methanolic extract of Siberian ginseng conferred growth inhibitory effects against a number of lung and colon cancer cell lines in vitro, with increasing concentration displaying a nonlinear inhibition in cancer cell differentiation from 12.5 to 200 μg/mL.[12]

CLINICAL APPLICATIONS

Adaptogenic Activity in Healthy Individuals

A fluid extract (33% ethanol) of *E. senticosus* root was administered to more than 2200 human subjects in clinical trials conducted in Russia designed to evaluate the adaptogenic effects of eleuthero. The male and female subjects ranged in age from 19 to 72 years. Dosages of the fluid extract (33% ethanol) ranged from 2 to 16 mL, one to three times a day, for periods of up to 60 consecutive days. The data indicated that eleuthero had the following effects:

- Increased the ability of humans to withstand many adverse physical conditions (e.g., heat, noise, motion, workload increase, exercise, decompression)
- Increased mental alertness and work output
- Improved the quality of work under stressful conditions and improved athletic performance

A double-blind, randomized, placebo-controlled, crossover study was designed to examine the effects of *E. senticosus* supplementation (800 mg/d) on the endurance capacity, cardiovascular functions, and metabolism of recreationally trained males for 8 weeks.[13] Although the cohort was small (9 subjects), there was a significant improvement in VO_2 peak (12% elevation) and endurance time (23% improvement) and a 4% increase in the highest heart rate. It was concluded that 8 weeks of eleuthero supplementation enhances endurance capacity, elevates cardiovascular functions, and alters the metabolism for sparing glycogen. Although several studies reported no effect of *E. senticosus* supplementation on endurance performance, it seems that the ergogenic effects are dependent on the duration of supplementation and not just the dose.

Adaptogenic Activity in Disease States

A fluid extract (33% ethanol) of *E. senticosus* root was administered to more than 2200 human subjects with various illnesses, including angina, hypertension, hypotension, acute pyelonephritis, various types of neuroses, acute craniocerebral trauma, rheumatic heart disease, chronic bronchitis, and cancer.[1] Eleuthero appeared to be effective in atherosclerotic conditions, as evidenced by its ability to lower elevated serum cholesterol and prothrombin levels, reduce blood pressure, and eliminate anginal symptoms in human subjects. Its action on blood pressure was found to be truly adaptogenic because eleuthero was also shown to increase blood pressure in subjects with hypotension.

Its effect in regulating blood pressure might be indicative of improved renal function. Patients with acute pyelonephritis given eleuthero extract had increased renal capacity, as measured by an increased secretion of phenol red.[1]

Eleuthero appears to have some psychotropic action because it was proven effective in the treatment of various psychological disturbances. Eleuthero consistently demonstrated an ability to increase one's sense of well-being, regardless of the psychological complaint (e.g., insomnia, hypochondriasis, various neuroses). This may be the result of improved balance of the biogenic amines, including serotonin, dopamine, norepinephrine, and epinephrine, because eleuthero extract administered to rats was shown to increase biogenic amine content in the brain, adrenals, and urine.[1]

Extracts of *E. senticosus* have been reported to reduce urinary excretion of calcium and hydroxyproline in glucocorticoid-induced osteoporotic rats.[14] An additional study investigated the prevention of bone loss by a standardized extract of dried *E. senticosus* stem bark (DES) in an ovariectomized (OVX) rat model of osteoporosis.[15] Eight weeks of treatment with DES significantly decreased the bone mineral density loss in the femur and inhibited bone markers such as serum alpha-fetoprotein (ALP), osteocalcin, and telopeptides of collagen type I levels

compared with the OVX control group without the influence of hormones such as estrogen. Oral administration of DES did not affect body weight gain, uterotrophic activity, or serum estradiol concentrations.

Data are insufficient to fully evaluate eleuthero's action in other disease states. However, it must be kept in mind that an adaptogen is nonspecific in its action and possesses a normalizing action regardless of the direction of the changes from physiological norms.

DOSAGE

The standard dosage of the fluid extract (33% ethanol) of *E. senticosus* roots used in most studies ranged from 2 to 4 mL (up to 16 mL), one to three times a day, for periods of up to 60 consecutive days. In multiple-dosing regimens, there is usually a 2- to 3-week interval between courses.[1,4]

Dosages include the following:

- Dried root: 2 to 4 g
- Tincture (1:5): 10 to 20 mL
- Fluid extract (1:1): 2 to 4 mL
- Solid (dry-powdered) extract (20:1): 100 to 200 mg

TOXICOLOGY

Toxicity studies in animals demonstrated that eleuthero extracts are virtually nontoxic. The median lethal dose of the 33% ethanol extract of eleuthero is 14.5 mL/kg in mice and greater than 20 mL/kg in rats. No long-term toxicity was observed when a daily dose of 5 mL/kg of the fluid extract was administered to rats. Teratogenicity was studied in three species (rats, rabbits, and minks), with no adverse effects observed.[1]

In human clinical studies, it was demonstrated that eleuthero extracts (33% ethanol) in the recommended dosage range were well tolerated, and side effects were infrequent. A few studies found mild side effects at higher dosages (4.5–6 mL three times daily) when used for long periods of time (≥60 days). Symptoms included insomnia, irritability, melancholy, and anxiety. Pericardial pain, headaches, palpitations, and elevations in blood pressure were reported in individuals with rheumatic heart disease.[1] These symptoms were likely a result of the mild stimulating effects of eleuthero and, although not serious, indicated the need to decrease the dosage, allow a washout period, or both.

DRUG INTERACTIONS

A clinical study in healthy humans indicated that extracts of eleuthero at generally recommended doses are unlikely to alter the levels of drugs primarily dependent on the CYP2D6 or CYP3A4 pathways for elimination.[16] However, in a case report, although a clear relationship could not be established, one person taking eleuthero with digoxin (Lanoxin) developed dangerously high serum digoxin levels.[17] Therefore simultaneous use with digoxin requires close medical supervision and regular monitoring of blood digoxin levels. In addition, eleutheroside B and eleutheroside E may inhibit the metabolism of drugs metabolized via CYP2C9 and CYP2E1 and have the potential to increase the toxicity of the drugs.[18]

Ephedra Species[1]

Joseph E. Pizzorno, ND, and *Michael T. Murray, ND*

OUTLINE

Ephedra sinica (family: Ephedraceae)
Common names: Chinese ephedra, Ma Huang, Chinese joint fir
Related species:
Ephedra distachya (European ephedra)
Ephedra trifurca or *Ephedra viridis* (desert tea)
Ephedra nevadensis (Mormon tea, cay note, canutillo, whorehouse tea, tapopote, teamster's tea)
Ephedra americana (American ephedra)
Ephedra gerardiana (Pakistani ephedra)

GENERAL DESCRIPTION

Ephedra spp. are erect, branching shrubs found in desert or arid regions throughout the world. The 1.5- to 4-ft shrubs typically grow on dry, rocky, or sandy slopes. The many slender, yellow-green branches of ephedra have two small leaf scales at each node. The mature, double-seeded cones are visible in the fall.

CHEMICAL COMPOSITION

The chemical analysis of the stems and branches of *Ephedra* spp. are focused on their alkaloid content. In *Ephedrea sinica,* the total alkaloid content can be up to 3.3%, with 40% to 90% of this being ephedrine (Fig. 77.1). The remaining alkaloids are primarily pseudoephedrine and norpseudoephedrine.[2,3] In *E. gerardiana,* the alkaloid content usually varies from 0.8% to 1.4%, with about 50% ephedrine and 50% other alkaloids (e.g., pseudoephedrine, *N*-methylephedrine, norephedrine).[3,4] *E. nevadensis* contains little or no ephedrine.

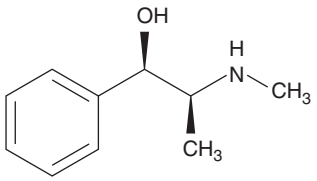

Fig. 77.1 Ephedrine.

Depending on species, parts used (aerial, stem, leaf, or a combination of stem and leaf), harvesting, and extraction techniques, the alkaloid content of commercially available ephedra products varies considerably. In a series of studies, the alkaloid content in ephedra-based products varied by as much as fivefold, with different brands exhibiting lot-to-lot differences ranging from 44% to 260%. Although some products listed the ephedrine content on the label, many did not. In addition to the variations in alkaloid content, commercial ephedra products usually contained other highly active botanicals, including kola nut, guarana, and St. John's wort, as well as many contaminants (e.g., heavy metals).[4,5]

HISTORY AND FOLK USE

E. sinica has been used for medicinal purposes in China since approximately 2800 BC. Ma Huang (the stem and branch) was used primarily in the treatment of the common cold, asthma, hay fever, bronchitis, edema, arthritis, fever, hypotension, and urticaria.[2]

The Chinese believed the effect of the root and rhizome (Ma Huanggen) to be the opposite of the stem and branches and limited its use to the treatment of profuse night sweating.[2] Two hypotensive principles (ephedradine A and B) have since been isolated from ephedra root, along with a hypertensive compound (1-tyrosine betaine or maokine).[2]

Western medicine's interest in ephedra began in 1923 with the demonstration that the isolated alkaloid ephedrine possessed several pharmacological effects. Ephedrine was synthesized in 1927 and has since been used extensively for clinical conditions in which sympathomimetic effects are desired.[4]

After ephedra-containing dietary supplements were linked to a high rate of serious side effects and numerous deaths, the US Food and Drug Administration (FDA) banned the sale of ephedra-containing supplements on April 12, 2004. However, this ban is not without controversy (see the "Toxicology" section).

PHARMACOLOGY

The pharmacology of ephedra centers around its ephedrine content. Ephedrine and pseudoephedrine have been extensively investigated

and are widely used in both prescription and over-the-counter (OTC) medications for asthma, hay fever, and rhinitis. In 1973 more than 20 million prescriptions contained one of these alkaloids. In 2000 ephedra was found in at least 200 OTC products, and it was estimated that as many as two to three billion doses were consumed that year in the United States.

Ephedrine

Ephedrine's basic pharmacological action is that of a sympathomimetic. Ephedrine stimulates both α- and β-adrenergic receptors, as well as the release of norepinephrine. Ephedrine shares many pharmacological actions with epinephrine, although ephedrine is much less active. Ephedrine also differs from epinephrine in its ability to be absorbed orally, its longer duration of action, and its more pronounced effect upon the central nervous system (CNS). The CNS effects of ephedrine are similar to those of amphetamines but, again, much less potent.[2–5] Fig. 77.1 illustrates its chemical structure.

The cardiovascular effects of ephedrine are also similar to those of epinephrine. It increases both diastolic and systolic blood pressure, cardiac output, and heart rate, but for a longer (about 10 times) period of time. Like epinephrine, ephedrine increases coronary, cerebral, and muscle blood flow at the expense of renal and splanchnic blood flow.[2–6]

The bronchial muscle relaxation induced by ephedrine is much less than epinephrine, but, again, the duration of action is much longer. Other smooth muscles, except for the human uterus, are generally affected by ephedrine in the same manner (mild relaxation) as epinephrine. Ephedrine relaxes the human uterus, whereas the effects of epinephrine are more complex.[2–5]

Extracts of ephedra were shown to inhibit complement in vitro, and a Chinese herbal medicinal prescription, *Makyo-kanseki-to*, was found to inhibit cyclic adenosine monophosphate activity.[7,8]

The principle adverse effects of ephedrine are CNS stimulation, nausea, tremors, tachycardia, and urinary retention.[2,3]

The major route of elimination of ephedrine is in the urine as the unchanged drug. The average half-life is 6 hours, although acidifying the urine decreases the half-life considerably. Alkalinization increases the half-life.[9,10]

Pseudoephedrine

Pseudoephedrine exhibits bronchodilating activity similar to ephedrine but has weaker pressor, cardiac, and CNS effects. Pseudoephedrine is often recommended over ephedrine in the treatment of chronic asthma because it has fewer side effects.

Pseudoephedrine demonstrated significant anti-inflammatory effects in various experimental models.[9–11] Other ephedra alkaloids, including ephedrine, also exhibited anti-inflammatory activity, although at much lower potency. Because the anti-inflammatory effect of pseudoephedrine is essentially identical in normal and adrenalectomized mice, the anti-inflammatory activity is not exerted via the adrenal glands. Instead, it appears that the anti-inflammatory activity of pseudoephedrine and other ephedra alkaloids is caused by inhibition of prostaglandin E_2 synthesis.

CLINICAL APPLICATIONS

Asthma and Hay Fever

Ephedra and its alkaloids have proven effective as bronchodilators for the treatment of mild to moderate asthma and hay fever. The peak bronchodilation effect occurs in 1 hour and lasts about 5 hours after administration.

The therapeutic effect of ephedra diminishes if used over a long period of time because of the weakening of the adrenal gland caused by ephedrine. Therefore it is often necessary to use ephedra in combination with herbs such as *Glycyrrhiza glabra* and *Panax ginseng* and nutrients such as vitamin C, magnesium, zinc, vitamin B_6, and pantothenic acid, which all support the adrenal glands.

The folklore herbal treatment of asthma involved the use of ephedra in combination with herbal expectorants. Expectorants are herbs that modify the quality and quantity of secretions of the respiratory tract, resulting in the expulsion of the secretions and an improvement in respiratory tract function. Commonly used expectorants include:

- *Glycyrrhiza glabra* (licorice)
- *Grindelia camporum* (grindelia)
- *Euphorbia hirta* (euphorbia)
- *Drosera rotundifolia* (sundew)
- *Polygala senega* (senega)

Common Cold

Ephedrine and pseudoephedrine are components of many OTC products for the self-treatment of the common cold. In China, ephedra, in combination with various other herbs, was found to be clinically effective in the treatment of cold symptoms, as well as those of influenza, pneumonia, whooping cough, and bronchitis.[2] Polysaccharide from *Ephedra sinica* lowers the recruitment of inflammatory cells, decreases the production of TNF-α, IL-6, IL-8, and MMP-9, and significantly reduces the expression of TGF-β1, P-Smad2, and P-Smad3, thus reducing airway and pulmonary inflammation.[12]

Weight-Loss Aid

In both human and animal studies, ephedrine was shown to promote weight loss.[3,13–21] Although ephedrine demonstrated an anorectic effect,[13] its main mechanism for promoting weight loss appeared to be increasing the metabolic rate of adipose tissue.[13–18] Therefore the weight-reducing effects of ephedra are most significant in those individuals with a low basal metabolic rate.[15] These effects can be greatly enhanced when used in combination with methylxanthines, caffeine, theophylline, and aspirin,[15–20,22] which potentiate the action of ephedrine and other ephedra compounds.

In one animal study, when ephedrine was used alone, it resulted in a 14% decrease in body weight and a 42% decrease in body fat. However, when used in combination with caffeine or theophylline, the decreases were 25% and 75%, respectively.[16] When either caffeine or theophylline was used alone, however, there was no significant loss in body weight. The greater decrease in body weight is likely a result of the increased metabolic rate and fat cell breakdown promoted by ephedrine and enhanced by caffeine and theophylline.

It is recommended that, for methylxanthines, *Camellia sinensis* (green tea) or extracts of *Cola* sp. be used rather than coffee or black tea.

One of the better designed studies on the use of an ephedrine/caffeine combination determined the safety and efficacy of an herbal supplement containing Ma Huang (90 mg/day ephedrine) and kola nut (192 mg/day caffeine) given to subjects for 6 months for weight loss.[21] A total of 167 subjects were randomized to receive either a placebo or ephedrine/caffeine combination. The subjects were monitored primarily for changes in blood pressure, heart function, and body weight. In addition to these parameters, body composition and metabolic changes were studied. Results demonstrated significant beneficial effects on body weight, body fat, and blood lipids of the herbal supplement in overweight men and women who were otherwise healthy. Herbal versus placebo treatment decreased body weight (−5.3 vs −2.6 kg), body fat (−4.3 vs −2.7 kg), and low-density lipoprotein cholesterol (−8 vs 0 mg/dL), and increased high-density lipoprotein cholesterol (+2.7 vs −0.3 mg/dL; $P = 0.004$). The ephedrine/caffeine mixture

produced small changes in blood pressure variables (+3 to −5 mm Hg) and increased heart rate (4 ± 9 beats/min), but cardiac arrhythmias were not increased. Compared with placebo treatment, the herbal supplement produced no adverse events and only minimal side effects consistent with the known stimulant action of ephedrine and caffeine (e.g., dry mouth, insomnia).

A 12-week, multicenter, double-blind, placebo-controlled, randomized study conducted at three clinical sites in New York state evaluated the efficacy and side effects of an herbal formulation containing ephedrine, caffeine, and other ingredients to promote weight loss.[23] One hundred and two overweight/obese volunteers between the ages of 18 and 65 years were randomized to receive either the active product or a placebo supplement. Subjects receiving the active treatment experienced, on average, 1.5 kg of weight loss and greater reductions in BMI and waist circumference compared with subjects receiving the placebo. The benefits were achieved in the absence of any lifestyle, dietary, or exercise change. In addition, lower doses of ephedrine alkaloids and caffeine were used, and subjects experienced results without an increase in blood pressure, pulse, or the rate of adverse events.

Obesity related human gut microbiota have been studied for identification of correlated bacteria and their mechanisms. It has been hypothesized that ephedra can have an influence on gut microbiota, and that influence may be associated with weight loss or metabolic markers or body composition indices. The antiobesity effects of ephedra via gut microbiota modulation was evaluated in a study of females between the ages of 40 and 65 who were weight-stable but obese.[24] The subjects were asked to take 2 g of ephedra extract two times per day for 8 weeks. After ephedra intake, mean value of body weight was decreased by 1.86 kg, mean BMI was decreased by 0.79 kg/m^2, and body fat was reduced by 1.17%. In correlation analysis, *Subdoligranulum*, *Oscillibacter*, and *Akkermansia* showed an association with changes of body weight and BMI. However, the influences of gut microbiota are unique according to indigenous microbiota and differences in individual sensitivity to ephedra.

DOSAGE

The optimum dosage of ephedra depends on the alkaloid content in the form used. The average total alkaloid content of *E. sinica* is 1% to 3%. When used in the treatment of asthma or as a weight-loss aid, the ephedra dose should have an ephedrine content of 12.5 to 25 mg and be taken two to three times daily. For the crude herb, an equal dose would be approximately 500 to 1000 mg three times a day. Standardized preparations are often preferred because they have more dependable therapeutic activity.

TOXICOLOGY

Ephedra can produce the same side effects as ephedrine (e.g., increased blood pressure and heart rate, insomnia, anxiety).

The FDA advisory review panel on nonprescription drugs recommended that ephedrine not be taken by patients with heart disease, high blood pressure, thyroid disease, diabetes, or difficulty in urination due to enlargement of the prostate gland. Nor should ephedrine be used in patients on antihypertensive or antidepressant drugs.

Pregnant women should also avoid the use of ephedra and ephedrine. Ephedrine administered to chick embryos resulted in cardiovascular teratogenicity and embryotoxicity at doses as low as 1 μmol/egg.[25] The teratogenic effect of ephedrine is potentiated by caffeine.[26] Presumably, this activity of ephedrine is the result of the production of nitrosamines.[27] Simultaneous vitamin C administration might reduce the formation of nitrosamines from ephedra alkaloids.[28,29]

A key reason the FDA issued a ban on ephedra products was the tremendous amount (more than 2000) of adverse event reports (AERs) filed with the FDA related to the use of supplements containing ephedra alkaloids.[30,31] However, when the Council of Responsible Nutrition studied the AERs filed with the FDA, it found that 98% of the AERs did not contain complete information, and in 81% of the reports, information on total daily intake of ephedra was not provided.[32] Of the 1173 reports, 121 were selected for further evaluation. Of the 121 selected cases, 47 were considered to contain serious adverse events, including 15 cases of stroke and stroke-like symptoms, 13 cases of seizures, 15 cases of cardiac arrest, and 2 cases of individuals who collapsed.

From the selected 121 cases, there were 8 reports of death: 6 were cardiovascular, 1 occurred in an automobile accident, and 1 was a spontaneous abortion. Among the 6 cardiovascular-related deaths, 5 were males and 1 was female. All 5 males who died from cardiovascular problems were using dietary supplements containing ephedra as an athletic performance enhancer. Additionally, 4 of the 5 were simultaneously using other performance-enhancing products such as caffeine. Therefore their deaths cannot be directly attributed to the use of ephedra. After extensive examination of these AERs, the report could not conclusively determine whether there were any unexpected toxicological effects due to the ephedra contained in the dietary supplements based solely on the information presented in the AERs.

Although there have been no large controlled studies on the possible association between prescribed ephedrine/caffeine and cardiovascular events in general, one study linked data from four different sources within Statistics Denmark on 257,364 users of prescribed ephedrine/caffeine for the period 1995 to 2002. The researchers analyzed the data using a case-crossover technique with a composite endpoint: death outside of a hospital, myocardial infarction, or stroke. To account for effects of chronic exposure and effects in naïve users, the authors performed a secondary case-control study nested within the cohort of ephedrine/caffeine ever users. Among 2316 case subjects, 282 (12.2%) were current users of ephedrine/caffeine. The case-crossover analysis yielded an odds ratio (OR) of 0.84. After adjustment for trends in ephedrine/caffeine use, the OR was 0.95. Subgroup analyses revealed no strata with significantly elevated risk. In the case-control substudy, there was no increased risk among naïve users or users with large cumulative doses. The analysis concluded that prescribed ephedrine/caffeine was not associated with a substantially increased risk of adverse cardiovascular outcomes.[33]

DRUG INTERACTIONS

As mentioned earlier, ephedrine should not be taken by patients with heart disease, high blood pressure, thyroid disease, diabetes, or difficulty in urination due to enlargement of the prostate gland. Nor should ephedrine be used in patients on antihypertensive or antidepressant drugs. Ephedrine will potentiate other stimulant/sympathomimetic drugs and will likely counteract antihypertensives.

1. Ephedra was once an extremely popular herbal product. That popularity ended on February 6, 2004, when the U.S. Food and Drug Administration (FDA) issued a ban on the sale of dietary supplements containing ephedra. This ban was finalized on April 6, 2004. The FDA made this decision based on increased reports of adverse events. Dietary supplements containing ephedrine alkaloids, like other sympathomimetics, raise blood pressure and increase heart rate. The FDA believed ephedrine-based products exposed users to several risks, including the consequences of a sustained increase in blood pressure (e.g., serious illnesses or injuries including stroke and heart attack that can result in death). There was also a risk of increased morbidity and mortality from worsened heart failure and proarrhythmic effects in susceptible individuals.

Epilobium Species (Fireweed)

Kathy Abascal, BS, JD, RH(AHG), and *Eric L. Yarnell, ND, RH(AHG)*

OUTLINE

Epilobium spp. (family: Onagraceae)
Synonym: *Chamaenerion* spp.
Common names: fireweed, willow herb, great willow herb *(Epilobium angustifolium),* rose-bay *(Epilobium angustifolium),* wickup *(Epilobium angustifolium);* small-flowered willow herb *(Epilobium parviflorum);* marsh epilobium *(Epilobium palustre),* wickop *(Epilobium palustre),* swamp willow herb *(Epilobium palustre)*

GENERAL DESCRIPTION

Epilobium is a genus of some 200 species that typically grow at relatively high latitudes or high altitudes.[1] This perennial is found in all parts of the world. It has tall, erect, and somewhat woody stems, from 2 to 7 feet tall, crowded with long, narrow, alternate leaves that are from 2 to 6 in. long. Its flowers range from lavender to pink to carmine-purple, and its pods are long, narrow, and filled with feathery seeds.[2] Most species have small flowers (e.g., *Epilobium parviflorum,* known as small-flowered willow herb). A few have large flowers (e.g., *E. angustifolium,* known as great willow herb). Despite the use of the term "willow," there is no relationship between *Epilobium* spp. and *Salix* spp. (willow) (Fig. 78.1).

CHEMICAL COMPOSITION

The aerial parts are rich in flavonoids[3] and flavonol glycosides based on kaempferol, quercetin, and myricetin skeletons.[4] The plants contain complex tannins such as ellagitannins (oenothein A and B) and gallotannins[5]; β-sitosterol; triterpenes[6]; and gallic, chlorogenic, and ellagic acids.[7] In the small-flowered species, myricetin is the predominant flavonoid. The large-flowered species have a completely different flavonoid pattern, with isoquercitrin being predominant (Fig. 78.2). The plant contains the highest content of the flavonoid myricetin 3-0-β-D-glucuronide shortly after flowering. All fireweed species contain oenothein B, which plays an important role in the plant's efficacy in vitro and in vivo.[8,9] Studies indicate that oenothein B is metabolized to urolithin by gut microbes. Urolithins are bioavailable and have demonstrated antioxidant, antiestrogenic, estrogenic, antimalarial, anti-inflammatory, and anticancer activities in a variety of cell models.[10]

HISTORY AND FOLK USE

Fireweed has been widely used as a medicine and as a food in many parts of the world. Native Americans used it for burning urination, male urination problems, coughs and sore throats, stomachaches and intestinal discomfort, bowel hemorrhages, gastritis, tuberculosis, and as a panacea for pain.[11] It was used as a poultice for boils; abscesses; carbuncles; bruises; infected sores, cuts, and wounds; and other skin ailments. Various Eskimo and Siberian tribes also used the plant to treat sores.[12] Young shoots were widely consumed as food and fodder, as were the roots and leaves. The seed fluff was used for weaving cloth, making thread, and starting fires. Fireweed is named *mjoelke* in Scandinavia, a derivation of the word *milk*, because of centuries of observation that cows grazing on the plant produce more milk.

Eclectic physicians considered fireweed unequaled as a treatment for summer bowel troubles and also used it in other types of diarrhea, including cholera infantum and typhoid dysentery.[13] The Eclectics often administered fireweed as an infusion, using frequent small doses (up to every 10 minutes). *E. hirsutum* was used in Egyptian and European folk medicine to treat inflammation, adenoma, and prostate tumors.[14] Europeans also used the plant to treat eczema, seborrhea, other skin conditions, and menstrual disorders.[15] The plant was also used for the treatment of benign prostatic hyperplasia.[16]

PHARMACOLOGY

Analysis of studies on fireweed is complex, given the subtle differences among species and differences in the actions of aqueous and alcoholic extracts. Overall, most fireweed species appear to have analgesic, antidiarrheal, anti-inflammatory, antimicrobial, antineoplastic, and prostate-related activities.

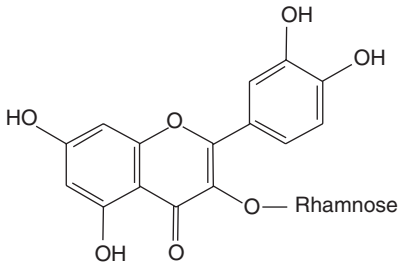

Fig. 78.1 *Chamerion angustifolium* infloresence.

Fig. 78.2 Quercitrin.

Analgesic Effect

Ethanolic extracts of *E. angustifolium* injected subcutaneously had a weak analgesic effect on mice in the hot plate test, whereas its analgesic effect was greater than that of acetylsalicylate in the acetic acid test.[17] In mice, an extract of *E. hirsutum* had an analgesic effect comparable to morphine and diclofenac.[18]

Antidiarrheal Effect

Ethanolic extracts of fireweed showed significant antidiarrheal and antimotility effects in a variety of animal models.[19]

Anti-Inflammatory Effect

Aqueous extracts of *E. angustifolium* (40 mg/kg orally) strongly reduced the release of prostaglandins and depressed edema in vivo.[20] Its effect on edema was equivalent to indomethacin (2 mg/kg). *E. parviflorum* did not suppress edema and had about 20% of the effect on prostaglandin release. Isolated myricetin-3-0-β-D-glucuronide was 10 times more effective than indomethacin at inhibiting edema in rats, was equally effective at inhibiting prostaglandin biosynthesis, and had a dose-related antiarthritic effect.[21,22] It inhibited both cyclooxygenase-1 and -2 nearly equivalently and inhibited 5-lipooxygenase comparably to nordihydroguaiaretic acid. It dose-dependently inhibited platelet aggregation equivalently to indomethacin, but in contrast to indomethacin, it induced no gastric ulcers. The compound may be safer than nonsteroidal anti-inflammatory drugs, because it prevents the arachidonic shunting that results in the formation of leukotrienes.

Antimicrobial Effect

Dilute extracts of fireweed are antimicrobial in vitro.[23] *E. angustifolium* and *E. rosmarinifolium* have the broadest spectrum of action, inhibiting bacteria, yeast, and fungi. *E. angustifolium* and *E. hirsutum* inhibited *Microsporum canis* at concentrations as low as 10 mcg/mL. In another study, *E. angustifolium* failed to inhibit *Aspergillus niger* but somewhat inhibited *Candida albicans* while strongly inhibiting *Staphylococcus aureus* and *Escherichia coli.*[24]

Antitumor Effect

Oenothein B, isolated from fireweed, showed some antitumor activity against sarcoma 180 in mice and some selectivity against lung cancer cells and two colon cancer lines, but did not have a noticeable effect on the prostate cancer lines tested.[25] In other studies, *E. angustifolium* had a specific and significant antiproliferative effect on human prostate epithelial cells.[26] In addition, several of its flavonoids were potent growth inhibitors when tested on various hormone-sensitive and hormone-nonsensitive cell lines.

Effect on Prostate and Prostatic Enzymes

Extracts of various fireweed species inhibited aromatase in vitro.[27] This action was primarily attributed to oenothein A and B, but other fireweed flavonoids also inhibited aromatase. Both oenothein A and B had a considerably greater inhibitory action on 5-α-reductase in vitro than the reference drug finasteride. The aqueous extract and ultrafiltrate of *E. angustifolium* had an antiandrogenic effect in intact rats, and the aqueous extract had a proandrogenic effect in castrated rats.[28] In another study, alcoholic extracts of fireweed failed to inhibit 5-α-reductase, whereas the aqueous extract showed significant inhibition.[29] This action was attributed to the compound oenothein B. Although data on the bioavailability of oenothein B are lacking, it appears that aqueous extracts of *E. hirsutum* are metabolized by gut microbes to dibenzopyran-6-one or urolithins.[30] Urolithins are bioavailable and have been shown to accumulate in mice prostate glands and inhibit cell proliferation[31]

CLINICAL APPLICATIONS

One randomized, double-blind, placebo-controlled trial of 57 healthy males diagnosed with benign prostatic hyperplasia (BPH) found that a combination product, ProstateEZE Max, significantly reduced daytime and nighttime urinary frequency and reduced the international prostate specific score (36% reduction vs. 8% in placebo group). ProstateEZE Max combines *Curcurbita pepo* (pumpkin) seed, *E. parviflorum,* lycopene, *Prunus africanum* (pygeum) bark, and *Serenoa repens* (saw palmetto) fruit.[32] However, no clinical studies were found specifically looking at any fireweed species by themselves. This is unfortunate, given preliminary studies indicated that fireweed might be more effective than drugs such as finasteride and indomethacin, as discussed earlier. The existing pharmacological research supports fireweed's well-established use in traditional medicine as a treatment for prostate disorders and as a topical medicine in various skin conditions.[33]

DOSAGE

Dosages for fireweed are not well established. Fireweed is traditionally administered as a standard infusion using 2 to 3 teaspoons of herb to 1 cup of boiling water, taken as needed.[34] The suggested dose for an aqueous/alcoholic tincture is 2 to 6 mL three times a day.

Aqueous/alcoholic tinctures appear to be more effective than tinctures with a high alcohol concentration.[35,36] No widely accepted standardization exists to ensure quality fireweed extracts, although flavonoid profiles can be used to distinguish the various species.[37,38]

Species grown in Africa appear to have a significantly higher content of oenothein B than the same species grown in Europe.[39]

TOXICOLOGY

Fireweed has no known toxic effects, and its lack of toxicity is underscored by a worldwide use as both food and fodder. The median lethal dose for injected ethanol extract in mice is 1.4 g/kg.[40]

DRUG INTERACTIONS

There are no documented drug interactions with fireweed. However, oral doses of *E. angustifolium* slightly increased the expression of CYP2D2 in rats and significantly decreased expression of CYP3A1 in one study; another found intraperitoneal delivery of an extract of *E. hirsutum* decreased CYP2E1 and CYP1A1, indicating a potential risk of interactions with drugs metabolized by these enzymes.[41,42]

Fatty Acid Metabolism

Lahnor Powell, ND, MPH, and *Edward C. Wallace, ND, DC*

OUTLINE

FATTY ACID STRUCTURE AND METABOLISM

Fatty acids derived from digestion and small intestine absorption or endogenous production are either converted into energy, stored as triglycerides, incorporated into cellular membranes, or they give rise to longer fatty acids.[1] The effect of fatty acids on health depends on their structure and quantity, plus the balance in relationship to other fatty acids. Fatty acids affect membrane permeability, the production of inflammatory molecules (eicosanoids), and free-radical generation, which are underlying processes thought to play a role in the pathophysiology of mood and cognition, cardiovascular disease, inflammatory conditions, obesity, and cancer.[2–12] This chapter focuses on fatty acid nomenclature, metabolism, and a review of their importance in health and disease.

NOMENCLATURE

The basic structure of a fatty acid consists of a hydrogen-carbon (hydrocarbon) open-chain molecule with a terminal carboxylic group (–COOH; Fig. 79.1).[11] Each carbon atom forms four bonds, either to another carbon or to a hydrogen atom. Nomenclature systems describe the number of carbon atoms and indicates the type and location of the bonds.[11,13] There are several nomenclature systems. In general, a numerical prefix describes the length of the hydrocarbon chain, and the suffix indicates the type and location of the bonds.[13] To describe the relative location of the hydrogen atoms for fatty acids containing double bonds, a cis- or trans- notation is used. When the hydrogen atoms and double bond are present on opposite sides, the trans- notation is used.[11] If the hydrogen atoms and double bond are present on the same side, the cis- notation is used.[11] The structural variances of fatty acids result in important differences in the form, function, and energetics of the molecule.

Saturated Fatty Acids

A saturated fatty acid carbon chain contains the maximum number of hydrogen bonds with a terminal carboxylic group (–COOH).[11] A familiar nomenclature system, from the International Union of Pure and Applied Chemists (IUPAC), uses a Latin numerical system to describe the number of carbon atoms.[13] A 16-carbon saturated fatty acid is termed *hexadecanoic acid,* with *hexa-* as the prefix for the number 16.[13] Lipid numbers nomenclature is an abbreviated system listing the number of carbon atoms. The lipid numbers nomenclature for hexadecanoic acid is 16:0.[11] The common nomenclature system, frequently used in the literature, aims to simplify the naming system. For example, hexadecanoic acid's common name is palmitic acid.[11]

Saturated fatty acids can range from 2 to 30 carbons (Fig. 79.2). The most common and important fatty acids are 12 to 22 carbons in length: stearic acid (octadecanoic acid C18:0), palmitic acid (hexadecanoic acid C16:0), myristic acid (tetradecanoic acid C14:0), and lauric acid (dodecanoic acid C12:0).[11,14–16] They are commonly found in plant and animal fats such as coconut, nutmeg, palm kernel oil, fish oil, and certain animal products such as dairy.[11,15] Because of their structure, saturated fatty acids are solid at room temperature and have better oil stability.[11] Oil stability describes the oil's heat index, or smoke temperature, and resistance to oxidation.[17] When an oil reaches its smoke point or has a low resistance to oxidation, it degrades or generates free radicals.[17] Accumulation of free radicals, also termed oxidative stress, can lead to changes in cell membranes and other structures, such as DNA, proteins, carbohydrates, and lipids.[18,19] If free radicals are not regulated by antioxidants, they can induce a variety of chronic and degenerative illnesses.[18,19] Compared with corresponding unsaturated fatty acids, saturated fats have a higher heat index and better oxidative stability, making them an ideal oil for cooking at higher temperatures.[17]

The saturated fatty acid structure, with its molecules packed tightly together, makes it challenging for the body to convert into energy. Fatty acids have been associated with many chronic conditions, including

Fig. 79.2 Structure of saturated fatty acids.

cardiovascular disease, cancers, and systemic inflammation.[12] This led influential health and nutrition agencies, including the World Health Organization and the American Heart Association, to recommend that saturated fatty acid intake be limited to 7% to 10% of daily calorie energy consumption or 24 grams.[15] Recent advances in nutrition research focused on individual saturated fatty acid structure, metabolism, and function. The research highlighted the importance of certain saturated fatty acids in gene expression, through the alteration of messenger RNA (mRNA; conveys genetic information from DNA), plus lipid metabolism by altering the production, secretion, and clearance of cholesterol.[12] Evidence of the effects of saturated fatty acids on cardiovascular health, insulin resistance, and stroke is still mixed.[14,16,20] Therefore careful incorporation of these specific fatty acids in the diet may be potentially beneficial for health.[11,14-16]

Unsaturated Fatty Acids

Unsaturated fatty acid carbon chains contain one or more double bonds with a terminal carboxylic group (–COOH), unlike saturated fatty acids, which contain no double bonds.[11] These fatty acids are subdivided into two groups depending on the number of double bonds. A single double bond is termed *monounsaturated,* and those with more than one double bond are termed polyunsaturated. The IUPAC name for an 18-carbon fatty acid with a double bond at position 9 is called octadec-9-enoic acid.[11,13] In addition to nomenclature systems describing the number of carbon atoms and location of the double bond(s), a "cis-" or "trans-" notation describes the configuration. A cis- notation means hydrogen atoms are on the same side as the carbon double bond, whereas a trans- notation means hydrogen atoms are on the opposite side of the carbon double bonds (Fig. 79.3).[11,21] The shape of the trans fatty acid creates a kink in the molecule that determines its fluidity state at room temperature and its molecular stability.[11] Lipid number nomenclature for the 18-carbon fatty acid with a single double bond at position 9 and hydrogen atoms on the same side of the double bond is 18:1cis-9.[11] The common name is oleic acid. The common name for an 18-carbon polyunsaturated fatty acid with double bonds at positions 9, 12, and 15 is alpha-linolenic acid (ALA).[11] The IUPAC name is 9, 12, 15-octadecatrienoic acid, and the lipid number is 18:3cis-9,12,15.[13]

Monounsaturated Fatty Acids

Monounsaturated fatty acids tend to be solid when chilled and are liquid at warmer temperatures. Compared with corresponding saturated fatty acids, monounsaturated fats have a lower heat index and

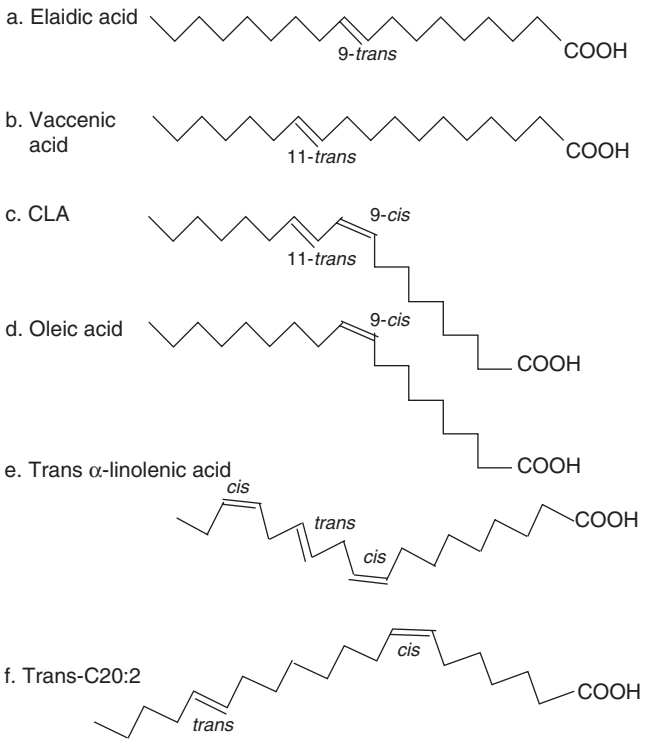

Fig. 79.3 Structure and examples of unsaturated fatty acids.

oxidative stability, making them less ideal for cooking at high temperatures.[17] In descending order, the most common monounsaturated fatty acids in the diet are oleic acid (18:1 cis-9/omega-9), palmitoleic acid (16:1 cis-7/omega-7), and vaccenic acid (18:1 cis-7/omega-7).[21] These fatty acids are found in olive oil, sesame, oil, canola oil, avocados, and many nuts and seeds.[11,21] The main sources of monounsaturated fatty acids have the cis-configuration. The most common trans-configuration monounsaturated fatty acid is elaidic acid (18:1 trans-9), found in hydrogenated vegetable oils and naturally in some meats in small amounts.[21]

The Mediterranean diet, which is high in monounsaturated fatty acids, continues to receive attention because of its association with lower cardiovascular disease risk, improvement in insulin sensitivity, decreased risk for certain cancers, and positive effects on cognition.[21–23] Two specific monounsaturated fatty acids consumed in great quantities in the Mediterranean diet are omega-7 and omega-9 fatty acids. Omega-7 fatty acids are found in fish (salmon and anchovy), olive oil, and macadamia oil, and omega-9 fatty acids are found in olive oil, canola oil, and sunflower oil. Because these fatty acids can assist with the regulation of blood sugar and fat metabolism or breakdown, they are receiving positive attention for the management of metabolic disorders (diabetes, cardiovascular disease, and obesity). [24–26]

Health and nutrition organizations recommend that 20% to 25% of total caloric energy be derived from monounsaturated fatty acids, although debate on dietary amounts continues.[12,21] National nutritional guidelines emphasize balance—by increasing monounsaturated fatty acid intake at the expense of saturated fatty acids—to gain the greatest health benefits.[21,23]

Polyunsaturated Fatty Acids

Because of the structure of polyunsaturated fatty acids, they tend to be liquids. Compared with monounsaturated fatty acids, polyunsaturated fats have a lower heat index and oxidative stability, making them less ideal for cooking at high temperatures.[17] The biological function of a

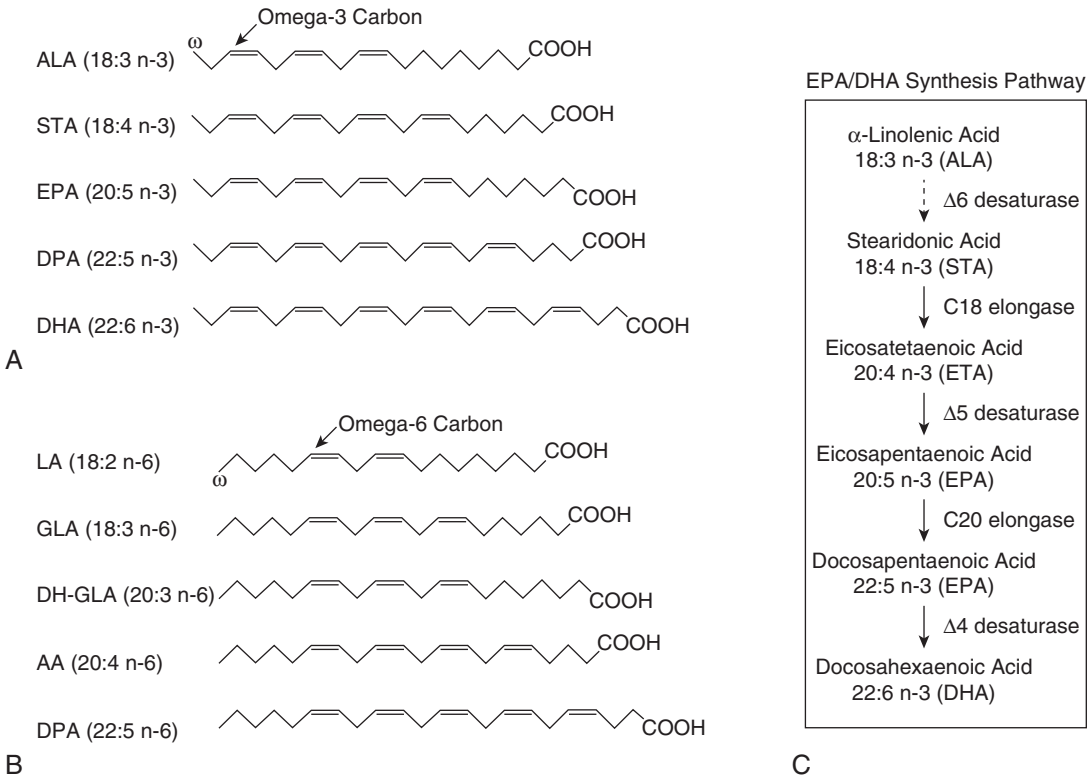

Fig. 79.4 Omega-3 and omega-6 fatty acid structures and eicosapentaenoic acid (EPA)/docosahexaenoic acid (DHA) synthesis pathway. (A) Omega-3 fatty acids include alpha-linolenic acid (ALA), stearidonic acid (STA), EPA, docosapentaenoic acid n-3 (DPA n-3), and DHA. (B) Omega-6 fatty acids include linoleic acid (LA), gamma-linolenic acid (GLA), dihomo-gamma-linolenic acid (DH-GLA), arachidonic acid (AA), and docosapentaenoic acid n-6 (DPA n-6). Additionally, the arrows in A and B point to the omega-3 and omega-6 carbon, respectively. (C) The EPA/DHA synthesis pathway is given with fatty acids and respective enzymes for each step. The omega-6 synthesis of LA (18:2 n-6) to DPA n-6 (22:5 n-6) uses the same enzymes. (From ResearchGate. Omega-3 fatty acids for nutrition and medicine: considering microalgae oil as a vegetarian source of EPA and DHA. <https://www.researchgate.net/Fig-1-Omega-3-and-Omega-6-Fatty-Acid-Structures-and-EPA-DHA-Synthesis-Pathway-A_fig1_5630480>. Accessed August 22, 2018.)

polyunsaturated fatty acid depends on the location of the last double bond respective to total carbon atoms.[7] Alpha-linolenic acid (ALA) lipid number nomenclature 18:3cis-9,12,15 describes an 18-carbon cis-polyunsaturated fat with double bonds at positions 9, 12, and 15.[11] The location of the last double bond is carbon 15, which is three carbons away from the tail of the 18-carbon fatty acid. Therefore this is considered an omega-3 fatty acid. If the last double bond is six carbons from the tail of the fatty acid, it is classified as an omega-6 fatty acid.[11] Polyunsaturated fatty acids are unique because the human body cannot synthesize precursors to the omega-3 and omega-6 series of fatty acids (Fig. 79.4).[7,11] These precursors are termed essential fatty acids. Therefore they must be consumed from food sources such as nuts and seeds and plant-based oils.[7,12,27]

Essential Fatty Acids

The essential precursor to the omega-3 series of fatty acids is 18:3cis-9,12,15 or ALA, found in green leafy vegetables and various nuts and seeds (walnuts, flaxseed, chai seeds).[7,12,27,28] The majority of ALA is used to generate energy. Only a small portion of ALA is converted to eicosapentaenoic acid (20:5cis-5,8,11,14,17 or EPA) and docosahexaenoic acid (22:6cis-4,7,10,13,16,19 or DHA); therefore dietary intake is important.[8,27,29] Direct sources of EPA and DHA are marine fatty fish (salmon, mackerel, and sardines), enriched foods (milk, yogurt, and margarines), and supplements.[27]

The essential precursor to the omega-6 series of fatty acids is 18:2cis-9,12 or linoleic acid (LA), found in plant oils (sunflower, safflower, grape seed, sesame, and corn oils), cereals, eggs, some grains, and poultry.[7,12,30] Polyunsaturated fatty acids are precursors to eicosanoids, or signaling molecules. Those of the omega-6 series are generally considered proinflammatory. However, certain omega-6 fatty acids—specifically dihomo-gamma-linolenic acid (C20:3cis-8,11,14 or DGLA)-derived metabolites—play an essential role in cognition, the reduction of inflammation, the promotion of cardiovascular health, and healthy growth and development.[7,8,12,30] Conversely, proinflammatory arachidonic acid (C20:4cis5,8,11,14 or AA) metabolites are associated with chronic inflammation, cardiovascular disease, and cancer.[7,30]

Polyunsaturated fatty acids can be metabolized into eicosanoids via cyclooxygenase enzymes (COX) and lipoxygenase (LOX) enzymes.[7] Eicosanoids are inflammatory mediators and include prostaglandins (PGs), thromboxanes (TXs), leukotrienes (LTs), and hydroxyeicosatetraenoic acids (HETEs).[6–8] AA (an omega-6 fatty acid) converts to 2-series prostaglandins (PGI2, PGE2, PGF2, and PGD2) and thromboxanes (TXA2), plus 4-series leukotrienes (LTA4, LTB4, LTC4, LTD4, and LTE4), contributing to inflammatory conditions like arthritis, obesity, cardiovascular disease, cancer, and inflammatory bowel disease (IBD).[7,12,30] EPA and DHA (omega-3 fatty acids), plus DGLA (omega-6), convert to the anti-inflammatory eicosanoids

3-series prostaglandins (PGI3, PGE3, PGF3, and PGD3) and thromboxanes (TXA3), plus 5-series leukotrienes (LTA5, LTB5, LTC5, and LTD5).[7,30] Because of the varied actions of polyunsaturated fatty acids, dietary intake should be based on balance. The current consumption of omega-6 to omega-3 is a ratio of 20:1, whereas our Paleolithic ancestors consumed equal amounts (1:1).[31] This dietary imbalance of omega-6 to omega-3 increases proinflammatory eicosanoids and their associated health risks.[7,12] Dietary recommendations suggest a decrease in omega-6 consumption or a balance of 2:1 to 5:1 (omega-6:omega-3) to manage and prevent chronic disease.[27,31,32]

Trans Fatty Acids

Trans fatty acids contain hydrogen atoms on the opposite side of the carbon double bond(s).[11] This slight change in configuration causes the fatty acid to be solid at room temperature, with a longer shelf-life than other unsaturated fatty acids.[11,15] A naturally occurring 18-carbon trans fatty acid with a single double bond at position 11 is called octadec-11-enoic acid (IUPAC), C18:1trans11 (lipid number), or vaccenic acid (common name).[33] Naturally occurring trans fatty acids are found in predominantly non–grass-fed meat and dairy products.[33,34] The industrial partial hydrogenation of liquid plant oils is a common source of synthetic trans fatty acids.[15] This process involves the addition of a hydrogen atom to a fatty acid, converting the double bond to a single bond.[33] Industrially manufactured, or synthetic, trans fatty acids are found in fried foods, potato chips, baked deserts, margarine, and shortening.[33,34] Although both trans fatty acids have a similar structure, industrially produced trans fatty acids have a greater negative effect on health than naturally occurring sources.[35] Synthetic trans fatty acids contribute to cardiovascular disease, stroke, and diabetes through the inhibition of anti-inflammatory polyunsaturated fatty acids.[35,36] Because of the health effect, current recommendations for the consumption of trans fatty acids are less than 1% of total caloric energy intake.[15,33,34]

METABOLISM AND BIOCHEMISTRY

Fatty acids derived from digestion and small intestine absorption or endogenous production are either converted into energy, stored as triglycerides, incorporated into cellular membranes, or they give rise to longer fatty acids.[1] In contrast to other macronutrients (carbohydrates and proteins), fatty acids yield the greatest energy per gram: 9 kcal/gram.[1] To generate energy, fatty acids enter the mitochondria through a series of transport proteins, enzymatic reactions, and free diffusion.

The first step combines the fatty acid with a coenzyme A molecule to generate acyl-CoA (fatty acid–CoA).[37] This process occurs within the cytosol of a cell. Specific transmembrane proteins are used to transport fatty acids into the cytosol, notably fatty acid transport proteins (FATPs) and fatty acid translocase (FAT).[37–39] FATPs are a family of six proteins (FATP1–FATP6), which are expressed differently in various tissues (i.e., adipose, skeletal muscle, brain, liver, kidney, lung, enterocyte, and brain).[38,40] FAT is expressed in macrophages, fat, muscle, intestine, and liver cells.[39,41] In addition to lipid metabolism, FAT is involved in angiogenesis, atherosclerosis, and inflammation.[41] Coenzyme A derived from pyruvate, a metabolite of glucose metabolism, enters the cytosol through translocation.[1] Once the fatty acid and coenzyme A are in the cytosol of the cell, fatty acyl-CoA synthase (FACS) generates an acyl-CoA molecule[37]:

$$\text{Fatty Acid (cytosol)} + \text{Coenzyme A (cytosol)} + \text{ATP} \xrightarrow{\text{FACS}} C_n - \text{Acyl - CoA} + \text{AMP}$$

Next, the acyl-CoA molecule moves from the cytosol into the mitochondria, either by diffusion or through transport by carnitine mitochondria transport proteins.[37] The length of the fatty acid chain determines how it enters the mitochondria. Short- and medium-chain fatty acids—shorter than 12 carbons—diffuse through the mitochondria membranes. Longer-chained fatty acids require the assistance of carnitine mitochondria transport proteins.[37]

Once the acyl-CoA molecule is within the mitochondrial matrix, it is shortened through a sequence of enzymatic reactions termed beta-oxidation.[37,42] This is a multistep catabolic process. The end products of beta-oxidation are an acetyl group, nicotinamide adenine dinucleotide (NADH), and flavin adenine dinucleotide F(ADH_2)[37,42]. All of these molecules enter the citric acid cycle (also known as the tricarboxylic acid cycle or Krebs cycle) or the electron transport chain to generate energy in the form of adenosine triphosphate (ATP)[37,42]:

$$C_n\text{ - Acyl CoA} + \text{FAD} + \text{NAD}^+ + H_2O + \text{CoA} \longrightarrow C_{n-2}\text{ Acyl CoA} + FADH_2 + \text{NADH} + \text{acetyl CoA} + H^+$$

Carnitine Mitochondria Transport Proteins and Deficiencies

Movement of the acyl-CoA molecule from the cytosol through the outer mitochondrial membrane is catalyzed by carnitine palmitoyltransferase I (CPT1). There are three isoforms of CPT1—CPT1a (liver), CPT1b (muscles), and CPT1c (neurons).[43] Initially, the enzyme splits the acyl-CoA into two molecules, acyl and CoA. The acyl group is joined to a carnitine molecule forming acyl-carnitine or palmitoyl-carnitine. This molecule is then transferred across the inner mitochondrial membrane, or the mitochondria matrix, by carnitine-acylcarnitine translocase (CACT).[43] Once the acyl-carnitine or palmitoyl-carnitine molecule is within the matrix, it is converted back into acyl-CoA by carnitine palmitoyltransferase II (CPT2).[43] This process releases a carnitine molecule, which is moved back into the cytosol of the cell, using CACT and diffusion, where it can then assist another acyl molecule to enter the mitochondria.[43] Once the acyl-CoA molecule is within the mitochondria, it can undergo beta-oxidation to generate ATP:

$$\text{Cytosol: } C_n\text{–Acyl} + \text{CoA} + \text{carnitine} \xrightarrow{\text{CPT1}} C_n\text{–Acyl-carnitine or palmitoyl-carnitie}$$

$$\text{Mitochondria: } C_n\text{–Acyl-carnitine or palmitoyl-carnitine} \xrightarrow{\text{CPT2}} C_n\text{–Acyl-CoA} + \text{carnitine}$$

Carnitine palmitoyltransferase I (CPT1) is considered the rate-limiting, or slowest, step needed to move acyl-CoA into the mitochondria for beta-oxidation. There is a rare genetic polymorphism for CPT1 that makes it difficult to use longer-chained fatty acids for energy production. It is generally diagnosed in childhood, and the primary symptom is hypoketotic hypoglycemia (low ketone and blood sugar levels).[44] Affected individuals are at risk of hepatomegaly, liver dysfunction, and/or elevated serum carnitine, potentially causing nervous system damage, liver failure, seizures, coma, and sudden death.[44]

Some individuals have a genetic polymorphism for CPT2, or the enzyme that assists with the conversion of acyl-carnitine or palmitoyl-carnitine into acyl-CoA energy production. There are several mutations of the *CPT2* gene: the lethal neonatal form is associated with cardiac damage, liver failure, seizures, and death shortly after birth; the severe infantile form is associated with increased risk of liver failure, nervous system damage, coma, and sudden death; and a benign adult form is characterized by rhabdomyolysis.[44]

Management for CPT1 and CPT2 genetic polymorphisms include frequent feedings or avoiding fasting, avoiding sustained exercise, stress management, maintaining optimal immune health, and a low-fat diet.[44]

Another genetic polymorphism that affects fatty acid and carnitine movement through the inner mitochondrial membrane is carnitine-acylcarnitine translocase (CACT) deficiency. Metabolic consequences include hypokinetic hypoglycemia (low ketone and blood sugar levels), elevated serum ammonia, elevated creatinine kinase and transaminases, dicarboxylic aciduria, and an abnormal acylcarnitine profile (low free carnitine and acylcarnitine species).[44] Symptomatic neonates present with a rapidly progressive form of CACT deficiency that is often fatal, whereas presentation later in life is generally milder. Dysfunction or damage can occur to the brain, heart, skeletal muscles, and liver, leading to progressive neurological, cardiac, and liver deterioration; coma; and sudden death.[44] The therapeutic approach is to avoid periods of fasting and hypoglycemia, restrict long-chain fatty foods, and implement carnitine supplementation as needed.

The transport of longer-chained fatty acids across the mitochondria membranes for subsequent beta-oxidation is dependent on carnitine. Carnitine can be synthesized by the body, obtained from the consumption of animal products, or acquired through exogenous supplementation. Endogenous carnitine synthesis occurs in the liver and kidney and, to a lesser extent, the brain. The essential amino acids methionine and lysine are joined to form carnitine with the assistance of several nutrient cofactors: pyridoxal phosphate (B_6), niacin (B_3), vitamin C, and iron.[43]

People on strict nonanimal product diets maintain carnitine levels, in part, because of efficient renal tubular resorption. Organic cation/carnitine transporter 2 (OCTN2) assists with reabsorption and the accumulation of carnitine in the liver, kidney, and muscles.[43] A genetic polymorphism of OCTN2 leads to urinary carnitine wasting and decreased accumulation within cells.[44] Unlike other carnitine genetic defects, OCTN2 affects plasma carnitine levels.[44] This autosomal-recessive disorder is aggravated by periods of fasting and low dietary carnitine intake.[44] Symptoms range from hypoglycemia and hepatic encephalopathy, experienced in early life, to skeletal or cardiac myopathy and cardiac-related sudden death.[43,44] Clinical management consists of carnitine monitoring and supplementation, monitoring cardiac and liver function, and avoiding hypoglycemic episodes (i.e., fasting).[43,44]

Beta-Oxidation

Georg Franz Knoop is credited with discovering fatty acid beta-oxidation in 1904.[37,42] His landmark experiment involved feeding specific fatty acid compounds to dogs and analyzing their urine. He noticed that the initial compound fed to the dog was shortened by two carbons when analyzed in urine. He concluded that fatty acid metabolism via beta-oxidation is the successive removal of two carbon fragments.[37,42] Other influential scientists confirmed and further developed Knoop's beta-oxidation theory. They identified genetic polymorphism enzyme deficiencies, clarified the role of carnitine in fatty acid metabolism, purified various beta-oxidation enzymes, and cloned genes responsible for disease-causing mutations.[37,42] Beta-oxidation is an important metabolic pathway for liver, heart, and skeletal muscle energy production.[42] During fasting, most tissues, excluding the brain, rely on beta-oxidation to generate energy.[42] The brain uses ketones—organic compounds created by the liver from fatty acids—as its energy source.[42]

As Georg Knoop discovered, beta-oxidation is a cyclic process, cleaving two carbon atoms from the acyl-CoA chain. Beta-oxidation is a series of four reactions, including oxidation, hydration, and cleavage of the acyl-CoA molecule.[37,42] Each cycle produces acetyl-CoA, nicotinamide adenine dinucleotide (NADH), flavin adenine dinucleotide ($FADH_2$), and water.[37] The total energy produced from a fatty acid depends on the carbon length. Each cycle of beta-oxidation has the potential to yield 17 ATP molecules using the products of beta-oxidation in the electron transport chain and the citric acid cycle.[1]

Oxidation

The initial step of the beta-oxidation cycle introduces a double bond between the second and third carbon (in relation to the terminal carboxylic group) of the acyl-CoA molecule. This process is catalyzed by acyl-CoA dehydrogenase (ACD), generating 2-trans-enoyl-CoA.[37,45,46] Flavin adenine dinucleotide (FAD) is a cofactor for this reaction. In humans, FAD is made from dietary riboflavin or vitamin B_2.[47] This molecule accepts the two hydrogen molecules released from the acyl-CoA molecule—$FADH_2$—which can be used to generate ATP:

$$C_n - \text{Acyl-CoA} + \text{FAD} \xrightarrow{\text{ACD}} \text{2-trans-enoyl-CoA} + FADH_2$$

There are several variations of ACD, based on the length of the acyl-CoA molecule: short-chain ACD (SACD), medium-chain ACD (MACD), long-chain ACD (LACD), and very long-chain ACD (VLACD).[48] Although the enzyme's active site varies in amino acid sequencing, the mechanism of action is similar. Unfortunately, ACD genetic polymorphisms can result in ACD enzyme deficiencies.[49] This autosomal-recessive inborn error of mitochondrial fatty acid oxidation is commonly diagnosed through newborn screening.[50–53] ACD deficiency prevents the body from converting fats into energy through beta-oxidation, which is essential, especially during periods of restricted caloric intake. Mortality and morbidity are highest in undiagnosed individuals.[49] Each ACD deficiency manifests slightly differently (see following discussion); however, the management principles are the same: frequent feeding or avoidance of fasting, consumption of a low-fat diet, and improving immune health to minimize infections.[49–53]

Medium-chain acyl-CoA dehydrogenase deficiency (MACDD) is the most common fatty acid oxidation disorder.[49,51] If not identified with newborn screening, symptoms of hypoketotic hypoglycemia (low ketone and blood sugar levels) typically manifest by age 3 or later in adulthood.[52] Although variable, individuals can experience episodes of vomiting and lethargy, mainly triggered by fasting or illness.[51,52]

Short-chain acyl-CoA dehydrogenase deficiency (SCADD), if not fatal, typically presents in early childhood by age 5.[50,54] Symptoms include developmental delay, seizures, behavioral disorders, and hypoglycemia.[50,54,55] People with SCADD can remain asymptomatic or experience muscle-related weakness and wasting in adulthood.

The last two ACD genetic polymorphisms, long-chain and very-long-chain dehydrogenase deficiencies, are rare. As early as days or weeks after birth, infants are lethargic and hypoglycemic, have hypertrophic cardiomyopathy, irregular heart rhythms, and respiratory failure, potentially leading to death.[53] With late-onset presentation, symptoms include lethargy, hypoglycemia, an enlarged liver, metabolic acidosis, coma, and respiratory or cardiac arrest.[53]

Hydration

The second reaction of the beta-oxidation cycle hydrates 2-trans-enoyl-CoA into 3-hydroxy-acyl-CoA. A water molecule adds a hydroxyl group (–OH) to the double bond at C2.[37] This process is catalyzed by the enzyme enoyl-CoA hydratase[37,56]:

$$\text{2-trans-enoyl-CoA} + H_2O \xrightarrow{\text{Enoyl-CoA hydratase}} \text{3-hydroxy-acyl-CoA}$$

Dehydrogenase

The hydroxyl group (–OH) from 3-hydroxy-acyl-CoA is dehydrogenated by NAD^+, which removes a hydride ion (H^+) from the hydroxyl group on the third carbon.[37] In humans, NAD is made from the essential amino acid tryptophan or salvaged from niacin or vitamin B_3.[57]

The enzyme that catalyzes the third step of beta-oxidation is 3-hydroxylacyl-CoA-dehydrogenase, resulting in NADH, H^+ molecules, and 3-ketoacyl-CoA[37]:

$$\text{3-hydroxy-acyl-CoA} \xrightarrow{\text{3-hydroxylacyl-CoA-dehydrogenase}} \text{3-keto-acyl-CoA} + \text{NADH} + \text{H}^+$$

Thiolase

In the final step of beta-oxidation, ketoacyl-CoA thiolase attaches a CoA group to 3-ketoacyl-CoA, yielding two molecules: an acetyl-CoA and a 2-carbon-shorter acyl-CoA.[37]

If the initial acyl-CoA molecule is an even-number carbon chain, it reenters the beta-oxidation cycle until two carbon acetyl-CoA molecules are formed as the end product.[37,56] The acetyl-CoA molecules are further used to generate energy from the citric acid cycle. Odd-number carbon chain acyl-CoA molecules result in the formation of a three-carbon propionyl-CoA and a two-carbon acetyl-CoA.[56] The propionyl-CoA is converted into succinyl-CoA through the action of propionyl-CoA carboxylase and methylmalonyl-CoA mutase.[56] Both the acetyl-CoA and succinyl-CoA molecules enter into the citric acid cycle to generate ATP:

$$\text{3-keto-acyl-CoA} + \text{CoA} \xrightarrow{\text{ketoacyl-CoA thiolase}} \text{C}_{n-2}\text{Acyl-CoA} + \text{Acetyl-CoA}$$

Peroxisome Beta-Oxidation

If a fatty acid or derivative is unable to be oxidized by mitochondrial enzymes, beta-oxidation can occur in peroxisomes.[58] Peroxisomes, a type of organelle, are located within the cytoplasm of cells.[59] They contain a variety of enzymes involved in various metabolic reactions, including energy production from certain fatty acids.[59] Peroxisome beta-oxidation is reserved for very long-chain fatty acids and long-chain fatty acids.[43,58] A CoA molecule is removed from the longer-chained fatty acyl-CoA through ATP-binding cassette (ABC) transporters, allowing entry into the peroxisomal membrane.[43,60] Similar to mitochondrial beta-oxidation, peroxisome beta-oxidation consists of oxidation, hydration, dehydrogenase, and thiolase enzymes.[58,60] However, as the fatty acid chain shortens, it can be exported to the mitochondria for the completion of beta-oxidation.[43,60] The primary function of peroxisome beta-oxidation is chain-shortening, whereas mitochondria beta-oxidation is focused on the generation of energy.[37,43]

MODIFICATION AND SYNTHESIS OF FATTY ACIDS

Fatty acids are predominately derived from the diet; however, the body can synthesize fatty acids from acetyl-CoA or change the structure and function of a fatty acid, by either introducing a double bond (desaturation) or adding carbon atoms (elongation).[61,62] Modification or endogenous production of fatty acids leads to functionally diverse fatty acids for energy production, incorporation into cellular membranes, or conversion into eicosanoid signaling molecules.[1]

De Novo Lipogenesis

De novo lipogenesis—or endogenous fatty acid synthesis—gives rise to fatty acids within the cytoplasm of cells.[62] The precursor, acetyl-CoA, is derived from pyruvate (a carbohydrate metabolite), fatty acid beta-oxidation, citrate from the citric acid cycle, and the breakdown of branched-chain amino acids (isoleucine, leucine, and valine).[1,62] Acetyl-CoA carboxylase, a biotin-dependent enzyme, catalyzes the first step, generating malonyl-CoA from acetyl-CoA, and requires carbon dioxide and ATP.[1,5] There are two isoforms of acetyl-CoA carboxylase (ACC)—ACC1 and ACC2—with expressions in different tissues (adipose, skeletal muscles, and heart); however, both are found in the liver.[5] Malonyl-CoA from ACC1 adds 2 carbon atoms to fatty acids, whereas malonyl-CoA from ACC2 is an inhibitor of carnitine palmitoyltransferase I (CPTI)[5,63]:

$$\text{Acetyl-CoA} + \text{CO}_2 + \text{ATP} \xrightarrow{\text{ACC}} \text{Malonyl-CoA}$$

ACC is regulated by several molecules. Insulin activates carboxylase, whereas epinephrine, an end product of de novo lipogenesis (acyl-CoA), and glucagon inactivate carboxylase.[1,5,37] Diet can also regulate ACC synthesis. A prolonged high-carbohydrate diet leads to an increase in ACC synthesis, and a prolonged low-calorie diet decreases ACC synthesis.[1,5]

Malonyl-CoA, generated from acetyl-CoA, extends the length of fatty acids through the addition of two carbons. This process is catalyzed by fatty acid synthase (FASN), a multienzyme protein, generating a saturated acyl chain with additional two carbon groups.[5,62,64] The primary end product of de novo lipogenesis is palmitate (C16:0 or hexadecanoic acid), a 16-carbon saturated fatty acid and stearic acid (C18:0 or octadecanoic acid), in smaller quantities.[64,65] The endogenous fatty acids are stored as triglycerides, incorporated into cell membranes as phospholipids, converted to ATP, or converted to longer fatty acids.[5]

Desaturation

Desaturation is the introduction of a double bond into a fatty acid chain. This process is catalyzed by endoplasmic reticulum membrane-bound enzymes: NADH-cytochrome b5 reductase, cytochrome b5, and a terminal desaturase.[2] Through a complex process of transferring electrons and reduced iron to interact with oxygen, a double bond is formed, releasing two molecules of water.

The location of the double bond depends on the type of enzyme. In humans, the name of the enzyme is delta (Δ) desaturase, which introduces a double bond, counted from the carboxyl end of the fatty acid.[2,8] Three Δ desaturases are found in mammals: Δ-9 desaturase, Δ-6 desaturase, and Δ-5 desaturase.[8] Delta-9 desaturase introduces a double bond between carbons 9 and 10, mainly generating monounsaturated fatty acids.[2,3,8] The primary product of this pathway is oleic acid (18:1 cis-9), which is incorporated into triglycerides and used for phospholipid synthesis.[2] Delta-5 and Δ-6 desaturase enzymes introduce a double bond between carbons 5 and 6 or carbons 6 and 7. These enzymes are responsible for the synthesis of highly unsaturated fatty acids (HUFAs).[2]

HUFAs function to maintain membrane fluidity, triglyceride synthesis, eicosanoid signaling (modulating inflammation and protecting the digestive tract epithelium), and gene expression regulation.[2,3] Unlike plants and lower eukaryotes, mammals lack the ability to add double bonds beyond carbon number 9, making dietary consumption of certain fatty acids metabolically essential.[8] Alpha-linolenic acid (ALA) is an 18-carbon fatty acid containing three double bonds at positions 9, 12, and 15.[11] The location of the double bonds makes this omega-3 fatty acid essential, meaning it must be supplied through dietary intake. ALA gives rise to other omega-3 series fatty acids: eicosapentaenoic acid (20:5cis-5,8,11,14,17 or EPA) and docosahexaenoic acid (22:6cis-4,7,10,13,16,19 or DHA) using desaturase enzymes.[8,11] Linoleic acid (LA) is also an 18-carbon essential fatty acid containing two double bonds at location 9 and 12.[11] LA gives rise to other omega-6 series fatty acids: dihomo-gamma-linolenic acid (C20:3cis-8,11,14 or DGLA) and arachidonic acid (C20:4cis5,8,11,14 or AA) using desaturase enzymes.[8,11]

There are several conditions that influence delta-desaturase activity: genetic polymorphisms, vitamin and mineral deficiencies, and insulin resistance. Delta-9 desaturase is encoded by stearoyl-CoA desaturase (SCD), whereas Δ-6 and Δ-5 desaturase are

encoded by fatty acid desaturase 1 (FADS1) and fatty acid desaturase 2 (FADS2).[2,8,30] These enzyme deficiencies lead to a reduction in beneficial fatty acids (i.e., oleic acid and EPA) while perpetuating chronic diseases (inflammation and cardiovascular disease) associated with the presence or deficiency of nonbeneficial fatty acids.[8] These enzymes are also influenced by the deficiency in cofactors: magnesium, vitamin C, vitamin B_2, vitamin B_6, and vitamin B_9. Therefore appropriate cofactors will improve the availability of various omega-3 and omega-6 series fatty acids.[66] Lastly, insulin enhances Δ-6 and Δ-5 desaturase, increasing eicosanoid production, which, in turn, enhances insulin's action.[2,66] Insulin resistance, therefore, affects these enzymes, leading to a decrease in eicosanoid production and inefficient insulin activity.[2,66]

Chain Elongation

Fatty acid elongation occurs within different compartments of cells, mainly the cytosol, mitochondria, and endoplasmic reticulum or microsomes.[4] In the cytosol, the addition of two carbons occurs as a part of de novo lipogenesis, producing palmitate (C16:0 or hexadecanoic acid) as the primary end product.[4] Within the mitochondria, acetyl-CoA and fatty acyl-CoA increase the carbon length of fatty acids catalyzed by enoyl-CoA reductase.[4] The microsomal fatty acid pathway, the principal pathway for elongation, uses products of de novo lipogenesis and dietary fatty acids to generate longer-chain fatty acids, catalyzed by elongase enzymes (Elovl 1–7).[4,30,67]

In combination with desaturation, elongation enzymes can generate longer-chained fatty acids from the metabolically essential omega-6 (DGLA and AA) and omega-3 fatty acids (EPA and DHA).[30,67] AA converts to 2-series prostaglandins (PGI2, PGE2, PGF2, and PGD2) and thromboxanes (TXA2), plus 4-series leukotrienes (LTA4, LTB4, LTC4, LTD4, and LTE4), contributing to inflammatory conditions.[7,12,30] EPA, DHA, and DGLA convert to anti-inflammatory eicosanoids: 3-series prostaglandins (PGI3, PGE3, PGF3, and PGD3) and thromboxanes (TXA3)s, plus 5-series leukotrienes (LTA5, LTB5, LTC5, and LTD5).[7,12,30]

HEALTH AND DISEASE

Saturated Fatty Acids in Health and Disease

Saturated fatty acids are associated with many chronic conditions, including cardiovascular disease, cancers, and systemic inflammation.[12] However, certain saturated fatty acids, ranging from 12 to 22 carbons, may play an important role in hormone production, cardiovascular health, gene transcription, lipogenesis, apoptosis, cellular membrane structure, and protein signaling.[12,14,16,20]

Dementia and Cognitive Decline

The saturated fatty acid link to dementia, elevated serum low-density lipoproteins (LDLs), and other chronic conditions, was based on an association with elevated serum cholesterol and elevated SFA intake.[68] However, a recent scientific trial failed to identify an association between SFA consumption and an increase in LDL cholesterol, visceral fat, or the incidence of metabolic syndrome, all of which are postulated to contribute to cognitive decline and dementia.[21] This trial evaluated the effects of specific SFAs on lipid metabolism and noticed an alteration in the secretion and clearance of cholesterol.[12] In descending order, the following SFAs raised total cholesterol and LDL cholesterol: myristic acid (tetradecanoic acid C14:0), lauric acid (dodecanoic acid C12:0), and palmitic acid (hexadecanoic acid C16:0), but not stearic acid (octadecanoic acid C18:0) or medium-chain saturated fatty acids. [11,14–16]

Cardiovascular Disease

Because of the link between saturated fatty acids and elevated serum low-density lipoproteins, it was postulated that the dietary intake of saturated fatty acids contributes to cardiovascular disease.[69] However, a comparison of two populations with similar intakes of saturated fatty acids and cholesterol—France and Finland—revealed different cardiovascular mortality rates.[70] This study highlights that certain saturated fatty acids (stearic acid and medium-chained saturated fatty acids less than 12 carbons), and balanced consumption with monounsaturated fatty acids, play an important role in cardiovascular health.[70,71]

Literature focusing on the quality of saturated fatty acids links the intake of stearic acid and medium-chained fatty acids (less than 12 carbons) to increases in larger, more buoyant LDL particles, which present a lower risk for cardiovascular disease compared with smaller, dense LDL particles, despite cholesterol content.[72–74] Therefore common cardiovascular risk factors, such as dyslipidemia, obesity, and metabolic syndrome, are not perpetuated by certain SFAs. Specifically, stearic acid (octadecanoic acid C18:0) and medium-chain saturated fatty acids decrease intestinal cholesterol absorption.[11,14–16,75]

Monounsaturated Fats in Health and Disease

The Mediterranean diet is often considered to be a healthy approach because of the dietary focus on monounsaturated fatty acids (MUFAs) and their association with lower cardiovascular disease risk, improvement in insulin sensitivity, a decreased risk for certain cancers, and positive effects on cognition.[21–23] Increasing MUFA intake and decreasing saturated fatty acids is recommended to achieve the greatest health benefits, specifically oleic acid (18:1 cis-9/omega-9), palmitoleic acid (16:1 cis-7/omega-7), and vaccenic acid (18:1 cis-7/omega-7).[21]

Cardiovascular Health and Metabolic Syndrome

Monounsaturated fatty acids demonstrate cardio-protective effects by promoting a healthy lipid profile, mediating blood pressure, and improving insulin sensitivity and glucose levels.[21,23,76] When MUFAs replace dietary saturated fatty acid intake, improvements in cardiovascular lipid profiles are noted, namely, lowering the ratio of total cholesterol to high-density lipoprotein (HDL) cholesterol.[21,23] In addition, when MUFAs replace dietary carbohydrates and specific saturated fatty acids (myristic acid, lauric acid, and palmitic acid), hypotensive effects, a reduction in heart rate, and improvement in insulin and glycemic control are noted.[21,23] Additionally, dietary MUFAs lead to a decrease in central adiposity, a reduction in visceral fat accumulation, and enhanced beta-cell function.[22,23,77]

Polyunsaturated Fats in Health and Disease

Alpha-linolenic acid (ALA) and linoleic acid (LA) are metabolically essential polyunsaturated fatty acids derived from dietary consumption or supplementation. ALA gives rise to EPA and DHA, whereas LA gives rise to DGLA and AA, after the combined efforts of desaturation and elongation enzymes.[8,11] EPA, DHA, and DGLA convert to anti-inflammatory eicosanoids—3-series prostaglandins (PGI3, PGE3, PGF3, and PGD3) and thromboxanes (TXA3), plus 5-series leukotrienes (LTA5, LTB5, LTC5, and LTD5)—which have been shown to decrease signaling proteins involved in inflammation, tumor necrosis factor alpha (TNF-α), and interleukin 6 (IL-6).[7,12,30] Arachidonic acid contributes to inflammatory conditions through conversion to 2-series prostaglandins (PGI2, PGE2, PGF2, and PGD2) and thromboxanes (TXA2), plus 4-series leukotrienes (LTA4, LTB4, LTC4, LTD4, and LTE4).[7,12,30] Because of the varied actions of polyunsaturated fatty acids, dietary intake guidelines focus on balance: favoring anti-inflammatory PUFAs (EPA, DHA, and DGLA) compared with the inflammatory PUFA (AA) because inflammation is considered a contributing factor, or a mediator, for many chronic conditions.[7,12,31]

Mood and Cognition

Polyunsaturated fatty acids (PUFAs) are present in all cellular membranes. Arachidonic acid and DHA are the PUFAs found in high concentrations within the brain.[78–80] Altered PUFA concentrations in the brain, resulting from dietary deficits in omega-3 and an abundance of omega-6 fatty acids, are thought to play a role in the pathophysiology of mood and cognition. Within brain membranes, PUFAs regulate neurotransmission, inflammation and oxidation, and neuroplasticity.[81] The unsaturated nature of omega-3 fatty acids encourages an increase in membrane fluidity that is necessary for proper functioning of cell membrane proteins, such as neurotransmitter receptors. A change in the omega-3 concentration in the brain has been shown to lead to an increase in serotonin receptors (5-HT_2) and a decrease in dopamine receptors (D_2).[81,82] This leads to altered neurotransmitter metabolism, release, and uptake.[82] Furthermore, proinflammatory cytokines (TNF-alpha and interleukin-6) alter serotonin metabolism and contribute to oxidative damage.[82] Anti-inflammatory omega-3 fatty acids counteract these cytokines, whereas AA contributes to an increase in the production of reactive oxygen species, inducing oxidative damage.[81–84] An increase in oxidative stress also leads to neuronal loss, cognitive impairment, and neurodegenerative diseases.[9] Lastly, omega-3 fatty acids have been shown to improve neuroplasticity through their incorporation into membranes and the generation of neurons.[80,81] Therefore alterations in the balance of AA and omega-3 contribute to mood and cognition. In fact, decreasing the ratio of omega-6 to omega-3 has been shown to reduce symptoms of anxiety and depression in mood disorders.[80–84]

Cardiovascular

Atherosclerosis is characterized by inflammation-derived eicosanoid production from arachidonic acid (AA). Thromboxane-A2 and leukotrienes (LTC4, LTD4, and LTE4) induce vasoconstriction, whereas thromboxane-A2 and leukotriene-B4 activate platelet aggregation and induce free radicals.[7,85,86] Furthermore, these eicosanoids stimulate proinflammatory cytokines (IL-1, IL-2, IL-6, and TNF-α), which contribute to obesity development and poor insulin sensitivity, which are associated with several comorbidities, including cardiovascular disease (coronary artery disease), high blood pressure, peripheral artery disease, and stroke.[31,87,88] The American Heart Association recommends that adults maintain a low ratio of AA to omega-3 fatty acids by consuming fatty fish a minimum of twice per week or 1 gram of EPA and DHA daily.[89]

Cancer

Three-series PG (PGI3, PGE3, PGF3, and PGD3), derived from EPA, DHA, and DGLA, can inhibit the growth of cancer cells through the induction of apoptosis; this is beneficial in proliferative diseases, like cancer.[90] Cancer cells evade apoptosis through several proposed mechanisms: modulation of eicosanoids, influencing gene expression, generation of intracellular oxidative stress, and affecting cellular signaling.[10] A balance of inflammatory-promoting fatty acids, AA, and anti-inflammatory omega-3 plus DGLA may affect cancer-cell–specific apoptosis and enhance conventional medical therapies.[10,91]

Inflammatory Conditions

Omega-3 fatty acids and DGLA give rise to anti-inflammatory eicosanoids (3-series prostaglandins (PGI3, PGE3, PGF3, and PGD3) and thromboxanes (TXA3), plus 5-series leukotrienes (LTA5, LTB5, LTC5, and LTD5).[17,22] Omega-6 AA contributes to inflammation through conversion to 2-series prostaglandins (PGI2, PGE2, PGF2, and PGD2) and thromboxanes (TXA2), plus 4-series leukotrienes (LTA4, LTB4, LTC4, LTD4, and LTE4).[7,12,15,30] Production of proinflammatory eicosanoids (AA) leads to an increase in inflammatory cytokine (IL-6, IL-2, IL-1, and TNF-alpha) production.[7] This contributes to inflammation, which is considered a contributing factor, or mediator, for several chronic conditions, including inflammatory bowel disease (IBD), asthma, osteoporosis/osteopenia, Alzheimer's disease, autoimmune conditions, and psoriasis.[7,27,92–97] Therefore anti-inflammatory fatty acid support can assist in the reduction of disease severity by decreasing proinflammatory cytokine production.

Trans Fatty Acids in Health and Disease

Increased intake of trans fatty acids, specifically those that are synthetic or industrially produced (in foods that contain partially hydrogenated oil, such as packaged snacks, fried foods, and margarine), coincides with adverse cardiovascular lipid profiles, increased inflammation, and endothelial dysfunction.[35] Trans fatty acids inhibit the Δ-6-desaturase enzyme needed to convert metabolically essential fatty acids into longer-chained anti-inflammatory fatty acids (EPA, DHA, and DGLA).[7] Because these anti-inflammatory fatty acids are also incorporated into phospholipids, trans fatty acid consumption negatively affects cell-membrane composition.

Cardiovascular Disease

Trans fatty acid intake corresponds to adverse cardiovascular lipid profile markers, including an elevation in the low-density lipoprotein (LDL) to high-density lipoprotein (HDL)–cholesterol ratio, an increase in triglycerides, an increase in lipoprotein (a), a reduction in LDL particle size, and an increase in LDL particle number.[35,36,98] Trans fatty acids are associated with the proinflammatory markers interleukin-6 (IL-6), high-sensitivity C-reactive protein (hs-CRP), and C-reactive protein (CRP).[35,36,99] These inflammatory substances potentiate atherosclerotic changes, and negatively affect measures of vascular endothelial function.[35] Their contribution to an increase in adipose tissue promotes further inflammatory changes and increased cardiovascular risk.[35]

Liver Dysfunction

An increase in lipid accumulation in hepatocytes, along with oxidative damage, can contribute to the pathophysiology of liver dysfunction.[100] EPA and DHA give rise to anti-inflammatory eicosanoids (3-series prostaglandins [PGI3, PGE3, PGF3 and PGD3] and thromboxanes [TXA3], plus 5-series leukotrienes [LTA5, LTB5, LTC5, and LTD5]), reducing lipid accumulation (fat deposits) and attenuating oxidative damage through up regulation of nuclear factor-like 2 (Nrf2), an anti-oxidant regulating protein protective against oxidative damage.[7,30,101] Additional evidence suggests that functional liver changes (increasing cholesterol accumulation, cholesterol secretion, and lipoproteins), systemic inflammation, and visceral fat accumulation can also contribute to insulin resistance.[102,103]

Mood and Cognition

Increased trans fatty acids, and the resulting decrease in omega-3 fatty acids, can lead to an increase in aggression, irritability, and poor word-recall performance.[104,105] The proposed mechanism of action is the inhibition of Δ-6 desaturase.[105] Because omega-3 fatty acids are incorporated into brain cellular membranes, decreased production can negatively affect neurotransmission, inflammation and oxidation, neuroplasticity, and, thereby, mood and cognition.[81,82,106] These same mechanisms are postulated to contribute to cognitive disorders, including dementia.[107]

TABLE 79.1 Fatty Acid Therapeutic Considerations in Disease

Condition	Therapeutic Considerations
Asthma	Decrease omega-6 and increase omega-3,[108–111] increase GLA,[112,113] and avoid trans fats.[35,36,114]
Cancer	Decrease omega-6 and increase omega-3.[115–119] Some evidence supports a protective effect with increased MUFAs[120,121]; otherwise, opinion is mixed.[122] Decrease saturated FAs[123,124] (opinion remains mixed and association unclear); avoid trans fats.[121,123,125]
Cardiovascular disease	Decrease omega-6 and increase omega-3,[108,126,127] decrease saturated FAs,[128,129] and substitute with MUFAs.[21,130,131]
Cognitive impairment	Decrease omega-6[132] and increase omega-3,[9,132] decrease saturated FAs,[107,132,133] substitute or increase MCTs,[134] increase MUFAs,[133] and avoid trans fats.[105,107]
Depression	Decrease omega-6 and increase omega-3[78,80,84,135]; avoid trans fats.[106]
Diabetes	Omega-6 may benefit,[136] avoid trans fats,[35] omega-3 may benefit (n-3 FAs have been found to positively affect concomitants of diabetes but not the condition directly), decrease saturated FAs,[137,138] and substitute or increase MUFAs.[130,139]
Eczema	Increase n-6 GLAs.[112,113] Some evidence exists for benefits from n-3 fish oils, but the studies are small and mixed. Consider zinc deficiency affecting the conversion of LA into GLA.[140,141]
Irritable bowel disease	Decrease omega-6[142]; increase omega-3.[142–144]
Obesity	Decrease omega-6,[88,145] increase omega-3,[87] increase MUFAs,[146] increase MCFAs.[147–149] SFA has mixed studies. Some show SFA increases adiposity; some show SFA decreases adiposity.
Osteoporosis	Decrease omega-6 and increase omega-3[27,93,150,151]; decrease saturated FAs.[152]
Psoriasis	Decrease omega-6 and increase omega 3.[96,108,126]

FA, fatty acid; *GLA,* gamma-linolenic acid; *MCFA,* medium-chain fatty acid; *MCT,* medium-chain triglyceride; *MUFA,* monounsaturated fatty acid; *SFA,* saturated fatty acid.

CONCLUSION

The basic structure of a fatty acid is a hydrogen-carbon chain with a terminal carboxylic group. Fatty acids are grouped into two main categories, saturated fatty acids and unsaturated fatty acids, based on the presence or absence of double bonds.[11] The number of carbon atoms plus the location of a double bond is the basis for the nomenclature system of fatty acids. A common system is the International Union of Pure and Applied Chemists (IUPAC) system, which uses a Latin numerical system to describe the number of carbon atoms plus the location of double bonds.[13] Although very descriptive, this system can be cumbersome, leading many to use simplified common names.[11]

Fatty acids derived from digestion and small intestine absorption or endogenous production are either converted into energy, stored as triglycerides, incorporated into cellular membranes, or they give rise to longer fatty acids.[1] They yield the greatest energy per gram, compared with other macronutrients, through mitochondria or peroxisome beta-oxidation.[1,37,42] In addition, the body is able to generate fatty acids using acetyl-CoA (de novo lipogenesis) and modify existing fatty acids by adding a double bond (desaturase) or increasing the carbon-chain length (elongation).[2,4,5] The process of elongation and desaturation gives rise to important omega-3 fatty acids—EPA and DHA—from essential alpha-linolenic acid. Omega-6 fatty acids—DGLA and AA—are formed from linoleic acid.[30,67]

The effect of fatty acids on health depends on their structure and quantity, plus the balance in relationship to other fatty acids. The structure, quantity, and balance of fatty acids help ensure proper fluidity and membrane permeability of cells, balance of eicosanoid production, and free-radical generation.[2–10] An impermeable and stiff cellular membrane, inflammation, and oxidative damage are underlying processes that are thought to play a role in the pathophysiology of mood and cognition, cardiovascular disease, inflammatory conditions, obesity, and cancer.[11,12] Therefore the strategic incorporation of fatty acids, through dietary intake or supplementation, can positively influence health. Examples of conditions that may be helped by a proper balance of fatty acids, along with recommendations for achieving a better balance, can be found in Table 79.1.

Fish Oils and Omega-3 Fatty Acids

John Nowicki, ND, Cristiana I. Paul, MS Nutrition, Alexander G. Schauss*, PhD,* and *Joseph E. Pizzorno*, ND*

OUTLINE

INTRODUCTION

Thousands of epidemiological, observational, experimental, and randomized controlled studies have been published on the effects of the omega-3 (ω-3) fatty acids in fish and fish oil on human health. The benefit of these fatty acids extends to an extraordinary number of chronic diseases and to many physiological systems and health outcomes, likely because of the cellular and physiological mechanisms of action. Fish oil is well established as an anti-inflammatory, perhaps one of the most critical, because it supplies the building blocks for the natural resolution phase of inflammation, it favorably affects the genetic expression of nuclear receptors and nuclear transcription factors related to inflammation, and it shifts the production of prostaglandin and leukotrienes to less inflammatory mediators. Fish oil also modulates cellular membrane structures, including their fluidity, which affects protein function, ion permeability, the activity of membrane-associated proteins, and signaling pathways with other cells and intracellular organelles. Rather than treating one specific target, fish oil modulates a variety of cellular pathways to improve function and reduce inflammation, giving it broad-based multisystem benefit. Research has helped clarify which individuals are more likely to benefit from fish oil, as well as more optimal dosing.

Initial scientific evidence of fish oil's benefits first appeared in the late 1970s, when it was claimed that fish oil consumption among Greenland Eskimos and other fish-eating populations might convey a lifetime protective effect against coronary heart disease (CHD).[1–3] A large study in the United States, the Diet and Reinfarction Trial (DART),[4,5] and two studies in Europe, the Gruppo Italiano per lo Studio della Sopravvivenza nell'Infarto miocardico (GISSI)-Prevenzione Trial and the Lyon Diet Heart Study,[6–8] supported the observational evidence from these indigenous populations and demonstrated that by increasing dietary ω-3 fatty acid intake, a significant decrease in ischemic heart disease occurred. In addition, the Japan Eicosapentaenoic Acid (EPA) Lipid Intervention Study (JELIS) trial randomized nearly 20,000 individuals to either a statin or a statin plus EPA and found a 19% reduction in major coronary events in patients using supplemental EPA, as well as a significant reduction in stroke.[9,10] In 2010 the Heart and Soul study documented a significantly lower risk of overall mortality in individuals with higher blood levels of EPA and docosahexaenoic acid (DHA).[11] This latter study is particularly important because it suggested that we have a biomarker for risk assessment, one that may avoid some of the biases (e.g., food frequency questionnaires, variability in fish oil products, etc.).

These studies and many others have had a profound effect on public health policymakers' perceptions of the importance of fish and fish oil to human health. For example, on February 8, 2002, the U.S. Food and Drug Administration (FDA) announced that it would permit the claim "consumption of omega-3 fatty acids may reduce the risk of CHD" to appear on labels of ω-3 fatty acid supplements containing a dose level of

DHA and EPA of up to 2000 mg/day. The FDA's decision to permit such a claim is significant and timely, in that by 2000, 1 million Americans were reported to have heart attacks annually. Based on these and several other studies, it is now estimated that this one change in diet could save at least 150,000 people annually from fatal heart attacks.[12–17] Of course, increased daily intake of 5 to 7 servings of fruits, vegetables, and nuts rich in antioxidants will also reduce the incidence of heart attacks.

In 2002 the American Heart Association (AHA) released a position paper advocating the consumption of oily fish twice per week among those without heart disease and at least 1 g/day of EPA/DHA among those with established coronary artery disease (CAD).[18] This marks the first time the AHA recommended a nutritional supplement for CAD prevention.

Although most clearly established for the prevention and treatment of cardiovascular disease, the benefit of dietary fish oil and fish oil supplements extends much more broadly to other conditions, including autoimmune, inflammatory, neurological, gastrointestinal, and respiratory conditions. For example, the EPA and DHA found in fish oil were shown in various studies to reduce the pain of rheumatoid arthritis (RA), menstrual cramps by decreasing inflammation, the risk of premature delivery in pregnancy, and low birth weights. Beneficial effects were also reported in the treatment or management of bipolar (manic-depressive) disorder, mild to moderate depression, Raynaud disease, systemic lupus erythematosus (SLE), immunoglobulin-A (IgA) nephropathy, chronic fatigue syndrome, irritable bowel disease, kidney stones, cystic fibrosis, psoriasis, and cancer. Additionally, DHA was shown to be important for neurogenesis of neuronal synapses and healthy eye development of fetuses and infants. Perhaps most importantly, fish oil has the potential to improve overall physiological function and well-being, not because it targets one specific abnormality but because it reduces systemic inflammation and supports optimal cellular function.

DESCRIPTION

Marine life is generally rich in two ω-3 fatty acids (also referred to as n-3 fatty acids), EPA and DHA, which enter the food chain through phytoplankton. These long-chained and highly polyunsaturated fatty acids (PUFAs) contain, respectively, 20 and 22 carbons and 5 and 6 double bonds, also referred to as 20:5n-3 PUFA and 22:6n-3 PUFA (Fig. 80.1). The 20:5n-3 PUFAs and 22:6n-3 PUFAs are abundant in shellfish, sea mammals, and fish, hence the reason Greenland Eskimos' diet is rich in EPA and DHA. By comparison, EPA and DHA levels are low or absent in domesticated land animals, in part because mammals lack the enzymes needed to insert a double bond in the n-6 or n-3 position. Thus, linoleic acid and α-linolenic acid (ALA), rich in several plant oils, are essential fatty acids and, slowly and with significant genetic variation, are enzymatically converted to EPA and DHA. Fish oil from herring, cod liver, wild salmon, mackerel, and sardines is particularly rich in ω-3 fatty acids containing EPA and DHA. Table 80.1[19] lists the relative concentration of fatty acids in various common fish species.

Wild-Caught Versus Farmed Fish

The habitat in which fish grow has a major effect on their fatty acid composition.[20] In the wild, fish consume food sources that contain high levels of ALA (18:3n-3). Fish raised in "fish farms" deserve mention. It has been reported that salmon raised in fish farms receive a steady diet of synthetic pigment to give them a rich pink hue; otherwise, they would be unappetizing given their rather morbid, pale-gray appearance. In the natural ocean environment, phytoplankton, which are rich in EPA and DHA, form the basis of the food chain for salmon and contribute to its pink color. Commercial fish foods contain less DHA and EPA and therefore lower concentrations of ω-3 fatty acids. Studies showed that wild fish have higher concentrations of ω-3 fatty acids than pond-reared and/or cultured fish grown in fish farms and fed commercial feedstuffs that are devoid of EPA and DHA.[21] Additionally, although wild fish are also increasingly contaminated, farmed fish often contain higher levels of toxins, such as organochlorines, brominated flame retardants, and methylmercury, particularly when they are also given fish meal as a food source.[22,23] Of particular concern, farmed fish typically have substantial contamination with polychlorinated biphenyls (PCBs) and other persistent organic pollutants (POPs). Research has shown that this contamination is from their feed, as well demonstrated in Fig. 80.2.

TABLE 80.1 Relative Concentration of Fatty Acids in Fish Oils and Mercury (Hg) in Fish

OIL	CHOLESTEROL (mg/100 g)	UNSATURATED			N-3 PUFAS		Hg (mcg/g)
		Mono- (%)	Poly- (%)	18:3 (%)	20:5 (%)	22:6 (%)

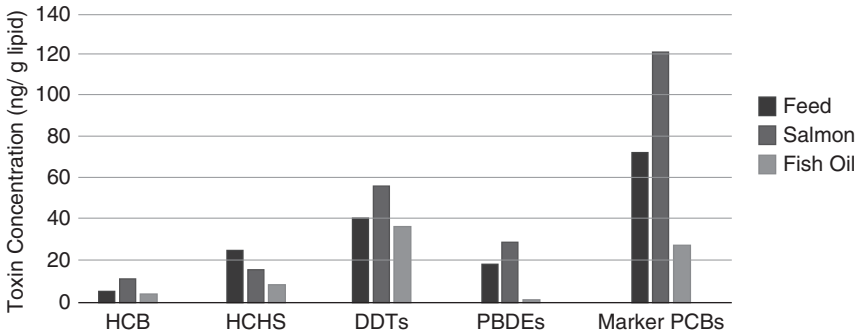

Fig. 80.2 The persistent organic pollutants in farmed fish are from their feed. (From Jacobs MN, Covaci A, Schepens P. Investigation of selected persistent organic pollutants in farmed Atlantic salmon *(Salmo salar),* salmon aquaculture feed, and fish oil components of the feed. *Environ Sci Technol.* 2002 Jul 1;36[13]:2797–2805.)

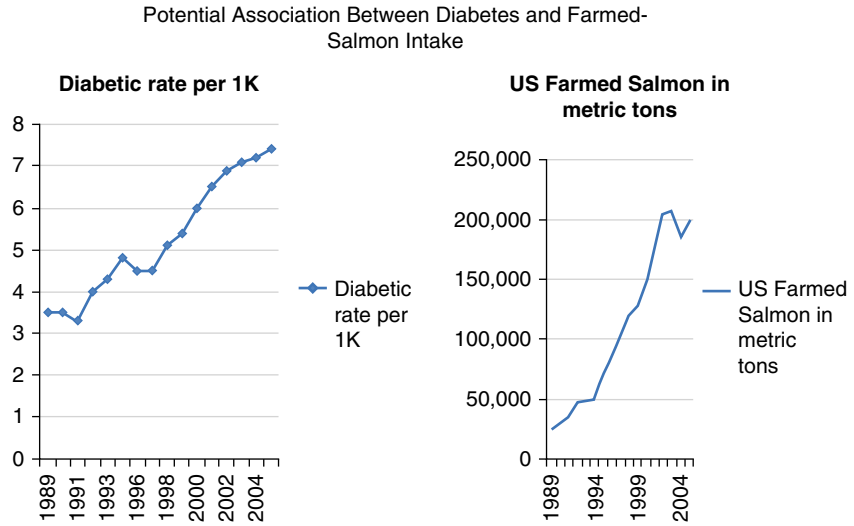

Fig. 80.3 Association between polychlorinated biphenyl (PCB) exposure from farmed-salmon and diabetes. (From Ibrahim MM, Fjaere E, Lock EJ, Naville D, Amlund H, et al. Chronic consumption of farmed salmon containing persistent organic pollutants causes insulin resistance and obesity in mice. *PLoS One.* 2011;6[9]:e25170.)

Although fish oil is associated with a reduction in insulin resistance, fish intake is now associated with an increased risk of diabetes.[24] Mice fed either a very high-fat diet or a Western diet, both of which included farmed salmon fillets, developed insulin resistance and obesity, and these negative effects were shown to be, in part, mediated by the presence of POPs in fatty fish.[25] Fig. 80.3 shows a compelling association between PCB exposure and diabetes incidence.

Other Sources of Omega-3 Oils

For individuals who do not or cannot consume seafood, foods such as tofu, canola oil, black currant oil, flaxseed oil (the best nonfish source), nuts, and soybeans are important sources of ALA (18:3n-3). However, soy-derived oils and foods and most nuts contain large amounts of ω-6 fatty acids that can reduce some of the therapeutic benefits of the ω-3 fatty acids, so finding a prudent balance between ω-3 and ω-6 fatty acids is suggested. Additionally, one analysis indicated that a dramatic 1000-fold increase in the consumption of soybean oil over the past century increased ALA intake, but it was offset by the increase in linoleic acid and therefore likely to depress tissue levels of EPA and DHA.[26] A review found that the fatty acids found in fish oil, particularly DHA, are substantially lower in tissues of vegetarians and vegans, including plasma levels, breast milk, and blood cells.[27] Fortunately, organically derived supplemental DHA and EPA from algae is now available for those wishing to avoid fish consumption.[28]

Dietary Requirement

The first suspected case of ω-3 fatty acid deficiency in humans was not reported until 1988, and the optimal intake of ω-3 fatty acids, both plant and marine based, is still not well established.[29] No Adequate Intakes (AIs) or Dietary Reference Intakes (DRIs) have been set so far by the Institute of Medicine for EPA and DHA or the long-chain ω-6 arachidonic acid (AA), although it has established AIs for the short-chain ω-3 (ALA of 1.1 g for women and 1.6 g for men). There are several factors that complicate the establishment of clear dietary requirements, and several lines of evidence offer some guidance. Evolutionary intakes of ω-3 fatty acids ALA and EPA+DHA estimated by Kuipers et al.[30] suggest a probable value of 9 g/day (range 8.7–9.3g) of ALA and 3.9 g/day (range 0.8–9.7g) of EPA+DHA per 2000 Kcal/day.

One of the factors involved is the proportional intake of ω-6 fatty acids to ω-3 fatty acids. It appears that the ratio of these two types of fatty acids, as well as their total intake, is important in determining health outcomes, and a change in both variables has occurred in Western diets over the past 150 years. Currently, the ratio of n-6:n-3 fatty acids in a typical Western diet is 15 to 20:1, whereas in wild animals, as well as humans throughout most of evolutionary history, it has been approximately 1:1.[31] This dramatically shifted ratio has skewed the metabolic products (prostaglandins, thromboxanes, leukotrienes, hydroxy fatty acids, and lipoxins) derived from AA (vs. n-3 acids) to favor a more inflammatory, prothrombotic, proaggregatory, provasoconstrictive, and proproliferative physiological state. The n-6:n-3 ratio was found to be important not only to the pathogenesis of cardiovascular diseases but also in cancer, in inflammatory and autoimmune diseases, and in brain function.[32]

One example that highlights the importance of the ratio between oils was demonstrated in a study of more than 400 healthy men and 450 healthy women. Researchers found that only at high n-6 intakes were DHA and EPA intakes inversely associated with some markers of inflammation, and a combination of both was associated with the lowest inflammation.[33] Similarly, the intake of n-3 fatty acids in women with a high intake of n-6 fatty acids has an inverse relationship with the risk of breast cancer.[34] This was confirmed in a very large prospective cohort study of Chinese women (Shanghai Women's Health Study), in which the relative intake was more important to the risk of breast cancer than total intake.[35] In other words, the consequence of low n-3 intake is particularly important given a background of high n-6 intake.

Another contributing factor may be variations in the activity of enzymes involved in eicosanoid synthesis. For example, there is some conversion from ALA to EPA and DHA, but this conversion is limited and has significant interindividual variation.[36] This conversion from ALA is estimated to be approximately 5% for EPA and less than 0.5% for DHA, and the desaturase enzymes involved are influenced by smoking, gender, age, trans fat intake, and n-6 fatty acid intake. One study found that despite large differences in the intake of n-3 fatty acids between fish eaters and nonfish eaters, the plasma levels were much closer than expected, likely due to increased conversion.[37] Also of importance is the individual variability of the activity of enzymes involved in mediating the physiological effects of fish oil. For example, variants in the 5-lipoxygenase *(ALOX5)* gene appear to modify the effects of fish oil on cardiovascular risk, as do polymorphisms in peroxisome proliferator–activated receptor-α (PPAR-α).[38–40]

Despite these limitations, most recommendations suggest a desired DHA and EPA total intake of approximately 0.5 to 1 g/day as preventative therapy, with higher doses indicated for treating specific conditions. A ratio of 2:1 to 1:2 EPA/DHA is often advocated, depending on therapeutic goals. For example, the Technical Committee on Dietary Lipids of the International Life Sciences Institute (North America) suggests an intake between 250 and 500 mg DHA+EPA per day for CAD prevention. Currently, even a 500-mg target would require at least a tripling of the current intake in most Western countries.[41]

Because the concentration of EPA and DHA in fish can vary depending on the growth environment, fish oil supplements can offer a viable and reliable source of ω-3 fatty acids standardized around the content of EPA and DHA (see Table 80.3). Most fish oil capsules contain between 300 and 500 mg EPA+DHA fatty acids per gram, whereas some are concentrated to contain as much as 700 mg EPA+DHA per gram. Patients using fish oil at the therapeutic levels discussed herein may require between 15 and 30 capsules daily to derive the described benefits, depending on their DHA+EPA content. At 9 calories/g of oil, this can represent a significant increase in caloric intake and may necessitate an increase in energy expenditure to avoid weight gain. We recommend using fish oil supplements that are highly concentrated to decrease unnecessary calorie intake.

EPA- and DHA-rich fish oil should be kept in capsules (e.g., soft gelatin with minimal plasticizer content[42]; see later discussion under "Oxidation") capable of providing an oxygen barrier. Otherwise, toxic lipid peroxides (e.g., malondialdehyde) and anisidine isomers may form. Encapsulated liquid sources generally do not have this protection unless they contain antioxidants. Encapsulated products typically contain fish oil, not fish liver oil. This distinction is important because fish liver oil contains the fat-soluble vitamins that, if taken in excessive amounts, can cause vitamin A toxicity, although some brands are reducing the vitamin A content during processing.

Explaining Inconsistent Results of Fish Oil Supplementation Trials

Several articles in the fish oil literature have reported equivocal or contradictory results. Many of these differences in outcomes can be explained by the use of olive oil as a placebo or the lack of control for saturated or ω-6 fatty acid intake, as well as an insufficient dose of n-3 fatty acids. For example, in the Alpha Omega trial, nearly 5000 patients with a previous myocardial infarction were given only 400 mg DHA/EPA, a dose less than one half that used in previous trials.[43] Not surprisingly, this low dose did not improve the rate of major cardiovascular events. It also raised plasma levels to a much lower degree than in previous trials that used a higher dosage.

Olive oil cannot be considered an inert placebo in trials that investigate effects on platelet function or CHD risk. Several studies showed that olive oil supplementation has similar inhibitory effects on various aspects of platelet function, including decreased platelet aggregation and thromboxane A_2 (TXA_2) release, increased platelet membrane oleic acid content, and decreased platelet membrane AA content.[44,45]

Further, an excess of oleic acid impairs incorporation of AA into platelet phospholipids.

An additional consideration that is often ignored is the background intake of the enrolled study population. For example, an increase in n-3 intake in Western populations showed a reduction in the risk of sudden death, a benefit not consistently shown in Japanese populations, where the background intake is much higher.[46]

The lack of a relevant biomarker, such as the ω-3 index (discussed in the following section), and the lack of consideration of an individual's genetic response are also variables that certainly contribute to the appearance of ineffectiveness. For example, studies that use food frequency questionnaires often do not accurately gauge n-3 intake. Additionally, they do not consider differences in fatty acid metabolism that are vital to determining more functional measures. An analysis of more than 700 individuals found that supplements and the intake of EPA-/DHA-rich food explained less than one half of the variability in red blood cell content, which may be due to the individual intake of linoleic and/or arachidonic acid because they all compete for incorporation in the cell membranes.[47]

Another possible complicating factor is the squalene found in olive oil and some deep-water fishes but not in other vegetable oils.[48] Other problems include the differing ratios of fatty acids, the position of the fatty acids on the glycerol backbone, and the susceptibility to peroxidation of the various fish oil preparations.[49]

Also, overprocessing of fish oil supplements can result in a loss of the fish oil's active constituents and, hence, an attendant decrease in its efficacy. This was demonstrated in at least two studies that looked at such variables as how processing affects levels of triglycerides, cholesterol, lipoprotein(a), atherogenic index, and fibrinogen after fish oil supplementation.[50,51]

PHARMACOLOGY

The effects of supplemental and dietary unsaturated fatty acids appear to be mediated through changes in serum lipids, altered ratios of prostaglandins, decreased platelet aggregation, and modification of cell membrane activity.[49] Omega-3 polyunsaturated fatty acids cause translocation and activation of endothelial nitric oxide synthase (eNOS) into the cytosol, resulting in vasodilation and improved endothelial function.[52] Additionally, n-3 fatty acids have been shown to modify gene expression and to directly reduce inflammation by binding to n-3–specific receptors. Omega-3 fatty acids (EPA, DHA, and docosapentaenoic acid [DPA]) are also the metabolic precursors to the resolvins, lipoxins, and protectins now shown to be essential to the resolution of inflammation.

In 2010 researchers published a breakthrough study in the journal *Cell,* which for the first time identified a new G-protein–coupled receptor, GPR120, that "functions as an n-3 FA receptor/sensor in proinflammatory macrophages and mature adipocytes."[53] Through this receptor, DHA and EPA mediated robust anti-inflammatory signaling, inhibiting both the toll-like receptor and tumor necrosis factor-α (TNF-α) pathways. This finding was quite important, in part because insulin resistance is modified by these pathways, and because these same researchers were able to document a direct insulin-sensitizing effect by EPA and DHA mediated via this receptor. This provides a direct and specific mechanism for improving insulin sensitivity.

Fish oils have also been shown to be the precursors for the modulators of the resolution phase of inflammation.[54] Resolvins, derived from EPA, and protectins, derived from DHA, have been shown to be crucial to both the resolution of inflammation and the initiation of tissue repair in multiple body systems. This modulation of inflammation by fish oil has also dramatically changed the way inflammation is viewed. It is now understood to be a carefully orchestrated active process, dependent on adequate intake of eicosanoid precursors, rather than a passive process.

Fish oils also appear to reduce triglycerides and decrease the production of the prothrombotic substance TXA_2 by occupying TXA_2 receptors and enhancing the production of the platelet antiaggregatory substance prostacyclin. These actions play an important role in inflammation, atherogenesis, thrombosis, and CHD. Fish meals that provide an average of 3.6 g/day of ω-3 fatty acids reduce platelet aggregation and platelet TXB_2 responses.[55] Significant decreases in platelet sensitivity to collagen, serum TXB_2 levels, and urinary TXB_2 metabolites were observed after ω-3 fatty acid treatment.[56] EPA supplementation was shown to decrease synthesis of the ω-6 platelet agonist TXA_2 coincident with formation of the inactive ω-3 form, TXA_3.[57,58] A longitudinal study showed a pronounced action of dietary ω-3 fatty acids to diminish platelet formation and endothelial deposition, which could lead to thrombosis.[59]

Through the vasodilatory effects of prostaglandin I3 (PGI_3), fish oils may improve peripheral circulation, thereby assisting very low-density lipoprotein (VLDL) cholesterol removal. This may be accomplished by altering membrane fluidity in a specific manner, thus affecting the activity of membrane-bound enzymes and resulting in changes in receptor activity, specificity, and signal transduction. The incorporation of fish oil into membranes was shown to have direct clinical consequences. For example, in a case-control study of more than 300 patients, a higher ω-3 fatty acid content in red blood cell membranes was associated with a 70% risk reduction in cardiac arrest.[60] Evidence also suggests that fish oils decrease hepatic synthesis of fatty acids and triglycerides and reduce secretion of VLDL cholesterol while displacing AA from tissue phospholipids. This results in ω-3 fatty acid levels that inhibit thromboxane synthesis.

Researchers noted that fish oil effects are selective. EPA and DHA not only displace AA from phospholipid pools and inhibit cyclooxygenase, but EPA also becomes a preferred substrate for cyclooxygenase when peroxide tone is high. This results in decreased production of the vasoactive and aggregatory prostacyclin (PGI_2) and increased production of PGI_3, which has more potent antiaggregatory effects. According to some researchers, increased bleeding time is due to either less TXA_2 or higher prostacyclin I_3 levels,[57] although others contend that EPA conversion to PGI_3 is the primary cause.[61] Many researchers believe this change is one of the primary factors that decrease the risk of atherosclerosis and thrombosis.[62–68] These findings may explain some of the epidemiological evidence of decreased CAD and prolonged bleeding time seen in some Eskimos and in those Japanese who eat a diet rich in fish.[69] Analyses also indicated that increases in bleeding time might have been exaggerated, with data pointing to minimal, if any, effect.

Fish oils rich in EPA and DHA were also found to suppress the production of inflammatory mediators found in patients with RA and psoriasis. The anti-inflammatory effect of the ω-3 fatty acids is probably due to reduced production of leukotrienes, interleukin-2 (IL-2), and TNF-α, all principal mediators of inflammation. One study found that the ability of fish oil to decrease TNF-α production was influenced by an inherent TNF-α production and by polymorphisms in the TNF-α and lymphotoxin α genes (also known as TNF-β).[70]

In relation to CAD, ingestion of fish oil and its effect on platelets, erythrocytes, neutrophils, monocytes, and liver cells are important in explaining its benefits. The increased concentrations of EPA and DHA from the ingestion of fish oil were shown to do the following:

- Decrease production of prostaglandin E2 (PGE2) metabolites
- Decrease production of TXA_2 (an active vasoconstrictor and platelet aggregator)

- Increase prostacyclin PGI3 (an active vasodilator and inhibitor of platelet aggregation)
- Increase production of leukotriene B5 (a weak inducer of inflammation; weak chemotactic agent)
- Decrease production of leukotriene B4 (a weak inducer of inflammation; inducer of leukocyte adherence and chemotaxis)

Fish oil, particularly DHA, was shown to modify mitochondrial membrane composition, improving mitochondrial function. DHA reduced the vulnerability to the opening of the mitochondrial permeability transition pore, a pathological feature of heart failure.[71,72]

CLINICAL APPLICATIONS

Cardiovascular Disease

No other clinical application for fish oil has been as well studied as cardiovascular disease, including hyperlipidemia, atherosclerosis, stroke, myocardial infarction, and atrial fibrillation. Perhaps because n-3 fatty acids inhibit the development and progression of atherosclerosis and reduce the systemic inflammation that underlies so much of cardiovascular pathology, fish oil has demonstrated benefit for a wide range of applications.[73] What has emerged as a potential biomarker for heart disease is the use of the ω-3 index, the sum of EPA and DHA expressed as a percentage of the total fatty acid content of red blood cell membranes. It was shown to be inversely associated with the risk for both fatal and nonfatal cardiac events, allowing clinicians to assess individual risk for their patients, and might serve as a tool for monitoring therapeutic efficacy.[74,75]

In a study of nearly 800 patients, the ω-3 index was associated with a 69% risk reduction in those with the highest compared with lowest levels for acute coronary syndrome, with an inverse linear relationship between risk and DHA/EPA levels. This amounts to a threefold greater risk in those with a low ω-3 index than those with a high index. In this study, "low" levels were defined as less than 4%, whereas "high" levels were more than 8%, suggesting a possible therapeutic target.[76] In the Heart and Soul study mentioned previously, those with an ω-3 index above the median had a 27% decreased risk of death compared with those with a baseline ω-3 index below the median, which was unaffected by adjustment for both traditional cardiovascular risk factors and inflammatory markers.[11] This was a prospective cohort study of nearly 1000 patients with stable CHD. Interestingly, in a study published in *Journal of the American Medical Association* in 2010, a subset of patients recruited from the Heart and Soul study was found to have an inverse relationship between the ω-3 index and the rate of telomere shortening over a 5-year period.[77]

Certainly, one population that warrants increased intake of DHA and EPA is those with an uncommon (6% of the population) genetic variant that predisposes them to rapid atherosclerotic progression. Individuals with two variants of the ALOX5 promoter have a greater risk for atherosclerosis, marked by an increase in carotid intima–media thickness. Increased consumption of n-6 fatty acids exacerbated this condition, whereas a higher intake of n-3 fatty acids blunted this atherogenic effect.[39]

Mechanisms of Cardiovascular Benefit

The EPA and DHA in fish oil inhibit the development of atherosclerosis, which can reduce the risk of multiple permutations of cardiovascular disease.[60] As discussed in the "Pharmacology" section, fish oil acts through diverse physiological mechanisms, related to resolution and inhibition of inflammatory pathways, as well as modulation of cellular membrane fluidity (Fig. 80.4). For example, EPA and DHA were shown to increase cell membrane fluidity, affecting intra- and intercellular signaling and ultimately improving cell function.[78,79] EPA and DHA were also shown to stimulate endothelial production of nitric acid, decrease production of inflammatory cytokines and IL-1, and inhibit monocyte migration into atherosclerotic plaques. EPA and DHA also affect gene expression, at least partly via activation of PPARs. In a randomized and double-blinded trial that enrolled more than 100 participants, supplementation with 1800 mg/day of EPA/DHA was shown to change the expression of more than 1040 genes in peripheral blood mononuclear cells, including genes involved in atherogenesis and inflammation, such as nuclear factor-κβ target genes, proinflammatory cytokines, nitric oxide synthase 3, and genes involved in eicosanoid synthesis.[80]

Several biologically active compounds derived from EPA/DHA have been elucidated through newly discovered pathways. These are potent mediators of cellular function, with anti-inflammatory actions and actions that promote the resolution of inflammation, and are thus known as "resolution-phase interaction products" or resolvins, as well as maresins.[81,82] The anti-inflammatory component of fish oil may at least partly explain its ability to slow the progression of atherosclerosis, as well as to stabilize atherosclerotic plaques against rupture.[83,84] Atherosclerotic plaques have been shown to incorporate EPA, and a higher EPA content was associated with greater plaque stability and a reduced number of foam and T cells.[85]

Fish oil also demonstrated lipid-lowering effects, likely mediated partly through the inhibition of VLDL and triglyceride synthesis without reducing the production of high-density lipoprotein (HDL) cholesterol.[86,87] The triglyceride-lowering effect appears to be dose dependent, with a greater effect on those with highly elevated triglycerides. This benefit is not seen with plant-source oils containing land-based α-linolenic fatty acid–rich polyunsaturated fat sources (e.g., flaxseed oil) or via reduction of intake of animal-source saturated fatty acids.[68] In a review of more than 40 studies that examined the use of fish oils for either primary or secondary prevention, fish oils were found to reduce the rates of all-cause mortality, cardiac and sudden death, and perhaps stroke.[88]

As mentioned previously, the AHA for the first time endorsed a nutritional supplement for cardiovascular disease prevention in 2002, advocating consumption of oily fish twice per week among those without heart disease, at least 1 g/day of EPA/DHA among those with established CAD, and 2 to 4 g EPA/DHA for individuals with hypertriglyceridemia.[18] However, there appears to be substantial variability between dietary intake and the ω-3 index (ω-3 blood levels), the latter of which was inversely associated with total mortality among individuals with CAD.[11] Optimal intake might be more appropriately determined using the ω-3 index as a benchmark, with evidence suggesting a target of 8% or higher.[89]

Elevated Serum Lipids

The most consistent effect of fish oils on serum lipids is a reduction in total triglycerides and VLDL cholesterol, especially in patients with severe hypertriglyceridemia. In general, dietary fish oils appear to both reduce undesirable serum-circulating fats and decrease the production of the prothrombotic thromboxanes. In most studies, fish oil supplementation causes a significant reduction in VLDL cholesterol, plasma triglycerides, plasma cholesterol, and LDL cholesterol. In hypertriglyceridemic patients, fish oil supplementation typically results in a significant decline in VLDL cholesterol levels because large decreases in triglyceride levels lead to a decrease in VLDLs.[67,90–93]

Studies also showed that fish oil induced favorable changes in LDL size. It is well established that plasma levels of small, dense LDL cholesterol are associated with plasma triglyceride concentrations, are more atherogenic, and are markers for cardiovascular disease risk.[94,95] Data from the Quantification of the Optimal n-6/n-3 ratio in the UK Diet

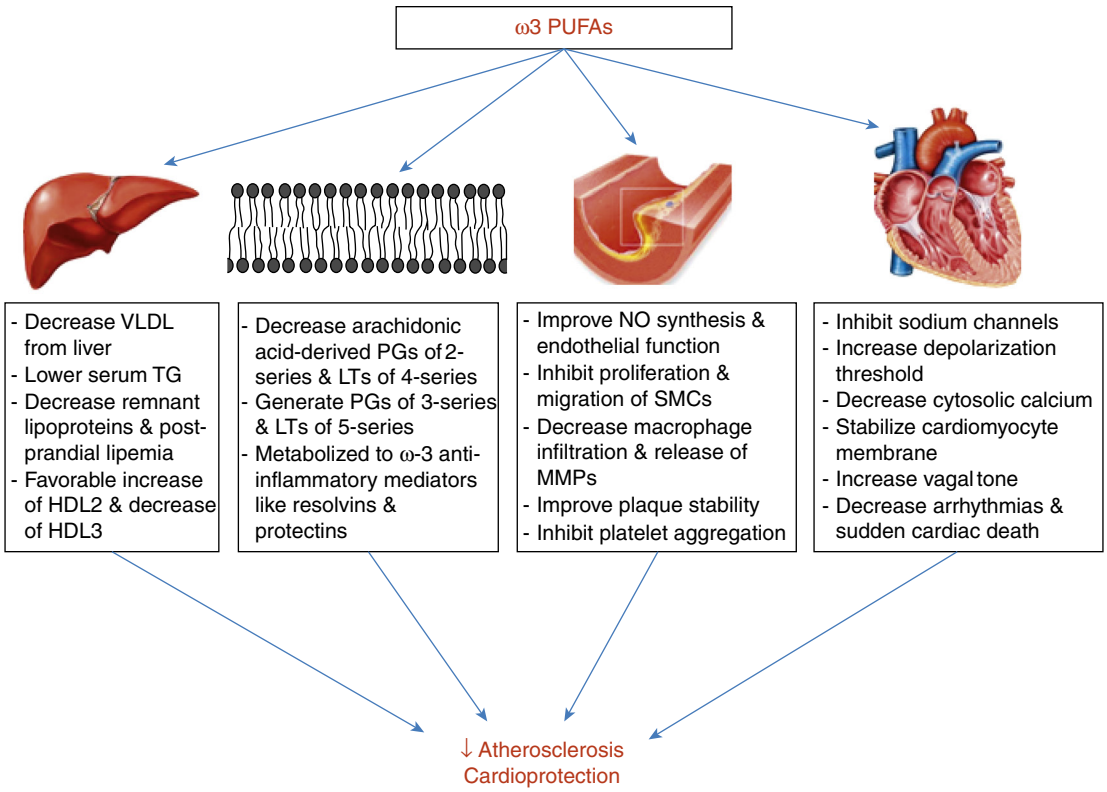

Fig. 80.4 Mechanisms of omega-3 fatty acids in cardioprotection. (From Goel A, Pothineni NV, Singhal M, Paydak H, Saldeen T, Mehta JL. Fish, fish oils and cardioprotection: promise of fish tale? *Int J Molecular Sci.* 2018;19[12]:ii: E3003.)

(OPTILIP) study indicated that DHA and EPA reduced the proportion of the small, dense LDL cholesterol, even if no changes were seen in total LDL cholesterol levels.[96] Data from JELIS, a large-scale intervention trial, found that EPA (1800 mg/day) was particularly effective in patients with the potent combination of risk factors of low HDL cholesterol and elevated triglycerides, reducing the risk of CAD in this group by 53%.[97]

Some studies did not find decreases of total cholesterol or LDL cholesterol after fish oil supplementation.[98–101] However, these equivocal studies used olive oil as a placebo, which, as discussed earlier, is a confounder. Additionally, beneficial changes to subfractions and particle size with DHA supplementation (3 g/day) were cited in one randomized trial, despite no significant effect on total LDL cholesterol levels.[102] Furthermore, an inverse relationship was found between serum EPA levels and oxidized LDL. Oxidized LDL is emerging as an important biomarker of cardiovascular risk and is a very early and critical step in the development of atherosclerosis.[103,104]

For patients with elevated serum cholesterol (>7.75 mmol/L = 300 mg/dL) or triglycerides (>5.64 mmol/L = 500 mg/dL), there is sufficient evidence to consider fish oil supplementation of 5 to 10 g/day if lower dosages (2–4 g/day) are not effective.[105] In one study of 365 patients, supplementation with 10 mL/day (9.2 g) of MaxEPA resulted in significant reductions in triglyceride levels, which were maintained over 4 years.[106] Continuing reductions were observed in persons remaining in the study for more than 4 years. The authors concluded that for triglycerides to remain depressed, it seems necessary to maintain a daily intake of 9.2 g MaxEPA (1 g MaxEPA contains 180 mg EPA + 180 mg DHA).

Fish oil (4 g/day) was also shown to improve the non-HDL cholesterol–lowering effect when combined with statin medications. Increases in HDL cholesterol, as well as decreases in total cholesterol and triglyceride levels, were seen when combined with atorvastatin versus atorvastatin alone.[107] Similar results were also documented when used with simvastatin.[105]

Hypertension

In one double-blind placebo-controlled randomized clinical trial, healthy men and women consumed a control oil or fish oil providing 0.7 g or 1.8 g EPA + DHA per day (intakes achievable through diet), in random order, each for 8 weeks to examine the effect of fish oil on systolic and diastolic blood pressure (BP).[108] Findings indicated that in adults with isolated systolic hypertension, daily doses of EPA + DHA as low as 0.7 g showed clinically meaningful BP reductions.

A meta-analysis of more than 30 trials (22 double blinded) investigating the effect of fish oils in reducing blood pressure found that higher doses (median dose 3.7 g/day) were associated with a reduction in systolic blood pressure of 2.1 mm Hg and diastolic blood pressure of 1.6 mm Hg, although lower doses (<0.5 g/day) might not have an effect. The BP-lowering effect of fish oil was found to be greater among those aged 45+, as well as among those with hypertension versus normotension.[109] Another review cited a number of mechanisms for a hypotensive effect of fish oil, including changes in eicosanoids, blood viscosity, hormonal cellular response, and renin secretion, as well as a decreased response to vasopressors,[110] although they also concluded the effect was likely to be small at a dose of 2 to 4 g fish oil per day.

Epidemiological evidence indicates a hypotensive effect of dietary fish consumption. The largest study is probably the International Study of Macro- and Micronutrients and Blood Pressure (INTERMAP) trial, an international cross-sectional epidemiological study of nearly 5000 men and women living in China, Japan, United Kingdom, and the United States. Researchers found an inverse relationship between total dietary n-3 fatty acids and systolic and diastolic BP, in both those with

hypertension and those with normotension, although the effect was considered small.[111]

Fish oil seems to have hypotensive effects, ranging from limited (dosages of 5 g/day or less) to substantially larger dosages,[55,68,112–119] although there is some conflicting evidence.[105] It has been proposed that fish oil depresses vascular response to the hormones involved in hypertension.[105] Another suggestion is that fish oil acts by increasing vasodilatory prostaglandins PGI_1 and PGI_3 and that this increase accounts for observed reductions in blood pressure.[105]

To test this hypothesis, one study examined the effect of fish oil on BP in men with mild essential hypertension.[120] One group received 10 mL of fish oil (3 g of ω-3 fatty acids), a second group received 50 mL (9 g of EPA and 6 g of DHA), a third group received 50 mL of safflower oil (39 g of ω-6 fatty acids), and a fourth group received 50 mL of a mixture of coconut, olive, and safflower oils. The latter group represented the approximate amount and ratio of fatty acids consumed in the average American diet (39% saturated fat, 46% monounsaturated fat, and 15% polyunsaturated fat). The group receiving the highest dose of fish oil (50 mL) had an average reduction of 6.5 mm Hg in systolic pressure and 4.4 mm Hg in diastolic pressure. None of the other groups, including the low fish oil–supplemented group, demonstrated BP reductions in the aggregate. The study did not find the expected association between increased production of PGI_1 and PGI_3 and sustained reduction in BP. This suggests that vasodilatory prostaglandins are probably not the primary mediators of BP reduction by fish oil consumption, although they may play a role.

Another proposed mechanism is that fish oils may facilitate excretion of sodium and fluid by the kidneys. This was supported by an unpublished double-blind, crossover study in which researchers placed healthy, nonhypertensive men and women on a diet supplemented with approximately 1 g/day of PUFAs for 28 days.[121] Each participant received capsules with either fish oil or safflower oil. The fish oil dose was similar to the amount consumed in a single daily serving of tuna, lake trout, or salmon. After 2 weeks, the subjects crossed over to the other supplement. The study found an average drop of 2 to 3 mm Hg in both diastolic and systolic BP in those who received fish oil supplements. The researchers also found that fish oil increased urine output by approximately 10%, performing much like a low-sodium diet. This resulted in a reduction in fluid volume. Unlike diuretics, the fish oil supplementation did not increase potassium excretion.

Stroke

In the Health Professional Follow-up Study, a prospective cohort with more than 12 years of follow-up, a significantly lower multivariate relative risk (RR = 0.57) of ischemic stroke was documented for men who ate fish one to three times a month compared with men who consumed fish less than once a month. Interestingly, higher levels of consumption did not further reduce the risk, and no effect was seen on hemorrhagic stroke.[122] A reduction in the risk of ischemic stroke by 30% was also shown in the Cardiovascular Health Study. This trial had nearly 5000 adults aged 65+ years and found a 30% lower risk of ischemic stroke with a fish intake of five or more times a week and 27% lower risk with a fish intake of one to four times a week, both compared with an intake of less than once a month. In this study, the benefit was limited to tuna or other broiled/baked fish. Consumption of fried fish or fish sandwiches was associated with an increased risk for total and ischemic stroke.[123]

A study with more than 30,000 participants in the United States examined the risk of stroke as it relates to fish consumption. This study examined possible explanations for the increased stroke risk in the "Stroke Belt and Buckle" in the southeastern United States, a region known for having at least a 50% higher incidence of stroke. The authors of this study concluded that regional and racial differences in fish consumption might help explain this anomaly; that is, those living in the Stroke Belt are less likely to have two or more servings of fish per week.[124]

An earlier study published in 1995 found that men who ate fish five or more times a week had a 40% lower risk of experiencing a stroke than men who ate fish less than once a week. A similar study in women by researchers at Harvard Medical School found even more impressive results for women.[125] In this study, 79,839 female nurses between the ages of 34 and 59 years were followed for 14 years, by which time 574 had experienced a stroke; 303 of the strokes were caused by blood clots, whereas another 181 were caused by a ruptured artery, and the remaining 90 were of undetermined origin. It was determined that women who ate fish once a week lowered their risk of a stroke of any kind by 22%. However, women who consumed fish five or more times per week reduced their risk by 52%. The investigators concluded that women whose intake of fish oils was 0.5 g/day or more had a 30% lower risk of a stroke than women whose intake was less than 0.1 g/day. Of interest was the finding that in those women who had a high fish or fish oil consumption, there was no evidence of an increased risk of hemorrhagic stroke. The researchers concluded that the protective effect of fish oils was due to their ability to inhibit platelet aggregation, lower blood viscosity, suppress formation of leukotrienes, reduce fibrinogen levels, reduce blood pressure, and reduce insulin resistance. Curiously, the beneficial effects were substantially more likely in women who did not take aspirin on a regular basis, although subsequent studies have not shown a relationship with aspirin intake.

In a subanalysis of the JELIS trial, a 20% reduction in stroke risk was shown for individuals taking EPA and a statin compared with those only taking a statin, although these results were limited to participants who had already experienced a stroke (i.e., secondary vs. primary prevention).[10] Currently, more direct intervention trials using fish oil for stroke reduction as the primary outcome are lacking.

Bypass Patients

Some studies demonstrated that fish oil supplementation might help prevent reclosing (restenosis) of the arteries after angioplasty. In one such study, bypass patients were supplemented with 4 g/day of fish oil.[126] One year later, those patients who consumed the fish oil supplements had an occlusion rate of 27%, whereas control patients had a 33% rate of occlusion, a relative improvement of 23%. Based on a postoperative evaluation 3 weeks after patients had cardiac transplantation, it was found that patients who consumed fish oil supplements had normal endothelium-dependent coronary vasodilation, which remained abnormal in patients who did not consume fish oil.

A much larger and well-conducted study published in the *Annals of Thoracic Surgery* documented a robust protective effect of fish oil after coronary artery bypass grafting (CABG). Of 2100 participants, 44% were given 850 to 882 mg of EPA and DHA as ethyl esters, in the average ratio of EPA/DHA of 1:2. In addition to a lower risk for late mortality (hazard ratio = 0.51–0.55), those consuming fish oil had roughly one half the need for repeat revascularization. Furthermore, they had lower adjusted risk for the composite of death, Q-wave myocardial infarction, or cerebrovascular events. Those with poor left ventricular function had a quite large 64% reduction in mortality when taking fish oil.[127] The authors of this study supported the use of fish oil supplementation for all patients as part of standard medical therapy after CABG.

Atrial Fibrillation

A link has long been suspected between fish oil consumption and atrial fibrillation based on epidemiological and experimental evidence,

although the benefit is not clearly established. A prospective cohort study (described previously in the "Stroke" section) found a reduction in the risk of stroke with broiled or baked fish, as well as a roughly 30% lower risk of atrial fibrillation for those consuming fish regularly, although not fried fish.[128] The association between fish oil intake and reduced fatal CHD and sudden cardiac death also lends strong support for its use in preventing ventricular arrhythmias.[129]

Additionally, fish oil targets several of the underlying abnormalities found in atrial fibrillation, including:

1. modulation of electrophysiologic and metabolic heterogeneities secondary to atherosclerotic disease;
2. modulation of cardiac myocyte metabolic activity and cardiovascular oxidant stress;
3. direct modulation of ion channel and transporter activity;
4. indirect modulation of ion channel and transporter activity, via modulation of autonomic nervous system activity; and
5. modulation of inflammatory pathways that promote ectopic electric activity and abnormal conduction.[130]

Also, atrial fibrillation is known to occur more frequently in damaged hearts, which may contribute to mitochondrial pathology and insufficient adenosine triphosphate production, an effect possibly modulated by fish oil.[131]

However, not all epidemiological studies found a protective effect, including the Rotterdam study and the Danish Diet, Cancer, and Health Study, two very large prospective cohort studies.[132,133] The Women's Health Initiative, a large cohort of healthy women, also reported no apparent benefit of increased fish consumption.[134]

A meta-analysis of randomized clinical trials published in the journal *Heart* also did not find benefit for the prevention of atrial fibrillation. However, this study had important limitations, including significant heterogeneity and methodological flaws in the included trials, and limited statistical power to detect a benefit. Its authors also acknowledged that most of the studies used a dose that might have been too low (3–4 g/day fish oil) to have a clinical benefit.[135] A randomized and placebo-controlled study published in *Journal of the American Medical Association* also found no benefit when giving 8 g of prescription ω-3 fatty acids (1 g prescription ω-3 fatty acids contains 375 mg of DHA and 465 mg of EPA) during the first 7 days and 4 g/day for 24 weeks.[136]

The optimal dosage and composition of fish oil for the prevention of atrial fibrillation is not well established. One prospective study of more than 2000 men found that blood levels of n-3 fatty acids appeared to be inversely associated with the risk of atrial fibrillation. However, they found that this protective effect was limited to DHA.

It is thus difficult to determine the role fish oil has in the incidence and the recurrence of atrial fibrillation, given the conflicting evidence published so far. It may be that optimal administration, dosage, and related factors play a role, but given the complexity underlying atrial fibrillation, it may also depend on the specific etiology and the timing. For example, some data suggest that fish oil is more likely to be of benefit for ventricular arrhythmias if CAD is also present, whereas those without heart disease were unlikely to benefit.[137]

Not all atrial fibrillations have the same pathology, with different pathophysiologic mechanisms characterizing distinct clinical presentations. Some authors suggested that n-3 fatty acids might be more likely to be of benefit for preventing the structural remodeling that leads to resistant and/or permanent atrial fibrillation, which is more likely with underlying heart conditions or after myocardial infarction.[138]

In summary, doses used clinically so far may not be sufficient for benefit, and not all presentations of atrial fibrillation may respond to treatment. Earlier treatment with fish oil is more likely to have an effect, before significant structural remodeling has taken place. Furthermore, given the mechanisms involved with fish oil, a longer time until benefit is seen might be expected, an effect not considered in many trials. For example, in the randomized trial cited previously by Kowey et al.,[136] almost half of recurrences occurred within the first 2 weeks of follow-up (of 24 total), suggesting insufficient time for the buildup of tissue levels.

Myocardial Infarction and Acute Coronary Syndrome

One of the largest trials to document a protective benefit for individuals after a myocardial infarction was the GISSI study.[139] In this large secondary-prevention trial, 1 g of n-3 fatty acids (containing 850–882 mg EPA/DHA ethyl esters) greatly reduced sudden cardiac death within 4 months of starting therapy and resulted in a reduction in all-cause and cardiovascular-related mortality. The reduction in the incidence of sudden cardiac death accounted for about 57% of the total improvement in mortality rates. At the end of the study, 2.7% of the placebo group participants died from sudden cardiac death compared with 2% in the fish oil group. Overall, cardiovascular death (including stroke) at the end of the study was 6.5% in the placebo group versus 5.5% in the fish oil group. There was no statistically significant difference in the incidence of nonfatal heart attacks between the fish oil and placebo groups. The researchers concluded that fish oils exerted their protective effect by preventing fatal ventricular arrhythmias rather than through an improvement in cholesterol profile. They did note a small drop in triglyceride levels of 4.6% in the fish oil group but found no significant differences in LDL and HDL cholesterol between the two groups. They also pointed out that the number of lives per 1000 patients that could be saved every year by giving heart attack survivors fish oil exceeded the number of lives per 1000 patients estimated to be saved by treating heart disease patients with high cholesterol levels with pravastatin. This puts fish oil supplements squarely in the category of a highly effective unpatentable heart drug, although Lovaza, a prescription-only form of fish oil, is now available.

Furthermore, a second trial with more than 9000 participants from the GISSI study found that treatment significantly reduced sudden death, with greater benefit in those with left ventricular systolic dysfunction (fourfold greater risk reduction), which increases the risk for mortality.[140]

The JELIS trial, a prospective trial that combined 1800 mg EPA with a statin for hypercholesterolemic patients, found a 51% reduction in risk for myocardial infarction or cardiac death over 5 years. A reduced risk for myocardial infarction was found for those with and without a previous myocardial infarction, although the effect was greater in those with the former. This study was particularly important because they were able to examine adherence to therapy and found a greater effect in those with complete adherence.[141,142]

These studies indicate that fish oil reduces the risk for myocardial infarction and cardiac death and that some populations receive quite significant benefit.

However, some studies did not find benefit for survivors of myocardial infarction in terms of reducing the rate of major cardiovascular effects. For example, a double-blinded, randomized trial with nearly 5000 participants reported no benefit with 400 mg/day of EPA+DHA. Participants in this study were also treated aggressively with other antihypertensive, antithrombotic, and lipid-modifying therapies, which greatly reduced their risk for subsequent cardiovascular events, which might have reduced any potential benefit of fish oil therapy. Additionally, this study was criticized for using too low a dose of fish oil for a clinically meaningful effect.[43] Similarly, the German OMEGA trial (a randomized, placebo-controlled trial to test the effect of highly purified ω-3 fatty acids on top of modern guideline-adjusted therapy after myocardial infarction), which also used aggressive therapies and

a fairly low dose of fish oil (460 mg EPA, 380 mg DHA), did not report a therapeutic effect.[143] The authors of this study reported limitations, including its low power to detect benefit, given the risk reduction associated with other therapies. Also, they reported that both groups (those receiving fish oil and those not) significantly increased their dietary fish consumption during the study period. Given the low dose used, it was not clear that those receiving supplements had a significantly higher intake of EPA/DHA than those who did not.

Considerable animal-based and experimental evidence shows that dietary fats modulate the electrical stability of the myocardium and that the appropriate fatty acids can reduce the vulnerability to arrhythmia during myocardial ischemia.[144–146] Raising the ω-3 fatty acids to higher levels in the myocardium may also prevent postinfarction ventricular fibrillation.[147–149] Data in humans with acute myocardial infarction found that 465 mg/day EPA and 375 mg/day DHA improved ultrasound indexes of endothelial function without affecting serum asymmetrical dimethylarginine levels, suggesting preclinical benefit.[150]

One early study (DART) evaluated the effect of dietary intervention in 2033 men recovering from myocardial infarction.[4] Patients were randomly allocated to receive one of four types of dietary advice:

1. Lowered intake of dietary fat
2. Consumption of at least two portions of fatty fish (200–400 g) a day
3. Supplementation with three capsules (1.5 g) of MaxEPA (1 g Max EPA contains 180 mg EPA + 180 mg DHA) a day
4. Increased dietary fiber intake

At the end of 2 years, those in the group consuming fish were found to have increased their EPA intake to four times that of other subjects. This group also experienced significantly lower mortality. The fat and fiber advice groups showed no differences in mortality. Although the rate of recurrence of heart attack was similar in all groups, the fish and fish oil group had a 29% reduction in risk of death compared with the other groups. These findings are in direct conflict with an earlier study showing no such benefits.[151] However, it may be significant that the earlier study was conducted over a short period of 6 weeks.

Even in patients with no apparent clinical evidence of arterial disease, fish consumption was shown to improve arterial wall function. One study found that in both healthy patients and those with non–insulin-dependent diabetes mellitus, those who ate fish showed significantly better compliance of their left subclavian artery and femoral arteries.[152]

Fish and fish oil intake were also associated with the risk of angina and acute coronary syndrome. In one case-control study, individuals with acute coronary syndrome were found to have a 20% lower EPA/DHA content in their red blood cell membranes than controls. Those with the highest levels had a nearly 70% lower risk for acute coronary syndrome than those with the lowest levels.[76] Another epidemiological study suggested that the benefit of dietary fish consumption might be limited to fatty fish (i.e., not lean fish), with a more apparent benefit in men.[153] Long-term fish consumption might be particularly protective, providing another rationale for fish oil use in those with increased cardiovascular risk.[154]

Interestingly, one study of men with acute coronary syndrome found that symptoms of depression increased as blood levels of EPA/DHA decreased, supporting a possible link between depression and cardiovascular outcomes.[155] Given the underlying pathophysiology, this seems quite plausible from a systems biology perspective.

A meta-analysis published in the *Annals of Medicine* in 2009 found an overall 29% and 23% reduction in risk for cardiac death and all-cause mortality, respectively, when using fish or fish oil. In patients with a previous myocardial infarction, the reduction in risk was even greater (57%). Surprisingly, they found an increased risk for sudden cardiac death in patients with angina with higher fish/fish oil intake.[156] This increased risk for participants with angina was unexpected because previous studies showed that fish oil supplementation reduced the number of angina attacks and reduced mortality in men recovering from myocardial infarction.[4,157] Significant rheologic improvements in patients with stable angina pectoris might occur after daily fish oil supplementation with 2.8 g of EPA and 1.8 g of DHA.[158] In a double-blind, placebo-controlled study, fish oil supplementation resulted in increased red blood cell deformability, reduced whole blood viscosity, and prolonged bleeding time compared with olive oil supplementation. The frequency of angina attacks decreased in both groups. However, neither type of oil affected exercise capacity or hemodynamic response to exercise.

Finally, as mentioned previously, a comprehensive review of the use of fish oils for either primary or secondary prevention concluded that they reduced the rates of all-cause mortality, cardiac and sudden death, and perhaps stroke.[88] Additionally, an analysis of more than 15,000 patients from the JELIS trial published in 2011 in the *Journal of Atherosclerosis and Thrombosis* found a significant reduction in major coronary events, defined as sudden cardiac death, fatal or nonfatal myocardial infarction, unstable angina pectoris, and angioplasty/stenting or coronary artery bypass grafting. Those with higher plasma levels of EPA (participants were supplemented with EPA only, not DHA) had the greatest reduction in risk.[159]

Immune Function

Several of the mechanisms by which fish oil modulates immune function have now been clarified, although much remains to be determined, including optimal dosing and the proportions of DHA/EPA necessary for a clinical effect. Additionally, how in vitro or ex vivo changes translate into clinical significance has not been well established. In healthy subjects, the effect of EPA and DHA on ex vivo lymphocyte proliferation was reported in at least 14 articles, at 27 different dose levels, ranging from 0.2 to 7 g EPA+DHA per day, whereas the influence on cytokine production by monocytes was evaluated in 24 studies in 46 treatment cohorts.[160] It was shown that increasing the EPA/DHA content of immune cells affected a number of immune functions and that DHA and EPA had varying effects. For example, in one double-blinded study of healthy volunteers, a marker of T-lymphocyte activation was inhibited by approximately 5 g/day of DHA, whereas EPA and olive oil had no effect.[161] Most studies, however, did not show any effect on lymphocyte activation, although differences were cited between different age groups and genders. Similarly, although some reports suggested an inhibitory effect on natural killer cell function and/or modulation of cytokine production by lymphocytes, there was considerable inconsistency among the studies, and no clear relationship exists.[160]

Per an excellent review published in 2007, the greatest modulation of immune function by fish oil was mediated via alterations in inflammatory cytokine production by monocytes, including IL-1β, TNF-α, and IL-6.[160] This ties in with an increased awareness of the links between inflammatory and immune function. Even here, however, there are inconsistencies. Not all studies documented an inhibitory effect (although none showed an increase in inflammatory cytokine production), and the expected dose-dependent relationship was not always observed. One very plausible hypothesis for these inconsistencies is that highly relevant genetic polymorphisms are often not considered, such as those that affect TNF-α production.[162]

Decreased production of the proinflammatory mediator PGE_2, as well as the incorporation of EPA and DHA into human inflammatory cells, does appear to follow a dose-dependent relationship, along with an inverse relationship between EPA and TNF-α and IL-1β in most studies. One study suggested that at supplementation levels of 1.65 g EPA+DHA per day, no effect was seen, and a threshold existed between 1.65 and 3.3 g EPA+DHA per day.[163] Data also suggest that

older individuals, as well as those with specific inflammatory conditions, might experience a greater therapeutic effect of fish oil than young, healthy individuals.

Some research also suggests that a higher n-6:n-3 ratio has an inhibitory effect on phagocytic function, suggesting a higher intake of n-3 fatty acids might improve this activity.[164] This was confirmed in one trial of healthy volunteers given 3 g/day fish oil (26% EPA and 54% DHA), which found an increase in phagocytic activity of 62% and 145% in neutrophils and monocytes, respectively.[165] Data has described resolvin D1 (derived from DHA) recognition sites on phagocytes (G-protein–coupled receptors), which mediate its actions, leading to enhanced phagocyte and clearance functions, as well as the resolution of acute inflammation.[166] Research published in 2009 in *Nature* also pointed to critical immune roles for other resolvins related to microbial sepsis and immune vigilance.[167]

Autoimmune and Inflammatory Diseases

Fish oils may play a role in the treatment of autoimmune disease (e.g., SLE, dermatomyositis, autoimmune nephritis, multiple sclerosis, celiac disease)[168–171] and inflammatory disorders (e.g., RA,[172] psoriasis,[173] atopic dermatitis[1]). This may be in part due to the chronic inflammation that often plays a role in the development and perpetuation of these conditions. For example, DHA may directly inhibit the release of AA in intestinal epithelial cells when stimulated by gliadin.[174] Furthermore, fish oils may help improve the comorbidities that often accompany autoimmune disease, such as the premature incidence and acceleration of atherosclerosis associated with SLE. Clinical trials in humans demonstrated a benefit not only for disease activity but also for improving markers of cardiovascular function. In one trial, patients with SLE taking 3 g MaxEPA (1g Max EPA contains 180 mg EPA + 180 mg DHA) had a significant reduction in disease activity (measured by Systemic Lupus Activity Measure [SLAM-R][175]). In a second randomized and double-blinded, placebo-controlled trial, participants given Omacor (1.8 g EPA and 1.2 g DHA per day) showed significant improvement in two markers of disease activity (British Isles Lupus Assessment Group and SLAM-R). Additionally, markers of endothelial function and oxidative stress improved after therapy.[176] Importantly, this study used olive oil as a placebo, which also showed benefit for several cardiovascular risk factors, yet fish oil provided a statistically significant benefit in comparison.

Rheumatoid Arthritis

Rheumatoid arthritis (RA) is in many ways a representative chronic inflammatory autoimmune disorder and may serve as a model for other conditions. The enzyme COX-2 is overexpressed in the synovium of patients, as are products of the enzyme 5-LOX. Interestingly, a study from Spain found decreased levels of ω-3 fatty acids in the blood and synovial fluids of male and female RA patients compared with healthy controls.[177] Epidemiological evidence suggested that RA might be linked to n-3 fatty acid intake. For example, it is rare among Eskimos, yet by comparison, 2% of the world's population is affected. Studies of the Japanese population confirmed an inverse relationship between high dietary fish consumption and a low incidence of RA.[178] Further support comes from a population-based, case-controlled study in women that found a decreased risk of RA in those who consumed the most fish.[172]

A number of reviews concluded that fish oil supplementation was associated with a number of benefits; it reduced pain, the number of tender joints, the duration of morning stiffness, and the use of nonsteroidal anti-inflammatory drugs (NSAIDs) in patients with RA and was associated with improved physical performance.[179] A meta-analysis of 17 randomized controlled trials published in 2007 in the journal *Pain* supported these conclusions, although the authors concluded that it might take several months of therapy for an effect.[180] This slow building effect might also explain the results of an earlier study that found that the anti-inflammatory effect of the fish oils continued for up to 4 weeks after cessation of supplementation.

The reduction in the use of NSAIDs is no small benefit. Growing concern about the adverse effects and safety of long-term NSAID use makes any therapy that reduces their necessity quite attractive. For example, in an extremely large meta-analysis published in 2011, every single NSAID evaluated, including ibuprofen and celecoxib, was associated with an increased risk for cardiovascular death.[181] In one small but well-controlled study, cod liver oil was able to reduce NSAID use more than 30% in 39% of patients versus only 10% of controls.[182] Fish oil was also shown to enhance the COX-inhibiting effect of other medications, specifically of paracetamol, offering additive clinical benefit.[183] Similar benefit for reducing disease activity was also cited for indomethacin.[184]

Interestingly, in a review of the efficacy of fish oil for RA, researchers looked at the combination of benefits, including a reduction in symptoms, decreased use of medications, and improvement in comorbidities, and concluded that an argument for the use of fish oil in RA is strong.[185] However, they also concluded that:

> *It is probable that the main barrier to clinician acceptance is the promotion of pharmaceutical use as the dominant treatment modality by the pharmaceutical industry sales force that attends to the "detailing" of doctors. In the absence of an equivalent marketing effort for fish oil, rheumatologists are not inclined to consider, or even be aware of fish oil as a potential component of routine therapy for RA patients, despite the efficacy for symptom relief, the NSAID sparing and the benefits for cardiovascular health, which is compromised in RA patients due to their disease.*

Sixty patients with active RA were involved in a prospective, randomized trial of a 12-week supplementation with fish oil (group I), fish oil with primrose evening oil (group II), or with no supplementation (group III).[186] The Disease Activity Score 28 (DAS 28 score), number of tender joints, and visual analog scale (VAS) score decreased notably after supplementation in groups I and II ($p < 0.001$). In plasma phospholipids, the n-6/n-3 fatty acid ratio declined from 15.47 ± 5.51 to 10.62 ± 5.07 ($p = 0.005$) and from 18.15 ± 5.04 to 13.50 ± 4.81 ($p = 0.005$) in groups I and II, respectively. The authors concluded that daily supplementation with n-3 fatty acids alone or in combination with GLA exerted significant clinical benefits and certain changes in disease activity in patients with RA.

As discussed earlier, the intake of n-3 fatty acids should probably not be considered in isolation because the ratio to n-6 fatty acid intake is quite significant. This is particularly true for RA. A low-AA diet, often vegan and gluten-free, has been used with considerable success for individuals with RA, possibly by supplying reduced amounts of inflammatory precursors. The beneficial effect of fish oil appears to be amplified by a low-AA diet.[187] The authors also cited a time-dependent effect (2 months before improvement) and the EPA/AA ratio as being decisive for clinical effectiveness.

Psoriasis

Despite its underlying inflammatory process, very little recent research has been conducted for the use of fish oil to benefit individuals with psoriasis. Psoriasis is accompanied by high concentrations of AA in the plaques and profound changes in the metabolism of eicosanoids, leading to an increase in proinflammatory agents. Fish oils presumably improve the condition by decreasing the levels of inflammatory leukotriene compounds, especially leukotriene B_4, a lipoxygenation

product of AA. The EPA in fish oil replaces the AA in phospholipids, leading to the formation of leukotriene B_5 rather than B_4, resulting in a much weaker inflammatory response.[188] This effect was demonstrated in neutrophils isolated from the peripheral blood of patients given fish oil to treat their psoriasis.[189] Patients who showed evidence of clinical response to fish oil therapy for their psoriasis were shown to have higher levels of leukotriene B_5 than those failing to improve.

In a controlled observational study, participants were given 2 capsules of Oravex per day (280 mg of EPA, 40 mg of DHA, 50 mg of thyme extract, 50 mg of olive leaf extract, 20 mg of green tea extract, 7.5 mg of zinc, 27.5 mcg of selenium per capsule), for a total of 560 mg EPA and 80 mg DHA. Compared with those treated topically with tacalcitol, those given Oravex and tacalcitol had a significantly greater improvement in several markers of disease severity and quality of life.[190]

Patients with psoriasis (vulgaris) were successfully treated with a low-fat diet supplemented with fish oil.[189] An impressive 77% (23% were nonresponders) of the patients reported either excellent, moderate, or mild improvement. It was interesting to note that several patients did not show improvement until at least 4 months after initiation of supplementation. Again, this may indicate the importance of allowing adequate time for clinical improvement after initiating fish oil therapy.

Etretinate is a powerful drug used to treat skin disorders such as psoriasis. It can cause serious adverse effects, however, when used in the regularly prescribed dose of about 1 mg/kg per day. One study showed that a combination of EPA and etretinate at a lower dose (0.3–0.5 mg/kg per day) worked as well as the pure, high dose and had significantly fewer side effects.[191] Forty-five percent of the patients in the combination group showed excellent improvement (more than 75%) compared with 15% in the pure etretinate group. The time to achieve a 50% improvement in symptoms was also considerably shorter in the combination group (5.1 weeks) than in the monotherapy group (7.6 weeks). Adverse reactions such as inflammation of the lips, dry mouth and eyes, and scaling were observed in both groups but were mild and tolerable. The researchers concluded that the combination regimen was effective in the treatment of psoriasis without marked adverse reactions.

Another study investigated whether topical application of fish oil to skin areas affected by psoriasis would alleviate symptoms. The clinical trial involved 25 patients with psoriasis who were randomly assigned to apply either fish oil or liquid paraffin to their psoriatic plaques and leave them covered for 6 hours overnight under an occlusive dressing.[192] The treatment was repeated daily for a 4-week period. Fish oil proved highly effective in reducing scaling (severity of scaling went from an average rating of 2.91 to 0.32 on a scale from 0–4), plaque thickness (from a rating of 2.21 to 0.52), and erythema (from a rating of 2.71 to 0.90). Itching was not relieved by the fish oil treatment. The 4-week liquid paraffin treatment was also effective in reducing erythema but was significantly inferior to the fish oil treatment in reducing scaling and had no significant effect on itching or plaque thickness. Both treatments were well accepted by the patients, and the researchers concluded that they were both clinically effective, with the fish oil treatment being superior to the paraffin treatment.

Asthma

Elevated intakes of n-6 fatty acids combined with low intakes of n-3 fatty acids may play a causative role in increasing asthma incidence. A recent review cited five epidemiological studies that all found a protective effect of maternal n-3 fatty acid consumption for asthma and atopic diseases. Intake during infancy and childhood was not as consistently shown to be beneficial, but the majority found a protective benefit.[193] The authors suggested that early life programming might help regulate immune system function. For example, children of mothers receiving fish oil during pregnancy had a nearly 40% lower risk of asthma in the 16 years after their birth compared with mothers receiving olive oil.[194] However, a long-term study found that dietary fatty acid modification, as implemented in a study from birth to age 5 years, did not reduce the prevalence of asthma, atopy, or other atopic disorders at age 8 years. However, the dose used in this study contained less than 200 mg n-3 fatty acids, along with a nearly identical amount of saturated fatty acids, per capsule. Compliance was also poorly monitored.[195]

The effectiveness of fish oil for treating established asthma is controversial. In one study, a small number of participants with exercise-induced asthma were given 3.2 g EPA and 2.0 g DHA per day and shown to have equal benefit when given the 5-LOX inhibitor montelukast.[196] However, not all trials documented benefit, although the parameters of some studies seem designed to better evaluate drug-type interventions than nutritional ones. For example, a controlled trial comparing placebo with n-3 supplementation reported no benefit on lung function or asthma control.[197] This study was only a 2-week study, and considering that the delay before benefit in other inflammatory conditions, such as RA, may be 2 to 3 months, it is worth bearing in mind the slower onset of action expected of fish oil therapy. Many of the clinical trials that did not find benefit were less than 2 months' duration.[198]

Lastly, a study documented increased asthma severity with a polymorphism of the ALOX5 promoter. Given that individuals with genetic variants in this promoter have been found to have an increase in cardiovascular disease risk that is mitigated by a diet high in n-3, future studies seem warranted to assess the potential benefit in asthmatic patients with or without this genetic predisposition.[199]

A note of caution: aspirin-intolerant asthmatics may have a worsening of symptoms, associated with the inhibition of COX by EPA.

Cancer

Fish and fish oil demonstrated multiple beneficial roles related to cancer, specifically both its prevention and as an adjunct to cancer treatment. They were associated with a reduced risk of several cancers, and both might improve the efficacy of other interventions, as well as reduce adverse effects associated with cancer therapy. In some studies, fish oil was also shown to increase survival times. Although specific mechanisms vary from various cancer sites, the ratio of n-6 to n-3 fatty acids might also be an important feature for cancer development. For example, AA was shown to be elevated in a variety of cancer cell types, whereas DHA and EPA were both depressed.[200–202] The role of resolvins and other eicosanoid mediators might include regulating inflammatory precursors to some cancers, such as colorectal cancer.[203]

Cancer Prevention

Most epidemiological studies showed some benefit of n-3 consumption on either cancer incidence or cancer-related mortality. A meta-analysis of fish consumption and prostate cancer risk found that although there was no association between the risk of developing prostate cancer and fish consumption, there was a 63% reduction in prostate cancer–specific mortality.[204,205] A very important case-control study of 466 men found that not only did those with the highest n-3 consumption have a 63% lower risk for aggressive prostate cancer compared with those with the lowest n-3 consumption, but a genetic polymorphism in the COX gene (SNP rs4648310) strongly modified this risk. Those with the polymorphism and a low n-3 intake had 5.5-fold increased risk for aggressive prostate cancer, a risk that was reversed with a high n-3 intake.[206]

A large epidemiological study of 23 dietary factors in countries with high and low risks of cancer found a strong association between the percentage of calories from fat and the risk of breast cancer.[207] Fish consumption was found to have the next most significant association, a negative correlation. As mentioned previously, for breast cancer, the ratio of n-3:n-6 fatty acids might be particularly important, as demonstrated by two large trials. One trial, which enrolled more than 70,000 women, found that those with high intake of n-6 combined with a low intake of n-3 fatty acid had more than two times the risk of developing breast cancer.[34,35]

A previous study of 4052 postmenopausal women found that not only was the type of dietary fat associated with breast cancer but also that this risk might be modified by the activity of the enzyme δ-9-desaturase. These women were followed for an average of 5.5 years, and those with DHA concentrations in the highest tertile had less than half the risk of breast cancer than did women in the lowest tertile. PUFAs overall were also protective, with ω-3 acids being somewhat more protective than ω-6 acids. Saturated fatty acid concentrations were not significantly related to breast cancer risk. A higher concentration of monounsaturated fats, especially oleic acid, was associated with a significantly increased risk. The researchers pointed out that most oleic acid in mammalian tissue is derived from saturated stearic acid through a process involving the enzyme δ-9-desaturase. Saturated fatty acids, cholesterol, carbohydrates, insulin, testosterone, and estrogen all activate this enzyme, whereas dietary PUFAs and fasting deactivate it. The researchers concluded that the δ-9-desaturase enzyme might be an important link between breast cancer risk and dietary fat consumption.[208]

A meta-analysis that examined 19 prospective cohort studies found a 12% decrease in the relative risk of colorectal cancer comparing high fish consumption with low fish consumption.[209] The largest study (nearly 500,000 men and women) contributing to this meta-analysis was the European Prospective Investigation into Cancer (EPIC) study, which found a 31% lower risk of colorectal cancer comparing highest with lowest fish intake.[210] An intervention trial using 2 g/day of EPA compared with placebo was shown to reduce the number and size of polyps in familial adenomatous polyposis, further strengthening the evidence for its effectiveness.[211]

This builds on a previous study in which 34 men and 26 women who had just undergone surgery to remove benign polyps from their colon were followed.[212] Patients were divided into four groups. Group 1 was supplemented with 1.4 g/day of EPA and 1.1 g/day of DHA, group 2 with 2.7 g of EPA and 2.4 g of DHA, and group 3 with 4.1 g of EPA and 3.6 g of DHA. Group 4 received placebo capsules containing olive oil. Biopsy samples from the lower part of the colon and blood samples were taken and analyzed at the start of the trial and at 30 days. Overall, patients in the fish oil groups experienced a significant decline in the number of abnormal cells in their colon lining compared with the placebo group. Further analysis showed that the reduction in the number of abnormal cells was limited to patients who had a large number of abnormal cells at the beginning of the trial. The researchers also noted a significant increase in EPA and DHA levels and a significant drop in AA levels in the biopsy samples from the fish oil–supplemented patients. A separate 6-month trial involving 15 patients taking 1.4 g/day of EPA and 1.1 g/day of DHA also showed a significant drop in the number of abnormal colon-lining cells. The researchers concluded that low-dose supplementation with fish oils inhibited the proliferation of those abnormal cells associated as precursors to polyps in patients at risk for colon cancer and that this effect could be maintained with long-term treatment. Similar to several other studies concerned with oxidation of fish oil in vivo, the authors cautioned that it might be advisable to increase vitamin E intake during fish oil administration.

A British investigation of the association between high dietary fat intake and the risk of developing breast and colon cancer revealed interesting findings concerning the incidence of cancer. The study compared cancer mortality rates in 24 European countries, Canada, and the United States with fish consumption and the intake of animal fats.[213] In countries where the animal fat intake was high, the researchers found a clear inverse correlation between the ratio of fish fat to animal fat and the risk of developing breast cancer in women and colon cancer in both men and women. A similar correlation was found between cancer risk and the ratio of fish fat to total fat intake. This led the investigators to conclude that fish and fish oils not only protect against colon cancer in men but also against colon and breast cancer in women. This protective effect, however, is only apparent in countries where the intake of animal fats is high. In other words, a high intake of fish or fish oils counteracts the detrimental effects of high animal fat consumption. The researchers further concluded that a 15% decrease in animal fat intake combined with a threefold increase in fish oil intake could possibly reduce male colon cancer risk by as much as 30% in countries with a high animal fat intake. A threefold increase in fish oil intake could be achieved by eating fish three times a week or by taking two standard fish oil daily supplements containing EPA and DHA.

A prospective cohort study published in the *Journal of the American Medical Association* in 2006 also found a protective effect of fish consumption on renal cancer. For women consistently reporting high consumption of fatty fish (once per week or more), a risk reduction of as high as 74% was observed compared with women reporting no fish consumption. Lean fish consumption did not reduce the risk of more than 60,000 women in this 15-year study.[214]

Cachexia and Treatment Efficacy

Some studies showed that fish oil supplementation, especially at higher doses, might help with weight stabilization in participants with cancer. For example, one early study found that supplementation with approximately 2.2 g of EPA and 1.4 g of DHA assisted stabilization of weight in patients with inoperable pancreatic cancer. Researchers not only documented weight gain and improved appetite, but these patients also survived an average of 8 months, compared with the expected survival time of 4.1 months typically reported for patients given chemotherapy.[215] In another study, 18 patients with inoperable pancreatic cancer, including 9 patients with Stage 4 tumors, were started on a dose of 2 g of fish oils (containing 360 mg/day of EPA and 240 mg/day of DHA).[216] The dose was subsequently increased by 2 g/day every week until the patients' body tolerance was reached, with an average final intake of 12 g/day. Before entering the trial, the mean weight loss among the patients was 2.9 kilos per month. After 3 months of fish oil supplementation, an average weight gain of 0.3 kilos a month was observed. Overall, 11 patients (61%) gained weight, 3 became weight stable, and 4 continued to lose weight, but at a significantly reduced rate. The concentration of EPA in plasma phospholipids increased from 0% to 5.3% of total fatty acids after 1 month of supplementation, whereas the concentration of DHA increased to 6.6% from a base level of 3.5%. The researchers concluded that fish oil supplementation arrested weight loss in cancer patients with cachexia.

A study published in the journal *Cancer* found a very significant benefit when supplementing patients with non–small-cell lung cancer (NSCLC) at a dose of 2.2 g/day of EPA. These patients also received chemotherapy and were compared with a group receiving standard of care only (i.e., chemotherapy without fish oil). Despite having a mean weight loss of 6.3% over the previous 6 months before chemotherapy, patients receiving EPA maintained weight, muscle mass, and adipose tissue throughout approximately 10 weeks of chemotherapy. Those who received standard of care only lost on average 2.3 kg over the same

period. This study also might have been the first to monitor body composition directly using computed tomographic imaging. They found that gains were made in muscle and adipose tissue, an important distinction from the accelerated weight gains sometimes observed in lean tissues (liver and spleen) in terminal stages. Additionally, those with the greatest increases in plasma levels of EPA had the greatest gains in muscle mass, suggesting again that a biomarker may be worth incorporating into fish oil therapy. Although this was a very small study, these gains were potentially quite significant, especially given the low dose of fish oil used.[217]

These same researchers also published a trial that enrolled patients with advanced NSCLC, and although the study was also small, it suggested a significant benefit of fish oil therapy. Patients received 2.2 g/day of EPA and 240 to 500 mg/day of DHA, along with standard-of-care chemotherapy, and were compared with those receiving chemotherapy alone. In this trial, fish oil supplementation appeared to increase the efficacy of chemotherapy, without increasing its toxicity. The authors reported an approximately twofold increase in response rates and clinical benefit compared with standard of care alone. Additionally, a greater portion of patients who received fish oil were still alive at the time of reporting than the control group, suggesting a likely increase in survival.[218] Other studies also reported benefits for treating patients with NSCLC with fish oil.[219]

Similar improvements in survival time were also seen in earlier studies of patients with other end-stage cancers with generalized malignancies. In one study, 60 patients with generalized solid tumors were divided into two groups: one group received 18 g of fish oil containing 170 mg of EPA and 115 mg of DHA per capsule, whereas the other received a placebo.[220] The fish oil group also received 200 mg of vitamin E daily to reduce oxidation in vivo from the effect of so much fish oil. Each group included 15 well-nourished and 15 malnourished patients. None of the well-nourished patients had cancer cachexia (abnormally low weight and general weakness). The researchers measured the levels of T cells, natural killer cells, and the synthesis of IL-1, IL-6, and TNF before the start of the supplementation and on day 40 of the trial. The study followed all patients until they died. Malnourished patients were found to have a considerably impaired immune function and a decreased production of TNF; both parameters were restored through fish oil supplementation. Malnourished patients overall had a much shorter survival time than well-nourished patients (mean of 213 vs. 481 days). Both malnourished and well-nourished patients who received fish oil and vitamin E survived significantly longer than did patients on placebo. The researchers speculated that fish oils exert their beneficial effect by decreasing the body's production of PGE_2, which is believed to play an important role in the initiation and progression of cancer. They concluded that supplementation with dietary ω-3 polyunsaturated fatty acids, specifically fish oils with an antioxidant such as vitamin E, might offer significant palliative support to cancer patients with end-stage metastatic disease.

Potential mechanisms for benefit were outlined in several reviews, including one published in the journal *Nutrition and Cancer* that called for major clinical trials to be conducted using fish oil as adjunctive therapy. The authors reviewed previous research and concluded that long-chain PUFAs not only had cytotoxic anticancer effects by themselves but also modulated the effectiveness of particular chemotherapeutic agents.[221] For example, DHA was shown in vitro to have synergistic toxicity with taxanes toward cancer cells and downregulated Her-2/neu oncogene expression, an effect confirmed in an animal model of breast cancer.[222,223] Other mechanisms included modulation of eicosanoid production, modulation of gene expression and of transcription factor activity (e.g., nuclear factor-κB), and alteration of membrane-associated signal transduction, to name just a few.[224] Interestingly, one study even suggested that fish oil might offer benefit for both breast cancer as well as cardiac arrhythmias through a similar mechanism, the regulation of a sodium channel, NaV1.5, although this has not yet been proven.[225] Lastly, one review cited both a cytotoxic effect of cancer cells and a protective effect toward healthy cells by the downstream products of DHA (protectins), allowing them to work "as both a sword and a shield."[226]

Despite considerable evidence for a beneficial effect of fish oil in the prevention and treatment of various cancers, not all research showed a positive effect. Although some studies might have been too short-term or used too low of a dose for a clinical effect,[227] others found benefit for only a subset of patients, even at higher doses.[228] Many older studies used fish oil with a very low concentration of DHA/EPA, requiring an intolerable number of pills, a limitation recent advances in available products might remedy. Also, the use of biomarkers, such as the ω-3 index, and genetic polymorphisms might help identify those most likely to benefit, as well as those who need higher dose supplementation. For example, a Phase II trial of DHA (1.8 g/day) given to patients with metastatic breast cancer receiving chemotherapy found that those who incorporated it the most (into plasma and/or red blood cells) delayed time to tumor progression and had longer overall survival compared with those who incorporated it the least.[229]

Migraine Headache

A role for inflammation in migraine was established for at least some migraineurs, yet surprisingly few studies have been conducted with fish oil for its prevention (benefit for an acute migraine seems unlikely). Two placebo-controlled studies were performed, both finding no benefit compared with placebo, yet methodological flaws are found in both. In both studies, olive oil was used as a placebo, and a high placebo effect was observed.[230,231] Well-designed clinical trials are early in the research process.

A systematic review and meta-analysis of randomized controlled trials showed that ω-3 intake had no effect on the frequency and severity of migraine but had a reduction effect of approximately 3.4 hours on the duration of migraine attacks.[232] Anecdotal reports indicate that patients with migraine headaches who were given 1 g/day of MaxEPA (1 g MaxEPA contains 180 mg EPA + 180 mg DHA), particularly males, had significantly less frequent episodes, less intense episodes, or both. These results might be due to changes in prostaglandin synthesis or reduction, or both, in platelet serotonin release, with a resultant reduction in cerebral vasospasm.

Diabetes

The relationship between fish consumption and diabetes incidence and treatment is not as simple as previously believed. As mentioned previously, a G-protein–coupled receptor was identified that modulates many of the physiological effects of DHA/EPA, including an increase in insulin sensitivity, and most epidemiological evidence suggests either no effect or a reduced incidence of diabetes among populations with higher fish intake.[233] For example, the incidence of diabetes is low in Greenland Eskimos.[234]

However, recent studies suggest that greater intake of fish might pose a risk for diabetes. One of the largest was a prospective study of more than 35,000 women (Women's Health Study), which found a linear increase in the risk for type 2 diabetes (T2D) with fish intake and particularly high risk for those consuming the highest portions (two or more servings of fish per day). This increase in risk with increasing n-3 fatty acid intake from fish was not observed with n-3 fatty acids from plant sources, which provides ALA.[235] This increase in risk with fish intake was also observed in three other prospective cohorts of both men and women in the United States (152,700 women and 42,504 men), with a 22% increase in risk in those consuming fish more than five times per week compared with those consuming it less than

once per month.[236] In a large prospective trial in China (the Singapore Chinese Health Study), no association between n-3 fatty acid intake from fish was seen, although ALA from plant sources reduced the risk of diabetes.[237] As discussed previously, contamination of the fish and fish oils with diabetes-inducing persistent and nonpersistent organic pollutants likely accounts for this discrepancy, especially in highly polluted China.

In one large prospective study of older adults, researchers measured the plasma phospholipid levels of EPA/DHA as well as ALA and examined the risk for diabetes. They speculated that many of the previous trials that found an increased risk for diabetes were prone to error, such as the error associated with food frequency questionnaires. Using a more objective biomarker, they found that phospholipid levels of EPA+DHA along with ALA were not associated with an increased risk of diabetes, and instead, those individuals with the highest concentrations of EPA+DHA or ALA had a lower risk of diabetes.[238] Earlier studies that used biomarkers in younger populations also found no increase in risk.[239,240]

Although further studies may help clarify the relationship, it is worth noting two additional points. One, as noted earlier, is that fish are becoming contaminated with compounds such as POPs, which have been associated with a surprisingly large increase in the risk for diabetes. Some studies showed fish consumption to be an important predictor for POPs serum levels.[241–243]

The second consideration is the favorable effect of fish oil on cardiovascular parameters, an important cause of morbidity and mortality among diabetics. In individuals with T2D, fish oil ingestion was demonstrated to favorably alter arterial wall compliance without adversely affecting cholesterol levels, blood pressure, or fasting blood sugar levels, thereby contributing to a reduced risk of the vascular complications seen in patients with insulin-dependent diabetes mellitus and non–insulin-dependent diabetes mellitus.[244,245] One study even showed a desirable significant decrease in VLDL triglyceride and cholesterol concentrations in T2D patients consuming three fish oil capsules a day containing 320 mg EPA and 530 mg DHA.[246] In another study, 2 g of fish oil per day given to the offspring of individuals with diabetes for 12 weeks was associated with reduced inflammation and markers of endothelial function. Thus, in those at an increased risk for diabetes, fish oil might have an important cardiovascular and metabolic benefit.[247] Interestingly, increased fish oil consumption might also reduce the risk of type 1 diabetes in those with increased susceptibility.[248]

A randomized double-blinded, placebo-controlled trial was conducted to determine the effect of fish oil administration on gene expression related to insulin action, blood lipids, and inflammation in women with gestational diabetes mellitus (GDM).[249] Participants with GDM (n = 40), aged 18 to 40 years, were randomized to take either 1000 mg fish oil capsules, containing 180 mg eicosapentaenoic acid and 120 mg docosahexaenoic acid (n = 20), or placebo (n = 20) twice a day for 6 weeks. Overall, compared with placebo, fish oil supplementation for 6 weeks in women with GDM significantly improved gene expression of peroxisome proliferator-activated receptor gamma (PPAR-γ), IL-1, and TNF-α but not gene expression of IL-8. Interestingly, these benefits were observed with relatively low doses of n-3 fatty acids.

Although fish oil has not always been shown to improve markers of diabetes and glucose control among those with T2D, its cardiovascular benefit warrants consideration for use in all patients with diabetes.[88,250]

Neurodegenerative Disease

Several lines of evidence point to a protective role for EPA and DHA for neurodegenerative diseases. DHA specifically is the predominant n-3 fatty acid in the brain and appears to play a key role in structures involved in the formation of new memories. Additionally, DHA is the precursor for neuroprotectin 1, an important neuronal modulator of function, with anti-inflammatory as well as antiapoptic functions. N-3 fatty acids, particularly DHA and its downstream metabolites, have been shown to act via several pathways associated with neurological function, including the following[251]:

- Facilitating the interaction of α-secretase with amyloid precursor protein to produce nontoxic fragments and prevent the formation of Aβ
- Shielding the essential recognition sequence and intramembrane cleavage site for γ-secretase
- Serving as a local sink for free radicals that reduce the enzymatic augmentation of γ-secretase activity, which can be induced by free radical damage to the protein complex, which is important for the regulation of normal γ-secretase function
- Directly inhibit fibrillation and formation of toxic oligomeric species of Aβ

Observational data also implied an important protective role of n-3 fatty acids. For example, participants in the Rancho Bernardo study had plasma levels of DHA, as well as dietary fish and dietary DHA levels, evaluated. Each of these variables was associated with the subsequent risk of developing either dementia or Alzheimer's disease. Having the highest levels of plasma DHA reduced the odds of all-cause dementia by 65% and Alzheimer's disease by 60%. Dietary DHA had similar benefits, and although fish consumption followed this trend, it was not a statistically significant association.[252] A study published in 2007 that enrolled more than 8000 participants found a quite important association. Overall, fruits and vegetables, as well as weekly consumption of fish, was associated with a reduced risk for dementia. However, although the protective effects of fruit and vegetable intake applied to all participants, fish consumption was only associated with those who did not carry the apolipoprotein-E ε-4 allele (*APOE*-ε4 allele). Similarly, excess n-6 consumption increased the risk of dementia more than twofold, but it was modified by two factors. It increased risk only if not compensated by high n-3 intake, and only among *APOE*-ε4 noncarriers. Thus the relationship between n-3 consumption was not only modified by other dietary factors, such as n-6 consumption, but also by genetic variables.[253] A similar association was found in the Cardiovascular Health Cognition Study, which found that fatty fish, but not lean fish, was associated with reduced risk for dementia, but again, only in noncarriers of the *APOE*-ε4 allele.[254]

A double-blind, randomized controlled trial has demonstrated that n-3 PUFA supplementation (480 mg DHA and 720 mg EPA per day) is associated with improved cognitive function compared with control group with placebo (olive oil) in patients with mild cognitive impairment.[255] In addition, several studies have reported that the effect of n-PUFAs in patients with Alzheimer's disease may be through an increase in the clearance of amyloid-β peptide, neurotrophic and neuroprotective factors, and anti-inflammatory effects.[256]

Regarding the treatment of neurodegenerative disease, efficacy also appears to be modulated by genetic predisposition. In an analysis of n-3 fatty acid erythrocyte membrane content and cognitive variation in a birth cohort study of cognitively normal volunteers, cognitive benefits were associated with higher erythrocyte n-3 content, but again, this was only significant in *ApoE*-ε4 noncarriers.[257]

Not all studies have shown benefit, perhaps because the optimal dose and composition have not yet been clearly established. For example, as evidenced in trials for major depression, although DHA is the predominant n-3 fatty acid in the brain, EPA appears to have a greater clinical effect. This may be why a controlled trial published in the *Journal of the American Medical Association* in 2010 that supplemented participants with 2 g/day of DHA (no EPA) did not find any evidence of benefit. This study also did not report *APOE* status.[258]

The first large-scale, well-designed trial was published in 2006 and used 1.7 g DHA and 0.6 g EPA per day or placebo among participants with mild to moderate Alzheimer's disease, all of whom were also taking a cholinesterase inhibitor. Although no difference in primary outcome was observed, a subgroup with mild disease demonstrated a significant reduction in decline compared with placebo. Although *APOE* status was reported, the treatment effects per *APOE* status were not. Importantly, only 31% of those in the treatment group were non–*APOE*-ε4 carriers. This study suggests those most likely to benefit are at earlier stages of disease.[259]

Overall, the bulk of the data suggest that those with earlier disease are more likely to benefit, but this benefit is mediated by *APOE* status (and perhaps other genetic polymorphisms) and perhaps by n-6 fatty acid intake. The optimal dosage and DHA/EPA composition are not known, but DHA by itself may not be effective. N-3 fatty acids from fish also appear to have a protective effect on other neurodegenerative diseases, including Parkinson's disease, likely through similar mechanisms.[260,261]

Depression

Several epidemiological studies showed a reduced risk for major depression, perinatal depression, and bipolar disorder with diets high in n-3 fatty acids.[262,263] Also, a meta-analysis of 14 trials found that lower levels of EPA, DHA, and total n-3 fatty acids levels in plasma and erythrocytes (data were combined) were associated with depression. When these studies restricted their analysis to studies that used *Diagnostic and Statistical Manual of Mental Disorders* criteria for major depressive disorder diagnosis, the magnitude of differences in EPA/DHA and total n-3 became larger.[264]

Regarding trials for the treatment of depression, results have been quite varied, often due to differences in methodology and the type and dose of fish oil used. However, most have shown a beneficial effect. A review of published randomized controlled trials indicated that studies that found positive effects generally included a high ratio of EPA to DHA, and 1 to 2 g/day might be necessary for effect, but higher levels were not associated with greater benefit.[265] Also, the earlier the supplementation of DHA/EPA is started during pregnancy, the greater the chance for benefit.[266] Despite DHA being a much more prevalent structural component of phospholipids in neuronal cell membranes compared with EPA, it is EPA that has more apparent effectiveness in clinical trials.[267] A second meta-analysis of randomized trials over a 40-year period also found a positive effect of n-3 fatty acids on both major depression and bipolar disorder.[268]

A small but important study also compared a fairly low dose of EPA (1 g/day) with fluoxetine for major depression and found that both were equally effective. Furthermore, when used together, they were more effective than either agent used alone. Given the likely differences in mechanisms of action, this is not surprising, and combination therapy should be considered in those not responding to monotherapy.[269]

A case-control study published in 2010 examined some of the links between cardiovascular disease and depression, which are known to have a high comorbidity rate. Among individuals with major depressive disorder, several cardiovascular risk factors indicated heightened risk, including a low ω-3 index.[270] This biomarker might provide a useful tool for determining the efficacy of n-3 fatty acid therapy for depression as well as cardiovascular disease.

Lastly, little attempt has been made to examine the role of genetic polymorphisms regarding the interaction between n-3 fatty acids and depression. This may be a promising area of investigation. A published study found that patients with chronic hepatitis C were more likely to experience depression when given interferon-α if they had polymorphisms in the *COX-2* gene or the phospholipase-A2 gene. Both of these genes are involved in eicosanoid metabolism and may modulate the influence of n-3 fatty acid therapy.[271]

Raynaud Disease

Preliminary evidence indicated that symptoms of Raynaud disease improved in primary but not secondary Raynaud phenomenon, based on a double-blind, placebo-controlled clinical trial involving 32 patients.[272] Patients were given either 12 1-g fish oil capsules daily for 12 weeks containing 4 g of EPA and 2.6 g of DHA, or a placebo. The group receiving the fish oil supplements reported significant alleviation of symptoms associated with Raynaud disease at the end of the study, including 5 patients who developed symptoms before the experiment began but could not induce symptoms at all after either 6 or 12 weeks of supplementation.

Malaria

Malaria afflicts more than 500 million people worldwide, with about 5% of victims dying each year. Unpublished studies at the U.S. Department of Agricultural Research Service Center in Beltsville, Maryland, found evidence that the ω-3 fatty acids in fish oil may be beneficial in the treatment of malaria.[273] In their research, mice were fed dietary fish oils for 4 weeks and then inoculated with parasites, either *Plasmodium yoelii* or *Plasmodium berghei.* As the mice continued to eat the diet high in fish oil, the parasites multiplied as usual. However, after 3 to 4 weeks, the mice were free of the parasites. The researchers suspected that the cause of the parasites' death was rupture of the parasites' cell membranes or red blood cell hosts. The researchers theorized that infected cells were more susceptible to rupture because the parasites fostered several destructive oxidative reactions to which a diet high in fish oils makes them more vulnerable. Subsequent studies are lacking, although one animal-based study found that fish oil without vitamin E may improve survival and reduce reinfection.[274] Human trials are lacking.

Renal Disease/Immunoglobulin-A Nephropathy

Fish oil supplementation was shown to be effective for several renal diseases, including IgA nephropathy, the nephrotic syndrome, and a deficit of n-3 fatty acids, which was demonstrated in several studies for those with end-stage renal disease. In a small study of continuous ambulatory peritoneal dialysis patients, a depletion of reduced n-3 fatty acids and a high ratio of n-6:n-3 fatty acids were observed.[275] Lower EPA and DHA in the plasma/serum phospholipids of those with chronic kidney disease was also documented, and intravenous n-3 therapy was used to restore normal levels.[276,277]

Both hypertriglyceridemia and hypercholesterolemia are common in patients with nephrotic syndrome. This association results in an increased risk of cardiovascular disease. Fish oils were found to lower serum triglycerides in patients with nephrotic syndrome and might therefore be of clinical benefit.[278] Unfortunately, no recent trials have examined this benefit.

IgA nephropathy is a kidney disease that can follow a viral infection of the gastrointestinal or upper respiratory tract. About 20% to 40% of all IgA nephropathy patients develop renal failure 5 to 25 years after diagnosis. One study at the Mayo Clinic found that fish oil supplementation could be effective in slowing down the progression of the disease.[272] The progression of the disease was judged by regularly measuring the level of creatinine in blood serum during the 2 years of the trial. A clear difference was observed. The patients in the fish oil group who received 12 fish oil capsules a day, containing 1.9 g of EPA and 1.4 g of DHA, had an average median increase in serum creatinine of only 0.03 mg/dL, whereas the patients in the placebo group experienced an increase of 0.14 mg/dL annually, indicating that their disease

was progressing significantly faster. After 4 years, 40% of the patients in the placebo group died or developed end-stage renal disease compared with only 10% in the fish oil group. No adverse effects of fish oil supplementation were observed. A recent reanalysis of this data did not find that body size was helpful in predicting optimal dosage.[279]

An additional study using 1.8 g/day of EPA for 1 year found small but significant benefits, including an improvement in the estimated creatinine clearance.[280]

Muscle and Bone

N-3 fatty acids have emerged as being of potential clinical importance for the health of both muscle and bone tissue. In a study of more than 1500 men and women from the Rancho Bernardo Study, a cohort of community-dwelling individuals, a higher n-6:n-3 fatty acid ratio (based on food frequency questionnaires) was associated with a lower bone mineral density of the hip in both men and women.[281] A second smaller study published in 2007 found that among young men (women were not studied) serum phospholipid levels of n-3 fatty acids, particularly DHA, were associated with peak bone mineral density in the total body and spine, and with bone accrual in the spine.[282]

Intervention data are still lacking, however. In one small trial that enrolled adults with depression, no change in C-terminal cross-linking telopeptide of type 1 collagen, a bone resorption marker, was seen after 1.45 g EPA/DHA for 12 weeks. However, this study could be criticized for using a low dose over a short period of time and evaluating only 1 marker of bone resorption, and the patient population did not necessarily start with increased bone resorption. This was a sample of patients of a wide range of ages with depression, not osteoporosis or other risk factors for bone loss. The authors' conclusion that n-3 supplementation might not be useful for preventing bone loss may only be appropriate to the population they studied, not more generally, and perhaps not using different doses or markers of bone health.[283] A study published in 2007 found just the opposite. Although researchers used plant-based n-3 fatty acids, which might not be equivalent to DHA/EPA, they did find that supplementation with ALA did have a protective effect and inhibited bone resorption. This indicates that in principle, n-3 fatty acids play an important role.[284] The effect of fish oil supplementation as an intervention to prevent and/or treat osteoporosis awaits well-designed clinical trials.

In a study published in 2008, a retrospective analysis was done of a cohort of nearly 3000 men and women aged 59 to 73 years. When examining multiple dietary influences on grip strength, a potential marker for muscle strength and function, fatty fish consumption emerged as having the greatest effect.[285] Although very small, a second interventional study compared the effects of either corn oil or n-3 fatty acid supplementation on muscle synthesis in older adults; 1.86 g EPA and 1.50 g DHA were shown to increase muscle protein synthesis. Particularly, supplementation augmented the hyperaminoacidemia–hyperinsulinemia induced synthesis of muscle, suggesting it may be beneficial for the treatment and/or prevention of sarcopenia.[286]

Pregnancy and Lactation

Many studies have been published on the effects of DHA and/or fish oil during pregnancy and lactation, with several indicating that maternal intake of n-3 fatty acids reduces the chance of premature birth, improves children's neurological development, and also reduces the risk of maternal depression.[262,287,288] No significant adverse effects were cited with intakes of up to 1 g/day DHA or 2.7 g/day long-chain n-3 fatty acids in randomized trials. As mentioned earlier, the sooner supplementation begins during (or before) pregnancy, the greater the chance for benefit, at least regarding maternal depression.[266]

A study published in *Journal of the American Medical Association,* however, did not find a reduction in maternal depression or improved cognition and/or language in the children of mothers given 800 mg DHA and 100 mg EPA during pregnancy and challenged existing thought regarding supplementation.[289] One possible limitation of this study was the failure to assess the n-3 intake of participants in the study, aside from the provided supplement, although cord blood determinations suggested a low intake in the control group. The median gestational age was 19 weeks in this study. Supplementation earlier or before conception may have had a greater effect. In contrast, a review of interventional and epidemiological studies supported the use of DHA and EPA supplementation for childhood cognition and development, as well as preventing childhood psychiatric disorders.[290]

Mercury toxicity is also of concern and may accompany increased fish consumption. A study published in 2008 found that although maternal fish consumption was associated with a benefit on children's cognition at age 3, mercury levels were associated with poorer test scores. This certainly suggests that obtaining fish oil from purified supplements or low-mercury fish is preferable and may provide greater benefit than is often cited due to fish consumption (which may be contaminated with mercury).[291] Recommendations to avoid fish (perhaps due to mercury) may be associated with worse outcomes, as suggested by an observational study published in the *Lancet* in 2007.[292]

Finally, an article published in 2011 suggested that genetic variation might significantly modulate n-3 fatty acid levels in pregnancy, children, and breast milk composition.[293] Here, too, the use of a biomarker such as the ω-3 index might be of clinical value.

TOXICITY AND TOXIN CONTAMINATION

Despite widespread use, toxicity with fish oil is quite rare, with the most frequent side effects being mild dyspepsia, nausea, and belching ("fish burps"). Of growing concern, however, is the increasing contamination by environmental toxins such as mercury and POPs (e.g., PCBs and organochlorine pesticides). An excellent risk and/or benefit analysis of fish consumption was published that offers a species-specific analysis of ω-3 content as well as mercury contamination of each species.[294] The authors of this study suggest that in theory, fish oil supplementation from a high-quality source avoids the contamination of consuming fish. Previous studies found the commercial fish oil to be free of mercury, PCBs, and organochlorines, but quality control is essential.[295] Additionally, supplements that use fish oil derived from small, cold-water fatty fish are much less likely to be contaminated.[296]

Care must also be taken to use fish oil, not fish liver oil, because the latter can be excessively high in vitamins A and D and possibly result in toxicity.

Finally, large dosages of fish oil supplements may result in a significant increase in total caloric intake, which can be ameliorated by an increase in energy expenditure.

Bleeding Time

Concerns have been expressed about prolonged bleeding time in populations having a relatively high intake of fish. Several studies showed that this effect appears to be dose dependent, although collagen-induced platelet aggregation was not shown to be inhibited.[297] Many studies showed that fish oil supplements prolong bleeding time, inhibit platelet aggregation, and decrease TXA_2 production.[62,112,298–308]

However, many of these studies are several decades old. In an editorial published in March 2007 in the *American Journal of Cardiology,* the author concluded that current research was nearly unanimous: "omega-3 fatty acid supplements do not increase the risk for clinically significant bleeding, even in patients also being treated with

antiplatelet or antithrombotic medications. Anecdotal reports of an increased bruising tendency have not been tested in a controlled setting." He also considered this to be at the "A" level of evidence (i.e., based on well-designed, randomized controlled clinical trials). One caution was that interactions with newer antiplatelet drugs such as clopidogrel have not been evaluated.[309] A second review in the same issue also concluded that clinical trials showed high-dose fish oil consumption to be safe, even when concurrently administered with other agents that may increase bleeding, including aspirin and warfarin. This review also suggested that the reported antiatherothrombotic effects of fish oils might outweigh the unproven bleeding risks, particularly for those patients at high risk for thrombosis.[310]

Some early research suggested that the effect of fish oil supplementation on bleeding time was largely determined by the dosage, duration, and composition of the supplement, and the typical treatment regimens are safe. In one double-blind, placebo-controlled trial, daily supplementation with 30 mL of a Scandinavian fish oil formulation (ESKIMO-3: 35% n-3 fatty acids, 18% EPA, and 12% DHA) given for both short (4 weeks) and long (6 months) durations resulted in no changes in bleeding time.[65] Another controlled study used 1.5, 3, or 6 g of fish oils (SuperEPA) as a supplement for 3 months and found no effect on bleeding time in 45 healthy male volunteers with normal triglycerides.[311] In the large Enoxaparin MaxEPA Prevention of Angioplasty Restenosis (EMPAR) trial (of more than 800 patients receiving fish oil and low-molecular-weight heparin), a decrease in bleeding frequency was seen in the fish oil group compared with placebo.[312]

Evidence as to the degree to which fish oil may affect fibrinolysis is conflicting. Plasma plasminogen activator inhibitor (PAI-1) is an inhibitor of fibrinolysis. Increased PAI-1 activity was linked to the development of myocardial infarction and thrombosis by several investigators. In at least one double-blind, randomized study conducted on an untreated essential hypertensive population, a modest increase in fibrinogen levels was observed after fish oil and corn oil intake by 4 g of ω-3 PUFAs.[313] However, no change in PAI-1 activity or tissue plasminogen activator activity was found. A crossover study found fish oil to have the same effect on PAI-1 activity as olive oil.[314]

No major bleeding events had been reported in trials as of 2018.

Oxidation

It was reported in an animal-based study that a diet rich in fish oil taken for many months can induce a deficiency of vitamin E, leading to cardiac necrosis.[315,316] For this reason, periodic vitamin E (mixed tocopherols or γ-tocopherol) supplementation may be warranted. However, there is no evidence that the incidence of cardiac necrosis is higher in Eskimos.

The ω-3 fatty acids found in fish oil are susceptible to oxidative breakdown. For this reason, they must be protected from oxidation by proper extraction and storage, encapsulation, or stabilization with an antioxidant such as vitamin E. Inappropriately stored fish oils (i.e., exposure to oxygen) may result in the formation of toxic lipid peroxides over time.

Measurement of Lipid Oxidation Products Is Essential in Fatty Acid Supplements

The consumption of essential fatty acid supplements and vegetable oils is increasing, with fish oil now one of the most frequently consumed nutritional supplements. However, the high concentration of unsaturated fatty acids in these products makes them more susceptible to spoilage and oxidative damage. Several factors accelerate spoilage of these oils, including the presence of reactive metals, high water content, or high temperatures during processing and storage.

Consumers perceive oxidative damage as rancidity or off-flavors and off-odors. The health implications of this damage are important. Oxidative damage diminishes the nutritional value of these oils by destroying vitamins and other nutrients. Oxidative products may also interact with protein and carbohydrates. In addition, the by-products of lipid oxidation may pose a health risk to consumers.

Some edible oils are more resistant to oxidative damage. For example, vegetable oils may naturally contain antioxidants such as tocopherols or vitamin E. Antioxidants prevent the oxidative reactives that can lead to rancidity. Many pathways of oxidation of lipids are not completely understood. Two pathways that have received attention are oxidative and hydrolytic rancidity.

Oxidative reactions tend to be more complex, and their by-products are difficult to measure. Initially, oxygen combines with free fatty acids to form hydroperoxides and free radicals. These reactions are influenced by many factors: the percentage of unsaturated fatty acids present in the oil; processing and storage temperatures; oxygen concentration; light exposure; presence of antioxidants in the oil; moisture content of the oil; and the presence of reactive transition metals, such as iron, nickel, or copper.

The primary oxidative products are unstable. Hydroperoxides are rapidly degraded to aldehydes, ketones, alcohols, and hydrocarbons. These secondary products are relatively stable and are responsible for the characteristic flavor and odor associated with rancid oils.

Historically, manufacturers of edible oils relied on two analytic tests to determine the level of oxidation in oil: the free fatty acid percentage and peroxide value. Two additional measures, the anisidine value and the total oxidation value, have become the focus of attention.

The percentage of free fatty acids in oil is an indication of freshness. As oil ages, triglycerides are cleaved to glycerol and free fatty acids through hydrolysis. Free fatty acids are more prone to oxidation than triglycerides, so their presence in oils increases the possibility of rancidity. A fresh, carefully processed oil has a free fatty acid percentage of less than 0.05%.

The peroxide value measures the level of hydroperoxides in oil. Hydroperoxides are the primary by-product of oxidation. For example, 4-hydroxy-hexenal is a by-product of DHA peroxidation known to be elevated in disease states.[317] Peroxide value alone is not indicative of the actual oxidative state of the oil because hydroperoxides decompose rapidly to secondary by-products such as aldehydes. Therefore an oil might also have a low peroxide value as a result of extensive oxidation rather than due to low levels of oxidation. In theory, fresh oil would have a peroxide value of zero. In practice, most vegetable oils have peroxide values ranging from 0.1 to 1. Besides the peroxide value, the anisidine value must also be calculated.

The anisidine value is a measure of the amount of α- and β-unsaturated aldehydes. Anisidine is an aromatic amine. Synonyms for anisidine include aminoanisole, methoxyaniline, methoxyphenylamine, and methoxybenzenamine. Anisidine has two isomeric forms. Both were reported to enhance mutagenicity in bacterial strains.[318] The ortho-anisidine isomer was associated with bladder tumors. Data on carcinogenicity are almost exclusively on the ortho-isomer, not the para-isomer, which most companies focus on when they measure anisidine values in fish oils.

The total oxidative value used to express the extent of oxidation of an oil is the sum of the peroxide value and the anisidine value. Tests for peroxide value should comply with the *American Oil Chemists, Society* (AOCS) *Official Method* Cd 8-53 and not exceed a maximum of 5 mEq/kg, whereas the para-anisidine value should comply with *AOCS Official Method* 18-90 and not exceed a maximum of 20.

Many commercially available oils contain high levels of hydroperoxides and secondary by-products of oxidation. In the 1990s, Shukla

TABLE 80.2 Analytic Constants of Various Encapsulated Essential Fatty Acid Oils (1985–1988)

Product	Peroxide Value (Px)	Anisidine Value (Av)	Total Oxidation (2 Px + Av)	Iodine Value	Percentage of Free Fatty Acids
Vegetable oils					
A	5.4	6	16.8	151.5	1.02

TABLE 80.3 Analytic Constants of the Same Brand of Fish Oil Capsules Bought in Four Different Countries

Country	Peroxide Value (Px)	Anisidine Value (Av)	Total Oxidation Value (2 Px + Av)
England	3.8	16.6	24.2
The Netherlands	1.8	34	37.6
Denmark	3.7	30.2	37.6
United States	2.2	20.6	25

Data from Kinsella JE, Lokesh B, Stone RA. Dietary n-3 polyunsaturated fatty acids and amelioration of cardiovascular disease: possible mechanisms. *Am J Clin Nutr.* 1990 Jul;52(1):1–28.

and Perkins[319] analyzed various oils for oxidative stability. Their results showed that fish oils were more prone to oxidation than vegetable oils. The total oxidation values of fish oils ranged from 20 to 60 compared with 5 to 20 for vegetable oils (Tables 80.2 and 80.3).[19]

Shukla and Perkins made the following recommendations to prevent oxidation during the manufacturing process[42]:

- Always use top-quality, freshly produced raw materials stored in temperature- and humidity-controlled facilities.
- Prevent exposure to oxygen by using closed, impermeable containers.
- Avoid exposure of raw materials to sunlight.
- Use stringent quality control.
- Use stainless-steel equipment.
- Minimize heating of oil during processing.
- Use antioxidants to prolong shelf life.
- When using soft gelatin capsules, choose a shell with the lowest concentration of plasticizer possible.

By the early 21st century, many manufacturers of fatty acid supplements and vegetable oils took the lead to protect consumers by producing oils with the lowest levels of oxidative by-products possible. Consumer education and accurate measurement of peroxide and anisidine values are vital to this effort.

DOSAGE

A daily dose of 1000 mg EPA+DHA may be sufficient as a general health adjunct. However, for more therapeutic indications, the dosage range based on most clinical studies is between 3 and 4 g/day of EPA+DHA. Research also suggests that biomarker assessment may be of value for determining the optimal dosage for a variety of conditions, especially protection against cardiovascular disease. In a small study, supplementation with 1296 mg EPA + 864 mg DHA per day increased the erythrocyte ω-3 index, a potential biomarker for at least cardiovascular disease risk, to near 8%.[320] Interindividual differences in eicosanoid metabolism as well as digestive and/or absorptive function, along with genetic polymorphisms, may call for more individualized dosing. As clearly evidenced by clinical trials such as those on RA, a benefit may not be seen for 2 to 3 months.

The optimal ratio of EPA/DHA is not well established and may vary for individuals as well as conditions. Research in depression suggests that although DHA is the more prevalent fatty acid in brain tissue, EPA may be more clinically effective. This should be kept in mind when considering other conditions, such as fish oil supplementation for neurodegenerative disease.

Also, the form of fish and fish oil supplements is an important consideration. In one small trial comparing cod liver oil supplementation with actual fish consumption, cooked salmon increased serum levels to a greater extent than cod liver oil, despite providing less total DHA/EPA.[321] This may be because in fish, the fatty acids are triacylglycerols and phospholipids, whereas in almost all refined fish oils used in studies, EPA and DHA were in the ethyl ester form. Currently, EPA/DHA supplements are widely available in the triglyceride, phospholipid, and ethyl ester forms. Although several studies have shown similar absorption for ethyl esters, phospholipids, or triglycerides, other studies have shown that EPA/DHA consumed as triacylglycerides increased the ω-3 index more rapidly and to a greater degree than the ethyl esters of DHA/EPA.[322–324] However, the clinical significance of this advantage has not yet been demonstrated, especially with chronic administration.

DRUG INTERACTIONS

Individuals known or suspected to have a bleeding disorder, as well as those prescribed therapeutic levels of aspirin or warfarin, should have their bleeding time parameters measured, although as previously described (see "Bleeding Time"), this risk is not likely to exist. Patients may benefit from fish oil when taking cyclosporine.[325] Fish oil may also have synergistic or additive effects with the cholesterol- and triglyceride-lowering drugs pravastatin and simvastatin and have broader therapeutic value.[326] Fish oil is likely to modulate the cytotoxicity of many chemotherapeutic agents, as previously described, to increase therapeutic efficacy without increasing toxicity. It may also reduce the adverse

effects of many chemotherapeutic regimens, including the unintentional loss of weight. It may increase the efficacy of some antidepressants without an increase in toxicity.[269] A thorough review by Stargrove et al.[327] found nearly every drug interaction to be a beneficial one.

CONCLUSION

A substantial body of evidence continues to grow, documenting the safety and efficacy of *uncontaminated* n-3 fatty acids from fish and fish oil for a broad range of diseases, as well as for improving optimal cellular and physiological function. The mechanisms by which EPA and DHA from fish oil modulate cellular function and membrane structure continue to be elucidated in greater detail, and the potential of biomarkers, such as the ω-3 index, and genetic variants related to fish oil metabolism highlight the need for individualized and targeted fish oil supplementation.

The list of conditions for which fish oil is of benefit extends well beyond this chapter because its use has been researched for most medical conditions. Many of the common and most well-established uses for fish oil have been highlighted, such as for cardiovascular disease and modulation of inflammatory activity. The growing contamination of fish and the potential decline in worldwide fish stocks are of considerable concern, especially given the broad-ranging benefit of this underconsumed nutrient. Also, a growing awareness of the importance of not just n-3 intake but also of the ratio of n-6 fatty acids may help increase the efficacy of its nutritional modulation. One article cited that despite a 0.005% change in human genes over the past 10,000 years, an extraordinarily significant shift in the ratio of n-6:n-3 has occurred, which might help explain so many of today's modern illnesses.[31]

Flavonoids—Quercetin, Citrus Flavonoids, and Hydroxyethylrutosides

Michael T. Murray, ND

OUTLINE

INTRODUCTION

Flavonoids, a group of polyphenolic plant pigments, are largely responsible for the colors of many fruits and flowers. Considerable research suggests that flavonoids may be useful in the treatment and prevention of many health conditions. Many of the medicinal actions of foods, juices, herbs, and bee pollen are now known to be directly related to their flavonoid content. More than 8000 flavonoid compounds have been characterized and classified according to their chemical structure. Flavonoids are a bit of an enigma to scientists because they are quite reactive compounds. They can enter into almost any type of reaction known to organic chemistry, such as oxidation-reduction reactions, carbonyl reaction, acid–base reactions, free-radical reactions, hydrophobic interactions, tautomery, and isomerizations.[1] As such, characterization of the many diverse physiological properties of flavonoids is a considerable challenge to biochemists and researchers alike. This chapter discusses a few representatives of this class of useful clinical agents (quercetin, citrus bioflavonoids, and hydroxyethylrutosides).

Another beneficial group of plant flavonoids is the proanthocyanidins (also referred to as procyanidins). Collectively, mixtures of proanthocyanidin dimers, trimers, tetramers, and larger molecules are referred to as procyanidolic oligomers (PCOs). Chapter 117 discusses PCOs.

HISTORICAL PERSPECTIVE

Flavonoids, and vitamin C, were discovered by Albert Szent-Györgyi (1893–1986), one of the most respected and honored biochemists of the 20th century. Szent-Györgyi received the Nobel Prize in 1937 for his discovery of some of the properties of these molecules.

Szent-Györgyi discovered the flavonoids while isolating vitamin C. A friend with bleeding gums had stopped the bleeding by taking a crude vitamin C preparation isolated from lemon. When the problem reappeared, Szent-Györgyi gave his friend a purer form of vitamin C. He expected to observe an even more impressive result, but the purer form of vitamin C did not work. Szent-Györgyi then isolated the flavonoid fraction from the original crude vitamin C preparation, gave it to his friend, and observed complete healing.

Szent-Györgyi termed his discovery "vitamin P" because of its ability to reduce vascular permeability, one of the hallmark features of scurvy. He went on to show that the clinical symptoms of scurvy are the result of a combined deficiency of vitamin C and flavonoids. However, because flavonoids could not fulfill all the requirements of a vitamin, the designation as vitamin P was abandoned. Although flavonoids are often referred to as "semiessential" nutrients, their importance in human nutrition appears to be as important to good health as the essential vitamins and minerals.

Good dietary sources of flavonoids include citrus fruits, berries, onions, parsley, legumes, green tea, and red wine. The average daily intake in the United States for flavonoids is estimated to be between 150 and 200 mg.

CHEMICAL DESCRIPTIONS

Quercetin

Quercetin (Fig. 81.1) is a flavonoid that serves as the aglycone for many other flavonoids, including the citrus flavonoids rutin, quercitrin, and hesperidin. These derivatives differ from quercetin in that they have sugar molecules attached to the quercetin backbone. Quercetin is

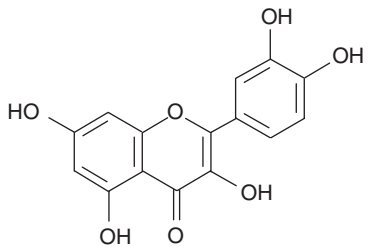

Fig. 81.1 Quercetin.

consistently one of the most active of the flavonoids in experimental studies, and many medicinal plants owe much of their activity to their high quercetin content.

Citrus Bioflavonoids

Citrus bioflavonoid preparations can include rutin, hesperidin, quercitrin, and naringin. Most of the clinical research on rutin and crude bioflavonoid complexes occurred before 1970. Since then, most of the clinical research has used a standardized mixture of rutinosides known as hydroxyethylrutosides (HERs). Impressive clinical results have been obtained in the treatment of capillary permeability, excessive bruisability, hemorrhoids, and varicose veins with HERs (discussed in the section "Collagen Matrix Support"). Citrus bioflavonoids can be viewed as providing similar effects to, but probably not as potent as, HERs or quercetin.

PHARMACOLOGY

As a class of compounds, flavonoids have been referred to as "nature's biological response modifiers" because of their ability to modify the body's reaction to other compounds, such as allergens, viruses, and carcinogens, as evidenced by their anti-inflammatory, antiallergic, antiviral, and anticarcinogenic properties.[2] In addition, flavonoids act as powerful antioxidants, providing remarkable protection against oxidative and free-radical damage[3]; they also have the ability to traverse the blood–brain barrier, thus exerting a neuroprotective effect.[4] Flavonoids are known to form strong ligand complexes with heavy-metal ions and may prove to be a good agent for heavy-metal detoxification.[1]

The practical aspect of this antioxidant activity was highlighted by the results of a study in 805 men designed to determine the effect of dietary flavonoids on protecting against heart disease. The study demonstrated an inverse correlation between flavonoid intake and death from a heart attack.[5] This effect was probably a result of the potent antioxidant effects of the flavonoids preventing, similar to vitamins C and E, the formation of oxidized cholesterol. However, the antioxidant activity of flavonoids is generally more potent and effective against a broader range of oxidants than the traditional antioxidant nutrients like vitamins C and E, selenium, and zinc.[6,7]

Because different flavonoids tend to provide different benefits, additional and more specific beneficial effects are discussed under the key selected flavonoid categories. There is significant overlap among these flavonoids, however.

Quercetin

Quercetin consistently demonstrates the greatest activity among the flavonoids studied in experimental models, particularly in vitro studies. The primary actions that are briefly reviewed here are its anti-inflammatory effects, inhibition of aldose reductase, antiviral activity, and anticancer properties.

Anti-inflammatory Effects

Quercetin has demonstrated significant anti-inflammatory activity because of direct inhibition of several of the initial processes of inflammation via interaction with calcium channels or calmodulin (the intracellular calcium-binding protein), or both. It works through other mechanisms as well, such as inhibiting mast cell and basophil degranulation, neutrophil and monocyte lysosomal secretion, prostaglandin (most notably, leukotriene) formation, lipid peroxidation, and the resultant cascade of effects that is often a result of these processes. For example, it inhibits both the manufacture and release of histamine and other allergic/inflammatory mediators. In addition, it exerts potent antioxidant activity and vitamin C–sparing action.[6–9]

Effect on Histamine Release

The release of histamine and other inflammatory mediators from mast cells and basophils is involved in the pathogenesis of acute allergic and inflammatory responses. Mast cells are widely distributed throughout the human body but are found in higher concentrations in the blood vessels of the subepithelial connective tissue of the respiratory tract, conjunctiva, gastrointestinal tract, and skin. Mast cell and basophil degranulation is an active process that requires calcium influx. Quercetin and many other flavonoids have been shown to be potent inhibitors of mast cell, neutrophil, and basophil degranulation. A generally accepted hypothesis for this action is that quercetin inhibits receptor-mediated calcium influx, thereby inhibiting the primary signal for degranulation. However, quercetin is also active under conditions in which the calcium channel mechanism is not operative, indicating that other mechanisms are responsible as well.[6–9]

Membrane Stabilization, Antioxidant Activity, and Hyaluronidase Inhibition

Quercetin inhibits many of the inflammatory processes attributed to activated neutrophils. This effect is probably a result of its membrane-stabilizing action, potent antioxidant effect (which prevents the production of free radicals and inflammatory leukotrienes), inhibition of the enzyme hyaluronidase (thus preventing the breakdown of the collagen matrix of connective tissue and ground substance), and finally inhibition of the proinflammatory cytokines. Quercetin's membrane-stabilizing effect could also account for its action in preventing mast cell and basophil degranulation. This effect also inhibits inflammation by decreasing neutrophil lysosomal enzyme secretion.[10] Neutrophils and monocytes contain lysosomes that, on secretion of their contents, contribute greatly to the inflammatory process.

Effects on Eicosanoid Metabolism

Excessive leukotriene formation has been linked to asthma, psoriasis, atopic dermatitis, gout, ulcerative colitis, and possibly cancer. Quercetin has been shown to inhibit many steps in eicosanoid metabolism. Its inhibition of phospholipase A2 and lipoxygenase enzymes is probably its most significant action (see Chapter 149 for diagram). The net result is a significant reduction in the formation of leukotrienes. The leukotrienes C4, D4, and E4 (composing the slow-reacting substances of anaphylaxis) are derived from arachidonic acid and are 1000 times as potent as histamine in promoting inflammation. Leukotrienes promote inflammation by causing vasoconstriction (thereby increasing vascular permeability) and bronchoconstriction (thus inducing asthma) and by promoting white blood cell chemotaxis and aggregation. The reduction of leukotriene formation by quercetin has significant anti-inflammatory effects.

Inhibition of Aldose Reductase

Quercetin is a strong inhibitor of aldose reductase, the enzyme responsible for the conversion of blood glucose to sorbitol. This compound is strongly implicated in the development of diabetic complications such

as diabetic cataracts, neuropathy, and retinopathy.[11] The mechanism by which sorbitol is involved in the development of diabetic complications is best understood by considering its involvement in cataract formation. Although the lens does not have any blood vessels, it is an actively metabolizing tissue that continuously grows throughout life. Elevated blood sugar levels result in shunting of glucose to the sorbitol pathway.

Because the lens membranes are virtually impermeable to sorbitol and lack the enzyme required to break down sorbitol (polyol dehydrogenase), sorbitol accumulates to high concentrations. These high concentrations persist even if glucose levels return to normal. This accumulation creates an osmotic gradient that results in water being drawn into the cells to maintain osmotic balance. As the water is pulled in, the cell must release small molecules like amino acids, inositol, glutathione, niacin, vitamin C, magnesium, and potassium to maintain osmotic balance. Because these latter compounds function to protect the lens from damage, their loss results in an increased susceptibility to damage. As a result, the delicate protein fibers within the lens become opaque, and a cataract forms.

Quercitrin, which is hydrolyzed by gut bacteria to yield quercetin and a sugar moiety, was shown to significantly decrease the accumulation of sorbitol in the lens of diabetic animals, effectively delaying the onset of cataracts.[12] In addition to its effect on aldose reductase, quercetin is also of value in diabetes for its ability to enhance insulin secretion and protect the pancreatic β cells from the damaging effects of free radicals, and for its inhibition of platelet aggregation.[6,7]

Antiviral Activity

Flavonoids as a group possess significant antiviral activity, with quercetin having the greatest antiviral activity against herpes virus type I, parainfluenzae 3, poliovirus type I, and respiratory syncytial virus.[13] Quercetin was shown, in vitro, to inhibit both viral replication and infectivity. In vivo studies in animals also showed quercetin to inhibit viral infection.[14] This would suggest that quercetin might be of some benefit in viral infections, including the common cold.

Anticancer Properties

Many flavonoids have also been shown to inhibit tumor formation, but again quercetin has consistently been the most effective. In experimental models, quercetin demonstrated significant antitumor activity against a wide range of cancers, including squamous-cell carcinoma; leukemia; and cancers of the breast, ovaries, colon, rectum, and brain. The cancer-preventive effects of quercetin have been attributed to various mechanisms, including antioxidative activity, inhibition of enzymes that activate carcinogens, modification of signal transduction pathways, and interactions with receptors and other proteins, such as the androgen receptor involved in the development and progression of prostate cancer.[15–17]

Clinically, quercetin holds great promise in reversing multidrug resistance (MDR) in cancer cells. Transporter-mediated active efflux of cytotoxic agents is one of the best-characterized mechanisms by which cancer cells develop MDR. Quercetin demonstrated multitargeted effects in reversing MDR.[17]

Citrus Flavonoids

Collagen Matrix Support

In addition to possessing antioxidant activity and an ability to increase intracellular levels of vitamin C, rutin, hesperidin, and HER exert many beneficial effects on capillary permeability and blood flow, primarily via strengthening endothelial cells and supporting collagen structures. Collagen, the most abundant protein of the body, is responsible for maintaining the integrity of "ground substance" and the integrity of tendons, ligaments, and cartilage. Collagen is also the support structure of the skin and blood vessels. Citrus flavonoids affect collagen metabolism in several ways.

They reinforce the natural cross-linking of collagen that forms the so-called collagen matrix of connective tissue and protect against free-radical damage with their potent antioxidant and free-radical–scavenging action. They also inhibit enzymatic cleavage of collagen by enzymes secreted by leukocytes during inflammation and microbes during infection. Like quercetin, citrus flavonoids also prevent the release and synthesis of compounds that promote inflammation and allergies, such as histamine, serine proteases, prostaglandins, and leukotrienes.[8,9] It is believed that the citrus bioflavonoid hesperidin possesses antihistaminic activity through its metabolite heparitin, a weak inhibitor of cyclooxygenase-2 enzymes. This metabolite is produced as a product of intestinal bacteria, which underscores the need for a balanced intestinal flora to gain the antihistamine benefits of citrus bioflavonoids.[18]

Bone Metabolism Effects

Histomorphometric research on ovariectomized mice showed that marked decreases in trabecular bone volume and trabecular thickness of the femoral distal metaphysis were significantly prevented by hesperidin. Additionally, calcium, phosphorus, and zinc concentrations in the femur were significantly higher in the hesperidin-fed group, whereas serum and hepatic lipids were lower in mice that consumed hesperidin-containing diets.[19]

PHARMACOKINETICS

Before discussing the clinical applications of quercetin, it is important to address absorption and metabolism. Previous pharmacokinetic studies in animals and humans indicated that little quercetin is absorbed intact, with the majority of the oral dose (53%) being excreted in the feces.[20,21] One of the main problems in studying the absorption of quercetin and other flavonoids is their degradation by microorganisms in the colon. To sidestep this issue, one study examined the absorption of quercetin in healthy ileostomy patients with complete small intestines.[22] The study examined the absorption of quercetin from fried onions (a rich source of quercetin glycosides), rutin, or 100 mg of pure quercetin. Absorption was defined as oral intake minus ileostomy excretion and corrected for degradation within the ileostomy bag. Absorption results were as follows: 52% from onions, 17% from quercetin rutinoside, and 24% for pure quercetin. These results indicate that humans do absorb appreciable amounts of quercetin and that absorption (but not necessarily pharmacological activity) may be enhanced when quercetin is bound to glucose. In other words, citrus bioflavonoid preparations or HERs, or both, may prove to be more effective clinically.

Subsequent studies shed additional light on the absorption and metabolism of quercetin. In a study of 35 healthy volunteers, the volunteers were randomly assigned to take 50, 100, or 150 mg/day (groups Q50, Q100, and Q150, respectively) of quercetin for 2 weeks. Fasting blood samples were collected at the beginning and end of the supplementation period. Compared with baseline, quercetin supplementation significantly increased plasma concentrations of quercetin by 178% (Q50), 359% (Q100), and 570% (Q150). The pharmacokinetics of quercetin were investigated in a subgroup of 15 volunteers. The areas under the plasma concentration–time curves ranged from 76.1 to 305.8 μmol/min/L(−1) (50- and 150-mg doses, respectively). Median maximum plasma concentrations of quercetin (431 nmol/L) were observed 360 minutes after intake of 150 mg of quercetin.[23]

In a much larger study, 1002 subjects were randomized to one of three groups: Q-500 (500 mg/day), Q-1000 (1000 mg/day), or placebo.

Quercetin supplementation over 12 weeks caused a significant increase in overnight-fasted plasma quercetin, with a net increase of 332 and 516 mcg/L for Q-500 and Q-1000 compared with 53.6 mcg/L for placebo. However, the increase in plasma quercetin was highly variable within each quercetin supplementation group.[24]

Quercetin is significantly metabolized into conjugates and smaller molecules. When healthy adults were given 1000 mg of quercetin daily for 3 months, it was extensively converted to isorhamnetin-3-glucuronide, which had the highest concentration at 3 months, followed by quercetin-3-glucuronide, quercetin-3-sulfate, and quercetin diglucuronide.[25]

Quercetin should be administered with dietary fat because it leads to improved absorption through intestinal micellization.[26]

Given the relatively poor bioavailability and high variability of absorption among subjects, improved clinical results may be achieved with newer forms of quercetin, such as enzymatically modified isoquercitrin (EMIQ) or phosphatidylcholine-bound quercetin to overcome these shortcomings (discussed in the section "Commercial Forms").

CLINICAL APPLICATIONS

Allergic and Inflammatory Conditions

Largely on the basis of in vitro studies, quercetin appears to be indicated in virtually all inflammatory and allergic conditions, including asthma, hay fever, rheumatoid arthritis, and lupus, and in diabetes and cancer. Clinical documentation in these areas, however, is lacking. In a study using a highly bioavailable EMIQ, very good results were achieved. In a parallel-group, double-blind, placebo-controlled study design, 20 subjects with hay fever caused by Japanese cedar pollinosis took two capsules daily of 100 mg EMIQ or a placebo for 8 weeks during the pollen season. During the entire study, the total ocular score and the ocular itching score for the EMIQ group were significantly lower than those of the placebo group. When limited to the individual periods, the total symptom score for the EMIQ group was significantly lower than that for the placebo group. The levels of serum cytokines, such as interleukin (IL)-4, IL-5, IL-12, IL-13, interferon-γ, and eotaxin and immunoglobulin-E, were not significantly downregulated by the intake of EMIQ, but the serum concentrations of oxidized low-density lipoprotein and thymus and activation-regulated chemokines were reduced.[27]

In another study of EMIQ in subjects with hay fever caused by Japanese cedar pollinosis, 24 subjects took 100 mg EMIQ or a placebo for 8 weeks, starting 4 weeks before the onset of pollen release. During the entire study period, the ocular symptom plus medication score for the EMIQ group was significantly lower than that of the placebo group. When limited to the pollen release period, ocular symptom scores and ocular congestion scores for the EMIQ group were significantly lower than that for the placebo group, whereas other scores for the EMIQ group, such as ocular itching scores, lacrimation scores, and ocular congestion scores, all tended to be lower. However, no significant differences were found in nasal symptoms between the two groups. These results indicate that EMIQ is useful in reducing the ocular symptoms of hay fever, especially ocular congestion.[28]

Topical application of quercetin showed anti-inflammatory effects. In a study of 40 patients with aphthous stomatitis randomly divided into two groups (group 1 patients used a benzydamine hydrochloride mouthwash three times daily; group 2 patients placed two to three dabs of quercetin three times daily directly on their ulcers), the topical application of quercetin cream to minor mouth ulcers relieved pain and produced complete healing in seven of the group 2 patients (35%) in 2 to 4 days, in 18 patients (90%) in 4 to 7 days, and in 20 patients (100%) in 7 to 10 days. Although aphthous ulcers typically resolve on their own in 1 to 2 weeks, the daily topical application of quercetin might be useful in accelerating the healing process of minor aphthous ulcers.[29]

Performance, Ergogenic, and Mitochondrial Effects

By far the most popular application, quercetin is in beverages designed for athletic performance. The commercial success of this application led to significant scientific investigation of quercetin's ability to improve physical performance. In a number of clinical trials, quercetin was shown to improve mental/physical performance and reduce infection risk after intense exercise.[30] In one small trial, 12 volunteers were randomly assigned to one of two treatments: (1) 500 mg of quercetin twice daily dissolved in vitamin-enriched Tang or (2) a nondistinguishable placebo (Tang). Baseline maximal oxygen consumption (VO_2max) and bike-ride times to fatigue were established. Treatments were administered for 7 days using a randomized, double-blind, placebo-controlled, crossover study design. After treatment, both VO_2max and ride time to fatigue were determined. Seven days of quercetin feedings were associated with a modest increase in VO_2max (3.9% vs. placebo) along with a substantial (13.2%) increase in ride time to fatigue. These data suggest that as little as 7 days of quercetin supplementation can increase endurance without exercise training in untrained participants. However, a similar study using treadmill testing failed to show the same sort of effect.[31]

In a more detailed study, 26 young adult males were given quercetin (1 g/day) or placebo for 2 weeks and then crossed over.[32] Subjects provided blood and muscle biopsy samples before and after supplementation periods and underwent 12-minute time trials on 15% graded treadmills after 60 minutes of moderate exercise preloads at 60% VO_2max. Plasma quercetin levels rose significantly during the 2-week quercetin supplementation period. Quercetin produced a 2.9% increased net distance in the 12-minute trial; skeletal muscle messenger RNA expression tended to increase (range, 16%–25%) during quercetin use for sirtuin 1, peroxisome proliferator-activated receptor γ coactivator-1α, cytochrome-c oxidase, and citrate synthase. Muscle mitochondrial DNA (relative copy number per diploid nuclear genome) increased by 4.1% with quercetin compared with a 6.0% decrease with the placebo. This result seems to indicate that quercetin does provide some benefit in improving physical performance in untrained volunteers.

In regard to moderately trained men and women, the data are not clear on indicators of performance, but quercetin showed other benefits in this group. In one study, 58 subjects were randomly assigned to quercetin (1 g/day) or placebo groups. Six weeks of dietary quercetin supplementation did not improve VO_2max or other indicators of performance.[33] In double-blind studies, however, quercetin (1 g/day) was shown to reduce upper respiratory infections in moderately trained individuals.[34,35] Of 20 trained male cyclists who received quercetin or placebo before, during, and for 2 weeks after a 3-day period in which subjects cycled for 3 hours/day at approximately 57% maximal workload, only 1 of 20 developed upper respiratory infection symptoms in the quercetin group compared with 9 of 20 in the placebo group.[34] In another study, a reduction in upper respiratory tract infection total sick days and severity was noted in middle-aged and older subjects ingesting 1000 mg/day quercetin for 12 weeks who rated themselves as physically fit.[35]

Although one small study of 16 male soldiers supplemented with 500 mg of quercetin twice daily showed no benefit in improving aerobic athletic performance (i.e., 75 minutes of loaded treadmill marching and a subsequent cycling time trial to complete 200 kJ of work,[36] a study with phosphatidylcholine-bound quercetin (Quercetin Phytosome), a more bioavailable form of quercetin, has been shown to be of particular benefit to athletes. For example, in a study in triathletes, Quercetin

Phytosome was shown to improve performance time and reduce postexercise muscular pain, cramps, and recovery time.[37] These benefits were attributed to its ability to reduce oxidative stress. Quercetin also exerts significant support for the immune system and antiallergy effects. This product is best for allergies, food sensitivities, and athletes.

Cardiovascular Effects

Various studies indicated quercetin and citrus bioflavonoids beneficially affected cardiovascular risk factors. In animal studies, increases in high-density lipoprotein and decreases in low-density lipoprotein cholesterol, total lipid, and triglyceride plasma levels in normolipidemic rats and in rats with diet and induced hyperlipidemia were observed.[38] Animal studies also showed antihypertensive effects in spontaneously hypertensive rats and normotensive rats.[39] EMIQ was even more effective based on animal studies that evaluated the antihypertensive effects and antiatherogenic effects in spontaneously hypertensive rats.[40,41]

A variety of human studies substantiated some of these effects and many more. Hesperidin and quercetin both improved endothelial function.[42,43] In particular, quercetin at a dosage of 200 mg/day augmented nitric oxide status and reduced endothelin-1 concentrations to improve endothelial function. In a pilot study with quercetin-4′-O-β-D-glucoside, which, like EMIQ, is a prodrug for quercetin, subjects given either 50 or 300 mg had significant inhibition of platelet aggregation at 30 and 120 minutes after ingestion.[44]

In one study, the effect of quercetin supplementation on blood pressure, lipid metabolism, markers of oxidative stress, inflammation, and body composition was studied in an at-risk population of 93 overweight-obese volunteers (aged 25–65 years of age) with metabolic syndrome traits in relation to apolipoprotein-E (Apo-E) genotype.[45,46] Participants were randomized to receive 150 mg/day quercetin in a double-blinded, placebo-controlled, crossover trial with 6-week treatment periods separated by a 5-week washout period. Participants were classified into the following three Apo-E phenotypes: Apo-E2 ($n = 3$), Apo-E3 ($n = 60$), and Apo-E4 ($n = 26$). Data were analyzed for the Apo-E3 and Apo-E4 subgroups. Quercetin decreased systolic blood pressure by 3.4 mm Hg in the Apo-E3 group, whereas no significant effect was observed in the Apo-E4 group. Quercetin decreased serum high-density lipoprotein cholesterol (i.e., from 52–47 mg/dL), resulting in a slightly increased ratio of low-density lipoprotein to high-density lipoprotein cholesterol in the Apo-E4 subgroup, whereas the Apo-E3 subgroup had no significant changes in these variables. Quercetin significantly decreased plasma oxidized low-density lipoprotein and tumor necrosis factor-α in the Apo-E3 and Apo-E4 groups, whereas no significant intergroup differences were found. Serum C-reactive protein and nutritional status (body weight, waist circumference, fat mass, fat-free mass) were unaffected compared with placebo. In conclusion, quercetin exhibited blood pressure–lowering effects in overweight-obese carriers of the Apo ε3/ε3 genotype but not in carriers of the ε4 allele. Although the degree of blood pressure reduction was not clinically meaningful in this study, in another randomized, double-blind, placebo-controlled, crossover study, 730 mg/day of quercetin for 28 days was shown to lead to meaningful reductions in systolic (−7 mm Hg), diastolic (−5 mm Hg), and mean arterial pressures (−5 mm Hg) in stage 1 hypertensive patients.[47]

The exact mechanism for quercetin is not known, although one study showed that it is not related to inhibiting the activity of angiotensin-converting enzyme or endothelin-1 nitric oxide production.[48] Quercetin is definitely cardioprotective; at a dosage of 120 mg per day, it was shown to reduce the total time and number of episodes of ST-segment depression and the number of premature ventricular contractions (PVCs) as demonstrated with 24 hour Holter electrocardiogram (ECG) monitoring.[49]

Gout

Quercetin may be helpful in gout through inhibition of xanthine oxidoreductase, the final step in intracellular uric acid production. In a double-blind, placebo-controlled, crossover trial, 22 healthy males (19–60 years) with baseline plasma uric acid concentration in the higher, but still considered healthy, range (339 [SD 51] μmol/l) were given either a tablet containing 500 mg of quercetin or a placebo daily for 4 weeks, with a 4-week washout period between crossover treatment. After quercetin treatment, plasma uric acid concentrations were significantly lowered by –26·5 μmol/l. This amount of 500 mg of quercetin contains the same bioavailable amount of quercetin as present in approximately 100 g of red onions.[50]

Chronic Venous Insufficiency, Capillary Fragility, Excessive Bruisability, and Hemorrhoids

A deficiency of hesperidin in the diet was linked with abnormal capillary leakiness, and pain in the extremities, causing aches, weakness, and night leg cramps.[51] Early studies demonstrated rutin to be effective in reducing capillary fragility, easy bruising, swelling and bruising after sports injuries, and nosebleeds.[52–54] More recent and much more extensive studies were performed with HERs. Positive double-blind clinical studies exist in the treatment of venous insufficiency, including varicose veins, hemorrhoids, diabetic vascular disease, and diabetic retinopathy.[55–67]

In double-blind studies of patients with chronic venous insufficiency, HER improved microvascular blood flow and clinical symptoms (pain, tired legs, night cramps, and restless legs) in 73% to 100% of patients.[55–66] Several studies were conducted on pregnant women, in whom HER was shown to be of great benefit in improving venous function and in helping relieve hemorrhoidal signs and symptoms. In one study, 90% of the women given HER (1000 mg/day for 4 weeks) had improved symptoms compared with only 12% in the placebo group.[66] Similar results in hemorrhoids not associated with pregnancy were also reported.[65]

In a very practical study, the effects of HER at a dose of 1 g/day on the prevention and control of flight microangiopathy and edema were studied in subjects with varicose veins and moderate chronic venous insufficiency who flew for more than 11 hours.[64] Measurements of skin laser Doppler resting flux venoarteriolar response, ankle swelling, and edema were made within 12 hours before and within 3 hours after the flights. The resulting edema after the flights was evaluated with a composite edema score (analog scale line). A group of 20 subjects was treated with HER (1 g/day, starting 2 days before the flight and 1 g for every 12 hours on day of travel). Another group of 18 subjects formed the control group. The length of the flights was between 11 and 13 hours; all seats were in coach class. Fifty patients were enrolled, and 38 patients were evaluable at the end of the trial. The results showed clearly that HER was useful for reducing the level of microangiopathy and the increased capillary filtration and in controlling edema in patients with venous disease during long flights. The higher level of flux and venoarteriolar response and the reduction in edema indicated a positive effect of HER on microcirculation.

There are a number of natural therapeutic agents to choose from in chronic venous insufficiency. In a double-blind study, the effects of HER were compared with micronized diosmin plus hesperidin (D+H). A first group of 90 patients with severe venous hypertension was randomized to treatment with HER or D+H. The HER group received oral HER (2 g/day); the D+H group received three 500-mg tablets daily every 8 hours for 8 weeks. A second group of 122 comparable patients was included in a registry following the same study format. The results show that HER was more effective in relieving signs and symptoms of chronic venous insufficiency and improving the quality-of-life scale in this study.[63]

Diabetes

Flavonoids appear to be important in the long-term care of diabetes for many reasons. One of the hallmark features of diabetes is a significant disturbance in blood flow through the small blood vessels. HERs appear to improve blood flow in diabetics significantly and can be useful in the treatment of diabetic microvascular disease and retinopathy. Flavonoids can also stimulate an otherwise weak insulin effect in several ways. For example, they can influence the protein phosphokinases, which modulate second-messenger pathways known to upregulate the gene encoding the glucose transporters.[1] PCOs or bilberry extracts may be better than quercetin, citrus flavonoids, and HER in diabetics.

Polycystic Ovarian Syndrome

Polycystic ovary syndrome (PCOS) is associated with low levels of the adipose-derived hormone adiponectin, even in the absence of adiposity. Because quercetin may reduce serum glucose, insulin, triglycerides, and cholesterol levels and increases the expression and secretion of adiponectin, researchers conducted a double-blind study in 84 women with PCOS. The treatment group received 1 g of quercetin (two 500-mg capsules) daily for 12 weeks, and the control group received a placebo. Quercetin slightly increased the level of total adiponectin by 5.56% and high-molecular-weight adiponectin by 3.9% compared with placebo. It also reduced the level of testosterone (0.71 ng/dL in quercetin vs. 0.77 ng/dL in placebo) and luteinizing hormone (LH; 8.42 IU/l in quercetin vs. 8.68 IU/l in placebo). HOMA-IR levels were also significantly lower in the quercetin (1.84) group compared with the placebo group (2.21). These results indicate that quercetin may have some benefit in the treatment of PCOS.[68]

Thalassemias

Although it may be difficult to treat the long-term outcomes of thalassemia conditions, it is possible that quercetin may serve to protect abnormally sensitive lymphocytes from common dietary substances. An in vitro study evaluated the effect of food mutagens on the lymphocytes from three different types of thalassemia patients: β-thalassemia major, β-thalassemia/Hb E, and a β-thalassemia trait with a 3.7-kb deletion. When the mutagen exposure was combined with quercetin, reduced sensitivities among the various thalassemic genotypes were observed in a dose-dependent manner.[69] Although human studies are necessary to confirm this beneficial effect, quercetin might be worth a try to attenuate the toxic mutagenic effects commonly found in these susceptible patients.

COMMERCIALLY AVAILABLE FORMS

Quercetin

Quercetin is available alone in powder and capsule form. However, if quercetin is being used for its anti-inflammatory properties, products that combine it with the pineapple enzyme bromelain may provide additional benefit. Bromelain (see Chapter 71) exerts antiallergy and anti-inflammatory activity on its own and may also enhance the absorption of quercetin. Combination preparations of protein-digesting enzymes, like bromelain, and flavonoids have been shown to potentiate each other's anti-inflammatory activity.[70]

EMIQ is a new form of quercetin that showed greater absorption in both human and animal studies. It is prepared by enzymatic deglycosylation and the subsequent α-oligoglucosylation of quercetin-3-O-rutinoside (rutin). The plasma level of quercetin conjugates is instantly increased by oral intake of EMIQ.[71,72] In a rat study, the absorption of EMIQ was compared with quercetin, quercetin-3-O-rutinoside (rutin), quercetin-3-O-glucoside (isoquercitrin [IQC]), quercetin-3-O-maltoside (Q3M), quercetin-3-O-gentiobioside (Q3G), α-monoglucosyl rutin (α-MR), and α-oligoglucosyl rutin (α-OR). Bioavailability (F value) was calculated from the concentrations of total quercetin in plasma from 0 to 12 hours after administration. The F value of quercetin was 2.0%, and those of IQC, Q3M, and EMIQ were 12%, 30%, and 35%, respectively. Quercetin Phytosome® (phosphatidylcholine-bound quercetin) has shown even greater bioavailability.[73] On a weight-equivalence basis, 500 mg of Quercetin Phytosome®, containing 200 mg of quercetin, versus 500 mg of quercetin produced blood levels 20 times greater than the quercetin.

Citrus Bioflavonoids

Mixed preparations of citrus bioflavonoids are the most widely used and least expensive flavonoid sources. However, mixed citrus flavonoids are the least active and generally the least quantified source of flavonoids because most commercially available sources of mixed citrus flavonoids only contain 50% flavonoids. Preparations containing pure rutin and hesperidin or those that clearly state the levels of rutin and hesperidin are superior to products that do not quantify the amount of the individual flavonoid components. HERs are probably the better choice when opting for the benefits in this class of flavonoids.

Dosages

The usual recommended dosage for quercetin is 500 mg two times daily. If quercetin is being used for its anti-inflammatory properties and bromelain supplementation is also indicated, administration with bromelain may enhance absorption. Combination preparations of proteolytic enzymes and flavonoids have been shown to have significant anti-inflammatory activity in experimental studies.[70] If used with bromelain, the amount of bromelain (1800 milk clotting units [mcu]) should be equal to the amount of quercetin.

Dosages used for HERs in double-blind clinical studies for the treatment of venous insufficiency and hemorrhoids ranged from 1000 to 3000 mg/day. This translates to a dosage of citrus bioflavonoids, rutin, and hesperidin of 3000 to 6000 mg/day.

Toxicity

Quercetin appears to be well tolerated in humans. A Phase I dose-escalation study was performed to evaluate the safety of quercetin in 30 untreated patients with chronic hepatitis C virus infection. Quercetin exhibited safety (up to 5 g daily), and there was a potential for antiviral activity in some hepatitis C patients. Quercetin also produced a "clinically meaningful" 0.41-log viral load decrease in eight of the subjects.[74]

Carcinogenic and teratogenic studies in rats and rabbits showed that quercetin does not have apparent side effects, even when consumed in large quantities (2000 mg/kg body weight and 5%–10% of total diet) for long periods of time (up to 2 years).[75–81] In addition, quercetin administration (up to 2000 mg/kg body weight) to pregnant rats had no teratogenic effects.[80] The weight of the available evidence supports the safety of quercetin.[82] As is true of any other compound, allergic reactions may occur. Although uncommon, if they occur, discontinue use. EMIQ has the status of generally recognized as safe in the United States.

Citrus bioflavonoids, rutin, hesperidin, and HER appear to be extremely safe and without side effects even during pregnancy.

Drug Interactions

Rutin, hesperidin, and HER do not appear to interact with any drug. Quercetin was shown to elevate the plasma concentrations of fexofenadine in healthy subjects, probably via the phosphoglycoprotein (Pgp)-mediated efflux in humans.[82] The Pgp enhances the uptake from the intestine of many drugs, including vinblastine, cyclosporine, digoxin, fexofenadine, and losartan, and can also increase the

oral bioavailability of drugs like nifedipine, felodipine, verapamil, and terfenadine, and inhibit the breakdown of various drugs, particularly caffeine, coumarin, and estrogens. Quercetin significantly induced the activity of Pgp, and this induced effect was more obvious in MDR1 3435 TT individuals.[83]

Unlike naringin from grapefruit, quercetin does not appear to affect CYP2C8 activity and has little possibility of interacting with drugs that are metabolized by this enzyme.[84]

Citrus bioflavonoid preparations generally are not an issue. However, if derived from grapefruit, they may contain naringin and interact with many drugs. Naringin activates Pgp and suppresses the expression of the cytochrome *P450 3A4* gene that can enhance oxidative decomposition of some drugs, including drugs used frequently in the therapy of cancer, human immunodeficiency virus, immune disorders, hypertension, and other serious conditions.[85] Avoidance of grapefruit juice and flavonoid preparations containing naringin is recommended where drug interactions are likely.

Ginkgo biloba (Ginkgo Tree)

Michael T. Murray, ND, and *John Nowicki, ND*

OUTLINE

Ginkgo biloba (family: *Ginkgoaceae*)
Common names: ginkgo tree, maidenhair tree

GENERAL DESCRIPTION

Ginkgo biloba is a deciduous tree that lives up to 1000 years old and grows to a height of 100 to 122 ft and a diameter of 3 to 4 ft (Fig. 82.1). Ginkgo has short horizontal branches with short shoots bearing fan-shaped leaves that measure 2 to 4 inches across. Because the leaf resembles a maidenhair fern, the ginkgo tree has been called "maidenhair tree." Ginkgo bears an inedible foul-smelling fruit and an edible ivory-colored inner seed that is sold in marketplaces in the Orient. Extracts from the leaves of the ginkgo tree are used medicinally.

CHEMICAL COMPOSITION

The active components of ginkgo leaves are the ginkgo-flavone glycosides or ginkgo heterosides (flavonoid molecules with sugars attached, which are unique to the ginkgo), several terpene molecules unique to ginkgo (ginkgolides and bilobalide), and organic acids.

Ginkgo biloba extract (GBE) is often standardized to contain 24% flavone glycosides because these molecules represent a convenient analytic reference group. Although they play a major role in the pharmacological activity of GBE, other components are also important. The three major backbone flavonoids of the *G. biloba* flavonols are quercetin, kaempferol, and isorhamnetin. The glucoside components are glucose and rhamnose, which are present as single sugars or disaccharides.

Other significant flavonoid components of the extract include proanthocyanidins, largely composed of dimers and oligomers of delphinoidine and cyanidine. The major terpene molecules of GBE, which account for 6% of the extract, are the ginkgolides and bilobalide

Fig. 82.1 *Ginkgo biloba.*

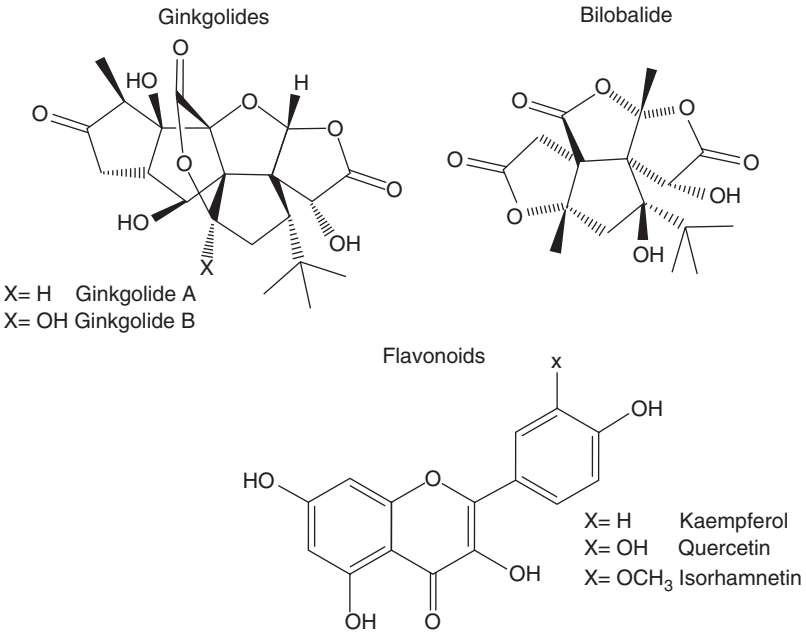

Fig. 82.2 Flavonoids and terpenes of *Ginkgo biloba*.

(Fig. 82.2). These substances are unique to ginkgo and are not found in any other plants. Other constituents of GBE include several organic acids. These compounds contribute valuable properties to the extract by making the usually water-insoluble flavonoid and terpene molecules of ginkgo water soluble.

HISTORY AND FOLK USE

G. biloba is the world's oldest living tree species. The sole surviving species of the family *Ginkgoaceae,* the ginkgo tree can be traced back more than 200 million years to the fossils of the Permian period, and for this reason, it is often referred to as the "living fossil."

Once common in North America and Europe, the ginkgo was almost destroyed during the Ice Age in all regions of the world except China, where it has long been cultivated as a sacred tree.

In the late 17th century, Engelbert Kaempfer, a German physician and botanist, became the first European to discover and catalog the ginkgo tree. The flavonoid kaempferol is named after Kaempfer. In 1771 Linnaeus named the tree *G. biloba.*

The ginkgo tree was brought to America in 1784 to the garden of William Hamilton near Philadelphia. The ginkgo tree is now planted throughout much of the United States as an ornamental tree. The ginkgo tree, which is the tree most resistant to insects, disease, and pollution, is frequently planted along streets in cities. The first green growth to reappear at the center of Hiroshima in 1946 was the sprout of a ginkgo tree that grew to be a normal, full-size tree.

G. biloba's medicinal use can be traced back to the oldest Chinese materia medica (2800 BC). Ginkgo leaves have been used in traditional Chinese medicine for their ability to "benefit the brain," relieve the symptoms of asthma and coughs, and help the body eliminate filaria.

In the late 1990s, ginkgo leaf extracts were among the leading prescription medicines in both Germany and France, where they accounted for 1% and 1.5%, respectively, of total prescription sales. In America, it was the top-selling botanical medicine in 1999, with $148 million in sales.[1] Ginkgo's popularity has waned a bit in the 21st century, but it remains among the top-selling natural products in Europe and North America.

PHARMACOLOGY

The GBE extract standardized to contain 24% ginkgo flavone glycosides has demonstrated remarkable diverse pharmacological effects. Interestingly, the total extract is more active than single isolated components. This suggests synergism between the various components of GBE, an explanation that is well supported in more than 2000 clinical and experimental studies using the extract.

General Effects

GBE exerts profound, widespread tissue effects, including membrane-stabilizing, antioxidant, and free-radical–scavenging effects. GBE also enhances the use of oxygen and glucose.[2,3,4]

Red blood cells provide excellent models for evaluating the effects of substances on membrane functions. Red blood cell studies using GBE demonstrated that in addition to directly stabilizing membrane structures and scavenging free radicals, GBE also enhanced membrane transport of potassium into the cell and sodium out of the cell by activating the sodium pump. In essence, GBE leads to better membrane polarization. This effect is particularly important in excitable tissues such as nerve cells.[2,3] GBE prevents metabolic and neuronal disturbances in experimental models of cerebral ischemia.[2,3,5–8] It accomplishes this by enhancing oxygen use and increasing cellular uptake of glucose, thus restoring energy production.

GBE also helps reestablish effective tissue perfusion during hypoxia. Particularly interesting is GBE's ability to normalize the circulation in areas most affected by microembolization, namely, the hippocampus and striatum. GBE promotes an increased nerve transmission rate, improves synthesis and turnover of brain neurotransmitters, normalizes acetylcholine receptors in the hippocampus (the area of the brain most affected by Alzheimer's disease), and inhibits β-amyloid deposition.[9]

Although the sample size was small, a study was conducted to evaluate the effects of a 6-week supplementation with 160 mg/day of a standardized extract of *G. biloba* or a matching placebo on aerobic performance, blood antioxidant capacity, and the level of brain-derived neurotrophic factor (BDNF) in healthy, physically active young men,

TABLE 82.1 Cellular and Membrane Mechanisms of the Vasoregulatory Effects of *Ginkgo biloba* Extract

Site of action	Upstream flow (arteriole)			Exchange area (capillary)			Downstream flow (venous)	
Tissue pathological condition	Arterial spasm	Arterial thrombosis	Vascular atony	Hypoxic vasoparalysis	Capillary hyperpermeability and plasma	Debilitated capillary walls	Venous relaxation and vasoparalysis extravasation	Venular spasms
Effects found with *Ginkgo biloba* extract	Vasorelaxation	Diminished platelet hyperaggregability	Restitution of arterial tone	Diminished accumulation of toxic wastes: K^+, CO_2, and lactate	Amelioration of capillary hyperpermeability	Increased capillary resistance	Venous tonic effect	Antagonism of experimental venous spasms
Cellular and membrane mechanisms explaining *G. biloba*'s effects	Release of EDRF from endothelium	Release of PGI_2	Direct effect	Consequence of venous tonic effect	Direct membrane effect	Direct membrane effect	Direct effect	Inhibition of PDE (?)
	Inhibition of PDE	Direct membrane effect	Potentiation of α-adrenergic effects[a]	Mitochondrial metabolic restart			Indirect effect via α-adrenergic effects	Release of dilating prostaglandins
	Potentiation of α-adrenergic effects[a]

[a]Partly through catechol-o-methyl transferase inhibition.

randomly allocated to two groups (n = 9 each). At baseline, and on the day after the treatment, the participants performed an incremental cycling test for the assessment of maximal oxygen uptake. Results showed that six weeks' supplementation with *G. biloba* extract in physically active young men may provide some marginal improvements in their endurance performance, expressed as VO_2max and blood antioxidant capacity, and elicit somewhat better neuroprotection through increased exercise-induced production of BDNF.[10]

Vascular Effects

The mechanisms of GBE's vascular effects were investigated using a number of in vivo and in vitro techniques (Table 82.1). Isolated vessel techniques allowed for the separation of GBE's effects on different parts of the vascular system (e.g., arterial, arteriolar, microcirculatory, venular, and venous components), whereas in vivo studies provided information on the total circulatory phenomena (i.e., GBE's ability to increase the perfusion rate to various regions).

In general, GBE exerts its vascular effects primarily through its effects on the lining of the blood vessels (vascular endothelium) and the system that regulates blood vessel tone. Its vasodilating action is explained by direct stimulation of the release of endothelium-derived relaxing factor and prostacyclin (a beneficial prostaglandin). In addition, GBE inhibits 3′,5′-cyclic guanosine monophosphate phosphodiesterase, an enzyme that results in relaxation of blood vessels.[2,11]

On the venous system, GBE stimulates greater tone, thus aiding the dynamic clearing of toxic metabolites that accumulate during ischemia (Fig. 82.3).[2,11]

GBE normalizes circulation by producing tonic effects. These effects are much more apparent in an ischemic vascular area than in a normally perfused area. However, despite intense investigation, many of GBE's tonic effects on vascular components are still largely unexplained. GBE can simultaneously combat the phenomena resulting from vascular spasm and, with the same efficiency, restore circulation to areas subject to vasomotor paralysis.

The importance of this dual action is becoming more apparent in cerebral insufficiency because single-direction drugs (i.e., vasodilators) can often aggravate the condition by preferentially dilating the healthy areas, thereby deflecting blood and oxygen away from the ischemic area.

Another prime clinical application of GBE's effects on vascular endothelium is early-stage diabetic nephropathy. In one 8-week clinical trial, in the GBE group, the brachial arterial endothelium-dependent dilation increased from 4.91% before treatment to 6.78% after treatment, whereas the level of von Willebrand factor decreased from 182% to 128.5%, and nitrous oxide increased from 50.16 to 70.65 μmol/L.[12]

GBE also protects against endothelial damage caused by oxidized low-density lipoprotein cholesterol, thereby preserving endothelial adhesive properties and disruption of ionic homeostasis.[13]

Platelet Effects

GBE and isolated ginkgolides have profound effects on platelet function, including inhibition of platelet aggregation, adhesion, and degranulation.[4] These effects appear to be a result of direct membrane and antioxidant effects, increased synthesis of prostacyclin, and antagonism of platelet-activating factor (PAF).

GBE and the ginkgolides were shown to be potent inhibitors of PAF.[4,14–16] PAF is a potent stimulator of platelet degranulation and is involved in many inflammatory and allergic processes, including neutrophil activation, increased vascular permeability, smooth muscle contraction (e.g., bronchoconstriction), and reduction in coronary blood flow. GBE and ginkgolides compete with PAF for binding sites and inhibit the various events induced by PAF.[2,3,17,18] These actions may be responsible for many of GBE's clinical effects. Interestingly,

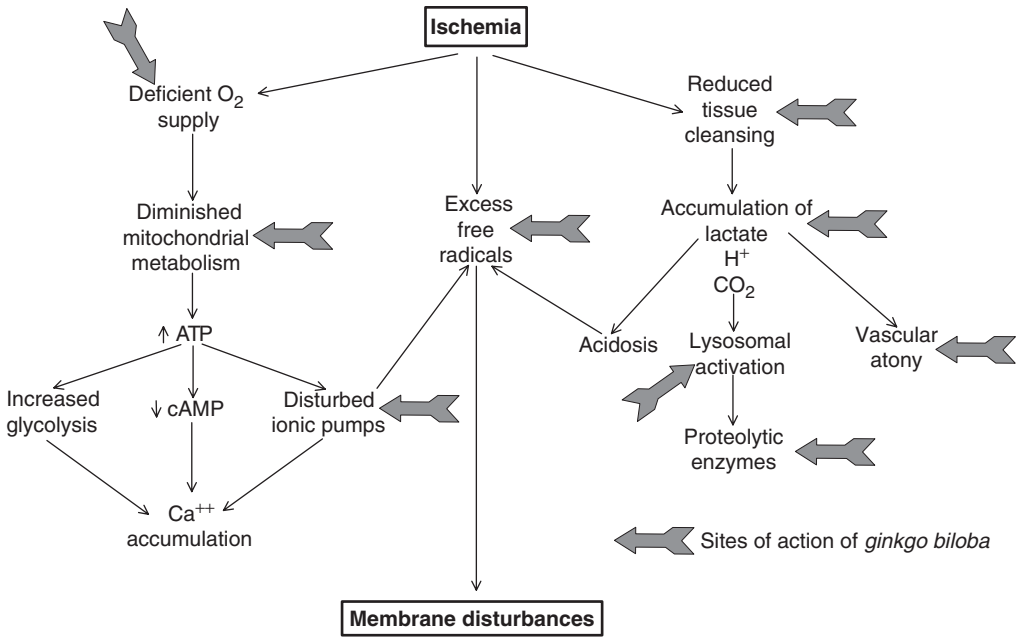

Fig. 82.3 The effect of *Ginkgo biloba* extract on ischemia.

despite these effects on PAF, GBE exerts no inhibition of platelet aggregation in humans.

ABSORPTION AND DISTRIBUTION OF *GINKGO BILOBA* EXTRACT

The pharmacokinetics (absorption, distribution, and elimination) of GBE were studied in rats using radiolabeled extracts.[2,3,4] After oral administration, at least 60% of the radiolabeled extract was absorbed. Because blood levels peaked after 1.5 hours, upper gastrointestinal tract absorption was suspected.

The flavonoids appear to have an affinity for organs rich in connective tissues, such as the aorta, eyes, skin, and lungs. Levels of radioactivity in these tissues are two to three times higher than those in blood and decrease little over time. Retained specific activity in the heart is twice that found in the skeletal muscles. Of the glands, the adrenals retain the greatest level of radioactivity.

At 72 hours, the hippocampus and striated bodies show radioactivity five times greater than that of the blood. This deposition pattern, which parallels the circulation improvement observed after ischemia caused by blood clotting in rats, is alleviated by GBE extracts. Other areas of the brain, such as the cerebral cortex, brainstem, and cerebellum, do not show such high levels of radioactivity.

Complexing GBE with phospholipids showed that the bioavailability of quercetin, kaempferol, and isorhamnetin was increased significantly, indicating these preparations might offer the best clinical response.[19] For central nervous system effect, complexing GBE with phosphatidylserine may prove superior to phosphatidylcholine (discussed in the section "Cerebral Vascular Insufficiency and Impaired Mental Performance").[20]

CLINICAL APPLICATIONS

GBE's primary clinical application has been in the treatment of vascular insufficiency. In more than 50 double-blind clinical trials, both patients with chronic cerebral arterial insufficiency and those with peripheral arterial insufficiency responded favorably to GBE. As described earlier, GBE exerts an extraordinary array of pharmacological activities that imply a broad spectrum of possible clinical applications, an implication borne out by the new applications of GBE, which are constantly being discovered.

Cerebral Vascular Insufficiency and Impaired Mental Performance

Cerebral vascular insufficiency is an extremely common condition in the elderly of developed countries because of the high prevalence of atherosclerosis. In well-designed studies, GBE displayed a statistically significant regression of the major symptoms of cerebral vascular insufficiency and impaired mental performance, including the following:

- Short-term memory loss
- Vertigo
- Headache
- Ringing in the ears
- Lack of vigilance
- Depression

Regression of these symptoms by GBE suggests that vascular insufficiency may be the major causative factor accounting for these so-called age-related cerebral disorders versus a true degenerative process.

In a comprehensive review, the quality of research on more than 40 clinical studies with GBE in the treatment of cerebral insufficiency was analyzed. The results indicated that GBE was effective in reducing all symptoms of cerebral insufficiency, including impaired mental function (senility). The quality of research was comparable to Hydergine (dihydroergotamine), a drug approved by the Food and Drug Administration (FDA) for use in the treatment of cerebral vascular insufficiency and Alzheimer's disease. Eight studies stood out as being extremely well designed and are summarized in Table 82.2.[14–17,21–23] It appears that by increasing cerebral blood flow, and therefore oxygen and glucose use, GBE offers relief from these effects of aging and may offer significant protection against their development.

G. biloba's antiaggregatory effect on platelets offers additional protection against a stroke. This was supported in a clinical study of post-stroke patients, which demonstrated that GBE improved blood flow and blood viscosity.[24] In another study using dynamic susceptibility

contrast-enhanced magnetic resonance imaging, elderly human subjects taking a modest dosage of 60 mg of GBE for 4 weeks experienced a significant increase of global cerebral blood flow, 15% in white matter and 13% in gray matter.[25]

In addition to improving blood supply to the brain, experimental and clinical studies showed that GBE increased the rate at which information was transmitted at the nerve cell level.[26,27] One study investigated the effects of acute doses of standardized GBE on memory and psychomotor performance in 31 healthy volunteers who were 30 to 59 years old.[28] It was a randomized, double-blind, placebo-controlled study with a five-way crossover design. Ginkgo improved working memory in all volunteers, especially those who were 50 to 59 years old. Fifty patients aged 50 to 85 years with mild cognitive impairment (MCI) and associated dual-task-related gait impairment participated in a randomized, double-blind, placebo-controlled, exploratory Phase IV drug trial of a *G. biloba* extract (Symfona forte 120 mg).[29] Subjects were divided into two groups. Patients allocated to the intervention group (IG) received standardized GBE LI 1370 (Symfona forte 120 mg; 25% standardized flavone glycoside, 6% terpene lactone content) twice daily for 6 months, whereas patients in the control group (CG) received identically appearing placebo capsules. After 6 months, dual-task-related cadence increased in the IG compared with the CG. This suggests that in patients with MCI, 120 mg of GBE twice daily for at least 6 months may improve dual-task-related gait performance. In the open-label phase, the IG was able to maintain most effects on the spatiotemporal gait parameters, indicating that long-term GBE intake over 1 year may be required to elicit more pronounced effects.[30]

GBE's memory-enhancing effects are not limited to the elderly. In another double-blind study, the reaction time in healthy young women performing a memory test was improved significantly after administration of GBE.[31] GBE complexed with phosphatidylserine might show even better results in these sorts of applications. In one study, 28 healthy young participants received 120 mg GBE, 120 mg GBE complexed with phosphatidylserine (Virtiva), 120 mg GBE complexed with phosphatidylcholine, and a matching placebo, on separate days 7 days apart.[19] Cognitive performance was assessed using the Cognitive Drug Research computerized test battery and Serial Subtraction tasks immediately before dosing and at 1, 2.5, 4, and 6 hours thereafter. In keeping with previous research utilizing the same methodology, 120 mg of GBE was not associated with markedly improved performance on the primary outcomes. However, administration of Virtiva resulted both in improved secondary memory performance and significantly increased speed in memory-task performance across all postdose testing sessions. Enhancement after GBE complexed with phosphatidylcholine was restricted to a modest improvement in secondary-memory performance, which was restricted to one postdose time point.

Cognitive Dysfunction

The prefrontal cortex (PFC) plays a central role in cognitive control functions, and dopamine in the PFC modulates cognitive control, thereby influencing attention, impulse inhibition, prospective memory, and cognitive flexibility. Because reduced prefrontal dopamine has been associated with impaired cognitive control,[32] interventions that improve prefrontal dopaminergic functions are of interest. A randomized, placebo-controlled, double-blind, pilot trial in 61 elderly volunteers with subjective memory impairment was conducted to evaluate the effects of GBE on cognitive functions related to prefrontal dopamine.[33] Indications for improved cognitive flexibility without

TABLE 82.3 Effect of *Ginkgo biloba* Extract on Cardiovascular Performance Measures

	TIME OF MEASUREMENT	
Parameter	**Week 0**	**Week 104**
Pain-free walking distance, m	62.9	172.4
Total walking distance, m	113.8	384
Rest flow, mL/100 mL/min	1.6	2.7
Peak flow, mL/100 mL/min	3.7	6.9
Doppler measurement after strain, mm Hg	46.5	72.6

changes in brain activation suggested increased processing efficiency with GBE, and together with a trend for improved response inhibition, results were compatible with mild enhancement of prefrontal dopamine. Ginkgo's putative neuroprotective and cognitive-enhancing properties have provided support for its use in treating neurological, psychiatric, functional, and physiological symptoms, including problems with memory, information processing, attention and concentration, psychomotor function, mood, fatigue, and activities of daily living. Clinical studies have shown that the cognitive domains yielding the largest proportion of significant effects of GBE versus placebo are in the following areas[33–38]:

- Fluid intelligence
- Selective attention
- Short-term and long-term verbal and visual memory
- Executive functions (e.g., planning, working memory, flexibility, and processing speed)

Alzheimer's Disease

GBE has been extensively investigated in cases of dementia, including Alzheimer's disease (AD). In addition to GBE's ability to increase functional brain capacity via the mechanisms described earlier, it was shown to normalize the acetylcholine receptor in the hippocampus of aged animals, increase cholinergic transmission, inhibit β-amyloid deposition,[9] and address many of the other major elements of AD.[2,3,39] Although preliminary studies in established AD patients were quite promising, at this time it appears that at best GBE only helps reverse or merely delay mental deterioration in the early stages of AD. However, even this application is fraught with conflicting results in double-blind studies. That is, in several studies, no benefit over placebo was observed in halting cognitive decline.[40] In more advanced cases of AD, GBE does not offer any significant advantage over placebo.

The benefits of GBE in early-stage AD were quite evident in several double-blind studies and a meta-analysis of studies of more than 6 months' duration.[41] In one study, 216 patients with AD or multiinfarct dementia were given either 240 mg/day of GBE or placebo for 24 weeks.[42] Improvements were noted in several clinical parameters, including the Clinical Global Impressions scale (Table 82.3). Similar results were seen in another double-blind study, in which the 240-mg dose was administered once daily.[42]

One study that deserves special mention is the first U.S. clinical study on GBE published in the *Journal of the American Medical Association*.[43] The study was conducted at six research centers. Harvard Medical School and the New York Institute for Medical Research approved the design of the study, in which 202 patients with AD were given either a modest dose of GBE (120 mg/day) or a placebo for 1 year. GBE not only stabilized AD but also led to significant improvements in mental function in 64% of the patients. There were no side effects with GBE.

The results from these positive studies indicate that GBE in early-stage AD or other causes of dementia may lead to some mild cognitive improvement and help enable patients maintain a normal life and avoid being institutionalized.

It is important to point out that direct comparison studies on ginkgo versus standard pharmaceutical regimens indicated similar efficacy in AD. A comparative analysis of studies of at least 6 months in duration demonstrated that GBE and second-generation cholinesterase inhibitors (e.g., tacrine, donepezil, rivastigmine, metrifonate) were equally effective in treating mild to moderate AD.[44] In a meta-analysis of 50 articles that examined the effect of ginkgo on objective measures of cognitive function in patients with AD, using standardized measures of cognition including the Alzheimer's Disease Assessment Scale–cognitive subscale, it was concluded that GBE produced comparable benefits to standard cholinesterase inhibitors.[45]

In addition to possibly being beneficial in early-stage AD, if the mental deficit is a result of vascular insufficiency or depression and not AD, GBE is usually effective in reversing the deficit.[2,3,4,46] Importantly, GBE should be taken consistently for at least 12 weeks to determine its effectiveness. Although some people with AD report benefits within a 2- to 3-week period, most will need to take GBE for a longer period of time.

Tinnitus

Permanent, severe tinnitus is an extremely difficult condition to treat. Previous studies showed contradictory results of GBE in the treatment of tinnitus. For example, in Meyer's study,[47] GBE improved the condition in all patients regardless of prognostic factor. However, in Coles's study,[48] 21 patients with tinnitus took GBE for 12 weeks: 11 reported no change, 4 reported slight to very slight improvement, and 5 reported that their tinnitus was worse. A possible explanation for these different results is that in Meyer's study, the patients had recent-onset tinnitus, whereas in Coles's study, 18 patients had tinnitus for at least 3 years.

A 1994 study of GBE in tinnitus used a two-part design: the first part was an open part, without a placebo control, and the second part was a double-blind, placebo-controlled, crossover study.[49] The 80 patients in the open study were referred to the Department of Audiology, Sahlgren's Hospital, Goteborg, Sweden, because of permanent severe tinnitus. Twenty patients reporting a positive effect with GBE (14.6 mg twice daily) after 2 weeks were recruited for the double-blind study. Patients were given either GBE or placebo for 2 weeks and then crossed over into the other group. The evaluation indicated that six patients preferred GBE, seven preferred placebo, and seven had no preference.

On the surface, this study seemingly indicated that GBE was ineffective for permanent, severe tinnitus. However, the study was designed for the GBE to fail. First, the dosage used (14.6 mg twice daily or 29.2 mg/day) was far less than the standard dosage of 40 mg three times daily (or roughly four times the daily dosage used in the study). Secondly, in studies on patients with cerebral vascular insufficiency, it is well established that GBE often takes at least 2 weeks before benefits become apparent. The longer that GBE is used, the more obvious the benefit. In a condition like permanent, severe tinnitus, 2 to 4 weeks is simply not enough time. However, given the small, insufficient dosage, it probably would not have mattered if the subjects had been studied for a longer period of time.

A study of 1121 healthy people between 18 and 70 years old with tinnitus that was comparatively stable showed no benefit over placebo when given 50 mg of standardized ginkgo three times a day.[50] Although these data were discouraging, it should be noted that outcome measures were obtained through questionnaires and phoned-in patient reports, without objective audiometric metering.

A review study of randomized, placebo-controlled clinical trials of GBE was conducted to determine the effectiveness of standardized extract (EGb 761) in the treatment of tinnitus.[51] The authors concluded there was evidence of efficacy for the standardized extract in the treatment of tinnitus from three trials in patients in whom tinnitus was the primary complaint, and supportive evidence exists from five trials in patients with age-associated cognitive impairment or dementia in whom tinnitus was present as a concomitant symptom. In all identified and retrieved studies using the standardized GBE (EGb 761®), this specific preparation was found to be superior to placebo in the treatment of tinnitus. The degree to which GBE is of benefit in permanent, severe tinnitus remains to be determined, but given GBE's excellent safety profile, it is certainly worth a try.

Cochlear Deafness/Ototoxicity

Ischemia is usually the underlying factor in acute cochlear deafness. GBE improved recovery in cases of acute cochlear deafness caused by unknown factors or caused by sound trauma or pressure (barotrauma).[52] GBE was also shown to be a protective agent against ototoxicity from treatment with the chemotherapeutic agent cisplatin, without decreasing antineoplastic efficacy.[53]

Senile Macular Degeneration and Diabetic Retinopathy

GBE appears to effectively address the multifactorial pathophysiology of senile macular degeneration, the most common cause of blindness in adults. In double-blind studies, GBE demonstrated a statistically significant improvement in long-distance visual acuity in both macular degeneration and diabetic retinopathy.[54,55] GBE has also demonstrated impressive protective effects against free-radical damage to the retina in experimental studies. Furthermore, GBE was shown to prevent diabetic retinopathy in rats, suggesting it might have a protective effect in humans as well.[2]

Peripheral Arterial Insufficiency

The primary lesion of peripheral arterial disease is the same cholesterol-containing plaque that is responsible for other conditions associated with atherosclerosis (e.g., coronary artery disease, cerebral vascular insufficiency).

The arterial obstruction or narrowing causes a reduction in blood flow during exercise or at rest. Clinical symptoms are caused by the consequent ischemia. The most common symptom of peripheral arterial disease is pain during exertion as a result of intermittent claudication. The pain usually occurs in the calf and is described as cramping, tightness, or severe fatigue. The pain is usually bilateral. The cause of the pain is not only reduced oxygen delivery but also an increase in the production of toxic metabolites and cellular free radicals. These free radicals accumulate and react with the lipid constituents of the cell membrane.

Pain at rest indicates a serious reduction in resting blood flow. It is obviously a sign of severe disease. The pain may be localized to one or more toes, or it may have a stocking-type distribution. The character of the pain is usually described as burning or gnawing and is generally worse at night. Cyanosis or pallor of the extremity is usually apparent. In moderate to severe narrowing of the artery, there are trophic changes, including a dry, scaly, and shiny epidermis. Hair may disappear, and the toenails may become brittle, ridged, and deformed.

In nine double-blind, randomized clinical trials of GBE versus placebo in two matched groups of patients with peripheral arterial insufficiency of the leg, GBE was shown to be quite active and superior to placebo (eight studies) and equal to pentoxifylline (one study).[2,3,4,55–60] Not only did measurements of pain-free walking distance (75%–110%) and maximum walking distance (52.6%–119%) dramatically increase, but plethysmographic and Doppler ultrasound measurements also demonstrated increased blood flow through the affected limb. Blood lactate levels also dropped.

In studies following strict methodology and with a sufficient number of patients for reliable evaluation, the demonstration that GBE improves limb blood flow, and improves walking tolerance, indicates that GBE is far superior to pentoxifylline, cilostazol, and standard medical therapy in peripheral arterial insufficiency. This includes other peripheral vascular disorders such as diabetic peripheral vascular disease, Raynaud's disease, acrocyanosis, and postphlebitis syndrome. In the treatment of intermittent claudication, the effects are somewhat modest, especially compared with exercise programs.[61,62]

The longer GBE is used, the greater the benefit. Table 82.3 summarizes a 2-year trial of GBE (160 mg/day) in the treatment of peripheral arterial disease (Fontaine stage IIb). Pain-free walking distance increased by more than 270%.[2]

The usual daily dosage of GBE is 120 mg (40 mg three times a day); however, some of the studies employed a dosage of 160 mg/day, including the study summarized in Table 82.3. Given the excellent safety profile of GBE, dosages similar to those used in cerebral vascular insufficiency (e.g., 240 mg/day) may prove to be more effective.

Sexual Dysfunction

Most cases of impotence (erectile dysfunction) are caused by impaired blood flow to erectile tissue. Evidence indicates that GBE might be extremely beneficial in the treatment of erectile dysfunction caused by lack of blood flow. Sixty patients with proven erectile dysfunction who had not reacted to papaverine injections up to 50 mg were treated with 60 mg/day GBE for 12 to 18 months.[63] The penile blood flow was reevaluated by duplex sonography every 4 weeks. The first signs of improved blood supply were seen after 6 to 8 weeks. After 6 months' therapy, 50% of the patients regained potency, and in 20%, a new trial of papaverine injection was then successful; 25% of the patients showed an improved blood flow, but papaverine was still not successful. The remaining 5% were unchanged. The improvement of the arterial inflow to erectile tissue is assumed to be because of the known effect of GBE on enhancing blood flow through both arteries and veins without any change in systemic blood pressure. Ginkgo's effects are more apparent with long-term therapy, and better results may have been obtained with a 120-mg/day dose to take full advantage of its effect on improving blood flow.

Antidepressant-induced sexual dysfunction is a prevalent side effect of most conventional antidepressant drugs. A study of 33 women and 30 men on selective serotonin-reuptake inhibitors (SSRIs) showed an overall 84% effectiveness rate at curbing symptoms, with GBE exhibiting a positive effect on all four phases of the sexual response cycle: desire, excitement (erection and lubrication), orgasm, and resolution (afterglow).[64] This research group also demonstrated the efficacy of ginkgo for these side effects after other management trials of cyproheptadine, yohimbine, amantadine, and buspirone hydrochloride failed.

In a study in women with sexual arousal disorder, a single dose of 300 mg GBE had a small but significant facilitatory effect on physiological, but not subjective, sexual arousal compared with placebo in 99 women with sexual dysfunction.[65] Long-term GBE administration at this dosage did not significantly enhance arousal responses beyond placebo. The authors concluded that (1) neither short- nor long-term administration of GBE alone substantially affected sexual function in women, (2) a substantial placebo effect on sexual function existed in women with sexual concerns, and (3) teaching women to focus on genital sensations during sex enhanced certain aspects of women's sexual functioning.

Premenstrual Syndrome and Idiopathic Cyclic Edema

Premenstrual syndrome (PMS) is often characterized by fluid retention, vascular congestion, increased capillary permeability, and breast tenderness. A double-blind, placebo-controlled study sought to determine the effectiveness of GBE in treating these symptoms.[66] The population studied was a group of 165 women between the ages of 18 and 45 years who had congestive symptoms for at least three cycles. The patients were then assigned to receive either GBE (80 mg twice daily) or placebo from day 16 of the cycle to day 5 of the next. On the basis of extensive symptom evaluation by patients and physicians, it was concluded that GBE was effective against the congestive symptoms of PMS, particularly breast pain or tenderness. Patients taking GBE also noted improvements in neuropsychologic assessments. These results indicate that GBE might hold some promise in the treatment of PMS.

Antidepressant Effects

The ability of GBE to improve general mood in patients with cerebral vascular insufficiency in double-blind studies led researchers to begin investigating GBE's antidepressive effects. In a double-blind study, 40 elderly patients (ranging from 51–78 years old) with depression who had not benefited fully from standard antidepressant drugs were given either 80 mg of GBE three times daily or a placebo.[67] By the end of the eighth week, the total score of the Hamilton Rating Scale for Depression in the GBE group dropped from 14 to 4.5. In comparison, the placebo group dropped from 14 to only 13. This study indicated two things:

1. GBE can be used with standard antidepressants.
2. GBE enhanced the effectiveness of standard antidepressants, particularly in patients older than 50 years of age.

Importantly, the dosage used in the study (80 mg three times daily) was higher than the standard dosage of 40 mg three times daily.

See the previous section "Sexual Dysfunction" regarding ginkgo's ability to decrease unwanted side effects of standard antidepressant medications.

Allergies/Asthma

Mixtures of ginkgolides, and GBE standardized to contain 24% ginkgoflavonglycosides, showed clinical effects in allergic conditions because of their inhibition of PAF, a key chemical mediator in asthma, inflammation, and allergies.[16,17]

In one double-blind placebo study, the ability of a mixture of ginkgolides to block the effects of PAF when PAF was injected into the skin was investigated.[16] Normally, when PAF is injected, it causes an immediate formation of a hive (classic wheal and flare reaction). However, if the ginkgolide mixture (120 mg) was given before PAF injection, it effectively counteracted the wheal and flare reaction. Specifically, the ginkgolide reduced the flare (reddened) area by a mean of 62.4% and the wheal (hive) volume by a mean of 60%.

A study from the Qingdao Hospital of Integrated Traditional and Western Medicine in Shandong, China, assessed the efficacy of an oral ginkgo liquor to alleviate airway hyperreactivity. It was found that the treatment significantly reduced airway inflammation and improved the pulmonary function and clinical symptoms of asthmatic patients.[68]

Mixtures of ginkgolides, and purified ginkgolides, are under investigation in several European countries. The hope is that they will be proven clinically effective in eczema, allergies, and many other conditions in which PAF plays a central role.[16,17]

Raynaud's Disease

Most common in young women (60%–90% of reported cases), Raynaud's disease is a condition of vasospastic response that causes areas of the body, including the fingers, toes, and tips of the nose and ears, to feel numb and cool in response to cold temperatures or stress. During a Raynaud attack, these blood vessels that supply the skin narrow, limiting blood circulation to affected areas. Ginkgo's vasodilating activity is most likely responsible for its effectiveness in treating this condition.

Given the side-effect profile of pharmaceutical treatments for Raynaud's disease, a double-blinded, placebo-controlled study evaluated the use of GBE to treat this difficult condition. A 10-week trial revealed a 56% reduction in the number of weekly attacks, whereas placebo reduced the number by 27%.[69] The World Health Organization recommends the use of ginkgo in Raynaud's disease, acrocyanosis, and postphlebitic syndrome.[70]

High-Altitude Sickness

In a study involving a Himalayan expedition of moderate altitude with gradual exposure, 44 volunteers were divided into a placebo group and a group that received 80 mg of ginkgo twice a day.[71] No subject in the ginkgo group developed acute mountain sickness, unlike 40.9% of subjects in the placebo group. Vasomotor disorders of the extremities were also prevented in the ginkgo group.

Future Applications of *Ginkgo biloba* Extract

There are many preliminary studies indicating possible clinical applications for GBE. For example, several studies have also shown the benefits of GBE on kidney function. One animal study showed improved kidney blood flow and function in hypertensive rats.[72] Another study found that ginkgo protects the kidneys from glyphosate.[73] Other animal studies have shown protection of the kidneys from mercury, uranium, naphthalene, and many other toxins.[74–76] Ginkgo also protects the kidneys from gut-derived endotoxins.[77] Ginkgo also has the ability to protect against numerous mitochondrial toxins, which strengthens the case for its use in kidney disease because mitochondrial damage in the kidneys mediates much of the nephrotoxicity.[78]

Other potential applications of GBE include angina, congestive heart failure, and acute respiratory distress syndrome. Its action on PAF may also make it useful for a great number of other applications in addition to allergies, including various types of shock, thrombosis, graft protection during organ transplantation, multiple sclerosis, and burns.

DOSAGE

Most of the clinical research on *G. biloba* used a standardized extract, containing 24% ginkgo flavone glycosides, has utilized dosages of 120 to 240 mg per day, usually in divided doses.

Devising a dosage schedule using other forms of ginkgo is difficult because of extreme variation in the content of active compounds in dried leaf and crude extracts. Whatever form of ginkgo is used, it appears to be essential that it is standardized for content and activity. For example, a standard 1:5 tincture obtained from crude ginkgo leaf with the highest possible flavonoid content would require 1 oz/day to provide the equivalent dosage level of the standardized extract.

Clinical research clearly shows that GBE should be taken consistently for at least 12 weeks to determine effectiveness. Although most people report benefits within 2 to 3 weeks, some may take longer to respond.

TOXICITY

GBE is extremely safe, and side effects are uncommon. In 44 double-blind studies involving 9772 patients taking GBE, the number of side effects reported was extremely small. The most common side

effect, gastrointestinal discomfort, occurred in only 21 cases, followed by headache (7 cases) and dizziness (6 cases).[4,46] Because of its inhibition of PAF, many practitioners are concerned that ginkgo may increase bleeding risk when used concurrently with warfarin (Coumadin), aspirin, and other antiplatelet therapies. However, a study evaluating the use of ginkgo and warfarin concurrently revealed no change in the international normalized ratio (INR), which is the blood test chosen to monitor the patient's possible bleeding risk in response to anticoagulation therapy.[79] Results from controlled studies consistently indicated that ginkgo did not significantly affect bleeding time or platelet aggregation, and it did not adversely affect the safety of coadministered aspirin or warfarin.[80]

In contrast to the tolerance of the leaf extract, contact with or ingestion of the fruit pulp produced severe allergic reactions.[81,82] Contact with the ginkgolic acids in the fruit pulp causes erythema and edema, with the rapid formation of vesicles accompanied by severe itching. This is similar to an allergic reaction to the poison ivy, oak, and sumac group, suggesting cross-reactivity between *G. biloba* fruit and this family. Ingestion of as little as two pieces of fruit pulp was reported to cause severe gastrointestinal irritation from the mouth to the anus. Because the ginkgo leaf does have a low level of irritative ginkgolic acids, animal studies were conducted to examine the possibility of adverse reactions from using ginkgo leaf extract. It was concluded that extracts of *G. biloba* taken orally were considered safe.[81]

DRUG INTERACTIONS

Ginkgo has been shown to have antagonistic effects on anesthetics, analgesics, anticoagulants, and antiplatelet agents because of ginkgo's inhibition of platelet aggregation.[82] As a result of these concerns, ginkgo should be used cautiously in patients taking these medications.

Because of its inhibition of PAF, many practitioners are concerned that ginkgo may increase bleeding risk when used concurrently with warfarin (Coumadin), aspirin, and other antiplatelet therapies. However, a study evaluating the use of ginkgo and warfarin concurrently revealed no change in the international normalized ratio (INR), which is the blood test chosen to monitor the patient's possible bleeding risk in response to anticoagulation therapy.[83] Results from controlled studies consistently indicated that ginkgo did not significantly affect bleeding time or platelet aggregation, and it did not adversely affect the safety of coadministered aspirin or warfarin.[84] In addition, a double-blind, placebo-controlled, randomized, two-way crossover trial found that *G. biloba* extract had no significant pharmacodynamic effects on warfarin and had no effects on prothrombin time and activated partial thromboplastin time.[85] Prudent caution suggests that patients taking warfarin should have their INRs closely monitored or refrain from ginkgo use.

Human clinical trials have demonstrated no clinically significant effects on CYP1A2, CYP2C9, CYP2C19, CYP2D6, CYP2E1, or CYP3A4.[86,87]

Ginkgo should be used with caution, or avoided, concomitantly with antiretrovirals because it may decrease the levels of selected antiviral therapies.[88,89]

Regarding the pharmacokinetic herb–drug interactions, the intake of standardized *G. biloba* extract together with synthetic drugs appears to be safe if daily doses up to 240 mg are consumed.[90]

Glucosamine

Michael T. Murray, ND

OUTLINE

GENERAL DESCRIPTION

Glucosamine is a simple molecule, manufactured in the body from glucose and an amine. One of the primary physiological roles of glucosamine is in the joints, where it stimulates the manufacture of glycosaminoglycans (GAGs), key structural components of cartilage. Glucosamine also promotes the incorporation of sulfur into cartilage. Because of this effect, glucosamine sulfate (GS) is thought to be the best source of glucosamine (Fig. 83.1).

As some people age, they apparently lose the ability to manufacture adequate levels of glucosamine. The result is that the synthesis of GAGs does not keep up with degradation. The inability to manufacture glucosamine at an adequate rate has been suggested to be the major factor leading to osteoarthritis (OA).

There are no food sources of glucosamine. Commercially available sources of glucosamine are derived from chitin—the exoskeleton of shrimp, lobsters, and crabs.

AVAILABLE FORMS

Glucosamine is commercially available as GS, glucosamine hydrochloride, and *N*-acetylglucosamine (NAG). GS, the only form of glucosamine that has been the subject of more than 300 scientific investigations and more than 20 double-blind studies, is the preferred form. GS has also been used by millions of people worldwide and is registered as an aid in OA in 70 countries. In fact, there may even be differences between the patented crystalline glucosamine sulfate preparation (Rottapharm/Meda) and other glucosamine formulations. Glucosamine products may vary substantially in molecular form, pharmaceutical formulation, and dose regimens.[1]

The patented crystalline glucosamine sulfate preparation is given as a highly bioavailable once-daily dose (1500 mg). Single high-dosage levels may prove more effective to allow glucosamine to reach the tissue levels required to affect mechanisms involved in the pathophysiology or healing of OA. Studies conducted with the crystalline form of GS are generally quite positive, whereas noncrystalline GS preparations and glucosamine hydrochloride (GH) have not shown the same degree of benefit, and in most studies, no benefit was noted. The European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) recommends the patented crystalline GS formulation over other glucosamine preparations because of a much stronger evidence base.[1,2]

Furthermore, when authors or manufacturers discuss GH or NAG, they often cite references of clinical studies that used GS or the combination of glucosamine hydrogen chloride (HCl) and chondroitin sulfate. On the basis of currently available clinical evidence, it appears that only GS provides proven clinical effectiveness when administered as an isolated agent (numerous studies showed the combination of glucosamine HCl and chondroitin sulfate to be effective). It does not appear to matter, however, if the GS is in true crystalline form whether it is stabilized with either sodium or potassium.[3] It also appears that in terms of symptom improvement, no further benefit is offered to GS if the formulation also includes chondroitin sulfate.[4] However, the combination of GS with methylsufonylmethane (MSM) may offer some additive effect to GS alone, and it is definitely useful to include MSM in combinations of glucosamine HCl plus chondroitin sulfate because of the sulfur.[5]

Glucosamine Sulfate Versus *N*-Acetylglucosamine

NAG differs from GS in that instead of a sulfur molecule, NAG has a portion of an acetic acid molecule attached to it (Fig. 83.2). GS and NAG are different molecules and appear to be handled by the body differently. Companies marketing NAG claim that this form is better absorbed, more stable, and better used than GS. These contentions are without support in the scientific literature. Detailed human studies on the absorption, distribution, and elimination of orally administered GS show an absorption rate as high as 98% and that, once absorbed, it is then distributed primarily to joint tissues, where it is incorporated into the connective tissue matrix of cartilage, ligaments, and tendons.[6] In addition, there are impressive clinical studies on thousands of patients. In contrast, the only clinical study with NAG used was as a polymer that is not yet available commercially.[7] Polymerization is thought to be necessary because of the poor oral availability of unbound NAG.

Further evidence of the superiority of GS to NAG is offered by studies on laboratory animals. Several studies demonstrated that glucosamine absorption and utilization are at least twice that of NAG.[8] It is well established that glucosamine is a more efficient precursor

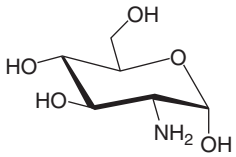

Fig. 83.1 Glucosamine.

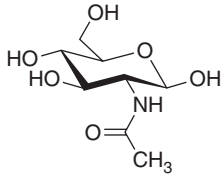

Fig. 83.2 *N*-acetylglucosamine.

of macromolecular hexosamine (GAG) than NAG. It is possible that NAG does not penetrate the cell membranes and, as a result, is unavailable for incorporation into glycoproteins and mucopolysaccharides.[7] The body preferentially uses GS rather than NAG. This preference appears largely because of the active processes that enhance absorption of GS in the intestines.[9]

The absorption of NAG by humans is poor for several reasons:

- NAG is quickly digested by intestinal bacteria.
- NAG binds with dietary lectins in the gut, resulting in a lectin–NAG complex, which is excreted in the feces.
- A large percentage of NAG is metabolized by intestinal cells.

In addition to the question of absorption, articular tissue cannot use NAG as well as it does glucosamine. These absorption and utilization problems suggest NAG is highly unlikely to possess the same kind of antiarthritic and anti-inflammatory properties that GS has been shown to possess.

Glucosamine Sulfate Versus Glucosamine Hydrogen Chloride

Sulfur is an extremely important component in the therapeutic effect of GS, and its substitution is likely to decrease the efficacy of supplemental glucosamine. Sulfur is an essential nutrient for joint tissue, where it functions in the stabilization of the connective tissue matrix of cartilage, tendons, and ligaments. Even healthy humans have low serum sulfate (0.3–0.4 mM) and synovial sulfur levels, but in OA, these concentrations are even lower. As far back as the 1930s, researchers demonstrated that individuals with arthritis were commonly deficient in this essential nutrient.[10,11] Restoring sulfur levels brought about significant benefit to these patients. In addition to sulfur playing a critical role in the manufacture of GAGs like chondroitin sulfate and keratan sulfate, sulfur was shown to inhibit the various enzymes that lead to cartilage destruction in OA (e.g., collagenase, elastases, and hyaluronidase).[12]

Because one of the primary effects of GS is to promote the manufacture of GAGs, a lack of the sulfur moiety may mean less GAG synthesis when glucosamine HCl is used. Therefore it is unlikely that glucosamine HCl will show the same excellent clinical results achieved with GS because it lacks this critical element.

Results from double-blind studies indicated that glucosamine HCl might be no more effective than a placebo in relieving OA. One double-blind, placebo-controlled, 10-week study examined the effects of glucosamine HCl in patients with OA of the knee.[13] Patients received either 500 mg of glucosamine HCl or a placebo three times daily. Forty-five patients received glucosamine HCl, whereas 53 received the placebo. The results indicated that 49% of patients who received glucosamine HCl felt they had improved compared with 45% of the placebo group. However, the difference between the two groups was not statistically significant. What these results call into question is the viability of glucosamine HCl as an effective form of glucosamine. Unfortunately, several large, well-publicized studies utilized this form. For example, the Glucosamine/Chondroitin Arthritis Intervention Trial (GAIT) study involved 1583 patients with symptomatic knee OA.[14] Patients were randomized to receive 1500 mg of glucosamine daily, 1200 mg of chondroitin sulfate daily, both glucosamine and chondroitin sulfate (same dosages as the single arms), 200 mg of celecoxib daily, or placebo for 24 weeks. The mean age of the patients was 59 years, and 64% were women. Overall, glucosamine and chondroitin sulfate were not significantly better than placebo in reducing knee pain by 20%. Compared with the rate of response to placebo (60.1%), the rate of response to glucosamine was 3.9% higher, the rate of response to chondroitin sulfate was 5.3% higher, and the rate of response to combined treatment was 6.5% higher. The rate of response in the celecoxib control group was 10.0% higher than that in the placebo control group. For patients with moderate to severe pain at baseline, the rate of response was significantly higher with combined therapy than with placebo (79.2% vs. 54.3%).

In an analysis of GAIT subjects with a radiographic confirmation of OA, the odds of achieving a 20% reduction in Western Ontario and McMaster Osteoarthritis Index (WOMAC) pain score compared with placebo were as follows: celecoxib, 1.21; glucosamine, 1.16; combination glucosamine/chondroitin sulfate, 0.83; and chondroitin sulfate alone, 0.69. These rates were not statistically significant.[15,16]

CLINICAL APPLICATIONS

Osteoarthritis

The primary use for GS is in the treatment of OA. This application has significant support in the medical literature because numerous double-blind studies have shown GS to produce much better results compared with nonsteroidal anti-inflammatory drugs (NSAIDs), placebo, or acetaminophen in relieving the pain and inflammation of OA.[17–21] Although some of the studies comparing GS with NSAIDs or acetaminophen showed similar reductions in pain and symptom scores, only GS improved indexes of joint function or markers showing improvement of cartilage structure. Typically, the advantages of GS over these other treatments were seen after 2 to 4 weeks of use, but there is some evidence that the longer GS is used, the greater the therapeutic benefit.

Not all studies showed clear positive results; a few exist that showed no greater benefit for GS over placebo in improving symptom scores.[22–26] However, it must be kept in mind that the placebo response in OA is quite high and may confound the true benefit of GS and other approaches to OA. Fortunately, there were several studies that showed objective improvements (discussed in the immediately following paragraphs).

The two longest placebo-controlled trials were 3 years in duration. The results from these studies showed, quite convincingly, that GS slowed down the progression of OA; produced regression of the disease in many cases, as noted by radiological improvements; and significantly reduced the incidence of total joint replacement even after as much as 5 years after GS discontinuation.[27–30]

In the first long-term study, 212 patients with knee OA were randomly assigned 1500 mg oral GS or placebo once daily for 3 years. Weight-bearing anteroposterior radiographs of each knee in full extension were taken at enrollment and after 1 and 3 years. The mean joint-space width of the medial compartment of the tibiofemoral joint was assessed by digital image analysis, whereas the minimum joint-space width (i.e., at the narrowest point) was measured by visual inspection with a magnifying lens. Symptoms were scored by the WOMAC OA index. The 106 patients on placebo had a progressive joint-space

narrowing, with a mean joint-space loss after 3 years of −0.31 mm. No significant joint-space loss occurred in the 106 patients on GS (−0.06 mm). Similar results were reported with minimum joint-space narrowing. As assessed by WOMAC scores, symptoms worsened slightly in patients on placebo compared with the clinical improvement observed in the group that received GS.[27]

To investigate the relationship between baseline radiographic severity of knee OA and the importance of long-term joint-space narrowing in more detail, a subanalysis of data from the 3-year trial was performed. Measurements of mean joint-space width, assessed by a computer-assisted method, were performed at baseline and after 3 years on weight-bearing anteroposterior knee radiographs. Those who received GS demonstrated a trend for significant reduction in joint-space narrowing in patients in the highest quartile of baseline mean joint-space width (>6.2 mm). In these patients, a joint-space narrowing of 14.9% occurred in the placebo group after 3 years, whereas patients from the GS group experienced a narrowing of only 6%.[31]

Of 414 participants randomized in the two long-term studies, 319 were postmenopausal women. In a subset analysis, after 3 years, postmenopausal participants in the GS group showed no joint-space narrowing, whereas participants in the placebo group experienced a narrowing of −0.33 mm. Percent changes after 3 years in the WOMAC index showed an improvement in the GS group (−14.1%) and a trend for worsening in the placebo group (5.4%). These results indicated that postmenopausal women might be especially responsive to GS.[27]

Additional insight into who might best respond to GS was provided in another analysis from this 3-year study that examined the ability of GS to improve a biochemical marker of collagen type II degradation (CTX-II).[32] At baseline, the 212 patients had an average concentration of urinary CTX-II of 222.4 ng/mmol creatinine. This was significantly above the CTX-II levels measured in urine samples from 415 healthy controls (169.1 ng/mmol). Although there was no significant difference in the CTX-II response in the placebo group and the glucosamine-treated group, those with high cartilage turnover presented a significant decrease in CTX-II after 12-month glucosamine treatment.

The group with CTX-II concentrations above normal average plus 1 standard deviation decreased 15.5% after 12-month therapy. The change in CTX-II in these patients correlated with the change in average joint-space width observed after 36 months. Increased baseline levels of CTX-II in the placebo group were associated with a worsening of the WOMAC index. These data indicate that measurement of urinary collagen type II C-telopeptide fragments enabled the identification of patients with high cartilage turnover, who appeared to be most responsive to GS therapy.

In the second study, 202 patients with knee OA were randomized to receive oral GS (1500 mg once a day) or placebo. Changes in computed tomographic radiographic minimum joint-space width were measured in the medial compartment of the tibiofemoral joint, and symptoms were assessed using the Lequesne (an index of severity of osteoarthritis) and WOMAC. Although symptoms improved more significantly in the GS group, the most telling result was the fact that progressive joint-space narrowing with placebo use was −0.19 mm after 3 years, whereas there was no average change with GS use (an increase of 0.04 mm was the average).[29]

Although a 2-year double-blind study failed to show any difference with either GS (1500 mg) or chondroitin sulfate (CS 800 mg) either alone or in combination versus the placebo group in terms of pain reduction, the combination of both GS and CS produced a statistically significant reduction of joint-space narrowing compared with placebo, with a mean difference of 0.10 mm. These results indicate that even if symptomatic improvement is not observed, GS may be exerting positive effects on joint structure.[33]

Another study sought to determine changes in levels of serum cartilage oligomeric matrix protein (COMP) and urine c-telopeptide of CTX-II as markers for cartilage turnover in patients with OA of the knee, in response to muscle strength training in combination with treatment with glucosamine, ibuprofen, or placebo. All three groups increased their muscle strength after 12 weeks of strength training. Glucosamine's reduction of serum COMP was statistically significant compared with both placebo and ibuprofen; the mean reduction with glucosamine was 13% versus placebo and 17% versus ibuprofen. This suggested an effect by glucosamine on the response of the OA cartilage to a period of joint loading in humans with knee OA. No effect was noted on CTX-II.[34]

Several head-to-head, double-blind studies also showed that GS produced much better results compared with NSAIDs and analgesics in relieving the pain and inflammation of OA, despite the fact that GS exhibited little direct anti-inflammatory effect and no direct analgesic or pain-relieving effects.[35–39] Although NSAIDs and analgesics, like acetaminophen, offer purely symptomatic relief, and NSAIDs may actually promote the disease process, GS appears to address the cause of OA. By promoting cartilage synthesis, thus treating the root of the problem, GS not only relieves the symptoms but also helps the body repair damaged joints. The clinical effect is impressive, especially when glucosamine's safety and lack of side effects are considered.

In one of the earlier comparative studies in which GS (1500 mg/day) was compared with ibuprofen (1200 mg/day), pain scores decreased faster in the first 2 weeks in the ibuprofen group. However, by week 4, the group that received GS experienced a significantly better improvement than the ibuprofen group.[35] Physicians rated the overall response as good in 44% of the GS-treated patients compared with only 15% of the ibuprofen group.

Additional studies designed to further evaluate the comparative effectiveness of GS versus NSAIDs provided even better evidence.[36–38,40] One study consisted of 200 subjects with OA of the knee given either GS (500 mg three times daily) or ibuprofen (400 mg three times daily) for 4 weeks.[36] Consistent with previous studies, the ibuprofen group experienced quicker pain relief. However, by the end of the second week, the group taking GS experienced results as good as those in the ibuprofen group, with one major exception: although the side effects with glucosamine were mild and affected only 6% of the group, ibuprofen produced more significant side effects much more frequently, with 35% of the group experiencing them.

A total of 319 patients with symptomatic OA of the knee received GS (1500 mg/day), piroxicam (20 mg/day), both drugs, or a placebo for 12 weeks followed by 8 weeks without treatment.[37] The main efficacy variable was represented by the Lequesne index, a standard method of assessing disease activity. In the GS group, the Lequesne index decreased by 4.8 points during treatment, for a decrease of 2.9 and 0.7 points, in the piroxicam and placebo groups, respectively ($p < 0.001$). The association did not differ from GS alone. GS did not differ in safety (14.8% incidence of adverse events during treatment) from placebo (23.7%) but was significantly better tolerated than piroxicam (40.9%) or the association (35%). The improvement in GS-treated patients persisted during the 8-week follow-up period, whereas the improvement with piroxicam did not. These impressive results with GS were achieved without side effects. Patients on GS had fewer side effects than the placebo and no dropouts. Table 83.1 provides the side effect and dropout values among the four groups.

In another study on OA of the knee (Table 83.2), GS showed comparable symptomatic relief but was better tolerated and produced residual benefit after discontinuation.[38]

TABLE 83.1 Side Effects and Dropouts From Glucosamine Compared With Piroxicam and Placebo

	Placebo	GS	Piroxicam	GS + Piroxicam
Incidence of side effects	24.4%	14.8%	40.9%	5.9%
Dropouts	3	0	20	3

TABLE 83.2 Results From a Double-Blind Study of Glucosamine Sulfate Versus Ibuprofen

Time	Glucosamine Sulfate	Ibuprofen
Knee Pain (Average Score)		
Before treatment	8.42	8.46
Wk 2	5.54	5.63
Wk 4	3.60	4.18
2 wk after treatment	3.26	3.84
Knee Swelling (Average Score)		
Before treatment	1.43	1.48
Wk 2	0.77	0.89
Wk 4	0.47	0.48
2 wk after treatment	0.36	0.54

	GLUCOSAMINE SULFATE		IBUPROFEN	
Clinical Improvement (Effectiveness)	After 4 wk	After 6 wk	After 4 wk	After 6 wk
Symptom-free	45%	55%	32%	36%
Improved	39%	32%	45%	41%
Unchanged	11%	7%	15%	14%
Worsened	5%	6%	8%	9%

Side Effects	Glucosamine Sulfate	Ibuprofen
Side effects	6%	16%
Dropouts	0%	10%

Data from Qiu GX, Gao SN, Giacovelli G, et al. Efficacy and safety of glucosamine sulfate versus ibuprofen in patients with knee osteoarthritis. *Arzneimittelforschung.* 1998;48:469–474.

Another study showed an obvious advantage of GS over ibuprofen in patients diagnosed with temporomandibular joint (TMJ) OA. In the double-blind study, 40 women and 5 men received either GS (500 mg) or ibuprofen (400 mg) three times daily for 90 days. Fifteen patients taking GS (71%) and 11 taking ibuprofen (61%) improved, with positive clinical response taken as a 20% decrease in TMJ pain and function. Between-group comparison revealed that patients taking GS had a significantly greater decrease in TMJ pain with function, effect of pain, and acetaminophen used between days 90 and 120 compared with patients taking ibuprofen.[40]

In addition to showing benefit in double-blind studies, oral GS was shown to offer significant benefit in an open trial involving 252 doctors and 1506 patients in Portugal.[41] This large study provided valuable clinical information on the appropriate use of GS. The patients received 500 mg of GS three times a day over a mean period of 50 days. Symptoms of pain at rest, on standing, on exercise, and limited active and passive movements, all improved steadily throughout the treatment period. Objective therapeutic efficacy was rated by doctors as "good" in 59% of the patients and "sufficient" in a further 36%. Although this was not a controlled study, a 95% response rate is impressive. The results with GS were rated by both doctors and patients as being significantly better than those obtained with previous treatment, including NSAIDs, vitamin therapy, and cartilage extracts. GS produced good benefit in a significant portion of patients who did not respond to any other medical treatment.

In the study, obesity was associated with a significant shift from good to fair. This finding may indicate that higher dosages may be required for obese individuals or that oral glucosamine is not enough to counteract the added stress of obesity on the joints. Patients with peptic ulcers and individuals taking diuretics were also associated with a shift from good to sufficient in terms of efficacy and tolerance. Individuals with peptic ulcers should take GS with foods. Individuals taking diuretics may need to increase the dosage to compensate for reduced effectiveness. The improvement with glucosamine lasted for 6 to 12 weeks after the end of treatment.

Use in Athletes: Prevention, Acute Injury, and Surgical Recovery

GS may have a role as a preventive measure against the development of OA, especially in athletes subjected to joint strain, and an aid to recover from minor acute joint injuries (i.e., sprains and strains). One study investigated the chondroprotective action of GS on articular cartilage in athletes, the levels of biomarkers for CTX-II, and type II collagen synthesis (CPII) compared between soccer players and non-athlete controls before and after taking GS or placebo. CTX-II and CPII levels were substantially elevated in soccer players compared with those in controls, indicating that cartilage metabolism (CTX-II and CPII) was increased in soccer players. GS administration (1.5 and 3 g/day for 3 months) significantly decreased the CTX-II level; however, the effect disappeared after withdrawal of administration. In contrast, GS administration did not essentially affect the increased level of CPII. Furthermore, cartilage damage was evaluated using the ratio of CTX-II/CPII. The ratio in soccer players was significantly higher than that in controls, suggesting that CTX-II was relatively more enhanced compared with CPII in soccer players than in control students. Of tremendous importance, the ratio was reduced by glucosamine administration but returned to the preadministration level after GS supplementation ended. Together, these observations suggest that glucosamine is expected to exert a chondroprotective action in athletes (soccer players) by preventing CTX-II but maintaining CPII, although the effect is transient and disappears after stopping use.[42]

In a study designed to examine the effects of 4 weeks of glucosamine administration on functional ability and the degree of pain intensity in competitive male athletes after acute knee injury, 106 patients with an acute knee injury were randomized to either take GS (1500 mg/day) or a placebo for 28 days.[43] No significant difference was found between the glucosamine and placebo groups in mean pain intensity scores for resting and walking and the degree of knee swelling at the 7-, 14-, 21-, and 28-day assessments. There was no significant difference between passive knee flexibility at the 7-, 14-, and 21-day assessments, but after 28 days of treatment, the patients from the glucosamine group demonstrated significant improvement in knee flexion and extension compared with the placebo group. These results showed modest benefits and suggest use, but additional measures certainly should be used to speed recovery.

GS was also assessed for its ability to aid recovery in athletes undergoing anterior cruciate ligament (ACL) reconstruction. Thirty patients took either GS (1000 mg) or a placebo daily in addition to engaging in identical physical therapy. Results revealed significant improvements in both groups after 8 weeks, but no significant difference was detected between groups in any of the parameters. Although GS supplementation did not improve the rehabilitation outcomes of athletes after ACL reconstruction, the study may not have used a sufficient dosage to observe an effect (see "Dosage" section).[44]

DOSAGE

The standard dosage for GS is 1500 mg/day. It appears that administration as a single dosage may produce better results. Obese individuals may need higher dosages based on body weight (e.g., 20 mg/kg body weight daily). Individuals taking diuretics may also need to take higher dosages. Athletes or individuals who are subjecting their joints to greater wear and tear may need to increase the dosage to 3000 mg to maintain positive cartilage synthesis.

SIDE EFFECTS AND TOXICITY

GS has an excellent safety record in animal and human studies. Because of these studies, many experts have recommended that GS "be considered as a drug of choice for prolonged oral treatment of rheumatic disorders." Side effects, when they do appear, are generally limited to light to moderate gastrointestinal symptoms, including stomach upset, heartburn, diarrhea, nausea, and indigestion. If these symptoms occur, GS should be taken with meals.

Regarding people who are "sulfur sensitive," an important distinction must be made. When patients report they are allergic to sulfur, what they usually mean is that they are allergic to the so-called sulfa drugs or sulfite-containing food additives. It is impossible to be allergic to sulfur because sulfur is an essential mineral. The sulfate form of sulfur is present in human blood. In short, GS is extremely well tolerated, and no allergic reactions have been reported.

Concern has been expressed that glucosamine may influence insulin secretion or action, or both, based primarily on in vitro studies with concentrations of glucosamine not possible to achieve with oral supplementation or at recommended dosages. Detailed human studies showed GS had no effect on insulin secretion or action in either healthy subjects, those with type 2 diabetes, or those with insulin resistance.[45–48] Long-term studies with GS actually produced a nonsignificant lowering of fasting blood glucose concentrations in all groups of subjects.[48]

One side effect that has come up in elderly subjects is that GS may increase intraocular pressure (IOP).[49] In a double-blind study,[44] patients with osteoarthritis were randomized into either GS (750 mg three times daily) or a placebo group. A comprehensive ophthalmological examination including IOP was performed at baseline, month 1, and month 3. At 3 months, about 34% in the treatment group and 12.5% in the placebo group had clinically significant (defined as ≥2 mm Hg) rise in IOP. These results need to be confirmed, but physicians should monitor IOP in glaucoma patients taking GS.

DRUG INTERACTIONS

GS may potentiate the effect of warfarin (Coumadin). The World Health Organization's adverse drug reactions database documents 21 spontaneous reports of increased international normalized ratio associated with glucosamine use, 17 of which resolved when glucosamine was stopped. Two additional case reports also exist. Given the widespread use of GS, it does not appear to be a significant concern. Nonetheless, the use of warfarin and glucosamine may lead to an increased international normalized ratio, and physicians should monitor accordingly.[50]

Glutamine

Kristaps Paddock, ND, and *Peter B. Bongiorno*, ND, MSAc, LAc*

OUTLINE

INTRODUCTION

Glutamine (Fig. 84.1) is the most abundant amino acid in blood and muscle tissue. It comprises approximately 6% of mixed whole body protein and is unique among amino acids in that it is a preferred fuel of rapidly dividing cells, such as intestinal and immune cells, and is important in maintaining pancreatic function.[1-3] Glutamine is involved in the transport of circulating amino nitrogen and is an important intermediary that allows for accelerated gluconeogenesis from amino acids that are released by the skeletal muscle during stress states.[4] In addition, glutamine is used as a precursor for DNA and glutathione synthesis.[5] As one of the principal fuels used by the cells of the intestinal lining, it accounts for 35% of enterocyte energy production.

Although readily available in the diet and synthesized in the body from glutamate and ammonia, supplementation is known to enhance the energy metabolism of the gastrointestinal mucosa, thus stimulating regeneration.[6] Although glutamine is not considered essential in healthy people, there is evidence that the increased need for glutamine in stressed states such as burns, septicemia, endotoxemia, intestinal failure, and critical illness may result in it being "conditionally essential."[3,7,8]

Food Sources

Typical food sources of glutamine include animal and plant proteins. Typical foods are cabbage, beef, chicken, fish, legumes, miso (a salty, fermented bean product), and dairy products.

Forms

The nomenclature of L-glutamine and glutamine are used interchangeably. D-glutamine is the stereoisomer of L-glutamine and does not have any known biological activity. L-glutamine is not soluble in water, and aqueous solutions are unstable at temperatures of 22°C to 24°C. As a result, the more soluble and more stable dipeptides such as alanyl-glutamine are used as delivery forms of L-glutamine in total parenteral nutrition solutions.[9,10]

Physiological Effects

Intestinal Repair and Protection

Animal and human studies suggest that glutamine stimulates intestinal mucosal growth[11] and protects from mucosal atrophy. Glutamine prevents intestinal mucosal damage and was shown to decrease bacterial leakage across the intestines after they are damaged, presumably by stimulating repair.[12] Glutamine is thought to accomplish this by strengthening epithelial tight junctions and also by preventing paracellular permeabilities through an epidermal growth factor receptor–dependent mechanism (Fig. 84.2).

In one tissue culture experiment, intestinal epithelium cells were treated with acetaldehyde to compromise barrier function. These cells were treated with L-glutamine, D-glutamine, L-asparagine, L-arginine, L-lysine, or L-alanine. Only the L-glutamine demonstrated a benefit by decreasing aldehyde effects on transepithelial resistance. Furthermore, L-glutamine–treated cells decreased permeability that was dose dependent. L-glutamine reduced the acetaldehyde-induced disturbance of transmembrane structures, such as occludin, zonula occludens-1, E-cadherin, and β-catenin from the intercellular junctions. Lastly, L-glutamine induced a rapid increase in the tyrosine phosphorylation of the epidermal growth factor receptor. No other amino acids demonstrated this effect.[13]

Acid Base Balance

Glutamine plays an important role in acid–base homeostasis.[14] Glutamine is synthesized from glutamate and the toxic alkaline waste product ammonia by the enzyme glutamine synthetase, which requires magnesium and adenosine triphosphate. When ammonia levels are elevated, the body effectively removes ammonia from the blood by synthesizing glutamine. Conversely, if the blood is too acidic, the glutamine

*Previous edition contributor

can be broken down into glutamate and ammonia, which increases blood pH. Ammonia can bind hydrogen ions to produce ammonium cations, which are excreted in the urine along with chloride anions. Bicarbonate ions are simultaneously released into the bloodstream. Clinical studies showed that relatively small oral doses of glutamine can elevate plasma bicarbonate concentrations in healthy adults.

In one study, 2 g of glutamine was dissolved in a cola drink and ingested over a 20-minute period 45 minutes after a light breakfast. Control subjects were given soda only. Blood samples were taken 1 week before, at baseline, and subsequently at three separate 30-minute intervals after ingestion of the glutamine drink or placebo. Eight of 9 subjects responded to the oral glutamine load with a significant increase in plasma glutamine at 30 and 60 minutes before returning to the baseline value at 90 minutes. Ninety minutes after the glutamine was administered, plasma bicarbonate concentration was found to be increased. Circulating plasma growth hormone concentration was elevated as well. Concomitant with enhanced renal acid secretion, glutamine ingestion also caused an increase in the glomerular filtration rate.[15]

The authors of this study explained that their results showed that it was unlikely L-glutamine was a direct precursor of bicarbonate. Instead, L-glutamine appeared to play an indirect role in accelerating acid secretion through mechanistic changes in the kidneys. Human studies showed that urinary ammonium excretion is altered by changes in glutamine intake.[16]

Chronic metabolic acidosis is a common clinical problem encountered in catabolic states such as sepsis, shock, and diabetes, and is a major factor in many biological derangements.[17] Because glutamine becomes an essential amino acid in catabolic states when the increased demand exceeds the body's capability to synthesize it,[18] glutamine supplementation may be quite useful to maintain pH homeostasis in patients with acidotic conditions.

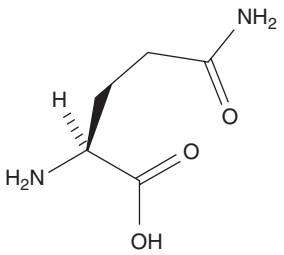

Fig. 84.1 Glutamine.

Glutathione Repletion

Glutathione (GSH) is a tripeptide consisting of glutamate, cysteine, and glycine (Fig. 84.3). As a reservoir source for glutamate in the body, the availability of glutamine appears crucial for the regeneration of glutathione stores in the liver during hepatic injury; in skeletal muscle after major trauma, sepsis, or surgery; and in chemotherapy-injured heart muscle.[19-21] Glutamine can enhance intracellular repletion of glutathione, an important scavenger of reactive oxygen species.[22] Rat studies demonstrated that during 5-fluorouracil–induced free radical–mediated hepatic injury, glutamine increased glutathione biosynthesis and preserved the glutathione stores in hepatic tissue.[19] A more recent study found that glutamine protected porcine enterocytes from cell death from oxidative damage by regulating glutathione synthesis.[23]

The promise of these in vitro and animal studies has also been verified by human studies. Seventeen patients who underwent a standardized surgical procedure were prospectively given 0.56 g/kg body weight/day of glutamine or a placebo. Using percutaneous muscle biopsies and blood samples, there were no significant decreases in total or reduced glutathione in the glutamine-supplemented group 24 and 72 hours after the operation. In contrast, the placebo group experienced total muscle glutathione losses of 47 ± 8% and 37 ± 11%, as well as reduced glutathione decreases of 53 ± 10% and 45 ± 16% at 24 and 72 hours, respectively. An in vivo study of 12 HIV+ patients found that daily supplementation of high-dose glutamine (20 g/day) increased plasma measurements of GSH; this same study also found that *N*-acetylcysteine was effective at increasing GSH levels.[24]

Protein Sparing

Glutamine is a regulator of muscle proteolysis,[25] and supplementation can attenuate loss of protein in the muscle. Experiments using animal cancer models demonstrated decreased protein loss and simultaneous protection of immune and gut-barrier function during radiation therapy in patients with advanced cancer.[5] In children with severe muscle

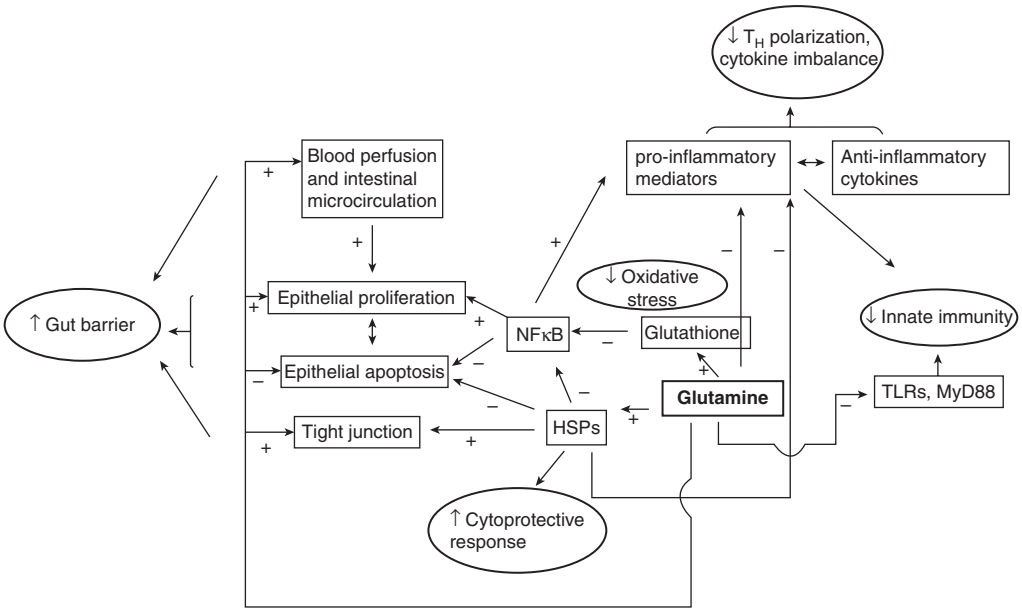

Fig. 84.2 The role of glutamine in intestinal repair and protection. (From Xue H. Glutamine therapy in colitis models. In: Rajendram R, Preedy V, Patel V, eds. *Glutamine in Clinical Nutrition. Nutrition and Health*. New York, NY: Humana Press; 2015.)

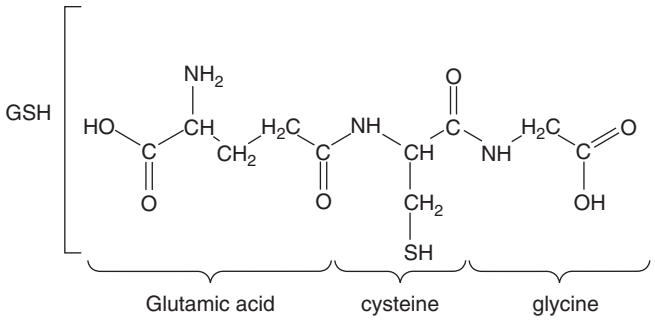

Fig. 84.3 Glutathione.

wasting, 5 hours of oral glutamine was shown to have protein-sparing effect (see later discussion on "Cachexia").[26]

Immune Support

Although poorly understood, it appears that glutamine has an immune-modulating effect by enhancing interleukin (IL)-6 levels[27] and lymphocyte function.[28] IL-6 plays an essential role in the final differentiation of β-cells into immunoglobulin-secreting cells, nerve cell differentiation, and acute phase reactants in hepatocytes. Exercise by itself is known to induce an elevenfold increase in plasma IL-6. Glutamine supplementation further enhances IL-6 levels.[27] The ability of lymphocytes to proliferate and generate lymphokine-activated killer cell activity in vitro was found to be glutamine dependent.[29] Additionally, glutamine-enriched parenteral nutrition demonstrated enhanced lymphocyte activity in patients who received high doses of chemotherapy after stem cell transplantation for hematologous malignancy.

CLINICAL APPLICATIONS

Intestinal Permeability–Related Conditions

A number of conditions are linked to intestinal permeabilities, including chronic urticaria,[30] inflammatory bowel disease (Crohn's disease),[31-33] celiac disease,[34] liver and biliary cirrhosis and cases of portal hypertension,[35,36] systemic sclerosis,[37] diabetes,[38] rheumatologic disorders,[39,40] cystic fibrosis,[41] alcohol overuse,[42] adult and child asthma,[43] HIV/AIDS,[44] nonsteroidal anti-inflammatory drug–treated arthritis patients,[45] moderate to major burn injuries,[46] corticosteroid use,[47] cardiopulmonary bypass patients,[48,49] and acute metal toxicities.[50] To evaluate these permeabilities, sucrose serves as a marker for gastroduodenal permeability and the urinary lactulose/mannitol ratio for intestinal permeability, after administration of these sugars.[30] From a naturopathic perspective, the underlying cause of many of these conditions may stem from food allergies that contribute first to chronic inflammation in the intestinal tract[30] and then to systemic endotoxemia. Certain conditions such as cardiopulmonary bypass can cause intestinal ischemia,[51] which is then the primary insult that causes permeabilities in these patients. The use of glutamine can help heal these permeabilities, thus removing a mode of pathogenesis in these variegated conditions.

Infectious Diarrhea

Animal models showed the usefulness of glutamine in diarrhea to augment sodium and water absorption and to enhance blood glucose and body weight.[52] A rat model of cholera toxin–induced diarrhea showed that glutamine was able to improve water and electrolyte intestinal absorption even better than traditional glucose solutions.[10] One placebo-controlled, double-blind, randomized trial human study evaluated glutamine to treat acute diarrhea in 128 otherwise healthy children. Of these 6- to 24-month-olds, 63 received 0.3 g/kg per day of glutamine and 65 controls received a placebo for 7 days. The average duration of diarrhea in the glutamine-treated group was significantly shorter than that of the placebo group (3.40 ± 1.96 vs 4.57 ± 2.48 days, respectively). However, no differences in serum IL-8 and secretory immunoglobulin-A were found between groups at the beginning of treatment or 1 week later.[53]

Clearly, glutamine holds promise for enhancing repair of mucosal injury caused by a wide range of infections or toxic agents and thus has great potential as a nutritional therapeutic for patients with enteric infection.[54]

Postsurgical Complications of the Gastrointestinal Tract

Patients undergoing abdominal surgeries such as gastrectomies, sigmoidectomies, cholecystectomies, colectomies, and rectal resections are at risk for the development of intestinal failure or short bowel syndrome (SBS). In SBS, a serious malabsorption of fluid, electrolytes, and other nutrients can occur, placing the patient at higher morbidity and mortality risk.[55] Trauma from abdominal surgery may also compromise the intestinal mucosa to the point where bacteria and endotoxins can easily transfer through the intestinal wall and invade tissue and blood in an event called bacterial translocation. Through inflammatory mechanisms, bacteria, and endotoxic septic conditions, the intestinal mucosal barrier can be adversely affected and cause further damage, thus forming a vicious circle. Severe cases result in systemic inflammatory response syndrome and multiple organ dysfunction syndrome.[56]

In a regimen that includes growth hormone and diet changes, glutamine can help difficult cases to enhance bowel adaptation. In one study of 10 patients with SBS who previously failed to adapt to enteral nutrients, 8 subjects received exogenous growth hormone, supplemental glutamine, and a modified high-carbohydrate, high-fiber diet. Two patients were treated with the modified diet alone. Three weeks of treatment with growth hormone, glutamine, and a modified diet significantly increased total caloric absorption from approximately 60% to 75%, protein absorption from 49% to 63%, and carbohydrate absorption from 60% to 82%. Water absorption increased from 46% to 65%, and sodium from 49% to 69%. Fat absorption did not change. Diet alone did not influence nutrient absorption or stool output. After 28 days of therapy, the patients were discharged and instructed to continue the diet and glutamine treatment.[57] It is unknown whether glutamine and diet changes alone, without concomitant growth hormone administration, would have the same positive effect.

In a second study, 20 patients who underwent abdominal surgery were randomized into two groups receiving oral administration of 30 g of glutamine or a placebo in divided doses for 7 days. Serum glutamine concentration was significantly decreased in the placebo group and increased in the glutamine group after 7 days. Markers of intestinal permeability were significantly increased in the placebo group and decreased in the glutamine group. Additionally, the serum markers of endotoxin, diamine oxidase, and malondialdehyde concentrations were significantly decreased in the glutamine group compared with those in the placebo group. Temperatures, heart rates, and white blood cell counts were also significantly lower in the glutamine group.[56]

Ischemia reperfusion of the gut is also a common event in various clinical conditions, such as trauma, burn, septic shock, cardiac or aortic surgery, and liver or small bowel transplantation, and is associated with a high death rate. Intestinal ischemia reperfusion can cause edema and disruption of the structural integrity and function of the intestinal mucosa and associated vascular tissue. It may set the stage for endotoxemic translocation of a number of bacteria, including *Escherichia coli, Enterococcus, Pseudomonas, Proteus,* and *Staphylococcus.* Studies of animal models demonstrated that glutamine, when supplemented as total parenteral nutrition, protected the intestines from morphological

and functional mucosal injury after intestinal ischemia reperfusion. Furthermore, intestinal permeabilities and the incidence of bacterial translocation in intestinal ischemia reperfusion animals were also prevented in a dose-dependent manner by glutamine supplementation.[58,59]

The gastrointestinal tract is susceptible to SBS, severe intestinal permeabilities, ischemia perfusion damage, systemic inflammatory response during trauma, various medical conditions, and abdominal postoperative periods. Glutamine can decrease intestinal permeability, maintain an intestinal barrier, and attenuate systemic inflammatory response in early postoperative patients.

Chemotherapy and Radiation Side Effects

Standard cancer therapies often include the use of chemotherapy and radiation, which can injure rapidly dividing intestinal cells. It was shown that during chemotherapeutic and radiotherapy insult, glutamine reduced degeneration of intestinal mucosa in rats, prevented intestinal mucosal injury,[58] protected liver function through enhanced glutathione biosynthesis and storage in hepatic tissue, increased immune function, and reduced permeability of the gut.[19,28]

In one investigation, 70 patients with colorectal cancer were randomly assigned to oral glutamine at 18 g/day or placebo before the first regimen of 5-fluorouracil and folinic acid administered intravenously for 5 days. Glutamine was given 5 days before, during, and after chemotherapy. Using D-xylose urinary excretion and cellobiose/mannitol evaluation, damage to the intestines was assessed at baseline, and 4 and 5 days after the end of the first cycle of chemotherapy. After one cycle of chemotherapy, the reduction in D-xylose absorption and reduction of mannitol was significantly greater in the placebo group (7.1% vs. 3.8% and 9.2% vs. 4.5%, respectively). Urinary recovery of cellobiose was not different between the study arms. Accordingly, the cellobiose/mannitol ratio increased more in the placebo treatment group. Furthermore, diarrhea parameters, and the average number of antidiarrheal opiate loperamide tablets needed, were reduced in the glutamine arm, thus supporting the positive clinical effect of this low-cost supplement.[11]

Oropharyngeal mucositis, or mouth sores, and accompanying swallowing difficulty are other untoward results of radiotherapy and can be a major source of suffering in patients with head and neck cancer. Glutamine during and after chemotherapy appears to be an excellent way to safely decrease the incidence of mouth sores. One investigation of 17 patients with head and neck cancer who received primary or adjuvant mouth irradiation for 5 days a week were randomized to either adjunctive glutamine suspension of 16 g in 240 mL normal saline or a saline placebo. Patients were instructed to swish the test solutions (30 mL) four times daily. The duration of objective oral mucositis was significantly shorter in the glutamine arm.[60] A second randomized, double-blind crossover trial observed 24 patients who were given a glutamine or placebo suspension to swish and swallow on days of chemotherapy administration and for at least 14 days after therapy. Significant improvement was observed in the glutamine group. Additionally, the duration of mouth pain was 4.5 days less in chemotherapy courses with concomitant glutamine supplementation. The severity of oral pain was reduced so significantly when glutamine was used that a patient could venture past soft foods 4 days sooner compared with placebo.[61]

Glutamine studies validating its use are also beginning to emerge in other areas of oncology. In a study of esophageal cancer patients, 13 patients were randomized into two groups, controls and a group that received oral glutamine supplemented at a dosage of 30 g/day for 4 weeks. It was observed that supplementation of glutamine enhanced lymphocyte mitogenic function and reduced permeability of the gut during radiochemotherapy.[5] Patients who underwent bone marrow transplant and myelosuppressive chemotherapy for acute myeloid leukemia also found that parenteral glutamine therapy could improve neutrophil recovery, although no change in neutropenic fever was shown.[62] Given that glutamine improves the structure and function of the gut, it is understandable that multiple parameters and markers of healthy physiological function will improve with its use.

It should be noted that glutamine's efficacy may depend on a number of other factors, including the specific chemotherapeutic prescribed and dosage. A study of 65 patients with advanced breast cancer receiving doxifluridine were prescribed 30 g/day of glutamine in three divided doses of 10 g each or a placebo for 8 consecutive days during each interval between chemotherapy, which was administered from days 1 to 4. In this case there was no statistical difference with regard to diarrhea morbidity, nor did glutamine affect the severity and duration of tumor growth.[63] Interestingly, a study of bone marrow transplantation patients found that allogeneic transplantation patients (those receiving bone marrow from another individual) did not have the same beneficial mouth pain reduction that autologous transplantation patients (those who donated their own marrow) experienced when receiving glutamine support. However, in the work mentioned previously, the amounts of glutamine were less than those used in other studies.

It was also theorized that methotrexate use in the allogeneic patients might have been responsible for the decreased protection. Nevertheless, in the allogeneic patients, the 28-day survival was still increased.[64] A third multicenter study of 129 patients found no protection against diarrhea when used adjunctively with pelvic radiation therapy. These patients received 4 g of glutamine or a placebo by mouth, which was also a significantly lower dose than the more successful studies employed.[65]

Although intestinal function is greatly compromised with chemotherapy and radiation treatment, cardiac function is commonly affected as well. The use of doxorubicin therapy for breast cancer is often limited by cardiomyopathic heart changes that often result in congestive heart failure. One rat study simulated doxorubicin treatment with and without glutamine support and found that oxidative damage to the heart was diminished in the glutamine-treated group, probably as a result of glutamine's ability to maintain cardiac tissue glutathione levels (see later discussion on "Cardiac Disease").[21]

Cachexia

Cancer-related cachexia is caused by a diverse combination of accelerated protein breakdown and slowed protein synthesis.[66] There has been considerable interest in giving supplemental glutamine to cancer patients because glutamine is taken up by the growing tumor, and any subsequent deficiency of glutamine in the host may cause cancer cachexia.[5]

One animal study found that glutamine levels in plasma and skeletal muscle were decreased in tumor-bearing rats, whereas glutamine production and the conversion of arginine to glutamine were increased. In rats supplemented with glutamine, total parenteral nutrition demonstrated a reduced whole body protein breakdown rate during chemotherapy.[5] A clinical study of patients with stage IV solid malignancies who had weight loss of at least 5% randomly assigned the participants in a double-blind fashion to either a control mixture of nonessential amino acids or treatment of 14 g/day of glutamine, along with the leucine metabolite β-hydroxy-β-methylbutyrate (3 g/day) and L-arginine (14 g/day). Within 4 weeks, the patients supplemented with the glutamine mixture gained 0.95 ± 0.66 kg of body mass, whereas control subjects lost 0.26 ± 0.78 kg during the same period. This effect continued over the 24 weeks, with no negative effect of treatment on the incidence of adverse effects or quality of life measures.[66]

Because the glutamine derived from skeletal muscle is trapped by the tumor, there is a theoretical concern that glutamine supplementation in cancer patients could potentially encourage tumor growth. One research group, however, showed that glutamine supplementation does not appear to enhance DNA content in tumor cells.[5,67] Additionally, some tissue culture studies provided evidence that glutamine might even inhibit cancer promotion.[68] Although research is necessary to clarify this point, given the immediate risk of mortality due to protein loss in cancer patients, it still would seem prudent to administer glutamine to those patients at greater immediate risk of cachexia-related death.

Human Immunodeficiency Virus

Loss of body cell mass and drug-associated gastrointestinal problems often occur in patients with HIV infection. In these cases, the patient's ability to survive can be affected in the long term. Given the role glutamine plays in cachexic body mass loss (see previous section on "Cachexia"), reversal of malabsorption,[69] and protection of the small intestine,[70] glutamine deficiency is a probable causal factor in HIV-associated wasting.[71]

Preliminary clinical studies suggested improvements in HIV-positive patients dosed at 8 g/day with regard to intestinal permeability and intestinal absorption. The authors of this study correctly suggested that at least 20 g/day might be necessary for more significant improvements.[72] A double-blind, placebo-controlled trial of 26 patients with greater than 5% weight loss since their disease onset used a glutamine and antioxidant regimen, including 40 g/day of glutamine in divided doses or 40 g of a glycine placebo for 12 weeks. Over 3 months, the glutamine/antioxidant group gained 2.2 kg in body weight (3.2%), whereas the control group gained only 0.3 kg (0.4%).

The glutamine-antioxidant group gained 1.8 kg in body cell mass, whereas the control group gained 0.4 kg. Of note, the intracellular water increased in the glutamine-antioxidant group but not in the control group.[73] Glutamine can help HIV patients decrease the severity of iatrogenic diarrhea. Twenty-five patients suffering for more than a month from nelfinavir-associated diarrhea were randomized in a double-blind, placebo-controlled, crossover trial to receive L-glutamine at 30 g/day or a placebo for 10 days. In this study, the L-glutamine significantly reduced the severity of nelfinavir-associated diarrhea and produced improved quality of life compared with placebo.[74]

Peptic Ulcers

Cabbage juice, a key source of glutamine, has been well documented as having remarkable success in treating peptic ulcers. One liter per day of the fresh juice, taken in divided doses, resulted in total ulcer healing in an average of only 10 days. Further research showed that the high glutamine content of the juice is probably responsible for the efficacy of cabbage in treating these ulcers. In a double-blind clinical study of 57 patients, 24 using 1.6 g/day of glutamine and the rest using conventional therapy (antacids, antispasmodics, milk, and bland diet), glutamine proved to be the more effective treatment. Half of the glutamine patients showed complete healing (according to radiographic analysis) within 2 weeks, and 22 of the 24 showed complete relief and healing within 4 weeks.[101] Although the mechanism for these results is unknown, it was postulated by the authors to be due to the role of glutamine in the biosynthesis of the hexosamine moiety in certain mucoproteins. These moieties may stimulate mucin synthesis, which would benefit peptic ulcer patients.

Severe Burns

Plasma glutamine levels were demonstrated to be profoundly decreased after severe burns in adults. This may at least partially explain the impaired cellular immunity that is seen in burn patients. Burn victims given glutamine showed better intestinal repair, a higher quality of wound healing, and reduced hospitalization. In one study, 48 severe burn patients were randomly divided into two groups: a control group that took a placebo, and a glutamine-treated group that received 0.5 g of glutamine/kg body weight/day, both for 14 days. After taking glutamine for 14 days, plasma glutamine concentration was significantly increased in the glutamine group compared with the control group. In addition, a greater quality of wound healing as well as shorter hospital stays were experienced in the glutamine-treated burn patients.[75]

In another study, dosage of L-glutamine at 0.6 g/kg per day did not result in an immediate whole body protein gain (an important factor in a burn patient's convalescence) and resulted in an insignificant increase in plasma glutamine.[4] However, this study measured only the first 48 hours, which might not have been enough time to show a long-term benefit.

Another study of 45 severely burned adults found that those randomized to receive enteral glutamine experienced a reduction in blood infection by a factor of three, and mortality risk was lowered.[76] Another investigation of burned patients whose total body surface burns ranged from 50% to 80% and third-degree burns ranged from 20% to 40%, but who did not have respiratory injuries, found improved gut permeability, initially decreased plasma endotoxin levels, and reduced hospitalization.[77]

Low-Birth-Weight Infants

Infants with a birth weight of less than 1000 to 1500 g may be especially susceptible to glutamine depletion, as nutritional supply of glutamine is limited in the first weeks after birth. This may increase morbidity by contributing to problems with gut integrity, as well as immune suppression.[3] One study of 35 ill preterm neonates of less than 1000 g were randomized to receive either glutamine-supplemented parenteral nutrition or standard parenteral nutrition. Although there were no significant differences between the groups in white cell count, differential white cell count, blood urea nitrogen, plasma ammonia, lactate, pyruvate, plasma glutamine, or glutamate, the median time to achieving full enteral nutrition was shorter in the glutamine group (13 vs. 21 days). Parenteral glutamine was well tolerated and considered safe for these preterm neonates.[78]

However, other studies found that formula supplemented with glutamine in growing preterm infants was entirely metabolized in the gut and did not have a discernable effect on whole-body protein and nitrogen kinetics.[79] A large multicenter, double-blind, randomized trial of infants with a birth weight of 401 to 1000 g were given either a control or 20% isonitrogenous solution by parenteral nutrition for up to either 120 days of age, death, or discharge from the hospital. Of the 721 infants who were assigned to glutamine supplementation, 370 (51%) died or developed late-onset sepsis, compared with 343 of the 712 infants (48%) assigned to control. Although no adverse effects were noted as a result of being given glutamine, this study demonstrated that glutamine did not decrease mortality. This study and others also found no reduction in the incidence of sepsis in these young patients.[80,81]

Exercise and Weight Lifting

Glutamine is considered to have an anabolic effect on skeletal muscle. Given the benefits on glutathione reserves, protein catabolism, and intestinal integrity, some glutamine enthusiasts believe that glutamine supplementation may be useful for exercise and strength training as well (Fig. 84.4). One small study suggested that oral glutamine increases growth hormone release.[15] Even so, clinical trials studying glutamine as an exercise performance enhancer are not encouraging.

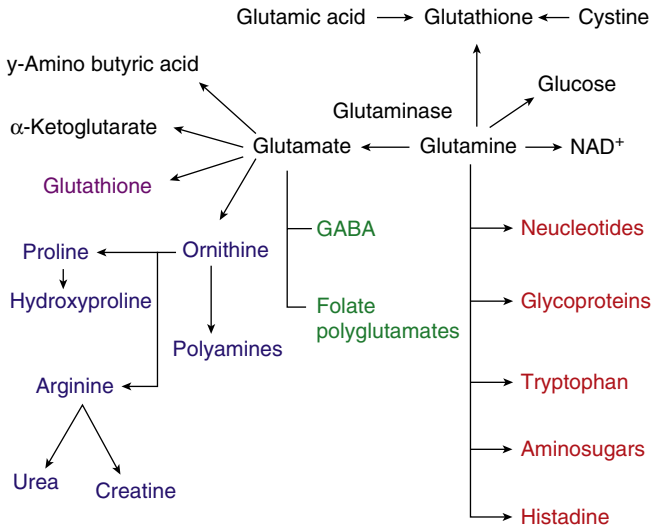

Fig. 84.4 The potential roles of glutamine in exercise.

A double-blind, placebo-controlled, crossover study had 6 resistance-trained men lift weights after the ingestion of glutamine or glycine at 0.3 g/kg body weight or a placebo. One hour after ingestion, subjects performed four total sets of exercise to momentary muscular failure, including two sets of leg presses at 200% of body weight and two sets of bench presses at 100% of body weight. Despite glutamine's possible role in exercise, there were no actual differences in the average number of maximal repetitions performed in the leg press or bench press exercises among these three groups.[82] Other studies using 0.3 to 0.9 g/kg of body weight also demonstrated no changes in exercise performance, body composition, or muscle protein degradation in young healthy adults.[83,84] It is possible that beneficial effects of glutamine are best detected only in patients with chronic illness and those with compromised physiology instead of normal, healthy individuals.

Cardiac Disease

Cardiac disease is a recognized stress on the physiology of the gastrointestinal and immune system. Animal studies supported the notion that glutamine can help recovery from cardiac ischemia and help the heart recover after reperfusion injury.[85,86] As noted earlier, glutamine can protect the heart from damage due to chemotherapy regimens by its glutathione-replenishing effect (see earlier discussion on "Chemotherapy and Radiation Side Effects").[19] The benefits to the gastrointestinal system in those heart patients experiencing ischemic gut episodes after cardiac bypass were also previously noted.[48,49] Animal research showed that greater levels of plasma glutamine also prevented decreases in the ratio between adenosine triphosphate to adenosine diphosphate in myocardial tissue.[86]

Unfortunately, little research has been done to evaluate the clinical use of glutamine in various cardiac situations. One investigation of patients with chronic stable angina received a single 80 mg/kg oral dose of glutamine or a placebo in a double-blind, random fashion 40 minutes before a standard exercise test. This single dose of glutamine significantly increased plasma glutamine concentration from 419 to 649 μmol/L. Moreover, the glutamine appeared to encourage positive changes in ST depression on the echocardiogram.[86] Clearly, more research is required, but given that heart disease is the leading reason for mortality, natural and safe treatments like glutamine should be further explored.

Crohn's Disease

The effect of glutamine on Crohn's disease might be expected to be positive, given its role as a nutrient source for enterocytes. However, studies have been mixed. One study failed to show an effect from a 4-week course of a glutamine-enriched diet in the treatment of active Crohn's disease.[87] Another failed to show an effect on small intestine permeability after long-term supplementation of 21 g/day of glutamine; patients were screened for plasma glutamine, plasma glutamate, plasma ammonium, Crohn's disease activity index, C-reactive protein, and nutritional status.[88] However, a more recent study found that glutamine did improve intestinal permeability and morphology in patients with Crohn's disease. Patients were administered 0.5 g/kg ideal body weight/day for 2 months and had significant improvements in permeability, as measured by lactulose mannitol excretion, and in morphology.[89] This study also included an active control group who were administered whey protein, and also experienced improvements in permeability and morphology. A review of the available literature available until November 2015 determined that there was insufficient evidence to draw conclusions on the efficacy or safety of glutamine in Crohn's disease.[90] The role of glutamine in Crohn's disease thus remains unresolved.

Sickle Cell Disease

Sickle cell disease is a complex condition in which increased oxidative stress causes deformation of the red blood cell protein hemoglobin, which then causes deformation of red blood cells themselves. These deformed cells are then prone to hemolysis by the spleen, causing the well-known anemia, as well as obstruction of capillaries, causing pain, necrosis, and organ damage. Starting in the 1990s, it had been observed that glutamine improved NAD redox potential and NADH levels in sickled RBCs, and that these changes might decrease oxidative susceptibility of red blood cells in the disease.[91] Later research also found that oral administration of 30 g of glutamine per day for at least 4 weeks decreased adhesion of sickle RBCs to endothelial cells.[92] More recently, a drug consisting only of l-glutamine has been approved to treat sickle cell anemia.

Other Conditions

A number of other medical conditions, such as alcoholism, pancreatitis, and brain injury, will further adversely affect the health of a patient who already has protein and energy needs and is more susceptible to infection. Although more studies are necessary, the following includes a few interesting conditions not mentioned earlier.

In alcoholics, glutamine supplementation (1 g/day) was shown to reduce voluntary alcohol consumption in uncontrolled human studies and experimental animal studies.[93-96] Despite the fact that this research is about 50 years old, there has never been any follow-up to these preliminary studies. This is unfortunate, because the results were quite promising, finding glutamine to be safe and relatively inexpensive. Related to alcoholism in many patients, individuals with acute pancreatitis also benefited from parenteral glutamine treatment with improvement in immune function, decreased systemic inflammation, and a trend toward shorter hospital stays.[1]

In an interesting study of 20 brain injury patients, 10 subjects were randomized to receive either an early enteral diet or the same formula with glutamine and probiotic added for a range of 5 to 14 days. The infection rate was found to be 100% in the control group, but only 50% in the glutamine group. The median number of infections per patient was significantly greater in the control group compared with the study group. Critical care stay and ventilation requirements were more than halved in the treatment group (10 vs. 22 days, and 14 vs. 7

days, respectively). Interestingly, probiotics were also used in the treatment group. This synergistic enhancement in gut flora may be useful to augment the already known benefits of glutamine.[97]

DOSAGE

The typical minimum oral dosage of glutamine is 100 mg three times a day, although the delivery method and actual effective dosage should be condition specific, meaning dosages are often much higher. The following points serve as guidelines:

- Severe burns: enteral dosage for individuals with severe burns was approximately 0.5 g/kg per day in most studies.
- Preventing and treating the side effects of chemotherapy involves the following:
- Patients treated with 5-fluorouracil received up to 18 g/day 5 days before, then during, and 5 days after treatment.[11]
- High-dose chemotherapy after stem cell transplantation: total parenteral nutrition enriched with glutamine 20 g.[28]
- Oral mucositis: 16 g mixed with 240 mL normal saline, and 30 mL is swished four times a day.[60]
- Esophageal cancer radiotherapy was given with a successful adjunctive oral glutamine supplement of 30 g/day for 4 weeks.[5]
- Cachexia patients were tested with dosages of 14 g/day combined with other amino acids.[66]
- Pediatric oncology patients: 0.65 g/kg was found to be a safe dose of glutamine to use in a clinical study in pediatric oncology patients.[98]
- Children with acute diarrhea: 0.3 g/kg per day was used successfully.[53]
- Peptic ulcers: drinking 1 L a day in divided doses was sufficient or 1.6 g/day for 1 month.[101]
- HIV patients: 30 to 40 g/day of glutamine to prevent medication-associated diarrhea and to improve intestinal permeability[73,74]; coadministration of antioxidants might also be helpful.
- Postabdominal surgeries: glutamine can be dissolved in warm water and taken orally or by gastric tube after the operation at 30 g/day for 7 days.[56]

TOXICITY

Glutamine, even at high doses, is without apparent side effects and is well tolerated.[4,54] Glutamine is synthesized from glutamate and the toxic alkaline waste product ammonia. If the blood is too acidic, the glutamine can be broken down into glutamate and ammonia, which will increase blood pH. Glutamate levels in the blood can increase slightly with high doses of supplemental glutamine administration (around 15 g in a single dose), but not with moderate doses (of about 5 g in a single dose). The higher doses may contribute to glutamate levels, and should be used with caution in patients with neurodegenerative diseases such as amyotrophic lateral sclerosis and multiple sclerosis.[99] In one pediatric oncology patient, a single dose of 0.75/kg was found to raise the blood ammonia level to an unacceptably high limit. Related to this, it was difficult to disperse the glutamine adequately at this dose, resulting in the suspension being found unpalatable.

DRUG INTERACTIONS

In cancer treatment, glutamine does not appear to change the efficacy of cancer drugs, rate of relapse, or progression of malignancy.[64] Some animal studies suggested that glutamine supplementation might even preferentially increase tumor retention of methotrexate, thus increasing the therapeutic window of this drug.[100] Many antiseizure medications, including phenobarbital, phenytoin, carbamazepine, primidone, and valproic acid, work to block glutamate activity in the brain. Because glutamine can convert to glutamate, clinicians should be cautious when using glutamine in patients using these medications.

Glycyrrhiza glabra (Licorice)

Michael T. Murray, ND

OUTLINE

Glycyrrhiza glabra (family: Leguminosae)
Common names: licorice, glycyrrhiza

GENERAL DESCRIPTION

Glycyrrhiza glabra is a perennial, temperate-zone herb or subshrub, 3 to 7 feet high, with a long, cylindrical, branched, flexible, and burrowing rootstock with runners (Fig. 85.1). The parts used are the dried runners and roots, which are collected in the fall.

CHEMICAL COMPOSITION

The major active component of licorice root is the triterpenoid saponin glycyrrhizin (also known as glycyrrhizic acid or glycyrrhizinic acid), which is usually found in concentrations ranging from 6% to 10% (Fig. 85.2). The intestinal flora is believed to hydrolyze glycyrrhizin, yielding the aglycone molecule (glycyrrhetinic acid) and a sugar moiety, resulting in absorption of both.[1]

A processed licorice extract, deglycyrrhizinated licorice (DGL), which is used in the treatment of peptic and aphthous ulcers, is made by removing the glycyrrhizin molecule. The active components of DGL are flavonoids. These compounds demonstrated impressive protection against chemically induced ulcer formation in animal studies.[2]

Other active constituents of licorice include isoflavonoids (e.g., isoflavonol, kumatakenin, licoricone, glabrol); chalcones; coumarins (e.g., umbelliferone, herniarin); triterpenoids; and sterols, lignins, amino acids, amines, gums, and volatile oils.[3]

HISTORY AND FOLK USE

The medicinal use of licorice in both Western and Eastern cultures dates back several thousand years. It was used primarily as a demulcent, expectorant, antitussive, and mild laxative. Licorice is one of the most popular components of Chinese medicines. Its traditional uses include treating peptic ulcers, asthma, pharyngitis, malaria, abdominal pain, insomnia, and infections.[3]

PHARMACOLOGY

Licorice is known to exhibit many pharmacological actions, including the following[3]:

- Estrogenic
- Aldosterone-like action
- Anti-inflammatory (cortisol-like action)
- Antiallergic
- Antibacterial, antiviral, and antitrichomonas
- Antihepatotoxic
- Anticonvulsive
- Choleretic
- Anticancer

- Expectorant
- Antitussive activities

Although much of the pharmacology focuses on glycyrrhizin and glycyrrhetinic acid, it is worth remembering that licorice has many other components, such as flavonoids, which may have significant pharmacological effects.

Estrogenic Activity

Most herbalists generally believe that glycyrrhiza exhibits alterative action on estrogen metabolism (i.e., when estrogen levels are too high, it inhibits estrogen action, and when estrogens are too low, it potentiates estrogen action when used in greater amounts).[4] Glycyrrhetinic acid has been shown to antagonize many of the effects of estrogens, particularly exogenous estrogens.[5] The estrogenic action of glycyrrhiza is a result of its isoflavone content, as many isoflavone structures (e.g., daidzein and genistein from soy) are known to possess estrogenic effect. The estrogenic activity of the isoflavones appears to be more significant than the estrogen antagonism of glycyrrhetinic acid.[6] Interestingly, these same components inhibit breast cancer cell growth.[7]

Fig. 85.1 *Glycyrrhiza glabra*. (From Grigorii_Pisotckii/iStock.com.)

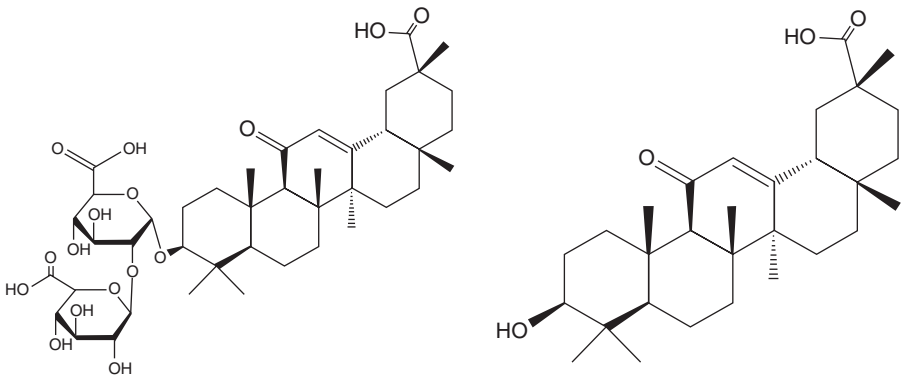
Pseudoaldosterone Activity

Long-term ingestion of glycyrrhiza in large doses leads to a well-documented pseudoaldosteronism syndrome (i.e., hypertension, hypokalemia, sodium and water retention, low plasma renin activity, and suppressed urine and serum aldosterone levels).[8-13] In normal subjects, the amount of glycyrrhizin needed to produce these side effects is between 0.7 and 1.4 g, which corresponds to approximately 10 to 14 g of the crude herb.[9] Although glycyrrhiza possesses mineralocorticoid activity (about four orders of magnitude lower than aldosterone) and binds to aldosterone receptors, it is largely without effect in adrenalectomized animals or in patients with severe adrenocorticoid insufficiency. Therefore it can be concluded that its primary effects are largely a result of glycyrrhetinic acid inhibiting the breakdown of aldosterone in the liver.[14] Glycyrrhizin and glycyrrhetinic acid were shown to suppress 5-β-reductase, the main enzyme in humans responsible for inactivating cortisol, aldosterone, and progesterone. These effects can be put to good use in the treatment of Addison's disease, a severe disease of adrenal insufficiency.[13]

Anti-Inflammatory and Antiallergic Activity

Glycyrrhiza has significant anti-inflammatory and antiallergic activity.[15,16] Although both glycyrrhizin and glycyrrhetinic acid bind to glucocorticoid receptors, and much of glycyrrhiza's anti-inflammatory activity has been explained by its "cortisol-like effects," many of the effects of glycyrrhiza actually antagonize or counteract cortisol.[17] Antagonism to such actions of cortisol includes activation of tryptophan oxygenase, accumulation of hepatic glycogen, stimulation of hepatic cholesterol synthesis, inhibition of thymus atrophy, and inhibition of adrenocorticotropic hormone synthesis and secretion. Glycyrrhizin does, however, reinforce cortisol's inhibition of antibody formation, stress reaction, and inflammation. Like its mineralocorticoid effect, glycyrrhiza's major influence on glucocorticoid metabolism is probably related to its suppression of 5-β-reductase activity, thus increasing the half-life of cortisol. Glycyrrhetinic acid can also increase the conversion of cortisol to the more powerful cortisone.[18]

Glycyrrhiza's major cortisol-like effect relates to its ability to inhibit phospholipase A_2.[19] This enzyme is responsible for cleaving lipids from biomembranes for eicosanoid metabolism. In addition to this effect, glycyrrhizin was also shown to inhibit cyclic adenosine monophosphate phosphodiesterase, thereby raising cyclic adenosine monophosphate levels and prostaglandin formation by activated peritoneal macrophages from rats.[20,21] Glycyrrhizin was shown to inhibit experimentally induced allergenic reactions, such as the Arthus phenomenon, the Shwartzman phenomenon, and Forssman anaphylaxis, and



Structure of Glycyrrhizin **Structure of Glycyrrhetinic acid**

Fig. 85.2 Chemical structures of glycyrrhizin and glycyrrhetinic acid. (Retrieved from https://www.sciencedirect.com/science/article/pii/S001429991730345X [accessed October 22, 2018]).

to be an antidote against many toxins, including diphtheria, tetanus, and tetrodotoxin.[21,22]

Glycyrrhizin exerts antithrombotic effects but does not potentiate the inhibitory activity of antithrombin III or heparin cofactor II toward thrombin.[23]

Immunostimulatory and Antiviral Effects

Glycyrrhizin and glycyrrhetinic acid were shown to induce interferon.[24] The induction of interferon leads to significant antiviral activity, because interferons bind to cell surfaces, where they stimulate synthesis of intracellular proteins that block the transcription of viral DNA. The induction of interferon is also followed by activation of macrophages and augmentation of natural killer cell activity.

Glycyrrhizin was shown to directly inhibit the growth of several DNA and RNA viruses in cell cultures (vaccinia, Epstein-Barr, herpes simplex, Newcastle disease, vesicular stomatitis viruses, severe acute respiratory syndrome [SARS]-associated coronavirus, and HIV) and to inactivate herpes simplex virus 1 (HSV-1) irreversibly.[25-28] Administration of glycyrrhizin to mice with herpetic encephalitis increased their survival rate on average about 2.5 times, whereas it reduced HSV-1 replication in the brain to 45.6% of the controls.[29] Glycyrrhizin, as stated earlier, also inhibited the thymolytic and immunosuppressive action of cortisone. Other licorice components exerted immunomodulatory effects as well.[30]

Anticancer Effects

Licorice components exert a wide range of anticancer effects.[31] The most active appear to be the flavonoids and coumarins. For example, isoliquiritigenin was shown to suppress colon cancer in mice via markedly decreasing both prostaglandin E_2 and nitric oxide production in mouse macrophage cells.[32] Isoliquiritigenin was also shown to significantly inhibit the proliferation of prostate and breast cancer cell lines in dose- and time-dependent manners.[7,33] Isoliquiritigenin also significantly reduced pulmonary metastasis in mouse renal cell carcinoma and prevented the leukocytopenia caused by administration of 5-fluorouracil.[34] A coumarin compound, identified as licocoumarone, was shown to be the factor in licorice that induces apoptosis.[35]

Antibacterial Activity

Alcohol extracts of glycyrrhiza displayed antimicrobial activity in vitro against *Helicobacter pylori, Staphylococcus aureus* (including antibiotic resistant strains), *Streptococcus mutans, Mycobacterium smegmatis, Bacillus subtilis, S. pyogenes, Haemophilus influenzae, Moraxella catarrhalis,* and *Candida albicans.*[36-39] The majority of the antimicrobial effects are due to isoflavonoid components, with the saponins having a lesser antibacterial effect.

Antihepatotoxic Activity

Glycyrrhetinic acid inhibits carbon tetrachloride and galactosamine-induced liver damage. The mechanism of action is prevention of nonenzymatic lipid peroxidation and inhibition of the production of free radicals by the enzymatic action of nicotine adenine disphosphonucleotide, reduced–cytochrome P450 reductase on CCl4.[40]

Memory-Enhancing Effect

Licorice may exert some memory-enhancing effects. In a study in mice, licorice was shown to enhance learning and memory in mice as determined by the elevated plus-maze and passive avoidance paradigm. Furthermore, licorice significantly reversed the amnesia induced by diazepam and scopolamine. Although anti-inflammatory and antioxidant properties may contribute favorably to the memory-enhancing effect, because scopolamine-induced amnesia was reversed as well, it is possible that the beneficial effect on learning and memory was a result of facilitation of cholinergic transmission.[41]

Antinephritic Activity

Glabridin, an isoflavan isolated from *G. glabra,* improved urinary protein excretion, total cholesterol, serum creatinine, and blood urea nitrogen levels after its oral administration to mice with glomerular disease.[42]

CLINICAL APPLICATIONS

Licorice is a component of more traditional Chinese and Japanese herbal formulas than any other herb and has been commonly used in Western natural medicine and herbalism for centuries. Although extremely pharmacologically diverse, the current clinical applications of licorice can be divided into four main categories:

- Use of DGL
- Use of oral licorice preparations containing glycyrrhizin
- Use of licorice flavonoid oil (LFO)
- Use of topical preparations containing glycyrrhetinic acid

The key use of DGL is in ulcerative conditions of the gastrointestinal tract (e.g., peptic ulcers, canker sores, inflammatory bowel disease), whereas the key uses of oral licorice containing glycyrrhizin include viral infections (e.g., the common cold, HIV and AIDS, viral hepatitis); premenstrual syndrome (PMS) and menopause; acute intermittent porphyria; Addison's disease; inflammation; syndrome X; and as a sweetening agent. Topical preparations containing glycyrrhetinic acid can be used in eczema, psoriasis, herpes, and melasma.

DEGLYCYRRHIZINATED LICORICE

Although glycyrrhetinic acid was the first drug proven to promote healing of gastric and duodenal ulcers,[43] most physicians using licorice in the treatment of peptic ulcers now use DGL. DGL was actually shown to be more effective than glycyrrhetinic acid, without side effects.[44]

DGL's mode of action is different than that of current drugs, such as antacids and H_2-receptor antagonists, which focus on reducing gastric acidity. Although effective, these treatments can be expensive, carry some risk of toxicity, disrupt normal digestive processes, and alter the structure and function of the cells that line the digestive tract. The latter factor is just one of the reasons why peptic ulcers develop again if antacids, cimetidine, ranitidine, and similar drugs are used.

Rather than inhibit the release of acid, DGL stimulates the normal defense mechanisms that prevent ulcer formation and stimulate healing of the damaged mucous membranes. Specifically, DGL increases the following[45,46]:

- The blood supply to the damaged mucosa
- The number of cells producing the mucus that protects the mucous membranes
- The amount of mucus the cells produce
- The life span of the intestinal cell

In addition, several flavonoid components of *G. glabra* have shown significant activity against *H. pylori,* including antibiotic-resistant strains.[38] To evaluate the effect of licorice in *H. pylori* eradication in 120 patients suffering from dyspepsia either with peptic ulcer disease (PUD) or nonulcer dyspepsia (NUD), licorice (380 mg twice daily) was given in addition to clarithromycin-based standard triple regimen for 2 weeks.[47] *H. pylori* eradication was assessed 6 weeks after therapy. Response to treatment was 83.3% in the licorice group and 62.5% in the control group.

Gastric Ulcers

Numerous clinical studies over the years found DGL to be an effective antiulcer compound. DGL was shown to be extremely effective in the

treatment of gastric ulcers.[48-52] In one study, 33 gastric ulcer patients were treated with either DGL (760 mg, three times a day) or a placebo for 1 month.[50] There was a significantly greater reduction in ulcer size in the DGL group (78%) than in the placebo group (34%). Complete healing occurred in 44% of those receiving DGL but only in 6% of the placebo group.

In several head-to-head comparison studies, DGL was shown to be more effective than cimetidine (Tagamet), ranitidine (Zantac), or antacids in both short-term treatment and maintenance therapy of peptic ulcers.[48,49,52] For example, in a head-to-head comparison with Tagamet, 100 patients received either DGL (760 mg, three times a day between meals) or Tagamet (200 mg, three times a day, and 400 mg at bedtime).[49] The percentage of ulcers healed after 6 and 12 weeks were similar in both groups. Although Tagamet is associated with some significant side effects, DGL is extremely safe to use.

Gastric ulcers are often a result of using alcohol, aspirin, or other nonsteroidal anti-inflammatory drugs, caffeine, and other factors that decrease the integrity of the gastric lining. Because DGL was shown in human studies to reduce the gastric bleeding caused by aspirin, DGL is strongly indicated for the prevention of gastric ulcers in patients requiring long-term treatment with ulcerogenic drugs such as aspirin, nonsteroidal anti-inflammatory agents, and corticosteroids.[51]

Duodenal Ulcers

DGL is also effective in duodenal ulcers. This is perhaps best illustrated by one study in patients with severe duodenal ulcers: 40 patients with chronic duodenal ulcers of 4 to 12 years' duration and more than six relapses during the previous year were treated with DGL.[53] All of the patients had been referred for surgery because of relentless pain, sometimes with frequent vomiting, despite treatment with bed rest, antacids, and anticholinergic drugs. Half of the patients received 3 g/day of DGL for 8 weeks; the other half received 4.5 g/day for 16 weeks. All 40 patients showed substantial improvement, usually within 5 to 7 days, and none required surgery during the 1-year follow-up. Although both dosages were effective, the higher dosage was significantly more effective than the lower dosage.

In another more recent study, the therapeutic effect of DGL was compared with that of antacids or cimetidine in 874 patients with confirmed chronic duodenal ulcers.[52] Ninety-one percent of all ulcers healed within 12 weeks; there was no significant difference in healing rate in the groups. However, there were fewer relapses in the DGL group (8.2%) than in those receiving cimetidine (12.9%) or antacids (16.4%). These results, coupled with DGL's protective effects and very low toxicity, suggest that DGL is a superior treatment of duodenal ulcers.

Aphthous Ulcers

Recurrent aphthous stomatitis (canker sores) is a common problem. DGL may be effective in promoting healing. In one study, 20 patients were instructed to use a solution of DGL as a mouthwash (200 mg powdered DGL dissolved in 200 mL warm water) four times daily.[54] Fifteen of the 20 (75%) patients experienced 50% to 75% improvement within 1 day, followed by complete healing of the ulcers by the third day. DGL in tablet form may produce even better results.

ORAL LICORICE PREPARATIONS CONTAINING GLYCYRRHIZIN

The most popular use of oral licorice preparations containing glycyrrhizin is in the treatment of viral illnesses, particularly the common cold. Licorice has long been used in this application. This historical use is justified by its immune-enhancing and antiviral effects. In addition, licorice components were shown to exert antibacterial action against the common pathogens *S. pyogenes, Haemophilus influenzae,* and *Moraxella catarrhalis.*[55]

Another popular use of licorice is in the treatment of gynecological issues, primarily PMS and menopause. Regarding PMS, because glycyrrhizin and glycyrrhetinic acid possess antiestrogenic effects and suppress the breakdown of progesterone, administration of licorice 2 weeks before the onset of menstruation (the midluteal phase) may help reduce PMS symptomatology. Clinical trials showed that taking licorice containing herbal combinations was useful in dysmenorrhea.[56] Isoflavones from glycyrrhiza showed an ability to inhibit serotonin reuptake, and therefore might also exhibit some antidepressant effects in PMS.[57]

Human Immunodeficiency Virus and Acquired Immunodeficiency Syndrome

Glycyrrhizin-containing preparations are showing promise in the treatment of HIV-related diseases, including AIDS. Although much of the research featured intravenous administration, this route of administration might not be necessary, as glycyrrhizin and glycyrrhetinic acid are easily absorbed orally and are well tolerated. This was most evident in a recent double-blind study on the clinical effectiveness of glycyrrhizin by long-term oral administration to 16 hemophiliac patients with evidence of HIV infection.[58] Patients received daily doses of 150 to 225 mg of glycyrrhizin for 3 to 7 years.

Helper and total T-lymphocyte numbers, other immune system parameters, and glycyrrhizin and glycyrrhetinic acid levels in the blood were monitored. The results indicated that orally administered glycyrrhizin was converted into glycyrrhetinic acid, which was detected in sera, without manifesting any side effects. None of the patients given the glycyrrhizin had progression of immunological abnormalities or development to AIDS. In contrast, the group not receiving glycyrrhetinic acid showed decreases in helper and total T-cell counts and antibody levels. Two of the 16 patients in the control group developed AIDS.

In another study, 10 HIV positive patients without AIDS took 150 to 225 mg/day of glycyrrhizin.[59] After 1 to 2 years, none developed symptoms associated with AIDS or AIDS-related complex, whereas 1 of 10 patients of a matched control group developed AIDS-related complex, and 2 progressed to AIDS and subsequently died.

The result of glycyrrhizin in HIV-positive and AIDS patients is almost immediate improvement in immune function. In one study, 9 symptom-free HIV-positive patients received 200 to 800 mg/day of glycyrrhizin intravenously. After 8 weeks, the groups had increased T-helper cells, improved helper/suppressor ratios, and improved liver function.[60]

In another study, 6 AIDS patients received 400 to 1600 mg/day of glycyrrhizin intravenously.[61] After 30 days, 5 of the 6 showed a reduction or disappearance of the P24 antigen, which indicates active disease. The results of these studies and others in HIV-positive and AIDS patients are encouraging.

Hepatitis

Some studies of HIV patients used an intravenous glycyrrhizin-containing product, Stronger Neo-Minophagen C (SNMC), consisting of 0.2% glycyrrhizin, 0.1% cysteine, and 2.0% glycine in physiological saline solution. This product is used in Japan primarily for the treatment of hepatitis. The other components, glycine and cysteine, appear to modulate glycyrrhizin's actions. Glycine was shown to prevent the aldosterone effects of glycyrrhizin, whereas cysteine aids the liver in detoxification reactions.

In addition to AIDS, SNMC demonstrated beneficial results in treating chronic hepatitis B and C, often difficult infections for the body to clear.[22,62-64] Specifically, SNMC was shown to improve liver function and lower levels of liver enzymes. Glycyrrhizin therapy appears particularly helpful in patients with chronic hepatitis C who fail to respond to interferon and in those who cannot be treated with it for various reasons.

Acute Intermittent Porphyria

This disorder of heme biosynthesis is characterized by recurrent attacks of neurological and psychiatric dysfunction. The symptoms include the following:

- Abdominal complaints of nausea, vomiting, and colicky pain, occasionally severe enough to present as an acute abdomen without fever or leukocytosis
- Variable neurological signs and symptoms (e.g., paresthesia, hypesthesia, neuritic pain, wrist or foot drop, loss of deep tendon reflexes)
- Variable mental and emotional disturbances, typically restlessness, disorientation, and visual hallucinations (seen in one third of patients)

Because estrogens are known to exacerbate or induce acute intermittent porphyria (AIP), it is quite possible that some of the so-called PMS symptoms are exacerbations of AIP caused by the midcycle estrogen surge.

A partial (50%) deficiency of uroporphyrinogen I synthase results in increased inducibility of aminolevulinic acid synthase by drugs and foreign chemicals and by 5-β-reductase steroid metabolites (potent inducers of aminolevulinic acid synthase). AIP is also associated with a marked deficiency in the activity of 5-α-reductase, resulting in increased 5-β-reductase activity.[65] Glycyrrhetinic acid and glycyrrhizin were shown to significantly reduce 5-β-reductase while increasing 5-α-reductase.[66] (Lead also increases 5-β-reductase activity, resulting in a presenting picture similar to AIP.[66] Chronic or acute lead toxicity must be ruled out in these patients.)

Obesity and Metabolic Syndrome

Preparations containing glycyrrhetinic acid may be effective in reducing various issues related to syndrome X or metabolic syndrome. For example, in a preliminary study, 15 normal-weight subjects (7 males, 22–26 years old, and 8 females, 21–26 years old), who consumed 3.5 g/day of a commercial preparation of licorice containing glycyrrhetinic acid for 2 months, had reduced body fat mass of 1.2% in men and 2.8% in women.[67] This weight loss might have been mediated not only via suppressing renin activity and aldosterone levels via inhibition of 11-β-hydroxysteroid dehydrogenase, but also via improving blood glucose control—a key goal in syndrome X.[68-70]

In another study, supplementation of a licorice root extract to moderately hypercholesterolemic patients for 1 month reduced plasma susceptibility to oxidation (by 19%). It also increased resistance of plasma low-density lipoprotein against three major atherogenic modifications: oxidation (by 55%), aggregation (by 28%), and retention (by 25%). It reduced plasma cholesterol levels (by 5%), which were caused by a 9% reduction in plasma low-density lipoprotein cholesterol levels, and reduced (by 14%) plasma triglyceride levels. Licorice extract supplementation also reduced systolic blood pressure by 10%.[71]

Addison's Disease

As described later in "Pseudoaldosterone Activity," licorice exerts an aldosterone-like effect that is useful in treating Addison's disease.

Inflammation

Virtually any inflammatory or allergic condition may be reduced by licorice by the mechanisms discussed earlier in the section on "Pharmacology." Historically, licorice was successfully used for treating asthma and other atopic conditions.[3,15]

Licorice was shown to enhance the action of corticosteroids like prednisone and prednisolone, as well as the levels of the body's own corticosteroids.[72,73] In one study, six subjects received an intravenous dose of prednisolone with or without 200 mg glycyrrhizin. Glycyrrhizin was found to significantly increase the concentration of total and free prednisolone by inhibiting its breakdown. Furthermore, the effects of prednisolone appeared to be potentiated by glycyrrhizin.[73]

One interesting application shown with positive clinical results in a double-blind study was reduction of postoperative sore throat.[74] Forty adults who underwent elective lumbar laminectomy were randomized into two groups of 20 patients each. One group received water (Group C); the other received 0.5 g licorice in water (Group L). Both groups gargled 5 minutes before anesthesia. Postoperative sore throat incidence and severity as well as postextubation cough were reduced for all time points in the licorice group compared with the water group at rest and on swallowing. Postextubation cough was reduced in Group L compared with Group C ($P < 0.05$). There was no difference in side effects between groups ($P > 0.05$).

A review study evaluated the possible application of the active components of licorice, glycyrrhizin (GL) and glycyrrhetinic acid (GA), in rheumatoid arthritis (RA) treatment based on the cyclooxygenase (COX)-2/thromboxane A2 (TxA2) pathway (Fig. 85.3).[75] The COX-2/TxA2 pathway, an auto-regulatory feedback loop, has been found to be a crucial mechanism underlying the pathogenesis of RA. Both nonsteroidal anti-inflammatory drugs (NSAIDs) and disease-modifying antirheumatic drugs (DMARDs) are typically prescribed medications for treatments of patients with RA. TxA2 is believed to be the nontarget of NSAIDs and DMARDs, and the limitations and adverse effects of those drugs may be, at least in part, caused by lack of the effects on the COX-2/TxA2 pathway. The active components of licorice, GL and GA, could not only potentiate the therapeutic effects but also decrease the adverse effects of NSAIDs or DMARDs through suppressing the COX-2/TxA2 pathway and hold the potential as a novel add-on therapy in the treatment of RA.

Sweetening Agent

Because glycyrrhizin is 50 to 100 times sweeter than sucrose, licorice can be used as a sweetening or flavoring agent to mask the bitter taste of other medications.[3]

LICORICE FLAVONOID OIL

LFO shows promise as an antiobesity and weight loss agent. It is standardized to contain 30% polyphenols with glabridin standardized at 3%. The flavonoids are extracted with ethanol and then solubilized in medium chain triglycerides oil (hence 70% of LFO is medium chain triglycerides). The extracted licorice flavonoids are hydrophobic compounds and virtually free of the hydrophilic compounds glycyrrhizin and glycyrrhizinic acid (there is less than 0.005% glycyrrhizic acid in LFO).

LFO decreases the activity of acetyl coenzyme A carboxylase and fatty acid synthase, the rate-limiting enzymes in the fatty acid synthetic pathway, while increasing the enzymatic activity of acyl coenzyme A dehydrogenase, the rate-limiting enzyme in the fatty acid oxidative pathway. These effects are thought to be responsible for the reduction in abdominal fat in animal and human studies.[76–79]

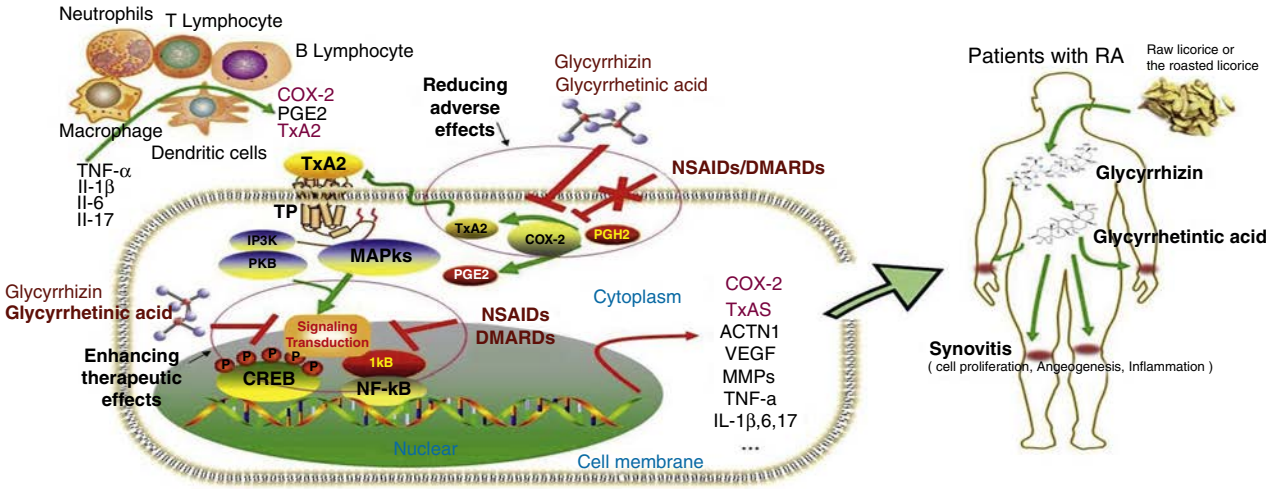


Fig. 85.3 The COX-2/TxA2 pathway is a crucial mechanism underlying the toxicity reducing and efficacy enhancing effects of glycyrrhizin (GL) and glycyrrhetinic acid (GA) to NSAIDs/DMARDs. *TNF*, Tumor necrosis factor; *IL*, interleukin; *RA FLS*, rheumatoid arthritis fibroblast-like synoviocytes; *COX*, cyclooxygenase; *TxA2*, thromboxane A2; *TP*, thromboxane A2 receptor; *PGH2*, prostaglandin H2; *PGE2*, prostaglandin E2; *NSAIDs*, nonsteroidal anti-inflammatory drugs; *DMARDs*, disease modifying antirheumatic drugs; *NF-κB*, nuclear factor κB; *CREB*, cAMP response element-binding protein; *MAPKs*, mitogen activated protein kinases; *PI3K*, phosphoinositide-3-kinase; *VEGF*, vascular endothelial growth factor; *ACTN1*, α-actinin-1; *MMPs*, matrix metalloproteinase. (From Huang QC, Wang MJ, Chen XM, et al. Can active components of licorice, glycyrrhizin and glycyrrhetinic acid, lick rheumatoid arthritis? *Oncotarget*. 2016;7[2]:1193-1202. PubMed PMID: 26498361.)

TABLE 85.1 Body Weight and Mass Compared With Baseline After Licorice Flavonoid Oil Treatment

Group	Baseline	4 Weeks	8 Weeks
Body Weight (kg)			
Placebo	73.13	73.07	73.39
900 mg	72.79	72.20	72.05
Body Mass Index (kg/m^2)			
Placebo	26.51	26.49	26.59
900 mg	26.22	26.01	25.97

In a double-blind study, 56 men and 28 postmenopausal women, aged 40 to 60 years with body mass indexes of 24 to 30 kg/m^2, were randomized into four groups: the placebo group took three placebo capsules per day, the low-dose group took one LFO capsule and two placebos per day (300 mg/day LFO), the middle-dose group took two LFO capsules and one placebo per day (600 mg/day LFO), and the high-dose group took three LFO capsules per day (900 mg/day LFO). The subjects in the 900 mg LFO group experienced significant decreases from baseline in body weight and body mass index compared with the placebo group (Table 85.1).[79]

The subjects in all three LFO groups, but not the placebo group, had significantly lower body fat masses compared with baseline after 8 weeks of treatment. Computed tomographic scans showed that visceral fat mass decreased significantly compared with baseline in the 900 mg LFO group (122.37–113.02 cm^2).

Another study with LFO was conducted to determine its ability to increase the muscle mass of elderly patients. Fifty subjects aged 54 to 90 years (7 men, 43 women), who underwent rehabilitation treatment for osteoarthritis of the knee, were assigned to either the LFO (300 mg per day) or placebo group. In the LFO group, muscle mass in the body trunk increased significantly after 16 weeks of LFO intake (+0.38 kg). In addition, the body fat percentage and body trunk fat percentage of the LFO group were also reduced.[80]

A safety study demonstrated that LFO is safe when administered once daily up to 1200 mg/day.[81] There were no clinically noteworthy changes in hematologic or related biochemical parameters.

TOPICAL APPLICATIONS

Eczema and Psoriasis

Glycyrrhetinic acid exerts an effect similar to that of topical hydrocortisone in the treatment of eczema, contact and allergic dermatitis, and psoriasis.[82–85] In several studies, glycyrrhetinic acid was shown to be superior to topical cortisone, especially in chronic cases. For example, in one study of patients with eczema, 93% of the patients applying glycyrrhetinic acid demonstrated improvement compared with 83% using cortisone.[86] In another study, a topical gel containing 2% glycyrrhetinic acid was shown to be effective for treatment of atopic dermatitis and was more effective than preparations containing 1% glycyrrhetinic acid in reducing the scores for erythema, edema, and itching over 2 weeks.[82]

Glycyrrhetinic acid can also be used to potentiate the effects of topically applied hydrocortisone by inhibiting 11-β-hydroxysteroid dehydrogenase, which catalyzes the conversion of hydrocortisone to an inactive form.[83] It also increases the permeation of topically applied steroids. In one study, glycyrrhetinic acid in a concentration of 0.1% in gel increased diclofenac sodium flux value tenfold compared with a control gel.[84]

Herpes Simplex

Clinical studies showed topical glycyrrhetinic acid and derivatives to be quite helpful in reducing the healing time and pain associated with cold sores and genital herpes.[87,88] As mentioned previously, glycyrrhizin inactivates HSV-1 irreversibly and stimulates the synthesis and release of interferon.[25]

Melasma

Two components, glabrene and isoliquiritigenin, can inhibit tyrosinase—a key enzyme in melanin biosynthesis.[89] Dermatological disorders such as melasma, age spots, and sites of actinic damage arise from the accumulation of melasma. Glabrene and isoliquiritigenin may serve as candidates for skin-lightening agents.

DOSAGE

The dosage of licorice for most clinical applications is based on the content of glycyrrhetinic acid. The exception is in the treatment of peptic ulcer. In this application, DGL is preferred, as it produces equally effective results compared with glycyrrhetinic acid but is free from any side effects.

For most purposes, the goal is to achieve a high level of glycyrrhetinic acid in the blood without producing side effects (discussed later in "Toxicology"). In general, the following doses three times a day are safe and effective in raising glycyrrhetinic acid levels:

- Powdered root: 1 to 2 g
- Fluid extract (1:1): 2 to 4 mL
- Solid (dry powdered) extract (4:1): 250 to 500 mg

In the treatment of AIDS, pure glycyrrhetinic acid products or extracts standardized for glycyrrhetinic acid are recommended. Toxicity can become a problem for patients taking licorice for any period longer than 1 month (see "Toxicology" and "Drug Interactions").

Dosage Instructions for Deglycyrrhizinated Licorice

To be effective in healing peptic ulcers, it appears that DGL must mix with saliva. DGL may promote the release of salivary compounds, which stimulate the growth and regeneration of stomach and intestinal cells. DGL in capsule form has not been shown to be effective.[90,91]

The standard dosage for DGL is two to four 380-mg chewable tablets between or 20 minutes before meals. Taking DGL after meals is associated with poor results.[92] DGL should be continued for 8 to 16 weeks, depending on the response.

Dosage Instructions for Licorice Flavonoid Oil

The standard dosage for LFO is 900 mg/day usually administered as 300 mg three times a day.

TOXICOLOGY

The main hazards of licorice administration are due to the aldosterone-like effects of glycyrrhetinic acid. If ingested regularly, licorice root (>3 g/day for more than 6 weeks) or glycyrrhizin (>100 mg/day) may cause sodium and water retention, hypertension, and hypokalemia.[8,9,93-95] Individuals with existing hypertension may be more predisposed to this effect via increased sensitivity to the inhibition of 11-β-hydroxysteroid-dehydrogenase by glycyrrhetinic acid.[18,82,96] Monitoring of blood pressure and electrolytes and increasing dietary potassium intake is suggested, as the pseudoaldosterone effects can be quite significant. The maximal effect on blood pressure with long-term ingestion is observed after 2 weeks of use.[97]

There is great individual variation in the susceptibility to the symptom-producing effects of glycyrrhizin, primarily due to differences in pharmacokinetics and conversion to the more potent glycyrrhetinic acid (100–200 times more active in suppressing 11-β-hydroxysteroid-dehydrogenase).[98] Adverse effects are rarely observed at levels below 100 mg/day, whereas they are quite common at levels above 400 mg/day.[9] However, some persons may be susceptible to long-term dosages at even lower levels, especially if the more potent glycyrrhetinic acid is available in free form. One study determined a no-effect level of glycyrrhetinic acid at 2 mg/kg, from which an acceptable daily intake of 0.2 mg/kg body weight can be extrapolated with a safety factor of 10. This translates to a consumption of 12 mg/day of glycyrrhetinic acid for a person with a body weight of 60 kg.[99]

Prevention of the side effects of glycyrrhizin may be possible by following a high-potassium, low-sodium diet. Although no formal trial has been performed, patients who normally consume high-potassium foods and restrict sodium intake, even those with high blood pressure and angina, have been reported to be free from the aldosterone-like side effects of glycyrrhizin.[100]

Licorice should probably not be used in patients with a history of hypertension or renal failure or in those who currently use digitalis preparations.

Licorice preparations containing glycyrrhizin may reduce serum and salivary testosterone levels in men. In one study, men consuming the equivalent of 500 mg of glycyrrhizin experienced a drop of 26% in serum testosterone levels.[101] However, in another study, no significant effect was noted.[102]

Licorice intake during pregnancy is generally regarded as safe, unless hypertension becomes an issue. There was one detailed study on maternal consumption of glycyrrhizin and how it affected birth weight.[103] Glycyrrhizin intake was calculated from detailed questionnaires on licorice consumption. Glycyrrhizin exposure was grouped into three levels: low (<250 mg/week), moderate (250–499 mg/week), and heavy (≥500 mg/week). Birth weight and gestational age (from ultrasound measurements) were obtained from hospital records. Babies with heavy exposure to glycyrrhizin were not significantly lighter at birth, but they were significantly more likely to be born earlier—2.52 days earlier. No other associations could be made.

DRUG INTERACTIONS

No significant reports of drug interactions have appeared, although on theoretical grounds, licorice components have shown considerable interactions with various enzyme systems. Licorice root extract and purified glabridin were shown to inhibit P450 3A4, a major human drug metabolizing P450 enzyme, in time- and concentration-dependent manners, thereby potentiating the action of many drugs.[104] Glycyrrhizin intake may be problematic for people on digitalis, diuretics, or antihypertensive medications. Also, individuals using oral hypoglycemic drugs or insulin need to monitor blood sugar levels closely when using glycyrrhiza.

Glycyrrhetinic acid can reduce the prevalence of side effects related to the diuretic activity of spironolactone. In a study of 32 women with polycystic ovarian syndrome, women who received 3.5 g of licorice a day with spironolactone eliminated symptoms related to volume depletion, and the activation of the renin-aldosterone system was significantly lower during spironolactone plus licorice than with spironolactone alone. The prevalence of metrorrhagia was also lower with the combined therapy.[105]

Hydrastis canadensis (Goldenseal) and Other Berberine-Containing Botanicals

Roy Upton, RH

OUTLINE

Hydrastis canadensis (family: *Ranunculaceae*)
Common names: goldenseal, yellow root, Indian turmeric, eye root, jaundice root
Berberis vulgaris (family: *Berberidaceae*)
Common name: barberry
Berberis aquifolium, Berberis nervosa (family: *Berberidaceae*)
Common names: Oregon grape, trailing mahonia
Coptis chinensis (family: *Ranunculaceae*)
Common name: coptis

INTRODUCTION

Berberine-containing plants have played a major role in the world's herbal traditions. The primary berberine-containing botanicals used in North America include goldenseal *(Hydrastis canadensis),* barberry *(Berberis vulgaris),* Oregon grape *(Berberis aquifolium),* and coptis *(Coptis chinensis).* The roots of these plants share similar indications and effects due to their high content of isoquinoline alkaloids, primarily berberine, which is common to these species. Additionally, goldenseal contains hydrastine, canadine, and tetrahydropalmatine. In addition to berberine, coptis contains coptisine, jatrorrhizine, and palmatine.[1,2] Barberry and Oregon grape, which botanically are alternately assigned to either the genus *Berberis* or *Mahonia,* in addition to berberine, contain jatrorrhizine, magnoflorine, and palmatine.[3] Other closely related berberine-containing species of North American and Eastern herbal traditions feature prominently as herbal medicines and include yellow root *(Xanthorrhiza simplissima)* and other species of *Berberis* or *Mahonia* (e.g., *Berberis nervosa* and *B. repens* from North America, *B. teeta* from India, and *Mahonia bealei* from China, among others). Most of these latter species of *Berberis* and *Mahonia* should be considered interchangeable.

The chief berberis alkaloid, berberine, has been studied extensively in both experimental and clinical settings. The general description, history and folk use, chemical composition, and specific clinical indications for the primary berberine-containing plants used in North America and pharmacology of berberine are presented here. Although the pharmacology of these plants is primarily discussed in terms of the activity of berberine, it is valuable to recognize that constituents other than alkaloids contribute to the efficacy of medicinal plants. In these particular cases, polysaccharides (in coptis and Oregon grape root)[4,5] and phenolic compounds (in Oregon grape root) are also present and are pharmacologically relevant (see Table 86.1).[6]

TABLE 86.1 Primary Alkaloids of Berberine-Containing Plants

Hydrastis canadensis[7,8]	*Berberis aquifolium*[1,2]	*Berberis vulgaris*[7,8]	*Coptis chinensis*[1]
Berberine (0.5%–6%)	Berberine	Berberine	Berberine (3.6%–7%)
Hydrastine (1.5%–4%)	Berbamine	Jatrorrhizine	Jatrorrhizine (0.1%–0.4%)
Berberastine (2%–3%)	Canadine	Berberubine	Palmatine (0.7%–1.5%)
Canadine (0.5%–1%)	Corypalmine	Berbamine	
Candaline	Mahonine	Bervulcine	
Corypalmine	Oxyacanthine	Palmatine	
Hydrastinine (degradation compound of hydrastine)	Isocorydine	Columbamine

GENERAL DESCRIPTION

Hydrastis canadensis

Goldenseal is native to eastern North America and is cultivated in Oregon and Washington. It is a perennial herb with a knotty yellow rhizome from which arises a single leaf and an erect hairy stem. In early spring, it bears two five- to nine-lobed rounded leaves near the top, which are terminated by a single greenish-white flower (Fig. 86.1). The primary parts used are the dried rhizome and roots, although the leaf is used in the southeastern parts of the United States.[7,8]

Berberis vulgaris

The common barberry is a deciduous spiny shrub that may reach 16 ft in height (Fig. 86.2). Native to Europe, it has been naturalized in eastern North America. The parts used are the whole rhizomes and roots and, less frequently, the bark of the stem and root.[7,8]

Berberis aquifolium

The Oregon grape is an evergreen, spineless, ornamental shrub that is 3 to 7 ft in height (Fig. 86.3). It is native to the Rocky Mountains from British Columbia to California. The parts used are whole rhizomes and roots and, less frequently, the bark of the stem and root.[8]

Fig. 86.2 *Berberis vulgaris*. (From https://www.istockphoto.com/photo/barberry-gm488402720-74107579. Accessed November 24, 2018.)

Fig. 86.3 *Berberis aquifolium*. (From https://www.istockphoto.com/photo/oregon-grape-gm485322828-71877603. Accessed November 24, 2018.)

Coptis chinensis

Coptis, also known as goldthread, is a perennial herb native to China. The parts used are the rhizomes and root.[9]

CHEMICAL COMPOSITION

The chemical structure of berberine, jatrorrhizine, and palmatine are shown in Fig. 86.4.

Hydrastis canadensis

Alkaloids isolated from *Hydrastis* include the following:

- Hydrastine (1.5%–4%)
- Berberine (0.5%–6%)
- Berberastine (2%–3%)
- Canadine
- Candaline
- Hydrastinine
- Other related alkaloids

Other constituents include meconin, chlorogenic acid, phytosterins, and resins.[1,2]

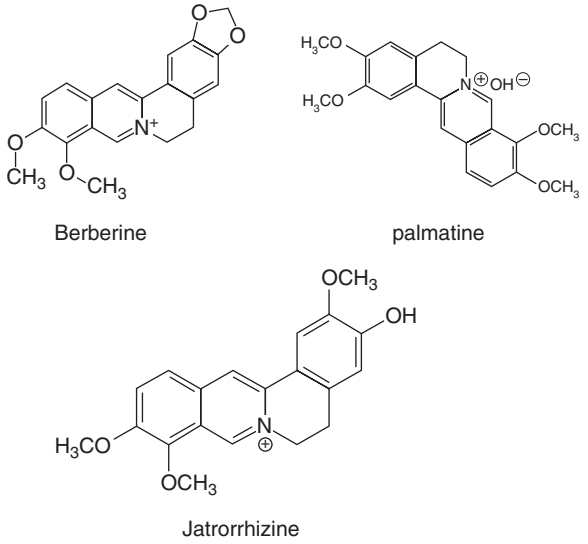

Fig. 86.4 Primary berberis alkaloids. (From https://en.wikipedia.org/wiki/Jatrorrhizine https://en.wikipedia.org/wiki/Berberine https://en.wikipedia.org/wiki/Palmatine. Accessed November 24, 2018.)

Berberis vulgaris

Barberry contains several alkaloids in its rhizomes and roots.

- Jatrorrhizine
- Berberine
- Berberrubine
- Berbamine
- Bervulcine
- Palmatine
- Columbamine
- Oxyacanthine

Barberry also contains chelidonic, citric, malic, and tartaric acids.[7,8]

Berberis aquifolium

Oregon grape contains the alkaloids berbamine, berberine, canadine, corypalmine, hydrastine, isocorydine, mahonine, and oxyacanthine. Resins and tannins have also been reported.[1,2]

Coptis chinensis

Goldthread root contains berberine (5%–8%) and other alkaloids similar to those found in goldenseal.[3]

HISTORY AND FOLK USE

Hydrastis canadensis

Native to North America, goldenseal root was used extensively by American Indians as an herbal medication and clothing dye. Its medicinal use centered around its ability to soothe the mucous membranes of the respiratory, digestive, and genitourinary tracts in inflammatory conditions induced by allergy or infection. The Cherokee and other tribes used goldenseal in disorders of the eye and skin.[7,8] Berberine was isolated from goldenseal root by early American naturalist Constantine Rafinesque in 1828. Goldenseal root featured prominently in the Eclectic medical practice of the mid-1800s, where it was recorded as among "their best articles"[10] and was used for gastrointestinal complaints, jaundice, infections, as a bitter tonic to regulate bile production, and as a uterine tonic. For many of these purposes, goldenseal was considered to have no equal.[11]

Berberis vulgaris

Barberry is native to most of Europe. Closely related species are found in North Africa and Asia. Barberry's historical use is as an antidiarrheal agent, bitter tonic, antipyretic, and antihemorrhagic.[7,8]

Berberis aquifolium

Oregon grape's historical and folk use is like that of goldenseal. In addition, Oregon grape was used in the treatment of chronic skin conditions such as acne, psoriasis, and eczema.[7,8]

Coptis chinensis

In China, coptis was used in the traditional medicine system to "drain fire," which refers to the treatment of conditions associated with infections and toxemia. It was used primarily in infectious conditions, similar to the historical use of goldenseal. Specific uses included fever, dysentery, gastrointestinal infection, furuncles, boils, and eye infections.[9]

PHARMACOLOGY

The primary medicinal value of goldenseal, barberry, Oregon grape root, and coptis is thought to be due to their high content of isoquinoline alkaloids, of which berberine has been the most widely studied. Berberine demonstrates antibiotic, anticonvulsant, antidiarrheal, anti-inflammatory, choleretic, carminative, hepatoprotectant, hypolipidemic, hypotensive, immunostimulatory, sedative, and uterotonic activity. Berberine's pharmacological activities strongly support the historical use of berberine-containing herbs.

Antimicrobial, Anti-infective Activity, and Gut Health

The most broadly celebrated of berberine's effects has been its antimicrobial activity. Although not as potent as many prescription antibiotics, berberine exhibits a broad spectrum of antimicrobial activity against a wide range of human pathogens that include bacteria, protozoa, and fungi, including the specific strains listed in Table 86.2.[7–9,12–21]

Most of these microbes have a significant effect on human health, with many affecting the gastrointestinal system. *E. histolytica* alone is responsible for approximately 55,000 deaths annually. Berberine exhibits broad-spectrum antibacterial activity against numerous strains of *Staphylococcus,* and additionally it enhances the efficacy of conventional antibiotic agents such as linezolid, cefoxitin, and erythromycin.[21]

Perhaps berberine's greatest potential contribution to human health is that pathogens generally fail to develop resistance to its antimicrobial effects.[22] As a result of the excessive use of antibiotics for decades, both used clinically for the treatment of infections and through exposure through the food chain from commercially raised foods, numerous bacteria have become resistant to standard treatment with antibiotics. Of these, methicillin-resistant *Staphylococcus aureus* (MRSA) is most well known and can cause serious skin infections and pneumonia that can result in death or cause other systemic infections that are resistant to treatment. MRSA most commonly occurs in hospital settings, as a result of the prevalence of patients with infectious disease, but can also arise from contact with generally healthy people.

Experiments were conducted to determine whether a variety of bacteria, including *E. coli, S. aureus, Bacillus subtilis, Proteus vulgaris, Salmonella typhimurium,* and *Pseudomonas aeruginosa*, could develop resistance to berberine. No resistance was observed after 200 generations of exposure of these bacteria to berberine.[23] Prevention of resistance was also demonstrated for berberine analogs against *Acinetobacter baumannii,* a bacterial pathogen that can cause serious infections of the blood, lungs, and brain.[24]

TABLE 86.2 In Vitro Sensitivity of Microorganisms to Berberine Sulfate

Organism	Inhibitory Concentration (mg/mL) (unless otherwise specified[a])
Bacteria	
Acinetobacter baumannii	2 nmol/mL
Bacillus cereus	25
Bacillus subtilis	25
Corynebacterium diphtheriae	6.2
Enterobacter aerogenes	2500.05
Escherichia coli	600.05
Klebsiella spp.	>100
Klebsiella pneumoniae	25
Proteus spp.	>100
Pseudomonas mangiferae	>100
Pseudomonas pyocyanea	>100
Salmonella paratyphi	>100
Salmonella typhimurium	>100
Shigella boydii	12.5
Staphylococcus aureus	6.2–50
Streptococcus pyogenes	12.5
Vibrio cholera	25
Fungi	
Candida utilis	12.5
Candida albicans	12.5
Candida glabrata	16 5 g/mL
Candida guilliermondii	16 µg/mL
Candida krusei	16 µg/mL
Candida tropicalis	31.3 µg/mL
Cryptococcus neoformans	150[b]
Microsporum gypseum	50[b]
Saccharomyces cerevisiae	100[b]
Sporothrix schenckii	6.2
Trichophyton mentagrophytes	100[b]
Other	
Entamoeba histolytica	200
Erwinia carotovora	100
Leishmania donovani	5.08
Mycobacterium tuberculosis	200[b]
Xanthomonas citri	3.1

[a]Minimum concentration that totally inhibits growth in a liquid medium at pH 8. Maximum concentration tested was 100 mg/mL, unless otherwise noted.

[b]Tested in a solid medium, which typically requires a concentration that is 4 to 10 times greater for the same level of inhibition.

Data from Kost'alova D, Kardosova A, Hajnicka V. Effect of *Mahonia aquifolium* stem bark crude extract and one of its polysaccharide components on production of IL-8. *Fitoterapia*. 2001;72(7):802–806. Wirth C, Wagner H. Vol. 2. Teaneck, NJ: World Scientific. He JM, Mu Q. The medicinal uses of the genus *Mahonia* in traditional Chinese medicine: an ethnopharmacological, phytochemical and pharmacological review. *J Ethnopharmacol*. 2013;175(2015):668–683.

Part of the ability of berberine to avoid developing bacterial resistance against it is that it works through multiple mechanisms of action. When an anti-infective agent, or any therapeutic agent, has a single mode of action, such as direct bactericidal activity, it is relatively easy for a pathogen, whose nature it is to survive and multiply, to quickly become resistant to the killing effects of the antibiotic. When an antimicrobial works through multiple actions, it is much more difficult for the pathogen to become resistant because it must find multiple ways to overcome the myriad of disparate killing effects of the agent.

In one study, researchers demonstrated berberine's ability to inhibit the adherence of group A *Streptococci* to host cells on the basis that the therapeutic effect of berberine appeared to be greater than its direct antibiotic effects.[25] Other studies showed that certain antimicrobial agents can block the adherence of microorganisms to host cells at doses much lower than those needed to kill cells or to inhibit cell growth. Berberine's ability to inhibit the adhesion of *Streptococci* to host cells has several modes of action. First, berberine causes *Streptococci* to lose lipoteichoic acid. Lipoteichoic acid is the major substance responsible for adhesion of bacteria to host tissues. If the bacteria cannot adhere, it cannot become infectious. Berberine also exhibited direct bactericidal activity against *Streptococci agalactiae,* a human pathogen that can cause meningitis, septicemia, and pneumonia. Another important action of berberine is preventing the adhesion of fibronectin to the *Streptococci,* as well as eluting already-bound fibronectin. The binding of fibronectin to *Streptococci* increases the virulence of the bacteria. In contrast, inhibition of fibronectin binding has clinical relevance in both treating and preventing select infectious diseases.[26,27]

A unique mechanism associated with berberine's antimicrobial activity is its ability to damage the DNA of bacteria.[21] Numerous other studies elucidate other mechanisms of action that contribute to berberine's antimicrobial activity, which include the inhibition of bacterial DNA duplication, bacterial RNA transcription, and bacterial protein synthesis; the inhibition of enzymes needed for bacterial proliferation; and the destruction of the bacterial biofilm and cell surface that make bacteria more susceptible to destruction by immune cells.[23] This multitude of actions makes berberine the ideal antibiotic for modern use, especially in MRSA. Moreover, berberine has been shown to restore the efficacy of previously resistant antibiotics, such as penicillin, ampicillin, and oxacillin.[28] The antimicrobial activity of berberine was also found to increase with pH in a number of organisms studied.[13] At a pH of 8, the antimicrobial activity of berberine in vitro is typically two to four times greater than it is at pH 7, which in turn is one to four times greater than at pH 6. This suggests that alkalinization will improve the clinical efficacy of berberine, particularly in the treatment of urinary tract infections.

Berberine also exhibits significant antifungal activity against *Candida albicans,* the overgrowth of which can result in both systemic and vaginal yeast infections. Excessive use of conventional antibiotics is a very common contributing factor to yeast overgrowth. The fact that berberine both acts as an antibiotic and kills *Candida,* again, makes it an ideal antibiotic of choice. Other fungi against which berberine exhibits antimicrobial activity include *Aspergillus, Cryptococcus,* and *Penicillium.*[21]

In addition to the direct actions of berberine, other studies show that other compounds in berberine-containing plants also contribute to overall antimicrobial activity because crude extracts often display greater antimicrobial activity than a comparable amount of isolated berberine.[29,30] In contrast to the previous report of berberine being resistant to bacterial resistance, one study showed *E. coli* to become resistant to pure berberine; however, no resistance was developed for the methanolic extract, demonstrating the synergism that exists in whole-plant extracts.[31] This underscores the strongly held belief of

medical herbalists that the activity of a botanical cannot be defined by a single compound.

A unique contribution of berberine to human health is its ability to promote healthy intestinal microflora. Most anti-infectious agents, such as conventional antibiotics, have a negative effect on gut flora and therefore digestion, assimilation, and gut-mediated immunity. Berberine promotes the growth of the *Akkermansia muciniphila, Bacteroides,* and *Ruminococcus* bacterial species normally found in healthy intestinal flora. Together, these mechanisms help reduce intestinal permeability,[32–34] which can reduce exposure to endotoxins that can trigger inflammatory responses, damage the liver and kidneys,[35] and contribute to the development of atherosclerosis.[36] In part, this broad spectrum of positive effects on gut health may be the primary underlying reason berberine-containing plants have been so highly regarded as traditional medicines for so long.

In addition to the effects already mentioned, berberine may have a positive effect on reducing the severity or incidence of colitis via an anti-inflammatory activity through modulation of interferon, interleukins, and prostaglandins in the gut and systemically. This was demonstrated in colitis induced in an animal model in which berberine improved body weight, reduced colon shortening, prevented colon damage, and reduced histological markers of inflammation.[37]

Immunostimulatory Activity and Anticancer Effects

There is an abundance of preclinical evidence for the effects of berberine in modulating immune responses and eliciting anticancer activity that suppresses the growth of a wide spectrum of tumors, including leukemia, melanoma, hepatoma, epidermoid carcinoma, glioblastoma, and oral carcinoma, as well as breast, lung, gastric, prostate, and cervical cancer. Berberine was also found to suppress chemical-induced carcinogenesis, tumor promotion, and tumor invasion in some animal models.[38]

In one study, berberine was shown to increase the blood supply to the spleen.[39] This improved blood supply may promote the optimal activity of the spleen by increasing the release of compounds, such as tuftsin, that potentiate immune function. Research shows that berberine influences splenic antibody response.[40] Berberine was also shown to activate macrophages, via both enhanced priming and triggering.[41] Other research demonstrated that total extract of barberry and its alkaloid fractions (berberine and oxyacanthine) elicits anti-inflammatory activity in both acute and chronic animal models of inflammation (Fig. 86.5). As in other studies reported, the total extract elicited a stronger anti-inflammatory response than the isolated fractions.[42] One study suggested the anti-inflammatory activity of berberine to be associated with a modulation, not an inhibition, of cyclooxygenase (COX) protein.[43]

Berberine exhibits potent anticancer activity both directly by killing tumor cells and indirectly by stimulating white blood cells.[39,41,44,45] Whereas most other actions attributed to berberine-containing plants are well established in the historical literature, anticancer effects seem to be a relatively modern discovery. Most anticancer data for berberine comes from in vitro and animal studies. One of the most significant effects was reported in a study demonstrating antitumor activity against human and rat malignant brain tumors.[44] Several experimental approaches were used in the study. In vitro studies were performed on a series of six human malignant brain tumor cell lines and rat 9L brain tumor cells. Berberine used alone at a dose of 150 mg/mL showed an average cancer cell kill of 91%. This kill rate was more than twice that of 1,3-*bis*(2-chloro-ethyl)-1-nitrosourea (BCNU), the standard chemotherapeutic agent for brain tumors, which had a cell kill rate of 43%. In vitro results do not always match the clinically relevant effects in vivo, so such reports have to be interpreted carefully. However, in this case, follow-up studies in rats with solid 9L brain tumors also demonstrated that berberine had antitumor effects. Rats treated with berberine (10 mg/kg) had an 81% cell kill. However, the combination treatment of berberine and BCNU exhibited additive effects on killing cancer cells. These results indicate that berberine may prove to be more effective than BCNU or, at the least, a valuable therapeutic addition in the treatment of difficult brain cancers.

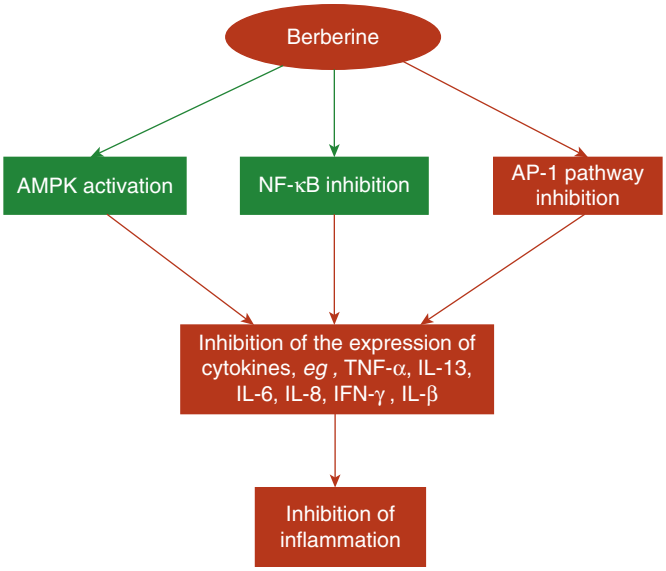

Fig. 86.5 Summary of the anti-inflammatory effect of berberine. (From Zou K, Li Z, Zhang Y, Zhang HY, Li B, Zhu WL, Shi JY, Jia Q, Li YM. Advances in the study of berberine and its derivatives: a focus on anti-inflammatory and anti-tumor effects in the digestive system. *Acta Pharmacologica Sinica.* 2017;38(2):157–167. PubMed PMID: 27917872.)

Another study demonstrated that berberine exhibited cytotoxic activity against nasopharyngeal carcinoma cells and inhibited the repair of cancer cell DNA that subsequently resulted in the death of cancer cells.[46] Berberine has also been shown to be cytotoxic against prostate cancer cells and to inhibit their proliferation in vitro, mediated primarily through the G1 phase-cycle arrest and caspase-dependent pathway.[47] Berberine has been shown to possess cytotoxic activity against numerous other cancer cell lines in vitro.[48] Whether this has any clinical relevance requires further in vivo research. In one such study, berberine combined with radiation demonstrated a synergistic anticancer effect in a lung cancer animal model.[49] The ability for berberine to increase the anticancer activity of numerous chemotherapeutic drugs has similarly been determined in animal models. Of particular interest is that berberine not only enhanced the anticancer effects of numerous chemotherapeutic agents but also decreased cardiac, renal, and hepatic toxicity associated with the chemotherapy.[38] Berberine exhibits antioxidant and antimutagenic effects that may have relevance in carcinogenesis.[50,51] If the in vitro and preclinical in vivo effects of berberine enhancing the efficacy of conventional chemotherapeutic drugs is realized in human trials, berberine will represent a novel adjunct to standard cancer therapy.

Antipyretic Activity

Historically, berberine-containing plants were used as febrifuges. Berberine produces an antipyretic effect three times as potent as aspirin in a pyretic model in rats.[52] However, although aspirin suppresses fever through its action on prostaglandins, berberine appears to lower

fever by increasing the immune system's handling of fever-producing compounds from microorganisms.

Type 2 Diabetes and Metabolic Syndrome

In another novel use, berberine possesses a wide range of antidiabetic effects, including an ability to increase insulin-receptor expression and improve glucose utility both in in vitro and in animal models, reduce insulin resistance through protein kinase C–dependent upregulation of insulin receptor expression, stimulate insulin secretion, block glucose absorption via inhibition of α-glucosidase and epithelial glucose transport, and reduce serum lipid levels in animal models of impaired glucose tolerance.[53–55] One insulin-independent hypoglycemic activity is associated with the stimulation of glycolysis and activation of AMP-activated protein kinase, representing a relatively novel herbal approach to the management of diabetes.[56]

In addition to the myriad of hypoglycemic activity elicited by berberine, the formation of advanced glycosylation end products and oxidative stress that leads to diabetic nephropathy is suppressed by the administration of berberine.[57]

Cardiovascular Effects

In more recent years there has been active research investigating the cardiac effects associated with berberine, most notably derived from *Coptis chinensis.* In animal models of cardiac hypertrophy and heart failure, berberine decreased plasma noradrenaline and adrenaline in the heart, increasing cardiac contractility and decreasing diastolic blood pressure and vascular resistance.[58]

CLINICAL APPLICATIONS

The broad antimicrobial effects of berberine, combined with the anti-infective and immune-stimulating actions reported previously, support the historical use of berberine-containing plants in infections of the mucous membranes as well as the gastrointestinal system. Although the primary focus of this activity is typically correlated with antimicrobial effects, berberine also has a protective effect on the epithelial cells of the gastrointestinal tissues, supporting one of most unique aspects of berberine-containing plants, decreasing intestinal permeability, which has significantly positive and broad-reaching effects on improving human health.[59,60] Lastly, clinical research on the use of berberine in the treatment of type 2 diabetes, dyslipidemia, and metabolic syndrome is extremely promising.[61]

Infectious Diarrhea and Bowel Health

Berberine showed significant success in the treatment of acute diarrhea in several clinical studies. It was found to be effective against diarrheas caused by *E. coli* (traveler's diarrhea), *Shigella dysenteriae* (shigellosis), *Salmonella paratyphi, Salmonella typhimurium* (food poisoning, infectious diarrhea), *Klebsiella species, G. lamblia* (giardiasis), and *V. cholerae* (cholera).[62–71]At least one clinical study demonstrated that patients with irritable bowel syndrome (IBS) taking berberine had better symptom control compared with placebo.[59]

Similar positive findings of the effects of berberine on supporting healthy gastrointestinal functioning are reported in preclinical research. Studies in hamsters and rats showed that berberine had significant activity against *Entamoeba histolytica,* the causative organism of amebiasis.[15,16] In another study of animals with hemorrhagic diarrhea, berberine successfully inhibited multidrug-resistant enterovirulent *E. coli.*[72]

There is good evidence that berberine is effective in treating the majority of common gastrointestinal infections, as evidenced by the widespread antimicrobial activity against major gastrointestinal pathogens such as *H. pylori, Salmonella typhi, G. lamblia, Entamoeba histolytica,* and *C. albicans.* In many cases, clinical studies demonstrate that berberine produces comparable effects to standard antibiotics. In several studies, the efficacy of berberine was found to be greater than that of conventional therapies.[64,67,68] For example, in a study of 65 children younger than 5 years of age with acute diarrhea caused by *E. coli, Shigella, Salmonella, Klebsiella,* or *Fecalis aerogenes,* those given berberine tannate (25 mg/6 hours) responded better than those treated with standard antibiotic therapy.[67]

In another study, 40 children ages 1 to 10 years and infected with the parasite *Giardia* received either berberine (5 mg/kg body weight each day), the drug metronidazole (10 mg/kg body weight each day), or a placebo of vitamin B syrup in three divided doses.[68] After 6 days, 48% of patients treated with berberine were symptom-free, and on stool analysis, 68% were *Giardia*-free. In the metronidazole (Flagyl) group, 33% of patients were without symptoms, and on stool analysis, all were *Giardia*-free. In comparison, 15% of patients on placebo were asymptomatic, and on stool analysis, 25% were *Giardia*-free. These results indicate that berberine was actually more effective than metronidazole in relieving symptoms at half the dose but less effective than the drug in clearing the organism from the intestines.

Finally, in a study of 200 adult patients with acute diarrhea, the subjects were given standard antibiotic treatment with or without berberine hydrochloride (150 mg/day). The patients receiving berberine recovered quicker.[64] An additional 30 cases of acute diarrhea were treated with berberine alone. Berberine arrested diarrhea in all of these cases, with no mortality or toxicity.

Despite these results, because of the serious consequences of an ineffectively treated infectious diarrhea due to highly pathogenic organisms, it is best to consider using berberine or berberine-containing plants as an adjunct to standard antibiotic therapy.

Much of berberine's effectiveness is undoubtedly due to a combination of its direct antimicrobial activity, inhibition of microbial attachment to mucous membranes, and blocking of the action of toxins produced by several pathogenic bacteria.[72–74] The toxin-blocking effect is most evident in diarrheas caused by enterotoxins (e.g., *V. cholerae, E. coli*), cholera, and traveler's diarrhea.[69–73]

Although cholera is a serious disorder that needs standard antibiotic therapy, traveler's diarrhea is usually self-limiting. Good results with berberine in the treatment of traveler's diarrhea have been obtained. In one study, patients with traveler's diarrhea randomly received 400 mg of berberine sulfate in a single dose or served as controls.[72] In treated patients, the mean stool volumes were significantly less than those of controls during three consecutive 8-hour periods after treatment. At 24 hours after treatment, diarrhea ceased in significantly more treated patients compared with controls (42% vs. 20%).

For people planning to travel to an underdeveloped country or an area of poor water quality or sanitation, the prophylactic use of berberine-containing herbs 1 week before, during, and 1 week after visiting may be useful.

Trachoma

Water extracts of berberine-containing plants have been employed to treat various eye complaints, including infectious processes, by cultures throughout the world. In older studies, berberine demonstrated a remarkable effect in the treatment of trachoma in patients with active lesions. Patients were treated with either 0.2% aqueous berberine chloride ophthalmic solution (two drops per eye, three times daily for 8 weeks), 20% sulfacetamide ophthalmic solution, or both. Although the 20% sulfacetamide solution relieved clinical symptoms completely, it did not eradicate the pathogen, *Chlamydia trachomatis.* By the end of treatment in the berberine group, patients were symptom-free and

tested negative for *C. trachomatis.* In 5 of 17 patients in the sulfacetamide treatment group, symptoms recurred 4 to 6 months after treatment. None of the berberine-treated trachoma patients suffered from recurrence up to 1 year after treatment. The combination of berberine and sulfacetamide ophthalmic solutions provided only slightly better improvement than did berberine alone; this group was bacteria-free after treatment, with no recurrent infections.[75,76] Trachoma is a major cause of blindness and impaired vision in underdeveloped countries, affecting approximately 500 million people worldwide, and results in blindness in 2 million of those affected. The drug sulfacetamide is currently the most widely used antitrachoma drug. In the aforementioned study, although sulfacetamide showed the best improvement (decrease in conjunctival discharge, edema, and papillary reactions), the conjunctival scrapings of all patients receiving sulfacetamide remained positive for *C. trachomatis,* showing the conventional treatment was primarily symptomatic. These patients had a high rate of recurrence of symptoms. In contrast, patients treated with the berberine solution showed mild ocular symptoms, which disappeared more gradually, but their conjunctival scrapings were always negative for *C. trachomatis.* These patients did not have relapse even 1 year after treatment, which suggests that berberine is curative for trachoma.[75,76]

Berberine's efficacy is believed to be due to stimulation of some host defense mechanism, rather than only a direct cytotoxic action on the organism. Because the berberine concentration used in these studies was 100 times less than the concentration of sulfacetamide, and berberine is much cheaper, it may be more cost-effective than other treatments for trachoma. This suggests that berberine (0.2% solution) is an appropriate therapy for many types of conjunctivitis.

Berberine in Liver Health

Cholecystitis and Cirrhosis of the Liver

Several clinical studies demonstrate that berberine stimulates the secretion of bile (choleretic effect) and bilirubin.[77–79] This is significant because bile production and secretion are the primary physiological mechanisms by which chemical waste products, hormones, and fat and cholesterol are removed from the body. Without this detoxification mechanism, precancerous hormones recirculate, and fats as cholesterol saturate the cardiovascular system. Bitter substances, and specifically berberine-containing plants, are among the oldest traditional herbal detoxification therapies used worldwide. There are also many health benefits of bilirubin, including antioxidant activity.[80]

In one clinical study of 225 patients, oral berberine at doses of 5 to 20 mg three times a day before meals for 24 to 48 hours resolved symptoms of chronic cholecystitis (gallbladder inflammation), decreased the bilirubin level, and increased the bile volume of the gallbladder.[77–79]

Berberine was shown to have a beneficial effect on liver cirrhosis. Cirrhosis results in an elevation of the amino acid tyramine, a sign of liver damage. Berberine both reduced tyramine in cirrhosis and prevented the elevation of serum tyramine after oral tyrosine load by inhibiting the enzyme tyrosine decarboxylase found in bacteria in the large intestine.[78] Excessive tyramine levels are also believed to be responsible for some of the cardiovascular and neurological complications of liver disease, such as hepatic encephalopathy. The accumulation of tyramine and its derivatives may cause lowering of peripheral resistance, with resultant high cardiac output, reduction in renal function, and cerebral dysfunction. This tyramine-lowering effect of berberine may have significance in other conditions as well.

Liver-Protective Effects of Berberine

Berberine has marked protective effects against chemical-induced liver damage, most notably against acetaminophen (Tylenol)-induced hepatotoxicity, whose excessive use remains one of the primary causes of liver failure worldwide. In the United States, acetaminophen is responsible for more than 50% of drug-induced liver injury (DILI) and more than 20% of liver transplants and has been for almost 40 years.[81] Berberine significantly ameliorates acetaminophen-induced elevations in liver enzymes, another sign of liver damage, and increases concentrations of endogenous antioxidants (e.g., glutathione), which protect against liver damage.[82] In one study, a high dose (100 mg/kg per day for 10 days) was protective against liver damage caused by methotrexate, a drug used in serious forms of psoriasis and rheumatoid arthritis.[83]

Cancer

Berberine and its derivatives have high activity against cancer and inflammation (Fig. 86.6). Berberine and another alkaloid found in berberine-containing plants, berbamine, were shown to exert beneficial effects as adjuncts in cancer therapy. Berbamine has been used in China since 1972 in the treatment of depressed white blood cell (WBC) counts resulting from chemotherapy and radiation. In one study, 405 patients with WBC counts less than 4000 were given 150 mg/day of berbamine (50 mg orally three times daily) for 1 to 4 weeks. Berbamine was viewed as "significantly effective" if WBC count increased to greater than 4000 after 1 week or increased to greater than 1000 after 2 weeks; "effective" if WBC count increased to greater than 4000 after 2 weeks or increased greater than 1000 after 4 weeks; and "ineffective" if there was no change in WBC count after 4 weeks of treatment. The overall results for the 405 patients were as follows:

- Significantly effective in 163 cases (40.2%)
- Effective in 125 cases (38.8%)
- Ineffective in 117 cases (29%)

The total effective rate was 71%. However, the WBC count before therapy was related to overall effectiveness. The effective rate was only 54.8% in 31 cases in which the WBC count was less than 1000 and 82.7% in cases in which the WBC count was between 3100 and 3800.[84]

Heart Disease

Several human investigations provide evidence for the benefit of berberine in heart disease. In one double-blind study, 156 patients with chronic congestive heart failure (CHF) and more than 90 ventricular premature complexes (VPCs) or nonsustained ventricular tachycardia, or both, on 24-hour Holter monitoring were randomly divided into two groups. All patients were given conventional therapy for CHF, consisting of angiotensin-converting enzyme inhibitors, digoxin, diuretics, and nitrates, along with 1.2 to 2 g of berberine per day or a placebo. Symptoms, a 6-minute walk test, left ventricular ejection fraction (LVEF), frequency and complexity of VPCs, and quality of life were assessed after 8 weeks of treatment and during a mean 24-month follow-up. The addition of berberine resulted in a significantly greater increase in LVEF and exercise capacity, improvement of the dyspnea-fatigue index, and a decrease of frequency and complexity of VPCs compared with the control group. There was also a significant decrease in mortality in the berberine-treated patients during long-term follow-up (7 patients receiving treatment died vs. 13 on placebo). There were no apparent side effects in the berberine group. Researchers concluded that berberine improved quality of life and decreased VPCs and mortality in patients with CHF.[85]

Similar findings were reported in another group of patients with refractory CHF in older studies. In this investigation, intravenous administration of berberine (0.2 mg per minute for 30 minutes) significantly decreased systemic and pulmonary vascular resistance, decreased blood pressure, and increased the cardiac and stroke index, both measures of increased cardiac competency and overall cardiac performance.[86]

A number of studies conducted between 2004 and 2008 establish beneficial antilipidemic effects associated with 500 mg berberine one

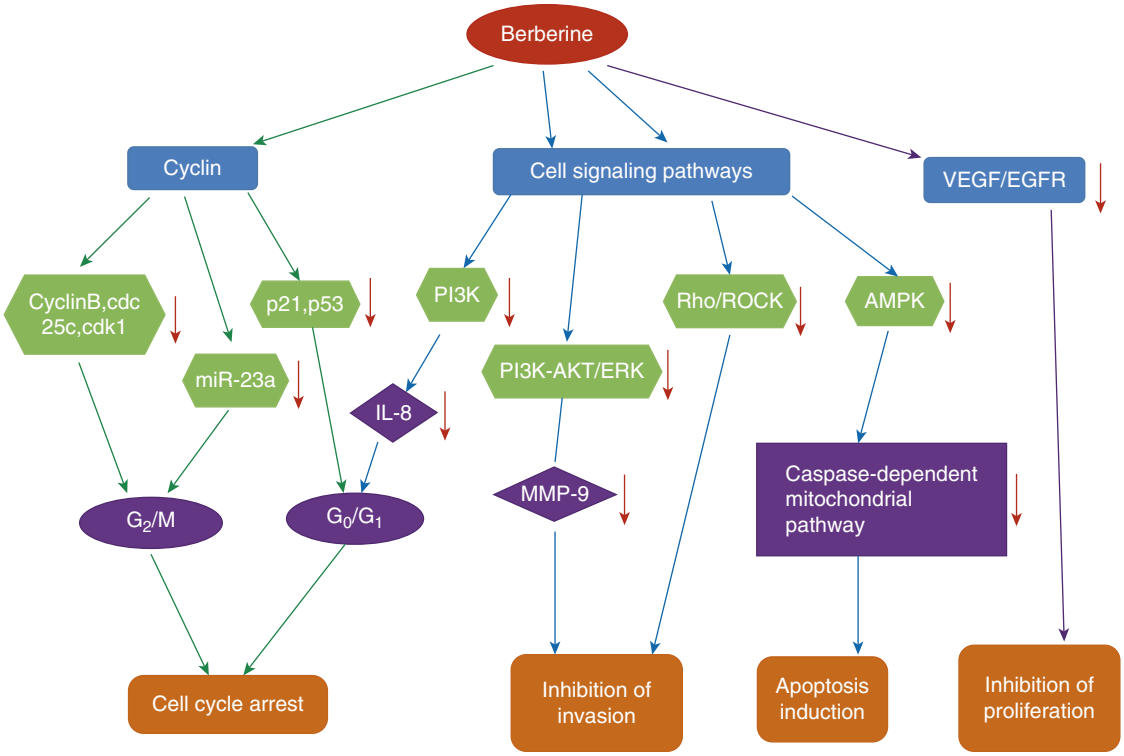

Fig. 86.6 Summary of the antitumor effect of berberine. "→" stands for inhibition or down-regulation. (From Zou K, Li Z, Zhang Y, Zhang HY, Li B, Zhu WL, Shi JY, Jia Q, Li YM. Advances in the study of berberine and its derivatives: a focus on anti-inflammatory and anti-tumor effects in the digestive system. *Acta Pharmacologica Sinica*. 2017;38(2):157–167. PubMed PMID: 27917872.)

to three times daily in patients with mild to moderate hyperlipidemia, including high cholesterol levels resistant to treatment with statin drugs. Most studies were 4 to 24 weeks in duration and resulted in reductions in low-density lipoprotein-cholesterol (LDL-C) levels of 20% to 32%, with positive results experienced within 4 weeks and greater results occurring with the longest duration of treatment.[87]

Type 2 Diabetes and Metabolic Syndrome

Human clinical studies validate the antidiabetic effects noted in in vitro and in vivo models showing that berberine (500 mg three times a day) significantly lowered fasting blood glucose, hemoglobin A_{1C} (HbA_{1c}), triglycerides, and insulin levels in patients with type 2 diabetes mellitus.[88–90] The efficacy of berberine in lowering the fasting blood glucose and HbA_{1c} was similar to that of metformin and rosiglitazone. For example, in one study, berberine reduced HbA_{1c} from 9.5% to 7.5%, fasting blood glucose from 10.6 to 6.95 mmol/L, postprandial blood glucose from 19.8 to 11.1 ± 0.9 mmol/L, and plasma triglycerides from 1.13 to 0.89 mmol/L.[91] In another study, berberine at a dosage of 1.0 g/day for 3 months decreased fasting blood glucose from 7.0 to 5.6 mmol/L, HbA_{1c} from 7.5% to 6.6%, triglycerides from 2.51 to 1.61 mg/dL, total cholesterol from 5.31 to 4.35 mg/dL, and LDL-C from 3.23 to 2.55 mg/dL.[90]

A meta-analysis of 27 human clinical trials of the effects of berberine on a variety of metrics in patients with diabetes similarly supported the potential benefits of berberine in diabetes. Berberine lowered fasting blood sugar levels, postprandial plasma glucose, glycosylated hemoglobin, hyperlipidemia, blood pressure, and total high-density lipoprotein cholesterol (HDL-C) and triglycerides and increased LDL-C. Berberine had a greater effect in lowering both fasting and postprandial blood sugar levels and glycosylated hemoglobin than lifestyle modification or placebo. In this study, berberine was equally as effective as oral hypoglycemic agents. No serious side effects were reported in these studies.[92] As for the treatment of hyperlipidemia, berberine with lifestyle intervention was better than lifestyle intervention alone, and berberine with oral lipid-lowering drugs was better than lipid-lowering drugs alone, in reducing the level of total cholesterol (TC) and LDL-C and raising the level of HDL-C. In the comparative study between berberine and/or lipid-lowering drugs, there was no statistical significance in reducing the level of TC and LDL-C, but berberine showed better effect in lowering the level of triglycerides and raising the level of HDL-C. In the treatment of hypertension, berberine with lifestyle intervention tended to lower the level of blood pressure more than the lifestyle intervention or placebo alone.[92]

Consistent with the in vitro and in vivo models, berberine-treated patients experienced a statistically significant increase in the percentages of peripheral blood lymphocytes that express insulin receptor expression.[88] In patients with chronic viral hepatitis (B and C), liver function was improved greatly through the reduction of liver enzymes. Additional mechanisms of value to patients with type 2 diabetes include the ability to inhibit aldose reductase, lower blood lipids levels (including the ability to reduce free fatty acid levels), and protect and improve endothelial function.[93] In a lipid-lowering trial in 32 hypercholesterolemic patients for 3 months, berberine (500 mg three times daily) reduced serum cholesterol by 29%, triglycerides by 35%, and LDL-C by 25%.[91] Berberine lowers LDL-C by upregulating hepatic LDL-C receptor expression through a mechanism of mRNA stabilization.[94] In recent years, considerable investigation of the potential use of berberine in treating metabolic syndrome has been conducted. Numerous studies demonstrate improvement in metabolic syndrome in vivo. In one study of humans with newly diagnosed type 2 diabetes, 0.5 g of berberine was given three times daily at the beginning of each meal. A reduction in fasting and postprandial blood

glucose was observed. Other beneficial effects, such as a reduction in plasma triglycerides, TC, and LDL-C, were also reported.[56] In at least two other clinical studies, similar reductions in triglycerides (35% and 22%), serum cholesterol (29% and 16%), and LDL-C (25% and 20%) were observed.[91,95] A meta-analysis of clinical trials in patients with dyslipidemia, including three trials of patients with type 2 diabetes, demonstrated that berberine significantly reduced TC, LDL-C, and triglyceride levels and significantly increased HDL-C.[96] Another systematic review of subjects with dyslipidemia, including patients with diabetes, similarly reported improvements in a number of metrics. Specifically, in patients with diabetes, significant reductions in TC, LDL-C, and triglycerides were observed with 500 mg berberine twice daily for 3 months.[97]

Bioavailability

Modern researchers tend to lack confidence in the ability of berberine to elicit any therapeutic effect because of early pharmacokinetic evidence that suggested it is poorly absorbed. For example, in an early study, it was found that only 0.043% of a 100-mg oral dose of berberine was recoverable from the urine of normal volunteers after 24 hours.[98] This is partly due to poor permeation of berberine through healthy intestinal tissues. Interestingly, intestinal permeability increases when tissues are inflamed, allowing for greater berberine absorption across diseased tissues. More recent data demonstrate that berberine and its four primary metabolites—berberrubine, thalifendine, demethyleneberberine, and jatrorrhizine—are detected in the liver 30 minutes after oral administration of berberine, and in bile they are detected 1 hour after oral administration.[99] Additionally, the absorption of berberine when consumed in berberine-containing plants or as whole-plant decoctions is 39% to 43% greater than when isolated berberine is consumed,[100] and it also increases with continued use.[101]

Although detailed pharmacokinetic data are lacking, berberine-containing plants have been used for many millennia for many of the indications for which berberine has been shown to be effective. The available clinical and preclinical evidence provides a strong basis for efficacy. Also, these plants have predominantly been used for a variety of antimicrobial activities that, in many cases, do not require systemic absorption for efficacy, instead eliciting an effect in tissues with which berberine comes in contact, such as in the gastrointestinal system.

Dosage

Because no detailed clinical studies have differentiated which berberine-containing herb to use for specific conditions, the following is offered as a guideline based on experimental studies and historical use. In general, the plants can be viewed as interchangeable.

H. canadensis

- Infective, congestive, and inflammatory states of the mucous membranes
- Digestive disorders
- Gastritis
- Peptic ulcers
- Colitis
- Anorexia
- Painful menstruation

Berberis vulgaris

- The treatment of gallbladder disease, including gallstones, and as a less expensive form of berberine in the treatment of the conditions listed earlier for goldenseal.

Berberis aquifolium

- Best used in the treatment of chronic skin diseases and in the conditions listed earlier for goldenseal.

Coptis chinensis

Can be used in the treatment of infective, congestive, and inflammatory states of the mucous membranes, fever, and infectious disorders of the skin

Dosages three times a day are as follows:

- Dried root or infusion (tea): 2 to 4 g
- Tincture (1:5): 6 to 12 mL (1.5–3 tsp)
- Fluid extract (1:1): 2 to 4 mL (0.5–1 tsp)
- Solid (powdered dry) extract (4:1 or 8%–12% alkaloid content): 250 to 500 mg
- Berberine sulfate: see dosage levels used in clinical studies referenced previously (e.g., in type 2 diabetes: 500 mg two to three times a day).

Quality Considerations

The quality of berberine-containing plants, most notably goldenseal, can vary widely. For example, goldenseal is very costly, which leads to widespread adulteration of the botanical in the herbal products industry. Although such adulterations are against the law, they nevertheless occur as extract manufacturers add lower-cost berberine-containing plants to increase the profitability of diluted goldenseal. Generally speaking, the dosage of these plants should be minimally based on berberine content, which is correlated with the intense bitterness of the plants. Because there is a wide range of quality in goldenseal preparations, standardized extracts are generally recommended. In one study of 20 products purchased at local pharmacies or health food stores, 17 were labeled as containing goldenseal root, and three contained goldenseal herb as the sole active herbal ingredient.[102] The berberine concentration varied from 0.82% to 5.86%, whereas the hydrastine concentration ranged from 0% to 2.93%. Only 10 of 17 products met the proposed U.S. Pharmacopeia standards for the hydrastine and berberine content of goldenseal root. Five products contained little or no hydrastine, unusual berberine-to-hydrastine ratios, and additional peaks not observed with other products. Luckily, the majority of adulterating species do not present a health hazard and have similar activity, but conversely, they may not yield optimal amounts of berberine.

ADVERSE EFFECTS AND TOXICITY

Berberine and berberine-containing plants are generally nontoxic at the recommended dosages. In the aforementioned meta-analysis of 27 human clinical trials of the effects of berberine in patients with diabetes, no noticeable adverse effects were reported.[92] However, berberine-containing plants are not recommended for use during pregnancy, and higher dosages may interfere with B vitamin metabolism. The oral median lethal dose in rats for berberine is greater than 1000 mg/kg body weight, indicating that the toxicity is extremely low.[103]

DRUG INTERACTIONS

Both positive and negative interactions between berberine and conventional medications can occur. Berberine may interfere with the absorption of tetracycline and related antibiotics. In one double-blind study, giving subjects 100 mg of berberine at the same time as 500 mg of tetracycline four times daily led to a reduction in the efficacy of tetracycline in subjects

with cholera.[68] However, another double-blind study showed no such interaction.[69] Nonetheless, simultaneous use of berberine and antibiotics should only be done with great care to ensure efficacy and safety.

Berberine produces significant inhibition of CYP3A enzymes in humans.[94,104] Because these enzymes metabolize most drugs, berberine may decrease the clearance of many medications, thereby increasing the amount that remains in the bloodstream and altering efficacy and safety. CYP3A is involved in the metabolism of approximately half the drugs that are used today, including acetaminophen, codeine, cyclosporine, diazepam, and erythromycin. Sometimes this inhibitory effect of berberine on CYP3A may be useful for improving a therapeutic benefit. For example, the combined use of cyclosporine with berberine markedly increased the blood concentration of cyclosporine in heart transplantation recipients, reduced the dosage of cyclosporine required, and showed no obvious adverse reaction.[105] There are a number of other potential positive herb–drug interactions associated with berberine. Berberine increases the effectiveness of statin drugs to lower cholesterol; in one study, the effect of a simvastatin and berberine combination was 30% greater than simvastatin alone.[106]

Berberine-containing plants may enhance the effects of oral hypoglycemic drugs through its multitude of antidiabetic effects. Patients on oral hypoglycemic drugs should take extra care in monitoring blood glucose levels if taking berberine-containing plants. Adjustment of the dose of conventional hypoglycemic agents may be required to maintain healthy blood sugar levels.

As noted, positive interactions between a number of chemotherapeutic drugs are recorded in the literature. Specifically, berberine decreased the toxicity of 5-fluorouracil, arsenic trioxide, nitrogen mustard, camptothecin, cetuximab, erlotinib, lapatinib, gefitinib, cisplatin, doxorubicin, paclitaxel, and tamoxifen and additionally increased the efficacy of radiation therapy.[38] Although not established in human clinical trials, the potential for such a positive interaction in the absence of demonstrable toxicity warrants clinical investigation.

5-Hydroxytryptophan

Michael T. Murray, ND

OUTLINE

INTRODUCTION

5-Hydroxytryptophan (5-HTP) is the intermediate between tryptophan and serotonin (Fig. 87.1).[1] Although the use of 5-HTP may be relatively new to most clinicians, it has been available through pharmacies for several years and has been intensely researched for the past three decades. It has been used clinically since the 1970s.

TRYPTOPHAN AND 5-HYDROXYTRYPTOPHAN METABOLISM

Once tryptophan is absorbed from the intestines, it is carried by the blood to the liver, along with other amino acids consumed during the meal. Ingested tryptophan can pass into the general circulation, metabolize into blood proteins, or convert to kynurenine (which then goes on to form nicotinic acid, picolinate, and other important metabolites) in the liver (Fig. 87.2). After conversion to kynurenine, it cannot be converted to serotonin. The same is likely true if the tryptophan is incorporated into blood proteins. Unchanged tryptophan can be converted to 5-HTP and then to serotonin. However, if this conversion occurs outside the brain, brain chemistry will not be influenced. Even under the best-case scenario, only 3% of a dosage of L-tryptophan in supplemental or dietary form is likely to be converted to serotonin in the brain.[2]

The manufacture of serotonin from tryptophan within the brain is highly dependent on the level of tryptophan or 5-HTP that crosses the blood–brain barrier. Although 5-HTP easily crosses the blood–brain barrier, the delivery of tryptophan into the brain depends on several factors. The first factor of importance is the level of free tryptophan in the blood. In a number of situations, the liver's conversion of tryptophan to kynurenine occurs at an elevated rate (i.e., stress, elevated cortisol levels, low B-vitamin status, and high doses of L-tryptophan [greater than 2000 mg]). These situations lead to increased activity of tryptophan oxidase and kynurenine formamidase, which convert tryptophan to kynurenine. Elevated levels of kynurenine block the entry of tryptophan into the brain and lower brain serotonin levels. Increasing tryptophan intake makes matters worse when tryptophan oxidase activity is increased.

Unlike 5-HTP, which easily enters the brain, the transport of tryptophan across the blood–brain barrier involves the binding of tryptophan to a transport molecule. Because tryptophan shares this transport vehicle with several other amino acids, when the ratio of tryptophan to these other amino acids is low, little tryptophan is transported into the brain. The protein in almost all foods contains relatively small amounts of tryptophan and larger proportions of other amino acids. This generally leads to low serotonin levels with a high-protein meal. The opposite occurs with a high-carbohydrate meal.

PHARMACOLOGY

Several pharmacokinetic studies showed that about 70% of a dose of 5-HTP taken orally is delivered to the bloodstream.[3,4] The remaining 30% is metabolized by intestinal cells.

Ample evidence from these pharmacokinetic studies, and clinical studies, indicates that once absorbed, 5-HTP is delivered to the brain, resulting in increased formation of not only serotonin but also other brain chemicals (e.g., the monoamines melatonin, endorphins, dopamine, and norepinephrine; Fig. 87.3). By raising brain serotonin levels, and through other effects, 5-HTP showed positive effects in the various conditions associated with low serotonin levels.

Besides raising serotonin and melatonin levels, 5-HTP was shown to raise β-endorphin levels. Many pain-relieving and mood-elevating

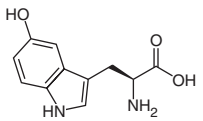

Fig. 87.1 Structure of 5-hydroxytryptophan.

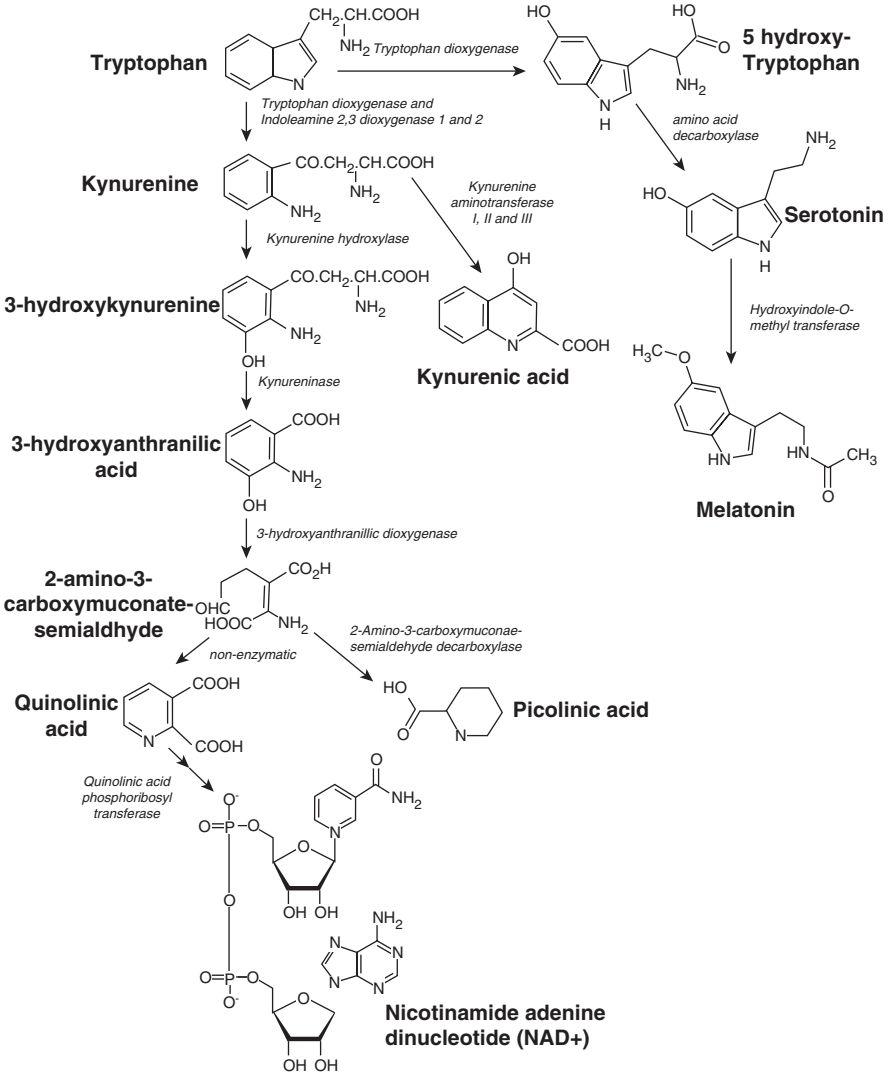

Fig. 87.2 Tryptophan metabolism pathways.

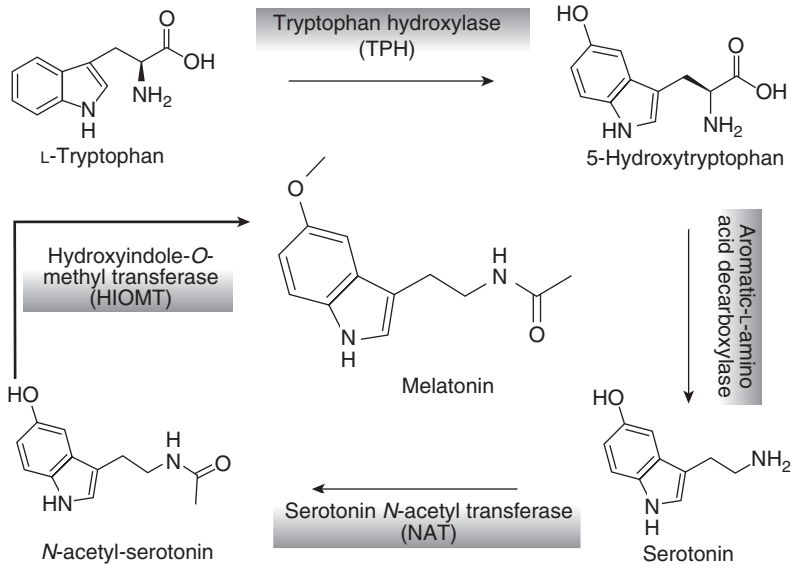

Fig. 87.3 Conversion of 5-hydroxytryptophan to serotonin and melatonin.

benefits of 5-HTP might be related more to its ability to enhance endorphin levels than to its ability to increase serotonin levels. This endorphin-increasing action is useful for both migraine and tension headaches, fibromyalgia, and other painful situations. In addition, raising endorphin levels produces significant effects on mood and behavior.

By raising serotonin, melatonin, and β-endorphin levels, 5-HTP has a significant effect on helping regulate and improve brain chemistry. 5-HTP was also shown to raise the levels of other important neurotransmitters, such as dopamine and norepinephrine.[5] The ability of 5-HTP to increase both serotonin (and other indolamines) and catecholamines is quite significant and unique to 5-HTP. It is an effect that 5-HTP does not share with L-tryptophan. The effective treatment of depression requires more than simply raising serotonin levels; catecholamine levels must also be increased; 5-HTP provides the brain with both sets of tools.

5-Hydroxytryptophan Versus l-Tryptophan

Nutrition-oriented physicians have long used precursor therapy for affecting brain chemistry. Unfortunately, L-tryptophan produced inconsistent results. These results were likely a result of its varying elevation of brain serotonin levels.

In a head-to-head comparison study of 5-HTP and L-tryptophan in the treatment of depression, 5-HTP proved superior.[6] The proposed reason is the fact that 5-HTP easily crosses the blood–brain barrier and is not affected by competing amino acids. 5-HTP affects brain chemistry in a broader and more positive fashion. L-Tryptophan is often effective in cases of low serotonin, especially insomnia, but 5-HTP is more broadly effective.

There are many advantages of 5-HTP over L-tryptophan. Chief among them is that 5-HTP easily crosses the blood–brain barrier and is one step further on the path to serotonin synthesis. The conversion of tryptophan to 5-HTP by tryptophan hydroxylase is the most important step in the manufacture of serotonin. This enzyme is inhibited by several factors, including the following:

- Stress
- Vitamin B_6 insufficiency
- Low magnesium levels
- Insensitivity to insulin
- Various hormones
- Genetic factors

In addition, as noted earlier, these same factors and others are known to increase the activity of tryptophan oxygenase, increasing the conversion of L-tryptophan to kynurenine.

Perhaps the biggest advantage of 5-HTP over L-tryptophan is that it is safer.[7] Although L-tryptophan is safe if properly prepared and free of the contaminants linked to eosinophilia myalgia syndrome (EMS), 5-HTP is inherently safer. The reasons are that taking L-tryptophan to produce positive effects in the treatment of depression, insomnia, and other low-serotonin conditions requires a relatively high dose (e.g., a minimum of 2000 mg in insomnia and 6000 mg in depression). At high doses such as these, L-tryptophan is potentially problematic because more L-tryptophan will be shunted toward the kynurenine pathway, and L-tryptophan promotes oxidative damage. Excessive levels of dietary tryptophan or high doses of L-tryptophan result in tryptophan actually acting as a free radical.[8] In contrast, 5-HTP is an antioxidant.[9] This antioxidant difference is a result of the additional molecule of oxygen and hydrogen in 5-HTP. This simple change in molecular structure allows the phenolic ring structure to effectively accept or quench the unpaired electron of a free radical.

BOX 87.1 Conditions Associated With Low Serotonin Levels

- Depression
- Anxiety
- Obsessive-compulsive disorder
- Obesity
- Carbohydrate craving
- Bulimia
- Insomnia
- Narcolepsy
- Sleep apnea
- Migraine headaches

CLINICAL APPLICATIONS

A massive amount of evidence suggests that low serotonin levels are a common consequence of modern living. The lifestyle and dietary practices of many people living in this stress-filled era result in lowered levels of serotonin within the brain. As a result, many people are overweight, crave sugar and other carbohydrates, experience bouts of depression, get frequent headaches, and have vague muscle aches and pains. All of these maladies are correctable by raising brain serotonin levels. The primary therapeutic applications for 5-HTP are low-serotonin states, as listed in Box 87.1.

Depression

Some of the first clinical studies on 5-HTP for the treatment of depression began in the early 1970s in Japan. The first study involved 107 patients with either unipolar depression or manic bipolar depression.[10] These patients received 5-HTP at dosages ranging from 50 to 300 mg/day. The researchers observed a quick response (within 2 weeks) in more than half of the patients. Seventy-four of the patients either experienced complete relief or significantly improved, and none experienced significant side effects. These promising results were repeated in several other Japanese studies. An interesting aspect in two of these studies was the fact that 5-HTP was shown to be effective in some patients (50% in one study, 35% in another) who had not responded positively to any other antidepressant agent.[11,12]

The most detailed of the Japanese studies was conducted in 1978.[13] The study enrolled 59 patients with depression (30 males and 29 females). The groups were mixed, in that both unipolar and bipolar depressions were included, along with a number of other subcategories of depression. The severity of the depression in most cases was moderate to severe. Patients received 5-HTP in dosages of 50 or 100 mg three times a day for at least 3 weeks.

The antidepressant activity and clinical effectiveness of 5-HTP were determined using a rating scale developed by the Clinical Psychopharmacology Research Group in Japan. The improvements among the various patients are detailed in Table 87.1. These results indicated that 5-HTP was helpful in 14 of 17 patients with unipolar depression and 12 of 21 patients with bipolar depression. The degree of improvement in most cases ranged from excellent to very good.

TABLE 87.1 Improvement in Various Subtypes of Depression

Subtype	IMPROVEMENT[a] 1	2	3	4	5, 6, 7	8	1 + 2 + 3/total[b]

Slight	0	2	2	2	1	1
Total	1	6	17	8	7	1

The results achieved in this open study were quite good, given how rapidly they were achieved. Thirty-two of the 40 patients who responded to 5-HTP did so within the first 2 weeks of therapy. Typically, in most studies with antidepressant drugs, the benefits are not apparent until after 2 weeks to 1 month of use. For this reason, the length of study when assessing antidepressant drugs should be at least 6 weeks because it may take that long to significantly affect brain chemistry in a positive manner. In contrast, many of the studies with 5-HTP were shorter than 6 weeks because statistically significant results were achieved so soon (Table 87.2). However, the longer 5-HTP is used, the better the results. Some people may need to be on 5-HTP for at least 2 months before they experience benefits.

The only major side effect noted in this study was mild nausea. The occurrence of nausea caused by 5-HTP is actually less frequent than that experienced with other antidepressant drugs (roughly 10% of subjects taking 5-HTP at a daily dose of more than 300 mg experience nausea compared with about 23% taking Prozac) and about the same as that which occurs with a placebo. In double-blind studies, about 10% or so of people taking the placebo typically complain of nausea. Nonetheless, mild nausea may be a natural consequence of elevated serotonin levels with 5-HTP. About 30% of the 5-HTP taken orally is converted to serotonin in the intestinal tract. This can lead to a mild case of nausea. Fortunately, this effect wears off after a few weeks of use.

A 5-HTP dosage of 150 to 300 mg/day is sufficient in most cases. For example, in one study, it was shown that 13 of 18 subjects with depression given 5-HTP at a level of 150 or 300 mg/day experienced good to excellent results.[14] This percentage of responders is quite good, but if the level of serotonin in the blood is viewed as a rough indicator of brain serotonin levels, some interesting conclusions can be made (Table 87.3). In some cases, a higher dosage may be necessary.

TABLE 87.3 Level of Serotonin in Blood (nanograms per milliliter): Controls, Responders, and Nonresponders

Beginning of the study	26	25	23
End of the study (30 days)	9	15	19

The measurements in Table 87.3 suggest that serotonin levels in depressed individuals are considerably lower than those found in normal subjects and that individuals who respond to 5-HTP show a rise in serotonin to levels consistent with normal subjects. The level of serotonin in those who do not respond to 5-HTP remains quite low. These results imply that nonresponders may require higher doses to raise serotonin levels or that additional support may be necessary. When prescribing higher doses, it is important that the 5-HTP be taken in divided doses not only to reduce the problem with nausea but also because the rate of brain-cell uptake of 5-HTP is limited.

The first studies of 5-HTP were open trials.[15] The antidepressive effects of 5-HTP were also compared with L-tryptophan in the early 1970s.[6] In one study, 45 subjects with depression were given L-tryptophan (5 g/day), 5-HTP (200 mg/day), or a placebo. The patients were matched in clinical features (e.g., age, sex) and severity of depression. The main outcome measure was a rating scale called the Hamilton Depression Rating Scale (HAM-D), the most widely used assessment tool in clinical research on depression.

The HAM-D score is determined by having the test subject complete a series of questions in which he or she rates the severity of symptoms on a numerical basis, as follows:

- 0—not present
- 1—present but mild
- 2—moderate
- 3—severe
- 4—very severe

Symptoms assessed by the HAM-D include depression, feelings of guilt, insomnia, gastrointestinal symptoms and other bodily symptoms of depression (e.g., headaches, muscle aches, heart palpitations), and anxiety. The HAM-D is popular in research because it provides a good assessment of the overall symptoms of depression. Table 87.4 shows the results of the study.

A review of head-to-head comparison studies showed that 5-HTP, at a dosage of 200 mg/day, produced therapeutic success on par with

TABLE 87.5 Change in Hamilton Depression Rating Scale Scores

	5-HTP + MAO	MAO + PLACEBO
Initial measurement	28.67	26.33

After 15 days	11.77	6.03

5-HTP, 5-Hydroxytryptophan; *MAO,* monoamine oxidase.
Modified from Alino JJ, Gutierrez JL, Iglesias ML. 5-Hydroxytryptophan (5-HTP) and a MAOI (nialamide) in the treatment of depressions. A double-blind controlled study. *Int Pharmacopsychiatry*. 1976;11:8–15.

tricyclic antidepressant drugs.[16] Research also showed that combining 5-HTP with clomipramine and other types of antidepressant drugs produced better results than any of the compounds given alone.[17–22] For example, in one study, 5-HTP combined with a monoamine oxidase inhibitor demonstrated significant advantages compared with the monoamine oxidase inhibitor alone (Table 87.5).[21]

This line of research suggests that 5-HTP might also be used in conjunction with St. John's wort extract and *Ginkgo biloba* extract, two herbal medicines with proven antidepressant activity.

Because 5-HTP was expensive in 1972, researchers developed a test to determine who was most likely to respond to it so that it would not be wasted on people who were unlikely to respond.[15,23] The test involved the patients first having a spinal tap to measure the level of 5-hydroxyindoleacetic acid (5-HIAA, the breakdown product of serotonin) in the cerebrospinal fluid (CSF). The drug probenecid, which prevents the transport of 5-HIAA from the CSF to the bloodstream, was administered for the next 3 days. As a result of this blocking action, the amount of serotonin produced over a 4-day period could be calculated by a repeat spinal tap on day 4. Because the 5-HIAA could not leave the CSF, it accumulated and provided a measure of serotonin manufacture.

The researchers discovered that the average level of 5-HIAA after 3 days of probenecid was significantly lower in depressed individuals than in controls matched for age, sex, and weight. This low level of serotonin reflected a decreased rate of manufacture within the brain. 5-HTP was most effective in patients with a low 5-HIAA response to 3 days of probenecid.[23–25] In other words, 5-HTP is most effective as an antidepressant when the amount of serotonin manufactured in the brain is reduced.

As stated earlier, 5-HTP often produces good results in patients who are unresponsive to antidepressant drugs. One of the more impressive studies involved 99 patients described as having "therapy-resistant" depression.[26] These patients did not respond to any previous therapy, including all available antidepressant drugs and electroconvulsive therapy. These therapy-resistant patients received 5-HTP at dosages averaging 200 mg/day but ranging from 50 to 600 mg/day. Complete recovery was seen in 43 of the 99 patients, and significant improvement was noted in 8 more. Such a significant improvement in patients with long-standing, unresponsive depression is quite impressive, prompting the author of another study to state the following[27]:

> *L-5-HTP merits a place in the front ranks of antidepressants instead of being used as a last resort. I have never in 20 years used an agent that (1) was effective so quickly; (2) restored patients so completely to the persons they had been and their partners had known; and (3) was so entirely without side effects.*

In an open-label study, 15 women with major depressive disorder who had failed selective serotonin-reuptake inhibitor (SSRI) or serotonin–norepinephrine-reuptake inhibitor (SNRI) monotherapy were treated with 5 g of creatine monohydrate daily and 100 mg of 5-HTP twice daily for 8 weeks. Mean HAM-D scores declined from 18.9 at pretreatment visits to 7.5 at the end of 8 weeks.[28]

TABLE 87.6 5-Hydroxytryptophan (5-HTP) Versus Fluvoxamine in Percentage Changes in the Hamilton Depression Rating Scale (HAM-D) Score

	Decrease in HAM-D	5-HTP (*n* = 34)	Fluvoxamine (*n* = 29)
After 2 wk	Mean decrease (%)	23	18.9
	<35% decrease	20	19

	<35% decrease	4	5
	35%–50% decrease	8	3
	50%–75% decrease	12	8
	>75% decrease	10	13

A 1987 review article on 5-HTP in depression highlighted the need for well-designed, double-blind, head-to-head studies of 5-HTP versus standard antidepressant drugs.[29] Although 5-HTP was viewed as an antidepressant agent with few side effects, the authors of this review felt that the big question to answer was how 5-HTP compared with the new breed of antidepressant drugs, the SSRIs like Prozac, Paxil, and Zoloft. In 1991 a double-blind study comparing 5-HTP with an SSRI was conducted in Switzerland.[30] In the study, 5-HTP was compared with the SSRI fluvoxamine (Luvox). Fluvoxamine is used primarily in the United States as a treatment for obsessive-compulsive disorder, an anxiety disorder characterized by obsessions and compulsions affecting an estimated 5 million Americans. Fluvoxamine exerts antidepressant activity comparable to (if not better than) other SSRIs like Prozac, Zoloft, and Paxil.

In the study, subjects received either 5-HTP (100 mg) or fluvoxamine (50 mg) three times a day for 6 weeks. The assessment methods used to judge effectiveness included the HAM-D, Self-Assessment Depression Scale (SADS), and physician's assessment (Clinical Global Impression). As indicated in Table 87.6, the percentage decrease in depression was slightly better in the 5-HTP group (60.7% vs. 56.1%). 5-HTP was quicker acting than the fluvoxamine, and a higher percentage of patients responded to 5-HTP than to fluvoxamine.

The advantages of 5-HTP over fluvoxamine are evident when looking at the subcategories of the HAM-D: depressed mood, anxiety, physical symptoms, and insomnia. For depressed mood, 5-HTP produced a 65.7% reduction in severity compared with 61.8% for fluvoxamine; for anxiety, 5-HTP produced a 58.2% reduction in severity compared with 48.3% for fluvoxamine; for physical symptoms, 5-HTP produced a 47.6% decrease in severity compared with 37.8% for fluvoxamine; and for insomnia, 5-HTP produced a 61.7% decrease in severity compared with a 55.9% decrease for fluvoxamine. However, perhaps more important than simply relieving insomnia was 5-HTP's ability to improve the quality of sleep. In contrast, antidepressant drugs greatly disrupt sleep processes. On the SADS, 5-HTP produced a 53.3% drop in SADS values compared

TABLE 87.7 5-Hydroxytryptophan (5-HTP) Versus Antidepressant Drugs: Comparison of Side Effects

	PERCENTAGE OF PATIENTS EXPERIENCING SIDE EFFECTS

SSRI, Selective serotonin-reuptake inhibitor.

with a drop of 47.6% for the fluvoxamine group. A drop greater than 50% is an excellent result. A 50% drop is the best SSRIs generally produce.

In another head-to-head comparison study, this time with fluoxetine, 5-HTP also showed q good antidepressant effect.[31] The study consisted of 60 patients suffering from their first depressive episode who were randomly divided to receive 5-HTP (group A) or fluoxetine (group B) for a period of 8 weeks. 5-HTP was given at 150 mg in three divided dosages during the first 2 weeks, and then the dose was doubled (300 mg) after the second week. The dosages were increased to 400 mg in three divided dosages after the fourth week. Thereafter, the same dosages were continued. All patients in group B were given fluoxetine 20-mg capsules along with two placebo dosages during the first 2 weeks and then increased to 30 mg along with placebo dosages after the second week. All patients were administered the HAM-D to assess the severity of depression at baseline, 2 weeks, 4 weeks, and 8 weeks. A final evaluation of both efficacy and tolerance was conducted using the Clinical Global Impression (CGI) scale at the end of the study.

Results showed that both treatment groups experienced a significant and nearly equal reduction in HAM-D scores beginning at week 2 and continuing through week 8. Twenty-two patients (73.33%) in the 5-HTP group and 24 patients (80%) in the fluoxetine group showed a positive response at the end of the study. 5-HTP was very well tolerated, and it was concluded that 150 mg represents a minimal effective dosage in depression for 5-HTP.

The existing data indicate that 5-HTP is equal to or better than standard antidepressant drugs, and the side effects are much less severe (Table 87.7). In the study comparing 5-HTP with fluvoxamine, this is how the physicians described the differences among the two groups: Whereas the two treatment groups did not differ significantly in the number of patients sustaining adverse events, the interaction between the degree of severity and the type of medication was highly significant: fluvoxamine predominantly produced moderate to severe side effects; oxitriptan (5-HTP) produced primarily mild forms of adverse effects.

Fourteen (38.9%) of the patients receiving 5-HTP reported side effects compared with 18 patients (54.5%) in the fluvoxamine group. The most common side effects with 5-HTP were nausea, heartburn, and gastrointestinal problems (flatulence, feelings of fullness, and rumbling sensations). These side effects were rated as being very mild to mild. In contrast, most of the side effects experienced in the fluvoxamine group were of moderate to severe intensity. The only subject to drop out of the 5-HTP group did so after 35 days (5 weeks), whereas four subjects in the fluvoxamine group dropped out after only 2 weeks. On the basis of studies on weight loss, the longer that 5-HTP is used (e.g., after 4–6 weeks of use), the less the problem with mild nausea.

5-HTP has been shown to have "equipotency" with SSRIs and tricyclic antidepressants in terms of effectiveness, but it offers several advantages in that it is better tolerated and associated with fewer and much milder side effects. In addition, many people prefer to use a natural substance like 5-HTP over synthetic drugs.

l-Tyrosine: an Adjunct to 5-Hydroxytryptophan

In the early 1970s, researchers discovered that in about 20% of patients who responded well to 5-HTP, the results tended to decrease after 1 month of treatment. The antidepressant effects of 5-HTP in these subjects began to wear off gradually after the first month even though the level of 5-HTP in the blood, and presumably the level of serotonin in the brain, remained at the same level as when they were experiencing benefits.[5]

The researchers discovered that although serotonin levels appeared to stay at the same levels after 1 month of treatment, the levels of the other important monoamine neurotransmitters, dopamine and norepinephrine, declined. As discussed earlier, when depressed patients are treated with 5-HTP, they experience a rise not only in serotonin but also in catecholamines like dopamine and norepinephrine. In about 20% of subjects, the catecholamine-enhancing effects of 5-HTP tended to wear off. Providing these patients with L-tyrosine, the amino acid precursor to the catecholamines, helped reestablish the efficacy of 5-HTP.[5] The dosage was 200 mg/day for 5-HTP and 100 mg/kg body weight for L-tyrosine. This dosage for L-tyrosine is quite high and requires substantial clinical supervision.

Anxiety and Panic Disorder

5-HTP showed an ability to relieve anxiety in studies in depressed individuals. Lowering the availability of serotonin to the brain by tryptophan depletion increased the vulnerability of patients with panic disorder to an experimental carbon dioxide panic challenge, and increasing the availability of serotonin inhibited the response to such a challenge. When 5-HTP or placebo was given to 24 patients with panic disorder and 24 healthy volunteers before a panic challenge, 5-HTP significantly reduced the reaction to the panic challenge in patients with panic disorder regarding subjective anxiety, panic symptom score, and number of panic attacks, as opposed to placebo.[32] These results indicate that 5-HTP might be helpful in relieving panic attacks.

Weight Loss

A considerable body of scientific evidence documents the major role serotonin in the brain plays in influencing eating behavior. A key finding is that when animals and humans are fed tryptophan-free diets, appetite is significantly increased, resulting in binge eating—carbohydrates would be preferable, but animals binge on whatever is available.[2,3] A diet low in tryptophan leads to low brain serotonin levels; as a result, the brain senses it is starving and stimulates the appetite control centers in a powerful way. This stimulation results in a preference for carbohydrates. When animals or humans are fed a carbohydrate meal, more tryptophan is delivered to the brain, resulting in more serotonin being manufactured. This scenario led to the idea that low serotonin levels lead to "carbohydrate craving" and play a major role in the development of obesity and bulimia.

Cravings for carbohydrates can be mild or quite severe. They may range in severity from the desire to nibble one piece of bread or cookie

TABLE 87.8 Effect of 5-Hydroxytryptophan (5-HTP) on Food Intake

	Food Intake (calories/day)	Protein Intake (g/day)	Carbohydrate Intake (g/day)
Pretreatment	2903	101	274
Placebo	2327	85	223
5-HTP	1819	79	176

to uncontrollable binging. At the upper end of the spectrum of carbohydrate addiction is bulimia, a potentially serious eating disorder characterized by binge eating and purging of the food through forced vomiting or the use of laxatives. The serotonin theory of bulimia is that low serotonin levels trigger binge eating, which leads to a rush of serotonin being produced and released in the brain.[33,34] This increased serotonin effect produces a brief reduction in feelings of stress and tension. This serotonin "fix" is short-lived and followed by feelings of guilt and low self-esteem. The current medical treatment for bulimia is the use of drugs that enhance the effects of serotonin. Although there are no reports in the medical literature of 5-HTP being used in the treatment of bulimia, given its effects on serotonin levels, it merits consideration.

5-HTP may help prevent the decline in serotonin levels associated with reduced calorie intake. Concentrations of tryptophan in the bloodstream and subsequent brain serotonin levels plummet with dieting.[35] In response to severe drops in serotonin levels, the brain puts out a strong message to eat. This situation sets up the scenario to explain why most diets do not work.

As far back as 1975, researchers demonstrated that giving 5-HTP to rats who were genetically bred to overeat and be obese resulted in a significant reduction in food intake.[36] It turns out that these rats bred to be fat had decreased activity of the enzyme that converts tryptophan to 5-HTP and subsequently to serotonin.

There is circumstantial evidence that many humans are genetically predisposed to obesity. This predisposition may involve the same mechanism as rats genetically predisposed to obesity. By providing preformed 5-HTP, this genetic defect is bypassed, and more serotonin is manufactured.

The early animal studies with 5-HTP as a weight-loss aid were followed by a series of three human clinical studies. The first study involved 19 significantly overweight female subjects with a body mass index (BMI) ranging from 30 to 40 kg/m^2.[37] Analysis of the pretreatment dietary intake concluded that these women tended to overeat carbohydrates. Food intake and eating behavior were assessed using a 3-day diet diary at the beginning and end of the two treatment periods. All food was carefully weighed before meals and weighed again if there were any leftovers. Participants also filled out a self-evaluation of appetite and satiety twice a week, and mood was evaluated using standard psychological tests.

The daily dosage of 5-HTP used in the study was 8 mg/kg body weight. Patients were given either 5-HTP or placebo 20 minutes before meals for 5 weeks, and after a 1-week interval, they were switched to receive the other treatment. No dietary restrictions were prescribed because the researchers wanted to answer the question, "Does 5-HTP reduce appetite and promote weight loss without any conscious effort?" To make sure that the women actually took the 5-HTP, researchers measured the level of the serotonin breakdown product, 5-HIAA, in the urine. Table 87.8 lists the results of the study.

These results with 5-HTP were achieved without the women making any conscious effort to reduce food consumption. The average amount of weight loss during the 5-week period of 5-HTP supplementation

Early satiety	7/7	6/7	2/7	2/7
Nausea	5/7	0/7	1/7	2/7

was a little more than 3 lb, compared with less than 1 lb of total weight loss during the placebo period.

Interestingly, evaluation of the various self-tests indicated that appetite or degree of initial hunger did not differ between the two groups. What differed was satiety. In other words, the 5-HTP did not reduce appetite before a meal, but after consuming an adequate amount of food, the satiety centers in the brain were stimulated, and the women did not feel hungry. As a result, their caloric intake was dramatically reduced.

The level of 5-HIAA, the breakdown product of serotonin, in the group receiving the 5-HTP increased by more than fiftyfold over the control group. This increase provided two things: (1) it assured researchers that subjects actually took the 5-HTP, and (2) it clearly indicated that 5-HTP increased serotonin manufacture.

The next study sought to determine whether 5-HTP helped overweight individuals adhere to dietary recommendations.[38] Fourteen overweight female subjects with a BMI between 30 and 40 kg/m^2 were enrolled in the double-blind study.[10] Again, analysis of the pretreatment dietary intake concluded that these women tended to overeat. The women were randomly assigned to receive either 5-HTP (300 mg) or placebo 30 minutes before meals. The 12-week study was divided into two 6-week periods. For the first 6 weeks, there were no dietary recommendations, and for the second 6 weeks, the women were placed on a 1200-calorie diet.

The women were seen every 2 weeks to evaluate body weight, diet diaries, self-evaluations of appetite, and satiety. The women were also asked if they experienced the presence of meat aversion; taste or smell alterations; early satiety; and nausea or vomiting, or both. To verify patient compliance, urinary measurement of 5-HIAA was again determined. As shown in Table 87.9, the women taking the placebo lost 2.28 lb, whereas the women taking the 5-HTP lost 10.34 lb.

Like the previous study, 5-HTP appeared to promote weight loss by promoting satiety. Although some women reported some aversion to meat or altered taste and smell, each woman (100%) reported early satiety (Table 87.10). Most of the women receiving 5-HTP also

experienced mild nausea during the first 6 weeks of the trial, but during the last 6 weeks, none complained of nausea. The fact that weight loss was accelerated during the second 6-week period makes it highly unlikely that 5-HTP promoted weight loss as a result of producing nausea.

One study with 5-HTP enrolled overweight women with a BMI ranging between 30 and 40 kg/m^2 and an overactive appetite.[39] The 28 subjects of the study were given either 5-HTP (300 mg three times daily before meals) or a placebo. For the first 6 weeks, there were no dietary restrictions, and for the second 6 weeks, the women were placed on a diet of 1200 calories/day. Carbohydrates contributed 53% of the calories, fats comprised 29%, and proteins provided 18%. No carbohydrate-rich foods were permitted between meals. Subjects were examined every 2 weeks to evaluate food intake and body weight. Routine blood measurements were also performed at the beginning, at 6 weeks, and at the end of the study. To verify patient compliance, urinary measurement of 5-HIAA was determined.

The results from this study were even more impressive than the previous studies, for several reasons. The group receiving the 5-HTP lost an average of 4.39 lb after the first 6 weeks and an average of 11.63 lb after 12 weeks. In comparison, the placebo group lost an average of only 0.62 lb after the first 6 weeks and 1.87 lb after 12 weeks. The lack of weight loss during the second 6-week period in the placebo group obviously reflected the fact that the women had difficulty adhering to the diet.

Early satiety was reported by 100% of the subjects during the first 6-week period. During the second 6-week period, even with severe caloric restriction, 90% of the women taking 5-HTP reported early satiety. Once again, many of the women receiving the 5-HTP reported mild nausea during the first 6 weeks of therapy. However, the symptom was never severe enough for any of the women to drop out of the study. No other side effects were reported.

On the basis of the urinary measurements of 5-HIAA, the women took their 300 mg of 5-HTP with meals and, as a result, achieved weight loss. The amount of weight loss was amplified by a better capability to adhere to a 1200-calorie diet. The structure of the dietary changes reflected primarily a reduction in pasta, bread, and other carbohydrate-rich foods (the study was conducted in Rome).

In the latest study, 25 overweight outpatients with non–insulin-dependent diabetes were enrolled in a double-blind, placebo-controlled study and randomized to receive either 5-HTP (750 mg/day) or a placebo for 2 consecutive weeks, during which no dietary restrictions were prescribed.[40] Results again indicated that patients receiving 5-HTP significantly decreased their daily energy intake by reducing carbohydrate and fat intake and reduced their body weight.

Insomnia

Several clinical studies showed 5-HTP produced good results in promoting and maintaining sleep in normal subjects and in those experiencing insomnia.[39–46] One of the key benefits with 5-HTP in the treatment of insomnia is its ability to increase sleep quality. This effect is evident by its ability to increase rapid eye movement (REM) sleep (typically by about 25%) while simultaneously increasing deep sleep stages 3 and 4 without increasing total sleep time.[39,42] The sleep stages that are reduced by 5-HTP to compensate for the increases are non-REM stages 1 and 2, the least important stages of sleep. In one of the studies, the subjects receiving 200 mg of 5-HTP increased their amount of REM sleep by 15.5 minutes during the 5-night study.[39] Subjects taking 600 mg of 5-HTP increased REM sleep time by an average of 20 minutes for the 5-night study. These results indicated that 5-HTP increased the amount of dream time by about 3 to 4 minutes a night.

Although there was a clear dose-related effect, the lower dosage is sufficient in most cases. In addition, taking too much 5-HTP may increase REM sleep to an abnormal level, leading to an increased risk for nightmares. That said, 5-HTP might prove effective in sleep terrors in children. To test this hypothesis, an open trial in a group of children with sleep terrors was compared with a group of children with the same disorder but without 5-HTP treatment.[47] 5-HTP was administered (2 mg/kg per day) at bedtime to 31 randomly selected patients for 20 consecutive days. After 1 month of treatment, 29 of 31 (93.5%) patients showed a positive response. In the comparison group without drug therapy, after 1 month, the episodes disappeared in only 4 children (28.6%), whereas 10 children (71.4%) showed persistence of episodes with the same frequency as before. After 6 months, 26 of 31 (83.9%) children treated with 5-HTP were sleep terror–free, whereas in five children (16.1%), sleep terror episodes persisted. Of the children in the comparison group, 10 (71.4%) continued to show sleep terrors at 6-month follow-up. These results represent preliminary evidence that treatment with 5-HTP is able to modulate the arousal level in children and induce a long-term improvement in sleep terrors.

Migraine and Tension Headaches

The relationship between serotonin and headaches is fully described in Chapter 198. Because patients with migraines have low levels of serotonin in their tissues, some researchers refer to migraine headaches as a "low-serotonin syndrome."[46] Although the primary benefit of 5-HTP in the prevention of both migraine and tension headaches is related to its ability to normalize underlying imbalances in the serotonin system, it also influences the endorphin system in a positive way.

Several clinical studies on the use of 5-HTP for headaches, both vascular and nonvascular, showed excellent results. In particular, the use of 5-HTP in the prevention of migraine headaches offers considerable advantages over drug therapy. Although a number of drugs were shown to be useful in the prevention of migraine headaches, all of them carry significant side effects.

The problem with drug therapy in the prevention of migraine headaches is perhaps best exemplified by one of the most commonly used drugs, methysergide (Sansert). Methysergide therapy for the prevention of migraine attacks is effective in about 60% to 80% of cases. However, this effectiveness is not without a high price because side effects are quite common and can be severe. Retroperitoneal fibrosis, pleuropulmonary fibrosis, and fibrotic thickening of cardiac valves may occur in patients receiving long-term methysergide maleate therapy. Therefore this preparation must be reserved for prophylaxis in patients whose vascular headaches are frequent or severe and uncontrollable and for those who are under close medical supervision.

Several studies compared 5-HTP with methysergide in the prevention of migraine headaches. In one of the largest double-blind studies, 124 patients received either 5-HTP (600 mg/day) or methysergide (3 mg/day) in identical pills for 6 months.[48] Treatment was determined successful if there was a reduction of greater than 50% in the frequency of attacks or in the number of severe attacks. Although 75% of the patients (30 of the remaining 40 patients) taking methysergide demonstrated significant improvement compared with 71% of the patients (32 of the 45 patients) taking 5-HTP, this difference was not viewed as statistically significant (Table 87.11). The advantage of 5-HTP over methysergide was demonstrated when researchers looked at side effects. Side effects were more frequent in the group receiving methysergide than in the 5-HTP group. Five patients in the methysergide group withdrew during the trial because of side effects.

Two other studies comparing 5-HTP with drugs used in the prevention of migraine headaches (pizotifen and propranolol) demonstrated that 5-HTP compared quite favorably in terms of effectiveness.[49,50]

TABLE 87.11 5-Hydroxytryptophan (5-HTP) Versus Methysergide: Clinical Effects of Treatment in 124 Patients

	Methysergide	5-HTP
No attacks (100% reduction)	35%	25%
Improvement (>50% reduction)	40%	46%
No improvement	12.5%	29%
Withdrawal because of side effects	12.5%	0%

Although these drugs have significant side effects, 5-HTP is extremely well tolerated even at dosages as high as 600 mg/day. One of the other key differences noted in these studies between 5-HTP and the other drugs was 5-HTP's ability to improve mood and relieve feelings of depression.

In a double-blind study of 5-HTP in chronic tension headache, 78 patients with chronic tension-type headaches were treated with 5-HTP (300 mg/day) or a placebo for 8 weeks.[48] In comparison with the group treated with a placebo, there were no statistically significant changes in the number of days with headache or in headache intensity in the group treated with 5-HTP; however, there was a significant decrease in the consumption of analgesics.[51] During the 2 weeks after treatment, there was also a significant decrease in the number of days with headache. Subjective opinion during this latter period was also favorable to 5-HTP.

Juvenile Headache

One of the best uses of 5-HTP is in chronic headaches in children. These headaches are a big problem because of the tremendous risk for side effects of the current drugs used to treat, and prevent, them. Several studies of 5-HTP in the treatment of chronic headaches in children and adolescents showed excellent results.[52–54] Given the risks of current drugs used in chronic childhood headaches, a trial of 5-HTP for 2 months certainly seems reasonable. If the headaches are also accompanied by sleep disorders, 5-HTP appears to be especially well suited.

In one study, 48 elementary and junior high students with recurrent headaches (at least one headache every 2 weeks) and sleep disorders, including difficulty in getting to sleep, frequent awakenings, sleepwalking, nightmares, and bedwetting, were divided into two groups.[52] Group A was given 5-HTP for 2 months, followed by a placebo for 2 months, whereas group B received just the opposite. It was necessary to divide group A into a nine-patient subgroup, group C. These nine patients did so well on the 5-HTP that they did not want to switch over to the other medication, although they had no idea whether they were, in fact, taking 5-HTP or were on a placebo. The dosage of 5-HTP was based on the child's weight (4.5 mg/kg per day).

The headache index was reduced by about 70% when the kids were taking 5-HTP compared with an 11.5% drop when they were taking the placebo. In the nine patients in group C, there was an 81.8% decrease in the headache index after the second month. Interestingly, these same patients only exhibited an 18.2% reduction after the first month. These results indicate that an evaluation of the benefits of 5-HTP in the treatment of headaches requires at least a 2-month trial. The failure to show benefit with 5-HTP in some studies in headaches might be because of the fact that they lasted less than 2 months. The 25 patients experienced a modest reduction in frequent awakenings, nightmares, sleepwalking, and talking while asleep and no change in difficulty falling asleep or in bedwetting.

TABLE 87.12 Serotonin and β-Endorphin Levels in Juvenile Patients with Headaches Before and After Administration of 5-Hydroxytryptophan (5-HTP)

	Serotonin (serum, mg/L)	Beta-Endorphin (plasma, pmol/L)	Beta-Endorphin (white blood cells, pmol/106 GB/L)
Migraine (13 subjects)			
Before	104.6	16.2	110.5
After	115.7	19.4	120.3
Tension-type (7 subjects)			
Before	90.7	14.5	142.3
After	97.2	17.6	152.4
Total (20 subjects)			
Before	100.5	15.7	129.3
After	108.3	18.4	140.4
Controls (17 subjects)			
	96	21.3	359.3

Overall, this study demonstrated very good effects in these children. Perhaps the most impressive aspect to consider, however, was the fact that these benefits were achieved without side effects. Not a single child reported a side effect while taking 5-HTP. Interestingly, for some reason, children rarely experience even mild nausea from 5-HTP.

The possible benefits of using 5-HTP in children with recurrent headaches or sleep disorders, or both, is far-reaching. Evaluation of the 48 children in the trial demonstrated inadequate school progress compared with their classmates. The children were shown to be of normal intellectual capacity but demonstrated inattentiveness similar to that observed in depression. Many of the children might have had depression. The unwillingness of the nine subjects in group C to switch to the other unknown medication (which was the placebo) is a strong indicator that these children and their parents noted some rather dramatic improvements beyond simply a reduction in headaches or improved sleep.

The manner in which 5-HTP may be of benefit in migraine headaches may not simply be the overcoming of some defect in serotonin synthesis. As noted previously, part of the clinical benefit of 5-HTP may be via an ability to increase the levels of β-endorphin. A decrease in β-endorphin levels in patients with migraine headaches, and tension headaches, was demonstrated by several investigators.[55,56]

A clinical trial measured the effects of 5-HTP on serotonin and β-endorphin levels in 20 juvenile patients with migraine or tension-type headaches.[57] Patients were monitored and evaluated for the frequency and intensity of headache attacks for 3 months before 5-HTP treatment and during 3 months of therapy. The researchers reported a statistically significant reduction in the headache score with 5-HTP treatment in both migraine and tension-type patients. These improvements were likely a result of increased β-endorphin levels, as noted in Table 87.12. However, the level of β-endorphins achieved with 5-HTP, especially as measured in the white blood cell, was still far less than that observed in control patients without recurrent headaches. These results imply that longer periods of 5-HTP supplementation may be required before there is a normalization of β-endorphin levels in children prone to headaches.

TABLE 87.13 Patients' and Physicians' Opinions on the Effectiveness of 5-Hydroxytryptophan (5-HTP) Versus Placebo in Fibromyalgia

Response	5-HTP	Placebo
Good	11	1
Fair	8	5
Poor	4	8
None	0	9

These results may indicate that 5-HTP alone is not able to raise β-endorphin levels sufficiently to reduce or eliminate headaches, suggesting that other therapies designed to increase β-endorphin levels should be used along with 5-HTP. Examples of other therapies that have been shown to raise β-endorphin levels are exercise, acupuncture, and biofeedback.

Fibromyalgia

The history of the development of 5-HTP as an effective treatment for fibromyalgia began with studies on the drug fenclonine.[58] This drug blocks the enzyme that inhibits the conversion of tryptophan to 5-HTP and, as a result, blocks serotonin production. During the late 1960s and early 1970s, it was thought that increased serotonin formation might promote migraine headaches (the opposite of what was later proved, i.e., increasing serotonin levels reduced the occurrence of migraine headaches). The researchers discovered that providing headache patients with fenclonine resulted in severe muscle pain. This effect was the exact opposite of what was expected, but it led to some important advances in the understanding of fibromyalgia—a way to induce its severe symptoms of (and symptoms nearly identical to) eosinophilia myalgia syndrome (EMS), the condition caused by contaminated L-tryptophan. The researchers also discovered that migraine patients had a greater reaction to the drug than nonheadache subjects. In most normal subjects, fenclonine produced no fibromyalgia. These occurrences highlighted just how sensitive migraine patients are to low serotonin levels.

Migraine headaches and fibromyalgia share a common feature: both are low-serotonin syndromes.[59] After more than 25 years of research, one of the lead researchers stated: "In our experience, as well as in that of other pain specialists, 5-HTP can largely improve the painful picture of primary fibromyalgia."[60]

A double-blind study in 50 patients with fibromyalgia found that 100 mg of 5-HTP three times per day significantly improved their symptoms.[61] As shown in Table 87.13, 5-HTP was rated substantially better than placebo by subjects and evaluating physicians. Improvements were noted in all symptom categories: number of painful areas, morning stiffness, sleep patterns, anxiety, and fatigue. In another study, 100 mg of 5-HTP taken three times a day demonstrated maximum results by day 30 of the 90-day trial.[62]

One of the primary benefits with 5-HTP in fibromyalgia may be its ability to improve sleep quality. A key finding in patients with fibromyalgia is a reduced REM sleep and an increase in non-REM sleep.[63] In addition, the deeper levels (stages III and IV) are not achieved for long enough periods. As a result, people with fibromyalgia wake up feeling fatigued and in pain. The severity of the pain of fibromyalgia correlates with the rating of sleep quality. For example, a study of 50 women with fibromyalgia syndrome recorded their sleep quality, pain intensity, and attention to pain for 30 days, using palm-top computers programmed as electronic interviewers.[64] They described their previous night's sleep quality within 30 minutes of awakening each day and rated their present pain at randomly selected times in the morning, afternoon, and evening. The researchers found that a night of poor sleep was followed by a significantly more painful day, and a more painful day was followed by a night of even poorer sleep. 5-HTP might help break the cycle by addressing the low serotonin level and by promoting restful sleep.

TABLE 87.14 Effect of 5-Hydroxytryptophan (5-HTP) on Depression in Parkinson's Disease

Patient No.	l-Dopa (mg/day)	Carbidopa (mg/day)	5-HTP (mg/day)	HAM-D	
				Before	After
1	1000	175	125	22	11
2	300	75	75	14	3
3	400	150	100	21	13
4	1000	100	100	12	6
5	500	125	500	18	22
6	1125	112.5	300	18	7
7	500	50	100	17	13

HAM-D, Hamilton Depression Rating Scale.

Parkinson's Disease

The use of 5-HTP in Parkinson's disease provides some benefit but only if used in combination with the drug Sinemet (the combination of L-dopa with the decarboxylase inhibitor carbidopa). Although brain levels of serotonin are decreased in Parkinson's disease, the reduction in dopamine receptors is more severe. Increasing serotonin levels with 5-HTP in patients not taking Sinemet is associated with worsening of symptoms, especially rigidity.[65]

One of the key benefits of taking 5-HTP in Parkinson's disease is that it can help counteract the negative effects that the L-dopa in the Sinemet has on sleep and mood.[66–68] In addition, 5-HTP was also shown to improve the physical symptoms of Parkinson's disease.

About 9 of 10 people with Parkinson's disease have depression. The degree of depression in Parkinson's disease is a reflection of the individual's serotonin levels. The lower the level of serotonin, the more severe is the individual's depression. One study examined the effect of 5-HTP in seven patients with Parkinson's disease, all of whom were on Sinemet.[65] The initial dosage of 5-HTP was 75 mg, which was increased by 25 mg every 3 days until the patients reported relief of their depression, or up to a maximum of 500 mg/day for 4 months. The impressive results obtained in these patients are shown in Table 87.14.

Six of seven patients responded to 5-HTP. It should be noted that the doses of 5-HTP in five of the six patients who responded ranged from only 75 to 125 mg. The only patient who did not respond took 500 mg of 5-HTP.

Seizure Disorders

Most of the recent research on 5-HTP focused on its use in the treatment of several seizure disorders.[69–74] 5-HTP showed good results in most (but not all) studies in patients with diseases characterized by myoclonus, with the exception of epilepsy, which is not helped by 5-HTP.

The best response to 5-HTP for myoclonus occurs in people who have intention myoclonus, which is most often produced as a result of ischemic damage to the brain. Intention myoclonus can be a problem after a stroke or heart attack, overdosage of a drug such as heroin, a severe asthma attack, or an adverse reaction to anesthesia or another chemical. Improvements with 5-HTP were demonstrated in patients with intention myoclonus. 5-HTP also

produced good results in patients with progressive myoclonus epilepsy, essential myoclonus, palatal myoclonus, and Friedreich's ataxia.

In a 1983 article, one researcher of 5-HTP stated: "Some helpless bedridden patients dramatically improved to the extent that they could walk again and resume independent living."[74] Because of the phenomenal results, 5-HTP was the first compound to be evaluated as an orphan drug by the Pharmaceutical Manufacturing Associations Commission on Drugs for Rare Diseases.

Irritable Bowel Syndrome and the "Leaky Gut"

Irritable bowel syndrome (IBS) is often accompanied by impaired intestinal barrier function and "leaky gut" syndrome. Decreased serotonergic function appears to play a part in the intestinal barrier dysfunction. In an interesting double-blind study, 15 patients with IBS and 15 healthy volunteers ingested either 100 mg 5-HTP or a placebo.[75] Oral 5-HTP administration significantly increased mucosal levels of 5-HIAA in both healthy controls and patients with IBS, with the latter group showing a significantly larger increase. Urinary lactulose/L-rhamnose ratios were significantly lower after administration of 5-HTP in healthy controls and were accompanied by redistribution of zonula occludens-1, pointing to reinforcement of the barrier. In IBS, expression of the tight-junction proteins was significantly lower compared with healthy controls, and 5-HTP resulted in a further decrease in occludin expression. These results indicate that in healthy controls, a reinforcement of the intestinal barrier was seen with 5-HTP intake, whereas such reaction was absent in patients with IBS. This could indicate the presence of a serotonin-mediated mechanism aimed to reinforce the function of the intestinal barrier, which seems to be dysfunctional in patients with IBS.

DOSAGE

Enteric-coated preparations are required to avoid nausea. The dosage should be started at 50 mg three times daily. If the response is inadequate after 2 weeks, increase the dosage to 100 mg three times daily. This recommendation will greatly reduce the mild symptoms of nausea often experienced during the first few weeks of 5-HTP therapy. Because 5-HTP does not rely on the same transport vehicle as L-tryptophan, it can also be taken with food. Because the half-life of 5-HTP is relatively short (3–4 hours, with peak serum levels achieved at 1–2 hours), more frequent dosing may be more effective than single higher doses.

For insomnia, the general recommendation is 100 to 300 mg, 30 to 45 minutes before retiring. Start with the lower dose for at least 3 days before increasing the dose.

TOXICOLOGY

The major concern with 5-HTP is a possible link to L-tryptophan and EMS. However, an important distinction must be made in the manufacturing process. Although L-tryptophan is produced via bacterial fermentation and filtration, 5-HTP is commercially available through an extraction process from the seed of *Griffonia simplicifolia,* an African plant. 5-HTP extracted from this natural source avoids the contamination problem associated with past manufacturing of L-tryptophan.

Detailed analyses of all evidence by the Centers for Disease Control and Prevention and other experts led to the conclusion that the cause of the EMS epidemic could be traced to a single Japanese manufacturer, Showa Denko.[76,77] Of the six Japanese companies that supplied L-tryptophan to the United States, Showa Denko was the largest (50%–60% of all the L-tryptophan). The L-tryptophan was used not only as a nutritional supplement but also in infant formulas and nutrient mixtures for intravenous feeding.

A single case report linked 5-HTP to a condition like EMS in 1980.[78] However, this case involved the use of high dosages of 5-HTP (1400 mg) over a 20-month period. Further examination of the patient indicated a defect in tryptophan metabolism that resulted in elevations in kynurenine. Such defects in tryptophan metabolism are common in patients with scleroderma, which shares many common features with EMS. It appeared that either the 5-HTP might have contained a contaminant to which this man was sensitive or that taking such high doses of 5-HTP over a prolonged period of time aggravated his abnormal handling of L-tryptophan.

There was also a report of a 28-year-old woman, her husband, and her two sons, 33 and 13 months old, who developed an EMS-like illness in response to contaminated 5-HTP.[76] The young boys inherited the inability to convert tryptophan to 5-HTP. As a result, they required daily administration of 5-HTP (5–7 mg/kg). Both boys received the 5-HTP almost from birth.

The mother was not taking 5-HTP, but she prepared it for the young boys by opening the capsules, mixing the powder in juice or water, and giving it to them orally with a syringe. She never took the 5-HTP; she only touched it with her hands as she emptied the capsules.

When the second boy was about 9 months old, the mother began experiencing symptoms of EMS. After consulting a physician in July 1991, it was noted that her eosinophil count was well over 30%. She continued to worsen and was hospitalized in August 1991 with a tentative diagnosis of EMS. At this time, she was referred to the National Institutes of Health for further evaluation.

Because of the possible link between the mother's symptoms and the 5-HTP, the boys and the father were also evaluated. The older boy had an eosinophil count of 9% (normal is 1%–4%), and the younger boy had a count of 6%. The father had no abnormalities.

The 5-HTP that the boys used was analyzed by high-pressure liquid chromatography and found to contain an impurity not found in the 5-HTP that the National Institutes of Health used in its studies for ataxia and myoclonus. Switching the boys to the contaminant-free 5-HTP brought about a normalization of the eosinophil counts. The mother's case was interesting because she was the most severely affected, and skin exposure was the only contact with the contaminated 5-HTP.

In 1998, researchers at the Mayo Clinic identified trace levels of a compound termed "peak X" as the key contaminant using a sensitive laboratory technique.[79] As a result, manufacturers of 5-HTP now screen for the presence of this compound to ensure that all of the 5-HTP on the marketplace is free from peak X as outlined in current Food and Drug Administration methodology. A minor chromatographic peak (peak X) reported in some 5-HTP samples lacks credibility because of chromatographic artifacts and infinitesimal concentrations and has raised undue speculations concerning its chemistry and toxicity. It might also be a moot point because extensive analyses of several sources of 5-HTP showed no toxic contaminants similar to those associated with L-tryptophan, nor the presence of any other significant impurities.[80]

There have been no reports of a single person developing EMS from 5-HTP despite its popularity over the past 20 years. Nonetheless, to be on the safe side, some experts recommend that long-term continual use of 5-HTP be monitored by regular (every 6 months) eosinophil determination.

Evidence that uncontaminated 5-HTP does not cause EMS is also provided by researchers who have been using 5-HTP for more than 25 years. They state: "EMS has never appeared in the patients of ours who received only uncontaminated L-tryptophan or 5-hydroxytryptophan

(5-HTP)."[81] Furthermore, researchers at the National Institutes of Health studying the effects of uncontaminated 5-HTP on various metabolic conditions have not observed a single case of EMS, nor has a case of elevated eosinophils been attributed to 5-HTP in these studies.[82] In short, there has never been a report of uncontaminated 5-HTP causing EMS.

Although there has never been a single person developing EMS from 5-HTP products proven to be free from the contaminants, long-term continual use of 5-HTP should be monitored by regular (every 6 months) eosinophil determination. For any person with scleroderma resulting from the problem with tryptophan metabolism noted in these patients, an eosinophil determination after the first month of 5-HTP use is indicated, especially if dosages are greater than 500 mg/day. In addition is the following advice:

- Do not use 5-HTP during pregnancy or lactation.
- Do not use 5-HTP in Parkinson's disease unless the patient is on Sinemet.
- Do not use 5-HTP in patients with scleroderma.

DRUG INTERACTIONS

Because 5-HTP is the direct precursor to serotonin, it should not be used by individuals taking antidepressant drugs without close medical supervision. Although 5-HTP has been used safely in combination with prescription antidepressant drugs in clinical studies, taking this combination could result in too much serotonin in the body. The result is a condition known as the "serotonin syndrome," characterized by confusion, fever, shivering, sweating, diarrhea, and muscle spasms.

5-HTP may antagonize the effects of drugs used in migraine headaches like methysergide and cyproheptadine, which block serotonin effects.

The drug carbidopa greatly enhances the half-life and produces an apparent clearance at least 14 times smaller, and an area under the curve that is 15.4 times greater, compared with 5-HTP 100 mg given without carbidopa.[83] By combining 5-HTP with carbidopa, increased bioavailability for brain penetration and decreased peripheral side effects would be expected because of reduced peripheral decarboxylation of 5-HTP to serotonin. However, in a double-blind study in healthy male volunteers, nausea and vomiting occurred dose-dependently as the most frequent side effects, resulting in dose-related dropout of 6.6% at 100 mg and 45.5% at 300 mg 5-HTP.[80]

Hypericum perforatum (St. John's Wort)

Peter B. Bongiorno, ND, MSAc, LAc

OUTLINE

Hypericum perforatum (family: Hypericaceae)
Common names: St. John's wort, Klamath weed, hypericum

GENERAL DESCRIPTION

Likely the most well-scientifically studied botanical of all time, St. John's wort *(Hypericum perforatum)* is a shrubby perennial plant with numerous bright yellow flowers (Fig. 88.1). It is commonly found in dry, gravelly soils, fields, and sunny places. St. John's wort is native to many parts of the world, including Europe, Asia, and the United States. It grows especially well in northern California and southern Oregon.[1]

The plant is glabrous throughout, green or sometimes glaucescent; the stems are erect, branched at the top, and 30 to 100 cm long. The leaves are (1) oval or elliptic; (2) oblong-ovate or rather narrow, oblong-linear, subobtuse, and flat; or (3) more or less revolute—marginated with numerous pellucid and a few black granular dots. The yellow flowers are numerous, forming a broad, paniculate, almost corymbose inflorescence, 7 to 11 cm long and 5 to 11 cm broad. The lanceolate bracts are 0.5 cm long and acute. The calyx is deeply parted, 5 mm long, and about two to three times shorter than the corolla. The sepals are lanceolate or narrow lanceolate 4 to 5 mm long, 1 mm broad, as long as the ovary, acute or acuminate, sparingly furnished with black oval dots, with a smooth or sparsely toothed margin. The petals are oblong to oblong-elliptic, 1.2 to 1.5 cm long and 0.5 to 0.6 cm broad, with or without numerous black granular dots and lines on the margin in the upper part, whereas the surface is full of yellow glandular dots, thin lines, and stripes. The three-bundled stamens are numerous; the ovary is ovoid, 3 to 5 mm long. The seed is 1 mm long, cylindric, brown, and minutely pitted longitudinally.[2]

The whole plant is used medicinally. Harvesting time is generally July through August. The plant must be dried immediately to prevent degradation of active principles.[3]

CHEMICAL COMPOSITION

Hypericum contains the acylphoroglucinol hyperforin, the naphthodianthones (hypericin and pseudohypericin, isophypericin, and protohypericin), flavonoids (such as hyperocide, quercitrin, and isoquecitrin), and numerous other compounds.[4] The most studied compounds are hypericin (Fig. 88.2), pseudohypericin, and hyperforin. These compounds are typically found in low concentrations, ranging from 0.0095% to 0.466% in the leaves and as much as 0.24% in the flowers.

Given its pleiotropic actions, researchers have been interested in the other chemical constituents (especially the various flavonoids and xanthones). The interest in these other components stems largely from pharmacological studies with commercially available extracts demonstrating effects and benefits beyond hypericin, pseudohypericin, and hyperforin. Studies looking at multifractionated extracts with higher levels of botanical components show better clinical outcomes.[5] For example, amentoflavone was shown to bind to benzodiazepine receptors and to act as a modulator of γ-aminobutyric acid, which may be a major anxiolytic mechanism.[2] The active components include[1]:

- Flavonoids (flowers 16%, leaves 12%, and whole herb 9%)
- Xanthones
- Phenolic carboxylic acids (caffeic, chlorogenic, ferulic, and gentisic acids)
- Essential oils (whole herb content 0.13%)
- Carotenoids
- Alkanes
- Phloroglucinol derivatives
- Phytosterols
- Medium-chain fatty acid alcohols

HISTORY AND FOLK USE

St. John's wort has a long history of folk use. Dioscorides, the foremost physician of ancient Greece, as well as Pliny and Hippocrates, used St. John's wort in the treatment of many illnesses. Its Latin name, *H. perforatum,* is derived from Greek and means "over an apparition," a reference to the belief that the herb was so obnoxious to evil spirits that a whiff of it would cause them to depart.

The naming of St. John's wort has its origins in folk traditions. One claims that the red spots, symbolic of the blood of St. John, appeared on the leaves of the plant on the anniversary of the saint's beheading. Another comes from a common medieval belief that if one slept with a piece of the plant under a pillow on St. John's Eve, "the Saint would appear in a dream, give his blessing, and prevent one from dying during the following year."

Many people from the time of the ancient Greeks through the Middle Ages believed St. John's wort to have magical powers. Recent research on St. John's wort appears to offer some explanation of this "magical" power. On the basis of a long history of use as a mood-elevating substance and preliminary in vitro experiments and clinical studies, in 1984, the German Commission E permitted the medicinal use of St. John's wort for depression, anxiety, or nervous excitement.

The Commission E evaluates efficacy of herbal medicines on the basis of a doctrine of reasonable certainty, in contrast to the U.S. Food and Drug Administration's doctrine of absolute proof. Herbal products can be marketed in Germany with drug claims if they are proven to be safe and effective. Whether the herbal product is available by prescription or over the counter is based on its application and safety of use. Herbal products sold in German pharmacies are reimbursed by insurance if they are prescribed by a physician.

Because the German system allowed companies to market their products according to the guidelines of the Commission E, many companies achieved commercial success allowing them to fund the necessary research to gain greater acceptance within mainstream conventional medicine. St. John's wort extract in the treatment of depression is a perfect case in point to illustrate how the Commission E monographs fueled the science of botanical medicine. For example, it was originally thought that hypericin acted as an inhibitor of the enzyme monoamine oxidase (MAO), thereby resulting in the increase of central nervous system (CNS) monoamines such as serotonin and dopamine. However, newer research indicates that St. John's wort possesses no in vivo inhibition of MAO. Apparently, the antidepressant activities are related more to modulating the relationship between the immune system and mood, as well as by inhibiting serotonin reuptake. In addition, it appears that although hypericin is an important marker that correlates with clinical efficacy, other compounds such as flavonoids are thought to play a major role in the pharmacology of St. John's wort.

More than 27 double-blind randomized trials, involving more than 3800 patients with mild to moderately severe depression, showed that St. John's wort extracts standardized for hypericin had excellent results in the treatment in mild to moderate depression, with far fewer side effects than standard antidepressant medications.[6] For patients with preexisting conductive heart dysfunction or elderly patients, high-dose hypericum extract is safer with regard to cardiac function than tricyclic antidepressants.[7]

PHARMACOLOGY

St. John's wort extracts (primarily of the flowering tops) have shown a wide variety of effects in experimental and clinical studies. Some of the activities demonstrated include the following[1]:

- Antidepressant effects
- Antiviral effects
- Antibiotic effects
- Increased healing of wounds and burns

Antidepressant Activity

As a testament to the wise complexity of the natural world, hypericum has a number of pleiotropic effects that are probably, in a synergistic fashion, responsible for its antidepressant activity. These include, but are not limited to, MAO A and B inhibition, modulation of IL-6 activity, serotonin reuptake inhibition, sigma 1-receptor activation, gamma amino butyric acid (GABA) inhibition, and hypothalamic gene transcription.

MAO Inhibition

Among the different biological hypotheses for depression, the biogenic amine hypothesis is the most widely accepted. This hypothesis suggests that depression is the result of a deficiency in function of the biogenic amines (e.g., serotonin, catecholamines, dopamine). These neurotransmitters are stored in granules within neurons. After stimulation of the neurons, these neurotransmitters are released into the synaptic cleft via exocytosis. After binding to postsynaptic receptors, the neurotransmitters are either taken up again and restored in the vesicles or they are catabolized by the enzymes MAO or catechol-O-methyltransferase

(COMT). Most antidepressant drugs increase the availability of these amines, particularly serotonin, by either inhibiting the reuptake or blocking MAO.

As stated earlier, initial studies indicated that St. John's wort extract's antidepressant action was based on the ability of crude hypericin preparations to inhibit both types A and B MAO.[8,9] As a result of this inhibition, there is an increase in the level of neurotransmitters within the brain that maintain normal mood and emotional stability, including serotonin, catecholamines, and dopamine. These preliminary results identified hypericin as the supposed active constituent. However, later chemical analysis of these crude hypericin preparations identified the active content as being as much as 20% of St. John's wort's other constituents, with flavonoids being the most important.[1] In other words, it is unknown to what extent hypericin or the flavonoids individually really contribute to any MAO inhibition.

A study was conducted to better understand the influence of hypericin, hypericum total extract, and hypericum fractions on the activity of MAO.[10] An inhibition of MAO was shown using the following concentrations:

- Hypericin to 10^{-3} mol/L
- Hypericum total extract to 10^{-4} mol/L
- One extract fraction up to 10^{-5} mol/L

The key result from this study, as well as in another in vitro/ex vivo study, was the demonstration that the concentrations of inhibition shown, particularly with regard to the inhibition of MAO activity, were likely insufficient to explain the clinically proven antidepressive effect of St. John's wort extract.[10,11] Therefore additional mechanisms are likely responsible for these clinical benefits. The same group also looked at effect on COMT and found no inhibition either.[10]

Modulation of IL-6 Activity

The modulating effect of St. John's wort extract on IL-6 is the most interesting, as it proposes a mechanism by which St. John's wort interacts with the link between the immune system and mood. The cytokine IL-6 is heavily involved in the communication between cells within and outside the immune system. With regard to the nervous system, IL-6 is known to modulate hypothalamic-pituitary-end organ axes, especially the hypothalamic-pituitary-adrenal axis. The hypothesis is that an elevation in IL-6 results in activation of the hypothalamic-pituitary-adrenal axis, leading to elevations in corticotropin-releasing hormone and other adrenal regulatory hormones—hallmark features in depression. St. John's wort extract showed an ability to reduce IL-6 levels; therefore this action may explain the clinical effectiveness of St. John's wort extract.[12]

Animal studies comparing the effects of hypericum in mice who produce normal IL-6 levels versus IL-6 knockout mice (those with no IL-6 expression) found higher levels of serotonin produced in the former group.[13] An in vitro study looked at blood in five healthy volunteers and four depressive patients. The release of IL-6, IL-1β, and tumor necrosis factor-α was measured quantitatively after an incubation time of 24 hours on microtiter plates. A massive suppression of IL-6 release was found with samples exposed to phytohemagglutinin-stimulated St. John's wort extract.[12] If these effects can be duplicated in vivo, it would provide a mechanism by which St. John's wort extract modulates release of corticotropin-releasing hormone and, subsequently, mood.

Serotonin Reuptake Inhibition

St. John's wort extract was also shown to inhibit the reuptake of serotonin in a similar fashion to drugs like fluoxetine (Prozac), paroxetine (Paxil), and sertraline (Zoloft). The study that demonstrated a 50% serotonin reuptake inhibition used the 0.3% hypericin content standardized extract at a concentration of 6.2 mg/mL and did not attempt to identify the active inhibitors. The authors of the study concluded that "the antidepressant activity of hypericum extract is due to inhibition of serotonin uptake by postsynaptic receptors." However, results were conflicting with regard to the effect of acute doses of St. John's wort extracts on the serotonergic system in rodents.[14] A marked increase of both serotonin and its metabolite 5-hydroxyindoleacetic acid (5-HIAA) was reported in rat brain cortex. Other researchers reported high 5-HIAA and serotonin levels in the mouse hypothalamus and hippocampus, but not in the cerebral cortex, where only 5-HIAA increased. However, other research found no significant changes in either serotonin or 5-HIAA after a schedule of treatment during the forced swimming test. One study of the rat locus coeruleus showed that systemic hyperforin induced a lasting and marked (100%–200%) increase in the extracellular concentrations of serotonin, but not 5-HIAA.[15]

Sigma 1-Receptor Activation and GABA Inhibition

There is growing research that St. John's wort may affect function via Sigma$_1$ σ receptors and GABA receptors. σ receptors were shown to play an important role in antidepressive effects because selective σ_1-receptor agonists, as well as typical antidepressants, reduced the immobility time in the forced swimming and tail suspension tests.[16] Research demonstrated that the pretreatment of rats with St. John's wort extracts or hyperforin trimethoxybenzoate could block other ligand binding to σ-receptors. The antidepressant-like activity of hyperforin trimethoxybenzoate was completely antagonized by pretreating rats with BD 1047, a selective σ_1 antagonist. These results, together with the previous observation that agonists at σ_1 receptors are active in antidepressant models in rats, suggest that St. John's wort's antidepressant effects might be mediated in part by an indirect action on σ-receptors.[14] Looking at lung vasculature in cats, St. John's wort showed a GABA receptor vasodepressant effect.[17] Other in vitro studies have also shown a GABA receptor inhibition by hypericum. This finding may indicate that GABA inhibition may also be partially responsible for its antidepressant action.

Hypothalamic Gene Transcription

A fascinating study evaluated the effect of both St. John's wort and antidepressant imipramine on gene transcription in the rat hypothalamus. The depressed patient's hypothalamus is known to manifest changes associated with food intake, decreased libido, and abnormal circadian rhythms. This research found a significant correlation of six genes directly modulated by both these test compounds. The probability of this occurring by chance was 1.14×10^{-23}. The functions of these specific genes include protein synthesis and degradation, cellular scaffolding and intracellular transport, mitochondrial and glycolytic energy metabolism, and cellular signaling through modulation of calcium-binding proteins. Although the implication of this research is not totally clear, the authors postulated that these modulated gene functions might be related to immune and inflammatory downregulation with neuronal protection from cellular injury.[18]

Amentoflavone, one of the many flavone contents in St. John's wort, was shown to cross the blood–brain barrier by passive diffusion.[19] This might account for the ability of this botanical to travel into the brain and affect CNS gene transcription. Nevertheless, one point regarding the probable synergistic effects of the St. John's wort constituents should be underscored: given the multitude of active components in this botanical medicine, it is likely that synergistic sites of action outside the CNS, in accordance with CNS effects, account for the complete and effective global actions of St. John's wort.

Extracts of St. John's wort were tested in various animal models designed to study its antidepressant effects. In these studies, St. John's wort extract was found to enhance the exploratory activity of mice in a foreign environment, extend the narcotic sleeping time in a dose-dependent fashion, antagonize the effects of reserpine, and decrease aggressive behavior in socially isolated male mice.[20] These activities are consistent with the expected effects of antidepressant compounds and appear to be the result of increased monoamine activity.

Antiviral Activity

In vitro studies showed that hypericin and pseudohypericin exhibit strong antiviral activity against herpes simplex virus I and II, as well as influenza types A and B and vesicular stomatitis virus.[21] These compounds also demonstrated remarkable antiviral activity against Epstein-Barr virus.[22]

Researchers from New York University Medical Center and the Weizmann Institute of Science in Israel generated a tremendous amount of excitement when they demonstrated the antiretroviral activity of hypericin and pseudohypericin.[23] This preliminary study examined the effect of these compounds on two animal retroviruses, Friend leukemia virus and radiation leukemia virus, both in vitro and in vivo (in mice). The researchers found the effective dose of hypericin in mice to be 1.5 to 2 mg/mL confirming the potency of a relatively small dose of this herbal extract.

Two possible mechanisms were described to explain the antiviral activity of both hypericin and pseudohypericin.[24] First was inhibition of assembly or processing of intact virions from infected cells—released virions contain no detectable activity of reverse transcriptase. Second, these compounds also directly inactivate mature and properly assembled retroviruses.

The antiviral activity of hypericin against HIV appears to require interaction with light to activate the hypericin.[25,26] Another requirement is sufficient concentrations, as entry of hypericin into infected cells depends on the concentration of hypericin in the blood. At sufficient concentrations, hypericin incubated with HIV-infected whole blood decreases culturable HIV, indicating significant antiviral activity.[27]

Antibacterial Activity

St. John's wort extracts have broad-spectrum antimicrobial activity against both gram-negative and gram-positive bacteria. The organisms studied included *Staphylococcus aureus, Streptococcus mutans, Proteus vulgaris, Escherichia coli,* and *Pseudomonas aeruginosa.*[28]

Pharmacokinetic Studies

Pharmacokinetic studies indicate that hyperforin, as well as hypericin and pseudohypericin, have adequate absorption to produce serum levels that correspond to the levels showing benefit in in vitro studies.[29] However, hyperforin is the only ingredient of *H. perforatum* that could be determined in the brains of rodents after oral administration of alcoholic extracts. This result and others seem to indicate that it may be the chief constituent responsible for the antidepressant effects of *H. perforatum.*

CLINICAL APPLICATIONS

As the only truly recognized herbal treatment for the condition, St. John's wort is most recognized for the treatment of depression. It can also be of benefit in the treatment of chronic viral infections, restless legs, and topically for various skin and pain conditions.

Depression

Extracts of St. John's wort standardized for hypericin content (most studies used the 0.3% hypericin content extract) have significant support in the treatment of mild to moderate depression. The official German Commission E monograph for St. John's wort lists psychovegetative disturbances, depressive states, fear, and nervous disturbances as clinical indications for St. John's wort.[30]

St. John's wort extract improved many psychological symptoms, including the following:

- Depression
- Anxiety
- Apathy
- Sleep disturbances
- Insomnia
- Anorexia
- Feelings of worthlessness

Even more impressive is that St. John's wort extract was able to achieve these benefits without producing significant side effects.

The history of meta-analyzing hypericum studies has been full of tumult and contradiction. One meta-analysis in 1996 of 23 randomized trials included 1757 outpatients with mainly mild or moderately severe depressive symptoms. It showed that hypericum extracts were significantly superior to placebo and as effective as standard antidepressants. This analysis revealed 0.8% dropouts for side effects with hypericum compared with 3.0% for standard antidepressant drugs. In this research, side effects occurred in 19.8% of patients on hypericum and 52.8% of patients on standard antidepressants.[31]

However, there were two well-publicized clinical studies claiming that hypericum was ineffective in treating depression.[32] One 8-week trial employed suboptimal doses of hypericum, using 900 mg/day for patients with severe depression. If there was no response, doses were increased to only 1200 mg/day. In a previous severe depression study, patients improved significantly on hypericum, compared with placebo and the antidepressant drug imipramine, on a dose of 1800 mg/day.[33,34] Given that the trial was funded by a company that manufactures antidepressant medications, and in light of a strong history of positive hypericum trials, it is doubtful that this accurately reflects the clinical ability of such a well-studied botanical.

A second 8-week study from 2002 made a similar suboptimal dosing error, and subsequently deemed hypericum to be ineffective. A valuable note in this study was that the comparison drug, sertraline (with a much stronger side effect profile than hypericum), was not any more effective than hypericum or the placebo.[35] The study generated considerable media attention as showing SJW is ineffective—ignoring or underplaying the other finding that the standard antidepressant was also ineffective.

A third meta-analysis in 2008 included only trials from 1995 to 2006 that were randomized and double-blinded, involving patients with major depression. Extracts of hypericum were compared with placebo or standard antidepressants, including fluoxetine, sertraline, imipramine, citalopram, paroxetine, and amitriptyline. In all, 29 studies involving 5489 patients were analyzed. Hypericum extracts tested in the trials were superior to placebo and equally effective as standard antidepressants. Patients given hypericum extracts dropped out of trials less frequently because of lower adverse effects than those given standard antidepressants. It was concluded that the results "imply that an attempt of treating mild to moderate major depression with one of the hypericum preparations positively tested in clinical trials is clearly justified," but added that evidence was "still insufficient to draw conclusions about the efficacy of hypericum for treating severe major depression." The authors cited that the mild physical side effects associated with hypericum might be enhancing the placebo effect. A second concern was that hypericum was popular in Germany, so the more robust effects in the studies from German-speaking countries might be attributable to an "allegiance" effect. A third concern was that, although positive, the larger-scale trials used in the analysis

produced overall smaller effects.[36] Another meta-analysis published in 2016 was consistent with past reviews. This review of randomized controlled trials examined 35 studies, evaluating a total of 6993 patients looking at hypericum extracts including 0.3% hypericin and 1% to 4% hyperforin. The herb exhibited over 50% greater response compared with placebo, with an effect at least as good as antidepressants and with significantly fewer adverse events.[37]

Hypericum has been compared head-to-head with leading antidepressant medications multiple times.[38,39] In an example randomized, controlled, double-blind trial, 70 patients with mild to moderate depression received one tablet of either hypericum extract or fluoxetine twice a day for 6 weeks. As evaluated by the 17-item Hamilton Rating Scale for Depression (HAMD), the von Zerssen depression scale (DS), and patients' response, there were significant decreases (P <0.001) in symptoms in the St. John's wort group (50%) and in the fluoxetine group (58%) on their HAMD scores. The hypericum extract achieved 83% of the efficacy of fluoxetine on the HAMD and 78% on the DS. Assessments by physicians and patients indicated considerable improvement with no between-treatment differences.[38] The authors concluded that the hypericum tested in this study was therapeutically equivalent to fluoxetine and that it was a reasonable alternative to synthetic antidepressants.

Another recent meta-analysis of St. John's wort reviewed 27 clinical trials with a total of 3808 patients comparing the use of St. John's wort and selective serotonin reuptake inhibitor (SSRI) medications. Study durations varied from a 4- to 12-week period, and revealed St. John's wort had comparable efficacy. Even more, there was also a significantly lower discontinuation and dropout rate compared with the drugs. Safety compared with SSRIs showed significantly lower discontinuation of the herb.[40]

Hypericum extract was similarly tested and proven at least as effective as sertraline in the treatment of mild to moderate depression in a small group of outpatients.[39] Efficacy and tolerability of hypericum extract was also compared with imipramine and was found equivalent to the drug in treating mild to moderate depression. In addition, as expected, patients tolerated the hypericum better.[41]

Although preliminary, St. John's wort may be a safe recommendation during pregnancy and postpartum depression (see "Pregnancy" and "Nursing" for more information). St. John's wort has also been studied in children. Three open-label trials in depressed children found benefit with minimal side effects. The first study of 101 children, less than 12 years of age, were administered 300 to 1800 mg/day at a standardized dose of 900 mcg hypericin.[42] A second, 8-week open-label trial in 33 youths from 6 to 16 years of age used a dose of 150 to 900 mg/day, and enjoyed an 80% response rate.[43] A third trial of 26 adolescents given 300 mg three times a day had an 82% response rate in the 11 patients who completed the study. However, in this study, 15 patients withdrew either because of noncompliance or worsening of symptomology.[44,45]

Seasonal Affective Disorder

Seasonal affective disorder (SAD) represents a subgroup of major depression with a regular occurrence of symptoms in autumn/winter and full remission in spring/summer (see Chapter 142 Affective Disorders for more discussion). Light therapy has become the standard treatment for this type of depression. Apart from this, pharmacotherapy with antidepressants also seems to provide an improvement of SAD symptoms.[46] SAD patients with major depression were randomized in a 4-week treatment study with 900 mg/day of St. John's wort extract (0.3% hypericin content) combined with either bright (3000 lux; n = 10) or dim light (less than 300 lux therapy). The significant reduction in the Hamilton Depression Scale in both groups (72% and 60%, respectively) indicated that St. John's wort extract might benefit patients with SAD as a sole therapeutic agent, as well as in combination with light therapy.

Insomnia

St. John's wort was shown to improve sleep quality and well-being in healthy elderly subjects.[47] With antidepressant drugs, particularly tricyclic antidepressants and MAO inhibitors, rapid eye movement sleep is reduced. St. John's wort did not interfere with rapid eye movement sleep like other antidepressants and was shown to increase the intensity of deep sleep during the total sleeping period as demonstrated by brainwave studies. Although St. John's wort improved sleep quality, it did not act as a sedative (i.e., it did not reduce sleep onset), nor did it change total sleep duration.

Mental Function

One of the most interesting comparative studies was a double-blind study in which St. John's wort extract (0.3% hypericin content) was compared with maprotiline in 24 healthy volunteers by measuring resting brainwave (electroencephalography) tracings and mental activity (visual and acoustic evoked potentials).[48] Interpretation of the differences in reactions indicated that, unlike maprotiline, which interferes with mental function, St. John's wort actually improved memory and other mental activities. Long-term administration of St. John's wort in rats improved learning and spatial memory with significant changes in the content of monoamines in several brain regions.[49]

Acquired Immunodeficiency Syndrome and Other Viral Infections

St. John's wort may be of value in the treatment of AIDS. In response to in vitro and animal studies, many AIDS patients began self-administering St. John's wort where patients reported feeling better with a more positive outlook, more energy, and less fatigue.[50,51] Hypericum seems to suppresses HIV-1 expression and inhibits its replication.[52] A St. John's wort protein called P27SJ has also been shown to minimize HIV-1 induced neurotoxicity in the brain by inhibiting viral replication and calming inflammatory response.[53] Small studies looking at AZT treatment with St. John's showed modest T-cell count increases of 13% from baseline. Another open pilot study of 18 HIV patients showed stable or even increasing counts of absolute T-helper cells over the 40 months, with lowered opportunistic infections[54] (for further information about HIV/AIDS, see Chapter 173).[55,56] St. John's wort may have negative reaction with protease inhibitor drugs and simultaneous use with HIV medications should be avoided.

Research suggests that St. John's wort may be a useful adjunctive treatment for herpes simplex, mononucleosis, and influenza, although further human studies are necessary to establish the optimal dosage of the standardized extract. Combined with its antidepressant activity, St. John's wort also appears to be a promising treatment for chronic fatigue syndrome.

Restless Legs Syndrome

Restless legs syndrome (RLS), also known as Willis-Ekbom disease, was treated with a low dose (300 mg qd) of St. John's wort extract in 21 patients with a concentrated extract for 3 months. Seventeen of these patients found significant relief. Researchers suggested it decreased thyroid levels by increasing thyroid hormone degradation through the CYP3A4 enzyme isoform and, perhaps, by increasing stimulates the expression of P-glycoprotein.[57]

Topical Application

St. John's wort has a historical use as an aid in wound healing and dermatological support. Research demonstrated antibacterial and wound healing activity. Although research is relatively scant,

hyperforin encourages growth and differentiation of keratinocytes, while hypericin acts as a photosensitizer that can be employed for selective treatment of nonmelanoma skin cancer.[58] St. John's wort preparations have also been used in burns, as a sunscreen, and in the treatment of muscular pain.[3] Oil-based preparations are preferred for topical applications.

DOSAGE

The dosages of St. John's wort preparations are based on their hypericin content. The overwhelming majority of the studies in depression used St. John's wort extract standardized to contain 0.3% hypericin and 3% to 5% hyperforin. This extract is produced via an extraction with 80% methanol (which is subsequently removed). Although hypericin and hyperforin are key components, this extract is composed of a wide range of compounds constituting the remaining 95% of the extract. Manufacturers of these standardized extracts employ high-performance liquid chromatography techniques to identify not only the hypericin, pseudohypericin, and hyperforin, but also related compounds, flavonoid components, xanthones, cinnamic acid, and several other key components. The point is that although the dosage is based on hypericin levels, assuring appropriate levels of these other constituents is also vitally important.

Dosing of three times a day is recommended because of its short half-life. To achieve the benefits noted in the clinical trials, it is difficult to recommend any other forms beyond standardized extracts. Nonetheless, here are dosage recommendations for various forms of St. John's wort:

- Dried flowers: 2 to 4 g three times a day
- Tincture (1:5): 3 to 6 mL three times a day
- Fluid extract (1:1): 1 to 2 mL three times a day
- Standardized solid (dry-powdered) extract (0.3% hypericin and 3%–5% hyperforin): 900 to 1800 mg a day

SAFETY/TOXICITY

Although the conventional medical community focuses on concerns for herbal and natural remedies in terms of safety, a balanced look at botanicals suggests both benefits and risk. Looking at St. John's wort, there seems to be an exemplary beneficial profile and definite concerns in terms of photosensitivity and drug interactions. There are also some beneficial drug interactions to consider. The literature on pregnancy and breast feeding suggests possible safety, but there is not enough literature to be clear.

The side effect profile of hypericum extract is minor, and is safer compared with the well-known side effects of antidepressant medications.[59] Also notable, there seems to be no memory impairment, an advantage for senior patients over conventional drugs.[60] St. John's wort also seems to be less toxic on the wallet: an Australian group studied the economic effects of St. John's wort versus antidepressants, and found the herbal remedy to have reduced cost profile compared with generic antidepressants with advantages as a result of its low incidence of adverse effects.[61]

Serotonin Syndrome Concern

A main concern in the literature is regarding excessive levels of serotonin called "serotonin syndrome" where symptoms can include mental status changes (e.g., agitation, hallucinations, and coma), autonomic instability (e.g., tachycardia, labile blood pressure, and hyperthermia), neuromuscular aberrations (e.g., hyperreflexia and incoordination), and/or gastrointestinal tract symptoms (e.g., nausea, vomiting, and diarrhea). Severe cases can resemble neuroleptic malignant syndrome, which includes hyperthermia, muscle rigidity, autonomic instability with possible rapid fluctuation of vital signs, and mental status changes. An example of this was reported in a study of four elderly patients who ostensibly developed serotonin syndrome as a result of an interaction between tramadol and mirtazapine.[62] Although polypharmacy of antidepressants caused this syndrome, no reports of natural substances causing this syndrome have been reported to date. Because its action on serotonin is minor at best, it is unlikely that hypericum would cause this syndrome. Nevertheless, monitoring is prudent when working with hypericum, and serotonin precursors tryptophan or 5-hydroxytryptophan along with SSRIs. There are case reports linking St. John's wort to mania, suggesting it may not be a good choice for bipolar disorder.[63]

Photosensitivity

Although hypericum was demonstrated to induce photosensitivity in some patients (less than 1% of people taking 900 mg once a day or more), this is not likely with standard dosages. Cases of photosensitivity occurred mainly in HIV patients using higher than normal quantities for an antiviral effect.[56] Because of the photosensitivity concern, avoidance of strong sunlight and other sources of ultraviolet light when using St. John's wort is often recommended to individuals, especially those with fair skin. However, although this recommendation may be appropriate, it must be pointed out that the therapeutic dosage of 2.7 mg/day of hypericin is about 30 to 50 times below the level found to produce phototoxicity.[64]

Pregnancy

Despite the ample research on St. John's wort, relatively little research has focused on safety in pregnancy and breast feeding. Animal pregnancy toxicology studies showed no change in maternal weight gain or gestational length[65] and no change in offspring anomaly rates.[66,67] These negative animal studies can be reassuring because they suggest a lack of structural or functional deficits attributable to hypericum exposure during gestation.[68] However, we must always keep in mind that rodents and humans have varying detoxification abilities.

Human studies are few. In 1998 there were reports of two women who took hypericum during their pregnancies to avoid using conventional synthetic medications. Both cases seemed to reveal no concerns. One of these cases was of a 38-year-old woman who started hypericum at 24 weeks' gestation. The pregnancy was unremarkable, with the exception of late onset of thrombocytopenia (which the author did not attribute to hypericum). The offspring was born healthy, had a normal birth weight, normal APGAR scores, and physical examination and laboratory results were normal. Infant behavioral assessment at 4 and 23 days was normal.[69]

One 2006 review by naturopathic physicians looked at the evidence on the use, safety, and pharmacology of hypericum. This review searched seven databases, including the Cochrane bases, MedLine, Natural Database, and Natural Standard. Some unpublished research and bibliographies were also included. Data were compiled according to grade of evidence. The researchers found varying levels of scientific evidence. They concluded that there was in vitro evidence from animal studies that hypericum during pregnancy does not affect cognitive development or cause long-term behavioral defects but found some evidence of lower offspring birth weight. It is important to remember that rodents have very different detoxification abilities, and extrapolation to humans may not be prudent. This review also pointed to weak scientific evidence that hypericum induced CYP450 enzymes, which may lower serum medication levels below therapeutic range, which would be of concern when administering medications during pregnancy. The authors concluded that caution is warranted with the

use of hypericum during pregnancy until further high-quality human research is conducted to determine its safety.[70]

The first study of hypericum looking to determine whether exposure could be associated with major malformations prospectively followed 54 subjects using hypericum and compared them with a matched group of 108 pregnant women taking other pharmacological therapy for depression, as well as a third group of healthy women, who were not exposed to any known teratogens. The study showed that malformation rates were similar across the three groups, with 5%, 4%, and 0% in hypericum, pharmaceutical subjects, and healthy groups, respectively. This was not different than the 3% to 5% risk expected in the general population. Live birth and prematurity rates were also not different among the three groups. The authors suggested this first human study on pregnancy the did provide some evidence of fetal safety.[71] More studies are very welcome.

Nursing

Albeit in its own infancy, studies using hypericum during breast feeding are starting to support its use and safety for depressed mood in mothers while breast feeding. Animal studies using doses up to 25 times the equivalent recommended human dose throughout lactation did not show any neurobehavioral or developmental effects in offspring.[65] One study evaluating the safety of St. John's wort while nursing studied 33 breast-feeding women over a 2-year period. Compared with 101 disease-matched and 33 age-matched controls, there were no statistically significant differences found in maternal or infant demographics or maternal adverse events. No significant difference was observed in the frequency of maternal report of decreased milk production among the groups, nor was a difference found in infant weight over the first year of life.[72] A review of multiple databases also suggested that hypericum consumption during lactation did not affect maternal milk production or infant weight, but could cause colic, drowsiness, or lethargy. The authors of this review concluded that hypericum use during lactation appeared to be of minimal risk but could cause some mild side effects.[70] St. John's wort may be a choice if other natural recommendations are not sufficient for the lactating female, although more data would be welcome to confirm safety.

DRUG INTERACTIONS

Historically, those taking St. John's wort have been advised to avoid foods and medications that are known to interact with MAO-inhibiting drugs (such as tyramine-containing foods like cheeses, beer, wine, pickled herring, and yeast). In addition, drugs such as L-dopa and SSRIs were categorically recommended to avoid. However, given recent research demonstrating the lack of in vivo MAO inhibition, this recommendation is no longer justified.

Strong evidence warrants precaution when combining St. John's wort with several pharmaceutic therapies. St. John's wort was found to decrease the plasma concentrations of alprazolam, amitriptyline, digoxin, cyclosporine, indinavir, irinotecan, methadone, nevirapine, simvastatin, tacrolimus, theophylline, warfarin, phenprocoumon, and oral contraceptives. In the case of cyclosporine, the interaction resulted in some transplantation graft rejections. Hypericum was also shown to decrease the bioavailability of the R and S forms of verapamil.[73,74]

When combined with serotonin reuptake inhibitors, antidepressants (e.g., sertraline, paroxetine, nefazodone), or buspirone, hypericum can theoretically contribute to "serotonergic syndrome," a syndrome caused by excess serotonin levels. This syndrome has been iatrogenically induced by psychotropic and nonpsychotropic pharmaceutic coadministration and may include symptoms such as agitation, confusion, severe shivering, diaphoresis, myoclonus, hyperreflexia, mydriasis, tachycardia, and fever.[75]

Women on oral contraception should be informed regarding the possible decrease in birth control efficacy with hypericum. St. John's wort causes an induction of ethinyl estradiol and norethindrone metabolism consistent with increased CYP3A activity and can contribute to intracyclic bleeding.[76] One study evaluated the use of St. John's wort and oral contraception. St. John's wort appeared to contribute to breakthrough bleeding in 7 of 12 women (vs. 2 of 12 women in the oral contraception alone group). When taking oral contraceptive pills with St. John's wort, women may experience breakthrough bleeding and should consider adding a barrier method of contraception.[77]

Although there is great concern for negative effects on drug metabolism, hypericum is now being studied for its positive effects on medication outcomes as well. One study using the platelet inhibitor clopidogrel found that 2 of 10 patients using clopidogrel were poor responders but use of 300 mg hypericum for 2 weeks in these patients resulted in an increase in platelet inhibition of 20%. A previous study using 300 mg three times daily demonstrated an increase of 36%. Furthermore, no negative changes were seen in patients on statin medications.[78] Hypericum may be a good choice in poor responders, or to help lower the dose necessary in normal responders experiencing side effects. A small open trial of 20 patients looked at concomitant use of metformin alone (1 gram) on glucose tolerance and insulin action compared with using with the herb. There was no apparent effect on the steady-state pharmacokinetics of metformin, save for a minor renal clearance reduction of the medication.[79]

Lobelia inflata (Indian Tobacco)

Michael T. Murray, ND

OUTLINE

Lobelia inflata (family: Campanulaceae)
Common names: Indian tobacco, pukeweed, asthma weed, gagroot, vomitwort

GENERAL DESCRIPTION

Lobelia is an indigenous North American annual or biennial plant with an erect, angular, hairy stem that contains a milky sap and grows from 6 inches to 3 feet in height. Numerous small, two-lipped blue flowers grow in spike-like racemes from July to November.

CHEMICAL COMPOSITION

Lobelia contains about 0.48% pyridine (piperidine) alkaloids composed mainly of lobeline (Fig. 89.1), with lesser amounts of lobelanine, lobelanidine, and other alkaloids.[1] Other constituents include resin, gum, lipids, and chelidonic acid.[2]

HISTORY AND FOLK USE

Lobelia was named after Matthias de Lobel (1570–1616), a famous French botanist and physician to the court of King James I. After chewing the plant, early settlers noted that the taste was similar to tobacco and produced effects like that of nicotine, the principal alkaloid in domestic tobacco, *Nicotiana tobaccum*. Native Americans also smoked the dried leaves to obtain the central nervous system effects of the alkaloids in the plant. Thus lobelia was commonly referred to as "Indian tobacco."

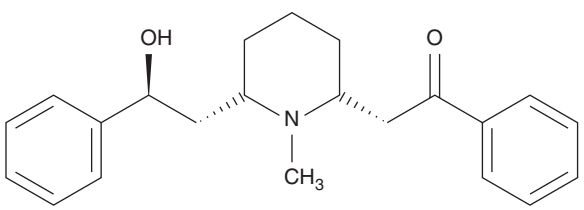

Fig. 89.1 Lobeline.

Lobelia became one of the most commonly used herbs by Thomsonians, who used it as an emetic, diaphoretic, expectorant, sedative, antispasmodic, and antiasthmatic. It has been used for the following conditions:

- Asthma
- Whooping cough
- Bruises
- Sprains
- Ringworm
- Insect bites
- Poison ivy symptoms

Thomson stated: "There is no vegetable which the earth produces more harmless in its effect on the human system, and none more powerful in removing disease and promoting health than lobelia."[3]

PHARMACOLOGY

Lobeline possesses many of the same pharmacological actions as nicotine, only less potent. However, its complex actions cannot be explained simply as being a weaker version of nicotine. Detailed pharmacological investigation comparing the effects of lobeline with nicotine indicate that lobeline possesses novel effects on nicotinic receptors.[4,5]

Respiratory Effects

One of the earliest known uses of lobeline was as a safe, short-acting respiratory stimulant. This respiratory stimulation was shown to be caused by direct stimulation of the carotid body chemoreceptors. The powerful respiratory stimulant action of lobeline has been used for stimulation of respiration in fever cases, cases of paralysis of respiratory centers caused by narcotic poisoning, alcohol, soporifics, morphine, narcosis, or spinal anesthesia. Lobeline has also been used to treat accident victims who have been buried, nearly drowned, hit by lightning or electrically shocked, and poisoned by asphyxiating gases.

Gastrointestinal Effects

The emetic action of lobeline is mediated by its stimulation of the emetic chemoreceptor trigger zone in the area postrema of the medulla oblongata (outside the blood–brain barrier) and activation of the vagal

and spinal afferent nerves that form the sensory input of the reflex pathways involved in vomiting.[6]

Central Nervous System Effects

One of the more promising lines of research with lobeline is that it appears to disrupt the fundamental mechanisms of dopamine storage and release. This action may help in antagonizing the neurochemical and behavioral effects of the psychostimulants amphetamine and methamphetamine. Lobeline was found to inhibit the amphetamine-induced release of dopamine in vitro and amphetamine-induced hyperactivity, drug discrimination, and self-administration in animal experiments.[7,8] Because lobeline is not addictive itself, it may reduce the abuse liability of these psychostimulants.

CLINICAL APPLICATIONS

Lobelia is primarily used as an expectorant in such conditions as pneumonia, asthma, and bronchitis. It appears that some of its actions may be mediated by the adrenal cortex.[9] Experimentally induced lung edema in rats was responsive to lobeline in many models that were unresponsive to any other medication. Furthermore, although lobeline causes bronchoconstriction in dogs and rats, in guinea pigs and (presumably) humans, the opposite—bronchodilation—occurs.[10]

Although effective when used alone in the treatment of asthma, it has traditionally been used in combination with other botanical agents, including *Capsicum frutescens* and *Symphlocarpus factida.*

Lobelia has also been used as an aid in stopping smoking with equivocal results from clinical trials.[11]

DOSAGE

- Dried herb: 0.2 to 0.6 g three times a day
- Tincture: 15 to 30 drops three times a day
- Fluid extract: 8 to 10 drops three times a day

TOXICOLOGY

Although lobelia has a reputation for being toxic, a thorough review of the medical literature was unable to find any well-documented case of serious problems or death caused by lobelia.[12] The main reason may be that lobelia causes nausea and vomiting when the amount used is too high, thereby avoiding absorption of toxic amounts. In general, a dosage of more than 1 mL of tincture one time is enough to produce significant nausea and possibly vomiting. Lobelia should not be used for more than 1 month consecutively and should be avoided during pregnancy and breastfeeding.

Like nicotine poisoning, toxic symptoms of lobelia include the following:

- Nausea
- Salivation
- Diarrhea
- Disturbed hearing and vision
- Mental confusion
- Marked weakness

Faintness and prostration ensue; blood pressure falls; the pulse becomes weak, rapid, and irregular; breathing is difficult; and collapse occurs, followed by convulsions. Death may conceivably result from respiratory failure. The antidote in acute poisoning is 2 mg of atropine, which is given subcutaneously.

DRUG INTERACTIONS

There are no known drug interactions with lobelia.

Medicinal Mushrooms

Anna Sitkoff, BS, ND

OUTLINE

INTRODUCTION

Mushrooms have a millennia-long history of consumption as food and medicine all over the world with their use documented in ancient writings and even Asztec pictographs. Scientific Western herbal materia medicas such as King's *American Dispensatory*, first published in 1854, and *Kuts-Cheraux's Naturae Medicina and Naturopathic Dispensatory*, published in 1953, have long provided clinical guidance for several mushrooms, few of which are mentioned here. Chinese medicine has explored their use far more extensively, which has led recently to substantial laboratory and clinical research. The astute reader will notice that the majority of the over 200 references in this chapter have been published in the past 10 years.

Medicinal mushrooms are one of the fastest growing categories of supplement sales and their market is projected to hit $50 billion in the coming years.[1] In vitro and in vivo research on medicinal fungi has revealed many promising ways to integrate this medicine into our current health care. The physiological activities are vast and target many of the physiological dysfunctions that are the root cause of disease: protecting mitochondria, decreasing inflammation, and reducing oxidative stress in the human system.

GENERAL DESCRIPTION

The fungi kingdom has been both feared and revered by mankind. Fungi come in many forms, from mold to jelly, giant underground mycelial mats to claws and phalluses. "Mushroom" is a commonly used name to describe macrofungi with a unique fruiting body, and they are categorized based on the morphology of the spores they produce, with a majority being basidiomycetes and some ascomycetes. Intriguingly, humans are more related to fungi than to florae, respiration and digestion being two fundamental and fascinating similarities that we have with them.

There are 14,000 to 22,000 known species of mushrooms, with an estimated 140,000 species worldwide, and about 7000 species that have known benefits for humans.[2] In relation to the number of known species, the number of investigated species is small. Medicinal mushrooms as a whole have immune-centric qualities, making them a valuable medicinal resource for common debilitating ailments such as cancer and autoimmunity.

CHEMICAL COMPOSITION

Mushrooms are all built from the same general chemical symphony. Among the most researched constituents are polysaccharides, triterpenes, phenolic compounds, ergosterol, ergothioneine, fatty acids, proteins, and trace elements. Each of these components plays a role in the human system to facilitate healing and general wellness. See Fig. 90.1 for a description of each class of chemical and its medicinal mechanism.

Polysaccharides

Biologic Response Modifiers

The fungal cell wall is composed of many layers—mannoproteins, β-(1,6)-glucan and β-(1,3)-glucan (Fig. 90.1), and chitin. Humans do not

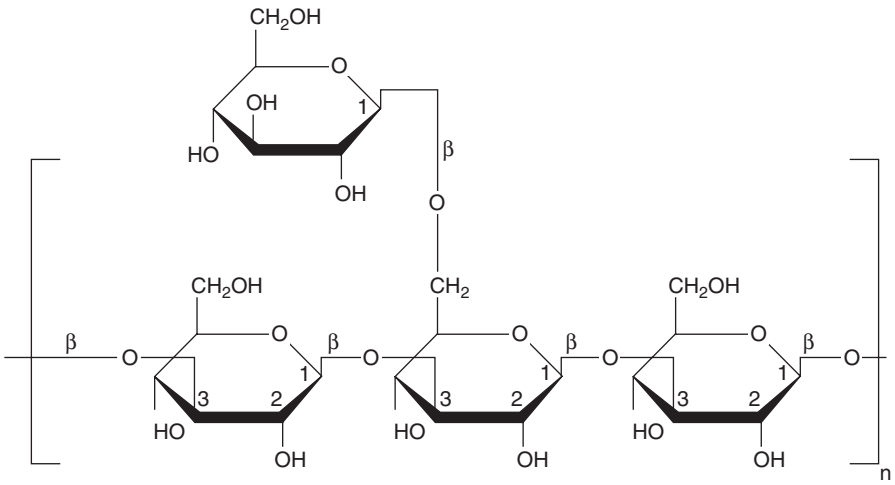

Fig. 90.1 Pleuran, a polysaccharide isolated from *Pleurotus ostreatus* (Oyster mushroom).

make chitinase and cannot use chitin for anything other than nondigestible fiber. Chitin can be broken down by different processing techniques, including heat. Once this is performed, the mannan and beta-glucan layers can be used as medicine. From an immunological perspective, these layers are considered pathogen associated molecular patterns (PAMPs) and bind to pathogen recognition receptors (PRRs) on cells in the innate immune system—macrophages, granulocytes, dendritic cells, and natural killer cells. The majority of binding occurs in the gut associated lymphoid tissue (GALT), where Peyer's patches contain cells of the innate immune system. Specific receptors that bind these β-glucans include dectin-1 and TLR-2.[3] Binding has a hormetic effect, creating a stress response in the immune system, stimulating the release of cytokines with anti-inflammatory, proinflammatory, antiviral, and anticancer activity. These cytokines stimulate an increase in natural killer cells and cytotoxic T cells—overall, generating a stress signal leading to a more primed immune system.

Blood Sugar Regulation

Polysaccharides inhibit the enzyme alpha-glucosidase, which is known to participate in the rise in blood sugar after a meal. Additionally, polysaccharides have also been shown to upregulate GLUT 4, an insulin-response glucose transporter, while downregulating NF-κB, a nuclear transcription factor that regulates inflammation.[4-6]

Antioxidant

Polysaccharides increase the activity of hepatic oxidative enzymes such as catalase, glutathione peroxidase, and superoxide dismutase, effectively increasing levels of glutathione and decreasing malondialdehyde levels (a marker of lipid peroxidation). Generally, these compounds support the innate antioxidant systems in relieving oxidative stress and free radical damage.[7]

Prebiotic

The oligosaccharides and polysaccharides contained in mushrooms are consumed by *Bifidobacterium* and *Lactobacillus*, two important bacteria in a healthy microbiome.[4,8,9]

Triterpenoids

As the mushroom matures from primordia to fruiting body, the enzyme CYP450 stimulates synthesis of triterpenes (Fig. 90.2); therefore, there are more of these compounds found in the fruiting bodies of mushrooms. The triterpenes are commonly lanostane triterpenes and may be referred to as "lanostanoids." Triterpenes are major compounds of interest in cancer research because they have been shown to be directly cytotoxic to many

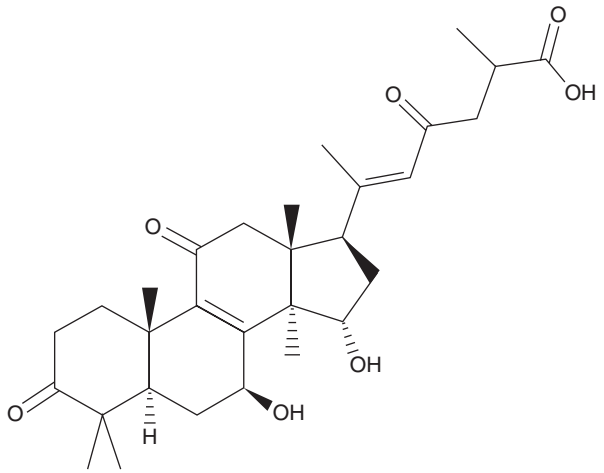

Fig. 90.2 Ganoderic acid, a triterpene isolated from *Ganoderma* spp. (Reishi).

cancer cell lines.[10-14] They also have specific antiviral activity through inhibition of the enzyme, neuraminidase.[15-17] These compounds are also beneficial in the treatment of hypersensitivity reactions, including allergy, asthma, dermatitis, and rhinitis by inhibiting histamine release from mast cells.[10]

Phenolic Compounds

Phenolic compounds are the building blocks for pigments in mushrooms, and once absorbed in the small intestine, they act as antioxidant, anti-inflammatory, and antiviral agents. The most well researched phenolic compounds among mushrooms are hispolon (Fig. 90.3) and phelligridin, both found in *Phellinus* spp. and *Inonotus obliquus*.[18-20]

Ergosterol

Ergosterol (Fig. 90.4) is as ubiquitous in mushrooms as cholesterol is in humans. It is formed by an almost identical metabolic process—the mevalonate pathway. When mushrooms are exposed to ultraviolet light, ergosterol is converted to ergocalciferol, or vitamin D_2. Vitamin D_2 is then converted to calcidiol in the liver and eventually calcitriol, active vitamin D_3, in the kidneys. There is clinical evidence to show that ergocalciferol-D2, although not as bioavailable as calcitriol-D3, could significantly improve vitamin D deficiency in human patients.[21] However, as many of the metabolic activities of vitamin D_2 are different from the vitamin D_3 produced in the skin of mammals, they should not be used interchangeably.

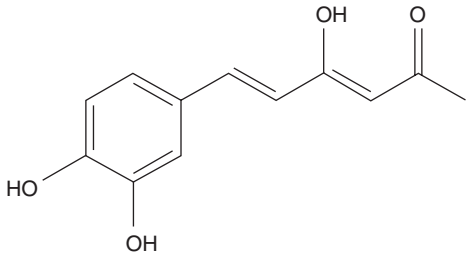

Fig. 90.3 Hispolon, a phenolic compound isolated from *Phellinus* spp. (Fire Sponge) and *Inonotus obliquus* (Chaga).

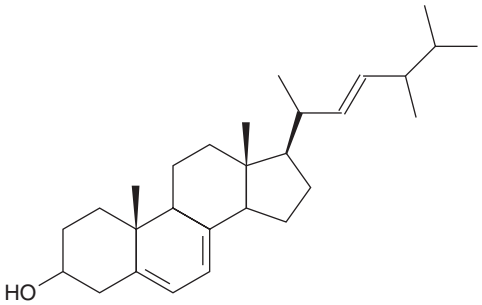

Fig. 90.4 Ergosterol.

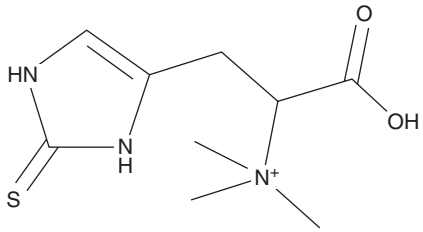

Fig. 90.5 Ergothioneine.

Ergothioneine

Ergothioneine (ERG; Fig. 90.5) is an amino acid derivative, a crystalline betaine, derived from histidine. The ERG transporter, OCTN1 (gene: SLC22A4)[22] is found on erythrocytes, fetal liver and bone marrow, ileum of the small intestine, trachea, kidney, cerebellum, lung, monocytes, seminal vesicles, and the lens and cornea of the eye.[23] Interestingly, OCTN1 is concentrated in the mitochondria, suggesting a role in protecting mitochondrial components from DNA damage.[23,24] When cells are depleted of OCTN1, they are more susceptible to oxidative stress, leading to mitochondrial damage, protein oxidation, and lipid peroxidation.

After ingestion, whether as an isolated molecule or in a whole mushroom, ERG is absorbed into the bloodstream, where it is highly bioavailable, and retained for up to a month. In a human trial observing ERG bioavailability, subjects consumed either 8 g or 16 g of mushrooms, and increases in red blood cell (RBC) ERG were observed. After 1 and 4 hours of consumption, the 16 g mushroom dose increased RBC ERG concentration compared with the control, and after 2 hours, RBC ERG concentration was significantly higher than the control.[25]

ERG chelates divalent metal cations: copper, mercury, zinc, cadmium, cobalt, iron, and nickel.[26-28] Cation binding may help prevent their participation in the generation of reactive oxygen species; for example, ERG has been found to protect DNA and protein against copper induced oxidative damage through formation of a redox-inactive EGT-Cu complex.

ERG enhances glutathione activity in rat liver cytosol in a dose dependent manner, leading researchers to postulate that declining ERG may play a role in age-related decline of glutathione and glutathione peroxidase. Furthermore, ERG levels are lower in the elderly with early stages of dementia and in Parkinson's disease patients relative to age-matched healthy controls.[29]

Of all the mushrooms analyzed, ERG was highest in the fruiting body of *Pleurotus ostreatus* (Oyster Mushroom), containing 26.4 mg per 85 g mushroom.[30]

Fig. 90.6 *Ganoderma lucidum.*

I. MUSHROOMS WITH HUMAN CLINICAL STUDIES

Reishi (*Ganoderma lucidum, G. applanatum, G. tsugae,* Lingzhi, 灵芝, 영지)

History and Folk Use

Reishi has been used in Chinese medicine for thousands of years and is considered one of the most important herbs; the name, Linghzi, translates to "herb of spiritual potency." It is said that the medicine of Lingzhi nourishes the heart, and in Chinese medicine the heart is the home of the "Shen," or "spirit." Aqueous extracts of the fruiting body were traditionally used to support the Shen by quieting the mind and relieving fatigue (Fig. 90.6 and Fig. 90.7).

Pharmacology

Antigout. *Ganoderma* spp. decrease uric acid accumulation through multiple mechanisms. In vitro, 2, 5 Dihydroxacetophenone, a bioactive compound from *G. applanatum,* and lanostanoids from *G. tsugae* bind to and decrease xanthine oxidase activity.[31,32] Significantly, xanthine oxidase is the terminal enzyme in the formation of uric acid. In an animal model, ethanol and water extracts of *G. applanatum* were administered to hyperuricemic mice, and the extracts lowered serum uric acid levels and increased both mRNA and protein levels of organic anion transporter (OAT1), which induced uric acid excretion. Additionally, renal uric acid reabsorption was blocked through inhibition of glucose transporter 9 (GLUT 9) and uric acid transporter 1(URAT1).[33]

Antiandrogenic. In vitro research and animal studies suggest that Reishi exhibits antiandrogenic effects via inhibition of the enzyme 5-α-reductase, which converts testosterone to dihydrotestosterone, an androgen hormone that is correlated with benign prostatic hyperplasia in older men. Fruiting body preparations of the mushroom significantly inhibited the growth of the ventral prostate in rats, and decreased levels of prostate specific antigen.[34-36] The ethanol extract of *G. lucidum* fruiting body containing ganoderol B and ganoderic acid DM was found to bind androgen receptors, inhibiting androgen induced lymph node carcinoma of the prostate as well as inhibiting 5-alpha reductase, respectively.[36]

Antiatherogenic. Lipid peroxidation of low-density lipoproteins (LDL) particles in the macrovasculature is a major contributor to the pathophysiology of atherosclerosis. Animal studies have demonstrated the antiatherogenic effects of *G. lucidum* polysaccharides, revealing that after administration, treated rats had decreased levels of triglycerides and LDL-c, lower liver weight, and increased high-density lipoprotein (HDL)-c, serum superoxide dismutase, and glutathione peroxidase compared with the control.[37] Other studies have explored beneficial cardiovascular effects via the quenching of free radicals that are responsible for lipid peroxidation; it is postulated that the antioxidant triterpenoids may be responsible for this effect.[38]

Blood sugar regulation. Ganoderic acids isolated from Reishi inhibit aldose reductase and alpha-glucosidase, two essential enzymes in the treatment of hyperglycemia.[39] *G. lucidum* also contains a protein, LZ-8, that demonstrates immunomodulatory and antitype 1 diabetes activity via decreasing lymphocyte infiltration and increasing antibody detection of insulin in pancreatic β-cells. Some studies have found that this immunomodulatory action is a result of LZ-8 stimulating FOXP3 regulatory T cells,[40] indicating a possible benefit for other autoimmune disease.

Antineoplastic. *G. applanatum* triterpenoids and polyketids have anticancer effects in vitro and in vivo in animal models. These triterpenoid compounds are anti-inflammatory, antioxidant, and have overall cytotoxic effects via upregulation of caspase-3 and increased P53 tumor suppressor gene expression.[41] In vitro, triterpenoids extracted from *G. lucidum* ganoderic acids have a number of anticancer actions that have been observed in cervical, breast, liver, lymphoma, melanoma, leukemia, lung, and colon cancers, including cancer cell-specific cytotoxicity, inhibition of cell proliferation, induction of apoptosis via caspase-3, suppression of cell adhesion, inhibition of angiogenesis, and inhibition of migration and invasion.[42,43]

Antiviral. *Ganoderma* triterpenoids also pose antiviral effects in vitro to H1N1 and H5N1 influenza viruses via inhibition of neuraminidase enzymes.[44] In addition to the antiviral terpenes, water soluble compounds exhibit antiviral activity; specifically, the hot water extract of *G. lucidum* significantly inhibits plaque formation of HSV-2.[45]

Clinical Applications

Antiandrogenic. In a randomized, double-blind, placebo-controlled and dose ranging study, *G. lucidum* was administered at a dose of 6 mg per day to men with lower urinary tract symptoms caused by prostate hyperplasia. Extracts of *G. lucidum* at this dose were found to be safe and effective in relieving urinary symptoms in men with symptoms of bladder outlet obstruction.[46]

Antineoplastic. *Ganoderma* polysaccharide, "Ganopoly," positively modulates the immune function of advanced stage cancer patients with lung, breast, colon, liver, or prostate cancer. Patients were treated with 1800 mg of 'Ganopoly' three times a day orally before meals for 12 weeks (5.4 g of isolated Ganopoly is equivalent to 30 g of fruiting body per day), resulting in an increase in interleukin 2 (IL-2), IL-6, and interferon γ (IFN-γ), while significantly decreasing IL-1 and tumor necrosis factor α (TNF-α). Additionally, there was a significant increase in mean natural killer (NK) cell activity compared with baseline.[47] Taken together, these findings suggest an immunomodulatory effect that could be of great benefit as an adjunct therapy in cancer treatment.

Antiviral. A human study found the combination of *G. lucidum* and *T. versicolor* at 400 mg/day for 2 months cleared oral human papilloma virus in 87.8% of cases compared with the control, which only cleared 5% of cases.[48]

Chronic fatigue syndrome. Female volunteers with chronic fatigue syndrome receiving 2 g of *G. lucidum* extract daily had a significant benefit in quality-of-life parameters compared with the control group. Average serum cortisol level, measured 12 weeks after the first dose, was increased up to 1.5 times from baseline measurement, leading the authors to conclude that women with chronic fatigue syndrome who generally have low cortisol levels can benefit from Reishi intake, and may also see a rise in serum cortisol.[49]

Dosage

Condition	Dose of Whole Mushroom	Timing
Maintenance[50]	1 g	daily
Skin allergies[50]	1.5 g	3x/day
Insomnia[50]	1.5 g	3x/day
Cholesterol lowering[50]	2 g	3x/day
Chemotherapy adjunct[50]	3 g	3x/day
Immune potentiating[50]	2 g	3x/day
Chronic fatigue[49]	2 g	daily
Immune support in advanced stage cancer patients[47]	30 g 1.8 g polysaccharide extract	daily 3x/day

Cordyceps (*C. sinensis, C. militaris,* Caterpillar fungus, dong chong xia cao, 冬虫夏草)

History and Folk Use

Cordyceps is an extraordinary mushroom and is considered an endoparasite—the mycelium takes over the life of insects, zombifies them, and grows an erect fruiting body, usually through the caput of an arthropod. According to ancient descriptions, *C. sinensis* possesses important pharmacological activities for protecting lung and kidney function and nourishes essential and vital energy. The Nepalese people observed livestock consuming Cordyceps and saw an increase in the animal's sexual vitality and general stamina. The people then began to consume the mushrooms as the other animals did and found that it improved their own vitality as well— increasing stamina, endurance, and treating impotence.

Pharmacology

Renal protective. *C. sinensis* significantly improves tubulointerstitial renal fibrosis, in vitro,[51] and polysaccharide extracts relieve the formation of reactive oxygen species and reduce kidney damage through inhibition of tumor growth factor β (TGF-β).[52]

Endurance. Though used widely by athletes, few ergogenic mechanisms have been demonstrated through in vivo animal models. *Cordyceps* spp. have been shown to stimulate the enzyme lactic acid dehydrogenase (LDH), accelerating the removal of lactic acid and increasing available adenosine triphosphate for anaerobic exercise.[53] *Cordyceps* spp. also contain the nucleoside "adenosine,"[54] which in exercise relaxes vascular smooth muscle, contributing to the local vasodilation that accompanies muscle contraction. Studies have found that during exercise-induced, higher-frequency contractions, adenosine contributes around 14% to 29% of the necessary vasodilation.[55]

Respiratory protection. *C. sinensis* may be beneficial for decreasing smoking-related cellular damage in lung tissue. In vitro research shows that Cordyceps decreases cigarette smoke extract (CSE)-induced cellular senescence. Activation of the oxidative, inflammatory, and oncogene signaling pathway iROS/PI3K/AKT/mTOR is enhanced by CSE treatment, and decreases when *C. sinensis* is administered.[56] Cordycepin, a derivative of the nucleoside adenosine, significantly reduces airway inflammatory cell infiltration via inhibition of ERK/NF-κB signaling pathway, which suppresses inflammatory mediators.[57-61] Cordyceps inhibits airway remodeling of asthma by downregulating TGF-β and suppressing p38MAPK signaling pathways, which indicates possible use as a treatment for allergic asthma.[62]

Antineoplastic. Cordycepin has been widely recognized for its therapeutic potential against many types of cancers through numerous mechanisms, inducing apoptosis, cell cycle arrest, and causing DNA damage in cancer cells, thereby killing cancer cells and controlling growth. Cordycepin also induces autophagy, inhibits tumor metastasis, and modulates the immune system. Although there have been many successful cases of cordycepin in anticancer research in vitro and in animal models, clinical trials have yet to be reported.[63] Cordycepin also reduces migration of human glioblastoma cells in vitro and decreases brain tumor size in mice, and actively downregulates the expression of integrin β1, FAK, and p-FAK, subsequently reducing cancer cell migration.[64]

Erectile dysfunction. *Cordyceps* has a history of use as an aphrodisiac, specifically aiding sexual endurance and erectile dysfunction. Studies indicate this mechanism is via a protein with vasorelaxant effects linked to the production of endothelial nitric oxide synthase (eNOS). These are preliminary results and the authors stress that further work on the mechanism of action is necessary.[65]

Clinical Applications

Exercise recovery. A double-blind placebo-controlled trial assessed the oxidative stress biomarkers in athletes supplementing with Cordyceps and Reishi mushrooms. The researchers found that after 3 months of supplementation with 1335 mg Cordyceps extract and 1170 mg Reishi extract per day, the athletes had significantly more free radical scavenging activity after a race than the placebo group.[54] These results could be an indication that these mushrooms are also beneficial for recovery after endurance exercise.

Chronic kidney disease. In a review of 22 studies that involved 1746 participants with chronic kidney disease (CKD) not receiving dialysis, Cordyceps preparations were found to significantly decrease serum creatinine, an important marker of CKD severity. Cordyceps preparation, as an adjunctive therapy to conventional medicine, can decrease serum creatinine, increase creatinine clearance, reduce proteinuria, and alleviate CKD-associated complications, such as increased hemoglobin and serum albumin.[66]

Another systematic review compared 3 to 12 g daily doses of Cordyceps-based immunosuppressant therapy with azathioprine-based immunosuppressant therapy. Both immunosuppressant therapies included cyclosporine A and prednisolone. Patients who took the Cordyceps-based immunosuppressant therapy had significantly lower blood urea nitrogen and serum creatinine, decreased serum uric acid, total cholesterol, alanine transaminase and aspartate transaminase liver enzymes, and increased HDL-cholesterol. Urinary leukocytes and erythrocytes were notably lower in the Cordyceps group along with lower infection rates. Based on these studies, Cordyceps is a safe adjunctive treatment that could be beneficial for patients with CKD.[67]

Immune-stimulating. A placebo-controlled trial observed the immune-stimulating effects of *C. militaris* fruiting body extract in healthy adult males: 1.5 g of mushroom was administered daily, and blood was drawn after 2 weeks and after 4 weeks. After 4 weeks, there was a significant increase in NK cells, IFN-γ, and IL-2 compared with the control group.[68]

Dosage

Condition	Dose	Timing
Chinese tonic dose	2–9 g	daily
Respiratory viral infection[69]	6–9 g	daily
Kidney support[67]	4 g	daily
Enhance cell-mediated immunity[68]	1.5 g	daily

Turkey Tail (*Trametes versicolor, Coriolus versicolor,* Kawaratake, Yun Zhi, 云芝)

History and Folk Use

In traditional Chinese medicine, Turkey Tail is called *Cloud Fungus.* It is said to replenish essence and qi, and regulate immune function. Traditionally, it was used to invigorate the spleen and eliminate dampness, arrest cough, and help with breathing difficulty (Fig. 90.8).

Fig. 90.8 *Trametes versicolor.*

Pharmacology

The majority of research that has been done on Turkey Tail has been focused on polysaccharide krestin (PSK) and polysaccharide peptide (PSP).

Gut microbiome. Turkey Tail has demonstrated prebiotic-like activity in vitro and in vivo. In vitro research has shown that the fermentation of PSP extract by gut bacteria increases the beneficial bacteria *Bifidobacterium* and *Lactobacillus* spp. while reducing less desirable bacteria, *Clostridium difficile, Staphylococcus* spp. and *Enterococcus* spp. This study also saw an increased level of lactate and beneficial short-chain fatty acids.[70]

Antineoplastic. PSK extract modulates the immune response through stimulation of both extracellular PRR (TLR2) and intracellular pathogen sensors (NLRP3 inflammasome).[71] There have been many peer-reviewed publications on Turkey Tail in cancer treatment, including 37 in vitro articles, 55 animal studies, 43 published human clinical studies, and 11 review articles in gastrointestinal, breast, and lung cancer. In the past 2 years, five more PSK trials in colorectal cancer have been published. *Trametes* water extract is made up of 62% polysaccharide and 38% PSK. After ingestion, PSK is highly bioavailable and can be found in the bone marrow, salivary gland, brain, liver, spleen, and pancreas in mice and rabbits within 24 hours. Once absorbed, PSK induces cytokine modulation, increasing TNF-α, IFN-γ, IL-2, and IL-8.[72]

Clinical Applications

Microbiome. In a preclinical trial with 21 women, PSP gel was administered intravaginally. There was improved epithelialization of the cervical mucosa and the concentration of *Lactobacillus* increased 54.5% while the pH decreased from 4.2 to 4.09.[9]

In a randomized clinical trial, 1200 mg of PSP was administered three times a day on an empty stomach alongside the antibiotic amoxicillin. Although amoxicillin alone led to an increase in *Escherichia* and *Shigella,* the PSP group had distinctive positive changes in the human microbiome, consistent with its activity as a prebiotic.[73]

Antineoplastic. PSK improves immune function, reduced tumor-associated symptoms, and extended survival time in lung cancer patients. In six randomized controlled trials, 3 g a day of PSK or PSP alongside standard chemotherapy showed benefit for immune function, performance status and body weight, and overall survival. PSK increases immune surveillance and offsets chemotherapy-induced bone marrow toxicity, and reduces depression of immune cells and immune cell activity during chemotherapy. PSK also increases NK cells and phagocytic activity, reduces TGF-β, and increases the antitumor response of peripheral blood mononuclear cells.[74]

In a randomized, double blind, placebo-controlled trial exploring palliative treatment for hepatocellular carcinoma, Turkey Tail was given as a standard, continuous daily dose of 2.4 g. These patients reported better physical, emotional, cognitive, and social functions compared with the placebo during treatment. They experienced higher cognitive function, less pain and increased appetite, and had reduced IL-17 and monocyte chemoattractant protein-1.[75]

In a Phase I clinical trial of *T. versicolor* in women with breast cancer, researchers found that up to 9 g per day of a Turkey Tail preparation is safe and tolerable and the women taking 6 g a day had a significant trend upward in NK cell counts.[76]

Dosage

Condition	Dose	Timing
Microbiome support[73]	1200 mg	3x/day
Cancer therapy adjunct[74-76]	3–9 g	daily

Chaga (*Inonotus obliquus*, Kabanoanatake)

History and Folk Use

Chaga sclerotium has been used as medicine in Eastern Europe at least since the 12th century. Historical accounts suggest that a Russian duke, Vladimis Monomach, cured himself of lip cancer using Chaga. The Khanty people, an ethnic group from Siberia, used this mushroom as medicine for digestive ailments and to prevent heart and liver disease. Chaga sclerotium grows out from the core of old birch trees, and consequently has medicinal compounds, betulin and betulinic acid, derived from these trees.

Pharmacology

The triterpenoid compounds extracted from Chaga inhibit proliferation of cancer cells, induce cell cycle arrest at various cell cycle checkpoints, enhance apoptosis, and enhance regulation of signal transduction pathways.[77] The triterpene inotodiol, specifically, has been shown to have an antihistamine effect via the inhibition of mast cell degranulation in the small intestine when administered to mice with food allergies.[78]

Antioxidant. The polysaccharides extracted from Chaga have antioxidant effects through their superoxide scavenging activity[79,80] The antioxidant mechanism may be as result of the supply of hydrogen by the polysaccharides, which combines with radicals and forms a stable radical to terminate the damaging radical chain reaction.

Anti-Inflammatory. Aqueous extract containing polysaccharides, proteins, and phenolic compounds was administered to mice with intestinal inflammation. The extract suppressed edema, mucosal damage, and inhibited nMRNA expression of proinflammatory cytokine TNF-α, and there was an overall inhibition of inflammatory transcription factor NF-κB.[81]

Hypoglycemic. Polysaccharide-rich aqueous extract exhibits hypoglycemic activities in vitro and in vivo. The animals in this study showed significant alpha-glucosidase activity inhibition, slowing the release of glucose in the intestine, and reducing postprandial hyperglycemia.[82]

Clinical Applications

Psoriasis and GI inflammation. A group of 50 patients suffering from psoriasis were treated with Chaga extract paste. Forty-three patients started the treatment with Chaga during the acute stage of psoriasis, and 7 started during the steady-state. Chaga extract was heated and one tablespoon of the extract was diluted in a glass of boiled water at room temperature. Chaga extract was administered three times a day 20 to 30 minutes before meals. Psoriatic rashes were significantly improved after 3 months of regular intake, and extensive psoriasis was completely cured in 16 patients. Overall, Chaga was found to be an especially useful treatment for patients with psoriasis co-occurring with chronic inflammatory diseases of the gastrointestinal tract and liver.[83,84]

Dosage

Condition	Dose	Timing
Traditional general dose[83]	3 g	daily
Psoriasis[84]	1 tbs extract	3x/day

Maitake (*Grifola frondosa*, Hen of the Woods)

History and Folk Use

Traditionally, Maitake has been used in China to improve the spleen, appease stomach ailments, treat hemorrhoids, and calm the mind and nerves. Also a delicious culinary mushroom, it is commonly used as

food. Some medicinal mushrooms are much too woody to eat (Reishi, Turkey Tail, and Chaga), but Maitake is easy to cook and tastes rather good. As a general principle: mushrooms should be eaten if palatable.

Pharmacology

β-D-glucans from Maitake have been named Maitake D fraction, or MD fraction, and have been the focus of many Maitake studies. Maitake also contains a significant amount of ergothioneine, and so possesses the beneficial antioxidant and neuroprotective qualities of ergothioneine described previously.

Immune modulation. In an animal study, Maitake extract decreased TNF-α and enhanced interferon activity in rats with invasive bladder cancer. MD fraction relieves colon inflammation via suppression of both TNF-α and signaling through NF-κB in vitro,[85] and enhances both innate and adaptive immunity, indicating use for defense against foreign pathogens and protection for general, healthy immune function.[86]

Antineoplastic. MD fraction has direct antiproliferative and cytotoxic effects in human cancer cells, including prostate, bladder, liver, brain, blood and breast. The mechanisms include a decrease in cell viability, increase in cell adhesion, and a reduction in the migration and invasion of human lung cancer cells. (Rossi) Fruiting body extract, which contains polysaccharides and phenolic compounds, displays an antiangiogenic effect in rats via inhibition of vaso-endothelial growth factor (VEGF) and extracellular signal–related kinase (ERK) through suppression of reactive oxygen species (ROS).[87] These in vitro and in vivo findings are meaningful when it comes to angiogenesis-associated diseases including retinopathies, benign and malignant angiogenic tumors, and progression of malignant tumors.

Clinical Applications

Neoplasia. Maitake polysaccharide extract was administered to postmenopausal women who had a history of breast cancer. At a dose of 5 mg/kg per day, increases in both suppressive and stimulatory cytokine blood markers were observed, including IL-10, IL-2, TNF-α, and IFN-γ,[88] which suggests an immunomodulatory action. Because this was a polysaccharide fraction and Maitake contains about 45% polysaccharides, if taking whole mushroom rather than polysaccharide extract, the dose should be doubled. In another human trial of patients with stage II to IV cancer, either cancer regression or significant symptom improvement was observed in 58% of liver cancer patients, 68.8% of breast cancer patients, and 62.5% of lung cancer patients.[88]

Polycystic ovarian syndrome. Insulin resistance is a prominent feature of polycystic ovarian syndrome (PCOS), and insulin sensitizing drugs are used to induce ovulation, typically clomiphene citrate (CC). In a clinical trial with 72 patients with PCOS, 26 women took Maitake extract, 31 women took clomiphene citrate, and 18 women received combined therapy. The ovulation rates were 76.9% for the Maitake patients and 93.5% for the CC patients, while combination therapy increased the ovulation rate to 87%. These results indicate the possibility of using Maitake as a monotherapy to induce ovulation in PCOS patients as well as a combination therapy with clomiphene citrate.[89]

Dosage

Condition	Dose	Timing
Chemotherapy adjunct[88]	5–7 mg/kg polysaccharide extract, 10 mg/kg whole mushroom	daily
Insulin regulation/ PCOS[89]	~1 g	3x/day

Fig. 90.9 *Pleurotus.*

Pleurotus ostreatus (Hiratake, píng gū, 平菇)

History and Folk Use

Oyster mushrooms have no boundaries—they grow everywhere, on most anything, and are used as food throughout the world. According to some resources, they were first cultivated in Germany during World War I as an important food source. Oyster mushrooms are an especially fascinating mushroom because they are considered carnivorous—they are one of the few mushrooms known to consume critters, specifically nematodes, as a nitrogen source (Fig. 90.9).

Pharmacology

Oyster mushroom contains the most ergothioneine of any known mushroom, and so the antioxidant and neuroprotective actions of ergothioneine are a major component of the medicinal benefit. Other unique compounds found in Oyster mushroom include chrysin, lovastatin, and GABA. The β-D-glucan on which the majority of the Oyster mushroom cancer research is focused is called "pleuran."

Respiratory support. Active treatment in children for recurrent respiratory tract infections with pleuran resulted in a significant reduction of peripheral blood eosinophils and stabilized levels of total IgE in serum. A potential mechanism proposed in the study was that allergic children have respiratory infections more often and through stabilization of IgE, these may be prevented.[90]

Antiatherogenic. There are many factors that aggregate and result in atherosclerosis. These include and are not limited to hypertension, hyperglycemia, hypercholesterolemia, and lipid peroxidation. Oyster mushroom research has demonstrated protection against all of those factors. In an animal study, rats were administered chrysin-rich *Pleurotus* extract. After administration there was a significant decrease in mean blood serum levels of glucose, lipid profile parameters, and hepatic marker enzymes and a simultaneous increase in enzymatic and nonenzymatic antioxidant parameters.[91]

P. ostreatus is the richest known source of ergothioneine, containing 118.91 mg/kg. As mentioned previously, ergothioneine protects against DNA damage and lipid oxidation. For hypertension, Oyster mushroom water extract inhibits angiotensin-converting enzyme (ACE)—a common mechanism in hypertensive medication.

Oyster mushroom also contains lovastatin, a naturally occurring statin compound that reduces LDL cholesterol through inhibition of HMG-CoA reductase.[92]

Clinical Applications

Atopic dermatitis. In a split-body study of 80 patients, topical *P. ostreatus*-based β-glucan cream application resulted in improvement

of both subjective and objective symptoms of atopic dermatitis. The patients applied the cream on one segment of the body with atopic dermatitis and no treatment on another atopic dermatitis segment. On the application site there was a significant decrease in the number of days and severity of atopic dermatitis.[93]

Respiratory disease. Pleuran extract from Oyster mushrooms has clinical evidence for application with various respiratory diseases. In a human study, chronic obstructive pulmonary disease (COPD) patients treated with 100 mg pleuran, 60 mg vitamin C, and 5 mg zinc had significantly lower incidence and shorter duration of exacerbations compared with the control (60 mg vitamin C and 5 mg zinc).[94]

In another double-blinded, placebo-controlled, randomized multicentric study, 175 children were treated with either pleuran or placebo over a 12-month period. Children treated with pleuran experienced a significant reduction in the frequency of recurrent respiratory tract infections.[90,95] These findings agreed with a Spanish study investigating 166 children aged 1 to 10 years old who were also treated with pleuran for recurrent respiratory infection.[96]

Advantageous respiratory effects of pleuran were also observed in adult athletes. A study included 50 athletes treated with pleuran over a 3-month period of time and found a significant reduction in the frequency of upper respiratory tract infections compared with athletes treated with placebo. Blood samples of the athletes showed significantly higher levels of circulating NK cells in the pleuran group compared with the placebo group.[97]

Antihyperlipidemic. Twenty subjects were randomized to take either one portion of soup containing 30 g dried oyster mushrooms or a tomato soup (placebo) daily for 21 days. Standardized blood concentrations of lipid parameters and oxidized LDLs were measured at baseline and after 21 days. Treatment with Oyster mushroom soup decreased both triacylglycerol and oxidized LDL levels significantly, and showed a significant tendency toward lowering total cholesterol values.[98]

Dosage

Condition	Dose	Timing
Atherosclerosis[98]	30 g dried mushroom	daily
Respiratory support[95,96]	10 mg/kg pleuran (Oyster mushrooms contain ~40% polysaccharide, so whole mushroom dose would be about 25 mg/kg)	daily

Lion's Mane (*Hericium erinaceus*, Yamabushitake, Hedgehog Mushroom, 山伏茸, 猴头菇)

History and Folk Use

Although Lion's Mane is now widely known for its nootropic effects, it was traditionally used in Chinese medicine to reduce gastrointestinal heat. This toothed mushroom can be cooked as food or taken as an extract. Historically, its major use was to lull gastrointestinal inflammation and cool gastrointestinal ulcers (Fig. 90.10).

Pharmacology

The most studied constituents in Lion's Mane are erinacines and hericenones, found in the mycelium and fruiting body, respectively. Erinacines are cyathin diterpenoids and have thus far only been found in mycelium extracts of Lion's Mane. Erinacine A and S have been shown to increase nerve growth factor mRNA expression whereas erinacine E is a kappa opioid receptor agonist, prompting further investigation of potential benefit for opioid addiction.[99] Hericenones are meroterpenoids that have anti-inflammatory effects through the inhibition of the inflammatory transcription factor, NF-κB. Hericerins are aromatic, anti-inflammatory compounds that inhibit COX-2, and reduce iNOS, PGE2, TNF-α, IL-6, and IL-1.[100,101]

Fig. 90.10 *Hericium erinaceus.*

Antifatigue. Animal studies demonstrated significant antifatigue activity through an increase in tissue glycogen content and a decrease in both blood lactic acid and serum urea nitrogen.[102]

Nervous system. There is speculation about the use of Lion's Mane for diabetic peripheral neuropathy, and although animal trials are promising, there is not a known treatment dose for humans. In an animal model, polysaccharides extracted from fresh fruiting bodies of Lion's Mane were administered to rats with peroneal nerve injury, and the rat's ability to respond to heat stimulus and general recovery was significantly improved compared with the control.[103,104] This aqueous extract contains neuroactive compounds that induce nerve growth factor synthase, which is important for promoting the growth and differentiation of neurons.

Another animal model demonstrated that aqueous extract of Lion's Mane fruiting body administered to rats with alloxan-induced diabetic neuropathic pain reversed diabetes-induced thermal hyperalgesia and mechanical allodynia. These diabetic rats also showed significant decrease in serum and urine glucose.[105]

Aqueous extracts also have been shown to ameliorate various Alzheimer's disease-related pathologies. Mycelial extracts containing erinacine A and S have been shown to inhibit plaque growth, diminish activation of glial cells, and promote hippocampal neurogenesis.[106]

An animal study found that Lion's Mane extract had anxiolytic effects with a chronic high-dose administration at 60 mg/kg. After 4 weeks at this dose, there was significantly less depressive behavior in the mice compared with the control group, and an increase in the number of proliferating cells in the subgranular zone of the dentate gyrus, thereby enhancing hippocampal neurogenesis. This proliferation is associated with an increase in nerve growth factor production stimulated by the mushroom extract.[107]

Gastrointestinal effects. In an animal study, mice with alcohol-induced gastric ulcers were administered a fruiting body polysaccharide extract of *H. erinaceus*. There was a significant improvement in treated mice compared with the control—fewer ulcerations, less inflammatory cytokines, and improved overall regulation of gastric secretions—suggesting use as an adjunct therapy for gastric ulcers.[108]

Clinical Applications

Depression and anxiety. The combined anti-inflammatory and nerve growth factor-enhancing actions have proven to reduce depression and anxiety, specifically in menopausal females. In one randomized, double-blind, placebo-controlled clinical trial, women

Fig. 90.11 *Lentinus edodes.*

were given four cookies with .5 g of powdered fruiting body or placebo for 4 weeks. The women who consumed the Lion's Mane cookies experienced significantly less anxiety and depression compared with the placebo.[109]

Gastrointestinal inflammation. Traditionally, Lion's Mane has been used to lull gastrointestinal inflammation and preliminary clinical research suggests that taking *H. erinaceus* before meals daily for 3 months improves symptoms of GI inflammation. In this study, patients who presented with chronic atrophic gastritis were given either Lion's Mane extract or placebo. The Lion's Mane group had significant improvement in upper abdominal pain, dysplasia, and an overall reduction in inflammatory infiltration.[110]

Dosage

Condition	Dose	Timing
Cognitive impairment[111]	1 g	3x/day
Depression and anxiety[109]	2 g	daily

Shiitake (*Lentinula edodes*, 椎茸, 香菇, 표고)

History and Folk Use

The legend goes that 5000 years ago a deity, Shennong, bestowed the world with Shiitake as well as all other medicinal mushrooms. Logs would be inoculated with Shiitake spores during a child's birth, and the child and the mushrooms would mature together until adulthood. At adulthood, the child would be lucky enough to inherit the fortune of the shiitake flush (Fig. 90.11).

Pharmacology

The majority of research regarding Shitake has explored a specific β-D-glucan, lentinan. Lentinan, like other β-D-glucans, has immune-centric qualities including antineoplastic and anti-inflammatory activity.

Antineoplastic. Lentinan inhibits both tumor angiogenesis and the growth of lung and colon cancers by increasing IFN-γ production.[112] Lentinan exerts antitumor effects in colon cancer cells both in vitro and in vivo. Cancer cell apoptosis is induced through two major pathways: the intrinsic pathway via overproduction of reactive oxygen species, and activation of caspase-9 and the extrinsic pathway through the increase of TNF-α, NF-κB inhibition, and activation of caspase-8 and 3.[113] Other studies have concluded that lentinan also inhibits tumor cell proliferation through targeting p53 tumor suppressor gene, increasing tumor cell apoptosis through caspase-3-dependent signaling pathways, and inhibiting angiogenesis through VEGF depression.[114]

Anti-Inflammatory. NF-κB is an important regulatory element for IL-8 expression in human epithelial cells; in an animal study, lentinan suppressed IL-8 gene expression, which indicates lentinan could be beneficial for intestinal inflammatory diseases, like irritable bowel disease (IBD), in humans.[115]

Oral antimicrobial. In vitro studies have explored the effect of Shiitake extracts containing adenine and oxalic acid on common bacteria implicated in caries and gingivitis. Adenine showed 50% biofilm inhibition with *Streptococcus mutans,* and 20% biofilm disaggregation, whereas oxalic acid showed biofilm inhibition of 80% for *Actinomyces naeslundii.*[116,117] The Shiitake mushroom aqueous extract (1 mg/mL) demonstrated antimicrobial activity against 84.6% of 39 microorganisms tested.[118] Sesquiterpenes, steroids, anthraquinone, benzoic acid derivatives and quinolones in shiitake extract all inhibit growth of *S. mutans.* Oil extract is the most efficacious in biofilm inhibition and disruption, potentially due to the carvicrol content in the oil extract, which significantly inhibited and disrupted *P. gingivalis.*[119]

Clinical Applications

Antineoplastic. Patients with gastric cancer were administered either chemotherapy alone or chemo-immunotherapy with lentinan. There was a significantly longer median overall survival time in the lentinan group and the researchers concluded that lentinan should be widely accepted for use as adjunctive chemo-immunotherapy treatment for advanced gastric cancer. The lentinan treated group was administered 2 mg/body (JP: This unclear dosage is what was reported in the study) weight via IV for 30 minutes every 2 to 3 weeks.[120] Lentinan provides synergistic actions with a molecular targeting agent and cytotoxic drugs through the modulation of antibody-dependent cellular toxicity and programmed cell death, which may support the idea that the chemo-immunotherapy prolongs the survival of metastatic gastric cancer patients, compared with chemotherapy alone.[121]

A case of recurrent ovarian cancer was successfully treated with immunotherapy alongside 2 mg IV lentinan administered every 2 weeks. In this case study, lentinan changed the Th1/Th2 balance such that the Th1 level exceeded Th2. The authors proposed that lentinan worked on cervical lymph node metastatic cancer by evading the immune surveillance system.[122]

Other studies exploring the use of lentinan as an adjunct to chemotherapy found less adverse side effects from the chemotherapy, improved IFN-γ production, and increased NK cell count.[123]

Dosage

Few clinical trials have been done with humans consuming whole mushroom or whole mushroom extract, and most research on Shiitake focuses on lentinan and cancer. This research is hopeful, yet it leaves the dosage for whole Shiitake mushroom unknown. Based on research with other mushrooms, dosage is most likely to be at least 3 g/day for immune-centric effects.

Agaricus blazei (Kawarihiratake, Himematsutake, 姬松茸)

History and Folk Use

Agaricus blazei is a mushroom originally native to a small village Piedade, in the highland areas in the province of Sao Paulo, Brazil.

Although originally from Brazil, this mushroom is now used commonly throughout Asia as food and medicine and is traditionally believed to fight physical and emotional stress.

Pharmacology

Antineoplastic. Antineoplastic activity was observed in three separate mouse studies, showing an increase in CD69 and CD49 T-cells in mouse colon cancer and an increase in CD3, CD19 and NK cell activity in mouse leukemia.[125,126,127] In vivo animal models and in vitro research have elucidated many antineoplastic mechanisms with an array of various malignancies; the most notable in vivo mechanisms were a decrease in metastases of both ovarian and lung cancers.[127]

In vitro human hepatocarcinoma and osteosarcoma cells treated with *A. blazei* polysaccharide extract had an increase in percent of apoptosis, and a decrease in cell growth.[128,129]

Antimicrobial. Hot water extract shows antiquorum sensing activity against *Pseudomonas aeruginosa,* an important antibacterial mechanism that should be further explored.[130]

Antioxidant. Phenolic compounds from *A. blazei* showed higher antioxidant activity compared with Shiitake.[131]

Clinical Applications

Cancer. *A. Blazei* mushroom extract was administered to gynecological cancer patients undergoing chemotherapy. Blood was drawn a few weeks after administration, and NK cell count was significantly higher in the mushroom extract group compared with the placebo group, and there was a significant reduction in chemotherapy-associated side effects.[132]

Diabetes. Either *Agaricus blazei* fruiting body extract (AbM) or placebo (cellulose) was administered in a 5-month trial with 536 registered patients with diabetes who had been taking gliclazide and metformin for more than 6 months. Subjects took either 500 mg of AbM extract or cellulose three times a day for 12 weeks; the capsule was taken with glicliazide 30 minutes before eating and metformin was taken 30 minutes after eating. The AbM group had improved insulin resistance, possibly due to an increase in adiponectin concentration after the 12 week treatment.[133]

Dosage

Condition	Dose	Timing
Diabetes adjunct[133]	500 mg	3x/day

Enokitake (*Flammulina velutipes*, えのき茸, 팽이버섯)

History and Folk Use

Enokitake has been consumed as food for millennia throughout Asia. Not surprisingly, an epidemiological survey of cancer deaths found that Enokitake mushroom farmers (who were consuming a lot of enokitake mushrooms) had lower rates of cancer deaths than controls who were not involved in farming.

Pharmacology

Similar to other medicinal fungi, Enokitake has an affinity for the immune system and contributes to cytotoxicity in cancer cells. The isolated constituent proflamin prolongs the survival of cancer-stricken mice by 85%.[134]

Microbiome modulation. An intriguing in vivo animal study found that Enokitake polysaccharide extract improves scopolamine-induced learning and memory impairment in mice by modulating gut microbiota composition. Through modulating the gut microbiome to a more favorable composition, there was a reduction in neuroinflammation and, therefore, an antagonizing effect of the scopolamine-induced memory deficit.[135]

Antimicrobial. In vitro research has demonstrated antioxidant and antimicrobial activity against *Staphylococcus aureus, Escherichia coli,* and *Bacillus subtillus.*[136]

Anti-Inflammatory. A recent review article explains that the immunomodulatory protein, FIP-fve, elicits its immunomodulatory effects by shifting toward a Th1 immune response. FVP-fve also successfully suppresses airway inflammation and hyper-responsiveness via inhibition of inflammatory cell infiltration and Th2 cytokines. This protein also inhibits host dust mite-induced asthma inflammation in mice.[137]

The water-soluble polysaccharide FVP-2 enhanced growth of primary hepatocytes from mice in vitro via inhibition of intracellular alanine aminotransferase (ALT) and portrayed anti-inflammatory effects via inhibition of iNOS, TNF-α, and COX-2 in vitro.[137]

Fig. 90.12 *Fomitopsis pinicola.*

Dosage

There are not enough clinical studies to propose specific dosage.

II. MUSHROOMS WITH LABORATORY AND ANIMAL RESEARCH BUT INSUFFICIENT HUMAN CLINICAL TRIALS

The following mushrooms have encouraging in vitro research and in vivo animal studies. Similar to the previously mentioned mushrooms, they have antineoplastic, anti-inflammatory, immune-modulating, and antioxidant qualities. These mushrooms have a long history of use, but a lack of human clinical trials.

Red Belted Polypore (*Fomitopsis pinicola*)

History and Folk Use

F. pinicola is one of the most commonly found polypore mushrooms throughout the world. Traditionally, it has been used for treatment of headache, nausea, liver problems, as a styptic, and as an anti-inflammatory agent. Interestingly, during the 1800s, eclectic physicians soaked the polypore in whiskey as a remedy for malaria-like symptoms (Fig. 90.12).

Fig. 90.13 *Phellinus igniarius.*

Pharmacology

Antineoplastic. In vitro, *F. pinicola* extract proves to employ many antineoplastic actions inhibiting cell migration, inducing ROS-dependent apoptosis, and causing p53 mediated G1 phase arrest in human colorectal cancer cells. The researchers postulate that ergosterol may play a role in these processes.[138]

Antioxidant. In vitro, both extracellular and intracellular polysaccharides consisting of mannose, rhamnose, xylose, and galactose portray strong free radical scavenging abilities, reducing UV- and H_2O_2-induced oxidative damage.[139] Another study investigating the antioxidant properties of *F. pinicola* uncovered that the antioxidant effects were mostly likely caused by the phenolic compounds contained in the mushroom extract.[140]

Anti-Inflammatory. Ethanol extract of Red Belted Polypore fresh fruiting bodies contains a number of lanostane triterpenes,[141] fomitopinic acids, and lanostane triterpene glycosides, fomitosides. In vitro, this extract selectively inhibits COX-2.[142]

Fire Sponge (*Phellinus linteus, Phellinus igniarius,* Mesima, Willow bracket)

History and Folk Use

The Yup'ik of Western Alaska called the fungus *arak,* and the mixture of tobacco and the ash *iqmik*—"thing to put in the mouth." It has been reported that 52% of First Nations people used this fungus. The mushroom was traditionally burnt to an ash and smoked with tobacco[143] (Fig. 90.13).

Pharmacology

Phellinus spp. contain two noteworthy phenolic compounds—phelligridin and hispolon. Phelligridins are antiviral,[144] whereas hispolon has analgesic, anti-inflammatory, and antineoplastic qualities.[19,145]

Antineoplastic. In vitro, hispolon has significant antitumor activity.[146,147] In one study exploring antineoplastic mechanisms of hispolon on human lung cancer cells, the proposed mechanism of action was an induction of G0/G1 cell cycle arrest.[146]

Ethanol extracts inhibit the proliferation of human hepatocarcinoma cell lines as well as rat heart vascular endothelial cells. When the extract was given in combination with chemotherapy, there was a synergistic inhibition of the proliferation of hepatocarcinoma.[148] This study and others suggest hepatoprotective qualities for the ethanol extract.[146]

Antiviral. The water extract is effective against influenza virus A and B, including H1N1, H2N3, and Avian flu. The extract interferes with events in the virus replication cycle, including viral attachment to the target cell.[149] Fruiting body extracts inhibit neuraminidase from H3N2, H1N1, and H5N1 influenza viruses.[144]

Immune modulation. The biologically active compounds that modulate the immune system have been found to have therapeutic value for slowing multiple sclerosis progression in mice.[150] After 3 weeks of being injected with the extract every other day, demyelination and immune cell infiltrations in the spinal cord were examined and there was a significant decrease in the daily incidence rate and clinical score of autoimmune encephalomyelitis.

Witch's Butter (*Tremella fuciformis, Tremella aurantia, Tremella mesenterica,* 雪耳)

History and Folk Use

In Chinese medicine this slimy mushroom is used for cooling, moistening, and nourishing the lungs, stomach, and kidneys. It has been used in body care products throughout Asia and is said to provide proper moisture to the skin. The traditional use for skin elasticity is to brew fruiting bodies as a thick gelatinous tea and apply to the skin with a cotton pad, rinsing after 30 minutes.

Pharmacology

Pharmacologically active polysaccharides make up the bulk of the fruit body at 60% to 90%, whereas with other medicinal mushrooms, polysaccharides make up a much smaller part of the biomass (closer to 10%–40%). These polysaccharides, like all fungal polysaccharides, demonstrate antioxidant and immune-modulating activities.[151]

Antidiabetic. Intraperitoneal and oral administration with a water-soluble polysaccharide from *T. fuciformis* and *T. aurantia* had significant hypoglycemic activity in normal mice and had significant antihyperglycemic activity in mice with streptozotocin-induced and genetic diabetes. These antidiabetic effects result from the increase in insulin secretion and the acceleration in glucose metabolism in the liver.[151]

Animal models administered with *T. mesenterica* had significantly decreased 2-hour postprandial serum concentrations of insulin without altering blood glucose concentrations. These results suggest that *T. mesenterica* has the ability to increase the insulin sensitivity, instead of increasing the insulin secretion, in normal rats.[153]

Clinical Applications

Cognitive impairment. Seventy-five subjects were randomly allocated to receive supplementation with *T. fuciformis;* this randomized clinical trial demonstrated that oral administration of *T. fuciformis* improved subjective memory complaints and cognitive performance in individuals with subjective cognitive impairment. Treatment was given in low doses of 600 mg per day or high doses of 1200 mg per day and there was significant improvement with short-term memory and executive performance in the high-dose treatment group. *T. fuciformis* supplementation was also associated with increases in gray matter volumes of several brain regions.[154]

Dosage

Condition	Dose	Timing
Subjective cognitive impairment[154]	1200 mg	daily

Fig. 90.14 *Psilocybe cyanescens.*

Psilocybe spp.

Psilocybe mushrooms have been used as ceremonial entheogens by cultures all over the world. In recent years, there has been a significant number of in vivo human trials exploring the benefits of psilocybin, an alkaloid derived from this mushroom. Psilocybin is being investigated for more complex psycho-emotional disorders such as addiction,[155-158] depression,[159] and end-of-life cancer-related psychological distress[160,161] (Fig. 90.14).

TOXICOLOGY

Many of these medicinal mushrooms are consumed as food in various parts of the world and are considered safe even when consumed in large quantities on a regular basis. One should be aware, however, that because some of these mushrooms can chelate heavy metals from their substrate, growing conditions must always be considered. Medicinal mushrooms must be obtained from dependable, certified organic sources.

Although mild side effects were reported in the literature, as with most natural health products, a practitioner will rarely run into these problems.

There were two reported cases of hepatic toxicity linked to the long-term use of Reishi.[162,163] There was also a case of chronic diarrhea in a 49-year-old man with non-Hodgkin lymphoma after prolonged consumption of Reishi extract.[164]

Prolonged consumption of Shiitake was linked to a few cases of dermatitis and photosensitivity.[165,166] Eosinophilia and gastrointestinal upsets were also observed with the use of Shiitake.[167]

DRUG INTERACTIONS

Drug interactions with medicinal mushrooms are more theoretical than clinically proven. The most common category of these drug interactions is one of "theoretical accumulation." Many of these mushrooms work on blood sugar, blood pressure, and blood lipid issues—the type of concerns for which patients are often already prescribed pharmaceuticals. Frequently, after consuming mushroom preparations together with the drugs for a month or so, the patient will require less or no pharmaceuticals for these conditions moving forward. These effects become less about drug–mushroom interactions and more about the mushroom preparation exerting its effects. Using mushroom preparation in diabetic or hypertensive patients requires close blood sugar monitoring during the first few months of treatment as the pharmaceutical dosage may require adjustment. The mushroom that has been highlighted the most in this area is Reishi because of its large range of therapeutic uses and the large number of people consuming it. Although anticoagulant, antiplatelet, immunosuppressant, and cytochrome p450 interaction concerns can be found in the literature, it is difficult to find research on actual cases of these problems. Again, concerns seem to lie more in the realms of theory and caution than actual cases.

SUMMARY

We have discussed a wide variety of potential medicinal applications for a wide variety of mushrooms, and many have extensive in vitro and in vivo research to support their efficacy. There is, however, a great need for more human clinical trials, though the trials that have been completed show positive therapeutic outcomes with few, if any, harmful side effects. There is wide use of mushroom polysaccharides as adjunctives to cancer therapies throughout Asia, though these strategies are underused in the United States. Recent interest in medicinal mushrooms has improved availability for lay people, but there continues to be little clinical use. As a consequence, there is still much to learn about specific dosage for many conditions, and further research is warranted.

A NOTE ABOUT PURCHASING MUSHROOM SUPPLEMENTS

When purchasing medicinal mushroom products, it is important to understand the extraction methods used in production. Mushrooms must be heated to properly extract the water-soluble polysaccharides, and cold ethanol extracts are not an appropriate delivery method for these compounds. When purchasing mushroom products as a liquid, the extract should have gone through a dual extraction process—with hot water and ethanol. When purchasing capsules, there should be powdered extract within the capsules, and if the label simply reads "mushroom powder," it is a good indication that the contents will be unprocessed mushroom powders that are generally indigestible. If a product is mycelium-based, the dose will most likely need to be higher because it will be diluted by the substrate the mycelium was growing on.

SUMMARY OF RESEARCH (TABLES 90.1 AND 90.2)

TABLE 90.1 Human Trials

Condition	Mushrooms	Dose Used in Trial
Bladder outlet obstruction	Reishi[46]	6 mg extract/day
Cancer treatment adjunct	Reishi[50]	1800 mg extract/day
	Turkey Tail[74-76]	3–9 g extract/day
	Maitake[86]	5–7 mg extract/kg/day
	Shiitake[121-123]	2 mg lentinan injections
	Agaricus[132]	
Oral HPV	Reishi and Turkey Tail[48]	400 mg/day
Chronic fatigue syndrome	Reishi[49]	2 g extract/day
Endurance support	Reishi and Cordyceps[54]	1170 mg/day (taken together)
		1335 mg/day
Chronic kidney disease	Cordyceps[66,67]	3–12 g/day
Microbiome dysregulation	Turkey Tail[73]	1200 mg PSP 3x/day
Psoriasis with GI inflammation	Chaga[84]	1 Tbs extract 3x/day
PCOS	Maitake[89]	1 g 3x/day
COPD	Oyster[94]	100 mg pleuran/day
Respiratory tract infections	Oyster[96,97]	10 mg pleuran/kg/day
Hyperlipidemia	Oyster[98]	30 g whole mushroom daily
Cognitive impairment	Lion's mane[111]	1 g 3x/day
	Tremella[154]	1200 mg/day
Depression and anxiety	Lion's Mane[109]	2 g daily
Diabetes	Agaricus[133]	500 mg 3x/day

TABLE 90.2 Proposed Actions From In Vitro Research and In Vivo Animal Studies

Action	Mushrooms	Microbes/Cancer Type	Compounds
Antioxidant	*Agaricus blazei*[169]		Ascorbic acid, carotenoids, ergothioneine, phenolic compounds, superoxide dismutase, tocopherols[168]
	Chaga[170-172]		
	Enokitake[173]		
	Maitake[174]		
	Reishi[175,176]		
	Shiitake[177,178]		
	Oyster[91]		
Antimicrobial	*Ganoderma spp.*[179-181]	*Staphylococcus aureus*	Sesquiterpene hydroquinones
	Shiitake[182,183,116,118,119]	*Streptococcus mutans*	
	Enokitake[136]	*Actinomyces naeslundii*	
	Agaricus blazei[130]	*Streptococcus mutans*	
		Porphyromonas gingivalis	
		Staphylococcus aureus	
		Escherichia coli	
		Bacillus subtilus	
		Pseudomonas aeruginosa	
Antiviral	Reishi[184]	HIV-1, H1N1, H5N1, HSV-2	Triterpenes
	Chaga[185]	Influenza A and B, HIV	PSK
	Shiitake[186-188]	HIV	Phelligridins
	Maitake[189]	HIV	
	Turkey Tail[190,191]	HIV	
	Phellinus spp.[144,149]	H1N1, H2N3, Avian flu, H3N2, H5N1	
Antitumor	Shiitake[112-114]	Lung, colon	Lentinan
	Cordyceps[63,64]	Glioblastoma	Cordycepin
	Red Belted Polypore[13,138]	Colorectal	Triterpenes
	Phellinus spp.[146,147]	Lung, liver	Hispolon
	Ganoderma spp.[41-43]	Cervical, breast, liver, lymphoma, leukemia, lung, colon	Triterpenes
	Turkey Tail[71,72]	Colorectal, breast	PSK
	Agaricus blazei[124-129]	Colon, leukemia, ovarian, lung, hepatocarcinoma, osteocarcinoma	Polysaccharide
	Maitake[85,87]	Prostate, bladder, liver, brain, blood, breast	MD fraction

Continued

TABLE 90.2 Proposed Actions From In Vitro Research and In Vivo Animal Studies—cont'd

Action	Mushrooms	Microbes/Cancer Type	Compounds
Antiallergic	*Ganoderma* spp.[39,192,193]		Triterpenes
Antiatherogenic	*Ganoderma* spp.[194,195]		Triterpenes
	Agaricus blazei[196,197]		β-glucans
	Shiitake[198]		Eritadine
	Oyster[91,199]		Chrysin, Lovastatin
Anti-inflammatory	Reishi[41]		Terpenes
	Chaga[81]		Phenolics, β-glucans
	Lion's Mane[100,101]		Hericenones, Hericerins
	Shiitake[115]		Lentinan
	Enokitake[137]		FVP-fve, FVP-2
	Red Belted Polypore[140]		Fomitopinic acid, Fomitosides
	Phellinus spp.[19,145]		Hispolon
	Maitake[174]		Ergosterol
Hypoglycemic	Maitake[200-202]		β-glucans
	Reishi[203-205]		Ganoderan A and B
	Turkey Tail[206]		PSP
	Chaga[207]		β-glucans
	Agaricus blazei[133,197,208]		β-glucans
	Cordyceps[209-211]		β-glucans
	Tremella spp.[152,153]		
Hepato-protective	*Ganoderma* spp.[211-214]		Triterpenes
Nootropic	Lion's Mane[103-105]		Erinacines, polysaccharides

Melaleuca alternifolia (Tea Tree)

Michael T. Murray, ND

OUTLINE

Melaleuca alternifolia (family: *Myrtaceae*)
Common name: tea tree

GENERAL DESCRIPTION

Tea tree *(Melaleuca alternifolia)* is a small tree native to only one area of the world: the northeast coastal region of New South Wales, Australia. The leaves, the portion of the plant that is used medicinally, are the source of a valuable therapeutic oil. Although there are more than 50 members of the *Melaleuca* family, the oil from the leaf of *M. alternifolia* has received the most research attention.

CHEMICAL COMPOSITION

Tea tree leaves contain about 1.8% of oil obtained via steam distillation.[1] This oil contains more than 48 compounds but is chiefly composed of the following[2]:

- 1-terpinen-4-ol
- 1,8-cineol
- Gamma-terpinene (see Fig. 91.1)
- *p*-cymene
- Other terpenes

The Australian standard (AS 2782–1985) "Oil of Melaleuca (Terpinen-4-ol Type)" sets a minimum content of terpinen-4-ol at 30% and a maximum 1,8-cineol content of 15%.[1]

HISTORY AND FOLK USE

The medicinal properties of crushed tea tree leaves were known to the Bundjalung Aborigines of northern New South Wales, Australia. The waters of a lagoon where tea tree leaves had fallen and decayed for hundreds of years were viewed as having tremendous healing properties.[1]

The popular name of tea tree was first reported in 1777, in Captain Cook's account of his second voyage, entitled *A Voyage to the South Pole.* The leaves of *M. alternifolia* were also used by the early settlers of Australia to make tea—hence, the further use of the popular name "tea tree."[1]

The first report of tea tree's medicinal use appeared in the *Medical Journal of Australia* in 1930.[3] A surgeon in Sydney reported impressive results using a solution of tea tree oil to clean surgical wounds. According to this report[3]:

> *The results obtained in a variety of conditions when it [tea tree oil] was first tried were most encouraging, a striking feature being that it dissolved pus and left the surface of infected wounds clean so that its germicidal action became more effective without any apparent damage to the tissues. This was something new, as most efficient germicides destroy tissue as well as bacteria.*

During World War II, tea tree oil was issued to soldiers to use as a disinfectant. The Australian Army went so far as to commandeer supplies of the oil and exempt leaf cutters from national service to maintain production. The production of tea tree oil during World War II was regarded as an "essential" industry.[1]

After World War II, the tea tree oil industry stagnated for more than 30 years. There were a number of reasons for this, including the general trend away from natural medicines and toward synthetic medical drugs. However, during the late 1970s and early 1980s, the Australian tea tree oil industry was reborn as successful plantations growing *M. alternifolia* were established.[1]

Tea tree oil has been used in the treatment of the following conditions[1]:

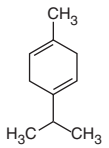

Fig. 91.1 Gamma-terpinene.

- Acne
- Aphthous stomatitis
- Boils
- Burns
- Carbuncles
- Corns
- Gingivitis
- Herpes
- Impetigo
- Infections of the nail bed
- Insect bites
- Lice
- Mouth ulcers
- Pharyngitis
- Psoriasis
- Ringworm
- Root canal treatment
- Sinus infections
- Skin and vaginal infections
- Thrush
- Tinea pedis (athlete's foot)
- Tonsillitis

A variety of tea tree oil–based cosmetic products exist in the marketplace, including toothpastes, shampoos and conditioners, creams, hand and body lotions, soaps, gels, liniments, and nail polish removers.

PHARMACOLOGY

Tea tree oil possesses significant antiseptic properties and is regarded by many as the ideal skin disinfectant. This claim is supported by its efficacy against a wide range of organisms, its good penetration, and its lack of skin irritation.[1] The therapeutic uses of tea tree oil are based largely on its antiseptic and antifungal properties. Bacteria and fungal organisms inhibited by tea tree oil are listed in Tables 100.1 and 100.2.[1,4–6]

CLINICAL APPLICATIONS

The historical uses of tea tree oil demonstrate its wide range of applications as an antiseptic. Three of the more popular and documented uses are in the treatment of skin infections, vaginal infections, and common foot complaints.

Skin Infections

Tea tree oil is useful in a broad range of dermal infections, not only because of its broad-spectrum antiseptic properties but also because of its capacity to mix with sebaceous secretions and penetrate the epidermis.

A clinical trial in patients with furuncles demonstrated that tea tree oil encouraged more rapid healing without scarring than was seen in matched control subjects.[7] Presumably, the positive clinical effects were a result of the oil's germicidal activity against *Staphylococcus aureus.* Tea tree oil efficiently kills *S. aureus* in the stationary growth phase and within biofilms, making it a promising tool for *S. aureus* eradication.[8] Furthermore, other studies have shown that tea tree oil is antimicrobial against antibiotic-resistant strains of *S. aureus.*[9,10] In the clinical trial, the method of application consisted of cleaning the site followed by painting the surface of the furuncle freely with tea tree oil two or three times a day.

For most skin infections, the most effective treatment appears to be direct application of full-strength, undiluted oil at the site of infection. If irritation occurs, diluted preparations may be tried.

TABLE 91.1 Bacteria Inhibited by *Melaleuca alternifolia* Oil

Bacterial Species	% (vol/vol)	
	MIC	MBC
Acinetobacter baumannii	1	1
Actinomyces viscosus	0.6	>0.6
Actinomyces spp.	1	1
Bacillus cereus	0.3	
Bacteroides spp.	0.06–0.5	0.06–0.12
Corynebacterium spp.	0.2–2	2
Enterococcus faecalis	0.5–>8	>8
E. faecium (vancomycin resistant)	0.5–1	0.5–1
Escherichia coli	0.08–2	0.25–4
Fusobacterium nucleatum	0.6–>0.6	0.25
Klebsiella pneumoniae	0.25–0.3	0.25
Lactobacillus spp.	1–2	2
Micrococcus luteus	0.06–0.5	0.25–6
Peptostreptococcus anaerobius	0.2–0.25	0.03–>0.6
Porphyromonas endodontalis	0.025–0.1	0.025–0.1

Lice Infestations

Pediculosis capitis (head lice infestation) treatment typically involves the application of topical insecticides such as a pyrethrin or permethrin. An in vitro study showed that tea tree oil exerted the greatest effect of essential oils tested against head lice.[11] A clinical study compared the efficacy and safety of three topical pediculicides. A pediculicide containing tea tree and lavender oil was compared with a product containing pyrethrins and piperonyl butoxide; the percentage of subjects who were louse-free 1 day after the last treatment with the tea tree oil and lavender product was 97.6% (41 of 42 patients) compared with 25% (10 of 40 patients) of those using the product containing pyrethrins and piperonyl butoxide.[12] These clinical results, along with in vitro studies, indicate that products containing tea tree oil are effective alternatives to pyrethrin-based products. However, it should also be mentioned that in an in vitro study looking at essential oils from tea tree, wild bergamot, clove, lavender, and Yunnan verbena, by far the best mite destruction was produced by clove oil, diluted either in coconut oil or sunflower oil.[13] Clove oil produced greater than 90% mortality within 2 hours in lice submitted to a 30-minute contact. The high content of eugenol was thought to be the main factor.

Oral Infections

Tea tree oil was shown to exert significant activity against oral pathogens, both bacterial and fungal, and was suggested to be a suitable alternative to chlorhexidine.[14] From a clinical perspective, these effects may best be used in the treatment of oral candidiasis (thrush). In one open study, 27 patients with acquired immunodeficiency syndrome (AIDS) and oral candidiasis that was clinically refractory to fluconazole were randomly assigned to receive either an alcohol-based or an alcohol-free melaleuca oral solution four times daily for 2 to 4 weeks. Overall, 60% of patients demonstrated a clinical response to the melaleuca oral solution (seven cases were cured, and eight cases were clinically improved) at 4-week evaluation.[15]

Tea tree oil appears to be quite useful in oral candidiasis in cancer patients. Often these yeasts are resistant to azole antifungal drugs. In one study, 301 yeasts isolated from the mouths of 199 patients with advanced cancer were shown to be susceptible to tea tree oil, including 41 yeasts that were known to be resistant to both fluconazole and itraconazole.[16]

A sublethal concentration of tea tree oil or terpinen-4-ol was shown to dramatically increase the activity of fluconazole against 32 clinical strains of fluconazole-resistant *Candida albicans.* The 24-hour exposure of fluconazole-resistant *C. albicans* strains to fluconazole with tea tree oil resulted in 62.5% of isolates being classified as susceptible, 25.0% as intermediately susceptible, and only 12.5% as resistant. Even better results were seen with terpinen-4-ol. These results demonstrate that combining tea tree oil with fluconazole may be the best approach in treating difficult yeast infections.[17]

Dandruff

There is evidence that dandruff appears to be related to the yeast *Pityrosporum ovale.* Because tea tree oil has antifungal activity against *P. ovale,* a 4-week study was designed to investigate the efficacy and tolerability of 5% tea tree oil shampoo versus a placebo in 126 male and female patients, aged 14 years and older, with moderate dandruff. The 5% tea tree oil shampoo group showed a 41% improvement in the quadrant-area-severity score, compared with an 11% improvement in the placebo group. Statistically significant improvements were also observed in the score for total area of involvement, the total severity score, and the itchiness and greasiness components of the patients' self-assessments. The scaliness component of patient self-assessment improved but was not statistically significant. There were no adverse effects.[18]

Acne

Topical application of tea tree oil is a suitable alternative to benzoyl peroxide preparations.[19,20] In one study, 124 patients with mild to moderate acne randomly received either a 5% gel of tea tree oil or 5% benzoyl peroxide lotion to be applied topically every day. After 3 months, both treatments produced a significant improvement in the mean number of both noninflamed and inflamed lesions, although with noninflamed lesions, benzoyl peroxide was found to be more effective. An important finding was that there were fewer reports of side effects (dryness, pruritus, stinging, burning, and skin redness) with tea tree oil (44% vs. 79%).[20]

Demodicosis

Demodex folliculorum and *Demodex brevis* are skin mites primarily found in the face, near the nose, the eyelashes, and eyebrows, but also occur elsewhere on the body. *D. folliculorum* is found in hair follicles; *D. brevis* in sebaceous glands. When these mite populations dramatically increase, it results in a condition known as demodicosis. There is also a link between *Demodex* infection with acne vulgaris and rosacea. Topical application of tea tree oil has been shown to be effective in improving demodex-related diseases.[21] In particular, tea tree oil at 50% concentration is effective in reducing *Demodex* mite counts and the surface inflammation associated with blepharitis, conjunctivitis, and keratitis. However, tea tree oil can also cause ocular irritation, so it has been suggested that because terpinen-4-ol is the most potent ingredient, using terpinen-4-ol alone would not only enhance its potency in killing *Demodex* mites but also reduce the adverse effects noted with the other ingredients in tea tree.[22]

Common Foot Problems

Tea tree oil, in emollient form (8% tea tree oil) or in solution (40%), can be massaged into the feet daily for the treatment of tinea pedis, foot irritation, and bromhidrosis (severely foul-smelling feet).

One researcher concluded, after 6 years of using different concentrations and preparations, that tea tree oil eradicated or improved the symptoms of tinea pedis when used daily by patients at home.[4] He also reported that even undiluted forms had little effect on onychomycosis (discussed further in "Fungal Nail Infection"). Diluted tea tree oil in solution was found to reduce foot irritation and promote wound healing with surgical incision in cases of corns, calluses, bunions, and hammer toes and was extremely effective in diminishing bromhidrosis.

In tinea pedis, one double-blind study found that 10% tea tree oil cream compared quite favorably with the antifungal tolnaftate in relieving symptoms but was less effective in eliminating the fungi from cultures.[5] Specifically, both the tea tree group (24 of 37 patients) and the tolnaftate group (19 of 33 patients) showed significant improvement in the four clinical parameters of scaling, inflammation, itching, and burning, but only 30% of the subjects who applied tea tree oil cream tested culture negative, compared with 85% in the tolnaftate group.

In another double-blind trial, 158 patients with tinea pedis were randomly assigned to receive either placebo or a 25% or 50% tea tree oil solution.[23] Patients applied the solution twice daily to affected areas for 4 weeks and were assessed after 2 and 4 weeks of treatment. A marked clinical response was seen in 68% of the 50% tea tree oil group and in 72% of the 25% tea tree oil group, compared with 39% in the placebo group. Mycologic cure was assessed by culture of skin scrapings taken at baseline and after 4 weeks of treatment. The mycologic cure rate was 64% in the 50% tea tree oil group compared with 31% in the placebo group. Four (3.8%) patients applying tea tree oil experienced moderate to severe dermatitis that improved quickly upon cessation of the study medication.

Fungal Nail Infection

Fungal nail infections (onychomycosis) are the most common cause of nail disease, affecting approximately 2% to 13% of the population. Standard medical treatments include débridement, topical antifungals, and systemic antifungals. All current therapies have high recurrence rates. Oral therapy has the added disadvantages of high cost and potentially serious adverse effects.

One study compared the efficacy and tolerability of the topical application of 1% clotrimazole (CL) solution with that of 100% tea tree oil for the treatment of toenail onychomycosis.[24] The 117 patients received twice daily applications of either 1% CL solution or 100% tea tree oil for 6 months. Débridement and clinical assessment were performed at 0, 1, 3, and 6 months. Culture specimens were obtained at 0 and 6 months. Each patient's subjective assessment was also obtained 3 months after the conclusion of therapy. After 6 months of therapy, the two treatment groups were comparable on the basis of culture cure (CL = 11%, tea tree = 18%) and clinical assessment documenting partial or full resolution (CL = 61%, tea tree = 60%). Three months later, about half of each group reported continued improvement or resolution (CL = 55%, tea tree = 56%). These results indicate that topical therapy with tea tree oil, in conjunction with débridement, provides excellent improvement in nail appearance and symptomatology.

Vaginal Infections

Tea tree oil demonstrates germicidal activity against a number of common vaginal pathogens and opportunistic organisms, including *Trichomonas vaginalis* and *Candida albicans.*[25]

A 40% solution of tea tree oil emulsified with isopropyl alcohol and water was found to be highly effective for the treatment of cervicitis, chronic endocervicitis, trichomonal vaginitis, and vaginal candidiasis.[25] Weekly in-office treatment (usually four to six were necessary) involved thorough washing of the perineum, labia, and vagina with a suitable scrub (the commercial product pHisoHex was used in the study). After drying, the affected areas were washed with a 1% tea tree oil solution. This was followed by insertion of a tampon (three 4 × 4–inch sponges) saturated with the 40% tea tree oil solution. Patients were instructed to remove the tampon after 24 hours.

For infectious processes—trichomonas and candidiasis—daily vaginal douches containing 1 quart of water with a 0.4% concentration of the oil were prescribed. No irritation, burning, or other side effects were reported or observed with either the office applications or the douches.

DOSAGE

A number of commercial products contain tea tree oil. Tea tree oil can be used as a topical antiseptic for reducing microbial counts in wounds, surgical incisions, and skin and vaginal infections. In addition, tea tree leaves can be used to make teas that may be of benefit in cases of sore throat, tonsillitis, sinus infections, and colitis.

TOXICITY

Tea tree oil appears to be very safe for use as a topical antiseptic.[26] However, it may cause allergic contact dermatitis in some individuals. During a 3-year period, seven patients were seen in an outpatient dermatology clinic in Kona, Hawaii, for contact dermatitis because of the use of commercially available product containing 100% tea tree oil.[27] The patients were treating preexisting skin conditions, which included foot fungus, dog scratches, insect bites, and rashes. All patients presented with an eczematous dermatitis. Patch tests indicated that all patients were sensitive to a 1% solution of tea tree oil. Individuals should apply the oil to a small area of skin before using tea tree oil for the first time so as to avoid contact dermatitis over a larger area.

The oral ingestion of tea tree oil cannot be recommended because it could lead to a toxic reaction. However, folk use suggests that oral ingestion of tea from the leaves is reasonably safe.

DRUG INTERACTIONS

Tea tree oil may produce a synergistic effect with other topical antimicrobials. In an in vitro study, tea tree oil and tobramycin in combination produced significantly lower minimum inhibitory concentrations against *Escherichia coli* and *Staphylococcus aureus.*[28] A similar synergism was demonstrated between tea tree oil and the antifungal compound amphotericin in inhibiting *Candida* species.[29]

Melatonin

Ron Reichert, BA, ND

OUTLINE

INTRODUCTION

Melatonin (*N*-acetyl-5-methoxytryptamine) is a neurohormone synthesized in reply to neuronal signals arriving from the suprachiasmatic nucleus (SCN) of the anterior hypothalamus.[1,2] Its action in promoting sleep and the associated sleep/wake cycle is primarily the result of two G protein–coupled receptors within the SCN called MT1 and MT2.[3] Both receptors modulate neuronal activity within the SCN and influence circadian rhythm activation.[4] Biochemically, melatonin is synthesized as follows: l-tryptophan to 5-hydroxytryptophan to serotonin. The biogenic amine serotonin is then converted to *N*-acetylserotonin and ultimately into melatonin with the rate-limiting steps for melatonin production catalyzed by two enzymes, arylalkylamine *N*-acetyl transferase and hydroxyindole-*O*-methyltransferase (Fig. 92.1).[5] Melatonin is secreted by the pineal gland in response to darkness. This latter action has been elegantly described as the "opening of the sleep gate."[6]

PHARMACOKINETICS

Peak plasma concentrations of endogenous melatonin in adults reach a high of 60 to 70 pg/mL and typically occur between 2:00 and 4:00 AM.[5] Supplementary exogenous melatonin, according to the result of one human study, has a 15% absolute bioavailability at the 2- and 4-mg oral doses.[7] In another study using 250 mcg of daytime melatonin in healthy volunteers, it was noted that melatonin had a rapid absorption, with a mean time to reach maximal concentration (T_{max}) of 23 minutes. The mean terminal half-lives of melatonin were 36 ± 6 minutes and 45 ± 14 minutes, in men and women, respectively.[8] Sustained-release melatonin (2 mg), in contrast, has a T_{max} of 3 hours, which is delayed in the presence of food (T_{max} 0.75 hours). Terminal half-life is 3.5 to 4 hours.[9]

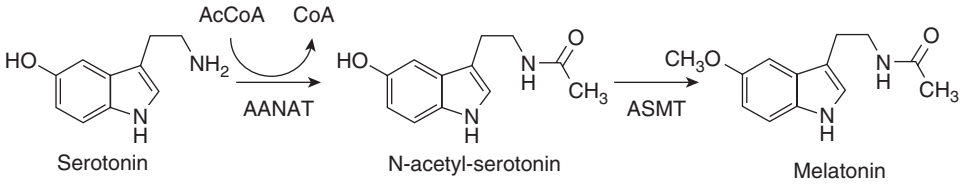

Fig. 92.1 Synthesis of melatonin.

CLINICAL APPLICATIONS

Jet Lag

Melatonin for the treatment of jet lag has been extensively studied in controlled studies and proven to be remarkably successful in reducing jet lag symptoms.[10] In one early double-blind, placebo-controlled study, 20 healthy volunteers (8 women, 12 men; 28–68 years) engaging in long-haul air flights across five time zones were invited to participate to explore the effects of melatonin on their jet lag symptoms. Subjects were randomly assigned to 5 mg of melatonin or placebo for 3 days before their outward flight (London to New Zealand) and during the flight between 10:00 AM and 12:00 PM local time, as well as for 3 days after their arrival between 10:00 PM and 12:00 AM . According to the results of visual analog scale (VAS) testing, those using the melatonin had less overall jet lag symptoms at day 10 (mean score 2.15) versus placebo (3.40; $P < 0.01$). Moreover, the melatonin group experienced a better adaptation pattern in terms of sleep pattern, daytime tiredness, and normal energy levels than the placebo group ($P < 0.05$).[11] Although this latter study suggested an optimal time pattern for melatonin use in an eastbound flight, another author noted that bedtime may not be an ideal time to employ melatonin on a westbound flight that crosses less than six to eight time zones. He suggested employing a lower dose of melatonin (0.5 mg) on the westbound flight later in the evening as "melatonin has the least phase shifting effects when it overlaps with endogenous secretion."[12]

Acute Sleep

It is estimated that 50 to 70 million American adults have difficulty sleeping.[13] This issue of poor sleep quality can have profound consequences for the individual and society at large, including an increased risk of accidents and mood and behavioral changes, as well as a reduction in work productivity.[14] One of the numerous options available to help improve overall sleep is melatonin, both in healthy adults as an acute remedy for insomnia and in the elderly dealing with issues of chronic insomnia. The acute use of melatonin in healthy adults without insomnia at doses of 0.3 to 1 mg at 8:00 or 9:00 PM significantly reduces sleep-onset latency and latency to stage 2 sleep compared with the placebo (P <0.001). Moreover, melatonin does not produce any "sleep hangover" symptoms (according to the Profile of Mood States and Four Choice Reaction Time Test) commonly associated with benzodiazepine-type drug use.[15]

Insomnia in the Elderly

Most elderly individuals report sleeping an average of 7 hours a night. Although the total amount of sleep time does not change as we age, alterations in sleep architecture are common.[16] This includes a decrease in both deep sleep (stages 3 and 4 slow wave sleep) and rapid eye movement (REM) sleep, as well as an increase in stage 1 (light) sleep.[17] Older individuals also have a reduction in endogenous melatonin production (likely due to a deterioration in the neuronal functioning of the SCN), which in turn disrupts the normal wake/sleep cycle.[18]

In a controlled clinical trial, 30 men and women over 50 years of age with both chronic insomnia and normal sleep patterns were randomized to receive capsules with either 0.1, 0.3, or 3 mg of melatonin or placebo 30 minutes before bedtime for 7 days. Treatments were separated by a 1-week washout period. Using polysomnography, the researchers concluded that although melatonin did not improve sleep efficiency in normal subjects, those with chronic insomnia had significant improvements in sleep efficiency at all three melatonin doses used, with the 0.3 mg dose triggering the strongest effect ($P <$ 0.0001). The physiological dose acted primarily in the middle portion of the night and raised plasma melatonin levels to normal. The authors noted that 3 mg of melatonin significantly raised plasma levels throughout a portion of the day and triggered reductions in core body temperature after ingestion of the hormone.[6]

Prolonged Release Melatonin in the Elderly

After a 2-week single blind run-in period, 354 elderly men and women (55–80 years of age) with primary insomnia were randomized to receive 2 mg of a prolonged release (PR) melatonin or placebo 2 hours before bedtime, for 3 weeks. Subjects enrolled in the study were asked to complete a sleep diary measuring quality of day and night, plus a battery of sleep questionnaires including the Pittsburgh Sleep Quality Index (PSQI), Leeds Sleep Evaluation Questionnaire (LSEQ), as well as quality-of-life (World Health Organization-5 [WHO-5] Well Being Index) and clinician Clinical Global Impression (CGI) scores. At the conclusion of the trial, those who took the melatonin had improved (26%) quality of sleep and morning alertness as recorded by the LSEQ in contrast to placebo (15%) ($P = 0.014$). Sleep latency, as noted by the PSQI results, improved in subjects employing the PR melatonin by 24.3 minutes compared with 12.9 minutes for the placebo group ($P = 0.028$). Quality of life as recorded by the WHO-5 Index was also improved in the active group ($P = 0.034$).[19] A similar study supported the latter conclusion with a positive effect found on the restorative value of sleep in elderly patients using 2 mg of PR melatonin. Moreover, melatonin users did not experience any rebound insomnia or withdrawal symptoms at the conclusion of the controlled study. The authors noted that plasma cortisol increased in middle-aged adults, and this phenomenon might impair sleep. Administration of PR melatonin in older adults with primary insomnia may delay the production of nighttime cortisol, with subsequent improvements in both sleep quality and morning alertness.[20]

Magnesium, Melatonin, and Zinc on Primary Insomnia and the Elderly

Magnesium, along with zinc, is crucial for the endogenous synthesis of melatonin according to the results of one study. Elderly men and women (n = 43; average age 78.3 years) living in a long-term care facility were invited to participate in a double-blind, placebo-controlled study of 60 days' duration on melatonin, zinc, and magnesium on primary insomnia. Each volunteer was randomized to receive a 100 g pear pulp food supplement with 5 mg melatonin, 225 mg of magnesium, and 11.25 mg of zinc, or placebo 1 hour before bedtime for 2 months. At the conclusion of the trial, those employing the active supplement experienced an improvement in their overall PSQI scores compared with placebo ($P < 0.001$). Moreover, the LSEQ results confirmed that

those employing the food mixture not only had better quality of sleep but had greater ease getting to sleep ($P < 0.001$). Quality of life was measured by the Medical Outcomes Study Short-Form 36 scale, which noted that the active group had better physical and mental functioning after 8 weeks of treatment ($P = 0.006$). Adverse effects were minimal, with only two participants in the treatment group complaining of headache, whereas one volunteer in the placebo group complained of epigastric pain.[21]

Insomnia in Perimenopausal Women

In a series of case reports, 11 perimenopausal women (45–52 years) with insomnia were treated with 7.5 to 15 mg of mirtazapine for 2 to 4 weeks. Two milligrams of melatonin were then added to the treatment regimen, along with a concomitant reduction and discontinuation of mirtazapine for 30 to 90 days. Global PSQI scores decreased from 17.45 at baseline to 8.55 at the second visit (mirtazapine and PR melatonin) to 6 by the third visit (PR melatonin) ($P < 0.01$). These latter changes were paralleled by a similar drop in PSQI sleep latency scores, with 52.73, 21.36, and 18.64 minutes at baseline, visit 2, and visit 3, respectively ($P < 0.01$). Volunteers also noted that their quality of life as measured by the WHO-5 score improved significantly by 89% from baseline ($P < 0.01$).[22]

Chronic Sleep Onset Insomnia in Children

Pediatric insomnia is estimated to affect 1% to 6% of children, but can be significantly elevated to 50% to 75% if there are other associated psychiatric or neurodevelopmental issues such as attention deficit hyperactivity disorder (ADHD), autism spectrum disorders (ASDs), and epilepsy.[23]

A group of children (49 boys, 13 girls; aged 6–12 years) with chronic sleep-onset insomnia of more than 12 months' duration were randomized to receive 5 mg melatonin or placebo at 7 pm for 30 days. Using several questionnaires measuring overall health status (RAND General Health Rating Index and Functional Status II), children who used the melatonin had better outcomes in terms of eating, sleeping, response to attention, fatigue, illness, and overall health than those who received the placebo ($P < 0.05$). In addition, melatonin users had an advancement in their sleep onset by 57 minutes ($P = 0.003$), a reduction in sleep latency by 17 minutes ($P = 0.048$), and a decrease in their dim light melatonin onset (DLMO) by 82 minutes ($P < 0.001$).[24]

Insomnia, Melatonin, and Chronic Obstructive Pulmonary Disorder

Approximately 40% of patients with chronic obstructive pulmonary disorder (COPD) complain of sleep disorders.[25] Treatment of sleep disorders in this population group may help improve their overall quality of life as noted in one study employing melatonin.[26] Thirty-nine patients (64–67 years of age on average) with stage II to IV COPD were randomized to receive 3 mg of melatonin or placebo 1 hour before bedtime for 21 days. In the 25 patients who completed the study, the overall PSQI score was significantly improved in those employing the melatonin ($P = 0.012$). In addition, components of the PSQI including an improvement in sleep latency ($P = 0.008$) and an increase in sleep duration ($P = 0.046$) were noted in the active group. There was no difference between active and placebo groups in the Epworth Sleepiness Scale (ESS), lung function parameters (forced expiratory volume in 1 second [FEV1], forced vital capacity [FVC], and FEV1/FVC ratio), or functional exercise capacity as measured by the 6-minute walking distance test. Four of the 25 cases reported adverse events including mild headache and dryness of mouth in the melatonin group and tongue swelling, mouth dryness, and loss of appetite in the placebo group.[27] A subsequent controlled study in patients with COPD has shown that a similar dose of melatonin decreases 8-isoprostane from a baseline measure of 20.41 ± 2.92 pg/mL to 12.70 ± 2.18 pg/mL ($P = 0.04$) by month 3. Moreover, dyspnea was improved significantly by melatonin treatment ($P = 0.01$) without changes in lung function or exercise capacity. A significant increase in interleukin-8 (IL-8) was seen in the placebo group only ($P = 0.03$).[28]

Tetraplegia, Sleep Disruption, and Melatonin

Individuals with spinal cord injury, especially tetraplegia, have higher rates of sleep disturbances and subsequently poorer quality of life.[29] Eight individuals with chronic complete tetraplegia (average age 49.5 years) were randomized to receive 3 mg of melatonin capsules or placebo 2 hours before bedtime for 3 weeks. In those taking the melatonin, the proportion of light sleep (stages 1 and 2 sleep) significantly increased after melatonin use ($P < 0.05$). In addition, quality of life as measured by Assessment of Quality of Life Questionnaire (AQoL) subscale 'psychological wellbeing' was significantly improved after melatonin use compared with placebo ($P < 0.01$). Similarly, values on the Basic Nordic Sleepiness Questionnaire (BNSQ) item number 12 (i.e., how many hours of sleep per night the participant was experiencing), were significantly elevated after melatonin use in contrast to placebo ($P < 0.05$).[30]

Melatonin, Beta-Blockers, and Insomnia

In the U.S. an estimated 22 million people use beta-blockers on a regular basis. As this class of medications suppresses nighttime melatonin secretion, it could explain the insomnia linked to this drug.[31] Sixteen patients (age 45–64 years) using beta-blockers (i.e., atenolol or metoprolol) were randomized to receive 2.5 mg melatonin or placebo every night for 3 weeks. In comparison with placebo, 3 weeks of melatonin supplementation significantly increased total sleep time (+36 min; $P = 0.046$), sleep efficiency (+7.6%; $P = 0.046$), and reduced sleep onset latency to Stage 2 (-14 min; $P = 0.001$) as recorded by polysomnography. In addition, and in comparison to placebo, melatonin also significantly increased stage 2 sleep time (+41 min; $P = 0.037$) but did not alter the duration of other sleep stages.[31]

Fibromyalgia

Fibromyalgia (FM) is a challenging condition with characteristic symptoms that include widespread and variable chronic pain, as well as fatigue, stiffness, cognitive disturbances, depression, and insomnia.[32] Although alterations in the secretion of melatonin have been observed in FM patients, whether or not this latter phenomenon contributes to the pathophysiology of this disease remains controversial.[33] Several studies suggested, however, that melatonin is of value in treating this chronic musculoskeletal condition.

Twenty-one female patients (average age 51 years) who met the American College of Rheumatology (ACR) criteria for primary FM for at least 6 months before their participation in an uncontrolled pilot study were invited to help evaluate the effects of a 3 mg capsule of melatonin 30 minutes before bedtime for 1 month. Of the 21 patients who completed the study, 19 were found to have a significant reduction from baseline in musculoskeletal tender point count (−28.6%), severity of pain (−33.4%), and sleep disturbances (−67.2%) as measured by VAS ($P < 0.05$). Although fatigue, depression, and anxiety did not show statistical improvement on VAS, the overall physician and patient VAS global treatment assessment scores of FM disease status (with 10 representing the worst score) improved from 7.6 to 5.7 and 7 to 4.7, respectively. Four patients experienced mild and transient side effects during the trial, including tremor, heartburn, anxiety, and somnolence.[34]

In another randomized, double-blind placebo-controlled trial, 101 patients (6 men, 95 women; 18–65 years) with ACR confirmed primary FM were randomized to one of four treatment groups: (A) 20 mg/day fluoxetine and placebo; (B) 5 mg/day melatonin and placebo; (C) 20 mg/day fluoxetine with 3 mg/day melatonin; and (D) 20 mg/day fluoxetine and 5 mg/day melatonin for 2 months. Using the Fibromyalgia Impact Questionnaire (FIQ) to evaluate the clinical outcomes, the researchers determined that compared with baseline, both fluoxetine and melatonin as single therapies significantly reduced within-group symptom scores by 21.5% and 18.9%, respectively ($P < 0.05$). However, those volunteers combining fluoxetine and melatonin at both 3 and 5 mg doses experienced nearly comparable (28.8% vs. 28.9%) and highly significant reductions in their FIQ scores ($P < 0.001$). Although all treatments reduced FIQ pain scores, it was interesting to note the reduction in fatigue scores in groups B, C, and D by 23.7%, 20.3%, and 34.7%, respectively, compared with only 9.9% in the fluoxetine-only treatment group. Fluoxetine as a single agent did not alter the rest/sleep score compared with the significant improvements seen in groups B, C, and D.[35]

Chronic Fatigue Syndrome

Much like FM, chronic fatigue syndrome (CFS) is associated with a number of symptoms, including intense and disabling fatigue that does not improve with rest.[36] One of the factors contributing to fatigue and sleep disturbances in CFS is disruption in the hypothalamic-pituitary-adrenal axis.[37] However, under research scrutiny, both adults and adolescents with CFS have increased levels of melatonin, suggesting the hormone has no role to play in this disorder.[37] Research on DLMO concluded that a certain subset of CFS patients may respond to the therapeutic use of melatonin. DLMO is a naturally occurring event that may account for delayed sleep phase syndrome in 10% of chronic insomniacs.[38]

Twenty-nine patients (24 women, 5 men; average age 33.2 years) with CFS were asked to take 5 mg of melatonin at bedtime for 3 months. Using the checklist individual strength (CIS) questionnaire to measure several variables, the authors determined that the total score ($P = 0.006$), as well as the subscores of fatigue ($P = 0.017$), concentration ($P = 0.031$), motivation ($P = 0.010$), and activity ($P = 0.008$), improved significantly after 90 days of melatonin use. Moreover, those patients with late DLMO (>21.30 hours) overall CIS and its subscores were better than in those CFS patients with early DLMO.[39]

Children With Epilepsy

Seizure-free epileptic children (n = 31; 3–12 years of age) with a history of either partial or generalized seizures and using 10 mg/kg per day of sodium valproate participated in a double-blind, placebo-controlled study of 8 weeks' duration. The children were randomized to receive either melatonin tablets (6 mg for those less than 9 years of age and less than 30 kg body weight or 9 mg for those more than 9 years of age and more than 30 kg body weight, to be taken in the evening) or comparable placebo 1 hour before bedtime. The primary end point of the study was evaluated using the parental Sleep Behavior Questionnaire. By the conclusion of the controlled trial, those children using the additional melatonin had a significantly greater average percentage reduction in their total sleep scores (24.4%) compared with placebo (14.4%) ($P < 0.05$). Moreover, the median reduction in the parasomnia scores significantly favored those who took melatonin (60%) relative to the placebo (36.4%) ($P < 0.05$). No adverse effects were noted during the trial.[40] In another placebo-controlled trial, 11 children aged 6 to 11 years with epilepsy were randomized to receive 9 mg of sustained release melatonin or placebo 30 minutes before bedtime for 1 month. At the conclusion of the trial, melatonin decreased mean sleep latency by 11 minutes ($P = 0.02$) and mean wake after sleep onset (WASO) by 22 minutes ($P = 0.04$) in contrast to placebo. Sleep diaries revealed that children who employed melatonin slept 11 minutes more ($P = 0.1$) and woke up 18 minutes later ($P = 0.048$) in contrast to those employing placebo. Furthermore, and compared with placebo, the use of melatonin increased stage 3 by 5.5% ($P = 0.04$) and REM latency by 58 minutes ($P = 0.04$) and decreased REM % by 5.8% ($P = 0.01$). Melatonin did not alter seizure frequency. Four children reported adverse events while taking melatonin compared with two children on placebo.[41]

Autism/Fragile X Syndrome

In a recent review and meta-analysis, the authors noted that children with ASDs not only have a higher incidence of sleep-associated problems, but that melatonin use led to significant improvements in sleep duration and sleep-onset latency compared with placebo ($P < 0.01$). This poor sleep pattern in turn can lead to a worsening of overall autistic behavior symptoms.[23]

In one double-blind, placebo-controlled, crossover trial, 18 subjects (16 boys, 2 girls; mean age 6 years) with ASD or fragile X syndrome, or both, and insomnia were randomized to receive 3 mg melatonin or placebo 30 minutes before bedtime for 14 days. After 2 weeks, subjects were crossed over, such that the active group received placebo and vice versa. Children were evaluated using actigraphy and parentally recorded sleep diaries. After 4 weeks and in 12 of 18 children who had complete data sets, the authors noted that those using the melatonin had an improvement in the total night's average sleep duration (+21 minutes longer than placebo; $P = 0.02$), a reduction in sleep latency time (28 minutes vs placebo; $P = 0.0001$), and a 42-minute earlier sleep-onset time in contrast to the placebo group ($P = 0.02$).[42]

A controlled clinical trial supports the use of melatonin in children with ASD and neurogenetic disorders (NGD). In this study, 125 children and adolescents (2–17.5 years of age; 92 males, 33 female consisting of 96.8% ASD, 3.2% Smith-Magenis syndrome) whose sleep did not improve while employing behavioral interventions were randomized to receive prolonged-release melatonin (2 mg escalated to 5 mg) or placebo for 13 weeks. At the conclusion of the trial, participants who employed sustained-release melatonin slept on average 57.5 minutes longer at night compared with 9.14 minutes with placebo ($P = 0.034$). Moreover, sleep latency (SL) decreased on average by 39.6 minutes on average in the active group and 12.5 minutes with placebo ($P = 0.011$).[43]

Children With Insomnia and Attention Deficit Hyperactivity Disorder

Twenty-seven children (6–14 years of age) diagnosed with ADHD and insomnia and employing stimulant medications (i.e., methylphenidate, dextroamphetamine), participated in a controlled trial. Those subjects who did not respond to a 10-day sleep hygiene regimen were randomized to receive 5 mg of melatonin or placebo 20 minutes before bedtime for 1 month. Compared with the placebo, children who took melatonin had a significant reduction in sleep-onset latency as measured by somnolog (46.4 minutes vs. 62.1 minutes placebo) and actigraphy ($P < 0.01$) at the conclusion of the trial. Adverse events were considered mild by the investigators. Melatonin treatment and the subsequent improvement in sleep did not, however, improve ADHD symptoms as noted by Conner's Attention Deficit Scale, Parent version scores.[44]

One hundred and five medication-free children (aged 6–12 years) with ADHD were randomized to receive 3 mg of melatonin or 6 mg of melatonin if body weight was less than 30 kg or greater than 30 kg, respectively, or placebo at 7:00 PM for 30 days. Those subjects who used

melatonin had advancements in sleep onset as measured by actigraphy (26.9 ± 47.8 minutes), compared with a delay (10.5 ± 37.4 minutes) in the placebo group ($P < 0.0001$). Additionally, there was a significant increase in total sleep time (19.8 ± 61.9 minutes) versus a reduction (13.6 ± 50.6) seen in the placebo group ($P = 0.01$). Children treated with the active compound showed an advance in DLMO of 44.4 ± 67.9 minutes compared with a delay in children who received the placebo ($P < 0.001$). No changes were noted in behavior and cognition. Adverse events did not differ between active groups and placebo.[45] A long-term 3.7-year follow-up using the same group of children (93% response rate) verified that melatonin use was not associated with any serious side effects but also did not provide a permanent cure for insomnia in ADHD children.[46]

Children With Migraine/Tension-Type Headaches

Tension headaches and migraines are two of the more likely reasons that will cause children to complain of pain. Annual prevalence for migraine and tension-type headaches can vary with between a 3% to 11% and a 10% to 24% occurrence, respectively.[47]

In an uncontrolled pilot study, 22 children (10 boys and 12 girls; age range 6–16 years) with various types of long-standing (average 40.05 ± 30.2 months) headache-type discomfort (13 recurrent migraines/no aura; 8 chronic tension-type headaches; 1 migraine with aura) participated in a 12-week study on the effects of oral melatonin. After a 1-month washout period in which all preventive therapy was discontinued, the children were asked to take 3 mg of melatonin at bedtime for 90 days. At the conclusion of the study and according to the results of a structured daily headache diary, the frequency (i.e., the number of attacks per month) and the duration of attacks (hours) decreased from 12.3 to 5.7 and 13.5 to 9.7, respectively ($P < 0.001$). Pragmatically, and as the authors noted, 14 of the 21 subjects (one child stopped the melatonin due to excessive somnolence) had a greater than 50% reduction in headache attacks. Notably, four of the children had complete resolution of their headaches.[48]

Functional Dyspepsia

Postprandial fullness and early satiation, along with epigastric pain and burning without evidence of upper gastrointestinal structural pathology on endoscopy, are the hallmark of Rome III diagnostic criteria for functional dyspepsia.[49] One group of researchers suggested that melatonin use stimulates enterocytes to produce bicarbonate, which in turn may help neutralize gastric hydrogen chloride and, therefore, reduce symptoms as evidenced by the following study.[50] Sixty patients (18 men, 42 women; ages 19–39 years) with a 3- to 12-year history of nonulcer dyspeptic symptoms (i.e., chronic or recurrent epigastric pain) were randomized to receive 5 mg of melatonin or placebo in the evening for 3 months. After 12 weeks of treatment and using a 10-point scale (0 = no symptoms; 10 = maximum symptoms) for therapeutic evaluation, 17 of 30 (56.6%) patients using the melatonin had their condition resolve completely, such that they did not require further treatment, whereas an additional 9 of 30 (30%) patients experienced a partial improvement in symptoms (i.e., reduction in nighttime gastric pain) ($P < 0.01$). Although 4 patients in the active treatment group noted no change in symptoms, a larger percentage of subjects (93.3%) using placebo noted no change in their condition. The authors noted that those who had a previous infection with *Helicobacter pylori* were less likely to respond to melatonin treatment.[50]

Irritable Bowel Syndrome

It is estimated that 7% to 15% of the U.S. population has irritable bowel syndrome (IBS), a painful abdominal condition that is primarily associated with diarrhea and/or constipation, along with a number of other symptoms, including gas and bloating.[51] Recent research showed that the excretion of the urinary metabolite of melatonin (6-sulphatoxymelatonin) was significantly lower in subjects with IBS than controls ($P = 0.0004$), suggesting that melatonin is involved in the pathogenesis of IBS by acting on the enterochromaffin cells in the gastrointestinal tract.[52]

In a double-blind, placebo-controlled study, 18 patients (12 men, 6 women; ages 18–65 years) with IBS were randomized to receive 3 mg of melatonin at bedtime or a matching placebo for 2 months. By the conclusion of the trial, those subjects taking melatonin had a 45% improvement in their overall IBS symptom scores (i.e., pain severity and frequency, bloating) compared with 16.7% in those taking placebo ($P < 0.05$). Moreover, the extracolonic symptom scores, including headache, backache, body aches, thigh pain, and lethargy, were significantly lower in the melatonin group compared with pretreatment values ($P < 0.001$) and the placebo group ($P < 0.05$). Overall, those subjects taking the melatonin experienced an improved quality of life score (43.63%) in contrast to those taking placebo (14.64%) ($P < 0.05$). Three subjects experienced side effects, including decreased libido and drowsiness.[53]

In another controlled study, 80 postmenopausal women (mean age 55.3 ± 6.4 years) with constipation-predominant IBS (IBS-C) (n = 40) and diarrhea-predominant IBS (IBS-D) (n = 40) received 3 mg of melatonin in the morning and 5 mg of melatonin in the evening or a placebo for 6 months. Clinical outcomes were evaluated using a 10-point VAS (mild [1–4 points], moderate [5–7 points], and severe [8–10 points]) along with patient observations recording the changes in visceral pain, abdominal bloating, constipation and/or diarrhea along with a urinary marker (urinary 6-sulfatoxymelatonin [6-HMS]) of melatonin metabolism.

After 6 months of treatment, the researchers determined that in those with IBS-C, there was a negative correlation ($r = -0.714$) between symptom scores and the excretion of 6-HMS. In contrast, in those patients with IBS-D, this correlation was positive ($r = 0.409$). As such, only the IBS-C group employing the melatonin had statistically significant reductions in IBS symptoms at both the 4- ($P < 0.05$) and 6-month ($P < 0.01$) mark. In the IBS-C group, melatonin decreased the intensity of visceral pain and abdominal bloating in 70% of patients ($P < 0.01$) and constipation in 50% of patients ($P < 0.05$).[54]

Gastroesophageal Reflux Disease

In 2004 it was estimated that 20% of the American population has gastroesophageal reflux disease (GERD), which is responsible for 64.6 million prescriptions annually.[55] According to several studies, melatonin is of therapeutic value with or without omeprazole.

In this study, 36 individuals with GERD were selected and equally placed into four groups: control; 3 mg melatonin at bedtime; 20 mg of omeprazole twice daily; and 3 mg of melatonin and 20 mg of omeprazole twice daily for 2 months. After 8 weeks, those using the melatonin alone had a significant reduction in GERD symptoms, increase in lower esophageal sphincter (LES) pressure (better LES tone), increase in serum gastrin, a reduction in gastric basal acid output, and an increase in serum melatonin levels ($P < 0.05$). In contrast, although omeprazole was also effective in reducing GERD symptoms ($P < 0.05$), it did not alter LES tone in a significant fashion. The combination of melatonin and omeprazole had similar results in the single melatonin group, but had a better reduction in basal acid output and an increase in serum gastrin ($P < 0.05$).[56]

Individuals (141 men, 210 women; mean age 44 years) with at least one episode of moderate to severe heartburn within the previous week before the onset of treatment within a clinical trial were randomized to receive 6 mg melatonin plus vitamin B_6 (25 mg), vitamin B_{12} (50 mcg),

folic acid (10 mg), tryptophan (100 mg), methionine (100 mg), and betaine (100 mg) or one capsule (20 mg) omeprazole per day in the evening for 40 days. After 40 days, individuals using the natural product combination had 100% reduction in symptoms as measured by a five-point severity scale, compared with the reduction in symptoms seen (65.7%) in the omeprazole group ($P < 0.05$). As an observation, those 34.3% of the subjects who experienced a persistence of their GERD symptoms with the use of omeprazole had complete resolution of their symptoms after 40 days with the natural combination of vitamins, melatonin, and amino acids.[57]

The authors suggested that the efficacy for their combination medication was a result of several factors. Melatonin may block the production of nitric oxide synthase, which may help lower the degree of LES relaxation. Melatonin also stimulates the production of bicarbonate, which protects against the action of gastric acid production. Moreover, the combination of vitamin B_6, tryptophan, and vitamin B_{12} may decrease acute gastrointestinal pain as a result of serotonin inhibiting the nociceptive system. Methionine and betaine may induce S-adenosyl methionine production, which has both anti-inflammatory and analgesic properties.[57,58]

Cancer

According to the results of a systemic review, melatonin decreased the risk of death from solid tumors at the 1-year mark.[59] This was supported by several independently published articles, primarily by one of the premier researchers on melatonin use and cancer, Professor Paolo Lissoni.

Nonsmall Cell Metastatic Lung Cancer

One hundred patients (59 men, 41 women; average age 39–81 years) with metastatic nonsmall cell lung cancer were randomized to receive chemotherapy (cisplatin and etoposide) every 21 days for four cycles or chemotherapy plus 20 mg of melatonin in the evening. Patients in the melatonin group continued to use melatonin after chemotherapy cessation. Reviewing the clinical response after 60 to 72 months of follow-up, the authors determined that those using the melatonin and chemotherapy combination had a significantly better complete and partial response (35%; 17 of 49 patients) to treatment versus the chemotherapy group (18%; 9 of 51 patients) ($P < 0.05$). Moreover, a progressive disease state was seen in 20 of 51 patients in the chemotherapy group in contrast to 6 of 49 patients in the chemotherapy/melatonin group ($P < 0.01$). Side effects of chemotherapy, including neurotoxicity, thrombocytopenia, weight loss of more than 10%, and asthenia, were notably reduced in the melatonin group. Overall 5-year survival rate was significantly longer in those concomitantly treated with melatonin ($P < 0.001$). Three of the 49 patients were still alive 5 years from the date of therapy onset in the combination group, compared with no patients in the chemotherapy alone section.[60]

Metastatic Solid Tumors: Gastric, Colorectal, and Nonsmall Cell Lung Cancer

Three hundred and seventy patients with metastatic nonsmall cell lung cancer, colorectal cancer, or gastric cancer were randomized and treated with the appropriate chemotherapy alone or chemotherapy plus melatonin 20 mg/day in the evening. After 24 months, the overall response rate (complete and partial remission) was higher in the melatonin and chemotherapy group (68 of 167 patients; 36%) versus chemotherapy alone (37 of 183 patients; 20%) ($P < 0.001$). In addition, the 2-year survival rate in those using melatonin adjunctively was better (47 of 187 patients; 25%) versus those employing chemotherapy as a sole treatment (24 of 183 patients; 13%) ($P < 0.05$).[61]

Metastatic Breast Cancer

Melatonin may enhance the effects of the drug tamoxifen according to the results of one preliminary study. Fourteen women (age 42–80 years) with metastatic breast cancer whose breast cancer did not respond to tamoxifen therapy (n = 3) or who had progressed after their disorder had stabilized (n = 11) on tamoxifen participated in this Phase II trial. After a 1-month washout of tamoxifen, patients were given melatonin 20 mg in the evening, 1 week before starting tamoxifen and 20 mg midday for at least 12 months. Although no complete response to the combination therapy was noted in any of the patients, 28.5% (4 of 14 patients) did achieve a partial response. Moreover, 10 of 14 patients were still alive after 1 year. Serum levels of insulin-like growth factor (IGF-1) were reduced in response to the treatment at both 1 ($P < 0.05$) and 3 months ($P < 0.01$). Prolactin levels were also reduced from 25 ± 3 ng/ml^{-1} to 13 ± 2 ng/ml^{-1} after 12 weeks ($P < 0.05$). No toxicity was noted.[62]

Metastatic Prostate Cancer

Fourteen men (mean age of 71.5 years) with metastatic prostate cancer (tumor grades G2 [n = 9] and G3 [n = 5]) whose prostate-specific antigen (PSA) scores had worsened using a combination of triptorelin (3.75 mg intramuscular every 28 days) and flutamide (750 mg/day by mouth for 1 month only) participated in this open clinical trial. After a 30-day washout period in which no triptorelin was given, patients were asked to begin melatonin 20 mg at night 7 days before starting their monthly injections of luteinizing hormone-releasing hormone (LHRH) analog drug. After 90 days, 8 of 14 patients had a greater than 50% reduction in their PSA scores compared with pretreatment values. In addition, average PSA serum concentrations were reduced from a pretreatment value of 421 ± 118 ng/mL to 108 ng/mL ($P < 0.05$) after 3 months of melatonin and triptorelin. IGF-1 and prolactin serum values were significantly reduced in patients using the combination of the two drugs ($P < 0.05$).[63]

Taxane-Related Neuropathy

Although the two types of taxanes (paclitaxel and docetaxel) are widely used in oncology, they have several side effects, including neuropathy.[64] A recent study suggested that melatonin might help with this issue. In this open-label Phase II pilot study, 22 women with breast cancer (33–68 years of age) who underwent chemotherapy with taxanes were instructed to take 21 mg of melatonin at bedtime for up to 6 months. Using the National Cancer Institute-Cancer Treatment Center's scale for neuropathy, the authors noted that, "in our trial, patients receiving melatonin during taxane chemotherapy had a reduced incidence of all grade neuropathy (46%) compared with historical controls (around 60%)." Fifty-five percent of the patients (n = 11) reported no neuropathy (grade zero). Adverse events included nausea, vomiting, and fatigue. None of the patients reported any incidence of daytime sedation.[65]

Cachexia

Progressive weight loss, anorexia, and reduction in the body's cell mass are hallmarks of cancer-related cachexia.[66] The cytokine tumor necrosis factor-alpha (TNF-α) plays a role in cancer cachexia according to the conclusions of one trial. Patients (56 men, 30 women; 39–76 years) with untreatable solid tumors (i.e., breast, colorectal, gastric, nonsmall cell lung cancer, etc.) and metastasis to various sites were stratified according to tumor type and randomized to either standard care (nonsteroidal anti-inflammatory drugs and opioids for pain) or standard care plus melatonin (20 mg in the evening) for at least 3 months. The authors noted that at the end of 16 weeks, weight loss of

greater than 10% occurred in 32% of the patients treated with conventional care versus only 4% of the patients treated with melatonin and conventional care ($P < 0.01$). Concomitantly with the lower reduction in weight loss, serum values of TNF-α were also significantly lower in patients using the standard care and melatonin compared with the standard care group alone ($P < 0.01$).[67]

Melatonin and Solid Tumor Cancer Therapy: Meta-Analysis

Melatonin has shown to be an effective adjunctive therapy in cancer patients with solid tumors using 20 mg per day. In a meta-analysis, melatonin significantly improved complete and partial remissions (16.5 vs. 32.6%; $P < 0.00001$) as well as the 1-year survival rate (28.4 vs. 52.2%; $P = 0.001$). Melatonin use was also associated with a reduction in radio-and chemotherapy-related side effects including thrombocytopenia (19.7 vs. 2.2%; $P < 0.00001$), neurotoxicity (15.2 vs. 2.5%; $P < 0.0001$), and fatigue (49.1 vs. 17.2%; $P < 0.00001$). No severe adverse events were noted in the randomized control trials.[68]

Breast Cancer and Insomnia

Sleep disruptions in those with cancer are a significant clinical issue and require intervention.[69] In a controlled trial, 48 patients (aged 30–75 years) scheduled for a lumpectomy or mastectomy for breast cancer were randomized to receive 6 mg of melatonin or placebo 1 hour before bedtime 3 days preoperatively until 2 weeks postoperatively.[70] At the conclusion of the trial and according to actigraphy, the administration of oral melatonin significantly improved sleep efficiency ($P = 0.007$) and reduced wake after sleep onset ($P = 0.01$) during the entire 14 day postoperative period only.[70] No changes were noted with VAS and Karolinska Sleepiness Scale outcomes along with other actigraphy variables.[70] A second controlled study found that 95 postmenopausal breast cancer survivors who completed active cancer therapy had improved their sleep quality with 3 mg of melatonin or placebo at bedtime over a 4-month time period. Compared with placebo, those who were given melatonin had significantly greater improvements in subjective sleep quality as measured by the PSQI score (i.e., −0.1 in the placebo group compared with −1.9 in the melatonin group; $P < 0.001$).[71]

Topical Melatonin and Breast Irradiation Dermatitis

Forty-seven patients median age 54 to 55 years of age with stage 0-II breast cancer treated with radiation therapy were randomized to receive a melatonin-containing emulsion or placebo cream and apply the cream twice a day over the treated breast (not less than 2 hours before radiation treatment) for the 5 weeks during the radiotherapy and 2 weeks thereafter. At the conclusion of the study (2 weeks postradiation), those taking melatonin had favorable results: 59% (13 patients) had no toxicity (grade 0) and 41% (9 patients) had grade 1/2 dermatitis. This is in contrast to the placebo group, which had 11% with grade 0 (2 patients) and 90% with grade 1/2 (17 patients) dermatitis ($P = 0.03$). Four women treated with melatonin developed a localized and regional cutaneous allergic reaction presenting as maculopapular rash that resolved with treatment.[72]

Fertility

It is estimated that about 6.1 million women in the U.S. between the ages of 15 to 44 years have difficulty with either becoming pregnant or staying pregnant. Because the success rate with in vitro fertilizations (IVFs) and subsequent pregnancies can vary,[73] researchers have considered other options, including melatonin. One hundred fifteen women (24–45 years) who had not become pregnant using IVF were divided into two groups and given 3 mg of melatonin at 10:00 PM from the fifth day of the previous menstrual cycle until the day of oocyte retrieval. Those using the melatonin in conjunction with the second IVF had a higher fertilization rate (50.0 ± 38.0%; $P < 0.01$) compared with the first IVF trial (20.2 ± 19.0%), with a higher number of pregnancies (19.6%; 11 of 56 patients) being reported. In contrast, the nonmelatonin users had no improvement in their fertilization rates (20.9 ± 16.5% first IVF vs. 22.8 ± 19.0% second IVF), resulting in a lower number of successful pregnancies (10.2%; 6 of 59 patients) during the second IVF-ET trial. The difference between the two groups' pregnancy rates was not statistically significant. In an additional analysis of 54 infertile women, it was determined by the authors that 3 mg of melatonin at 10:00 PM or 200 mg of vitamin E (given from the fifth day of the previous menstrual cycle until oocyte retrieval) three times a day significantly decreased the intrafollicular oxidative stress by decreasing the 8-OHdG concentrations compared with the first IVF cycle ($P < 0.05$).[74]

Forty-six infertile women (38–42 years of age) who had not conceived previously using IVF were recruited to receive 2 g of myoinositol plus 200 mg of folic acid in the morning and the latter combination in the evening plus 3 mg of melatonin daily for 90 days. After 3 months of using the treatment, a second cycle of IVF was instituted, resulting in a significant improvement in the number of embryos (0.48 ± 0.51 vs. 0.80 ± 0.69; $P = 0.01$) and the quality of the embryos transferred (0.13 ± 0.48 vs. 0.35 ± 0.48; $P = 0.01$). The implantation rate during the second IVF cycle was 22.8% compared with 0% in the initial IVF cycle, resulting in 13 pregnancies. Four of the 13 pregnancies were not successful and spontaneously aborted.[75]

Depression

Although 6 mg of slow release melatonin for 4 weeks did not show significant improvement in major depressive disorder symptoms, some individuals may benefit from melatonin use, such as those with depression and delayed sleep phase syndrome and women during perimenopause or menopause.[76]

Depression and Delayed Sleep Phase Syndrome

In a double-blind, placebo-controlled crossover trial, 13 men (age 35.6 ± 14 years) and 7 women (aged 30.8 ± 12.4 years) with established delayed sleep phase syndrome were divided into groups: those with (group I; n = 8; 3 men and 5 women) or without depression (group II; n = 12; 4 women and 8 men) based on a clinical assessment and the results of the Center for Epidemiological Studies Depression Scale (CES-D) and the Hamilton Depression Rating Scale (HDRS). Patients were randomly assigned to either 5 mg of melatonin or placebo and asked to consume the medication between 7:00 PM and 9:00 PM for 4 weeks followed by a 1-week washout before treatment crossover for another 4 weeks. Those in group I had a significant reduction in their HDRS and CES-D scores in comparison to placebo ($P < 0.05$). Moreover, according to polysomnographic results, sleep-onset latency was reduced in both groups I and II compared with both placebo and baseline measures ($P = 0.03$).[77]

Depression in Menopause/Perimenopause

Women with either perimenopause (n = 36), premenopause (n = 25), and postmenopause (n = 18), ranging in age from 42 to 62 years, were divided into two age groups (42–49 years and 50–62 years) and given either 3 mg of synthetic melatonin or placebo at bedtime between 10:00 PM and 11:00 PM for 6 months. Subjects were evaluated for salivary melatonin and serum levels of several hormones, including thyroid-stimulating hormone (TSH), T3, T4, luteinizing hormone (LH), follicle-stimulating hormone (FSH), prolactin, estrone, estradiol, and progesterone at time 0, 3, and 6 months. After 6 months of treatment, melatonin use significantly increased T3 and T4 ($P < 0.0001$) compared with time 0. The placebo group also had increases in T3 after 3

months ($P < 0.05$) but not at 6 months. TSH was not affected by either treatment group. Melatonin use also reduced plasma LH levels in the younger group of women (28.6%) but not in the older group ($P < 0.05$). FSH levels were also significantly reduced, especially in women with low basal melatonin levels ($P < 0.05$). In contrast to placebo, women who took melatonin had an improvement in their mood state, with only 6.7% of the active group reporting morning depression compared with 21% of the placebo users ($P < 0.05$).[78]

Alzheimer's Disease

Alzheimer's dementia (AD) is a growing concern both in the U.S. and throughout the global community. It is estimated that there were 24.3 million people worldwide with dementia in 2001, and that this figure would rise to 81.1 million by the year 2040.[79] Similarly in America, AD is expected to increase to an estimated 13 million by the year 2050.[80] In addition to a deterioration in memory and day-to-day functioning, sundowning syndrome or nocturnal delirium are a common behavior, found in 2.4% to 25%, respectively, of those diagnosed with AD.[81] Sundowning can occur typically between 3:00 PM and 7:10 PM and is associated with a heightened degree of agitation, irritation, and confusion.[82] Because this problem can cause great distress for both caregivers and health care professionals, several researchers noted that sundowning is a form of circadian rhythm disturbance, and that the associated delirium would respond well to melatonin.[83]

Sundowning Phenomenon in Alzheimer's Disease

In a retrospective study, 14 patients (8 women, 6 men; average age 72 years) diagnosed with AD received 9 mg melatonin daily at bedtime for 22 to 35 months. The researchers concluded that although melatonin use significantly improved their sleep quality ($P = 0.001$), none of the other neuropsychiatric test parameters (i.e., Functional Assessment Staging [FAST] or Alzheimer's Disease Assessment Scale [ADAS]) showed any difference between initial and final assessment. However, the condition of sundowning was no longer clinically detectable in 12 of 14 patients. Moreover, the melatonin users did not exhibit the typical cognitive and behavioral deterioration normally seen in these patients over a 1- to 3-year evolution of dementia. No side effects were noted.[84]

In a preliminary pilot study, 11 nursing home participants (8 women, 3 men; 79–82 years) with dementia received one 3 mg tablet of melatonin in the evening for 3 weeks. Using the Nurses Ratings of Sleep Patterns Questionnaire as an assessment tool, sleepiness during the daytime hours (how long and how often the residents napped) was significantly reduced ($P = 0.0245$ and $P = 0.0105$), but no changes were noted in the evening or nighttime hours. Frequency of agitation, as recorded by the Cohen-Mansfield Agitation Inventory, was significantly reduced in five subjects ($P = 0.05$), especially during the evening hours when sundowning is most prevalent.[85]

Alzheimer's Dementia

In this randomized controlled trial, 20 patients with confirmed AD (3 men, 17 women; 67–90 years of age) were randomized to receive either 3 mg of melatonin or placebo at 8:30 PM daily for 1 month. In those using the melatonin, actigraphic data demonstrated that the melatonin users had an increase in the amount of mean evening sleep time (33.2 ± 37.6%) compared with a reduction in placebo users (0.2 ± 13.7%) ($P = 0.017$). Similarly, there was a reduction in the nighttime activity counts in the active group (−44.9 ± 21.9%) compared with the increase (29.8 ± 77%) seen with placebo use ($P = 0.014$). There was no change in daytime sleep or activity between the two groups. Those using the melatonin also had a significantly improved ADAS cognition and noncognition scores (−4.3 ± 3.6 and −4.1 ± 2.2) versus placebo (−0.3 ± 3.7 and −0.8 ± 1.0), respectively ($P = 0.017$ and $P = 0.002$).[86]

In another controlled study, 80 patients (50.7% women; 49.3% men; average age 75.3 years) diagnosed with mild to moderate Alzheimer's dementia with or without insomnia and receiving standard therapy (i.e., acetylcholinesterase inhibitors) were treated for 2 weeks with placebo and then randomized to receive 2 mg of prolonged release melatonin or placebo nightly for 24 weeks, followed by 2 weeks placebo. Overall and at the conclusion of the trial (24 weeks), those patients treated with prolonged release melatonin had significantly better cognitive performance than placebo, as measured by the Instrumental Activities of Daily Living (IADL) ($P = 0.004$) and Mini Mental State Examination (MMSE) ($P = 0.044$). Sleep efficiency (as measured by the PSQI subscale 4) was also improved with the use of the prolonged release melatonin ($P = 0.017$). Mean AD Assessment Scale-Cognition (ADAS-Cog) scores did not differ between the groups. On further analysis of the comorbid insomnia (PSQI ≥ 6) subgroup, the use of prolonged-release melatonin resulted in significantly different outcomes versus the placebo in mean IADL ($P = 0.032$), MMSE score (+1.5 vs. −3 points) ($P = 0.0177$), and sleep efficiency ($P = 0.04$). Moreover, the reduction in median ADAS-Cog values in the active group (−3.5) were significantly better than placebo (+3 points) ($P = 0.045$). Adverse events that were noted during were not considered to be related to the use of prolonged release melatonin.[87]

Headache

Migraine

Individuals with chronic migraines have decreased levels of urinary 6-sulphatoxymelatonin levels, supporting melatonin's role in the pathophysiology of migraine. In an open study, 34 patients (29 men, 5 women) with episodic migraines were given 3 mg of melatonin 30 minutes before bedtime for 3 months. Compared with baseline and after 12 weeks of therapy, melatonin use decreased headache frequency, intensity, and duration ($P < 0.001$). Complete resolution of the migraine was seen in 25% of the patients. The use of medication (i.e., analgesics and triptan) for the treatment of migraine was also reduced ($P < 0.001$).[88] These promising initial results were confirmed in a placebo-controlled trial comparing melatonin with amitriptyline for migraine prevention. One hundred and seventy-eight men (n = 83) and women (n = 95) (average age 36.6–37.2 years) with two to eight migraine attacks per month were randomized to one of three groups for 12 weeks: placebo, melatonin 3 mg, or amitriptyline 25 mg taken at bedtime. After 3 months of treatment and compared with placebo, both melatonin and amitriptyline significantly reduced the number of days with migraine headaches by 1.6 and 1.1 days, respectively ($P < 0.05$). The mean attack duration was also reduced by 4.8 hours in the melatonin group and by 4.4 hours in the amitriptyline group in contrast to placebo (−2.5 hours) ($P < 0.05$). Moreover, the number of analgesic medications and headache intensity were reduced similarly in both active groups. However, the proportion of responders (defined as patients with a higher than 50% improvement in headache frequency along with the number of migraine-associated headache days) was superior in the melatonin group (54.4%) versus amitriptyline (39.1%) ($P < 0.05$) and placebo (20.4%) ($P < 0.01$). During the course of the trial, there were no serious adverse events. Daytime sleepiness, dry mouth, gastralgia, weight gain, and constipation were the most common side effects reported by the participants.[89]

Cluster Headache

Twenty cluster headache (2 chronic; 18 episodic) patients (15 men, 5 women; 30–40 years) who met the International Headache Society (IHS) criteria were invited to participate in this trial. After a 1-week washout period in which prophylactic treatment was stopped, patients were randomized to receive 10 mg of melatonin in the evening or

placebo for 14 days. Those employing the melatonin had a significant reduction in daily attacks, from 3.31 to 1.51, by the end of week 2 ($P < 0.03$). There was also an observed decrease in daily analgesic use by the melatonin group, but this was not statistically significant ($P < 0.06$). Additionally, and in contrast to placebo, headache frequency was reduced in both the first ($P < 0.03$) and second weeks of melatonin treatment ($P = 0.01$). However, the 2 chronic cluster headache patients did not respond to melatonin use. The authors speculated that melatonin could act by modulating 5HT2 receptors, inhibit the synthesis of prostaglandin E_2, or increase the activation threshold level of aminobutyric acid pain pathways.[90]

Primary Headache (Tension and Migraine)

In this open clinical trial, 49 patients (11 men, 38 women; average age range 38.65–45.25 years) (12 with chronic tension-type headache and 37 with migraine) were given 4 mg of prolonged release melatonin, 30 minutes before bedtime for 6 months. At the termination of the study, melatonin had a favorable effect on attack frequency, reducing the number of migraine and tension headache episodes from baseline 4.72 ± 0.73 and 15.91 ± 6.88 ($P = 0.033$) to 2.18 ± 0.84 and 5.33 ± 2.57 ($P < 0.001$), respectively. The Headache Impact Test score (HIT) measuring quality of life was significantly reduced in both tension type ($P = 0.002$) and migraine headaches ($P < 0.001$).[91]

Tinnitus

A perception of a ringing or roaring or a humming sound within the ears without any acoustic stimulation is known as tinnitus.[92] It was speculated by researchers that melatonin could assist in the reduction of tinnitus symptoms by reducing labyrinth pressure.[93] Based on case reports in which melatonin use symptomatically improved tinnitus patients, one group of medical investigators embarked on a double-blind, placebo-controlled, crossover study in 30 patients (15 men, 8 women; average age 64.4 years) with this condition. Patients were randomized to either 3 mg of melatonin 1 to 2 hours before bedtime or placebo for 30 days. After a 7-day washout, patients were crossed over for another 30 days. Of the 23 patients who completed the study, there was no statistical difference between active and placebo groups in terms of Tinnitus Handicap Inventory (THI) scores. However, those melatonin users (n = 9) with an initial pretreatment THI score of 47.6 and who reported an overall improvement in their symptoms had significantly higher than the average pretreatment scores (25.1) compared with melatonin users (n = 14) who did not respond to therapy ($P = 0.02$). This suggests that patients with higher initial THI scores are more likely to respond to melatonin use. In addition, 7 of 15 patients who reported difficulty in falling asleep secondary to tinnitus symptoms were able to fall asleep more readily, in contrast to only 3 of 15 patients in the placebo group ($P = 0.04$). Bad dreams were noted as a side effect in 17% of both the active and placebo users.[94]

A controlled trial employing 102 subjects with tinnitus determined that only the combination of 3 mg melatonin in the evening with a sulodexide (250 mg twice daily for 40 days; then 250 mg/day for another 40 days) significantly improved their symptoms as measured by THI scores and acufenometry evaluation compared with melatonin alone.[95]

Melatonin's effectiveness is confirmed in adults with chronic tinnitus according to the results of a prospective randomized, double-blind, crossover clinical trial. In this study participants (n = 61) were randomized to 3 mg oral melatonin or placebo on a nightly basis for 1 month followed by a 30-day washout period and then each group was crossed over into the opposite arm. At the conclusion of the trial, in those taking melatonin, there was a significantly greater reduction in both audiometric tinnitus matching (TM) and Self Rated Tinnitus (SRT) scores ($P < 0.05$) from baseline in contrast to the placebo group. The authors note that, "melatonin is most effective in men, those without a history of depression, those who have not undergone prior tinnitus treatments, those with more severe and bilateral tinnitus, and those with a history of noise exposure."[96]

Melatonin, Zinc, and Type 2 Diabetes: Lipid and Glycemic Control

Type 2 diabetes is a global epidemic and the number of those afflicted with this disorder has quadrupled over the past 3 decades.[97] Although there are many therapeutic options, melatonin and zinc may be of value in stabilizing blood glucose and reducing cardiovascular risk in this population group. In one randomized controlled trial, 46 patients (21 men, 25 women aged 40–64 years) with type 2 diabetes and poor glycemic control using metformin were selected and allocated into three groups: group A (n = 15) dietary changes and 10 mg of metformin per day and placebo; group B (n = 18) dietary changes and 10 mg of melatonin plus 50 mg of zinc acetate per day plus 10 mg of melatonin per day; or group C (n = 13) dietary changes along with 10 mg of melatonin plus 50 mg of zinc acetate per day for 3 months. Seventeen healthy subjects (9 males and 8 females) in the same age range as that of patients served as controls.

At the conclusion of the trial, group A patients had a significant decrease in fasting plasma glucose levels (9%) after 90 days ($P < 0.01$), whereas hemoglobin A1C (HbA_{1c}) had a significant reduction ($P < 0.01$) after 30 days of treatment (14%) but did not change at 90 days in contrast to baseline. Group B had a significant decrease ($P < 0.01$) in fasting plasma glucose (25%) and HbA_{1C} (17%) levels after both 30 days of treatment. In this latter group, glycated hemoglobin levels showed a further 26% reduction after 3 months. Compared with baseline, Group C treatment resulted in a 23% decrease in fasting plasma glucose levels after 90 days ($P < 0.01$) along with a 15% and 29% reduction ($P < 0.01$) in HbA_{1C} levels after 30 and 90 days, respectively. C peptide levels did not change in any of the three groups ($P > 0.05$). Comparative analysis determined that the adjunct use of melatonin and zinc with metformin (group B) produces the highest reduction in fasting plasma glucose levels compared with the other tested groups ($P < 0.05$).[98]

Using the same study design noted previously, the combination of zinc and melatonin with or without metformin resulted in improvements in lipid levels. Overall and after 90 days, both group B and group C had significant reductions ($P < 0.01$) in total cholesterol levels (14% and 11%, respectively), compared with group A, which had elevations in total cholesterol (13%). Compared with baseline, group A recorded a 7% increase in triglycerides whereas groups B (−18%) and C (−21%) had a reduction in triglycerides after 3 months of treatment ($P < 0.05$). In addition, groups B (+47%) and C (+32%) had a significant increase in high-density lipoprotein cholesterol levels compared with baseline ($P < 0.01$). Although low-density lipoprotein (LDL) levels did not change in group A, both groups B and C recorded a decrease of 22 and 26%, respectively, in contrast to baseline ($P < 0.01$). Treatment with melatonin and zinc plus metformin (group B) or melatonin and zinc (group C) resulted in significant reduction in microalbuminuria (MAU) (−37 and −36%, respectively), compared with baseline ($P < 0.01$).[99]

Metabolic Syndrome

In a clinical study, 33 patients (12 men, 18 women) with metabolic syndrome who had not responded to 3 months of lifestyle changes were given 5 mg of melatonin 2 hours before bedtime for 2 months. After 1 month of treatment and compared with baseline, those with metabolic syndrome had a significant reduction in body mass index (BMI) (kg/m^2)

($P < 0.05$), systolic blood pressure (mm Hg) ($P < 0.01$), diastolic blood pressure ($P < 0.05$), thiobarbituric acid reactive substances (um/gHb) ($P < 0.05$), and an increase in fibrinogen levels ($P < 0.05$). At the 60-day mark, there was no change in BMI or fibrinogen levels, but the results showed a decrease in LDL-C ($P < 0.05$) along with further reductions in systolic ($P < 0.001$) and diastolic ($P < 0.01$) blood pressures. There was also a reduction in thiobarbituric acid reactive substances ($P < 0.01$) and an increase in catalase (U/g Hb) ($P < 0.01$).[100]

Atopic Dermatitis (AD) in Children

In this controlled clinical trial, 48 subjects (median age, 7 years; age range, 1.8–17.1 years) with atopic dermatitis and sleep disturbances were randomized to receive 3 mg of melatonin or placebo at bedtime for 4 weeks. Melatonin treatment not only resulted in a decrease of the SCORing Atopic Dermatitis (SCORAD) index by 9.1 compared with placebo ($P < 0.001$), but also a reduction of the sleep-onset latency by 21.4 minutes ($P = 0.02$). No side effects were noted from the use of melatonin.[101]

Cataract Surgery

Forty patients (21 men 19 women aged 68.5–72.8 years) scheduled for cataract surgery were randomized to receive 10 mg of oral melatonin or placebo 90 minutes before surgery. Compared with the placebo group, those employing the melatonin had significant reductions in anxiety after premedication ($P = 0.04$) and intraoperatively ($P = 0.005$). Pain scores were significantly lower in the melatonin group than in the control group at the end of surgery (6 minutes; $P < 0.002$) and in the recovery room (7 minutes; $P < 0.032$). The authors note that there was a lower need for fentanyl during surgery as 15 patients in the control group and only 7 patients in the melatonin group required additional fentanyl boluses ($P = 0.007$). In addition, intraocular pressure decreased in the melatonin group and this reduction was maintained until the end of the surgical procedure ($P < 0.001$). Adverse events were minimal, with 1 patient in the melatonin group complaining of dizziness, and another patient in the control group had nausea.[102]

BMI, Melatonin, Fluoxetine, and Postmenopausal Women

Sixty-four women, aged 54 to 65 years with a BMI approximately 30 (kg/height in m^2), were randomly allocated into two groups: Group I (n = 30) was administered fluoxetine (1 × 20 mg in the morning) and placebo (in the evening) for 6 months. Group II (n = 34), in contrast, was given fluoxetine (1 × 20 mg in the morning) and melatonin (5 mg in the evening) for 6 months. Although both groups were effective in improving anxiety and decreasing depression scores from baseline, there were no significant differences between groups. However, in group II taking the fluoxetine combined with melatonin, the improvement of the sleep quality index was faster and resulted in highly statistically significant reductions from 15.8 ± 2.4 points to 9.4 ± 2.0 points ($P < 0.01$) after 12 weeks and 7.7 ± 1.5 points ($P < 0.001$) after 15 weeks. In group I, the sleep quality index in group decreased from 14.9 ± 2.5 points to 12.9 ± 2.6 points after 12 weeks ($P < 0.05$) and to 10.9 ± 1.9 points after 24 weeks ($P < 0.01$). In group II, the BMI decreased non-significantly from 30.9 ± 3.1 to 29.6 ± 2.8 ($P > 0.05$) after 12 weeks decreased significantly to 26.3 ± 3.2 ($P < 0.05$) after 24 weeks. By comparison, in group I, BMI decreased slightly from 30.1 ± 3.5 to 28.5 ± 2.9 ($P > 0.05$), but after 24 weeks, the BMI returned to the baseline value of 29.5 ± 3.1 ($P > 0.05$).[103]

Nicotine Withdrawal

Despite the fact that smoking is strongly associated with increased cardiovascular disease risk, many individuals continue to smoke.[104] One of the factors contributing to engaging in smoking cessation is the symptoms associated with acute nicotine withdrawal. In one study, 12 subjects (19–53 years) who had smoked on an average for 3 to 27 years were given 0.3 mg of melatonin or placebo at 11:30 PM on the second night of the experiment, 3.5 hours after nicotine withdrawal. Those using the melatonin had significant reductions in VAS self-rating scores for anxiety ($P < 0.01$), irritability ($P = 0.001$), anger ($P < 0.05$), and craving for cigarettes ($P < 0.005$), compared with placebo.[105]

Vascular Protection in Smokers

In this controlled study, 63 volunteers (46 men, 17 women; average age 31.7–34.6 years) were split into two groups (smokers and nonsmokers) and then randomly divided into four groups: (a) nonsmoker with oral placebo (n = 15); (b) nonsmoker with oral melatonin (n = 16); (c) smoker with oral placebo (n = 17); and (d) smoker with oral melatonin (n = 15). Each group was given 3 mg/day of melatonin or placebo 1 hour before bedtime for 2 weeks. Compared with placebo group, melatonin not only lowered the concentration of fibrinogen ($P = 0.04$) and free fatty acids ($P = 0.04$) but also decreased the expression of the markers for vascular injury including intercellular adhesion molecule-1 ($P = 0.004$), vascular cell adhesion molecule-1 ($P = 0.001$), and endothelin-1 ($P < 0.0001$) in smokers.[106]

Nonalcoholic Steatohepatitis

In this preliminary study, 42 patients with histologically confirmed nonalcoholic steatohepatitis were asked to consume 2 x 5 mg of melatonin (n = 30) or placebo (n = 12) daily for 12 weeks. All patients were enrolled in a lifestyle program consisting of walking for 30 to 60 min/day along with dietary interventions.

In those taking the melatonin, alanine aminotransferase (IU/L) levels decreased significantly from 118.0 (79.2–158.5) at baseline to 66.0 (55.0–79.5) at week 12 ($P < 0.001$). In contrast, alanine aminotransferase (IU/L) levels in the placebo group also decreased significantly from 120.0 (81.3–135.0) at baseline to 83.5 (70.7–100.0) at week 12 ($P < 0.05$). Aspartate aminotransferase levels (IU/L) decreased significantly in only the melatonin group from 76.5 (64.2–114.2) at baseline to 47.0 (38.2–58.7) at week 12 ($P < 0.001$). In addition, and unlike placebo, the melatonin group had significant reductions in gamma-glutamyl transferase (IU/L) from 113 (75.8–210.8) at baseline to 60 (47.3–85.3) by week 12 ($P < 0.001$).[107]

Ulcerative Colitis

Sixty patients (38 women and 22 men, aged 26–49 years) with left-sided ulcerative colitis who were in clinical remission for the past 12 months were divided into two equal groups of 30 patients. Patients were given the drug mesalazine in daily doses 2 x 1.0 g and melatonin 5 mg daily at bedtime (group I) or placebo (group II) for 1 year. At the end of the study, using the Mayo Clinic Disease Activity Index (MCDAI) score, group I increased from 1.50 ± 0.51 at baseline to 2.75 ± 1.86 points ($P < 0.01$) compared with placebo, which had significantly higher MCDAI (1.61 ± 0.68 points to 5.10 ± 2.22 points) scores ($P < 0.05$). Similarly, C-reactive protein (CRP) levels in the melatonin group remained within the normal range (from 3.49 ± 1.40–4.1 ± 72.10 mg/dL) in contrast to placebo, which increased from 3.85 ± 1.29 to 13.13 ± 6.08 mg/dL ($P < 0.01$). Additionally, in the placebo group, there was a significant reduction in serum hemoglobin from 12.05 ± 0.69 to 10.93 ± 0.81 g/dL. In comparison, the melatonin group experienced a slight decrease in serum hemoglobin levels from 12.29 ± 0.87 to 11.76 ± 1.09 g/dL ($P < 0.01$). Although there was a strong placebo effect, melatonin may have value in maintaining remission in ulcerative colitis.[108]

DOSAGE

Melatonin has been used at a variety of different dosages as described in the Clinical Applications section. For its most popular use to enhance

sleep quality the typical dosage is 3 mg 30 to 45 minutes before bedtime. Dosage ranges for the clinical applications are given in Table 92.1. In general, use the same dosage level used in the positive clinical studies for the specific application.

Side Effects and Contraindications

Common side effects of high dosage melatonin use include headaches, dizziness, nausea, and drowsiness.[109] One author notes that, "despite the well-recognized role of melatonin in the regulation of reproduction in photoperiodic species, it seems unlikely that chronic ingestion of moderate melatonin doses will have a profound impact on reproductive function in humans."[110] However, without further clinical evidence of safety, melatonin should not be employed in pregnancy and lactation. One study in women noted that high-dose melatonin (300 mg/day for 4 months) could significantly reduce mean LH levels in contrast to nonmedicated controls ($P < 0.001$) (see Table 92.1).[111]

DRUG INTERACTIONS

Although melatonin overall has an excellent safety record, clinicians should be cognizant of several drug interactions, especially zolpidem and melatonin.

Zolpidem

In a controlled study, 16 healthy subjects (12 men, 4 women; average age 59.4 years) were randomized to receive placebo, 2 mg prolonged release melatonin, 10 mg zolpidem, or both active medications for 2 days in the evenings (8:00 PM) with a 2- to 10-day washout period between treatments. Psychomotor functions (i.e., reaction time, vigilance), memory, dexterity, sedation, and simulated car driving were evaluated at 1 to 4 hours, the next morning after drug administration. The results demonstrated that compared with placebo, PR melatonin on its own did not impair any of the variables tested. However, the use of zolpidem and zolpidem with PR melatonin significantly impaired memory and psychomotor performance 1 to 4 hours after administration. In a simulated driving task, the number of collisions significantly increased at the 1- to 4-hour mark by 1.4 and 2.8 in the zolpidem ($P < 0.05$) and zolpidem-PR melatonin ($P < 0.001$) groups compared with placebo, respectively. No changes were noted by the investigators the next morning, except that the decline in memory recall was still evident with zolpidem.[112]

Fluvoxamine

The bioavailability of melatonin is increased by the coadministration of the selective serotonin reuptake inhibitor fluvoxamine. When 50 mg of fluvoxamine was used in concert with 5 mg of melatonin, on average, there was a seventeenfold increase ($P < 0.05$) in the area under concentration-time curve (AUC) and a twelvefold higher ($P < 0.01$) serum peak concentration (C_{max}) of melatonin. The terminal elimination half-life was not significantly affected.[113]

Fluoxetine

Melatonin was employed in concert with fluoxetine to reduce the incidence of dyskinesia. In a case report, one 23-year-old male with obsessive-compulsive disorder and major depression developed shoulder and neck dyskinesia after taking 60 mg fluoxetine for 4 months. Because the patient and the doctors did not want to stop the medication, which had proven clinically helpful, they added 6 mg of melatonin twice a day. Within 2 weeks the dyskinesia resolved. Secondary to experiencing daytime drowsiness, the patient discontinued the melatonin with a reappearance and worsening of the dyskinesia. Resumption of the melatonin 6 mg at nighttime again resolved the problem within 2 weeks of onset. The authors noted that the antioxidant effects of melatonin might help scavenge the toxic free radicals that may trigger dyskinesia.[114]

Caffeine

Caffeine intake can affect the bioavailability of melatonin, which is likely caused by the inhibition of CYP1A2 activity. In 12 healthy volunteers, when 600 mg of caffeine was coadministered with 6 mg of melatonin, the C_{max} and AUC of melatonin were increased on average by 142% ($P = 0.001$) and 120% ($P < 0.001$), respectively. The inhibitory effect of caffeine was more pronounced in nonsmokers and in individuals with the *1F/*1F genotype.[115]

CYP1A

As melatonin is metabolized by CYP1A in vitro, there are a number of potential drug interactions that could occur, including coadministration of acetaminophen, omeprazole, theophylline, warfarin, and estradiol. Caution should be exercised by clinicians when administering melatonin and prescription medications metabolized by CYP1A.[116]

Progesterone

In women, 300 mg melatonin and 75 mg of melatonin combined with 0.3 mg of the synthetic progestin norethisterone caused a significant decrease in LH, estradiol, and progesterone levels compared with a nonmedicated control group in the first and fourth months of the investigation ($P < 0.05$). This strongly suggests that melatonin and progesterone have an additive effect and should not be used by women taking progesterone.[117]

TABLE 92.1 Dose Ranges

Condition	Dose
Alzheimer's dementia (+ sundowning symptoms)	3–9 mg in the evening 2 mg of prolonged release melatonin
Acute insomnia	0.3–1 mg at bedtime
Atopic dermatitis (children)	3 mg of melatonin at bedtime
Beta-blockers and insomnia	2.5 mg at night
Cancer (solid tumors: breast, lung, prostate)	20 mg in the evening
Breast irradiation dermatitis and topical melatonin	Cream applied twice daily not less than 2 hours before radiation treatment
Cachexia	20 mg in the evening

Continued

TABLE 92.1 **Dose Ranges—cont'd**

Condition	Dose
Taxane-related neuropathy	21 mg at bedtime
Breast cancer and insomnia	3–6 mg at bedtime
Cataract surgery	10 mg of melatonin 90 minutes before surgery
CFS and insomnia	5 mg at bedtime
Chronic insomnia	0.3–3 mg 30 minutes before bedtime
Children and insomnia	5 mg at 7 PM
Depression	
Delayed sleep phase syndrome	5 mg at 7–9 PM
Perimenopausal/menopausal	3 mg at 10–11 PM
COPD and insomnia	3 mg 1 hour before bedtime
Epilepsy and insomnia	6 mg for those less than 9 years of age and less than 30 kg in the evening; 9 mg for those greater than 9 years of age and greater than 30 kg
ASD and insomnia	2–5 mg before bedtime
ADHD and insomnia	3 mg for those less than 30 kg and 6 mg for those greater than 30 kg at 7 PM
Fibromyalgia	3 mg 30 minutes before bedtime
Functional dyspepsia	5 mg in the evening
GERD	3–6 mg in the evening
Headache	
Children: migraine prevention	3 mg at bedtime
Adults: migraine	3 mg at bedtime
Adults: cluster headache	10 mg at bedtime
Adults: tension headache/migraine	4 mg prolonged release melatonin 30 minutes before bedtime
IBS	3 mg in the evening
IBS-C	3 mg in the morning and 5 mg in the evening
Infertility in women with IVF	3 mg in the evening
Jet lag	
Eastbound	5 mg, 3 days before and 3 days after, in the evening local time
Westbound	0.5 mg in the evening
Metabolic syndrome	5 mg 2 hours before bedtime
NASH	5 mg twice a day
Nicotine withdrawal symptoms	0.3 mg in the evening
Tinnitus	3 mg in the evening
Type 2 diabetes (glycemic control and cholesterol)	10 mg of melatonin and 50 mg of zinc acetate
Tetraplegia and insomnia	3 mg 2 hours before bedtime
Ulcerative colitis (maintain remission)	5 mg daily at bedtime
Vascular protection (in smokers)	3 mg 1 hour before bedtime

ADHD, Attention deficit hyperactivity disorder; *ASD*, autism spectrum disorder; *CFS*, chronic fatigue syndrome; *COPD*, chronic obstructive pulmonary disease; *GERD*, gastroesophageal reflux disease; *IBS*, irritable bowel syndrome; *IVF*, in vitro fertilization; *NASH*, nonalcoholic steatohepatitis.

Melissa officinalis (Lemon Balm)

Kathy Abascal, BS, JD, RH(AHG), and *Eric L. Yarnell, ND, RH(AHG)*

OUTLINE

Melissa officinalis (family: *Lamiaceae*)
Common names: lemon balm, balm, melissa, balm mint

GENERAL DESCRIPTION

Melissa officinalis, a mint, has square stems and opposite leaves (Fig. 93.1). The leaves are used medicinally and exude a lemony odor when brushed or crushed. Lemon balm is native to southern Eurasia. The word *balm* is derived from the term "balsam," referring to the delightful odor of the plant. The genus name *Melissa* is derived from a Greek word for bees, which are strongly attracted to this plant.

CHEMICAL COMPOSITION

Lemon balm leaves contain volatile oil, giving the plant its scent of lemon. Two major classes of terpenoids are found in this oil—hydrocarbon terpenes, particularly citrals a and b (Fig. 93.2), and sesquiterpenes, particularly β-caryophyllene.[1] Lemon balm is also a rich source of flavonoid glycosides.[2,3] More than 3% of the dry weight of lemon balm is composed of rosmarinic acid, a phenylpropanoid derivative (Fig. 93.3).[4]

HISTORY AND FOLK USE

Lemon balm has been used for millennia in Europe, primarily for dyspepsia and nervousness.[5] The ancient Greeks also used it for wound healing and insect bites.[6] The 17th-century herbalist Nicholas Culpeper lauded the benefits of lemon balm in enhancing digestion, relieving melancholy, and "opening the brain."[7]

The Basque people used lemon balm as a digestive for nervous stomachs and as a sedative for insomnia, hysteria, depression, and for heart palpitations caused by nerves. They also used it for neuralgias and to regulate menses and combined it with cloves as a topical treatment for toothaches.[8]

The eclectic physicians in North America used lemon balm as a moderate stimulant, diaphoretic, and antispasmodic.[9] The standard infusion was often combined with lemon juice to treat fevers and painful menstruation. The Cherokee used the plant similarly, and the Costanoan tribe used the decoction for infants' colic and stomachaches.[10]

PHARMACOLOGY

The pharmacodynamics of lemon balm are complex because of the large number of active and secondary constituents present in the plant. The volatile oil fraction appears to have antimicrobial, antiviral, and antiparasitic activity and contributes to the anxiolytic and relaxing effects of lemon balm. The flavonoids and rosmarinic acid are antioxidant, anxiolytic, sedative, and antiviral, and they inhibit both

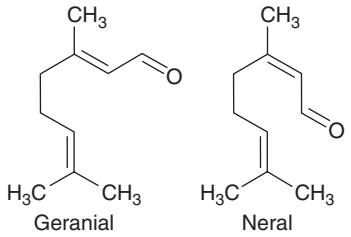

Fig. 93.2 Citral a (geranial) and citral b (neral).

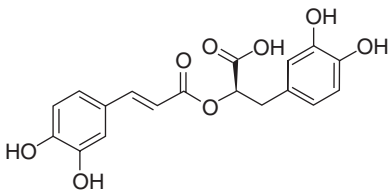

Fig. 93.3 Rosmarinic acid.

complement and protein synthesis. Various extracts of these constituents show similar properties and antithyroid effects.

Sedative Effects

Animal studies confirmed that lemon balm has a calming effect. For instance, a tincture of lemon balm was sedative, analgesic, and hypnotic in mice and potentiated phenobarbital.[11] In vitro studies on human neurons with ethanolic extracts of lemon balm showed that it has cholinergic activity.[12]

Antiviral Effects

Lemon balm consistently showed antiviral and antiretroviral effects in vitro, particularly against herpes simplex virus but also against HIV-1.[13–16] The volatile oil of lemon balm was active against *Trypanosoma brucei* but had minimal activity against *Leishmania major.*[17]

Thyroid Effects

Lemon balm has diverse effects on the thyroid gland and thyroid hormones. It inhibits rat iodothyronine deiodinase and prevents bovine thyroid-stimulating hormone (TSH) from stimulating human thyroid membranes in vitro.[18,19] The latter effect was a result of adduct formation between polyphenols and TSH, thereby preventing TSH receptor binding. Adducts also formed with immunoglobulin-G antibodies formed in patients with Graves' disease, which mimicked TSH, blocking their binding to the TSH receptor in vitro.[20]

Other Effects

Preliminary investigations suggest a wealth of other miscellaneous effects: rosmarinic acid inhibited C3 and C5 convertases, suggesting an anti-inflammatory effect.[21,22] Lemon balm flavonoids show potent antiperoxidative activity.[23] Lemon balm was antiulcerogenic in rats in one trial, both alone and in combination with various other herbs.[24]

CLINICAL APPLICATIONS

Herpes Simplex Virus

Two clinical trials investigated the effect of lemon balm on herpes labialis lesions. In one double-blind trial, 116 patients with an acute outbreak of herpes were randomly assigned to receive treatment with a cream containing a 70:1 extract of lemon balm or placebo.[25] Redness was reduced more in the lemon balm group, but other symptoms were not significantly different from the placebo group. No major adverse effects occurred in either group.

In a second double-blind trial, 66 patients were randomly assigned to apply either a lemon balm cream or placebo.[26] Average daily symptomatic relief was significantly better in those given lemon balm. Other measures of efficacy were not significantly different between the groups, although there was a consistent trend in favor of lemon balm.

Anxiety, Agitation, Insomnia, Memory

Lemon balm has been studied in people with mild anxiety and as a relaxant in healthy people. In a double-blind study, 102 individuals with mild anxiety were randomly assigned to receive either a lemon balm combination product or placebo for 8 weeks.[27] Those taking the lemon balm product had significantly less overall anxiety, nervousness, excitability, and emotional lability than subjects taking the placebo. In a study of 24 healthy individuals, a mixture of lemon balm and *Valeriana officinalis* (valerian) had a dose-dependent anxiolytic effect.[28]

Another randomized, double-blind crossover trial administered varying doses of lemon balm extract to 20 healthy individuals.[29] At lower doses, lemon balm had a calming effect, and at moderate doses, it increased alertness, an effect lost at the highest dose tested. In vitro investigations suggested that these results might have been mediated by the cholinergic effects of lemon balm constituents.

A combination product of valerian, passion flower, lemon balm, and butterbur extracts (Ze 185) was administered to 72 healthy men in a randomized, placebo-controlled, double-blind study with three parallel groups (Ze 185, placebo, or no treatment) for 4 days. The active treatment did not affect salivary cortisol levels but significantly attenuated the subjective anxiety response to a stress test.[30]

A randomized, placebo-controlled clinical trial (n = 100 female teenagers) found that lemon balm capsules (600 mg/2 capsules/day for 3 months) improved the psychosomatic symptoms score, anxiety, depression, sleep, and "social function disorder" significantly compared with a placebo.[31]

In a double-blind study of 72 patients with clinically severe agitation and severe dementia, lemon balm lotion applied topically twice daily significantly reduced agitation compared with a sunflower oil placebo.[32] Lemon balm oil, placebo, and donepezil were not found to have a significant sedative effect in a rigorous multicenter study of Alzheimer's patients with severe agitation (n = 81).[33]

A randomized, double-blind, placebo-controlled 4-month trial of children diagnosed with attention deficit hyperactivity disorder (ADHD) found a highly significant improvement in all four dimensions of the Test of Variables of Attention (TOVA) in those getting an herbal formula containing lemon balm. However, the exact formula was not provided, and it appears that other herbs (e.g., *Paeonia lactiflora, Withania somnifera, Centella asiatica, Bacopa monnieri,* and *Spirulina platensis*) that could plausibly improve ADHD were present in greater amounts in the formula.[34]

Young children (>12 y.o., n = 914) diagnosed with pathological restlessness and/or nervous dyssomnia participated in an open, multicenter study of a mixture of 160 mg valerian and 80 mg lemon balm per tablet. For 4 to 5 weeks, each child took between 1 and 4 tablets per day, and the core symptoms of restlessness and dyssomnia improved significantly. There were no adverse events related to the test medicine.[35]

A study of 24 children compared a lemon balm tincture with a placebo over a month's time and found it did not reduce muscle activity in children with bruxism.[36]

In a double-blind, randomized, placebo-controlled study of healthy adults older than 40 years (n = 44), 5 mL of a tincture of salvia *(Salvia officinalis),* rosemary *(Rosmarinus officinalis),* and lemon balm did

not differ from placebo in either immediate or delayed word recall, although a somewhat younger subgroup showed some improvements in verbal episodic memory.[37]

A double-blind trial in 98 individuals with mild insomnia compared a combination of valerian root and lemon balm with placebo for 1 month.[38] The extract was significantly more effective than placebo in improving subjectively rated sleep quality, although recordings of sleep quality on a visual analog scale did not show any differences between the two groups. A similar combination product had a positive action in a study of 918 children with restlessness and dyssomnia.[39] Lemon balm was approved by the German Commission E for the treatment of nervous sleeping disorders.[40]

One hundred women (50–60 years old) with a score of ≥5 on the Pittsburgh Sleep Quality Index were randomized to take either 2 capsules daily containing 160 mg of valerian and 80 mg of lemon balm or starch in a triple-blinded approach. One month postintervention, a statistically significant improvement in sleep was noted.[41]

Premenstrual Syndrome

A double-blind, randomized, placebo-controlled trial of high school girls ($n = 100$) found that 1200 mg of lemon balm "essence" daily from day 1 to the last day of their menstrual cycle for three cycles significantly reduced premenstrual syndrome (PMS) symptoms.[42]

Dyspepsia and Irritable Bowel Syndrome

Lemon balm leaf was approved by the German Commission E for the treatment of dyspepsia and possibly irritable bowel syndrome (IBS).[40] No clinical trials documenting the efficacy of lemon balm alone for digestive disorders could be found. All trials included lemon balm only as a component of herbal combination products. A systematic review of the formula Iberogast I (Iberogast, in addition to lemon balm, contains *Iberis amara* [bitter candytuft], *Matricaria recutita* [chamomile], *Mentha x piperita* [peppermint], *Carum carvi* [caraway], *Glycyrrhiza glabra* [licorice], *Angelica archangelica* [garden angelica], *Chelidonium majus* [greater celandine], and *Silybum marianum* [milk thistle]) found the formula efficacious in dyspepsia.[43] Another preliminary study of 32 patients with IBS found that a mixture of lemon balm, *Mentha spicata* (spearmint), and *Coriandrum sativum* (coriander) reduced abdominal pain and bloating.[44] In infants, a mixture of lemon balm, *Matricaria recutita* (chamomile), and *Foeniculum vulgare* (fennel) reduced colic symptoms.[45] Although these trials did not address the efficacy of lemon balm in isolation, they do support the historical use of lemon balm in patients with dyspepsia or IBS.

Infantile Colic

In a multicenter randomized comparative study, 176 infants with colic were given 1 mL of a mixture of lemon balm, chamomile (*Matricaria chamomilla* L.), and *Lactobacillus acidophilus,*[46] 10^8 units of *L. reuteri* DSM 17938 in 5 mL oil, or 60 mg of simethicone daily for 28 days. The herbal mixture and the probiotic treatment were equally effective and superior to simethicone in reducing the mean daily crying time.[47]

Hyperlipidemia

In a parallel, randomized, double-blind, placebo-controlled trial, 58 patients with hyperlipidemia (total cholesterol [TC] = 200–260 mg/mL, low-density lipoprotein [LDL] = 100–160 mg/dL) took 1000 mg of lemon balm leaf or starch placebo 3×/day for 2 months. LDL decreased significantly, as did aspartate aminotransferases. No changes were seen in other tested serum parameters.[48]

Arterial Stiffness

In an open-label, parallel-group, comparative trial, 28 healthy individuals drank 200 mL/day of lemon balm or barley tea for 6 weeks. The improved brachial ankle pulse wave velocity in the active group suggests that lemon balm tea may reduce arterial stiffness, especially in those with significant stiffness. Lemon balm tea also suppressed the reduction of skin elasticity in female test subjects and generally appeared to improve glycation-associated tissue damage.[49]

Cardiac Palpitations

Individuals ($n = 55$) with benign palpitations received 500 mg of freeze-dried lemon balm twice daily for 14 days in this double-blind, randomized, placebo-controlled clinical trial. Lemon balm significantly reduced the frequency and self-reported intensity of episodes of palpitations compared with placebo.[50]

Radiation Protection

In a single open study, workers in a medical radiology department used lemon balm tea (1.5 g in 100 mL water twice per day) for 30 days.[51] Plasma catalase, superoxide dismutase, and glutathione levels rose, whereas DNA damage, myeloperoxidase, and lipid peroxidation product levels all fell significantly compared with baseline. Controlled trials are warranted in people exposed to chronic low-dose ionizing radiation.

DOSAGE

Lemon balm is traditionally employed as a tea or tincture. The dried leaf should still smell strongly of lemon and should be dark green; if not, it is of inferior quality. For a tea, 2 to 3 teaspoons of herb are steeped in 1 cup hot water for 10 to 15 minutes; three cups of this are drunk daily.[51] The dose of a tincture, made preferably from fresh material and as concentrated as possible (1:2–1:3 weight/volume ratio), is taken 2 to 6 mL three times daily.[52]

There is no widely accepted standardization to ensure quality lemon balm extracts, although a minimum 0.05% volatile oil content is recommended by the German Commission E.40 Pure volatile oil of lemon balm may also be used at a dose of 1 to 3 drops taken internally three times daily in adults, or by topical application to the skin in a cream, lotion, or fixed oil base. Because of the expense of extracting the oil from this plant, however, there are many adulterated products on the market that contain lemon scent, lemongrass, or other lemon-scented herbs and not lemon balm.

TOXICOLOGY

In a pharmacokinetic study, lemon balm containing 500 mg rosmarinic acid caused no adverse effects and did not affect liver, kidney, or blood cell function parameters.[53] An ethanolic lemon balm extract was antigenotoxic in mice, whereas the aqueous extract was not. Neither extract was genotoxic.[54] However, in an Ames assay, a water extract of lemon balm was found to have a significant genotoxic and mutagenic effect, whereas the methanol and chloroform extracts lacked mutagenicity.[55]

Despite the theoretical concern that it might suppress thyroid function in euthyroid or hypothyroid patients, there are no published reports of this occurrence. Controlled trials in humans established that lemon balm, combined with extracts of *V. officinalis* (valerian) root, does not interfere with the ability to drive or operate heavy machinery.[56] In one case study, a patient arrived at the emergency room (ER) with restlessness, tremor, distractibility, and sweating after discontinuing lemon balm, raising the possibility that lemon balm may present a risk of dependency and can lead to withdrawal symptoms.[57] In contrast, a review found that lemon balm dose-dependently reduced opioid withdrawal syndrome, with no mention of the herb itself causing issues.[58]

DRUG INTERACTIONS

There are no documented drug interactions for lemon balm. It does not interact with alcohol.[55] Given its effects on thyroid function in vitro, there is a theoretical concern that the herb may have additive or synergistic effects with thyrosuppressive drugs and may interact in unpredictable ways with thyroid hormone replacement agents. Lemon balm should be combined with these classes of drugs only under careful supervision by an experienced health-care professional.

Mentha piperita (Peppermint)

Michael T. Murray, ND

OUTLINE

Mentha piperita (family: *Labitae*)
Common name: peppermint

GENERAL DESCRIPTION

Peppermint is a natural hybrid of garden spearmint *(Mentha spicata)* and water mint *(Mentha aquatica)*. First described in England in 1696, peppermint now grows all over the world. The two most popular varieties are white peppermint (*Mentha piperita* var. *officinalis*) and black peppermint (*M. piperita* var. *vulgaris*). Both are typical members of the mint family, that is, herbs with square stems, horizontal rhizomes, and lanceolate leaves with a serrated edge. Black peppermint has deep red stems with purplish-tinged dark green leaves, whereas white peppermint has green stems with lighter green leaves. Both varieties produce purple flowers during the summer months. For medicinal effects, the aerial portion of the plant is the most widely used.

CHEMICAL COMPOSITION

The major medicinal component of peppermint is its volatile oil, which can be found in concentrations of up to 1.5% in the herb but is usually present in the range of 0.3% to 0.4%. The principal components of the oil are menthol (28%–29%; Fig. 94.1), menthone (20%–31%), and menthyl acetate (3%–10%), although gas chromatographic analysis of peppermint oil typically shows more than 40 different peaks. Most of the volatile oil components are terpenoids.[1]

The composition of menthol and other volatile oil components is sensitive to climate and latitude and also to the maturity of the plant. Pharmaceutical-grade peppermint oil is produced by distilling the fresh aerial parts of the plant harvested at the very beginning of the flowering cycle. The oil is standardized to contain no less than 44% free menthol and a minimum of 5% esters calculated as menthyl acetate. The ketone component (calculated as menthone) usually ranges from 15% to 30%, with the remainder of the oil being composed of various terpenoids.[1] Menthol is also synthesized by hydrogenation of thymol.

Other components of peppermint herb that may contribute to its medicinal effects are polymerized polyphenols (19% of dry weight), flavonoids (12%), tocopherols, carotenes, betaine, and choline.[2]

HISTORY AND FOLK USE

Although peppermint was not officially recognized until the 17th century, mints have been used for their medicinal effects for thousands of years. Records from the ancient Egyptian, Greek, and Roman eras show that other members of the mint family, particularly spearmint *(M. spicata)*, were used.[1]

The most popular uses of peppermint for medicinal purposes were in the treatment of indigestion and intestinal colic, colds, fever, and headache.

PHARMACOLOGY

The pharmacology of peppermint is attributed almost entirely to its menthol components. The major categories of actions for peppermint and menthol are as follows:

- Carminative
- Antispasmodic
- Choleretic
- External analgesic
- Nasal decongestant

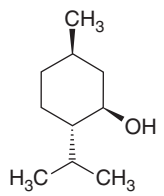

Fig. 94.1 Menthol.

Carminative Effects

Carminatives promote the elimination of intestinal gas. Peppermint and peppermint oil are well-accepted carminatives. Although the exact mechanism of action has not been determined, one proposed mechanism is relaxation of the esophageal sphincter, which leads to the release of gas pressure in the stomach.[3]

Antispasmodic Effects

The mechanism behind peppermint oil's antispasmodic effects was determined. Researchers concluded that peppermint oil inhibits contractions of isolated smooth muscles by blocking the influx of calcium into the muscle cells.[4,5] Researchers hypothesized that the clinical effectiveness of peppermint oil in the treatment of irritable bowel syndrome (IBS) is a result of inhibition of the hypercontractility of intestinal smooth muscle, thereby returning the muscle to its proper tone.

Choleretic Effects

Choleretics stimulate the flow of bile. Menthol and related terpenes were shown to exert a choleretic effect and to improve the solubility of the bile.[6–10]

External Analgesic Effects

The external analgesic and counterirritant effects of menthol are well accepted. When applied to the skin, peppermint oil or menthol stimulates the nerves that perceive cold and simultaneously depresses those for pain. The initial cooling effect is followed by a period of warmth.

CLINICAL APPLICATIONS

Peppermint oil is the most extensively used of all the volatile oils. Pharmaceutic preparations often use peppermint oil or menthol for its therapeutic and flavoring properties. For example, it is used extensively in antacid products and irritant laxatives for both its flavor and its therapeutic effects. The same is true for its inclusion in mouthwash preparations and after-dinner mints.

The pharmacological effects of peppermint and peppermint oil are useful in a number of clinical situations. The most notable are as follows:

- IBS
- Intestinal colic
- Gallstones
- Musculoskeletal pain
- The common cold

Irritable Bowel Syndrome

Enteric-coated peppermint oil (ECPO) was shown to be quite helpful in improving gastrointestinal (GI) function in individuals with IBS, a common functional disorder of the large intestine characterized by some combination of (1) abdominal pain; (2) altered bowel function, constipation, or diarrhea; (3) hypersecretion of colonic mucus; (4) dyspeptic symptoms (flatulence, nausea, anorexia); and (5) varying degrees of anxiety or depression.

Several double-blind studies showed ECPO to be effective in relieving all symptoms of IBS in approximately 70% to 85% of cases within 2 to 4 weeks.[11–18] In one trial, 42 children between 8 and 10 years old with IBS were given ECPO or a placebo for 2 weeks. The dosage was one capsule three times daily for children weighing 30 to 45 kg and two capsules three times daily for children weighing more than 45 kg. After 2 weeks, 76% of the ECPO group reported significant improvements, compared with only 19% in the placebo group.[15]

In one double-blind study, 57 patients with IBS, with normal lactose and lactulose breath tests and negative antibody screening for celiac disease, were treated with peppermint oil (two enteric-coated capsules twice per day or placebo) for 4 weeks in a double-blind study. Results showed that 75% of the patients in the ECPO group showed a more than 50% reduction of basal total IBS symptoms score compared with 38% in the placebo group.[16]

In an 8-week randomized double-blind, placebo-controlled study on 90 outpatients with IBS, the number of subjects free from abdominal pain or discomfort changed from 0 at week 0 to 14 at week 8 in the ECPO group and from 0 to 6 in controls. The severity of abdominal pain was also reduced significantly in the ECPO group compared with controls.[17]

One of the central findings in IBS is a hypercontractility (excessive contraction) of intestinal smooth muscle. Peppermint oil, especially when combined with caraway oil, inhibits the hypercontractility of intestinal smooth muscle, making it useful in IBS and in esophageal spasm and intestinal colic.[19] It may also affect gallbladder and small intestine function. A pharmacodynamic study of 90 mg peppermint oil and 50 mg caraway oil demonstrated that complete inhibition of gallbladder emptying was caused by both oils, and the transit time in the small intestine and the orocecal transit time were significantly prolonged by peppermint oil.[20]

Although effective on its own, ECPO is best used within a comprehensive treatment protocol for IBS (see Chapter 183).

Nonulcer Dyspepsia

In addition to its effects in IBS, ECPO has benefits in nonulcer dyspepsia (NUD), gastroesophageal reflux disorder (GERD), and intestinal overgrowth of *Candida albicans* (a common yeast implicated in many cases of IBS) and *Helicobacter pylori.*

NUD and GERD are basically catch-all terms that reflect a kind of wastebasket diagnosis that doctors use when they cannot find any real reason for a patient's upper gastrointestinal (GI) dysfunction, just as IBS is used as a wastebasket diagnosis for lower GI dysfunction. Symptoms of NUD and GERD include heartburn, difficulty swallowing, feelings of pressure or heaviness after eating, sensations of bloating after eating, stomach or abdominal pains and cramps, and the symptoms of IBS. About 3 of every 10 patients with NUD and GERD also meet the criteria for IBS.

Several of the clinical studies in patients with IBS featured the combination of peppermint oil and caraway oil in an enteric-coated capsule (ECPCO). The results of these trials indicated that this combination produced better results than peppermint oil alone for symptoms of IBS. Later studies also indicated that the combination of peppermint and caraway oils was quite helpful in improving NUD.[20–22] In one double-blind study, 120 patients with NUD were given either the ECPCO combination or cisapride (Propulsid) for 4 weeks.[21] The mean reduction of pain score was comparable in the two groups (4.62 for ECPCO; 4.6 for cisapride). Other symptoms of NUD also improved in a similar fashion. Positive results were also found in *H. pylori*–positive individuals.

Although the ECPCO combination is extremely safe at recommended levels, cisapride caused fatal heart rhythm problems. According to the U.S. Food and Drug Administration, at least 111 people died as a result of cisapride use, and nearly 400 experienced heart abnormalities. Cisapride (Propulsid) was subsequently taken off the market.

Cholelithiasis

Several studies showed that a formula containing menthol and related terpenes (menthone, pinene, borneol, cineol, and camphene) demonstrated efficacy in dissolving gallstones.[6–10] This approach to gallstone removal offers an effective alternative to surgery and was shown to be

safe even when the formula was consumed for prolonged periods (up to 4 years). Terpenes, like menthol, help dissolve gallstones by reducing bile cholesterol levels while increasing bile acid and lecithin levels in the gallbladder. Because menthol was the major component of this formula, peppermint oil, especially if enteric-coated, may offer similar benefits.

External Analgesic

Menthol and related substances can be used as counterirritants in the treatment of arthritis, fibromyositis, tendonitis, and other inflammatory conditions involving the musculoskeletal system.

The Common Cold

Menthol and peppermint oils are often employed in the treatment of the common cold as components of topical nasal decongestants, cough and throat lozenges, ointments, salves, and inhalants. Whether the use of these products is of benefit has not been proven in clinical studies. However, their popularity appears to represent their ability to help make breathing easier during the common cold. The best method for using menthol or peppermint oil is to apply commercial preparations to the upper chest during periods of rest so that the vapors can be inhaled continuously.

Peppermint tea may also be of benefit during the common cold. Peppermint and other members of the mint family demonstrated significant antiviral activity in addition to a mild diaphoretic effect.[23] The most active antiviral components, the polyphenols, are concentrated in the tea.[2] Peppermint oil also showed antiviral activity against Newcastle disease, herpes simplex, and vaccinia.

Headache

In a double-blind, placebo-controlled, randomized crossover trial, topical application of peppermint oil to the forehead and temples resulted in a statistically significant decrease in muscle tension as reported subjectively and measured objectively by electromyographic activity of the temporal muscle. In addition, the oil application decreased sensitivity to pain.[24]

Endoscopy and Colonoscopy

A 20-mL oral solution containing 0.8% L-menthol suppresses peristalsis in patients undergoing endscopy.[25] Taking ECPO capsules before colonoscopy has also shown benefits. In a double-blind study, 65 adult patients undergoing colonoscopy were randomized to receive either ECPO or a placebo 4 hours before the procedure.[26] Premedication with ECPO was beneficial in terms of the time required for cecal intubation and total procedure time, reducing colonic spasm, increasing endoscopist satisfaction, and decreasing pain in patients during colonoscopy.

DOSAGE

Peppermint is most widely used as a tea (infusion), on its own or in combination with other botanicals. The infusion is usually prepared with 1 to 2 teaspoons of the dried leaves per 8 oz of water.

The dosage of peppermint oil administered in an enteric-coated capsule for the treatment of the IBS is one to two capsules (0.2 mL per capsule) three times daily between meals. This dosage is also appropriate for the treatment of gallstones.

The dosage of menthol as an external analgesic is 1.26% to 16% applied to the affected area no more than three or four times daily.

TOXICOLOGY

Peppermint herb is generally regarded as safe when used as a tea; however, hypersensitivity reactions have been reported. Adverse reactions to ECPO capsules are rare but include hypersensitivity reactions (rash), heartburn, bradycardia, and muscle tremor.

When applied topically, peppermint oil or menthol can induce contact dermatitis and hypersensitivity reactions. The likelihood of the development of such a reaction is enhanced when heating pads are used in conjunction with topically applied preparations containing menthol.[27]

In rats, the lethal dose of menthol for 50% of subjects is 3280 mg/kg. The fatal oral dose in humans is calculated at 1 g/kg. In one study, repeated high-dose feeding of rats for 28 days with peppermint oil produced signs of dose-related brain lesions, but the dosage (40 mg/kg) given to the rats far exceeded that used in humans.[1,28,29]

DRUG INTERACTIONS

Peppermint oil may enhance the oral bioavailability of certain drugs. Most notably, in a study in rats, peppermint oil (100 mg/kg) tripled the mean cyclosporine maximum concentration and increased the area under the concentration-versus-time curve.[30] This dosage does not reflect the dosage used in clinical studies; however, physicians should be aware that peppermint oil may raise serum levels of certain drugs when the agents are coadministered.

Microbial Enzyme Therapy

Corey Resnick, ND

OUTLINE

INTRODUCTION

Enzymes derived from fungal species such as *Aspergillus oryzae, A. niger,* and *Rhizopus spp*. have been shown to be safe and effective in the treatment of a variety of clinical disorders. In some cases, fungal enzymes may be more effective than animal-derived enzymes or other available therapies. Some fungal enzyme preparations are particularly well suited for clinical application because of their inherent ability to resist degradation by stomach acid and their ability to hydrolyze physiologically or pathologically important substrates over a wide pH range.

Clinically, fungal enzyme preparations are most often administered orally at mealtime to aid digestion by hydrolyzing dietary substrates such as fats, carbohydrates, and proteins. They have also been used intravenously for the treatment of vascular obstruction, thrombotic disorders, and ischemic disease. Controlled studies in humans and animals have demonstrated efficacy of various fungal enzyme preparations administered orally or parenterally in a wide range of conditions, including the following:

- Maldigestion and malabsorption
- Pancreatic insufficiency
- Functional gastrointestinal disorders
- Steatorrhea
- Gluten-related disorders
- Lactose intolerance
- Oligosaccharide-induced gastrointestinal symptoms
- Arterial obstruction
- Ischemic disease
- Thrombotic disease

This chapter reviews evidence of efficacy for fungal enzyme preparations in a number of the previously mentioned conditions. It also presents indirect evidence that some portion of orally administered fungal enzymes may be absorbed intact in an enzymatically active form. To the extent that such absorption does occur, fungal enzyme supplements administered orally between meals may be of possible benefit as an adjunct in the treatment of systemic conditions, such as the following:

- Inflammatory conditions
- Food allergies

DIGESTIVE ENZYME DEFICIENCIES

Adequate digestion is a prerequisite for normal gastrointestinal function and overall health. Deficiencies in digestive enzymes and imbalances in gastrointestinal pH can lead to impaired digestion, which can cause or aggravate a number of conditions, including the following[1–6]:

- Pancreatic insufficiency
- Maldigestion and malabsorption
- Intestinal permeability defects
- Food intolerance
- Gastrointestinal discomfort
- Food allergy
- Autoimmune conditions
- Bacterial overgrowth

Oral administration of supplemental digestive enzymes can help treat enzyme deficiencies and improve conditions that are related to impaired digestion such as these.

ACID-STABLE FUNGAL ENZYMES

Oral supplementation with acid-stable fungal enzymes, also known as plant enzymes or microbial enzymes, has been shown to be safe and effective in the treatment of a number of disorders in humans and animals. In individuals with gastrointestinal pH imbalances, these enzymes may offer advantages over conventional pancreatin and enteric-coated pancreatic enzyme preparations.[2,7–10]

Pancreatic enzymes have optimal activity in neutral to alkaline conditions around pH 7 and above. They are unstable in acidic conditions. As a result, exposure to gastric acid can destroy up to 90% of orally administered pancreatic lipase and 65% of pancreatic trypsin

according to some studies.[10] Enteric-coated preparations are designed to protect pancreatic enzymes from gastric acidity; however, these do not work reliably in all cases.[2,10,11] This is because most patients with pancreatic insufficiency are not able to concentrate bicarbonate sufficiently to alkalinize the upper small intestine. As a result, enteric-coated tablets or capsules often fail to dissolve and deliver their enzymes in the duodenum or jejunum as intended. The resulting jejunal hyperacidity can also inhibit pancreatic enzyme activity even if enteric coatings do dissolve as intended.[2,7,10,12] Gastric hyperacidity can also lead to impaired fat digestion by causing acidic jejunal pH.[12] Although H_2 receptor antagonists, such as cimetidine, are often used along with pancreatin to lessen intragastric inactivation, this approach is unsuccessful in improving lipid digestion in many patients and carries the possible risk of adverse side effects.[13]

Studies show that certain acid-stable fungal enzyme preparations are naturally stable and enzymatically active in both acid and alkaline pH conditions. For example, lipase preparations derived from both *A. oryzae* and *R. arrhizus* were shown to be active and stable in the broad range of pH 2 to pH 10.[7,8] As a result, such preparations do not require enteric coatings or coadministration of pH-altering drugs. They are effective even in patients with gastrointestinal pH imbalances, such as pancreatic insufficiency, jejunal hyperacidity, and gastric hyperacidity, which can limit the effectiveness of pancreatic enzymes.

As a result of their broad pH range of activity, acid-stable fungal enzymes begin digesting food in the acid environment of the stomach and continue working in the alkaline pH of the small intestine.[2,10,14] As discussed in this chapter, the following fungal enzymes have been shown to aid digestion in humans when administered orally at the time of food consumption:

- Lipase
- Protease
- Amylase
- Prolyl endopeptidase
- Dipeptidyl peptidase IV
- Lactase
- Alpha-galactosidase
- Phytase
- Cellulase

CLINICAL APPLICATIONS

Pancreatic Insufficiency and Other Digestive Disorders

Studies have compared the efficacy of pancreatic enzymes and acid-stable fungal lipase in the treatment of exocrine pancreatic insufficiency in humans and animals. Some studies showed that acid-stable fungal lipase is effective at a substantially lower dose of enzyme activity than that required for pancreatin to reduce pathologically elevated fecal fat levels, stool weight, and diarrhea.[7,8]

A controlled, crossover-design clinical trial in 17 patients with severe pancreatic insufficiency compared the effects of an acid-stable fungal enzyme preparation with conventional pancreatic enzymes and enteric-coated pancreatin. One group of nine patients with pancreatoduodenectomy and bowel resection (Whipple procedure) was found to have pancreatic enzyme levels less than 10% of normal on stimulated secretion before the trial. A second group of eight nonsurgical patients had stimulated pancreatic enzyme levels less than 29% of normal. Both groups were placed on a diet containing 100 g/day of fat. Stools were collected for 72 hours before treatment beginning 5 days after discontinuing all medications and supplemental enzymes. Thereafter all patients were placed on consecutive 2-week periods of treatment, beginning with enteric-coated pancreatin (100,000 International Pharmaceutical Federation [FIP] lipase units [LU]), followed by conventional pancreatin (360,000 FIP LU), and finally, acid-stable fungal lipase (75,000 FIP LU). The fungal enzyme preparation and both of the pancreatic enzyme preparations also contained protease and amylase activity. Stools were collected for the last 72 hours of each treatment period and analyzed for fecal fat content and stool weight. All three of the enzyme treatment protocols led to a significant reduction in fecal fat excretion in both groups ($P < 0.05$), and all patients became virtually symptom-free with regard to diarrhea and abdominal discomfort. Of note, the enteric-coated pancreatin dosage was one-third higher and the conventional pancreatin dosage was nearly five times higher than that required for fungal lipase to produce comparable clinical improvement.[8]

A similar randomized, placebo-control, crossover-design study in dogs compared the effectiveness of 4000 LU of acid-stable fungal lipase derived from *A. oryzae* to 60,000 LU of lipase from pancreatin in the treatment of surgically induced pancreatic insufficiency and steatorrhea. Dogs in the placebo group had significant weight loss as a result of malabsorption and pathologically elevated fecal fat content and stool weight. Compared with placebo, dogs in both enzyme treatment groups experienced significant reductions in fecal fat and stool weight, with no significant weight loss. In this study, the enzyme dose of pancreatin was 15 times higher than that required for the acid-stable fungal lipase to produce comparable clinical results.[7]

One controlled clinical trial showed that an acid-stable fungal lipase derived from *Rhizopus arrhizus* was effective at reducing steatorrhea by 56.5% and stool weight by 45.2% compared with placebo in seven patients with pancreatic insufficiency. The study also demonstrated that the fungal lipase retained greater than 80% of its enzyme activity under conditions of simulated gastric acidity at pH 3 for 1 hour.[15]

Another study in 100 outpatients evaluated the efficacy of a fungal enzyme preparation containing lipase derived from *R. arrhizus* and protease and amylase from *A. oryzae* in a range of gastrointestinal complaints, including epigastric pain and pressure, flatulence, heartburn, belching, and nausea. Investigators reported that 96% of patients experienced some relief of symptoms and rated treatment outcomes as good to very good in 65% of patients.[16]

Some clinical trials reported on the efficacy of enzyme preparations containing protease, amylase, cellulase, and hemicellulase derived from *A. oryzae* in combination with pancreatic enzymes in the treatment of a range of digestive disorders.[17,18] One double-blind, placebo-controlled, crossover design study in a group of 31 outpatients (ages 17–75 years) and 23 geriatric hospital inpatients (ages 70–90 years) found that this enzyme combination was significantly effective in the global improvement of diverse gastrointestinal symptoms ($P < 0.05$) that included pain, nausea, heartburn, bloating, flatulence, constipation, and diarrhea.[17]

Gluten-Related Disorders

Adverse reactions to gluten in the diet can lead to a broad range of gastrointestinal and systemic conditions caused by several different pathophysiological mechanisms that have been referred to collectively as "gluten-related disorders."[19–21] Among the most widely recognized, celiac disease is caused by an autoimmune reaction to dietary gluten. It affects about 1% of the Western population.[22] Other less well-known forms of gluten-induced autoimmune disease include dermatitis herpetiformis and gluten ataxia. Nonautoimmune allergic reactions to gluten can also occur as in the case of wheat allergy.[19,20] Other forms of gluten intolerance include nonceliac gluten sensitivity, which can produce a variety of gastroenterological[21] and neurological symptoms.[19,23,24] The actual prevalence of all forms of gluten-related disorders combined is not known with certainty. However, data from one

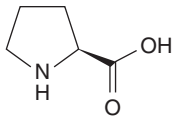

Fig. 95.1 Proline.

review study indicate that adverse reactions to gluten in the diet may affect about 10% of the population.[19]

Gluten is a type of protein found in wheat, barley, and rye. It consists of two main fractions: gliadins and glutenins. Adverse reactions to gluten appear primarily as a result of unusually high amounts of the amino acid proline that it contains, comprising as much as 20% of the molecule.[25] The proline-rich peptide bonds in gluten make it resistant to digestion by proteolytic enzymes in the gastrointestinal tract (Fig. 95.1). As a result, the intestinal mucosa is exposed to undigested gluten-derived polypeptides. A number of these peptides have been shown to cause pathological reactions in sensitive individuals.[22,25,26]

The most effective way to manage gluten-related disorders is for affected individuals to maintain a strict gluten-free diet. However, that can often be hard to accomplish. In addition to the difficulty of compliance and potential social challenges of avoiding foods known to contain gluten, exposure to hidden sources of gluten in the diet is a common problem. One study estimated that unsuspected sources of gluten contained in many prepared foods such as sauces, salad dressings, flavorings, thickeners, etc., may result in daily exposure to 10 to 1000 mg of hidden gluten—even among individuals trying to maintain a gluten-free diet.[27] This has led to a search for therapeutic interventions to ease the burdens of a gluten-free diet and the consequences of accidental exposure to hidden gluten. Beginning as early as the 1950s, studies have examined the efficacy of various proteolytic enzymes derived from fungal and bacterial sources capable of hydrolyzing and thereby degrading the gluten molecule with the goal of reducing its toxicity to sensitive individuals. Some of these have shown great promise in mitigating the challenges of gluten-related disorders by reducing the risk of exposure to hidden gluten. This section reviews evidence of efficacy for some of these enzymes, alone and in combination.

Prolyl Endopeptidase

Celiac disease is an autoimmune condition triggered by reactions that occur in the small intestine to immunogenic gluten-derived peptide fragments, or epitopes, in genetically susceptible individuals. Signs and symptoms can be severe and include abdominal pain and distension, chronic diarrhea, malabsorption, weight loss, anemia, fatigue, and increased risk of osteoporosis and intestinal cancers.[22] Some of these immunogenic peptides are described by the number of amino acids in the peptide chain followed by the suffix "-mer." For example, a 33-mer from α-gliadin and a 26-mer from γ-gliadin are known to trigger proinflammatory T-cell reactions leading to mucosal damage. Antibodies to immunogenic gluten-derived peptides that are produced by activated T-cells and B-cells cross-react with host tissues leading to inflammation, mucosal atrophy, loss of digestive function, nutrient malabsorption, and other GI and systemic disorders.[22,28]

Recent studies have shown that a specific type of protease derived from *Aspergillus niger* is capable of hydrolyzing proline bonds within these immune-reactive gluten epitopes. This enzyme is known as *Aspergillus niger*-derived prolyl endopeptidase or prolyl endoprotease (AN-PEP). It is a proline-specific endopeptidase that primarily cleaves the hard-to-digest proline peptide bonds in the interior portions of gluten peptides.

A 2006 study measured the effectiveness of AN-PEP at detoxifying immunogenic gluten epitopes in vitro. After intact gluten and gluten predigested with pepsin and trypsin were treated with AN-PEP they no longer triggered reactions in gluten-sensitive T-cells. Destruction of all 14 of the tested immune-reactive gluten peptides was confirmed by mass spectrometry, enzyme-linked immunosorbent assay, high-performance liquid chromatography, and Western blot testing. AN-PEP was found to be active and stable from pH 2 to 8 with optimal activity at pH 4 to 5.[29]

An in vitro study in 2008 measured the effectiveness of AN-PEP at breaking down immunogenic gluten peptides from a slice of bread and, in a second experiment, from a gluten-containing "fast food" test meal. Samples of digested food were taken from the stomach and intestinal compartments of a simulated gastrointestinal model (TIM system). These were analyzed for the presence of immunogenic peptides from gliadins and glutenins using T-cell proliferation assays, monoclonal antibody-based assays, and Western blot testing. AN-PEP degraded almost all the immune-active gluten peptides in the stomach before they could reach the duodenum.[30]

A randomized, double-blind, placebo-controlled, crossover study in 2015 measured the ability of AN-PEP to digest gluten in the stomach of 12 healthy volunteers. Each subject was given a liquid low- or high-calorie meal containing 4 g of gluten with either AN-PEP or placebo administered to the stomach via catheter. Gastric and duodenal samples were aspirated over a period of 4 hours and analyzed for content of an immunodominant α-gliadin epitope using enzyme-linked immunosorbent assay and Western blot analysis. Compared with placebo, AN-PEP significantly lowered α-gliadin concentrations in the stomach and duodenum ($P < 0.001$) and lowered α-gliadin in the duodenum from low ($P < 0.001$) and high ($P = 0.013$) calorie meals. Almost all the gluten was degraded in the stomach within a 1-hour period from both low and high calorie meals. A dosage of 1,600,000 Protease Picomole International (PPI) units of AN-PEP significantly enhanced digestion 4 g of dietary gluten in the stomach before entering the duodenum in this study.[21]

Dipeptidyl Peptidase IV

Unlike proteases from the stomach and pancreas that are unable to hydrolyze proline-peptide bonds, the brush border membrane of the intestinal mucosa produces a protease, dipeptidyl peptidase IV (DPP-IV), which can degrade some of the proline-rich immunogenic peptides in gluten.[28,31] Clinical studies have shown that DPP-IV levels are substantially depressed in celiac patients. Other brush border digestive enzymes are also depressed in celiac patients during periods of active disease (e.g., lactase, sucrase, maltase). However, other brush border enzymes return to normal levels in celiac patients who are in remission and DPP-IV remains consistently depressed in these patients.[28,32]

In contrast to AN-PEP, which cleaves proline-peptide bonds mainly in the interior of gluten-derived peptides, DPP-IV is a proline-specific exopeptidase capable of cleaving proline-containing dipeptides at the N-terminal end of gluten peptides.[28] In vitro studies have shown that porcine-derived DPP-IV is able to break down immunodominant epitopes from gliadin.[28,32] DPP-IV derived from *Aspergillus oryzae* has also been shown to enhance the breakdown of immunogenic gluten epitopes in vitro.[27]

Some research has suggested that gluten may also cause neurological symptoms in susceptible individuals. A 2006 literature review found several studies showing a drastic or complete remission of schizophrenic symptoms after withdrawal of gluten from the diet in a subset of patients.[33] In addition to larger gluten-derived immunogenic peptides such as 33-mer and 26-mer that can cause autoimmune reactions found in celiac disease, other smaller gluten-derived peptides may cause neurological symptoms not mediated by immune

mechanisms. A 1992 study isolated four different peptides from wheat gluten with chain lengths of 4 to 5 amino acids that were highly specific for delta opioid receptors found in the brain. These were termed gluten exorphins, or glumorphins. One of these peptide sequences, known as glumorphin A5, was found at 15 locations in wheat glutenin.[23]

It has been hypothesized that opioid peptides derived from gluten and casein may also play a role in autism spectrum disorders (ASD), although this has not been conclusively proven. Children with autism have significantly higher serum levels of IgG antibody to gliadin compared with healthy controls, particularly in those with gastrointestinal symptoms.[34] A two-stage, randomized, controlled study of children with ASD on a gluten-free and casein-free diet reported significant group improvements in core autistic and related behaviors after 8 and 12 months on the diet.[35] A study in 2012 found that glumorphin A5 was present in the urine of children with autism but not in normal control subjects.[24] Glumorphin A5 contains an N-terminal proline dipeptide like other gluten derived peptides that can be degraded by DPP-IV; however, this has not been confirmed in controlled clinical studies.

Efficacy of Enzyme Combinations

In addition to the individual activities of AN-PEP and DPP-IV, there is evidence that some combinations of proline-specific fungal peptidases are more effective at detoxifying dietary gluten than single enzymes alone. As an exopeptidase, DPP-IV has been shown to hydrolyze proline dipeptide bonds at the N-terminal ends of immunogenic gluten epitopes. As an endopeptidase, AN-PEP has primarily been shown to hydrolyze proline-peptide bonds in the interior of gluten peptides. AN-PEP has also been shown to have exopeptidase activity capable of hydrolyzing some proline-peptide bonds at the ends of these peptides; however, it does not cleave all such bonds.[29]

One study showed that a proline-specific bacterial oligopeptidase used in combination with AN-PEP was able to hydrolyze the N-terminal proline-dipeptide bonds that were resistant to digestion by AN-PEP alone.[29] Another study showed that the combination of DPP-IV derived from *Aspergillus oryzae* with an *Aspergillus niger*-derived protease was more effective than either enzyme alone in detoxifying gluten. The exopeptidase activity of DPP-IV accelerated the clearance of short peptides, thereby facilitating access of longer gluten fragments to the active site of the other enzyme. The combination of enzymes resulted in significantly enhanced degradation of immunogenic gluten epitopes.[27] These in vitro studies indicate that oral supplementation with a combination of proline-specific fungal peptidases may provide synergistic benefits by hydrolyzing different portions of the molecule, resulting in more complete and efficient gluten degradation. Future studies may help determine which combinations of such enzymes may offer greater efficacy for detoxifying dietary gluten in sensitive individuals.

Lactose Intolerance

Deficient secretion of intestinal lactase (β-galactosidase) can produce signs and symptoms of dietary lactose intolerance, including abdominal pain, diarrhea, bloating, flatulence, and an increase in breath hydrogen excretion. Studies indicate that lactase deficiency occurs in more than half of the adult human population.[36] Some degree of lactose maldigestion is also a common problem in children, occurring in 76% of apparently healthy children in one study and 56% in another controlled trial.[37] Maldigestion of lactose can result from genetic nonpersistence of intestinal lactase some time after weaning as well as from acquired lactase deficiencies. Deficient lactase production may or may not produce clinical symptoms of lactose intolerance.[3] A study of 232 children with intestinal biopsies found that lactase activity decreased significantly with age and correlated with degree of intestinal injury. Other studies also showed that intestinal secretion of lactase, sucrase, and maltase were decreased in conditions with intestinal mucosal injury and morphological changes, including those seen in celiac disease and chronic diarrhea.[38–41]

A number of controlled human studies showed that fungal lactase administered orally at the time of milk consumption or added to milk at mealtime was each effective at preventing or treating signs and symptoms of intolerance in lactose-intolerant individuals.[3,37,42] One double-blind, placebo-controlled study showed that oral supplementation with fungal lactase taken at the time of lactose consumption was significantly effective at reducing breath hydrogen excretion and treating clinical symptoms in 18 children with lactose intolerance (ages 8–14 years). Test subjects were given tablets containing β-galactosidase derived from *A. oryzae* coingested with a lactose solution (3000 Food Chemicals Codex [FCC] lactase units [ALU]/5 g lactose) after a minimum fast of 8 hours. Breath hydrogen was measured every 30 minutes and clinical symptoms were monitored for the 120-minute test period. Lactase treatment successfully lowered breath hydrogen to below lactose malabsorption threshold levels in 89% of patients ($P < 0.001$). In the placebo group, 89% experienced abdominal pain, 83% bloating, 61% diarrhea, and 44% experienced flatulence. In the lactase group, only 6% experienced abdominal pain, 6% had diarrhea, and none of the test subjects experienced bloating or flatulence.[3]

Oligosaccharide Intolerance

Oligosaccharides contained in legumes and other vegetables can produce symptoms such as flatulence, bloating, abdominal pain, and diarrhea in many individuals. These carbohydrates are resistant to digestion by gastrointestinal enzymes and are therefore available for uptake and fermentation by colonic microflora resulting in the production of gases such as hydrogen. Studies have shown that oral administration of alpha-galactosidase enzyme derived from *Aspergillus niger* is safe and effective at breaking down these dietary oligosaccharides and preventing or reducing flatulence and related abdominal symptoms in sensitive individuals.

A double-blind crossover trial compared the effects of alpha-galactosidase and placebo administered with a test meal of vegetarian chili in 19 subjects. They were asked to keep a careful record of gastrointestinal symptoms for 6 hours after the meal, including the passing of intestinal gas. The number of flatulence events was significantly reduced during the follow-up period in those taking alpha-galactosidase versus placebo ($P = 0.016$).[43]

A double-blind, placebo-controlled study in 2007 measured the effect of alpha-galactosidase on intestinal gas production and symptoms of abdominal pain, discomfort, flatulence, and diarrhea in 8 healthy volunteers. Doses of 300 GalU or 1200 GalU of alpha-galactosidase or placebo were administered with a test meal containing 420 g of cooked beans and breath hydrogen and gastrointestinal symptoms were monitored for 8 hours. Compared with placebo, both doses of alpha-galactosidase decreased breath hydrogen excretion and significantly reduced total symptom scores.[44]

IMPROVING NUTRIENT BIOAVAILABILITY

Dietary supplementation with fungal enzymes has been shown to improve nutrient bioavailability in humans and animals. The effect of supplementation with lipase, amylase, protease, cellulase, and lactase from *Aspergillus niger* in combination with bromelain was studied in 16 clinically stable nursing-home patients receiving enteral nutrition by intubation before and after three consecutive 15-day feeding

periods. Supplementation with the enzyme mixture improved nutritional status as measured by significantly improved blood protein levels compared with the nonsupplemented diet ($P = 0.02$). Albumin concentration and lymphocyte count also tended to improve with enzyme administration.[45]

Bioavailability of minerals can be considerably reduced by dietary phytate. Humans and monogastric animals produce little or no endogenous phytase in the gastrointestinal tract.[46] A controlled clinical trial in humans showed that dietary supplementation with an acid-stable fungal phytase from *A. niger* increased absorption of iron from the diet. The study also showed that the fungal phytase was stable and active across a broad range from pH 1.0 to 7.5, and that it initiated digestion of dietary phytate beginning in the stomach.[14] Animal studies showed that supplementation with fungal phytase helped improve zinc, calcium, and phosphorus bioavailability, and increased bone strength in a dose-dependent manner.[47,48]

Studies showed that supplementation with fungal cellulase helped increase nutritional value of dietary grains in animals. Cellulase significantly improved digestibility of dietary cell wall components and increased solubility of calcium, phosphorus, iron, zinc, and copper associated with cell walls.[49] Studies using multienzyme combinations, including fungal amylase, protease, invertase, phytase, and cellulase, showed increased digestibility of nutrients and improved growth in pigs and chickens.[50,51]

VASCULAR DISEASE

A number of placebo-controlled clinical studies confirmed the effectiveness of a proteolytic fungal enzyme in the treatment of chronic arterial obstruction in humans.[52–55] A single-blind, placebo-controlled, crossover study evaluated the effectiveness of protease from *A. oryzae* versus placebo in 18 patients (ages 63–75 years) with stable intermittent claudication.[52] Patients were divided into an experimental group and a placebo group of nine subjects each, and all patients were assessed before testing. Translumbar aortogram, Doppler ultrasound, and peripheral systolic blood pressure were used to assess the patency of eight different arterial segments in each patient (a total of 72 arterial segments in each group). Anticoagulant therapy with warfarin was introduced after assessment and continued throughout an observation period of 3 months and a subsequent trial period of 2 weeks. Patients were reassessed after the 3-month observation period. Thereafter a series of six intravenous infusions of fungal protease or normal saline placebo was given to experimental and control groups, respectively, over the 2-week trial period. Assessment of peripheral circulation was repeated at the end of the trial period. No other form of therapy was given, except warfarin for anticoagulation. Before treatment, patients in the experimental group were found to have 27 obstructed segments (completely obstructed), 34 stenosed segments (partially obstructed), and only 11 patent arterial segments. Patients in the placebo group had 25 obstructed, 26 stenosed, and 21 patent arterial segments before treatment.

At the end of the 3-month observation period, no changes in Doppler ultrasound findings or peripheral blood pressure were found in either group. At the end of the 2-week trial period, three of the stenosed arterial segments in the placebo group had progressed to complete obstruction, and none of the obstructed segments had become patent (i.e., 4% worse). In the protease group, 16 of the 17 arterial segments that were completely obstructed became patent and one improved to stenosed status during the 2-week treatment period. Overall, treatment with the fungal protease infusion improved patency of 33 of 72 arterial segments, a 46% improvement ($P < 0.001$).

Further analysis of results from this study suggested that an increase in the number and/or dosage of protease infusions might have resulted in even greater improvement in obstructed and stenosed arterial segments. Other studies showed intravenous administration of fungal protease to be effective in the treatment of arterial obstruction in patients with more advanced conditions, such as gangrene and other severe ischemic disease.[53,55]

PHARMACOLOGY OF FUNGAL PROTEASES

Fungal proteases have been used for many years in food production and medical applications. The most common fungal proteases used in medical and dietary supplement applications are derived from *Aspergillus oryzae* and *A. niger*. *A. oryzae*–derived protease preparations are used orally for the prevention and treatment of digestive disorders and are treated as drugs for this purpose in some countries.[17,18,56] *A. oryzae* produces three main proteases that are naturally acid-resistant and that exhibit aggregate proteolytic enzyme activity over a broad range from pH 3 to 9.[56,57] One of these three proteases, sometimes referred to in the literature as *A. oryzae* protease I, was used for treatment of vascular disease in the previously cited clinical trials.[52,53] Studies showed that the thrombolytic effects it exhibited were caused by its fibrinolytic activity.[58,59] It also has hydrolytic enzyme activity against fibrinogen. It does not affect the plasminogen–plasmin system nor does it interfere with normal blood clotting in therapeutic doses.[60]

A. oryzae protease I has a molecular weight of about 35 kDa.[59] It is carried in the blood bound to protease inhibitor proteins α_2-macroglobulin and α_1-antitrypsin.[52,59] These are the same plasma proteins that act as carriers for trypsin, chymotrypsin, and bromelain.[61–63] These protease inhibitors help maintain a protective balance by modulating proteolytic activity in the blood while also maintaining the proteases they carry in an enzymatically active form.

As mentioned previously, acid-stable fungal protease has been used and studied clinically to aid digestion of dietary protein in the gastrointestinal tract on oral administration at mealtime.[17,18,56] Anecdotal reports suggested that some clinicians also administer fungal protease supplements orally between meals as an adjunct in the nutritional treatment of inflammatory conditions and food allergies. A possible mechanism of action for these applications is supported by indirect evidence that some portion of orally administered fungal enzymes is probably absorbed intact and retains enzymatic activity in the blood.

Absorption of Orally Administered Enzymes

Contrary to long-held theories that the healthy intestinal mucosa is an essentially impermeable barrier to intact proteins, including enzymes, there is compelling evidence that such macromolecules can and do pass intact from the human gut into the bloodstream under both normal and pathological conditions.[1,64–67]

Numerous whole proteins, including animal and plant-derived enzymes, were shown in human and animal studies to be absorbed intact into the bloodstream after oral administration. Several human studies showed that exogenous pancreatic trypsin (molecular weight approximately 23 kDa) and chymotrypsin (25 kDa) were absorbed intact in an enzymatically active form after oral administration.[68–70] Studies showed that an enteropancreatic circulation normally exists, in which pancreatic enzymes are absorbed from the gut intact and while enzymatically active, travel in the circulation, are reabsorbed by the pancreas, and resecreted back into the gut mixed with newly synthesized enzymes.[71,72]

Other examples of enzymes and other proteins that are absorbed intact on enteral administration include amylase (54 kDa), elastase, chymotrypsinogen, human albumin and lactalbumin, bovine

albumin, ovalbumin, lactoglobulin, and other large molecules, such as ferritin (500 kDa) and botulism toxin (1000 kDa).[64–67,70,73–75] Studies also demonstrated the intact absorption of orally administered plant enzymes, such as bromelain (24 kDa), papain (39 kDa), and peroxidase from horseradish (40 kDa).[61,70,76]

Some studies examined the quantitative significance of the absorption of orally administered enzymes. A randomized, double-blind, placebo-controlled trial measured the absorption of orally administered bromelain in 19 healthy men (ages 18–45 years). Enteric-coated bromelain was given to the test group in six daily doses, averaging 660 mg each over a 2-day period. Bromelain was found to be absorbed intact in an enzymatically active form and in time-dependent concentrations in the blood of all subjects in the test group. Individuals in the placebo group had no detectable bromelain levels. Total bromelain measured in the blood of test subjects over a 4-day monitoring period was equivalent to approximately 0.7% of the administered oral dose.[61]

Studies in animals looked at the percentage of total administered doses of pancreatic enzymes and papain that were absorbed intact after enteral administration. One study in rats found that approximately 27% of the total administered dose of trypsin, 14% of chymotrypsin, 8% of amylase, and 6% of the administered dose of papain were absorbed into the bloodstream as intact macromolecules in an enzymatically active form after enteral administration.[70]

Based on indirect evidence in humans and animals such as this, it appears likely that some portion of *A. oryzae*–derived protease and other fungal enzymes is absorbed intact after oral administration between meals. To the extent that such absorption does occur, orally administered fungal proteases may exhibit therapeutic properties in the systemic circulation and tissues. These properties include fibrinolytic activity that may be of potential benefit in the treatment of inflammatory conditions in various tissues throughout the body. They also include the ability to hydrolyze dietary proteins and polypeptides that may be of potential benefit in the treatment of food allergies.

FOOD ALLERGIES

Under healthy conditions, adequate protein digestion, normal intestinal permeability, and healthy immune function are important physiological mechanisms that act together to limit the amount of undegraded dietary proteins and polypeptides that is absorbed into the general circulation. Under pathological conditions, these food-derived macromolecules can act as antigens and contribute to food allergies.[1,67,77] Fungal protease administered orally at mealtime helps hydrolyze dietary protein in the gut[17,18,56] and may therefore help reduce the supply of foreign macromolecules available to leak into the bloodstream. In addition, it is possible that fungal protease administered orally between meals may be partially absorbed in an enzymatically active form and help to some extent "digest" dietary protein-derived antigens in the blood. This could potentially reduce the quantity of circulating antigens and be of benefit in the treatment of food allergies or perhaps even food-linked autoimmune disorders. Further research is needed to evaluate these proposed mechanisms of action and confirm whether fungal enzyme supplementation may be a useful adjunct in the treatment of food allergies.

SUMMARY

Research has shown that certain enzymes derived from fungal species such as *A. oryzae, A. niger,* and *Rhizopus spp*. are safe and effective at increasing digestion and treating certain digestive disorders when administered orally at mealtime. These enzymes are inherently stable on exposure to stomach acid and exhibit digestive enzyme activity on a wide variety of dietary substrates over a broad pH range. Because of these properties, fungal enzymes may offer clinical advantages over pancreatic enzymes and pH-altering drugs in some conditions such as pancreatic insufficiency.

Indirect evidence suggests that fungal enzymes may be partially absorbed in an intact and enzymatically active form when administered orally between meals. To the extent that such absorption does occur, it is possible that orally administered *A. oryzae* protease may have potential benefit as an anti-inflammatory agent as a result of its known fibrinolytic activity; however, any efficacy in this application remains unproven. Further research is also needed to confirm a possible benefit for the use of fungal enzymes in the treatment of food allergies.

Natural Medicines Quality Control

Joseph E. Pizzorno, ND

OUTLINE

BACKGROUND

Dietary supplements (DSs) are obviously beneficial to promote health, restore balance, and treat disease. People take them for long periods of time, often for years and years. A sensible strategy for limiting contaminants in DSs, making sure that they are authentic and the potency they claim to be, is to require suppliers to prove that they routinely do thorough testing to verify and assure those quality parameters. DS prescribers and consumers need to ask for legitimate proof of quality from each manufacturer.

Before launching into the details and challenges of product quality control, the author and editors want to acknowledge and commend those nutritional supplement manufacturing companies that perform most, or all, of the processes necessary for quality verification. Unfortunately, too many in the industry—retail, mail order, professional, and online—fall short in providing legitimately verified quality DSs.

Abbreviations and Definitions

COA: Certificate of analysis.

DS: Dietary supplement(s).

DS CGMPs: Dietary Supplement Current Good Manufacturing Practices. The "current" is included because they are subject to updating and changes, and DS manufacturers are responsible for staying current with the updates in the regulations.

DS manufacturer: A company that obtains raw materials from domestic or foreign suppliers and uses those materials to manufacture, label, and sell capsules, tablets, powders, liquids, etc.

EMA: Economically motivated adulteration.

FDA: Food and Drug Administration.

FP: Finished product.

HPLC: High-performance liquid chromatography. An instrument used to analyze and check for the potency level(s) of botanical and nonbotanical raw materials and FPs.

HPTLC: High-performance thin layer chromatography. An instrument used to analyze and check for the correct genus and species (identity) of botanical raw materials.

OOS: Out-of-specification (studies).

RM: Raw material, also known as a component or DS ingredient used to make the final DS.

Scientifically valid method: This is from the preamble section of the FDA CGMP final rule for Manufacturing, Packaging, Labeling, or Holding Operations for Dietary Supplements: "Consistent with the view that we expressed in the 2003 CGMP Proposal, we believe a scientifically valid method is one that is accurate, precise, and specific for its intended purpose. In other words, a scientifically valid test is one that consistently does what it is intended to do."

SOPs: Standard operating procedures.

Supplier: A domestic or foreign company that sells DS raw materials, as a distributor, broker, agent, or it may be the original direct manufacturer.

Verify: To prove the truth of, as by evidence; confirm; substantiate; to ascertain the truth or correctness of, as by examination; to act as ultimate proof or evidence of; serve to confirm.

STATE OF THE INDUSTRY

There are approximately 1500 DS manufacturing companies in the United States. In addition, there are a number of marketing companies that have their DSs made by a private label contract manufacturer and sell their brand nationally or worldwide. Many of these manufacturing

companies historically have performed little or no testing on their raw materials (RM) or their finished DSs. They accept a certificate of analysis (COA) from their supplier. The COA is just a piece of paper that says the material is what it is supposed to be. When a DS manufacturer blindly accepts a COA as the "sole" proof of authenticity, potency, and purity, they relinquish their verification role. Why do they do this? Because it is quick, easy, cheap, and saves money, hassle, delay, and personnel. In short, they take the easy way out. This practice is likely to continue until practitioners and consumers knowledgeably demand quality or the Food and Drug Administration (FDA) clamps down and puts noncompliant manufacturers out of business or makes them comply under the threat of constant scrutiny, steep fines, or shutting down their business. The chain of events needed to produce high-quality DSs is too long and complicated to "trust" it will happen with consistent integrity without comprehensive testing of raw materials and finished products (FPs).

Pharmaceutical drugs are all too frequently sold as DSs. Unscrupulous DS manufacturers or marketing companies will sell products for weight loss, erectile dysfunction, fatigue, athletic performance, etc. These products are advertised as DSs, but the active ingredient is a pharmaceutical drug. In addition, drug and disease claims are often used in the marketing of DSs. These two practices give the DS industry a bad name, tarnishing the legitimate manufacturers and leading the FDA to mistrust companies that produce DSs.

THE FOOD AND DRUG ADMINISTRATION

The FDA has had regulatory oversight of the DS industry for 15 years or longer. In 2007 they put into place Current Good Manufacturing Practices (CGMPs) regulations. The regulations are basically rules to follow when manufacturing DSs, much like a strict recipe that has to be followed to get the intended outcome. They are "the law," and every manufacturer has to follow them. For about a decade the FDA has been conducting inspections of DS companies to see if they are complying with regulations. Word on the street is that many manufacturers are not complying. Maybe they will at some point in the future, but how will you know if a particular company is, or is not, complying with DS CGMPs?

Points regarding the FDA:

- The FDA's mission is to promote and protect the public health by helping safe and effective products reach the market in a timely way, and monitoring products for continued safety after they are in use.
- The FDA is probably underfunded and overburdened. At present, they probably do not have the capacity to strictly oversee the DS industry and enforce wide compliance in a short period of time.
- The DS CGMP regulations were written loosely so as to be flexible. This is a serious problem because it allows each manufacturer to apply "their own" interpretation of what it will take to comply with the regulations, possibly resulting in poor-quality DSs in the marketplace.
- Because the regulations were written to be flexible, the FDA gives little to no guidance on the detailed specifics of "Expected Best Practices" to DS manufacturers. The lack of FDA specific guidance parameters keeps everybody guessing as to whether or not the way "they" interpret the regulations will be acceptable to the FDA.
- The FDA will strictly enforce the DS CGMPs. As they do, it is likely to bring significant positive change to the DS industry that will ultimately benefit the consumer.

If a DS manufacturer says that they are in compliance with FDA CGMPs, it does not mean they have done enough to adequately test and verify their raw materials and FPs and to ensure that the final product is authentic, potent, and has maximum freedom from contamination. In addition, it is important to know that the FDA has mandated by law that if a product has an expiration date or best used by date on the label, the DS manufacturer has to have data to support the expiration date time period.

What data do DS manufacturers have to show? The FDA is silent on this point. The FDA CGMPs do not give any guidance to the industry as to what is acceptable to meet this requirement. This is a perfect example of the FDA providing no guidance on an important part of the DS CGMPs and leaving it to the DS manufacturer to guess and interpret what may be adequate.

Basics of Food and Drug Administration Current Good Manufacturing Practices

Companies that supply DS ingredients (domestic or foreign) to DS manufacturers do not have to follow the FDA DS CGMPs. According to the FDA, this means that the responsibility for the quality of raw material ingredients falls on the FP DS manufacturer and not on the supplier of the materials. This is unfortunate and a major deficiency in the DS CGMPs. Why? Because companies that supply ingredients to DS manufacturers can produce and sell poor-quality or tainted ingredients and are not held accountable. If the supplier of the ingredients and the manufacturer that uses the ingredients had to follow the same regulations, there would be a synergy to bring quality ingredients to the marketplace.

The following information comes from the FDA's website (www.fda.gov), and it gives enough detail to see what DS manufacturers must do to comply with these legally required regulations. The FDA DS CGMPs are not voluntary but must be followed because they are the law. All DS manufacturers are required to follow these rules as of June 2010.

CGMP Final Rule

- The current good manufacturing practices (CGMPs) final rule will require that proper controls are in place for dietary supplements so that they are processed in a consistent manner, and meet quality standards.
- The CGMPs apply to all domestic and foreign companies that manufacture, package, label, or hold dietary supplements, including those involved with the activities of testing, quality control, packaging and labeling, and distributing them in the United States.
- The rule establishes CGMPs for industry-wide use that are necessary to require that dietary supplements are manufactured consistently as to identity, purity, strength, and composition.
- The requirements include provisions related to:
  - The design and construction of physical plants that facilitate maintenance
  - Cleaning
  - Proper manufacturing operations
  - Quality control procedures
  - Testing final product or incoming and in-process materials
  - Handling consumer complaints, and
  - Maintaining records

Consumer Benefits

- Consumers should have access to dietary supplements that meet quality standards and that are free from contamination and are accurately labeled.
- The rule will give consumers greater confidence that the dietary supplement they use has been manufactured to ensure its identity, purity, strength, and composition.

- The rule addresses the quality of manufacturing processes for dietary supplements and the accurate listing of supplement ingredients. It does not limit consumers' access to dietary supplements, or address the safety of their ingredients, or their effects on health when proper manufacturing techniques are used.

Manufacturers

- Under the Dietary Supplement Health and Education Act (DSHEA), manufacturers have an essential responsibility to substantiate the safety of their products and for determining that any representations or claims made about their products are substantiated by adequate evidence to show that they are not false or misleading.
- The CGMPs will help ensure manufacturers produce unadulterated and properly labeled dietary supplements.
- Under the CGMP rule, manufacturers are required to:
  - Employ qualified employees and supervisors.
  - Design and construct their physical plant in a manner to protect dietary ingredients and dietary supplements from becoming adulterated during manufacturing, packaging, labeling, and holding.
  - Use equipment and utensils that are of appropriate design, construction, and workmanship for the intended use.
  - Establish and use master manufacturing and batch production records.
  - Establish procedures for quality control operations.
  - Hold and distribute dietary supplements and materials used to manufacture dietary supplements under appropriate conditions of temperature, humidity, light, and sanitation so that the quality of the dietary supplement is not affected.
  - Keep a written record of each product complaint related to CGMPs.
  - Retain records for 1 year past the shelf life date, if shelf life dating is used, or 2 years beyond the date of distribution of the last batch of dietary supplements associated with those records.
- Examples of product quality problems that the rule will help prevent are:
  - Dietary supplements that contain ingredients in amounts that are greater than those listed on the label
  - Dietary supplements that contain ingredients in amounts that are less than those listed on the label
  - Wrong ingredient
  - Other contaminant (e.g., bacteria, pesticide, glass, lead)
  - Foreign material in a dietary supplement container
  - Improper packaging
  - Mislabeling

The regulations mandate that each DS manufacturer set, document, and meet quality specifications for raw material ingredients and FPs. Each manufacturer gets to set its own specifications based on what it feels and/or thinks is important and complies with the regulation to ensure the four buzz words: identity, purity, strength, and composition. Herein lies a major problem with the CGMPs. The FDA gives little if any guidance on setting specifications.

"Purity" is one of the buzz words; one aspect of purity is contamination. Part 111.70 of the regulation states, "You must establish limits on those types of contamination that may adulterate or may lead to adulteration of the finished batch of the dietary supplement to ensure the quality of the dietary supplement." No guidance is given as to the types of contamination to consider. In CGMP seminars conducted around the country in the past few years, the FDA mentioned some examples of contamination and ultimately stated that the DS manufacturer should know globally what contaminants to consider.

Here is an example to illustrate:

- DS manufacturer "A" sets a specification for testing for a wide panel of chemical solvent residues in each batch of received RMs, examines those results for acceptable limits, and approves or rejects materials based on those limits.
- DS manufacturer "B" sets a specification for testing for chemical solvent residue only if they are listed on the suppliers' COA, examines those results for acceptable limits, and approves or rejects materials based on those limits.
- DS manufacturer "C" sets a specification that does not include chemical solvent residue testing.

Each DS manufacturer set a specification per the CGMPs, but each was different. Are they all acceptable to the FDA? We do not know. Which manufacturer's products would you prefer to prescribe?

THE IMPORTANCE OF QUALITY CONTROL

The first reason quality control is very important is clinical effectiveness. In other words, will it have the intended physiological effect on the body? Great quality does not always ensure significant clinical response, but most would agree that a low potency product or one that was not even what it claimed to be is not likely to help patients.

The second reason quality control is very important is that some sort of contamination may be present in the product. Long-term use of contaminated DSs may possibly cause harm. Depending on whether it is botanical or nonbotanical, the contaminants present could be lead, mercury, cadmium, arsenic, an array of chemical solvents, aflatoxins (liver toxins from mold growth), herbicides and pesticides, harmful bacteria, and industrial chemicals.

Unfortunately, with RMs coming from all over the world, contamination is a risk that is unavoidable.

Food and Drug Administration Definition of Quality

The FDA DS CGMP regulation has specific definitions for quality and quality control.

- Quality means that the dietary supplement consistently meets the established specifications for identity, purity, strength, composition, and limits on contaminants, and has been manufactured, packaged, labeled, and held under conditions to prevent adulteration under section 402(a)(1), (a)(2), (a)(3), and (a)(4) of the act.
- Quality control means a planned and systematic operation or procedure for ensuring the quality of a dietary supplement.

The only test specifically mandated by the FDA that must be performed is identity testing. The need for further testing is open to interpretation by the DS manufacturer.

A More Specific and Robust Definition of Quality

A DS is a quality product or not based on three parameters.

Is It Real?

In other words, is the RM authentic (i.e., has it been properly identified via a test method that is widely accepted as scientifically valid)? If no testing was performed to verify or identify the RM, and it was used in an FP anyway, its inclusion in the product not only could have resulted in decreased response; it may have actively caused harm.

Identifying and authenticating botanical products can be challenging especially if they are powdered extracts versus plant parts or powdered plant parts that have not been extracted. Plant parts (leaves, roots, stems) when whole or in pieces can be identified more easily by

gross and microscopic examinations to ensure compliance with published criteria that are specific to the plant. Most powdered botanical extracts need to undergo some sort of chemical or technical testing to verify correct genus and species.

Vitamins, amino acids, and many other nonbotanical materials are somewhat easier to chemically identify than botanicals, and botanicals are much more prone to adulteration.

Mineral forms can also present a serious challenge to truly authenticate. For example, magnesium glycinate is thought to have some absorption advantage over magnesium oxide and other magnesium forms. Magnesium glycinate is supposed to be magnesium chemically bonded in a particular way to glycine. This is a true chelate (i.e., one molecule). Some mineral RM suppliers skip the bonding part either in part or completely and just mix magnesium carbonate or magnesium oxide with glycine and call it magnesium glycinate. In essence, it is a dry blend of two compounds with only partial or no bonding.

Is It the Potency It Claims to Be?

In most cases (there are some exceptions for skip lot testing if an RM supplier is properly qualified; see "Supplier Certification and Skip Lot Testing") testing every lot of material received for potency helps ensure a consistently potent FP. If most lots are solely identified as authentic and not tested for potency, this does not document the potency of the FP.

Much of the potency issue has to do with label claims as well. Some examples:

Scenario 1: If a licorice extract product has a label stating licorice extract 12% 200 mg (i.e., the licorice extract contains 12% glycyrrhizin), one would have to verify the potency (by testing) of the RM going into the FP and would also have to verify by testing that there was 12% glycyrrhizin in the FP.

If a label has a potency claim, the DS manufacturer has to prove that the claim was met and the FP contained 100% of the labeled potency claim. Always meeting 100% of a potency claim is stipulated by current DS labeling law.

Scenario 2: Another option could be a licorice extract 200 mg with no glycyrrhizin claim. The label just says licorice extract 200 mg. The amount of glycyrrhizin does not have to be verified at the RM or the FP stage. The only thing that has to be verified is that 200 mg is in each capsule, and that it is really licorice. In this scenario, the potency of the product has not been verified. It could be high, low, or really low.

Scenario 3: The same label of licorice extract 200 mg product as in Scenario 2. The label just says licorice extract 200 mg. The amount of glycyrrhizin does not have to be verified as RM or at FP stage, but the conscientious manufacturer tested anyway to ensure the potency of the material at the RM stage (i.e., how much glycyrrhizin is in the RM). To stay consistent, let us say the potency was 12% glycyrrhizin, because this is the level known to be clinically effective. No need to test at the FP stage because no label claim for a specific potency is made. The only need is to verify that 200 mg is in each capsule. In the end, the potency was verified by the RM testing.

The difference between Scenarios 2 and 3 is the DS manufacturer in case 3 had full knowledge and verified the potency of the licorice extract RM, whereas in Scenario 2, the DS manufacturer may not have had a clue as to how potent the FP licorice extract is (high or low) because no testing was performed on the RM or FP.

Clearly, no matter what the obligation is regarding potency testing per label claim, it is always best to know the strength of a botanical going into an FP. This can only be accomplished through potency testing the RM batch. A point of clarification must be made. Many botanical RM products do not have marker compounds to test, or there is no scientifically valid method that exists to perform the potency testing. In this case no potency/strength testing is the only option.

Ideally, one should ask and know if a DS manufacturer is routinely conducting potency/strength testing on RMs and/or FPs.

Does the Product Contain Any Contaminants?

Another way of saying this is: does it have maximum freedom from contamination? Usually, contaminants can only be found through testing the RM. It is generally not possible to detect low level contamination by relying on physical inspection and no testing. A physical inspection may find plastic, metal, glass, bug parts, and other filth.

As noted previously, the FDA CGMP regulations leave it up to the DS manufacturer to determine whether contaminant testing will be done and, if so, to set the acceptable specification(s) for such testing. Some DS manufacturers perform comprehensive contaminant testing, some perform partial testing, and some perform none. As a prescriber of DSs, which contaminant testing profile makes you feel most comfortable and safe?

CONTAMINANT TESTING

Nonbotanical Raw Materials

Heavy Metal(s) Where Indicated

An example of heavy metal contamination is lead content in calcium and magnesium or products made from the shells of shellfish.

Solvent Residue

Many vitamins, minerals, amino acids, enzymes, and glandular products are manufactured using one or more chemicals or chemical solvents. Currently, the natural products industry has no limits on chemical or solvent residue allowed in natural products. One could use and comply with the allowable chemical and solvent limits for the pharmaceutical industry. Testing a panel of multiple solvents is recommended when trying to find residual solvent levels in botanicals or nonbotanicals. Why a panel? Most DS suppliers do not give adequate, accurate, or often any information regarding residual solvent levels on the COA for an RM under consideration for purchase. Often DS manufacturers in the industry will do no testing for any solvents if there are no solvents listed on the COA. This is a mistake, because when a wide net is cast looking for solvent residue, one or more solvents are frequently found.

Bacterial, Yeast, Mold

All batches of RMs and FPs should be tested for these microbiological parameters.

Miscellaneous Items to Consider Where Appropriate

For example, test for melamine levels in protein powders or foods.

Botanicals

Heavy Metal(s)

Every batch of RM should be tested for lead, mercury, cadmium, and arsenic.

Solvent Residue

A panel of multiple solvents is recommended when trying to find residual solvent levels in botanicals as previously explained.

Bacterial, Yeast, Mold

All batches of RMs and FPs should be tested for these microbiological parameters. Some forms of botanical materials are more prone to having higher levels of these items compared with nonbotanical materials.

Herbicide, Pesticide, and Fungicide Residue

Ideally, every batch of botanical product purchased should be tested for residual amounts of a variety of herbicides, pesticides, and fungicides. Certified organic botanical products can be exempted. There are a number of testing profiles to choose from: FDA, United States Pharmacopoeia (USP), European Pharmacopeia, or the California Department of Food and Agriculture. Testing broadly for organochlorines, organophosphates, organonitrogens, and carbamates is ideal and covers a wide spectrum. Every batch should be tested because plant medicines come from all over the world, and various countries have strict or lax rules on what is allowed or not allowed to be applied on crops. Despite rules and regulations in some third-world countries, there could be a lack of enforcement, which creates a big hole for skirting the rules and even more of a reason to test comprehensively every batch received. For example, testing of a sample of kava extract from Indonesia could reveal residues of dichlorodiphenyltrichloroethane (DDT), which is banned in the United States and has been for years. The FDA has a zero-tolerance limit for DDT and its metabolites.

Aflatoxin Residue

Aflatoxins are toxic metabolites produced by certain fungi that are in or on foods and plant materials. Four different aflatoxins, B1, B2, G1, and G2, have been identified, with B1 being the most toxic, carcinogenic, and prevalent. Aflatoxins are probably the best known and most intensively researched fungal toxins in the world. Aflatoxins have been associated with various diseases, such as aflatoxicosis in livestock, domestic animals, and humans throughout the world. Aflatoxins have received greater attention than any other fungal toxins because of their demonstrated potent carcinogenic effect in susceptible laboratory animals and their acute toxicological effects in humans. Many countries have attempted to limit exposure to aflatoxins by imposing regulatory limits on food and feed for animals. The FDA has set a limit of less than 20 ppb for total aflatoxins in food and feed. The European Union has a much lower overall tolerance (10 ppb), and is more specific for limits on individual aflatoxins, especially B1 at 2 ppb or 5 ppb depending on the food.

Fish Oil and Vegetable Oil Products

Heavy Metal(s)

Every batch of RM should be tested for lead, mercury, cadmium, and arsenic.

Bacterial, Yeast, Mold

All batches of RM and FP should be tested for these microbiological parameters.

Dioxins, Dioxin-Like Compounds

Testing every batch received is ideal because levels of these chemicals are present from batch to batch. The same can be said for polychlorinated biphenyls (PCBs), as explained in the following. Fish oil processing can remove many of these residues if the crude material is cleaned. Some portion of the crude fish oil sold worldwide and used to make capsules or liquid fish oil is not cleaned and may contain higher levels of these chemicals.

Dioxin is a generic term used to describe a family of 210 compounds. The most dangerous of this family are 17 members of this group characterized by the presence of chlorine atoms in the 2, 3, 7, and 8 positions. Each of those 2, 3, 7, 8-substituted congeners has been assigned a Toxic Equivalent Factor, which is used for the computation of the Toxic Equivalency Quotient. This scale is used in risk assessment studies to calculate the probability of causing cancer and other life-threatening diseases in humans. The European Union has set a fish oil for human consumption tolerance limit for dioxins.

Polychlorinated Biphenyls

PCBs are a mixture of individual chemicals that are no longer produced in the United States, but are still found in the environment. Health effects that are associated with exposure to PCBs include acne-like skin conditions in adults and neurobehavioral and immunological changes in children. PCBs are known to cause cancer in animals. The Department of Health and Human Services concluded that PCBs may reasonably be anticipated to be carcinogens. The Environmental Protection Agency and the International Agency for Research on Cancer determined that PCBs are probably carcinogenic to humans.

Rancidity Testing

Oil products ideally should be tested for primary oxidation byproducts (peroxide levels) and secondary oxidation byproducts (anisidine levels). A high level of any of either is indicative of rancidity of long-chain fatty acids in the oil product. It is critical to test for both because peroxides are transitory and can drop to a low level as they transform into secondary oxidation byproducts (anisidines). Once an oil has started down the path of rancidity, it usually proceeds to higher levels of rancidity.

FINISHED PRODUCT EXPIRATION DATE AND STABILITY TESTING

Many DS companies have no data to support their expiration date or "best if used by" claims. The following information is taken from the preamble portion of the FDA DS GMP regulations:

> *"Because the final rule does not require that you establish an expiration date, we (the FDA) decline to offer guidance on the type of data that are acceptable to support an expiration date, other than to repeat that any expiration date that you place on a product label (including a "best if used by" date) should be supported by data."*

Because the FDA gives no guidance on the matter, what should be asked of a DS manufacturer? Strength/potency testing is probably most important because the potency of the product over time might be critical to the product producing intended results.

Some questions to ask are:

1. Are you conducting any stability testing on your FPs?
2. If so, what testing? Strength/potency? Bacteria, yeast, mold testing?
3. If no testing is taking place, are you performing physical parameter inspections (appearance; weight; integrity of the capsule, tablet, or powder, etc.)?
4. If no testing is taking place, how do you verify the strength/potency of the product over the shelf life expiration dating period? What data do you have to support the expiration date period and stability of your product(s)?

ASSESSING QUALITY VIA COMPREHENSIVE TESTING

Start with the concept that "you only find what you look for." This can and should be applied to DS RM ingredients. When a DS manufacturer buys an RM (domestic or foreign), generally they cannot just tell that the material is of good quality. The measure of quality of a DS FP is a function of the quality of the ingredients that went into it. If a DS manufacturer looks at the quality of an ingredient in a cursory manner and only performs the

most minimal of tests, some essential quality parameters may be missed, and the ingredient goes unverified overall. If comprehensive testing is performed for an array of quality parameters, the ingredient may be deemed verified as a quality ingredient if the test results are acceptable.

The definition of verification is repeated to make a point about the value of assessing quality via comprehensive testing. To verify means:

- To prove the truth of, as by evidence; confirm; substantiate
- To ascertain the truth or correctness of, as by examination
- To act as ultimate proof or evidence of; serve to confirm.

Verification of quality via testing provides evidence, proof, substantiation, and confirmation of quality parameters. How else can it be achieved? Testing is king when it comes to confirming and assessing the quality parameters of DS ingredients and FPs.

If a DS manufacturer does extensive and comprehensive testing on all RM ingredients that go into the FP, the overall quality of the FP is mostly assured. To fully ensure quality in this scenario, the only items left to test on the FP would be strength/potency (if potency claims are made) and microbiological profile to make sure it did not become contaminated with bacteria, yeast, or mold as it went through manufacturing. Ideally, the FP would also be run through a metal detector to rule out the possible introduction of metal pieces from the manufacturing process. Finally, if any of the active constituents could be damaged by the manufacturing process, such as a heat labile substance, its potency should be checked before quality control release.

SUPPLIER CERTIFICATION AND SKIP LOT TESTING

The FDA DS CGMPs allow for certifying a DS supplier. Once a DS supplier is certified, the DS manufacturer can perform reduced testing of RM batches (i.e., skip certain testing parameters because they have done enough due diligence to "trust" the DS supplier's quality).

The FDA CGMP regulation in Subpart E, §111.75 states:

A firm may rely upon a certificate of analysis (COA) from its supplier of a component (in other words, not test), provided that certain criteria are met, which include the following:

- The firm first qualifies the supplier by establishing the reliability of the supplier's COA through confirmation of the results of the supplier's tests or examinations
- Maintains documentation of how it qualified the supplier
- Periodically reconfirms the supplier's COA
- Quality control personnel review and approve the documentation setting forth the basis for qualification (and requalification) of any supplier
- Some questions remain regarding these guidelines. The FDA gives no acceptable criteria on establishing reliability of the supplier—does this need to happen once, twice, six times? How was this confirmed? How often is the COA from the supplier reconfirmed? Every year, 2, 3, or 5 years?

Officials from the FDA have said the following at numerous trade shows and conferences. Unfortunately, this provides no guidance for DS manufacturers. "We anticipate that Industry will be creative in qualifying the global supply chain." In addition, the FDA has told the DS industry that qualifying a supplier must include an onsite comprehensive audit of the supplier's facility (wherever it may be) and manufacturing and quality assurance processes for the ingredients in question.

LABORATORY TESTING AND LABORATORY QUALITY

DSs are tested by contract laboratories to ensure identity (assure authenticity without adulteration), purity (assess contamination levels), and strength (verify the claimed potency). Laboratories use "methods" to test DSs. Ideally, a validated method would be used for the specific item in the specific mix of ingredients. However, few laboratories have adequately validated methods to cover all situations.

The most pressing issue regarding laboratory quality assurance is, by far, the lack of available validated methods. Method validation shows that a method is suitable and fit for its purpose—demonstrating accuracy and reproducibility. It is easy to define and hard to implement because many different, time-consuming experiments need to be performed to accomplish it. Method validation is extremely important in the DS industry, especially because the FDA requires manufacturers to support their ingredient label claims.

Validating a method proves beyond a reasonable doubt that the results are accurate and reproducible. Method validation is absolutely necessary to ensure the highest degree of reliability. In addition, method validation is needed to settle variant results from laboratory to laboratory. If the laboratory has a variety of quality systems in place, then this may not be completely necessary within a single laboratory.

The quality systems of any laboratory are paramount to achieving the goal of consistently producing accurate, precise, and reproducible results. However, there is no systematic way to know that laboratories are producing accurate results. Many of them do not have the necessary systems or methods in place to ensure quality results. Some laboratories start out using a validated method, but later "modify" the method to suit their purposes. By doing this, they invalidate the validation because the method has been changed. This "method rigging" may introduce inaccuracies and unreliability in the results.

Quality systems every contract laboratory should employ include:

- Use of appropriate reference standards
- Repeatability studies
- Ensuring system suitability requirements are performed, such as:
  a. Determining whether the instrument is calibrated properly and operating correctly
  b. Following written standard operating procedures (SOPs)
  c. Performing out-of-specification (OOS) studies. An OOS study is triggered when a laboratory gets a test value that is either substantially lower or higher than the anticipated value. The OOS study verifies that the laboratory had everything correct (by rechecking all necessary parameters) when the analysis was run. Then the laboratory repeats the analysis to see if the same value is obtained or not
  d. Regularly performing recovery studies using pure compound for recovery to test extraction performance and equipment. A recovery study is when the analyst prepares a sample (extraction) with a known concentration of substance and runs it in the machine. The recovery of the result should be the concentration expected. If not, something is wrong with the equipment or sample preparation (extraction)
  e. Ensuring the method used is based on good, valid science, and is applicable for the DS being tested
  f. Allowing independent audits of procedures, practices, and data

If an officially approved validated method is not available, a scientifically valid analytic method is one that is based on scientific data or results published in, for example, scientific journals, references, textbooks, or proprietary research. These methods can yield good results if they are not changed to any significant degree and they are appropriate for the analysis. The author had a schisandra extract (*Schisandra chinensis* or *S. sphenanthe*) tested at one laboratory that yielded a 10% schisandrins result and at another laboratory that yielded a less than

2% result. The first laboratory was using a method that was designed to test material in blood or serum and not a botanical extract. Clearly, it was not a "good science" method because it was not appropriate for the intended purpose.

Validated methods are the gold standard for obtaining accurate laboratory results. Unfortunately, official (meaning recognized by the government) or unofficial validated methods do not exist for many dietary supplements. The bottom line: only trust the laboratories that follow and adhere to the quality systems outlined previously and strive to use scientifically valid methods when validated methods are not available.

ECONOMICALLY MOTIVATED ADULTERATION

Economically motivated adulteration (EMA) is the fraudulent, intentional substitution or addition of a substance in a product for the purpose of increasing the apparent value of the product or reducing the cost of its production (i.e., for economic gain). EMA includes dilution of products with increased quantities of an already present substance (e.g., increasing inactive ingredients of a drug with a resulting reduction in strength of the FP, or watering down of juice) to the extent that such dilution poses a known or possible health risk to consumers, as well as the addition or substitution of substances to mask dilution.

Examples of Products That Are Prone to Economically Motivated Adulteration

- Ginkgo biloba extract: The most common method of adulterating ginkgo is to add an inexpensive flavonoid source that artificially inflates the total flavonoid level in the extract to meet the required 24%. Rutin, a flavonoid source extracted from buckwheat with a low cost, has been the most common additive used for this purpose. *Sophora japonica* (Japanese Pagodatree) is also used to artificially elevate the flavonoid level of ginkgo extract.
- Panax and American Ginseng extract: Ginseng root is widely considered the source of the herb's therapeutic activity; however, large quantities of the leaf can be added to surreptitiously and artificially increase levels of some ginsenosides.
- Goldenseal root extract: Goldenseal root naturally contains a compound called berberine at a concentration of approximately 4% to 8%. Goldenseal root extract can be spiked with added pure berberine or substituted with other berberine containing plants.
- *Coptis chinensis* extract: This can be spiked with berberine or substituted with other berberine containing plants.
- Bilberry extract 25% anthocyanosides: The anthocyanoside content can be manipulated by blending in cheaper berries, such as black currant and elderberries; reports showed even amaranth dye has been used to spike bilberry in an attempt to fool the testing and pass as a quality product.[1]
- Saw palmetto extract: This extract may be spiked with exhausted plant effluent (powder left over after the plant is extracted) or adulterated with palm oil. Addition of palm oil allows for the fatty acid content to meet the claim, but it throws off the natural balance of fatty acids in the extract, which can be detected with proper testing. In addition, unripe berries can be used versus the traditional use of ripe fruit.
- Grape seed extract: Addition of cheap flavonoids can allow a poor-quality product to pass as high-quality product.
- Black cohosh extract: Other cohosh species are used rather than *Cimicifuga racemosa*. The substituted species are not therapeutically active or have a different therapeutic activity.
- Pomegranate extract: Ellagic acid can be added to the pomegranate extract to fraudulently meet the guaranteed amount in the final extract without spending the money on expensive pomegranate dry material.
- Fish oil: This can be adulterated with vegetable oils. Proper analytic testing of the fatty acid profile and examination of fat ratios can usually detect if a fish oil product has had vegetable oil added.
- Protein powders: Addition of a plastic-like agent called melamine can artificially raise the apparent protein level. A test is available to detect the adulteration of protein powders with melamine. Melamine can cause serious health problems, including death.

RESIDUAL CHEMICAL SOLVENTS IN DIETARY SUPPLEMENTS

It is important to note that solvent residue testing is not mandated as part of the FDA guidelines for CGMPs in regard to DSs. It is up to the DS manufacturers themselves to determine whether solvent residue testing is needed.

This is a big hole in the FDA CGMPs because many RM components used to manufacturer DSs have some level of chemical solvent residue. The question is how much chemical residue is present, and is the level acceptable, safe, and will not cause harm over a long period of ingestion? Hence unacceptable residual solvent levels will be an ongoing quality challenge for many DS manufacturers and thus an ongoing quality concern.

A Solvent Primer

The issue of solvents is complex and involved. Official US policy began in 1997 when a joint initiative involving both regulators and research-based industry members from numerous countries published the *International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use, ICH Harmonised Tripartite Guideline, Impurities: Guideline for Residual Solvents.* This was then adopted by the FDA. Based on these guidelines, the USP revised Chapter 467, "Residual Solvents," in 2007. This then became official policy on July 1, 2008. Basically, there are four classes of solvents. The following is a simple primer based on the more current USP revisions.[2]

Note that these guidelines are for pharmaceutical products. There are no guidelines for DSs. So, in the absence of DS residual solvent guidelines, it seems obvious to use the existing standard for pharmaceuticals rather than do nothing and completely ignore the issue.

Class I Solvents

These solvents should not be employed in the manufacture of drug substances, excipients, and drug products (and hence natural medicines, either) because of their unacceptable toxicity or their deleterious environmental effects. However, to produce a drug product (or natural medicine), if their use is unavoidable, then their levels should be restricted, as shown in Table 96.1.

Class II Solvents

These solvents should be limited in use because of their inherent toxicity. There are 27 in this category, with acceptable limits from 50 to 4840 ppm. Some examples are chloroform, cyclohexane, hexane, methanol, and toluene.

Class III Solvents

These solvents are regarded as less toxic and of lower risk to human health. There are also 27 in this category, all with limits of 5000 ppm. Some examples are acetone, dimethyl sulfoxide, ethanol, ethyl acetate, and methyl acetate.

TABLE 96.1 Class I Solvents (Solvents That Should Be Avoided)

Solvent	Acceptable Limit (ppm)	Concern
1,1,1 Trichloroethane	1500	Environmental hazard
1,1 Dichloroethene	8	Toxic
1,2 Dichloroethane	5	Toxic
Benzene	2	Carcinogen
Carbon tetrachloride	4	Toxic and environmental hazard

Class IV Solvents

These solvents may be of interest, but no toxicity data were found.

THE BUYING DECISION

Most consumers and practitioners do little or nothing to assess and verify product quality before they choose a supplier or make a buying decision. All too often our buying decisions are based on what other people, clinicians, educators, books, magazines, and DS company marketing materials have told us. We may like an ad, the packaging, the salesperson, believe the company's quality story, be influenced by their marketing claims, or recognize that the company has good clinical education that ties their products to the education piece. In essence, usually everything but evidence of quality verification drives our decision. It is critical to verify quality claims.

To verify is to prove the truth of something by presentation of evidence. People do not usually ask for that evidence to verify that a manufacturer is providing verified quality products. Why not? Probably because we are too busy, we assume companies are providing the quality we seek, we are not educated enough to know how to separate the marketing hype from the real evidence of quality verification, and lastly the average person may be too intimidated to call the company and ask very pointed quality questions.

This is a huge missing piece. Health care professionals would be wise to demand to see the evidence that supports the marketing claims of quality products. If we choose not to, we must realize that we could be prescribing subpotent, inauthentic, and/or contaminated products.

The author (and editors) has seen far too many examples of subpotency, lack of authenticity, contamination, and a general lack of quality assurance all across the supply chain that feeds the natural products industry. If we think that all the companies we purchase from have done all their quality assurance homework and have applied it, we need to think again. We do not know because most companies do not divulge what they do or, more importantly, what they do not do regarding the full story of the quality assurance they apply to their products.

The bottom line take home message is this: step out of your comfort zone and call companies you intend to purchase from and do your best to determine their quality practices by asking very pointed questions and requesting some proof to support their answers. You can read and become familiar with the questionnaire provided in this chapter to give you some idea of what to ask for. Asking for some level of accountability from the company you plan to buy from is better than blindly assuming they are performing adequate quality assurance to protect you and your patients.

Verifying the quality of a brand has to be done by asking the company if they have in place and consistently follow a comprehensive testing protocol to test RMs and FPs at release and conduct FP stability testing. You can use the questionnaire provided here to give you information and guidance on what questions to ask and the necessary information to gather.

DIETARY SUPPLEMENT PRICING AND QUALITY

A specific brand of DS may carry a high price. A high or low priced DS does not necessarily correlate with product quality. Two thoughts to consider regarding price and quality: First, a low or very low priced DS product is not likely to have been put through comprehensive quality testing. The cost of consistently performing comprehensive quality testing on DS products is very steep, and product pricing needs to reflect that financial investment. Second, full adherence with DS FDA CGMPs is very, very costly, as it requires financial investments in testing, personnel education and training, facility system changes, and experienced quality managers to run the quality department and comply with developing and maintaining the volumes of documentation dictated by FDA CGMPs. The days of cheap DSs are probably coming to an end.

CURRENT GOOD MANUFACTURING PRACTICE CERTIFIED PROGRAMS

In the United States and abroad, there are government and nongovernment agencies that conduct audits of DS manufacturers to assess their CGMP compliance with the standard set by the auditing agency. If the DS manufacturer successfully passes one or more necessary audits, it gets a "CGMP Compliant" or "CGMP Certified" certificate from the auditing agency. DS manufacturers use these certifications to trumpet their quality. The comprehensive nature of the audit process and criteria applied to receive a pass varies from auditing body to auditing body. All certification programs contain some value, but some may have serious limitations and may not tell clinicians all they need to know to trust a DS manufacturer and their products. Be aware that certification does not guarantee quality, and also that lack of certification does not mean lack of quality.

There are items to consider regarding these independent CGMP certifying bodies. First, the FDA CGMPs trump all of these auditing bodies because compliance with the FDA legally required regulations are currently most important. I have already described some of the "confusing and not spelled out" FDA CGMP interpretation and compliance issues. Until those issues are defined and specified, any outside auditing agency is making their best guess and applying their interpretation of what will pass with the FDA. Second, the most important quality practice to verify and understand with any DS manufacturer is how comprehensively they conduct testing to verify identity, strength/potency, purity (contamination), and shelf life dating. None of these CGMP Certified seals will give you that information. You must attempt to get that information directly from the DS company.

Quality Questionnaire, a Tool to Help Verify Quality Claims and Testing Practices

The road to ensuring high quality is successfully traveled when clinicians ask for, obtain, and evaluate DS manufacturer supplied information on CGMP compliance and valid evidence (test results) of a product's identity (authenticity), purity (maximum freedom from contamination), strength/potency, and shelf-life strength.

A questionnaire entitled, "The Manufacturer Quality Assurance Self-Audit Form," is available for use.[3] It is reprinted in the Appendix. The form is intended to give clinicians a basis upon which to question or request documentation from manufacturers and/or suppliers about

their quality control/quality assurance practices and testing programs. There is also an attending compliance document that can be used to evaluate some of the responses obtained from DS manufacturers.

> *"Not having the information you need when you need it leaves you wanting. Not knowing where to look for that information leaves you powerless. In a society where information is king, none of us can afford that."*

Naturally Occurring Antioxidants

Robert A. Ronzio, PhD

OUTLINE

A growing body of research implicates excessive oxidative damage in multiple disease processes as well as aging. This chapter first examines free radicals and reactive oxygen species, in oxidative stress as participants in cell signaling, then considers the role of antioxidants in redox regulation in human health.

FREE RADICALS AND NONRADICAL OXIDANTS

Free Radicals

These molecules possess an unpaired electron; therefore they participate in single-electron oxidations. In the body, the hydroxyl radical (•OH) is one of the most reactive free radicals, precluding any useful physiological role. Less reactive radicals, nitric oxide (NO•) and superoxide (O_2•−), are able to participate in autocrine and paracrine functions. In isolated systems, a chain initiation event generates free radicals, such as alkyl (RO•) and peroxyl (ROO•) radicals. Radical propagation steps repeated many times can lead to chain reactions. However, it is unlikely that free radical chain reactions are propagated in vivo, due to abundant molecular targets, radical scavenging enzymes, and low-molecular-weight antioxidants.

In addition to free radicals, the body generates an array of nonradical oxidizing agents that participate in electron-pair oxidations. This group includes hydrogen peroxide (H_2O_2), lipid peroxides (ROOH), hypochlorite, peroxynitrite, quinones, and disulfides. Nonradical oxidants vary in their reactivity, with hypochlorite and peroxynitrite representing potent oxidizers and H_2O_2 a much less reactive, diffusible signaling molecule.

Reactive Oxygen Species

Reactive oxygen species (ROS) represent more or less reactive oxidizing agents, whether or not they are free radicals. They include superoxide and H_2O_2. H_2O_2 is not very reactive; however, it spontaneously forms hydroxyl radicals in the presence of iron and copper ions. Superoxide is not highly reactive, either, and superoxide concentrations in the cytoplasm and mitochondria are usually held in check by superoxide dismutases (SODs), which yield H_2O_2. Nonspecific usage of the term *ROS* is not useful because "ROS" cannot be induced, measured, or inhibited. As oxidizing agents, individual rate constants vary from 2×10^{-2} to 2×10^{9}.

Normal metabolism generates ROS according to several mechanisms and initiates a variety of toxic reactions, including lipid peroxidation, direct inhibition of mitochondrial respiratory chain enzymes, inactivation of glyceraldehyde-3 phosphate dehydrogenase, inhibition of membrane sodium/potassium ATP-ase activity, and inactivation of membrane sodium channels, which all play a role in the pathophysiology of inflammation (Fig. 97.1).

Oxidases

Nicotine adenine disphosphonucleotide (NADPH) oxidase is the only enzyme that exclusively produces superoxide; therefore it is carefully regulated. Peroxisomes oxidize fatty acids while producing ROS. Xanthine oxidase oxidizes purines from DNA, RNA, and adenosine triphosphate (ATP). Microsomal mixed-function oxidases (cytochrome P450) generate ROS in the detoxification of metabolites and xenobiotics. Drugs that cause peroxisome proliferation, such as clofibrate, can stimulate the production of H_2O_2 by this mechanism.

Cyclooxygenase and Lipoxygenase

Inflammation activates the arachidonic acid cascade, which converts arachidonate to eicosanoids that mediate inflammation and activate NADPH oxidase to increase the production of ROS.[1]

Redox Cycling

Several xenobiotics, such as paraquat and alloxan, catalyze the formation of superoxide through cyclic reactions, promoting auto-oxidation.

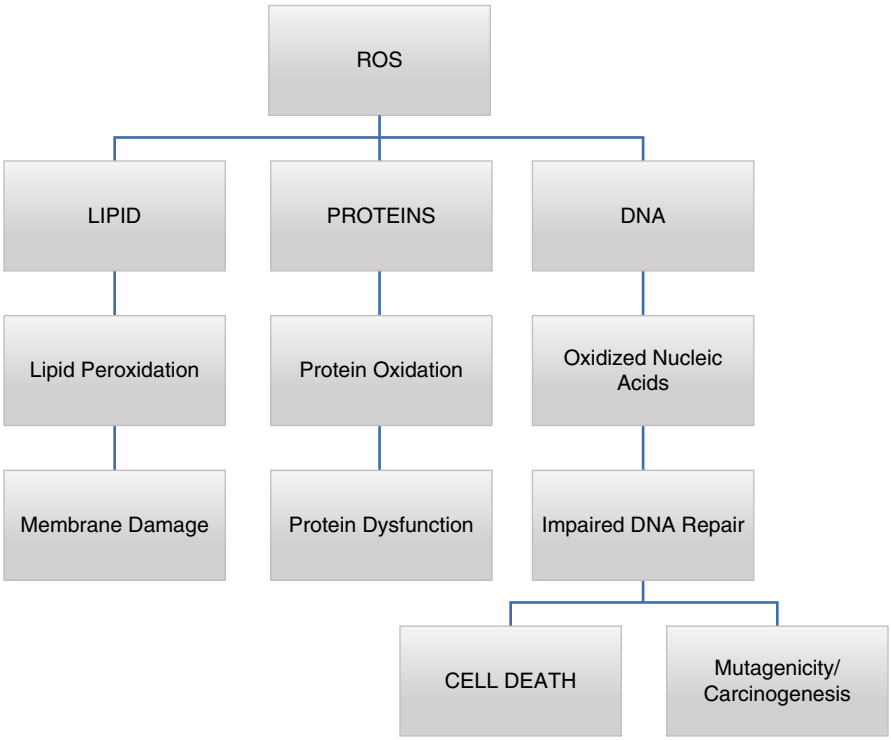

Fig. 97.1 Potential effects of reactive oxygen species.

Reactive Oxygen Species Generated Directly from Oxygen

In the presence of reduced iron or copper ions, oxygen can produce H_2O_2 and hydroxyl radicals. Oxygen can also react spontaneously with heme proteins such as myoglobin, hemoglobin, and cytochrome c to generate superoxide. Excessive iron and iron overload may cause hydroxyl radical production. Consequently, the release of iron from storage sites during inflammation and injury may promote the spontaneous production of free radicals.[2]

Oxidative Stress

The term *oxidative stress* refers to a shift in the ratio of reducing agents to oxidants and its consequences in the body. In this sense, oxidative stress occurs when oxidants outweigh the various antioxidant systems as a result of excessive ROS production and/or limited antioxidant defenses. An expanded definition of oxidative stress now includes dysfunctional redox signaling and imbalanced regulatory mechanisms, which emphasizes the role in signal transduction. During oxidative stress, endogenous defenses may be consumed, or they may not be replenished by recycling. Decreased dietary intake of antioxidant nutrients or malabsorption syndromes can reduce antioxidant defenses and create chronic imbalances, setting the stage for disease.

OXIDATIVE STRESS AND TOXICANT EXPOSURE

Toxic Metals

Arsenic, cadmium, mercury, and lead have all been shown to cause increased DNA oxidation, measurable with 8-OHdG. Iron, copper, chromium, vanadium, and cobalt undergo redox-cycling reactions producing toxicity, whereas mercury, cadmium, and nickel deplete glutathione and bond to sulfhydryl groups of proteins.[3] Lead not only generates ROS but also causes a reduction in the activity of ROS-quenching enzymes, such as superoxide dismutase, catalase, and glutathione peroxidase, resulting in diminished antioxidant defense. At the cellular level, cadmium provokes the generation of ROS, which indirectly modulates gene expression and signal transduction and reduces the activities of proteins involved in antioxidant defenses.[4] The carcinogenic effect of arsenic may be related to the activation of redox-sensitive transcription factors involving NF-kβ and AP-1.[5]

Persistent Organic Pollutants

Exposure to organophosphate pesticides will lead to DNA oxidative damage, resulting in an increase of 8-OHdG. Malathion, a commonly used organophosphate pesticide, generates free radicals that induce oxidative stress in human erythrocytes through the inhibition of catalase, glutathione peroxidase, and superoxide dismutase.[6] Oxidative stress from malathion exposure may also be a result of damage to mitochondrial complexes by inhibiting the activity of Complex IV.[7] A positive correlation has been found between farmers exposed to pesticides and oxidative stress biomarkers.[8]

Air Pollution

Diesel exhaust particles, probably the most toxic component of urban outdoor air pollutants, are a mixture of carbon particles, organic chemicals, heavy metals, and free radicals, causing DNA oxidative damage that is measurable with elevated 8-OHdG levels. Persons exposed to traffic in their work (e.g., traffic officers) have higher levels of 8-OHdG, indicative of increased oxidative damage.[9]

Urban air pollution has long been positively associated with respiratory and cardiac problems and increased mortality rates. Particulate matter (PM) is one of the major components of urban air pollution and has been linked to increased levels of 8-OHdG. PM causes significant oxidative damage in the tissues and organs to which it is distributed and has been associated with increased mortality, primarily from cardiovascular,[10] respiratory,[11] and neoplastic diseases.[12] A study in Taiwan demonstrated that exposure to indoor air pollutants caused an increase in oxidative damage, aggravating sick building syndrome–related symptoms.[13] Peruvian women exposed to wood smoke from indoor cooking fires also had higher urinary 8-OHdG levels.[14]

Drugs

Nonsteroidal anti-inflammatory drugs (NSAIDs) have been shown to induce ROS in cardiac and cardiovascular-related cells, which may explain the increased risk of heart attack and stroke associated with NSAID use. Rofecoxib, a cyclooxygenase-2 (COX-2) inhibitor, was removed from the market because its extended use was found to increase the risk of atherothrombotic events. It is now known that the cardiotoxicity of rofecoxib was not related to COX-2 inhibition but rather to the oxidative modification of low-density lipoproteins and cellular membrane lipids, which contributed to plaque instability and thrombus formation.[15]

Radiation

Ionizing radiation can cause DNA damage, gene mutation, apoptosis, and cancer. The toxic effects of radiation result from rapid generation of ROS through radiolysis of water molecules as well as secondary reactions leading to increased levels of ROS, which can diffuse within the cell and delay the toxic effects.

Tobacco

Chronic tobacco smoke inhalation induces an intracellular oxidative environment characterized by decreased concentrations of circulating antioxidants, increased oxidation of glutathione, and increased levels of DNA damage. Tobacco smoke has long been linked with elevated levels of 8-OHdG in smokers and in those exposed to secondhand smoke. One study of smokers showed 50% higher 8-OHdG levels compared with nonsmokers,[16] with cessation of smoking resulting in a 21% drop in 8-OHdG levels after 4 weeks.[17]

OXIDATIVE STRESS, AGING, AND CHRONIC DISEASE

Aging refers to the time-dependent alteration in function in the form of cellular and systemic functional decline, with increased morbidity and mortality. The increased prevalence of chronic degenerative diseases can be viewed in terms of irreversible cellular deficits.

Free Radical Theory of Aging

According to the free radical theory of aging, free radicals from normal metabolism or external sources gradually overcome antioxidant mechanisms, leading to cumulative oxidative damage to essential cellular elements: proteins, DNA, and lipids.[18]

More than 100 conditions provide circumstantial evidence linking oxidative damage to disease processes, although these correlations do not distinguish cause or consequence. This list includes several forms of cancer,[19,20] atherosclerosis,[21,22] hypertension, diabetes mellitus,[23] cataracts,[24] inflammation and autoimmune disease,[25,26] lung disease,[27] neurological disorders including Alzheimer's disease and Parkinson's disease,[28,29] hepatitis,[30] obesity,[31] and fibromyalgia and chronic fatigue syndrome,[32] in addition to cell death[33] and attributes of aging.[34,35] Psychological stress and responses to social stressors can affect antioxidant enzymes and oxidative stress, and vice versa.[36]

Oxidative stress is linked to aging and senescence in two lines of research. One is based on increased levels of oxidative products in senescent cells and organs. As an example, carbonylated proteins were markedly elevated in the last third of life in human lens, brain, and skin fibroblasts and rat liver.[37] The second, stress-induced premature senescence, demonstrates that a chronic stress response, induced in cells using subtoxic levels of H_2O_2 or other oxidants, can lead to a senescence phenotype (gene overexpression).

The consequences of oxidative stress are often subtle: Increased membrane fluidity and damage to membrane receptor proteins may alter cellular regulatory mechanisms such as signal transduction, inactivation of proteins required for ATP production, or calcium homeostasis. The more or less continuous production of ROS by activated phagocytes during chronic, possibly low-level inflammation may eventually deplete antioxidant defenses, allowing ROS to attack cells, with ensuing tissue injury.

Recognition of mitochondrial dysfunction led to an update of free radical theory.[38] An estimated 3% of oxygen molecules passing through mitochondria are converted to superoxide due to leakage of the electron transport chain.[39] Thus mitochondria can be considered a prominent source of ROS. Mitochondria also produce H_2O_2 and lipid peroxides, which can damage highly susceptible mitochondrial DNA and alter mitochondrial membrane permeability to release apoptogenic substances such as cytochrome c. H_2O_2 can act as a powerful inducer of a senescent phenotype across multiple cell types.[40] Elevated ROS produced by impaired mitochondria has been suggested as a primary cause of aging.[41]

Hydroxyl Radicals, Nitric Oxide, and Peroxynitrite

Hydroxyl radicals are extremely powerful oxidants, and they probably diffuse only several angstroms before attacking cell constituents and forming characteristic decomposition products of lipids, proteins, and DNA.[42] Superoxide rapidly forms hydroxyl radicals in the presence of transition metal ions.

Reactive Nitrogen Species: Linkage to Superoxide

Reactive nitrogen species (RNS) include peroxynitrite and its reaction products, such as NO_2. High, sustained levels of NO and superoxide, precursors of peroxynitrite ($ONOO^-$), are associated with tissue toxicity, cancer, and inflammatory conditions, such as arthritis, juvenile diabetes, and ulcerative colitis.[43] Under inflammatory conditions, simultaneous production of superoxide and NO can increase 1000-fold, and production of peroxynitrite can increase by a million-fold.[44] Associated oxidative stress can result from increased production of superoxide, which reacts spontaneously with NO to produce ($ONOO^-$). Excessive superoxide can come from upregulated xanthine oxidase or cytochrome P450. ROS uncouple nitric oxide synthase (NOS) to produce superoxide rather than NO. Thus exposure of human endothelial cells to lysophosphatidylcholine leads to downregulation of endothelial NOS and SOD and thus a superoxide overload.[45,46] As a highly reactive peroxide, $ONOO^-$ yields secondary free radicals as nitrogen dioxide. A preponderance of NO and superoxide toxicity is due to $ONOO^-$, triggering nitration reaction and cell death.[47]

In nonalcoholic fatty liver disease, an isoform of NADPH oxidase, NOX1, is up-regulated. Mice deficient in NOX1 had increased protein nitrotyrosine adducts in hepatic sinusoids, as did wild-type mice fed a high-fat and high-cholesterol diet. Up-regulation of NOX1 in sinusoidal endothelial cells may be responsible for peroxynitrite-mediated cell injury.[48]

Reactive Oxygen Species: Broad-Spectrum Antibiotics

Infection, toxic exposure, ischemia, and trauma activate phagocytic cells—macrophages, monocytes, neutrophils, and eosinophils—to create ROS.[49] The binding of immune complexes, bacterial endotoxins, or other inflammatory agents to cell-surface receptors triggers a respiratory burst, a localized production of ROS able to oxidize viruses and bacteria. Excessive superoxide from NADPH oxidase undergoes dismutation to H_2O_2 via SOD. Myeloperoxidase in lysosomes then converts H_2O_2 and the chloride ion to hypochlorite, which spontaneously produces highly reactive chloramines from amines.

Oxidative Stress: Redox Regulation of Cell-Signaling Cascades

Physiological levels of ROS influence cell regulatory processes as diverse as apoptosis, cell growth, and chemotaxis.[50,51] Many signal cascades are sensitive to redox balance and can be modulated by ROS and antioxidants. Essential to these pathways are multiple protein kinases, whose phosphorylation products are often other kinases or kinase inhibitors. Related protein phosphatases reverse those effects. Rather than isolated enzyme systems, cross talk is achieved via ROS and RNX signaling to control responses, such as inflammation.

Transcription Factors

Nuclear factor-κB (NF-κB) and activating protein-1 (AP-1) help regulate inflammation and the response to oxidative stress. These factors bind to antioxidant response elements (AREs) in promoter regions to induce transcription of proinflammatory molecules. Transcription factors can boost defenses against ROS, depending on which signaling cascade is activated, to increase transcription of glutathione-S transferase (GSH S-transferase), metallothionein-1, and manganese-dependent SOD.

Nuclear Factor-κB

The NF-κB pathway represents a premier proinflammatory signaling pathway by proinflammatory cytokines as interleukin-1 (IL-1) and tumor necrosis factor-alpha (TNF-α). Proinflammatory cytokines and lipopolysaccharide (LPS) promote NF-κB activation. NF-κB upregulation leads to the production of cytokines, chemokines, and adhesion molecules. As such, it may contribute to chronic oxidative stress and diseases, such as rheumatoid arthritis, hypertension, and even overweight and obesity.[52] With age, NF-κB expression in the body increases, a link to chronic systemic inflammation.

Nuclear Factor Erythroid-2 Related Factor-2

Nuclear factor erythroid-2 related factor-2 (Nrf2) acts as a master redox switch in cellular defense against oxidative stress. It induces antioxidative enzymes, Phase II detoxifying enzymes, and stress-responsive proteins, as well as NADPH:quinone reductase, glutamate cysteine ligase, GSH S-transferase, GSH peroxidase (GPx), and thioredoxin. Nrf2 also controls genes involved in metabolism, such as NADPH generation and oxidation of fatty acids, while suppressing those involved in gluconeogenesis and lipogenesis.[53] Release from its inactive cytoplasmic complex is redox-dependent.[54]

Activating Protein-1

The transcription factor activating protein-1 (AP-1) controls additional processes affecting cell proliferation and apoptosis suppression, including COX-2 expression. As an example of AP-1 activation, epidermal growth factor and platelet-derived growth factor bind to their receptors, activating phosphatidylinositol kinase, followed by Rac (guanosine triphosphatase [GTPase]) activation, in turn stimulating NADPH oxidase to produce superoxide.[55]

Protein Kinases and Protein Phosphatases

The kinase family includes the protein kinase C (PKC) group, which includes serine/threonine kinases that are dependent on calcium and

phospholipids, the mitogen-activated protein kinase (MAPK) family (extracellular signal-regulated kinases, Jun N-terminal kinase [JNK], and p38 kinases), and tyrosine protein kinases. Related phosphatases reverse their actions. Members of these broad enzyme families participate in posttranscriptional control due to their redox-sensitive cysteinyl domains.[56] As cell-signaling proteins, PKCs are especially sensitive to redox stress and to ROS as a second messenger during the cell proliferation and differentiation essential for cardiovascular health.[57] As an example, vasocontraction occurs when angiotensin II binds to its receptor and activates PKC, in turn activating NADPH oxidase to produce superoxide, which destroys NO. As another example, H_2O_2 from SOD can oxidize catalytic cysteinyl moieties of tyrosine phosphatases, thereby preventing inactivation of tyrosine kinases, including Src, to stimulate AP-1.

Proinflammatory Cytokines

Transcription factors can be activated by inflammatory cytokines, such as TNF-α. AP-1 activation (with NF-κB inhibition) blocks the production of proinflammatory cytokines, including interleukin (IL)-1β, IL-2, IL-4, IL-6, and TNF-α.

Proinflammatory Eicosanoids

The arachidonate cascade features proinflammatory hydroperoxides and endoperoxide eicosanoids: prostaglandins such as PGG_2, PGH_2, and PGE_2 (via COX); leukotrienes; and hydroxyeicosatetraenoic acid (via lipoxygenase). COX-2 can be induced by superoxide, H_2O_2, and inflammatory cytokines such as IL-1 and TNF-α. Stimulated lipoxygenase can trigger ROS production through sequential activation of GTPase (Rac), PKC, and phosphorylation of the NOx subunit of NADPH oxidase, leading to activation of plasma membrane NADPH oxidase and ultimately to superoxide synthesis.[58]

Calcium Homeostasis

Transcription factors can also be regulated through calcium-signaling mechanisms, and H_2O_2 can stimulate calcium release from mitochondria. Thus H_2O_2 increases L-type calcium channels and calcium influx by vascular smooth muscle cells linked to hypertension.[59]

Apoptosis and Cell-Cycle Regulation

Programmed cell death is regulated by complex pathways involving the transcription factors described previously; therefore, it, too, relies on the cellular redox balance. Oxidative stress triggers apoptosis in several model systems, and apoptosis may be regulated by antioxidants.[60,61] Conditions ranging from diabetes mellitus and heart failure to HIV infection may entail altered apoptosis.[62]

Reactive Oxygen Species: Xenobiotic, Phytochemical, and Carcinogen Metabolism

ROS modulate components of the cytochrome P450 system and can activate potential carcinogens. In contrast, Phase II detoxification enzymes (sulfotransferases, quinone reductase, GSH S-transferase, uridine diphosphate glucuronyl transferase) can block carcinogenic effects and modulate detoxification.[63]

Reactive Oxygen Species: Secondary Messengers in Signaling Cascades

Nitric Oxide

Physiological NO levels regulate multiple processes; thus NO produced by the endothelial isoform of NOS (eNOS) regulates vasodilation. In response to proinflammatory cytokines, large amounts of NO are produced during inflammation by phagocytic cells via the inducible isoform (iNOS).[64] NO participates in protein S-nitrosylation. NO reacts with cysteinyl residues to form S-nitrosothiols. As an example, increased NO production yields reversible cysteinyl S-nitrosylation at the active site of protein tyrosine phosphatases.[65] High levels of NO induce apoptosis by stimulating the release of cytochrome c from mitochondria. This activates the AKDK1, cyclic-dependent kinase-1 (CDK1), and JNK pathways, ultimately leading to active caspases that trigger cell death.[66]

Hydrogen Peroxide

The primary source of H_2O_2 is superoxide, constitutively produced by mitochondria and NADPH oxidases. To control H_2O_2, catalase and peroxidases specifically degrade H_2O_2, whereas SOD limits superoxide to curtail H_2O_2 accumulation. A high steady-state level of H_2O_2, associated with chronic inflammation, increases the production of NF-κB and AP-1 via posttranscriptional modification. H_2O_2 oxidizes cysteinyl moieties in redox-switching proteins; this process activates tyrosine kinases and inhibits related phosphatases,[67] leading to nuclear factor translocation to promote neutrophil binding with increased expression of adhesion molecules, including vascular cell adhesion molecule-1 (VCAM-1) and intercellular adhesion molecule-1 (ICAM-1). ROS, like H_2O_2, can oxidize GSH peroxidase, peroxiredoxins (Prx), and inactive transcription factors directly by oxidizing cysteinyl moieties, leading to the formation of protein disulfides or sulfenic acid derivatives.[68] Chronic vascular oxidative stress may reflect nonspecific host responses with induction of the NF-κB pathway and repression of the Nrf2 pathway.[69]

LABORATORY ASSESSMENT OF OXIDATIVE STRESS

Current methods measure a small fraction of potential oxidation products, given the wide range of ROS and possible cell targets. Measurement of oxidized macromolecules due to ROS provides three classes of biomarkers: protein oxidation products, lipid oxidation products, and nucleic acid oxidation products. These include products of protein degradation as protein carbonyls[70] and nitrosylated adducts; urinary and/or plasma products of lipid peroxidation, such as F_2 isoprostanes[70] and aldehydes, such as malondialdehyde from lipid fragmentation; as well as products of purine oxidation, such as 8-oxo-2-deoxyguanosine.[34,71]

Antibody-based methods have been used to identify and quantify oxidative posttranslational modified proteins. The most common include Western blotting, immune staining, and immunocytochemistry, although accuracy relies on the specificity of antibodies used.[72] As an example, systemic nitro-oxidative stress has been studied in perinatal asphyxia and neonatal hypoglycemia.[73,74] Polyunsaturated fatty acids are susceptible to free radical attack, yielding hydroperoxides in situ, which are released from membranes by phospholipases. Other lipid oxidation products include ketones such as 4-hydroxynonenal. The accuracy of analysis of unmodified or derivatized lipids by chromatography/mass spectroscopy far exceeds that of the commonly used thiobarbituric acid (TBAR) assays.

The guanine moiety of DNA is particularly susceptible to oxidation, yielding a premutagenic lesion involved in GC:TA transversion mutations.[75] Inflammation and oxidative stress are related mechanistically, and certain markers of systemic inflammation offer a secondary window to examine oxidative stress. C-reactive protein can serve as a marker for systemic inflammation, as well as liver dysfunction,[76] and levels can be reduced by antioxidant supplementation.[77]

Gamma-glutamyltransferase (γ-glutamyltranspeptidase [GTT]) is linked to the redox state and to the GSH/oxidized GSH (GSSH) balance; therefore it promotes GSH production. GTT may be useful in

assessing oxidative stress associated with type 2 diabetes, metabolic syndrome,[78] and Alzheimer's disease,[79] in addition to coronary heart disease and stroke.[80]

ANTIOXIDANTS

Generally, antioxidants inhibit the oxidation of molecules targeted by radicals and ROS.[81] To prevent oxidative stress, organisms possess an elegant antioxidative defense network. Broadly, antioxidants can be classified as endogenous or exogenous. Endogenous antioxidants include proteins as blood constituents, metal ion–binding proteins and enzymes, as well as low-molecular-weight molecules produced by metabolism. Exogenous antioxidants can be considered dietary constituents in animal products, fruits, vegetables, and other plant-based foods. Endogenous and exogenous antioxidant systems cooperate and rely on each other for optimal effectiveness.

There is an apparent "pecking order" among antioxidants; some are more readily oxidized than others and will be consumed rapidly unless replenished or recycled.[82] Certain antioxidants are preventive inhibitors that block the initiation of free radical attack. Preventive inhibitors include defensive enzymes such as catalase, SOD, and peroxidases (GPx), as well as low-molecular-weight compounds, including reduced GSH. Beta-carotene, chelating agents such as organic acids, and plant polyphenols represent preventive antioxidants when they quench singlet oxygen or sequester metal ion catalysts. Antioxidants can function as chain breakers, which convert free radicals to stable products and thus block free radical chain reactions. Vitamin E and ascorbic acid are chain-breaking antioxidants.

Laboratory Assessment of Antioxidant Activity

Successful preventive measures for ROS-related disease rely on the early assessment of the presence of oxidative stress and its molecular sequelae. As a starting point, accurate measurement of the total antioxidant capacity may assist in evaluating both physiological and nutritional factors involved.[83] The ferric ion reducing ability (FRAP) assay has been used to correlate serum total antioxidant capacity (TAC) with metabolic risk factors. Ingestion of foods with high TAC values was found to reduce markers of systemic inflammation and liver dysfunction.[76,84] Other methods rely on peroxyl radical scavenging (ORAC), total reactive antioxidant potential (TRAP), total oxidant scavenging capacity (TOSC), hydroxyl radical scavenging (deoxyribose assay), and organic radical scavenging (DPPH). Although international standards are unavailable, these protocols continue to be used, for example, to study the effects of omega-3 fatty acids and vitamin D supplementation on pregnancy outcomes in patients with gestational diabetes.[85] As a further example, the ORAC is often used to compare the antioxidant activity of foods and complex mixtures. This assay measures the decay in fluorescence (possibly from peroxyl radicals), and results are expressed as "trolox equivalents."[86]

ORAC values for foods were published by the U.S. Food and Drug Administration (FDA).[87] However, the USDA removed the ORAC database from its website after concluding that values of antioxidant capacity are not relevant to physiological effects of putative bioactive compounds. The TAC content (FRAC) of more than 3000 foods and supplements has also appeared.[88] It can be misleading to market the health benefits of foods based on measures of total antioxidant content. Yet some evidence suggests the utility of ORAC values to assess dietary and oxidant intake and guide choices of foods and natural products, with the goal of reducing the risk of cancer, cardiovascular disease, and metabolic syndrome.[89,90] Cellular antioxidant activity (CAA), as measured by the ability to quench peroxyl radical-induced fluorescence of a fluorescein probe in cultured hepatoma cells, was developed to account for update and metabolism of antioxidants.[91] It is worth noting that CAA values of flavonoids do not correlate with ORAC values.

Studies of ROS and radical quenching by antioxidants frequently employ single time points (end-point assays). A more reliable approach evaluates the IC_{50}, the concentration of antioxidant yielding 50% inhibition of a given oxidant or radical. It also is important to compare antioxidant activities in several assay systems. Studies showed that procyanidolic oligomers (PCOs) found in numerous foods and used in supplements (e.g., pine bark and grape seed extract) effectively quench diphenyl picrylhydrazyl radicals.[93] Galloyl catechins were shown to be more effective than simple catechins in the inhibition of NADPH-dependent lipid peroxidation of rat liver microsomes.[92]

Endogenous Antioxidants: Enzyme Systems

Superoxide Dismutase: Antioxidant Role for Manganese, Copper, and Zinc

SODs efficiently convert superoxide to H_2O_2. The mitochondrial isoform (SOD2) requires manganese, whereas the cytoplasmic (SOD1) and extracellular (SOD3) enzymes require both copper and zinc. SOD2 is induced during acute inflammation,[94] whereas SOD3 in vessel walls plays a major role in regulating vascular ROS.[95] Knockout mice lacking SOD2 die several days after birth due to massive oxidative damage. Mice lacking SOD1 develop ROS-related pathologies with reduced life span. Several lines of evidence suggest an involvement of SOD in neurological abnormalities. Mutations in the SOD1 gene account for 20% of patients with a familial dominant form of amyotrophic lateral sclerosis, although the mechanism is unknown.[96] Overexpression of SOD2 in a mouse model of Alzheimer's disease was shown to reduce brain superoxide and prevent memory losses.[97]

SOD may be effective in treating experimental ulcerative colitis.[98] High-risk premature infants treated with prophylactic recombinant human SOD1 had reduced early pulmonary injury at 1 year.[99] SOD supplementation may also improve stress and fatigue in healthy adults.[100] Intravenous administration of derivatized SOD can raise SOD activity in adults. [101] Micronutrient supplementation can increase endogenous SOD among patients with type 2 diabetes administered a combination of vitamins E and C.[102] In a rabbit model, copper supplementation inhibited the progression of atherosclerosis via increased SOD expression and potentiating NO-mediated pathways.[103] Indeed, serum SOD is linked to vascular function in hypersensitive and diabetic patients.[104]

Catalase

The iron-dependent enzyme catalase converts H_2O_2 to diatomic oxygen extremely efficiently. It occurs widely in cells and is a component of peroxisomes. Animal studies with catalase, usually in conjunction with SOD, suggest protection against ischemic injury to the lung,[105] intestinal ROS damage,[106] and radiation.[107] Examination of human atherosclerotic coronary arteries revealed that vascular antioxidant enzymes, including catalase, were selectively elevated in smooth muscle cells and macrophages in atherosclerotic lesions.[108] In contrast, knockout mice lacking catalase were phenotypically normal, possibly due to effective scavenging by peroxidases.[109] In the cardiac proteome of wild-type and transgenic mice, overexpression of catalase was linked to decreased cysteinyl oxidation among 82 proteins, including mitochondrial and contractile proteins, implicated in pathways of cardiac disease.[110]

The Peroxidase Family

Glutathione Peroxidase (GPx): Antioxidant Role for Selenium. GPxs reduce H_2O_2 as well as lipid peroxides with GSH as the reducing agent. Unlike catalase and SOD, GPxs require selenocysteine. GPxs exist as

several isoforms. GPx-1 is a cytoplasmic isoform that prefers H_2O_2 as a substrate. GPx-4 has a high affinity for lipid hydroperoxides, reducing membrane lipid peroxides to nontoxic fatty acid alcohols.[111]

GPx-1 expression is regulated in part by the availability of selenium and by selenocysteine during protein synthesis. By limiting H_2O_2 accumulation, GPx-1 can modulate mitochondrial function and growth-factor–mediated regulation. GPx has been implicated in age-related diseases, including cancer and cardiovascular disease. Antioxidant enzymes, including extracellular GSH peroxidase, are induced by the oxidative stress associated with lung diseases.[112] GPx-1 can block oxidative stress induced by cigarette smoke. Among patients with chronic obstructive pulmonary disease, exposure to cigarette smoke provoked protein unfolding in lung epithelial cells, which was reversed in vitro by GPx-1.[113] Mice lacking GPx-1 have a normal life span; however, they develop early cataracts. In contrast, GPx-4 knockout mice do not survive early embryonic development.[114]

Peroxiredoxins (Prx). This group of six thiol peroxidases reduces H_2O_2, lipid peroxides, and peroxynitrite via an active-site cysteinyl, –SH. The PrxII isoform is one of the most abundant proteins in erythrocytes. Prxs control intracellular levels of H_2O_2 to regulate cell signaling in various cell types and have been implicated in carcinogenesis, tumor metastasis, and drug resistance. Mice lacking PrxI or PrxII develop severe hemolytic anemia and are prone to cancer due to elevated H_2O_2. Prx1 knockout mice exhibit atherosclerotic lesions due to endothelial cell dysfunction.[115] NO may protect macrophages against oxidative and nitrosative stress by inducing Prx.[116] PrxII can express dual roles in cancer progression. Decreased expression is correlated with enhanced proliferation and metastasis of melanoma cells. In contrast, PrxII has been shown to be overexpressed in prostate, cervical, and esophageal cancer. PrxII also plays a role in colorectal cancer, apparently by helping maintain colorectal cancer stem cell–like behavior.[117]

Storage and Transport Proteins

Ferritin, Transferrin, and Ceruloplasmin

Free iron and copper ions catalyze the conversion of H_2O_2 to hydroxyl radicals; therefore proteins that bind these ions help protect tissues against ROS. Transferrin (which has a high affinity for iron) and ceruloplasmin (which binds copper) can be considered part of the antioxidant defenses.[118] Iron stored in ferritin does not participate in the generation of free radicals. Under normal circumstances, little unbound iron is present in cells. However, with chronic inflammation, unbound iron may be released from ferritin, posing a potential hazard. Iron storage disease is linked to oxidative damage. Studies of H_2O_2-resistant cell lines suggest that adaptation to chronic oxidative stress includes increased cellular antioxidant defenses, including elevated levels of mitochondrial ferritin, GSH, and GPx.[119]

Metallothionein

Metallothionein, a small, cysteine-rich protein, binds many metals. It exists as isoforms, induced by cytokines, toxic metals, oxidative stress, inflammation, axonal development, and apoptosis. Mitochondrial-specific ROS generators can increase the production of metallothionein in the liver by 3.7- to 11.8-fold in mice, far more than SOD or GSH peroxidase.[120] Similarly, acute ethanol-induced hepatotoxicity and associated oxidative stress were curtailed in mice that had been genetically manipulated to overexpress metallothionein, compared with wild-type mice.[121] The isoform MT-II is mainly expressed in neurons and is induced by oxidative stress and metals. It has been implicated in neuroprotection and after brain injury. Using an in vitro model of stroke as well as animals with cerebral artery occlusion, exogenous application of MT-II was shown to protect against ischemic injury.[122]

Selenoprotein P

Nearly 60% of plasma selenium is represented by selenoprotein P, which transports selenium to tissues. In vitro, selenoprotein P protects against peroxynitrite-induced damage and reduces phospholipid hydroperoxides.[123]

Redox Regulation: The Glutathione System

Glutathione (GSH)

GSH is a sulfhydryl-reducing agent containing cysteine that occurs in millimolar concentrations in most cells, where it acts as a detoxifying agent, assists amino acid transport, and quenches free radicals, in addition to regulating the internal redox environment of cells. Together with ascorbate, GSH participates in the regeneration of vitamin E, which emphasizes the intracellular cooperation of antioxidants. Reduced GSH reacts directly with singlet oxygen, hydroxyl radicals, and superoxide radicals to form oxidized glutathione (GSSG).

GSH Reductase

GSH reductase reduces GSSG with NADPH, linking thiol regulation to robust glucose metabolism. GSH reductase helps maintain a high GSH/GSSG ratio. Oxidative stress reduces this ratio, activates transcription factors, and increases production of IL-1 and TNF.[124] NADPH and GSH are cofactors for other reductases that help regenerate tocopherol and ascorbate, demonstrating the principle that overall metabolic balance is a prerequisite for adequate antioxidant defense.

GSH Transferase

GSH S-transferase adds GSH to endogenous and exogenous electrophilic compounds and is considered a component of Phase II detoxification enzymes. Modified products are cleared from the cell with multidrug-resistance–associated proteins. This transferase also functions in the synthesis of prostaglandin E2 and leukotriene C4 and D4. Like GSH peroxidases and Prxs, GSH S-transferase requires an ample supply of reduced GSH for optimal activity.

GSH and Neuroprotection

With aging, there is a general decline in GSH levels, and low GSH levels are associated with a variety of chronic conditions, such as diabetes, age-related macular degeneration, gastrointestinal disorders, and neurodegenerative diseases.[125]

In the brain, GSH serves to detoxify xenobiotics and has an important role in antioxidant defense and the regulation of intracellular redox status. This extends its reach to gene expression and cell differentiation in the brain. Dysregulation of glutathione homeostasis has been implicated in neurodegenerative diseases, including Alzheimer's, Parkinson's, and Huntington's disease, as well as amyotrophic lateral sclerosis.[126] In a transgenic mouse model of Alzheimer's disease, the formation of mixed disulfide protein on brain and blood preceded amyloid plaque appearance.[127] In a neuronal-like cell line, exposure to oxidized low-density lipoprotein cholesterol (LDL-C) revealed increased cytotoxicity, lowered the GSH/GSS6 ratio, and increased β-amyloid production.[128]

Redox Regulation: The Thioredoxin System

The thioredoxin system contains two components: thioredoxin (Trx) and Trx reductase. Trx is a small sulfhydryl protein that acts as a reducing agent for Prxs and ribonucleotide reductase. Trx also promotes the activation of several transcription factors.[129] Trx reductase is a selenocysteine-containing enzyme that specifically catalyzes the reduction of Trx. Together, Trx and Trx reductase function as a widespread redox-regulating mechanism with multiple roles in intracellular signaling and resistance to oxidative stress. Thus thioredoxin activates apoptosis signal-regulating kinase-1. It reduces redox factor-1, which

then reduces oxidized (inactive) transcription factors such as NF-κB and Nref-2.[130] Apurinic/apyrimidinic endonuclease 1 (APE-1), a dual-functional DNA repair enzyme that can also reduce transcription factors (such as AP-1 and p53), is regenerated by thioredoxin, linking DNA repair to the cellular redox balance.[131]

Antioxidant Enzymes: Transactivation of Antioxidant Response Elements

Nuclear transcription factors such as Nfr2 can be regarded as a cell-sensing system for oxidative and electrophilic stress, which is responsive within 15 minutes after exposure to a stressor.[132] Transactivation of AREs is regulated by the redox balance, in which nuclear factor Nrf2 migrates to the nucleus in response to ROS, where it activates genes responsible for a battery of antioxidant enzymes, including Prx-6, GPx, GSH transferase, and Trx, as well as Phase II detoxifying enzymes.[133] The Nrf2–ARE pathway represents a master antioxidant mechanism especially relevant to diabetic dysfunction.[134]

Antioxidant enzyme levels tend to decrease with age-related conditions.[135,136] Several antioxidant enzymes are often induced during the oxidative stress associated with age-related diseases. As an example, in human atherosclerotic coronary arteries, catalase, GSH peroxidase, and SOD were upregulated in atherosclerotic lesions, possibly as the result of oxidative stress.[108] Upregulation of Trx1, Trx2, and TrxR2 can occur in aging skeletal muscle, although their role in redox-regulated adaptions to failed muscle functioning remains unclear.[137]

Micronutrients as Antioxidants

Vitamin C

Ascorbic acid can react with a wide range of ROS, including superoxide, singlet oxygen, hypochlorite, and sulfur radicals.[138] Ascorbic acid is an efficient chain-breaking antioxidant in human plasma,[139] where it protects lipids and membranes by scavenging peroxyl and hydroxyl radicals.[140] Vitamin C can reduce heavy-metal toxicity.[141] In animal models, high levels of ascorbate compensated for low GSH production, and vice versa. A combination of ascorbate with vitamin E is possibly more effective than ascorbate alone for older adults.[142] Ascorbic acid functions with GSH and lipoic acid to regenerate α-tocopherol. To recycle ascorbate, dehydroascorbate is reduced back to ascorbate via GSH and NADPH.

The recommended dietary allowance (90 mg for men >19 years old; 75 mg for women >19 years old) is probably an underestimate. Healthy young women may require at least 400 mg/day of ascorbic acid, according to tissue-saturation studies.[143]

Cardiovascular Disease. Observational studies suggest that ascorbic acid has, at best, modest effects on the risk of coronary heart disease. Although a meta-analysis found no benefit with vitamin C supplementation on survival and cardiovascular disease (CVD) risk,[144] others reported benefits with high supplemental vitamin C.[145] The Nurses' Health Study suggested that vitamin C intake of more than 359 mg/day (diet plus supplements) reduced the risk of CVD.[146] For diabetic postmenopausal women, high vitamin C supplementation correlated with an increased risk of CVD mortality.[147] The Physicians' II study found that vitamin C supplementation at 500 mg/day was not cardioprotective for middle-aged men.[148] Another randomized controlled study (the MRC/BHF Heart Protection Study) did not find that vitamin C supplementation reduced the risk of CVD.[149]

Hypertension. In young healthy women, a higher level of plasma vitamin C was associated with decreased blood pressure.[150] A meta-analysis of 29 short-term trials indicated that a median supplementation dose of 500 mg/day significantly reduced blood pressure in healthy and hypertensive adults.[151]

Cancer. High ascorbic acid intake has been linked to a reduced risk of cancers of the oral cavity and esophagus,[152] ovaries,[153] stomach,[154] and colon. However, a pooled analysis of eight prospective studies found that vitamin C intake was unrelated to lung cancer.[155] Treatment of male physicians aged equal to or more than 50 years with 500 mg ascorbic acid daily for 8 years found no reduced risk of prostate cancer or total cancer.[156] Several studies suggested that extracellular ascorbate at millimolar concentrations (achieved via intravenous or intraperitoneal administration) can help increase survival rates.[157] A plausible mechanism involves ascorbate reduction of transition metals (cupric to cuprous, ferric to ferrous), which react with oxygen, yielding superoxide and H_2O_2, to which tumor cells are susceptible.[158]

Neurodegeneration. The brain possesses one of the highest ascorbic acid concentrations in the body. The Rotterdam Study suggested that a high intake of ascorbic acid and vitamin E was associated with a reduced risk of Alzheimer's disease, especially among cigarette smokers.[159] Although the ascorbate levels in the plasma or cerebrospinal fluid (CSF) of 32 patients with Alzheimer's disease did not correlate with cognitive decline over 1 year, the ratio of CSF ascorbate/plasma ascorbate increased, which was possibly related to an impaired ability of the brain to concentrate neuroprotective nutrients.[160] Supplementation of ascorbic acid was associated with a lower incidence of severe cognitive impairment among elderly volunteers.[161] In an animal model, intraperitoneal injection of ascorbic acid prevented disruption of the blood–brain barrier, resulting in sustained somatosensory function.[162]

Cataract. Although some investigations reported the risk of cataracts and retinal damage with lowered vitamin C status, a prospective study employing 500 mg of vitamin C, 400 IU of vitamin E, and 15 mg of β-carotene found no effect on the development or progression of cataracts.[163]

Diabetes. A 12-year prospective study of nondiabetic participants in the European Prospective Investigation into Cancer and Nutrition (EPIC) Norfolk Study noted that those with the highest 20% of plasma vitamin C had a 62% lower risk of developing type 2 diabetes compared with those in the lowest 20%.[157] Another cross-sectional study noted an inverse relationship between the levels of ascorbic acid and hemoglobin A1c.[164]

Vitamin C: A Cell Response Modifier? Generally, vitamin C appears to function primarily as an antioxidant in modulating the redox balance in a variety of situations, such as attenuating cytochrome P450 detoxification or plasma C-reactive protein levels. Vitamin C was able to increase the efficiency of generating mouse and human pluripotent stem cells from somatic cells, in part by attenuating cell senescence.[165] In other research, the expression of five functional protein groups related to signaling, apoptosis, and activated transcription, among others, was detected in vitamin C–treated T cells.[166] As an additional factor relevant to neurodegenerative disorders, ascorbic acid can switch central nervous system (CNS) metabolism from glucose consumption over to lactate oxidation to maintain synaptic functioning.[167]

Vitamin E (Tocopherols)

Vitamin E refers to four tocopherols (α, β, γ, δ) and tocotrienols (α, β, γ, δ) that possess an unsaturated isoprenoid side chain. Vitamin E represents a primary chain-breaking antioxidant of lipids, lipoproteins, and membranes, where it acts as a peroxyl radical scavenger, creating a tocopheryl radical. This radical will decompose unless converted back to tocopherol by ascorbic acid, GSH, and coenzyme Q_{10} (CoQ_{10}), illustrating that antioxidant defenses complement one another.[139,168] Vitamin E can exacerbate hypertension in susceptible people. High levels may antagonize other fat-soluble vitamins, thus decreasing bone mineralization. This vitamin may be contraindicated in patients receiving anticoagulants or in those with a vitamin K deficiency.

Vitamin E supplements often incorporate synthetic α-tocopherol, a mixture of D and L isomers, but only the D form (RRR-α-tocopherol) is active in the body. Esterified α-tocopherol is considerably more stable than unesterified tocopherol, and supplements often use esters of vitamin E, which are readily hydrolyzed and absorbed. As with other fat-soluble vitamins, supplementation is prudent in patients with malabsorption syndromes.

Immunity. α-Tocopherol may increase the T-cell–mediated response, which is impaired with aging. Supplementing healthy elderly people (consuming an otherwise typical diet) with 60 to 800 mg vitamin E improved several aspects of cell-mediated immunity within 6 to 12 months.[169] Among older adults (mean age 70), supplementation with 200 mg/day of synthetic vitamin E for 3 months increased neutrophil chemotaxis and proliferation, natural killer cell activity, and IL-2 production.[170] An RCT of nursing home residents found that supplementation with 200 IU synthetic vitamin/day for 1 year reduced the risk of upper respiratory tract infections.[171] In other research, ingestion of 268 mg/day of natural vitamin E for 8 months significantly reduced serum immunoglobulin-E, with apparent normalization of most lesions in patients with atopic dermatitis.[172]

Cardiovascular Disease. Hypothetically, the oxidation of LDL-C and other lipoproteins can initiate atherosclerosis. Increasing dietary vitamin E intake to more than 20 times the usual intake in a Western-type diet was suggested to reduce the risk of heart disease and its manifestations, such as myocardial infarction, among low-risk populations.[173] However, randomized, placebo-controlled clinical trials with α-tocopherol (200–800 IU/day) in Western populations have been mainly negative.[174]

Only 5 of 12 clinical studies on vitamin antioxidants and CVD reported reduced cardiovascular death and nonfatal myocardial infarction. These include the Cambridge Heart and Antioxidant Study (CHAOS), the Women's Health Study (reduced risk of sudden death from CVD), and the Secondary Prevention With Antioxidants of CVD in End-Stage Renal Disease (SPACE) study of hemodialysis patients who were at high risk of oxidative stress. Inconsistent results with vitamin E may reflect compounding variables, including the heterogeneity of risk factors for coronary heart disease; treatment for the late course of disease versus treatment for early-onset oxidative stress[175]; and genotypic differences among subgroups, for example, the haptoglobin 2-2 genotype in patients with type 2 diabetes.[176] Potentially harmful effects of supplemental vitamin E were reported in three of these (increased risks of stroke and heart failure). As is typical of reductionistic approaches to medicine, α-tocopherol is only one of eight tocopherols found in nature, with others, such as gamma and delta tocopherols, having many important health benefits beyond simply antioxidant activity. This is discussed in more detail later in the chapter.

Neurodegenerative Disease. A high intake of vitamin E and vitamin C was found to be associated with a reduced risk of Alzheimer's disease according to the Rotterdam study.[159] A meta-analysis concluded that circulating vitamin E, C, and A were significantly reduced in patients with Alzheimer's disease versus healthy individuals.[177] In a controlled trial of patients with moderately severe Alzheimer's disease, α-tocopherol administered at a daily level of 2000 IU delayed the onset of severe dementia or death in comparison with controls.[178] However, a controlled clinical study of patients with mild cognitive impairment found that treatment with 2000 IU vitamin E failed to slow mental decline.[179] A multicenter RCT found that supplementation with 2000 IU vitamin E daily for 2 years delayed the decline in daily functioning, yet it failed to alter cognition according to standardized tests.[180] Little evidence suggests that long-term supplementation with vitamin E alone improves cognition among healthy adults.

More generally, it is unrealistic to expect that dosing with one or two antioxidants can substitute for multiple synergistic factors that support interlocking regulatory pathways in reducing risks of chronic degenerative disease.

Cancer. Most clinical studies have not demonstrated the benefits of vitamin E supplementation in reducing the risk of most cancers. Effects of antioxidant supplementation often depend on the subject's nutritional status. Clinical studies with vitamin E illustrate this principle. The Shanghai Breast Cancer Study observed a 20% reduction in breast cancer risk with vitamin E supplementation among women with low dietary intake.[181] The Linxian General Population Nutrition Intervention Trial, which included adults deficient in several micronutrients, examined the effects of 50 mcg/day of selenium, 30 mg/day of vitamin E, and 15 mg/day of β-carotene. Supplementation led to decreased all-cause mortality, including overall cancer risk.[182] In contrast, U.S. studies of vitamin E on cancer rates reported negative results for breast cancer,[183] endometrial cancer,[184] lung cancer (pooled analysis of eight studies),[185] and cancer incidence and cancer mortality.[186]

Although earlier studies suggested an inverse association between vitamin E intake and the risk of prostate cancer, the Physician's Health Study II of men aged 50 years or older found no reduction in the risk of prostate cancer and other site-specific cancers or the risk of total cancer after synthetic vitamin E supplementation (400 IU daily for 8 years).[187] Supplementation of men (ages >55 years) with vitamin E 400 IU per day for up to 12 years increased the risk of prostate cancer by 17%. Men who took vitamin E together with selenomethionine (200 mcg per day) had no higher risk than those taking a placebo.[188] Unknown compounding variables in such studies include the uncertain status of vitamin D, ω-6 fatty acids, and γ-tocopherol, and male hormones in addition to possible polymorphisms for the α-tocopherol–associated protein.[189]

Diabetes. Whether α-tocopherol can benefit diabetes has not been established through large, well-controlled clinical studies. A meta-analysis of 14 small RCTs of patients with type 2 diabetes found that vitamin E supplementation of 200 to 1000 IU/day for 6 to 27 weeks had no significant effects on glycemic control (assessed by fasting glucose and insulin levels and by hemoglobin A1c).[190]

Gamma-Tocopherol. Although the typical U.S. diet supplies twice as much γ-tocopherol as the α form or tocotrienols, α-tocopherol predominates in the body, due to selection by liver tocopherol-transfer protein, which preferentially incorporates α-tocopherol into lipoproteins. Gamma-tocopherol is also rapidly degraded. It selectively blocks reactive nitrogen species and complements antioxidant actions of α-tocopherol.[191] Gamma-tocopherol can protect pancreatic β-cells against NO inhibition in vitro.[192] Mice supplementation with a mixture of α- and γ-tocopherol (not α-tocopherol alone) reduced age-related transcriptional changes in the brain.[193] Clinical findings using γ-tocopherol are limited. Patients with metabolic syndrome treated with γ-tocopherol 800 mg and α-tocopherol 800 mg/day for 6 weeks had significantly decreased markers of inflammation and oxidative stress (high-sensitivity C-reactive protein and nitrotyrosine) compared with placebo.[194] The EPIC Study found no correlation between plasma levels of either α- or γ-tocopherol and the risk of prostate cancer.[195] Cigarette smokers supplemented with γ-tocopherol experienced short-term benefits on vascular endothelial activity during smoking cessation.[196]

Tocotrienols. Tissue distributions of tocotrienols and tocopherols differ, which is perhaps indicative of selective mechanisms in various tissues.[197] Tocotrienols can induce apoptosis in prostate cancer and breast cancer cells.[198] Tocotrienols can suppress inflammatory markers, such as IL-6, TNF-α, and NO, by stimulated macrophages.[199] Clinical studies are in their infancy. Hypercholesterolemic subjects treated with mixtures of tocotrienols daily for 28 days did not have

improved serum lipid or glucose concentrations or lipid peroxidation (urinary 8-iso-prostaglandin F2a).[200] In contrast, treatment of healthy adults with tocotrienols 160 mg/day for 6 months according to a randomized, double-blind protocol resulted in reduced DNA damage.[201]

Vitamin E: A Cellular Response Modifier? Several studies suggest that vitamin E administration can increase the expression of genes related to Th1/Th2 ratios in older mice.[202] Alpha-tocopherol can block upregulation of NF-κB, PKC, and p38 MAPK pathways to prevent inflammatory cytokine production in stimulated human monocytes and in human dendritic cells.[203] The variation in cytokine responses to vitamin E in elderly populations seems to reflect polymorphisms in cytokine genes.[204] Physiologically relevant concentrations of α-tocopherol were found to interfere with the cytotoxic and cytostatic actions of several protein kinase inhibitors, whereas other antioxidants did not affect the action of these inhibitors on cell-cycle arrest or cell death.[205] Nonetheless, such observations reflect the altered redox state of cells and tissues. For example, vitamin E may protect membrane domains and polyunsaturated fatty acid pathways from ROS as its underlying mechanism of action, rather than its involvement in specific signaling actions.[206]

Carotenoids

Carotenoids, plant pigments, are conveniently divided into carotenes and xanthophylls (oxygenated carotenes). The best-known carotenoid, β-carotene, represents only 25% to 33% of plasma carotenoids. In general, carotenoids are versatile antioxidants. Beta-carotene is especially effective at low oxygen tension, as found in tissues.[207] Increased carotenoid levels have been associated with decreased LDL-C oxidation.[208] They can quench ROS produced during inflammation and modulate levels of proinflammatory prostaglandins and leukotrienes.[209,210]

Lung Cancer. Although retrospective studies suggested an inverse correlation, analysis of pooled results from six prospective cohort studies found no relationship between dietary β-carotene and the reduction of lung cancer risk.[211] A systematic review of prospective studies concluded that dietary intake of total carotenoids did not significantly reduce the risk of lung cancer.[212] Supplementation has been studied in large RCTs. The two studies (the Alpha-Tocopherol, Beta-Carotene Cancer Prevention Trial [ATBC] and the Beta-Carotene and Retinol Efficacy Trial [CARET]) reported an increased risk of lung cancer in high-risk groups supplemented with 30 mg β-carotene/day.[213] In contrast, the Physicians' Health Study (only 11% smokers) found no effect with β-carotene supplements at a level of 50 mg every other day.[214]

Prostate Cancer. A meta-analysis of 15 case-control studies showed an inverse relationship between blood levels of lycopene and the risk of advanced-stage cancer. There was no risk association in nonaggressive disease.[215] Dietary lycopene intake was not related to prostate cancer risk in a large prospective study.[195] The question remains whether consumption of lycopene-rich foods can lower the risk of prostatic cancer.

Breast Cancer. An inverse relationship between the consumption of carotenoid-rich fruits and vegetables and the risk of breast cancer was found to be strongest among premenopausal women.[216] For women who were smokers and did not use supplements, dietary α-carotene and β-carotene intake was inversely associated with the risk of breast cancer.[217] Pooled analysis of 14 case-control studies reported a reduction in breast cancer risk with increased blood levels of total carotenoids, α-carotene, and lutein.[218] In contrast, the Women's Health Study found no link between lycopene intake and a reduced risk of breast cancer.

Cardiovascular Disease. Although several prospective studies found that higher intake of carotenoid-rich foods correlated with reduced risk of CVD, others did not.[145] Four RCTs found no effect of oral β-carotene, ranging from 20 to 50 mg/day, in preventing CVD.[214] Thus, although diets rich in β-carotene are often linked to reduced risk of cardiovascular disease, the benefits may derive from other constituents in fruits and vegetables.

Adult Macular Degeneration. The xanthophylls lutein and zeaxanthin are the only carotenoids in the retina and macula, where they filter blue light. Cross-sectional and retrospective case-control studies suggest that increased consumption of carotenoids, especially lutein and zeaxanthin, is linked with a lower risk of advanced age-related macular degeneration (AMD).[219] Yet another study of more than 4000 subjects found no evidence that β-carotene supplementation prevented or delayed AMD with intermediate risk of adult macular degeneration or with advanced AMD in one eye when supplemented with lutein (10 mg/day) and zeaxanthin (2 mg/day) in combination with vitamin C, vitamin E, β-carotene, and zinc according to the Eye Disease Study (AREDS-2) protocol.[220] Supplementation did not slow the progression to advanced AMD. Research extending this study to various combinations of carotenoids suggests that lutein and zeaxanthin can reduce disease progression compared with β-carotene alone.

Carotenoids: Cell Response Modifiers? The interpretation of the effects of β-carotene and other provitamin A carotenoids is complicated by their potential formation of retinoids, which are well-known regulatory species. Although they are effective antioxidants, non–provitamin A carotenoids (lycopene, lutein, canthaxanthin, and astaxanthin) do not present this complication. Much of lycopene's activity relates to its antioxidant actions; however, its metabolites could provide regulatory effects.[221] The nonprovitamin A carotenoids may affect cancer cells through increased apoptosis, decreased cell-cycle progression, or decreased production of cytokines. Alternatively, lycopene's inhibition of cancer cell proliferation may involve increased gap-junction–mediated intercellular communication.[222]

Coenzyme Q_{10} (Ubiquinone)

Ubiquinones contain side chains with isoprene units, and the predominant form in humans is ubiquinone 10 (CoQ_{10}). It functions as an essential electron carrier in mitochondrial ATP production. As the only lipophilic antioxidant synthesized in the body, CoQ_{10} also stabilizes membranes, and it helps recycle α-tocopherol.[223] Ubiquinol, the reduced form of CoQ_{10}, protects LDL-C against lipid peroxidation.[224] CoQ_{10} synthesis requires vitamins B_2, B_6, B_{12}, and folate, and synthesis may be suboptimal in people with a low intake of these micronutrients.

Immunity. CoQ_{10} may enhance the immune system. Supplementation of healthy volunteers with CoQ_{10} was found to increase white blood cell levels and decrease lymphocyte DNA damage (3 mg/kg daily for 12 weeks).[225]

Cardiovascular Disease. In an RCT of patients at risk for CVD, 6-month treatment with a combination of vitamins C and E, CoQ_{10}, and selenium increased arterial elasticity, lowered glycosylated hemoglobin, and increased high-density lipoprotein cholesterol (HDL-C) compared with controls.[226] CoQ_{10} has been used with conventional therapy in the treatment of congestive heart failure. Studies employing doses ranging from 100 to 200 mg/day for up to 3 months reported minor improvements.[227] Drugs such as β-blockers and 3-hydroxy-3-methyl-glutaryl-coenzyme A reductase inhibitors lower serum levels of CoQ_{10}.[228] However, the necessity of CoQ_{10} supplementation in these situations remains uncertain. A meta-analysis of 14 RCTs of various CoQ_{10} protocols suggests an improvement in exercise capacity, with a significant difference in left heart ejection as the end point.[229] Conversely, an RCT of 420 patients with cardiac failure receiving standard therapy and 300 mg of CoQ_{10} daily for 2 years found that CoQ_{10} significantly reduced major adverse cardiovascular events.[230]

Thiols in Redox Balance

Alpha-Lipoic Acid

As a coenzyme of pyruvate dehydrogenase and α-ketoglutarate dehydrogenase, α-lipoic acid (ALA) is required in the mitochondrial catabolism of carbohydrates and fatty acids. ALA also scavenges hydroxyl radicals, peroxynitrite, superoxide, and peroxyl radicals, and it can regenerate endogenous antioxidants, including ascorbic acid and GSH.

Diabetes. A meta-analysis of four RCTs with intravenous ALA of 600 mg/day indicated a significant improvement in diabetic neuropathy.[231] Whether oral ALA supplementation offers benefits is less clear. The highest tissue level of lipoic acid likely attainable from oral doses is less than 10% of other intracellular antioxidants such as GSH.[232] The effect of lipoic acid supplementation on long-term glycemic control remains uncertain. For example, a controlled study of 72 patients with type 2 diabetes reported that oral supplementation with 600 mg ALA daily for 4 weeks improved insulin sensitivity by 25%.[233]

Aging and Neurological Disease. Animal studies suggest that high-dose ALA and/or acetyl-L-carnitine can improve brain function,[234] reduce brain lipid peroxidation, and increase brain antioxidant enzyme activities in the brains of aged rats,[235] especially in the hippocampus.[236] Aged mice supplemented orally with ALA had increased glucose tolerance, energy expenditure, and skeletal muscle mitochondria biogenesis, but they also had increased loss of lean body mass.[237] It is not clear that these results can be extrapolated clinically. Patients with varying stages of Alzheimer's disease administered 600 mg/day of ALA for 48 months showed slowed disease progression in patients with mild, not moderate, dementia.[238]

Cardiovascular Disease. ALA supplementation was used in mouse models of ischemia-reperfusion and atherosclerosis, where it slowed the formation of atherosclerotic lesions.[239] In a rat model of diabetes, intraperitoneal ALA reduced cardiac apoptosis and caspase expression and enhanced MnSOD activity and GSH levels.[240] Feeding high-dose ALA reduced myocardial oxidant production to levels observed in healthy young rats.[241] Limited research has focused on the question of oral administration of ALA to improve vascular function in diabetes. As an example, supplementation of patients with diabetic neuropathy with 300 mg ALA/day for 4 weeks improved flow-mediated vasodilation.[242]

Obesity. Preliminary data for metabolic syndrome are suggestive. A study of 1127 of obese and preobese subjects supplemented for 4 months with ALA 800 mg/day reported a significant reduction in weight, blood pressure, body mass index, and abdominal circumference.[243]

Alpha-Lipoic Acid: A Cell Response Modifier? ALA can induce several Phase II antioxidant and thiol-protective enzymes, including enzymes needed for GSH synthesis. Old rats treated with ALA intraperitoneally were found to have increased γ-glutamylcysteine ligase (GGL) activity, reflecting induced Nrf2 binding to ARE and increased transcriptional levels of GGL subunits, thus reversing the age-related losses.[244] ALA activated protein kinase B (Akt), increasing the survival of cultured neuronal cells exposed to oxidative stress.[245]

N-ACETYLCYSTEINE AND GLUTATHIONE

As a supplement, *N*-acetylcysteine is an effective precursor for GSH. GSH synthesis is regulated in part by cysteine availability. It is deacetylated in the gut to free cysteine, and oral supplementation can efficiently raise intracellular GSH[246] in model systems and in healthy individuals.[247] *N*-acetylcysteine may play a supportive role in improving GSH status and maintaining cell redox balance, countering ROS, and attenuating drug toxicity as a conjugating agent in drug metabolism.[248] Orally administered GSH may increase intestinal GSH levels via a GSH transport system.[249]

Oxidative Stress. Supplementation of healthy, trained men with *N*-acetylcysteine (1800 mg/day for 3 days before exhaustive resistance exercise) significantly increased plasma thiols and TAC and reduced lipid peroxidation and protein oxidation.[250] An RCT of hypertensive patients with type 2 diabetes reported that 6-month treatment with *N*-acetylcysteine and arginine significantly reduced systolic blood pressure and lowered levels of oxidized LDL-C, C-reactive protein, VCAM-1, and protein oxidation (plasma nitrotyrosine), suggesting improved endothelial function, along with reduced oxidative stress.[251]

To examine the role of glutathione and Nrf2-dependent detoxification in age-related sensitivity to redox cycling, hepatocytes from young and old mice were studied. Exposure to xenobiotic insult led to a marked decline in GPx4 and GSH and a concomitant increase in lipid peroxidation. These differences were accentuated in hepatocytes from old mice. Pretreatment with *N*-acetylcysteine reduced cell death by more than twofold. These results suggest that *N*-acetylcysteine might help maintain glutathione levels and attenuate age-related decline in Nrf2–GSH dependent detoxification.[252]

MINERALS AND REDOX BALANCE

Magnesium

As a cofactor for nearly all ATP-requiring reactions, magnesium is integral to intermediary metabolism. Low magnesium status is linked to inflammation and activation of the systemic stress response. Subclinical magnesium deficiency is common in the United States, and magnesium deficiency is correlated with chronic diseases associated with aging.[253]

In rodents, low magnesium status caused the release of substance P, leading to increased circulating inflammatory cells, cytokines, and ROS, with depletion of antioxidants associated with cardiomyopathy.[254] Furthermore, magnesium deficiency promoted senescence in primary human fibroblasts.[255] Experimental magnesium deficiency created systemic inflammation with leukocyte and macrophage activation, inflammatory cytokine release, the formation of acute-phase proteins, and oxidative stress. A study of young male athletes and sedentary controls suggested that supplementation with 500 mg magnesium daily for 28 days reduced DNA oxidation in peripheral blood lymphocytes.[256] Possible mechanisms include opening calcium channels and activation of NF-κB.[257] High fructose intake, for example, from excessive consumption of high-fructose corn syrup, coupled with low magnesium status could set the stage for oxidative stress, insulin resistance, and metabolic syndrome in susceptible individuals.[258] A meta-analysis concluded that dietary magnesium intake is inversely related to the prevalence of metabolic syndrome.[259]

ZINC

Beyond its role in SOD, zinc is required by many transcription factors, including tumor-suppression protein p53. "Zinc fingers"—domains that bind multiple zinc atoms—stabilize these proteins. In addition to stabilizing membranes, zinc is involved in apoptosis, hormone release, and nerve transmission.[260] Given the high prevalence of zinc deficiency, subclinical zinc deficiency manifests as inflammation and oxidative stress, and it often accompanies aging.[261] That zinc deficiency diminishes immune function, especially Th1 activity, is well established. Zinc is essential for IL-2–mediated T-cell activation. The mechanism seems to rely on the activation of NF-κB signaling, resulting in increased expression of cytokines as TNF-α, IL-1B, IL-2, and IL-6.[262] The ability of zinc supplementation to influence cytokine production is consistently reported. However, attenuation or potentiation seems to be dose dependent. Thus daily supplementation with 45 mg or more

zinc may decrease in vivo–generated proinflammatory cytokine production in stimulated mononuclear cells.[263] Reduced cytokine production and T-cell activation was reported for elderly men and women supplemented with less than 20 mg zinc/day.[264]

METABOLITES AS SECONDARY ANTIOXIDANTS

L-Carnitine

L-Carnitine is synthesized mainly by the liver and kidney, then transported to tissues using fatty acids and carbohydrate as fuel. Fatty acid transport into mitochondria relies on a carnitine shuttle for β-oxidation. A decline in carnitine correlates with the age-related decline in mitochondrial energy production and increased ROS.[265] After demonstrations that supplementation with acetyl-L-carnitine reversed age-related decline in tissue carnitine levels in rats, later experiments showed that animals supplemented with high doses of ALA and acetyl-L-carnitine for 1 month exhibited improved substrate binding of brain carnitine acetyltransferase,[234,266] improved memory,[267] and decreased DNA damage.[268] Whether such improvements with high doses of acetyl-L-carnitine translate into long-term benefits in preventing age-related declines in memory and energy for patients remains to be investigated. Supplementation with 1000 mg/day for 12 weeks in patients with coronary artery disease increased HDL-C and Apo-A1 levels.[269] In a related study, this protocol led to reduced lipid peroxidation and increased levels of antioxidant enzymes (CAT, SOD, and GPx), suggesting a potential increase in antioxidant defenses with *N*-acetyl-carnitine supplements.[270]

URIC ACID (URATE)

Uric acid is a waste product of purine metabolism that occurs in high levels in plasma. Urate is a broad-spectrum antioxidant capable of scavenging free radicals, and it can chelate transition metals.[271] Uric acid is responsible for 21% to 34% of the total plasma antioxidant activity, in which it appears to protect α-tocopherol from peroxyl radicals.[272] Also, assays of TAC indicated that 49% of the TAC of human plasma is due to uric acid.[273] Although a ubiquitous antioxidant, elevated urate is not necessarily beneficial.

MELATONIN: A HORMONE WITH ANTIOXIDANT POTENTIAL

In addition to helping set the circadian rhythm and sleep patterns, melatonin acts as an antioxidant in vitro and in vivo.[274] In senescence-accelerated mice, long-term administration of physiological levels of melatonin corrected hepatic mitochondrial dysfunction, suggesting that melatonin may reduce the oxidative damage associated with aging.[275] Melatonin can act by inhibiting the expression of eNOS in laboratory animals.[276] It can also upregulate SOD and catalase in the brain and liver of rats exposed to carcinogens.[277] In an experimental model of diabetes, melatonin was shown to reduce lipid peroxidation and upregulate GSH reductase, GPx, and γ-glutamylcysteine synthetase.[278] As applied to oxidative stress in obesity, melatonin may play a role in benefiting calorie-restricted diets. In a small study, patients were supplemented with 10 mg melatonin daily or placebo for 30 days. After melatonin supplementation, levels of adiponectin and GPx increased, whereas lipid peroxidation was decreased. Furthermore, melatonin facilitated weight loss.[279] In keeping with its putative role as an anti-inflammatory agent, melatonin has a protective effect in the activation of the NLRP3 inflammasome, which responds to environmental agents, including pathogens, as well as to endogenous danger signals such as mitochondria-derived ROS.[280]

NONNUTRITIVE ANTIOXIDANTS

Polyphenols

Phytochemical antioxidants include polyphenols, which are composed of phenolic units. They are classified according to the number of ring structures as flavonoids, stilbenes, lignans, and phenolic acids. The persistent interest in polyphenols is due to their probable contribution to the health benefits of fruit- and vegetable-rich diets.

FLAVONOIDS

Flavonoids (bioflavonoids) represent one of the largest classes of polyphenols, and more than 5000 different flavonoids have been identified. They fall into 12 major subclasses, differing according to their antioxidant properties, physiological activities, and bioavailability.[281]

Dietary Patterns. For typical Western diets, the estimated daily consumption of total flavonoids is in the range of 100 to 200 mg,[282] although intake reflects cultural and even regional preferences. As examples, simple phenolic acids (caffeic acid, ferulic acid, gallic acid, and coumaric acids) accounted for 75% of total phenolic intake among Finnish adults, whereas flavonoids accounted for 24% of the total.[283] In an adult Spanish population, the mean intake of total flavonoids was shown to be 313 mg/day, with proanthocyanidins accounting for 60% of the total.[284]

Flavonoid Bioavailability/Biotransformation. The uptake of individual flavonoids including polymers such as proanthocyanidins is generally quite limited. Most flavonoids have very low water solubility. Phosphatidylcholine complexes of flavonoids may improve uptake.[285] Absorbed aglycone flavonoids are often conjugated (sulfates, glucuronides) or methylated by intestinal and liver systems, then excreted. Such flavonoid derivatives may have different biological effects than parent compounds. Additionally, colonic bacteria can degrade polyphenols by ring session, and absorbed monophenols often act differently than parent compounds. Enterohepatic and enteric recycling of flavonoid metabolites is another complication.[286] Analysis of the plasma and urine of healthy volunteers 2 hours after ingesting 200 mg of quercetin or green tea flavonoids failed to detect increases in any of 71 aromatic metabolites observable at 5 hours after ingestion, suggesting that flavonoid metabolites may not be responsible for rapid responses to ingested flavonoid-rich foods or beverages.[287]

Direct Antioxidant Activity. In vitro, various flavonoids scavenge a variety of radicals[288,289] and block LDL-C oxidation.[290] As chelators, flavonoids can inhibit spontaneous generation of hydroxyl radicals[291] catalyzed by copper and iron ions. Although data are conflicting, it appears that flavonoids and their derivatives probably make small contributions as direct antioxidants in vivo.[292] The observed increased antioxidant capacity in plasma after ingestion of fruits, fruit juice, and flavonoid-rich foods may be due to increased production of the antioxidant uric acid rather than due to flavonoids.[293,294] Peak plasma concentrations of flavonoids and their metabolites after acute ingestion are often less than 1 μmol/L, several orders of magnitude lower than plasma or intracellular concentrations of ascorbic acid, uric acid, and GSH.[295]

Effects on Cell-Signaling Pathways. Results of cell-culture studies and animal testing indicate that antiinflammation, antidiabetic, neuroprotective, and anticancer activities depend on modification of cell-signaling pathways. As examples, potential targets include the protein kinase/protein phosphatase families that ultimately regulate transcription factors. Additionally, flavonoids can alter growth-factor signaling by preventing receptor binding.

Flavonoids in Cancer Prevention. The different flavonoid subclasses provide multiple compounds with varying biological

activities. Therefore it is difficult to generalize the activities of specific flavonoids. Evidence for a relationship between flavonoids and cancer incidence is conflicting. Among healthy postmenopausal women, there was an inverse association between the incidence of lung cancer and the intake of flavanones and proanthocyanidins for current or past smokers—those with the highest intake of quercetin had a lower incidence of lung cancer—and in men, those with the highest intake of myricetin had a reduced risk of prostate cancer.[296] In contrast, among elderly Dutchmen, dietary catechins mainly from tea were not associated with a reduced risk of lung cancer or epithelial cancers.[297] In earlier studies, flavonoid consumption was not associated with reduced cancer risk in this population,[298] although it was inversely related to mortality due to coronary heart disease (CHD).[299]

Flavonoids can reduce inflammation by blocking the expression of inflammatory mediators. Screening flavonoid, flavonoid metabolites, and combinations of flavonoids plus metabolites according to their ability to inhibit induction of TNF-α by isolated human monocytes revealed that combinations of flavonoid metabolites can be more effective than individual flavonoids or individual metabolites used singly.[300] Using a coculture system of intestinal epithelial and endothelial cells, researchers demonstrated that cyanidin-o-glucoside, one of the most common flavonoids, inhibited inflammation signaling, including selective inhibition of the NF-κB pathway.[301]

Flavonoids in Cardiovascular Protection. Variable results have been obtained from studies of dietary flavonoids and antioxidants in medicinal plants and the risk of chronic disease, such as cardiovascular disease.[302] Whether increased consumption of flavonoid-rich foods can reduce the risk of CVD is not clear. For example, a study of postmenopausal American women found significant reductions in the risk of CVD and all-cause mortality with increased flavonoid intake.[303] Results of the Cancer Prevention Study II Nutrition Cohort suggested an inverse relationship between total dietary flavonoid intake and the risk of stroke and total CVD, especially for men.[304] In contrast, a study of U.S. women reported no significant relationship between consumption of flavanols and flavones and CHD.[305] There was no strong relationship between flavonoid intake and total CHD among American male health professionals.[306] Caution is needed in interpreting these prospective studies due to omissions, such as the failure to (1) include all flavonoid subclasses, (2) calculate flavonoid intake based on more complete databases for flavonoid content of foods, and (3) make adjustments for the overall quality of diets. Other dietary factors besides flavonoids (vitamins, fiber, other phytochemicals) contribute to potential bias.

Specific Antioxidant Mechanisms for Polyphenols in Vivo? Interpretation of polyphenolic "antioxidant effects" is complicated by several factors. Most data regarding polyphenol activities come from cultured cells and tissues and often test concentrations of individual flavonoids that far exceed those found in vivo. Flavonoids such as quercetin and green tea catechins rapidly produce H_2O_2 as an artifact under typical cell-culture conditions, thereby complicating interpretation. The identity of the polyphenolic species affecting cells and tissues is uncertain due to their biotransformation. Localized concentrations of active species in vivo are also uncertain.

Depending on the experimental design, polyphenols can inhibit COX, lipooxygenase, telomerase, xanthine oxidase, cytochrome P450, and protein glycation, as well as modulate drug transport systems and platelet function. Flavonoids may influence multiple signaling pathways, making it difficult to assign specific actions. As an example, red wine polyphenols administered to rats for 16 weeks inhibited chemically induced colon cancer.[307] In the process, responses to oxidative stress were downregulated. Microarray analysis of cellular changes after polyphenol treatment for 14 days revealed the following frequencies of downregulated genes: receptors and signal transduction, 22%; transport and binding proteins, 14%; inflammatory and immune response, 11%; metabolic enzymes, 4%; gene expression/control, 4%; xenobiotic metabolism, 3%; and cell-cycle regulation, 3%. In the final analysis, the observed protective effects of flavonoid-rich foods in humans may be independent of flavonoids.

Gastrointestinal Tract as Primary Target for Polyphenols? The gastrointestinal (GI) tract is continuously exposed to ROS and RNS from multiple sources. The gut epithelium may not adapt to long-term oxidative stress, and because of low initial levels of defensive enzymes, it may be susceptible to oxidative damage with even moderate inflammation.[308] After ingestion of flavonoid-rich foods, phenolic compounds are present in the stomach and intestinal lumen at much higher concentrations than those found in plasma.[309] Of particular interest are inflammatory bowel disease, gastric ulcers, and liver disease.[310,311] ROS are present at high levels in the colons of patients with ulcerative colitis.[312] Green tea polyphenols can reduce inflammation in models of inflammatory bowel disease.[313]

Polyphenolic by-products of intestinal metabolism, such as hydroxybenzoic acid and protocatechuic acid, exhibit important properties. As an example, they can induce apoptosis in gastric cancer cells.[314] Bioactive metabolites from dietary polyphenols can affect both the commensal gut microbiome and the host immune system. Animal studies implicate direct interaction with the gut epithelium as a prerequisite. In a rodent model of chemically induced colitis, oral administration of apple polyphenols downregulated intracellular signal cascades in the gut epithelium and infiltrated neutrophils.[315] This effect was not observed with polyphenols during peritoneal administration.

FLAVONOIDS FROM FOOD SOURCES

Soy

Studies with vascular cells suggest that soy isoflavones can increase eNOS activity[316] while activating the redox-regulated Nfr2–Keap1 signal pathway to increase the transcription of Phase II enzymes and antioxidant enzymes.[317]

Cardiovascular Disease. Some epidemiological studies correlated soy, especially soy protein, with a reduced risk of CHD.[318] Several RCTs reported cardiovascular benefits with improved systemic arterial function after a meal enriched with soy isoflavones.[319] In an RCT, supplementation of postmenopausal women with genistein for up to 36 months decreased homocysteine and fasting glucose.[320] However, the results were inconsistent.

Cancer. A meta-analysis of soy isoflavone consumption and risk of breast cancer observed a protective effect only among studies of Asian populations.[321] This analysis failed to find a dose–response relationship between total isoflavone consumption and breast cancer incidence. Interventional studies using high doses of soy isoflavones have found altered breast fluid, a predictor of breast cancer risk.[322]

Soy isoflavones can suppress tumors in animal models. Genistein can induce apoptosis via downregulation of Bcl-2 and Bcl-XL, anti-apoptotic proteins in human hepatoma cell lines, as well as in breast, prostate, pancreatic, and non–small-cell lung cancer cells.[323] Genistein also inhibits activation of the NF-κB and Akt signaling pathways that normally balance cell survival and apoptosis.[324] A meta-analysis suggested a significant association between the consumption of soy-based foods and a reduction in the risk of prostate cancer.[325] Nonetheless, epidemiological studies on the relationship between a reduced risk of breast cancer and soy intake have yet to provide definitive evidence for taking soy supplements.

BERRIES

Berries, currants, grapes, and certain tropical fruits and vegetables contain high levels of polyphenols, including flavanols, flavan-3-ols, tannins, and hydroxycinnamates and anthocyanins. Cyanidin-3-glucoside is the most prevalent anthocyanidin. Cell-culture studies, animal models, and limited clinical trials suggest anthocyanins may help prevent age-related deterioration and disease, including CVD and neurological disease.[326]

Cardiovascular Disease. Small-scale RCTs suggest that short-term consumption of blueberries, strawberries, cranberries, and other berries can improve several cardiovascular parameters, such as blood pressure, endothelial function, and serum lipids. A review of clinical trials using grape juice found an inverse relationship between dose and flow-mediated dilation.[327] In another study, healthy volunteers (50–70 years) consumed a mixed-berry beverage (blueberries, black-currant, elderberry, lingonberries, strawberries, and tomatoes [total polyphenols = 295 mg]) or control (polyphenol-free) beverage daily for 5 weeks. The berry intervention significantly reduced LDL-C and blood glucose levels compared with controls. Test subjects with the berry beverage also performed better on a test of working memory.[328]

Wine contains abundant polyphenols, and drinking red wine can increase the antioxidant capacity of serum.[329,330] A meta-analysis of 133 RCTs studying the effects of flavonoids and flavonoid-rich foods suggests that red wine consumption did not improve flow-mediated dilation, alter blood pressure, or change LDL-C levels.[318] Results for grape juice consumption have also been mixed. Overweight volunteers who consumed 480 mL/day of grape juice for 12 weeks did not have improved plasma antioxidant capacity or lipid profiles.[331]

Cancer. Black raspberries inhibited induced esophageal carcinogenesis in a rodent model, apparently by suppressing oxidative stress via NF-κB/MAPK signaling.[332] Analysis of the Nurses' Health Study and the Health Professionals Follow-Up Study found no association between the risk of colorectal cancer and consumption of flavonoid classes in tea, blueberries, and oranges.[333] Another meta-analysis found no significant association between high flavonoid consumption and the risk of lung cancer.[334]

Diabetes. Several intervention studies suggest beneficial effects of berries and fruits for patients with diabetes as well as for at-risk individuals. As an example, an 8-week RCT found that treating healthy obese or overweight volunteers with 2 g grape polyphenols daily for 8 weeks prevented a fructose-induced increase in oxidative stress and insulin resistance.[335]

Patients with diabetes supplemented with cherry extracts providing 600 mg anthocyanins/day for 6 weeks experienced reduced levels of HbA1c and triglycerides.[336] Compared with placebo, ingestion of 320 mg anthocyanins daily for 24 weeks improved lipid profiles, decreased markers of oxidative stress, and improved TAC while reducing insulin resistance in patients with type 2 diabetes.[337]

Neurodegeneration. Regular consumption of berries may help preserve cognitive health during aging. Analysis of the Nurses' Health Study concluded that a high intake of blueberries and strawberries could delay cognitive aging by approximately 2.5 years.[338] Furthermore, increased consumption of total flavonoids as well as anthocyanidins correlated with reduced rates of cognitive decline.

Flavonoids may promote neurogenesis and synaptic growth for memory-related regions such as the hippocampus, via increased production of neurotrophins.[339] As antioxidants, they may provide protection for inflammatory mediators due to activated microglia or hypertrophic astrocytes. Additionally, flavonoids can increase NO production to augment cerebral blood flow.

Blueberries have been implicated in the preservation of cognition and brain health. Anthocyanins or their metabolites seem to cross the blood–brain barrier. Supplementation of rodents with blueberry preparations reduced NF-κB (indicator of oxidative stress), augmented the cyclic adenosine monophosphate (AMP) response element-binding protein (central to neuronal growth and maintenance), and increased the production of brain-derived nerve factor, all of which correlated with enhanced memory.[340] An RCT indicated that blueberry supplementation can activate blood oxygen-dependent signaling in specific brain regions in older adults with mild cognitive impairment.[341] Clinical trials with berries and anthocyanins are limited, and carefully designed studies of larger groups are needed.

COCOA

Cocoa is a source of flavan-3-ols, especially (-)–epicatechin and procyanidins. Their relationship to oxidative stress and TNF-α–mediated signaling have been studied.

Cardiovascular Disease. Cocoa consumption is linked to a reduced incidence of CVD in the elderly population, and it is associated with increased peripheral blood flow.[342] Overweight adults who ingested cocoa beverages experienced significantly improved flow-mediated dilation in a randomized trial.[343] Furthermore, administration of 40 g/day cocoa powder for 4 weeks significantly reduced ICAM-1 and P-selectin in high-risk patients with CVD.[344] An RCT of healthy male adults observed short-term benefits of cocoa-flavored consumption, as assessed by increased HDL-C, lower LDL-C, and reduced blood pressure.[345] A meta-analysis of 18 RCTs found that consumption of cocoa beverages and chocolate bars for up to 18 months significantly increased flow-mediated dilation.[346]

In terms of mechanisms, (-)–epicatechin elevates NO in endothelial cells via inhibitors of NADPH-oxidase. Among human cohorts, cocoa and cocoa flavonols reduced markers of inflammation, including decreased IL-1B, VCAM-1, IL-10, and ICAM, in hypertensive adults.[347]

Neuroprotection. Cocoa flavonoids have been associated with cognitive improvements in healthy elderly adults. The Cocoa, Cognition and Aging Study examined this question in detail. Older adults consuming an intermediate dosage of cocoa flavanols (520 mg/day) or a high dosage (993 mg/day) for 8 weeks showed improved cognitive function.[348] Nonetheless, negative results on cognition from cocoa supplementation have also been reported. Possible mechanisms include improved glucose metabolism, insulin sensitivity, improvements in endothelial function, and improved cerebral blood flow.[349]

Diabetes. Results of epidemiological studies of dietary intake of flavanols from various sources have been inconsistent. Even so, a meta-analysis of RCTs concluded that moderate consumption of chocolate (up to 6 servings/week) is associated with reduced risk of CVD, stroke, and type 2 diabetes.[350] As an example of an intervention trial, daily consumption of 100 g of dark chocolate bars (147 mg catechins/day) improved insulin sensitivity and reduced blood pressure in glucose-intolerant hypertensive patients.[351] Cell-culture studies to define the antidiabetic mechanisms of flavonoids can improve redox states and increase GPx and Gr via Nfr2 signaling, yielding increased reductions in GSH.

TEA

The health benefits of tea are likely related to polyphenolic content. The total flavonoid content in green tea and black tea is 138 mg and 118 mg per 100 mL, respectively. Flavanol-3-ols (catechins) are a major class of

tea flavonoids, represented by epigallocatechin, epigallocatechin-3 gallate (EGCG), epicatechin-3 gallate (ECG), and (-)–epicatechin (EC). Tea flavonoids comprise 30% to 40% by weight in brewed tea extract. Increased consumption of flavon-3-ols in U.S. adults correlated with reduced proinflammatory cytokines and oxidative stress, although tea consumption per se did not correlate with a composite inflammation score.[352] Theaflavins are additional derivatives found in black tea. They are formed from green tea catechins by oxidation and fermentation. These condensation products are poorly absorbed; consequently, systemic effects probably reflect the actions of microbial metabolites.

Cancer. Tea flavonoids may block signal transduction pathways and induce apoptosis in various tumor cells, including skin, prostate, colon, breast, and lung. EGCG blocked the growth of human cervical cancer cells via cell-cycle arrest and induced apoptosis.[517] It did so by inhibiting tyrosine kinases, thus blocking MAPK signaling pathways and NF-κB and AP-1.[518] Green tea catechins can limit DNA oxidation, lipid peroxidation, and free radical production in smokers.[519]

Analysis of nearly 200 epidemiological studies examined associations between green tea consumption and risks of cancer at different sites and found that the majority of reports did not show a preventive effect. Inhibition with green tea consumption was more frequent among Asian populations, according to case-control studies.[353,354] However, tea consumption may help specific subgroups, such as lowering the risk of breast cancer only among women with low catechol-*O*-methyl transferase.[355]

Intervention studies are a more effective way to establish the protective effects of tea on cancer risk. In a double-blind study, patients at risk for prostate cancer treated with green tea catechins 600 mg/day for 1 year had a cancer rate of 3% compared with a 30% rate for the placebo group.[356] A prospective study of patients after resection for colon cancer or polypectomy employed a daily dose of EGCG 20 mg and apigenin 20 mg for up to 4 years. The recurrence rate of neoplasia was 7% for treated patients versus 47% for untreated patients.[357]

Cardiovascular disease. In apolipoprotein-E gene knockout mice, an animal model of atherosclerosis, theaflavin with quercetin reduced the formation of atherosclerotic lesions and vascular superoxide and ILB-4 while increasing vascular endothelial NOS activity, NO production, and vasodilation.[358] A meta-analysis of seven cohort and case-control studies reported an 11% decrease in the risk of myocardial infarction with daily consumption of three cups of tea.[359] A later meta-analysis of nine observational studies suggested that consumption of the equivalent of three cups of green or black tea daily was associated with a significantly reduced risk of ischemic stroke.[360]

Diabetes. A meta-analysis of RCTs regarding the possible health effects of green tea paints a conflicting picture. Analysis of seven trials with patients with diabetes and prediabetes found no effect of green tea or green tea extracts on fasting blood glucose and insulin levels or on glycemic control (as glycated hemoglobin, HbA1c, or insulin sensitivity).[361] Another meta-analysis found that green tea extract given to individuals with prediabetes, individuals with diabetes, or overweight individuals for 4 to 6 weeks improved fasting glucose and HbA1c levels, especially with high doses of catechins.[362]

BOTANICAL EXTRACTS AND ISOLATED FLAVONOIDS

Pine Bark Extract

Pine bark extract (PBE) represents a complex mixture of polyphenols enriched in procyanidolic oligomers (PCOs), containing two to seven monomers of catechin and epicatechin. PCOs are effective antioxidants in vitro and can protect and/or regenerate α-tocopherol and vitamin C. PBE can upregulate antioxidative enzymes in cultured cells[363] and also protect rodents against hepatotoxicity and oxidative stress.[364]

Inflammation. PBE can inhibit the production of ROS by macrophages blocking the expression of proinflammatory cytokines, such as IL-1β.[365] Plasma from subjects treated with PBE can block NF-κB activation and the production of matrix metalloproteinases in human monocytes.[366] Rodents fed diets supplemented with PBE had increased plasma antioxidant capacity and reduced lipid peroxidation (thiobarbituric acid reactive substances).[367] Plasma taken from healthy subjects 30 minutes after ingestion of a single dose of 300 mg of PBE had inhibited COX-1 and COX-2 in human monocytes.[368] These observations suggest that PCOs may be useful in reducing inflammation; standardized PBE has been used to treat capillary dysfunction in patients with diabetes, venous abnormalities,[369] and knee osteoarthritis.[370] As an example, the San Valentino Osteoarthritis Study found that a standardized PBE (Pycnogenol) reduced pain and stiffness and improved the flexibility of osteoarthritic joints.[371]

GRAPE SEED EXTRACT

Wine flavonoids including PCOs are effective antioxidants in vitro. They can reduce lipid peroxides and decrease the susceptibility of isolated LDL-C to oxidation. Grape seed extract (GSE) has been employed as a source of monomeric and oligomeric favon-3-ols.

Oxidative Stress. GSE treatment led to a significant postprandial reduction in plasma lipid hydroperoxides and increased antioxidant capacity in healthy volunteers.[372] Male smokers administered GSE had significantly decreased platelet reactivity compared with control subjects given a placebo.[373] Healthy volunteers consuming 430 mg GSE showed a 33% improvement in redox states 24 hours after ingestion.[374]

Diabetes. Several studies suggest that GSE may benefit patients with diabetes. Patients with type 2 diabetes received GSE 600 mg/day according to a controlled double-blind protocol. After 4 weeks, significant decreases were observed for plasma fructosamine and high-sensitivity C-reactive protein, and significant increases were seen for whole-blood GSH compared with placebo.[375] A meta-analysis of 16 RCTs concluded that GSE is associated with beneficial effects on blood pressure, especially in obese subjects and patients with metabolic disorders.[376]

Neurological Disease. Animal experiments indicate that GSE can limit lipid peroxidation in the brain.[377] GSE polyphenols have been shown to inhibit protofibril formation and protofiber oligomerization in a mouse model of Alzheimer's disease.[378]

Chemoprevention. GSE can inhibit the proliferation of a variety of cancer cell lines involving regulatory targets, such as MAPKs, NF-κB, and phosphoinositide 3-kinases (PI 3-kinases), and inhibit angiogenesis.[379] Furthermore, pretreatment with GSE protected rodents against experimentally induced hepatotoxicity, pulmonary toxicity, and doxorubicin-induced cardiotoxicity by suppressing oxidative stress.[377,380]

GINKGO BILOBA

A variety of evidence suggests the benefits of *Ginkgo biloba* extract for vascular insufficiency, cerebral insufficiency, and improved cognition. Most studies utilized a standardized extract, EGb 761.

Oxidative Stress. In part, the beneficial effects appear to be related to antioxidant and anti-inflammatory actions, and it is likely that active constituents, ginkgolides, and related flavonoids reduce oxidative stress.[381,382] Cell-culture studies suggest that EGb 761 can raise GSH levels and induce γ-glutamylcysteinyl synthetase, the rate-limiting enzyme in GSH synthesis.[383] Damage to human endothelial cells

exposed to oxidized LDL-C could be prevented by EGb 761.[384] Rats treated with EGb 761 had increased catalase and SOD activity and reduced lipid peroxidation in the hippocampus, striatum, and substantia nigra compared with controls.[385]

Aging and Dementia. Mice supplemented with EGb 761 also had less ROS-induced apoptosis in lymphocytes than untreated mice; this result was greater in old mice than in young animals.[386] In clinical studies, patients with type 2 diabetes treated with EGb 761 for 3 months were found to have reduced markers of lipid peroxidation in platelets, possibly via inhibition of the COX-1–mediated cascade.[387] Large randomized trials (the GEM Study and the Guid Age Study) found no benefits of EGb 761 supplementation for age-related cognitive decline.[388,389] A recent RCT of patients with vascular cognitive impairment found that EGb 761 treatment for 6 months slowed cognitive deterioration in only one of four neuropsychological tests.[390]

SILYMARIN

Silymarin, a flavonoid concentrate from milk thistle, and silibinin, a principal constituent of silymarin, can scavenge ROS and decrease inflammation.

Hepatoprotection. Silymarin reduced oxidative stress and prevented liver necrosis in mice exposed to toxic agents.[391] Silymarin blocked the production of TNF-α, interferon-γ, and IL-2 by stimulated peripheral blood mononuclear cells and T cells isolated from hepatitis C virus–infected and noninfected subjects.[295] Phase I to II trials of silymarin treatment have not demonstrated a consistent reduction in liver function tests and viral load or improved liver histology in patients with hepatitis C,[392] a conclusion supported by a systematic review and meta-analysis.[393] Another meta-analysis of silymarin in the treatment of nonalcoholic fatty liver disease found a significant reduction in only a single marker of liver status (aspartate transaminase and alanine transaminase).[394]

Diabetes. An open trial with patients with cirrhotic diabetes treated with 600 mg/day silymarin for 12 months reported a significant reduction in glucosuria, glycosylated hemoglobin, and malondialdehyde levels compared with controls.[395] Similar positive results were found in an RCT of treatment of patients with type 2 diabetes with 600 mg/day silymarin for 4 months.[396] A meta-analysis of 5 RCTs found that silymarin administration can lead to a significant reduction in fasting blood glucose levels and HbA1c levels but not in lipid profiles.[397]

Cancer. Androgen-responsive prostate cancer cells can be inhibited by silymarin. Using a transgenic mouse prostate cancer model, a dietary phosphatidylcholine–silibinin complex inhibited tumor growth and metastasis by reducing the expression of metalloproteinases and vascular endothelial growth factor and its receptor.[398]

QUERCETIN

Quercetin, a well-studied flavonol, acts as a strong antioxidant in vitro and possesses anti-inflammatory properties in cultured cells.

Inflammation. Experiments with guinea pig epidermal cells suggest that flavonoids, such as quercetin, can inhibit COX-2 and 5-lipoxygenase pathways to curtail production of inflammatory eicosanoids.[399] Flavonoids may reduce the expression of adhesion molecules needed to recruit white blood cells to arterial walls, a property unrelated to their antioxidant potential. Quercetin and kaempferol inhibited adhesion molecule expression induced by TNF-α in human aortic endothelial cells.[400] Preexposure of hepatocytes to flavonoids blocked this inhibitory effect, suggesting that liver biotransformation reduces the ability of flavonoids to influence endothelial cells. Quercetin supplementation of healthy volunteers with quercetin (500 or 1000 mg) together with vitamin C (125 or 250 mg) daily over 12 weeks significantly increased plasma quercetin without changing plasma oxidant capacity (FRAP and ORAC).[401]

Exercise-Induced Oxidative Stress. Stress induced by strenuous exercise increased plasma cortisone and lipid peroxides and decreased SOD, GPx, and brain catalase in rats. Treatment with quercetin significantly increased these activities while lowering plasma peroxides.[402] In contrast, long-term quercetin supplementation (1000 mg/day) in athletes did not protect against exercise-induced oxidative stress, although supplementation led to a modest improvement in maximal oxygen uptake in untrained individuals.[369,403]

Cardiovascular Disease. The Zutphen study reported an inverse relationship between the incidence of stroke and CAD and the consumption of flavonoids, particularly quercetin.[299] Short-term consumption of quercetin may improve CVD risk factors, including endothelial function, in healthy volunteers and patients with CAD.

In an RCT with a crossover design, healthy men who ingested 200 mg of quercetin experienced reduced levels of plasma endothelin-1 and increased levels of plasma nitrite and S-nitrosothiols, biomarkers of NO production.[404] Hypertensive patients supplemented with 730 mg quercetin/day had significantly reduced systolic blood pressure.[405]

Chemoprevention. Quercetin can induce apoptosis and stimulate the production of antioxidant enzymes, such as NADPH, and quinone oxidoreductase activity in human breast cancer cells.[401,406] In a study of induced lung carcinogenesis in mice, quercetin pretreatment effectively prevented losses of SOD, catalase, GPx, GSH S-transferase, and GSH reductase while limiting tumor formation.[407] Quercetin can increase the life span of tumor-bearing mice by up to fivefold through the activation of mitochondrial apoptosis.[408] A case-control study found an inverse relationship between the intake of quercetin-rich foods and lung cancer risk, especially for heavy smokers. This effect corresponded to up-regulation of GSH transferase isozymes and downregulation of cytochrome P450 isoforms.[409]

RESVERATROL

Grapes, blueberries, and peanuts contain resveratrol and methylated resveratrol, members of the stilbene family of polyphenols. Resveratrol can act as an antioxidant to scavenge free radicals and other antioxidants in vitro. It can also protect human erythrocytes against H_2O_2-induced lipid peroxidation.[410] Stilbenes are rapidly cleared, and ingestion of acute doses of resveratrol by healthy subjects achieves only nanomolar plasma concentrations, levels several orders of magnitude less than those used for in vitro or animal studies.

Cardiovascular Protection. Exposure to resveratrol correlated with decreased myocardial damage associated with ischemia-reperfusion and inhibition of LDL-C oxidation.[411] Possible mechanisms relating to anti-inflammatory effects include inhibition of COX and lipoxygenase and blocking the action of NK-κB and AP-1 in cultured cells.[412] A proteomic and immunoblot study revealed differential up-regulation of proteins related to energy metabolism in diabetic rat hearts compared with normal hearts.[413] Resveratrol may also promote vasodilation. Resveratrol was found to activate human platelet eNOS, increase NO production, and reduce NOx activity, thus lowering superoxide production.[414] It also increases NO production in vascular endothelial cells.[415]

Supplementation with a resveratrol-rich grape preparation was examined in an RCT involving patients at high risk for CVD. Consumption of 8 mg resveratrol/day for 6 months followed by 16 mg/day for another 6 months reduced levels of C-reactive protein (CRP), TNF-α, and

plasminogen activator 1, together with decreased oxidized lipoprotein levels.[416] Although preliminary human studies suggest that resveratrol may benefit cardiovascular health, it is doubtful that consuming up to 2 glasses of red wine daily can provide enough resveratrol to achieve this effect.

Diabetes. A study using experimentally induced diabetes in rats found that resveratrol reduced glucose levels compared with untreated animals. Cardioprotection of diabetic rats involved induction of eNOS, vascular endothelial growth factor, and heme oxygenase.[417] In humans, resveratrol has been linked to improved glucose and lipid metabolism. As an example, patients with type 2 diabetes were treated with 1000 mg of resveratrol daily for 45 days. Comparison with baseline and placebo measures in patients with type 2 diabetes revealed improved HbA1c levels and improved insulin sensitivity. HDL-C levels increased, and LDL-C levels decreased.[418]

Chemoprevention. In various cancer cell lines, resveratrol exposure can stimulate apoptosis and inhibit cell proliferation.[419] A study of rats fed resveratrol demonstrated that high-dose resveratrol suppressed a transgenic rat model of spontaneous prostate cancer.[420] Yet several animal studies have reported a lack of effect of oral treatment with resveratrol on lung and colon cancer.

Aging and Neuro-Protection. Resveratrol can increase longevity in a variety of organisms, including mice.[421] It may modulate transcription of the sirtuin gene family implicated in senescence, endothelial function, and angiogenesis. Sirt1, a deacetylase that silences transcription, can be induced by resveratrol in vitro. It is worth noting that low doses of resveratrol can improve cell survival by up-regulating anti-apoptotic and redox-regulating proteins, whereas high doses induce cell death by downregulating redox proteins and inducing production of apoptotic proteins.[422] Although increased cerebral blood flow in healthy young adults given an oral dose of resveratrol (250 mg) has been reported in several investigations, reproducible benefits on cognition in humans remain to be established.[423] Questions of bioavailability, long-term safety, effective dosage, and optimal duration of treatment have not yet been defined.[424] It is worth pointing out that the administration of a resveratrol preparation (SRT501) led to serious side effects, including kidney failure. Safe ways of administering high doses of resveratrol would seem imperative before forming conclusions about clinical benefits.[425]

CURCUMIN

Curcuminoids are bright yellow pigments found in turmeric and represent a family of lipophilic diketones. Curcumin, the principal curcuminoid, is poorly absorbed. Serum concentrations in the nanomolar to micromolar range can occur with a single oral dose of up to 8 g.[426] Curcumin possesses pleiotropic activities due to its ability to modify diverse signaling molecules, including proinflammatory cytokines, apoptotic proteins, NF-κB, cyclooxygenases, C-reactive protein, adhesion molecules, and more.

Inflammation. Curcumin can scavenge ROS and RNS in vitro. In cultured colonic cells, curcumin inhibited iNOS; blocked lipoxygenase, COX-2, and phospholipase A; and reduced the production of proinflammatory prostaglandins, thromboxanes, and leukotrienes by inhibiting NF-κB activation.[427] Consumption of 200 mg/day of curcuminoids decreased serum lipid peroxide levels and LDL-C lipid peroxidation in healthy subjects.[428]

Oral administration of emulsified curcumin to arthritic rats attenuated inflammation, implicating the gut–brain axis. Curcumin apparently corrected an imbalance between sympathetic and parasympathetic activity, increased vagus nerve excitability, and enhanced gut–brain acetylcholine synthesis.[429]

Clinical studies of curcumin on inflammatory conditions are preliminary. For example, an RCT of patients experiencing remission of ulcerative colitis examined high-dose curcumin supplementation in addition to standard treatment. After 6 months, 2 of 43 patients relapsed compared with 8 of 39 patients in a placebo group.[430]

Cancer. Curcumin can induce apoptosis and inhibit angiogenesis and the production of matrix metalloproteinases in several cancer cell lines. Oral curcumin administration inhibited a mouse model of familial adenomatous polyposis,[431] and it inhibited the growth of human tumors in xenotransplant animal models.

In clinical trials, curcumin has exhibited activity against multiple types of cancer. These studies demonstrated that curcumin is well tolerated at doses up to 8 g/day. As examples, treatment of patients with colorectal cancer with curcumin at a dose of 1.08 g/day for 30 days improved weight gain while reducing serum TNF-α and inducing p53 expression.[432] When patients with lung cancer who were smokers were treated with 1.5 g/day for 30 days, they had lowered urinary excretion of mutagens.[433] A Phase I trial of patients with advanced breast cancer treated with curcumin 6 g/day according to a rotation schedule demonstrated that combination with docetaxel was well tolerated.[434]

Neurodegeneration. In mouse models, curcumin can reduce Alzheimer's disease pathology. In vitro studies have shown that curcumin can block amyloid beta (Aβ) aggregation. Curcumin can cause major structural changes in amyloid aggregates and potentially reduce Aβ toxicity.[435] A mouse model of Alzheimer's disease treated with curcumin for 7 days reduced existing plaques and structural irregularities in dystrophic dendrites.[436] Of four clinical trials of curcumin supplementation for Alzheimer's disease, the two that have been reported found no significant differences in cognitive performance between treated and placebo groups.[437] Thus RCTs of patients with Alzheimer's disease that incorporated doses of curcumin ranging from 1 to 4 g per day for up to 6 months found no differences between curcumin and placebo.[438,439] Several studies of curcumin supplementation in Alzheimer's disease are ongoing or results have yet to be published.

THERAPEUTIC USE OF ANTIOXIDANTS

Immunodeficiency and Oxidative Stress

Adequate levels of proinflammatory cytokines help balance anti-inflammatory Th2-mediated responses; consequently, restoring balance is a logical therapeutic goal.[440,441] Supplementation with antioxidants, including vitamins C and E and carotenoids, along with selenium, copper, and zinc, may enhance aspects of innate and humoral immunity when used alone or in combination. These nutrients may improve lymphocyte proliferation, delayed hypersensitivity responses, and immune cell functions such as Th1 cytokine-mediated responses. However, an RCT of allergic individuals found no change in immune responses, serum antioxidant capacity, or markers of oxidative stress after 4-week supplementation with vitamins C and E, β-carotene, selenium, and zinc at levels several-fold higher than the recommended dietary allowances.[442]

A growing literature suggests that HIV infection is associated with oxidative stress. Sero-positive HIV patients were shown to have significantly reduced plasma TAC compared with healthy controls, a finding that correlated with significantly elevated lipid peroxidation and reduced levels of vitamins C and E, SOD, and oxidative stress, which may relate to HIV dementia.[443,444] A cross-sectional study demonstrated increased plasma lipid peroxide levels along with depleted GSH levels in HIV-infected individuals compared with healthy controls.[445] Low levels of reduced GSH could activate transcription factor NF-κB to increase transcription of the HIV genome.[446]

It is logical to propose that antioxidant treatment could benefit HIV-positive individuals, and polyphenols and other antioxidants can inhibit HIV infectivity of cells in vitro.[447] However, the results of clinical studies are mixed. An RCT found that oral supplementation with 1200 mg/day ALA for 10 weeks provided no benefit in treating HIV-related cognitive impairment.[448] A review of six RCTs concluded that β-carotene/vitamin A did not change overall mortality, morbidity, or CD4 and CD8 counts, whereas four RCTs of other micronutrients did find improved overall mortality.[449] Benefits of micronutrient supplementation in improving mortality among HIV-positive patients appears to involve correcting nutrient deficiencies.[450] As an added consideration, high levels of vitamin C or vitamin E can potentially interfere with indinavir therapy.[451]

EXERCISE AND OXIDATIVE STRESS

The health benefits of regular physical activity are well established. Physical inactivity is regarded as one of the most common risk factors for CVD. However, the exact mechanisms remain unclear. Some data suggest that long-term exercise increases antioxidant defenses as an adaptation. Clearly, effects vary depending on the type, intensity, frequency, and duration of exercise regimens, as well as individual fitness and medical history. Strenuous physical exercise increases ROS production and muscle fiber damage.

Regular physical activity promotes up-regulation of antioxidant defenses. Anti-inflammatory actions of exercise focus on skeletal muscle, with increased mitochondria biogenesis, increased IL-6 and IL-10, and decreased TNF-α; on adipose tissue, with decreased visceral fat, IL-6, and TNF-α and increased adiponectin; and on vasculature, with decreased NF-κB and VCAM-1.[452] The interplay of exercise-induced ROS and muscle redox-sensitive protein signaling seems to be linked to glucose homeostasis via stress-activated protein kinase and mitogen-activated protein kinase pathways.[453] Although vitamin C, vitamin E, ALA, L-carnitine, and flavonoids can attenuate certain signs and symptoms due to resistance training, they do not eliminate tissue injury.

The field is confusing because of differing markers of antioxidant status and differing training levels. Furthermore, many studies use blood levels of antioxidants and ROS-induced by-products as end points to assess antioxidant status after exercise, a practice that contributes to variable test results. It is questionable whether these end points represent tissue-level changes.

The benefits of micronutrient supplementation are most often seen in untrained subjects, rather than in athletes, especially when there are nutrient deficiencies. For example, supplementing with antioxidant vitamins such as E, C, and CoQ_{10} may decrease exercise-induced oxidative damage in untrained individuals, especially in older people.[454]

In resistance-trained men, supplementation with 1000 mg/day of vitamin C and 378 mg/day of mixed tocopherols or placebo for 14 days did not change markers of muscle injury or oxidative stress (blood protein carbonyls and peroxides).[455] Nonetheless, optimal doses of putative beneficial antioxidants and pretreatment intervals are unknown.[456] Currently, there does not appear to be enough clinical evidence for recommending antioxidant supplements for well-trained and well-nourished athletes.[457,458] Antioxidant supplementation may actually be counterproductive. As an example, an RCT of kayakers given standard antioxidants (vitamin C 400 mg, α-tocopherol 272 mg, β-carotene 30 mg, lutein 2 mg, selenium 400 mcg, zinc 30 mg, magnesium 600 mg) daily for 4 weeks found that supplementation failed to lower lipid peroxidation induced by strenuous exercise, and it reduced muscle recovery times.[459]

Do Antioxidants Explain the Health Benefits of Plant-Based Foods?

Consumption of plant-based foods rich in antioxidants was reported to decrease oxidative damage in humans by some authors,[309] although others have found little effect.[460] Analysis of data from the EPIC study found that eating five portions of fruits and vegetables daily lowered the overall risk of cancer by 9%, far less than expected.[461] Nonetheless, previous studies concluded that five servings could reduce the risk of stroke; of cancers of the oral cavity, bowel, and lung; and obesity.

Do antioxidants account for such benefits? Results of assays of antioxidant activity and assessments of oxidative stress reduction are suggestive, but as yet, there is no firm demonstration that in vitro measurements translate into specific health benefits. The FDA and the European Food Safety Authority concluded that claims cannot be made linking foods and food constituents to the protection of the body, cells, and molecules, such as DNA, proteins, and lipids, from oxidative damage.[462]

Because short-term interventions with vitamins C or E, β-carotene, or flavonoids have not demonstrated consistent health benefits, the data suggest that other plant food factors may account for such protection.[463] As an example, flavonoids seem to account for only a small percentage of the oxidant capacity of apple extracts.[294]

Antioxidant Supplementation for Disease Prevention?

A primary goal of supplementation is to correct any imbalances in an individual's nutritional status. Overall, studies suggest that the recommended dietary allowances for antioxidants are inadequate for optimal immune function for certain groups. A second goal of antioxidant supplementation is to support the body's defense systems and increase resilience. Antioxidant supplementation should be balanced against the oxidant burden.

The prevalence of subclinical deficiencies of nutrients with antioxidant roles may be quite high—magnesium (56%), zinc (12%), vitamin E (93%), and vitamin C (31%) for general populations, as judged by intakes less than an estimated average requirement.[34] More than 90% of Americans do not consume the dietary reference intake (DRI) for vitamin E of 15 mg, which is judged as adequate to prevent myopathy and neuropathy.[464] Success with antioxidant supplementation is most notable when there are deficiencies, overt or not. According to a metabolic "triage" hypothesis, low micronutrient intake can increase the risk of chronic degenerative diseases without overt deficiencies because the body's homeostatic mechanisms direct essential nutrients to support the most critical functions, leaving other functions with suboptimal levels.[34]

Multiple, complementary antioxidants are likely to be far more effective than large amounts of a single antioxidant because antioxidants often work synergistically.[465] Animal studies suggest that the consumption of a greater diversity of antioxidants is more effective than the use of single antioxidants. Daily supplementation with vitamin C (500 mg), vitamin E (400 IU), β-carotene (15 mg), zinc (80 mg), and copper (2 mg) significantly slowed the progression of advanced AMD, although this regimen did not affect the risk of cataracts or loss of visual acuity.[466] In other research, the combination of CoQ_{10}, vitamin E, and ALA was shown to act synergistically in protecting LDL-C against lipid peroxidation in vitro.[467]

Table 97.1 provides a summary of the safe upper limits of antioxidant nutrients as well as recommended allowances for adults (ages >50 years). Notably, the levels of vitamins and minerals sometimes prescribed in protocols may be considerably higher than these recommendations.

Increase Antioxidant Intake Without Supplements?

In general, the consumption of a broad spectrum of antioxidants in amounts geared to meet an individual's oxidant burden and nutritional

TABLE 97.1 Micronutrient Antioxidants for Older Adults (>50 years): Recommended Dietary Allowances (RDAs) and Tolerable Upper Intake Limits (TUILs)

Micronutrient	RDA Men	RDA Women	TUIL[a]
Vitamin A	900 μg/day	700 μg/day	3000 μg/day[b]
Vitamin C	90 mg/day	75 mg/day	200 0mg/day[b] (none established)[c]
Vitamin E	15 mg/day	15 mg/day	1000 mg/day[b] from supplements OR fortified foods (300 mg/day[c])
Beta-carotene	None established	None established	None established
Copper	900 μg/day	900 μg/day	10 μg/day (5 mg/day[c])
Magnesium	420 mg/day (adequate intake)	320 mg/day (adequate intake)	350 mg/day from supplements OR fortified foods[b]
Manganese	2.3 mg/day	1.8 mg/day	11 mg/day[b]
Selenium	55 μg/day	55 μg/day	400 μg[b]

[a]Tolerable upper intake levels represent intake from foods and supplements unless noted otherwise.

status may minimize the effects of genetic predisposition that compromise defenses against degenerative disease, promote optimal health, and slow the aging process. A safe and effective way to increase the intake of a broad spectrum of defined and undefined antioxidants relies on increased consumption of a variety of antioxidant-rich foods, especially colored fruits, vegetables, and legumes and beverages such as green tea. The utility of this strategy in designing clinical trials is illustrated by the MIND diet, based on the Mediterranean and DASH diets, which emphasizes 10 brain-healthy food groups, including green leafy vegetables, berries, nuts, and wine. This hybrid diet was shown to slow cognitive decline related to aging and to reduce the incidence of Alzheimer's disease.[468] Target dietary reference intakes for phytochemicals may eventually reflect composites beyond the currently recommended five daily servings of fruits and vegetables.[469]

LIMITS OF ANTIOXIDANT SUPPLEMENTATION

The frequent negative or conflicting results from clinical trials of antioxidant supplements may reflect wide variations in the nutritional status and heterogeneity of antioxidant intake in study populations, as well as biochemical individuality (genetic polymorphisms) and medical history, especially for an aging population for whom multiple pharmaceuticals are prescribed.

No single supplement, nutrient, or food can maintain the body's antioxidants and prevent disease, nor can single ingredients or foods cure a disease state. There are simply too many oxidants to be neutralized and too many layers of antioxidant defenses to be sustained, and the range of reactivity of water- and lipid-soluble ROS is far too great. Nor can antioxidant supplements substitute for a prudent diet and supportive lifestyle changes, including cessation of smoking, regular exercise, and effective stress management.

A personalized approach to nutritional interventions generally, and to antioxidant usage specifically, must consider individual variability. Yet major challenges remain: For most antioxidants, used singly or in combinations, the dosage, duration, efficacy, safety, and levels needed to sustain optimal health remain unknown. This is especially true for polyphenols.[470] In addition, a therapeutic window for beneficial effects is often inferred rather than clearly demonstrated.

PROOXIDANT EFFECTS

A further caveat is that antioxidant supplementation can be counterproductive. As discussed earlier, physiological levels of ROS are essential in maintaining homeostasis for multiple systems. Thus superoxide and NO play essential roles in maintaining the body's defenses and homeostatic mechanisms. Yet imbalanced antioxidants can create "antioxidative stress," in which antioxidants, especially exogenous species, can overwhelm the body's essential free radicals and ROS. Prooxidant effects of antioxidants depend on several factors, including their concentration and redox potential, the presence of other antioxidants or transition metals, and the activities of endogenous antioxidants.[471]

As examples of potential benefits versus harmful effects, acute supplementation with vitamins C, E, and α-lipid acid negated the reduction of blood pressure and the improvement in flow-mediated vasodilation due to exercise in elderly hypertensive men.[472] Transient oxidative stress, induced by short-term physical activity, can ameliorate insulin resistance. However, pretreatment with α-tocopherol 400 IU/day and vitamin C 1000 mg/day for 4 weeks prevented exercise-induced insulin sensitivity and blocked induction of endogenous antioxidant enzymes in healthy volunteers.[473] Quercetin and myricetin efficiently inhibited Trx reductase to induce apoptosis and cell-cycle arrest in tumor cell lines by direct binding and by semiquinone radical oxidation.[474] The Trx system broadly affects redox balance in normal cells and tissues, and its inhibition may be detrimental to health. Finally, moderate concentrations of ROS mediate defenses against microorganisms, as well as damaged or cancerous cells. Excessive antioxidant supplements could interfere with these essential processes.

VITAMIN E AND MORTALITY RISK?

A meta-analysis of 68 randomized trials found that supplementation up to 800 IU/day did not change the risk of all-cause mortality.[144] A more recent metaregression analysis of 29 clinical trials representing a total of 138,462 participants and vitamin E dosages ranging from 16.5 to 5000 IU/day found no causal relationship between high-dose vitamin E and mortality.[475] Indiscriminant use of high doses of vitamin E is not recommended.[188,476] Vitamin E can interfere with vitamin K–dependent clotting factors, and high doses increase the risk of bleeding in at-risk individuals.

Beta Carotene and Lung Cancer and Coronary Heart Disease?

As a further consideration, β-carotene may act as a prooxidant for those at risk for oxidative stress (smoking, alcohol consumption); β-carotene may also raise the risk of lung cancer in high-risk

populations unless protected by antioxidants like vitamin E.[477] When β-carotene is supplemented during oxidative stress, genotoxic cleavage products are produced, and these may account for the carcinogenic effects observed in the Alpha-Tocopherol, Beta-Carotene Cancer Prevention Study (ATBC) and Beta-Carotene and Retinol Efficacy Trial (CARET).[478] High levels of β-carotene may be contraindicated in smokers with myocardial infarction. In one study, the rate of fatal CHD rose in patients receiving 20 mg/day β-carotene (with or without α-tocopherol).[479] Carotenoids generally lose their effectiveness at high concentrations. This feature may account for the possible benefits of consumption of carotenoid-rich foods, although therapeutic doses of isolated carotenoids may be deleterious.[480]

Polyphenols and Mutagenicity?

The potential prooxidant actions of polyphenolic radicals are well documented.[481] Flavonoids are metabolized and detoxified by liver enzymes. Pharmacological doses of flavonoids can induce Phase I detoxification enzymes, increasing their ability to modify antioxidant metabolites for excretion. The trade-off lies in the possibly greater sensitivity to mutagens and carcinogens when toxins are transformed into potential mutagens.

Vitamin C, Toxicity, and Hypertension?

In vitro studies suggest that ascorbic acid can decompose lipid peroxides to genotoxins.[482] In vivo, these effects would likely require high ascorbate concentrations coupled with the depletion of tocopherol.[483] Vitamins C and E exhibit prooxidant activity in vitro under certain conditions. When exposed to catalytic levels of iron or copper ions, ascorbate promotes the formation of H_2O_2 and hydroxyl radicals.[484,485] Excessive dietary iron or iron accumulation could promote ascorbate-induced oxidation, and ascorbate could act as an oxidant in the presence of iron or copper released during inflammation or injury. In an RCT, hypertensive patients were treated with 500 mg ascorbic acid and/or 1000 mg grape seed polyphenols daily for 6 weeks. Although ascorbic acid alone reduced elevated systolic pressure, the combination significantly increased both systolic and diastolic blood pressure.[486]

LIMITATIONS OF ANTIOXIDANTS AS ADJUVANT CANCER THERAPY

Although antioxidant intake can influence the effectiveness of anticancer therapy and related adverse effects, results depend on the type of cancer, the mechanism of action of the prescribed drug, and the type and dosage of antioxidants.[487]

A systematic review found that 24 of 33 RCTs reported decreased toxicity of chemotherapy with concomitant use of antioxidants, including vitamin E and vitamin C, with one study of vitamin A reporting increased toxicity.[488] A study of pediatric patients with acute lymphoblastoma being treated with chemotherapy and concurrent supplementation with 400 IU vitamin E and 600 mg *N*-acetylcysteine daily for 28 days found that children taking the supplements experienced less liver toxicity, fewer blood abnormalities, and fewer blood transfusions.[489] The use of α-tocopherol succinate to inhibit tumor growth in vivo remains unproven. Because this derivative possesses no antioxidant activity, presumably its inhibition of cancer cell proliferation and induction of apoptosis in tumor cells relies on other mechanisms.

POTENTIAL NUTRIENT–DRUG INTERACTIONS AND PHYTOCHEMICAL–DRUG INTERACTIONS

The popularity of antioxidant supplementation comes with additional concerns regarding interactions with over-the-counter and prescription medications. The literature in these areas is steadily growing, and several useful compendia are available.[490–493] In addition, the editors of the *Pharmacist's Letter* publish the Natural Medicines Comprehensive Database, which is updated frequently.

Botanical supplements can promote hepatoxicity via inhibition of cytochrome P450 induction of their expression. As examples, green tea extract and isolated catechins can inhibit multiple cytochrome P450 isozymes in human liver, as well as in animal models. In addition, turmeric can inhibit drug metabolism in human liver microsomes, although human subject data are lacking.[494]

RESEARCH FRONTIERS

Redox Balance and the Gut Microbiome

Close relationships among commensals, pathogens, and the intestinal epithelium implicate ROS. As examples, *Lactobacilli* can activate NOX1 to enhance intestinal stem-cell proliferation. Disruption of the epithelial barrier can stimulate H_2O_2 release from the mucosal lining to alter the microbial redox balance and reduce virulence. H_2O_2 can directly kill pathogens, and it plays a role in intercellular microbial communication.[495]

REDOX BALANCE AND GASO-TRANSMITTER SYSTEMS

The ROS and RNS help regulate hydrogen sulfate (H_2S) and carbon monoxide, as well as NO. In particular, H_2S most likely acts as a signaling molecule to increase antioxidant defenses.[496] Lower levels of H_2S tend to be anti-inflammatory and neuroprotective. Hypothetically, H_2S regulates antioxidant genes while reducing NOX expression directly via thiol modifications, creating further linkage among H_2S, GSH, cysteine metabolism, and NO.[497]

REDOX BALANCE AND AGING

As described earlier, oxidative stress is a well-established factor in age-associated diseases. Clearly, protein dysfunction occurs during aging, and proteasome-mediated degradation of oxidized species is essential for homeostasis.[498] An increase in markers of systemic oxidative stress, such as protein carbonylation and the production of proinflammatory cytokines and lipid peroxides in older individuals, is matched by reduced expression of genes governing antioxidant responses.[499]

Any mechanisms must account for the linkage among calorie restriction, adipocyte SIRT1 activation, altered insulin sensitivity, and dysfunction of glucose regulation. Of the many proposals to account for the action of diet restriction on longevity, several relate to mitochondrial oxidative stress.[500] Cardiovascular risk factors (e.g., diabetes, hypertension, hypercholesterolemia, smoking) induce eNOS uncoupling and ROS/RNS production; eNOS glutathionylation is a possible mechanism. Strong evidence indicates that increased expression and/or activation of the NOX family, especially NOX4, plays a role in age-related disease.[501] There is interest in the role of ROS in a "geriatric syndrome," characterized by reduced functional reserve and increased vulnerability to oxidative stress.[502]

REDOX BALANCE AND MITOCHONDRIAL FUNCTION

Although global cellular oxidative stress would be expected to depend on ROS production versus ROS elimination (antioxidant defenses), ROS in mitochondria are much more dependent on highly localized ROS products than on antioxidants. Accordingly, ROS may not be viewed as by-products of the mitochondrial respiratory chain. Instead, mitochondrial ROS seem to be carefully regulated at more or

less constant levels while endogenous antioxidants and DNA repair enzymes are temporarily induced as needed.[500]

FUTURE DIRECTIONS: CONCEPTS AND STRATEGIES

Nutrigenomics

Redox homeostasis and antioxidant status depend on how the individual genetic makeup affects dietary responses and how gene–diet interactions promote disease, especially ways that food compounds affect gene expression regulating central pathways. The large-scale analysis of gene expression, individual proteins, and lipid markers, as well as the integration of metabolic pathways, can utilize functional analysis software. This approach demonstrated that a diet enriched in putative antioxidants can modulate low-grade oxidative stress and inflammation in overweight men.[503] The potential of herbs and botanicals in the prevention and treatment of conditions involving free radical pathology further enriches the future of antioxidant research.[504]

Nutrigenomics includes an examination of epigenetic processes, such as the role of microRNAs in chronic disease.[505] MicroRNAs typically regulate gene silencing, and they can be controlled by isolated nutrients and bioactive molecules, further indicating the importance of diet as related to inflammation, oxidative stress, and antioxidant defenses.

Polyphenols, particularly flavonoids, possess epigenome-regulating actions involving DNA methylation, histone acetylation, and deacetylation, as shown by studies of cultured cell lines. Quercetin, curcumin, EGCG, and berberine can function as sirtuin activators (histone acetyltransferase) while inhibiting histone deacetylase.[506] Genistein can act as an anticancer flavonoid in various cancer cell types via epigenetic control. Curcumin's pleiotropic effects in reducing liver damage in experimental cirrhosis include up-regulation of SIRT3, AMPK, and MnSOD.[507] Whether epigenetic regulation is caused by prooxidant effects or by the antioxidant nature of these flavonoids has not been established.

NUTRITIONAL COGNITIVE NEUROSCIENCE

The emerging discipline of nutritional cognitive neuroscience incorporates nutrient biomarker patterns and indices of brain health based on high-resolution magnetic resonance imaging (MRI) together with nutritional epidemiology.[508] The latter employs principal component analysis to discover nutrient biomarker patterns. With this method, a pattern of antioxidants, vitamins C and E, the B complex vitamins, and vitamin D has been associated with increased cognitive function.[509] High-throughput analytical chemistry permits examination of up to thousands of metabolites of the metabolome.[510] This approach has identified possible biomarkers for individual foods and dietary patterns, such as raspberries, citrus fruits, and overall fruit and vegetable intake.[511] Neuroimaging has been used to examine the role of diet and nutrients in structural brain changes during aging. Through this method, preservation of brain volume during aging has been associated with α-tocopherol, tocotrienol status, and vitamin C status, as well as reliance on a Mediterranean-style diet.[512]

HORMESIS

The concept of hormesis has been recommended to understand how substances such as endogenous and exogenous antioxidants promote ROS production, especially in mitochondria. In this context, these agents may act as mild prooxidants at low concentrations (picomolar/submicromolar), as antioxidants at micromolar ranges, or as toxic prooxidants at high dosages (micromolar to millimolar). Theoretically, closely regulated constitutive ROS production could create a dynamic oscillating system, in which mitochondria and calcium flux play central regulatory roles.[513]

ROS INTERACTOME

As a conceptual approach to integrating the complexity of redox balance in metabolic control, a "reactive species interactome" has been proposed.[514] Accordingly, a multilevel redox regulatory system allows the rapid adaptation to stressors to enhance resilience. System-level analysis may help sort out the ROS precursors, reaction products, and antioxidant signatures. Currently, there are no standards for nutrigenetic research outcomes in guiding the development of dietary recommendations. Criteria for evaluating the validity of this research and developing dietary guidelines have been proposed.[515]

CONCLUSION

The broad outlines for antioxidant defenses against oxidative stress are established. However, our understanding of the inner workings of redox regulation remains incomplete, and details of the body's response to oxidative stress remain poorly understood. Hundreds of redox switches have been uncovered using large-scale proteomic analysis.[516] It is not clear how ROS are compartmentalized within a given cell type; indeed, monitoring ROS in vivo remains challenging. The translation of experiential findings into a therapeutic setting requires knowledge of how the same molecules mediate both pathological events and normal physiological responses. Threshold levels transforming "good" ROS into "bad" ones are likely to be different in healthy and diseased cells. These considerations apply to the development of personalized therapeutic protocols, advanced diagnostic procedures, and precise monitoring.

Opuntia Species (Prickly Pear)

Kathy Abascal, BS, JD, RH(AHG), and *Eric L. Yarnell, ND, RH(AHG)*

OUTLINE

Opuntia spp. (family: *Cactaceae*)
Common names: prickly pear, nopal

GENERAL DESCRIPTION

There are about 260 species of *Opuntia*.[1] These cacti are shrubs, and their flat, pear-shaped pads are stems or branches, not leaves, as many suppose. Some prickly pear varieties form thickets many feet tall and many feet across. Prickly pear's flowers range from yellow to orange and red to rose (Fig. 98.1). Their fruits come in shades of yellow through red to purple. Most species have glochids, sometimes referred to as tiny spines, although they are actually leaf hairs with tiny barbs.[2] The stems, fruits, and flowers are all used as medicines.

CHEMICAL COMPOSITION

Comparisons of the constituents of the many prickly pear species are sparse, and there is no indication that any particular species is a better medicinal plant. The pad is high in mucilage, consisting of carbohydrate-containing polymers.[3] The pads also contain a mixture of saturated and unsaturated long-chain aliphatic esters; daidzein; genistein; β-sitosterol; and vanillic, ferulic, myristic, palmitic, and stearic acids.[3–6] Prickly pear fruits are high in carbohydrates and contain the pigments indicaxanthin and betanin.[7] The flowers contain flavonoids such as quercetin and isorhamnetin-3 glucosides in varying amounts.[8]

HISTORY AND FOLK USE

Prickly pear has a long history of medicinal use. The Aztecs used prickly pear root with *Geranium* spp. (cranesbill) as a febrifuge, to alleviate hernias, and to soothe irritated livers.[9] The fruit and seeds were used to prevent diarrhea. Indigenous peoples along the Yaqui River used the fluid from roasted prickly pear pads to relieve pain.[10] In New Mexico, prickly pear pads were used as poultices for painful, inflamed skin conditions; for swollen glands in the neck; and for congested, purplish breasts in lactating women. The pads were also used as emollients for tumors, warts, and calluses. The Tarahumara used the pads for the pain of bites and burns, and the Paipai used them to heal festering wounds. The Yaqui and the Hispanics in New Mexico soak diced pads in water and drink the liquid for thirst and diabetes; they also use the roasted pad to treat diabetic infections. Prickly pear was brought from the Americas to Africa and Europe, and its medicinal uses followed.[11]

Today, the Moors apply the heated pads to swellings on the body, the South African Bantu use prickly pear for a variety of tumors, and Zimbabweans use prickly pear internally as a treatment for pain in gouty arthritis.[12,13] In the Canary Islands, prickly pear fruits are used topically for a variety of inflamed wounds and internally for gastrointestinal and bronchial problems. In the Mediterranean region, prickly pear pads are used to treat gastric ulcers, and in Sicilian folk medicine, a flower infusion is used for its diuretic and relaxant action on the kidneys.[14]

PHARMACOLOGY

Analgesic Effect

Prickly pear fruits and pads were found to have significant analgesic effects in mice.[15] Prickly pear fruit injected intraperitoneally (400 mg/kg) had an analgesic effect comparable to that of aspirin (70 mg/kg) in vivo.

Anti-inflammatory Effect

Prickly pear significantly reduced edema in rat paws and showed an anti-inflammatory effect in a mouse model of chronic inflammation.[16] The active constituent was identified as β-sitosterol. Another study showed that prickly pear *(O. dillenii)* fruit extract injected intraperitoneally had anti-inflammatory action.[17] Pretreatment with prickly pear

Fig. 98.1 *Opuntia* spp. (From RinoCdZ/iStock.com. Accessed November 23, 2018.)

significantly reduced edema dose-dependently, and its maximal effect was similar to that of indomethacin.

Antiviral Effect

After reports that a woman stopped frequent recurrent outbreaks of herpes genitalis by taking 2 g prickly pear a day, studies investigated the plant's antiviral effects.[18] In hamster kidney cells, prickly pear specifically reduced herpes simplex virus type 2 (HSV-2) replication at 3.5 mg/mL and completely inhibited replication at 15 mg/mL. Prickly pear also inhibited other herpes viruses (pseudorabies virus, bovine mammillitis virus, equine herpesvirus type 1, as well as the more cell-associated human herpes virus, cytomegalovirus, and varicella-zoster virus).
