To Dr. John Bastyr and all the natural healers of the past and future who bring the "healing power of nature" to all the people of the world.
Dr. Bastyr, the namesake for Bastyr University, exemplified the ideal physician/healer/teacher we endeavor to become in our professional lives.
We pass on a few of his words of wisdom to all who strive to provide the best of health care and healing: "Always touch your patients—let them know you care," and "Always read at least one research article or learn a new remedy before you retire at night."

PREFACE

This fifth edition of the *Textbook of Natural Medicine* (which has now been in publication since 1985) brings several new features and changes to our structure and format. We are especially excited that we are in full color for the first time, including images and figures. These dramatically improve our ability to present, in a more understandable and visually interesting way, the key concepts of and insights into the underlying causes of dysfunction and disease. We are also delighted that with all the new chapters and graphics, Elsevier has moved us back to the two-volume format. To better fit the content into two logical volumes, we changed the order (and some of the titles) of the sections. Syndromes and Special Topics moved to Section V because these fit better in Volume 2 with Section VI, Diseases. Pharmacology of Natural Medicines moved to Section IV because this fits better with Volume 1. As usual, we offer many new chapters, and we think the new chapter on sarcopenia is of particular importance. In addition to new chapters, some chapters have been renamed for better consistency, and some have been moved to sections that we felt were more appropriate. To facilitate utilization, the sections are now color coded, and we have provided alphabetical tabs to help readers in searching for specific diseases. Closely related diseases have been placed in a single chapter—for example, depression, dysthymia, manic phase, and seasonal affective disorder are all located in the chapter on affective disorders chapter—so becoming familiar with these groupings is essential for finding specific diseases. There are now 14 appendices that provide additional resources for the clinician. We worked with authors to make their writing more succinct and eliminate unnecessary content. We also reduced the length of Section VI by removing duplication of content from Section V in the therapeutics portion of the chapters. We hope you will be as pleased with the latest edition as we are.

Due to the substantial increase in pages this edition, to keep down costs we had to move all of the approximately 20,000 references to the online version.

Joseph E. Pizzorno
Michael T. Murray

ACKNOWLEDGMENTS

We would like to thank Inta Ozols, the original commissioning editor, our executive assistant Lavelle Brown (who so effectively organized and managed all the authors and chapters), and the dedicated staff at Elsevier (Kristin Wilhelm, Linda Woodard, Laurie Gower, Becky Leenhouts, Jeff Patterson, Julie Eddy, Clay Broeker, Margaret Reid, Deanna Sorenson, and Allison Kieffer) for their excellent work in making this the best edition ever.

SECTION 1

Philosophy of Natural Medicine

One of the key features of the various schools of natural medicine that differentiates them from conventional medicine is their strong philosophical foundation. The basic philosophical premise of naturopathic medicine, for example, is that there is an inherent healing power in nature and in every human being. We believe that a primary role of the physician is to "remove the blocks to cure" and enhance this innate healing power within his or her patients.

In many ways, this was the most difficult section of the textbook to write because, before this textbook, no comprehensive history of the social, political, and philosophical development of naturopathic medicine had ever been written. Even in the halcyon years of the 1920s and 1930s, the profession was never able to agree upon a concise philosophy. This situation has now changed.

In this section, we provide well-documented chapters detailing the roots of American natural medicine. After a century of maturation, the naturopathic profession has now widely agreed to a comprehensive definition, set of principles, and system of case analysis that provide a systematic guide for the application of these concepts in a clinical setting.

The seven fundamental principles of naturopathic medicine are as follows:

The healing power of nature *(vis medicatrix naturae)*
First, do no harm *(primum non nocere)*
Find the cause *(tolle causam)*
Treat the whole person
Preventive medicine
Wellness
Doctor as teacher

These principles translate into the following questions the practitioner applies when analyzing a case:

- What is the first cause; what is contributing now?
- How is the body trying to heal itself?
- What is the minimum level of intervention needed to facilitate the self-healing process?
- What are the patient's underlying functional weaknesses?
- What education does the patient need to understand why he or she is sick and how to become healthier?
- How does the patient's physical disease relate to his or her psychological and spiritual health?

We have further expanded on the philosophical basis of naturopathic medicine by having these concepts addressed by several authors whose backgrounds allow each of them a unique and, we believe, complementary insight into some of the fundamental questions of the goals of health care. Although the dominant school of medicine has essentially ignored these issues, we believe that the true physician cannot function without a sound philosophical basis to guide his or her actions. Without more than a superficial understanding of health and disease, the physician is more likely to function as a technician, temporarily alleviating symptoms while allowing the real disease to progress past the point of recovery. The huge and increasing burden of chronic disease in all age groups clearly validates the predictions of the founders of naturopathic medicine that primarily treating symptoms, while not addressing causes, results in increased chronic disease.

1

Functional Medicine: A 21st-Century Model of Patient Care and Medical Education

Robert Luby, MD, and *Leo Galland*, AB, MD*

OUTLINE

In this chapter, the basic principles, constructs, and methodology of functional medicine are reviewed. It is not the purpose of this chapter to recapitulate the range and depth of the science underlying functional medicine; books and monographs covering that material in great detail are already available for the interested clinician and for use in health professional schools (see Bibliography at the end of the chapter). The purpose is to describe how functional medicine is organized to deliver personalized systems medicine and is equipped to respond to the challenge of treating complex chronic disease more effectively.

WHAT IS FUNCTIONAL MEDICINE?

Functional medicine encompasses a dynamic approach to assessing, preventing, and treating complex chronic disease. It helps clinicians of all disciplines identify and ameliorate dysfunctions in the physiology and biochemistry of the human body as a primary method of improving patient health. This model of practice emphasizes that chronic disease is almost always preceded by a period of declining function in one or more of the body's physiological organizing systems. Returning patients to health requires reversing (or substantially improving) the specific dysfunctions that contributed to the disease state. Those dysfunctions are, for each of us, the result of lifelong interactions among diet, environment, lifestyle choices, and genetic predispositions. Each patient, therefore, represents a unique, complex, and interwoven set of influences on intrinsic functionality that, over time, set the stage for the development of disease or the maintenance of health. To manage the complexity inherent in this approach, functional medicine has adopted practical models for obtaining and evaluating clinical information that leads to individualized patient-centered therapies.

Historically, the word *functional* was used somewhat pejoratively in medicine. It implied a disability associated with either a geriatric or psychiatric problem. The authors suggest, however, that this is a very limited definition of an extremely useful word. The medical profession has not really produced an efficient method for identifying and assessing changes in basic physiological processes that produce symptoms of increasing duration, intensity, and frequency, although it is known that such alterations in function often represent the first signs of conditions that, at a later stage, become pathophysiologically definable diseases. By broadening the use of *functional* to encompass this view, functional medicine becomes the science and art of detecting and reversing alterations in function that clearly move a patient toward chronic disease over the course of a lifetime.

One way to conceptualize where functional medicine falls in the continuum of health and health care is to examine the functional medicine "tree." In its approach to complex chronic disease, functional medicine encompasses the whole domain represented by the graphic shown in Fig. 1.1, but it first addresses the patient's core clinical imbalances (found in the functional physiological organizing systems); the fundamental lifestyle factors that contribute to chronic disease; and the antecedents, triggers, and mediators that initiate and maintain the disease state. Diagnosis, of course, is part of the functional medicine model, but the emphasis is on understanding and improving the functional core of the human being as the starting point for intervention.

Functional medicine clinicians focus on restoring balance and improved function in the dysregulated systems by strengthening the fundamental physiological processes that underlie them and by adjusting the environmental and lifestyle inputs that nurture or impair them. This approach leads to therapies that focus on restoring health and function, rather than simply controlling signs and symptoms.

PRINCIPLES

Seven basic principles characterize the functional medicine paradigm:

- Acknowledging the biochemical individuality of each human being, based on the concepts of genetic and environmental uniqueness
- Incorporating a patient-centered rather than a disease-centered approach to treatment

*Previous edition contributor

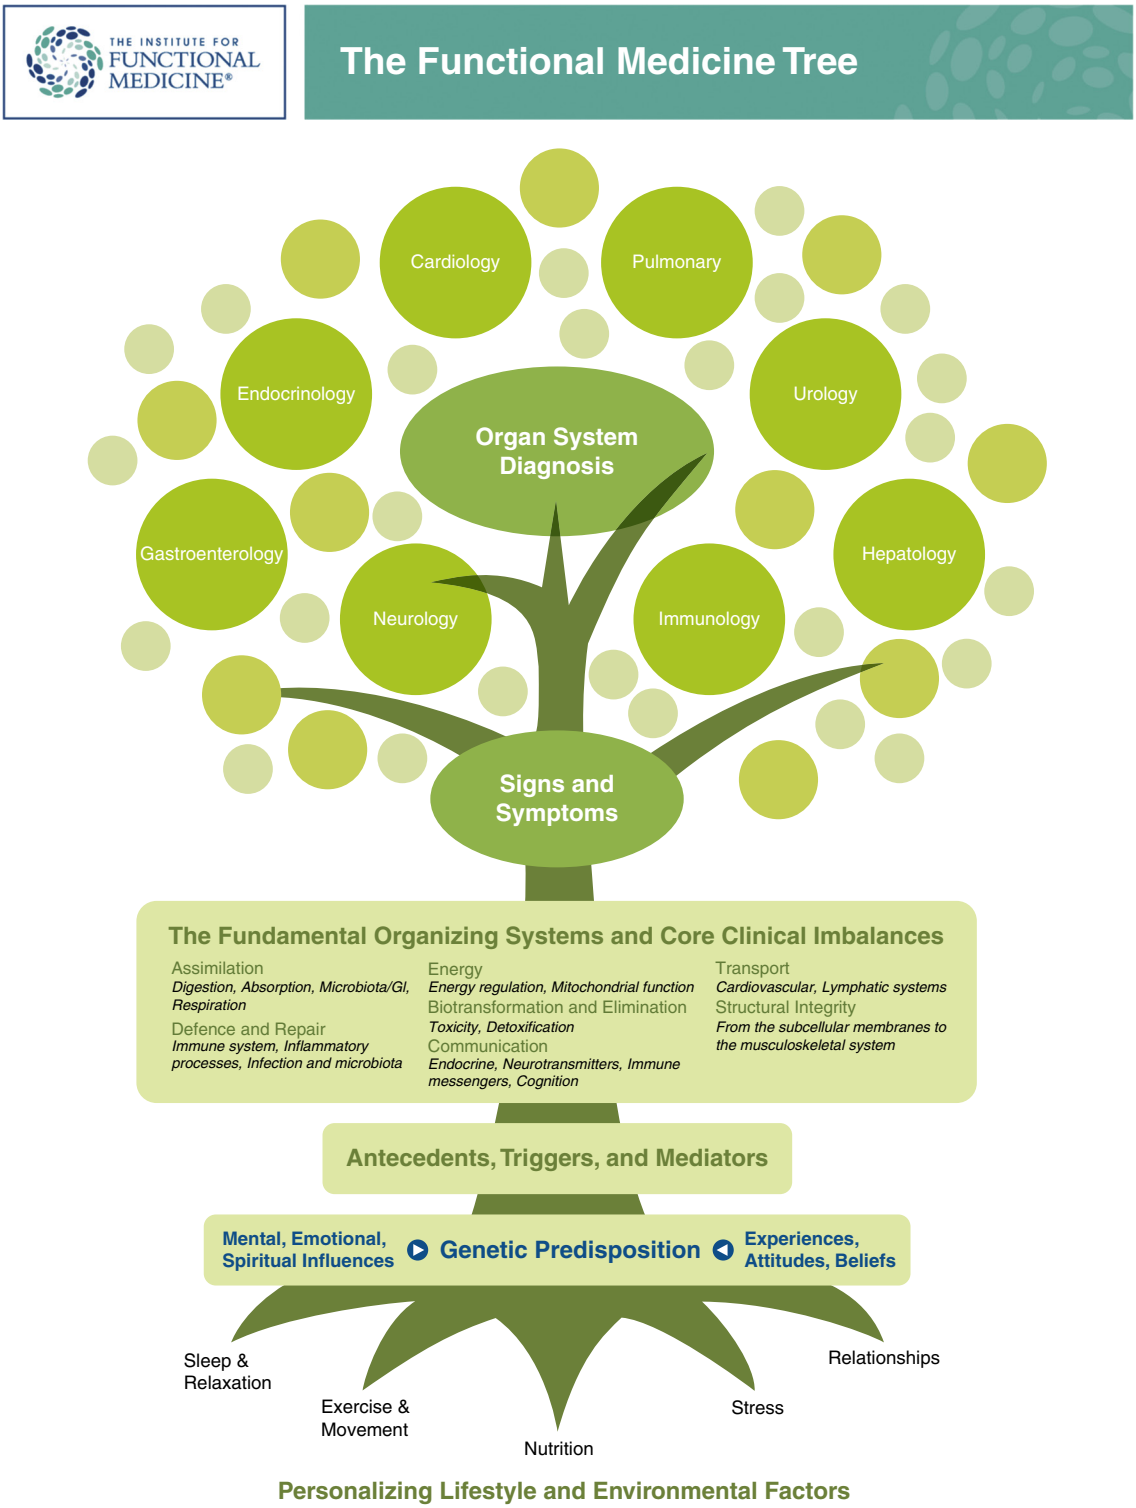

Fig. 1.1 The continuum of health and health care: the functional medicine tree. (Courtesy the Institute for Functional Medicine.)

- Seeking a dynamic balance among the internal and external factors in a patient's body, mind, and spirit
- Addressing the web-like interconnections of internal physiological factors
- Identifying health as a positive vitality—not merely the absence of disease—and emphasizing those factors that encourage a vigorous physiology
- Promoting organ, cellular, and subcellular function as the means of enhancing the health span, not just the life span, of each patient
- Staying abreast of emerging research—a science- and evidence-based approach

LIFESTYLE AND ENVIRONMENTAL FACTORS

The building blocks of life, and the primary influences on them, are found at the base of the functional medicine tree graphic (see Fig. 1.1). When we talk about influencing gene expression, we are interested in the interaction between lifestyle and environment in the broadest sense and any genetic predispositions with which a person may have been born—in a word, the epigenome. (Epigenetics is the study of how environmental factors can affect gene expression without altering the actual DNA sequence and how these changes can be inherited through generations.) Many environmental factors that affect gene expression are (or appear to be) a matter of choice (such as diet and exercise), others are very difficult for the individual patient to alter or escape (air and water quality, toxic exposures), and still others may be the result of unavoidable accidents (trauma, exposure to harmful microorganisms). Some factors that may appear modifiable are heavily influenced by the patient's economic status—if you are poor, for example, it may be impossible to choose more nutritious food, decrease stress in the workplace and at home, or take the time to exercise and rest properly. Existing health status is also a powerful influence on the patient's ability to alter environmental input. If you have chronic pain, exercise may be extremely difficult; if you are depressed, self-activation is a major challenge.

The influence of these lifestyle and environment factors on the human organism is indisputable,[1,2] and they are often powerful agents in the attempt to restore health. Neglecting to address them in favor of merely writing a prescription—whether for pharmaceutical agents, nutraceuticals, or botanicals—means the cause of the underlying dysfunction may itself remain unaddressed and further able to contribute to the genesis of other disease conditions. In general terms, the following factors should be considered when working to reverse dysfunction or disease and restore health:

- Diet (type, quality, and quantity of food; food preparation; calories, fats, proteins, carbohydrates)
- Nutrients (both dietary and supplemental)
- Air and water
- Microorganisms (and the general condition of the soil in which food is grown)
- Physical exercise
- Trauma
- Psychosocial and spiritual factors, such as meaning and purpose, relationships, work, community, economic status, stress, and belief systems
- Xenobiotics
- Radiation

FUNDAMENTAL PHYSIOLOGICAL PROCESSES

There are certain physiological processes that are necessary to life. These are the "upstream" processes that can go awry and create "downstream" dysfunctions that eventually become expressed as disease entities. Functional medicine requires that clinicians consider these in evaluating patients so that interventions can target the most fundamental level possible. These processes are as follows:

1. Communication
   - Intracellular
   - Intercellular
   - Extracellular
2. Bioenergetics/energy transformation
3. Assimilation
4. Structural integrity
5. Biotransformation/elimination
6. Defense and repair
7. Transport/circulation

These fundamental physiological processes are usually taught early in health professions curricula, where they are appropriately presented as the foundation of modern, scientific patient care. Unfortunately, subsequent training in the clinical sciences often fails to fully integrate knowledge of the functional mechanisms of disease with therapeutics and prevention, emphasizing organ system diagnosis instead.[3] Focusing predominantly on organ-system diagnosis without examining the underlying physiology that produced the patient's signs, symptoms, and disease often leads to managing patient care by matching diagnosis to pharmacology. The job of the health care provider then becomes a technical exercise in finding the drug or procedure that best fits the diagnosis (not necessarily the patient or the underlying physiological dysfunction), leading to a significant curtailment of critical thinking pathways: "Medicine, it seems, has little regard for a complete description of how myriad pathways result in any clinical state."[4]

Even more important, pharmacological treatments (and even natural remedies) are often prescribed without careful consideration of their physiological effects across all organ systems, physiological processes, and genetic variations.[5] This was notably exemplified by the cyclooxygenase-2 inhibitor drugs that were so wildly successful on their introduction, only to be subsequently withdrawn or substantially narrowed in use because of collateral damage.[6,7]

CORE CLINICAL IMBALANCES

The functional medicine approach to assessment, both before and after diagnosis, charts a course using different navigational assumptions. Every health condition instigates a quest for information centered on understanding when and how the specific biological system(s) under examination became dysregulated and began manifesting dysfunction and/or disease. Analyzing all the elements of the patient's story, the signs and symptoms, and the laboratory assessment through a matrix focused on functionality requires analytical thinking and a willingness on the part of the clinician to reflect deeply on the underlying biochemistry and physiology. The foundational principles of how the human organism functions—and how its systems communicate and interact—are essential to the process of linking ideas about multifactorial causation with the perceptible effects called disease or dysfunction.

To assist clinicians in this process, functional medicine identified and organized a set of core clinical imbalances that are linked to the fundamental physiological processes (organizing systems). These serve to marry the mechanisms of disease with the manifestations and diagnoses of disease. Many common underlying pathways of disease are reflected in these clinical imbalances. The following list of imbalanced systems and processes is not definitive, but some of the most common examples are provided. We recommend that the organizing systems be considered in the order as shown in the following list:

- Digestion
- Absorption

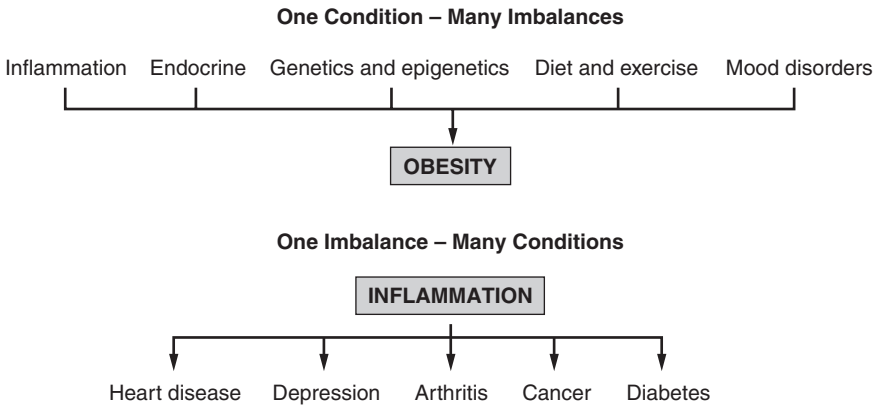

Fig. 1.2 Core clinical imbalances—multiple influences. (Courtesy the Institute for Functional Medicine.)

- Microbiome/gastrointestinal
- Respiration
- Immune system
- Inflammatory processes
- Infection and microbiome
- Energy regulation
- Mitochondrial function
- Toxicity
- Detoxification
- Endocrine
- Neurotransmitter
- Immune messengers
- Cognition
- From the subcellular membranes
- To the musculoskeletal system

Using this construct, it becomes much clearer that one disease and/or condition may have multiple causes (i.e., multiple clinical imbalances), just as one fundamental imbalance may be at the root of many seemingly disparate conditions (Fig. 1.2).

The most important precept to remember about functional medicine is that restoring balance—in the patient's lifestyle and/or environment and in the body's fundamental physiological processes—is the key to restoring health.

ANTECEDENTS, TRIGGERS, AND MEDIATORS[8]

What modern science has taught us about the genesis of disease can be represented by three words: *triggers, mediators,* and *antecedents.* Triggers are discrete entities or events that provoke disease or its symptoms. Microbes are an example. The greatest scientific discovery of the 19th century was the microbial etiology of the major epidemic diseases. Triggers are usually insufficient in and of themselves for disease formation; however, host response is an essential component.

It is, therefore, the functional medicine practitioner's job to know not just the patient's ailments or diagnoses but also the physical and social environment in which illness occurs, the dietary habits of the person (present diet and preillness diet), his or her beliefs about the illness, the effect of illness on social and psychological function, factors that aggravate or ameliorate symptoms, and factors that predispose to illness or facilitate recovery. This information is necessary for establishing a functional medicine treatment plan.

Identifying the biochemical mediators that underlie host responses was the most productive field of biomedical research during the second half of the 20th century. Mediators, as the word implies, do not cause disease. They are intermediaries that contribute to the manifestation and/or continuation of disease. Antecedents are factors that predispose to acute or chronic illness. For a person who is ill, antecedents form the illness diathesis. From the perspective of prevention, they are risk factors. Knowledge of antecedents provides a rational structure for the organization of preventive medicine and public health.

Medical genomics seeks to better understand disease by identifying the phenotypic expression of disease-related genes and their products. The application of genomic science to clinical medicine requires the integration of antecedents (genes and the factors controlling their expression) with mediators (the downstream products of gene activation). Mediators, triggers, and antecedents are not only key biomedical concepts; they are also important psychosocial concepts. In person-centered diagnosis, the mediators, triggers, and antecedents for each person's illness form the focus of the clinical investigation.

Antecedents and the Origins of Illness

Understanding the antecedents of illness helps the physician understand the unique characteristics of each patient as they relate to his or her current health status. Antecedents may be thought of as congenital or developmental. The most important congenital factor is gender: women and men differ sharply in susceptibility to many disorders. The most important developmental factor is age; what ails children is rarely the same as what ails the elderly. Beyond these obvious factors lies a diversity as complex as the genetic differences and separate life experiences that distinguish one person from another.

Triggers and the Provocation of Illness

A trigger is anything that initiates an acute illness or the emergence of symptoms. The distinction between a trigger and a precipitating event is relative, not absolute; the distinction helps organize the patient's story. As a general rule, triggers only provoke illness as long as the person is exposed to them (or for a short while afterward), whereas a precipitating event initiates a change in health status that persists long after the exposure ends.

Common triggers include physical or psychic trauma, microbes, drugs, allergens, foods (or even the act of eating or drinking), environmental toxins, temperature change, stressful life events, adverse social interactions, and powerful memories. For some conditions, the trigger is such an essential part of our concept of the disease that the two cannot be separated; the disease is either named after the trigger (e.g., strep throat) or the absence of the trigger negates the diagnosis (e.g., concussion cannot occur without head trauma). For chronic ailments like asthma, arthritis, or migraine headaches, multiple interacting triggers may be present. All triggers, however, exert their effects through the activation of host-derived mediators. In closed-head trauma, for example, activation of N-methyl-d-aspartic acid receptors, induction of nitric oxide synthase, and liberation of free intraneuronal calcium

BOX 1.1 Common Illness Mediators

Biochemical Hormones
Neurotransmitters
Neuropeptides
Cytokines
Free radicals
Transcription factors

Subatomic
Ions
Electrons
Electrical and magnetic fields

Cognitive/Emotional
Fear of pain or loss
Feelings or personal beliefs about illness
Poor self-esteem, low perceived self-efficacy
Learned helplessness
Lack of relevant health information

Social/Cultural
Reinforcement for staying sick
Behavioral conditioning
Lack of resources because of social isolation or poverty
The nature of the sick role and the doctor–patient relationship

determine the late effects. Intravenous magnesium at the time of trauma attenuates the severity by altering the mediator response.[9,10] Sensitivity to different triggers often varies among persons with similar ailments. A prime task of the functional practitioner is to help patients identify important triggers for their ailments and develop strategies for eliminating them or diminishing their virulence.

Mediators and the Formation of Illness

A mediator is anything that produces or perpetuates symptoms or damages tissues of the body, including certain behaviors. Mediators vary in form and substance. They may be biochemical (e.g., prostanoids and cytokines), ionic (e.g., hydrogen ions), social (e.g., reinforcement for staying ill), psychological (e.g., fear), or cultural (e.g., beliefs about the nature of illness). A list of common mediators is presented in Box 1.1. Illness in any single person usually involves multiple interacting mediators. Biochemical, psychosocial, and cultural mediators interact continuously in the formation of illness.

CONSTRUCTING THE MODEL

Assessment

Combining the principles, lifestyle and environment factors, fundamental physiological processes, antecedents, triggers, mediators, and core clinical imbalances demands a new architecture for gathering and sorting information for clinical practice—in effect, a new heuristic to serve the practice of functional medicine. (Heuristics are rules of thumb—ways of thinking or acting—that develop through experimentation and enable more efficient and effective processing of data.) This new model includes an explicit emphasis on principles and mechanisms that infuse meaning into the diagnosis and deepen the clinician's understanding of the multivalent contributors to physiological dysfunction. Any methodology for constructing a coherent story and an effective therapeutic plan in the context of complex chronic illness must be flexible and adaptive. Like an accordion file that compresses and expands upon demand, the amount and kind of data collected will necessarily change in accordance with the patient's situation and the clinician's time and ability to piece together the underlying threads of dysfunction.

The conventional assessment process involving the chief complaint, history of present illness, and past medical history sections must be expanded (Fig. 1.3) to include a thorough investigation of antecedents, triggers, and mediators and a systematic evaluation of any imbalances within the fundamental organizing systems. Personalized medical care without this expanded investigation falls short.

The Functional Medicine Matrix Model

Distilling the data from the expanded history, physical examination, and laboratory findings into a narrative storyline that includes antecedents, triggers, and mediators can be challenging. Key to developing a thorough narrative is organizing the story using the Functional Medicine Matrix Model form (Fig. 1.4).

The matrix form helps organize and prioritize information and also clarifies the level of present understanding, thus illuminating where further investigation is needed. For example:

- Indicators of inflammation on the matrix might lead the clinician to request tests for specific inflammatory markers (such as highly sensitive C-reactive protein, interleukin levels, and/or homocysteine).
- Essential fatty acid levels, methylation pathway abnormalities, and organic acid metabolites help determine the adequacy of dietary and nutrient intakes.
- Markers of detoxification (glucuronidation and sulfation, cytochrome P450 enzyme heterogeneity) can determine the functional capacity for molecular biotransformation.
- Neurotransmitters and their metabolites (vanilmandelate, homovanillate, 5-hydroxyindoleacetate, quinolinate) and hormone cascades (gonadal and adrenal) have obvious utility in exploring messenger molecule balance.
- Computed tomographic scans, magnetic resonance imaging (MRI), or plain radiographs extend the view of the patient's structural dysfunctions. The use of bone scans, dual-energy x-ray absorptiometry scans, or bone resorption markers[11,12] can be useful in further exploring the web-like interactions of the matrix.
- Newer, useful technologies such as functional MRIs, single-photon emission computed tomography, and positron emission tomographic scans offer a more comprehensive assessment of metabolic function within organ systems.

It is the process of completing a comprehensive history and physical using the expanded functional medicine heuristic and then charting these findings on the matrix that best directs the choice of diagnostic evaluations and successful treatment.

Therapies should be chosen for their potential effect on the most significant imbalances of the particular patient. A completed matrix form facilitates review of common pathways, mechanisms, and mediators of disease and helps clinicians select points of leverage for treatment strategies. However, even with the matrix as an aid to synthesizing and prioritizing information, it can be very useful to consider the effect of each variable at five different levels:

1. Whole-body interventions: Because the human organism is a complex adaptive system, with countless points of access, interventions at one level will affect points of activity in other areas as well. For example, improving the patient's sleep beneficially influences the immune response, melatonin levels, and T-cell lymphocyte levels and helps decrease oxidative stress. Exercise reduces stress, improves insulin sensitivity, and improves detoxification. Reducing stress (and/or improving stress management) reduces cortisol

levels, improves sleep, improves emotional well-being, and reduces the risk of heart disease. Changing the diet has myriad effects on health, from reducing inflammation to reversing coronary artery disease.

2. Organ-system interventions: These interventions are used more frequently in the acute presentation of illness. Examples include splinting; draining lesions; repairing lacerations; reducing fractures, pneumothoraxes, hernias, or obstructions; or removing a stone to reestablish whole-organ function. There are many interventions that improve organ function. For example, bronchodilators improve air exchange, thereby decreasing hypoxia, reducing oxidative stress, and improving metabolic function and oxygenation in a patient with reactive airway disease.
3. Metabolic or cellular interventions: Cellular health can be addressed by ensuring the adequacy of macronutrients, essential amino acids, vitamins, and cofactor minerals in the diet (or, if necessary, from supplementation). An individual's metabolic enzyme polymorphisms can profoundly affect his or her nutrient requirements. For example, adding conjugated linoleic acid to the diet can alter the peroxisome proliferator–activated receptor system, affect body weight, and modulate the inflammatory response.[13–15] However, in a person who is diabetic or insulin resistant, adding conjugated linoleic acid may induce hyperproinsulinemia, which is detrimental.[16,17] Altering the types and proportions of carbohydrates in the diet may increase insulin sensitivity, reduce insulin secretion, and fundamentally alter metabolism in the insulin-resistant patient. Supporting liver detoxification pathways with supplemental glycine and *N*-acetylcysteine improves the endogenous production of adequate glutathione, an essential antioxidant in the central nervous system and gastrointestinal tract.

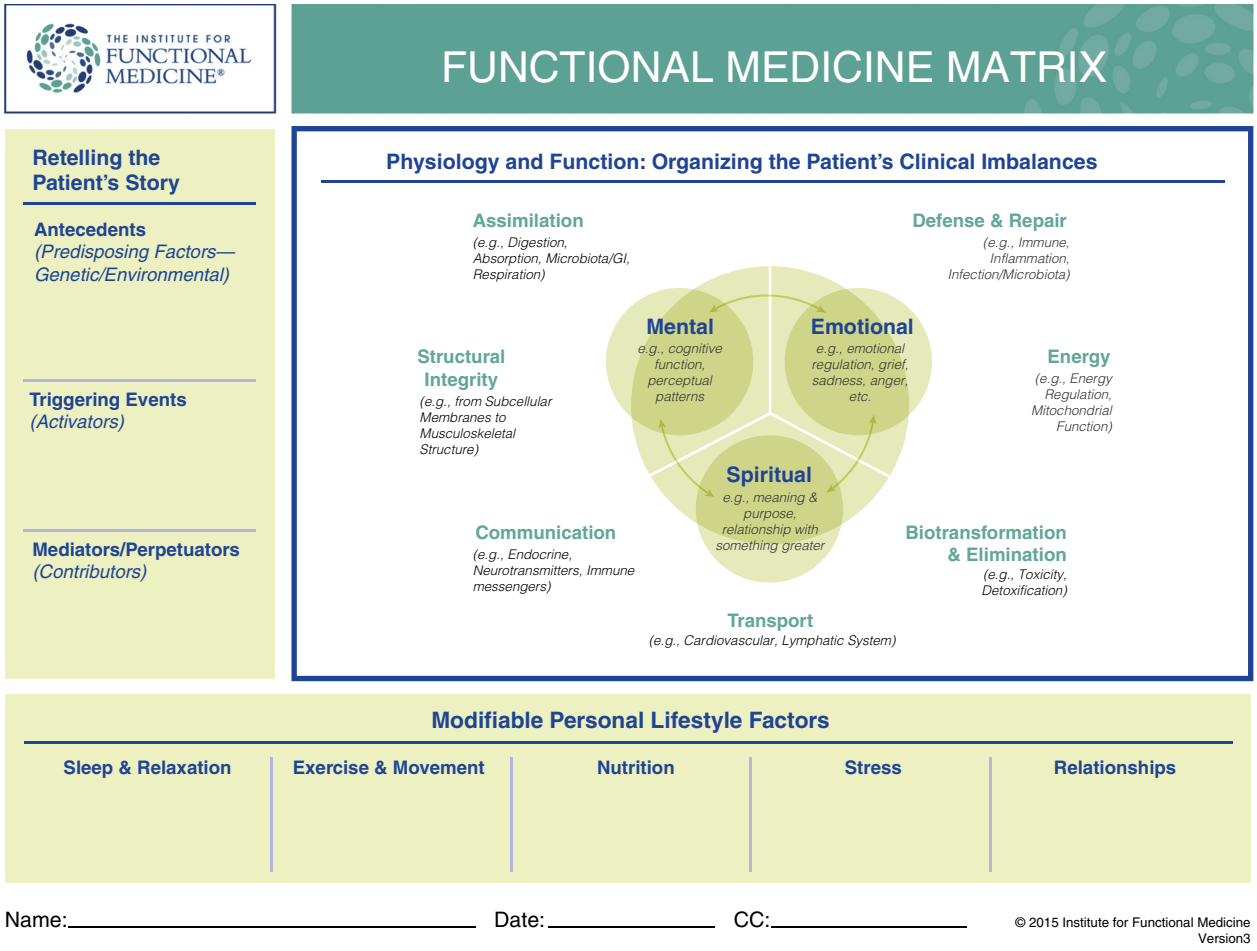

Fig. 1.4 The Functional Medicine Matrix Model. (Courtesy the Institute for Functional Medicine.)

4. Subcellular/mitochondrial interventions: There are many examples of nutrients that support mitochondrial function.[18,19] Inadequate iron intake causes oxidants to leak from mitochondria, damaging mitochondrial function and mitochondrial DNA. Making sure there is sufficient iron helps alleviate this problem. Inadequate zinc intake (found in more than 10% of the U.S. population) causes oxidation and DNA damage in human cells.[19] Ensuring the adequacy of antioxidants and cofactors for the at-risk individual must be considered in each part of the matrix. Carnitine, for example, is required as a carrier for the transport of fatty acids from the cytosol into the mitochondria, improving the efficiency of β-oxidation of fatty acids and resultant adenosine triphosphate production. In patients who have lost significant weight, carnitine undernutrition can result in fatty acids undergoing ω-oxidation, a far less efficient form of metabolism.[20] Patients with low carnitine may also respond to riboflavin supplementation.[20]
5. Subcellular/gene-expression interventions: Many compounds interact at the gene level to alter cellular response, thereby affecting health and healing. Any intervention that alters nuclear factor-κB entering the nucleus, binding to DNA, and activating genes that encode inflammatory modulators, such as interleukin-6 (and thus C-reactive protein), cyclooxygenase-2, interleukin-1, lipoxygenase, inducible nitric oxide synthase, tumor necrosis factor-α, or a number of adhesion molecules, will affect many disease conditions.[21,22] There are many ways to alter the environmental triggers for nuclear factor-κB, including lowering oxidative stress; altering emotional stress; and consuming adequate phytonutrients, antioxidants, alpha-lipoic acid, eicosapentaenoic acid, docosahexaenoic acid, and γ-linoleic acid.[21] Adequate vitamin A allows the appropriate interaction of vitamin A–retinoic acid with more than 370 genes.[23] Vitamin D in its most active form intercalates with a retinol protein and the DNA exon and modulates many aspects of metabolism, including cell division in both healthy and cancerous breast, colon, prostate, and skin tissue.[24] Vitamin D has key roles in controlling inflammation, calcium homeostasis, bone metabolism, cardiovascular and endocrine physiology, and healing.[24]

Experience using this model, along with improved pattern-recognition skills, will often lessen the need for extensive laboratory assessments. However, there will always be certain clinical conundrums that simply cannot be assessed without objective data, and for most patients, there may be an irreducible minimum of laboratory assessments required to accumulate information. For example, in the clinical workup of autism spectrum disorders in children, heavy-metal exposure and toxicity may play an important role. The heavy-metal body burden cannot be sensibly assessed without laboratory studies. In most initial workups, laboratory and imaging technologies can be reserved for those complex cases in which the initial interventions prove insufficient to the task of functional explication. When clinical acumen and educated steps in both assessments and therapeutic trials do not yield expected improvement, laboratory testing often provides rewarding information. This is frequently the context for focused genomic testing.

The Healing Partnership

No discussion of the functional medicine model would be complete without mention of the therapeutic relationship. Partnerships are

formed to achieve an objective. For example, a business partnership forms to engage in commercial transactions for financial gain; a marriage partnership forms to build a caring, supportive, home-centered environment. A healing partnership forms to heal the patient through the integrated application of both the art of medicine (insight driven) and the science of medicine (evidence driven). An effective partnership requires that trust and rapport be established. Patients must feel comfortable telling their stories and revealing intimate information and significant events.

In the 20th century, contemporary medicine, traditionally considered a healing profession, evolved away from the role of healing the sick to that of curing disease through modern science. Research into this transition revealed that healing was traditionally associated with themes of wholeness, narrative, and spirituality. Professionals and patients alike report healing as an intensely personal, subjective experience involving a reconciliation of meaning for an individual and a perception of wholeness. The biomedical model as currently configured no longer encompasses these characteristics.

Contemporary medicine considers the wholeness of healing to be beyond its orthodoxy—the domain of the nonscientific and nonmedical.[25] We disagree. To grasp the profound importance of the healing partnership to the creation of a system of medicine adequate to the demands of the 21st century, an emerging body of relevant research was reviewed.[26–28] As Louise Acheson, MD, MS, associate editor of the *Annals of Family Practice,* articulated insightfully in that journal[29]: "It is challenging to research this ineffable process called healing."

Hsu and colleagues asked focus groups of nurses, physicians, medical assistants, and randomly selected patients to define healing and describe what facilitates or impedes it.[30] The groups arrived at surprisingly convergent definitions: "Healing is a dynamic process of recovering from a trauma or illness by working toward realistic goals, restoring function, and regaining a personal sense of balance and peace." They heard from diverse participants that "healing is a journey" and "relationships are essential to healing."

Research into the role of healing in the medical environment has generated some thoughtful and robust investigations. Scott et al.'s[26] research into the healing relationship found very similar descriptions to those of Hsu et al.[30] The participants in the study[27] articulated aspects of the healing partnership as follows:

1. Valuing and creating a nonjudgmental emotional bond
2. Appreciating power and consciously managing clinician power in ways that would most benefit the patient
3. Abiding and displaying a commitment to caring for patients over time

Three relational outcomes result from these processes: trust, hope, and a sense of being known. Clinician competencies that facilitate these processes are self-confidence, emotional self-management, mindfulness, and knowledge.[27] In this rich soil, the healing partnership flourishes.

The characteristics of a conventional therapeutic encounter are fundamentally different from a healing partnership, and each emerges from specific emphases in training. In the therapeutic encounter, the relationship forms to assess and treat a medical problem using (usually) an organ-system structure, a differential diagnosis process, and a treatment toolbox focused on pharmacology and medical procedures. The therapeutic encounter pares down the information flow between physician and patient to the minimum needed to identify the organ-system domain of most probable dysfunction, followed by a sorting system search (the differential diagnosis heuristic). The purpose of this relationship is to arrive at the most probable diagnosis as quickly as possible and select an intervention based on probable efficacy. The relationship is a left-brain–guided conversation controlled by the clinician and characterized by algorithmic processing and statistical thinking.[31,32]

The functional medicine healing partnership forms with a related but broader purpose: to help the patient heal by identifying the underlying mechanisms and influences that initiated and continue to mediate the patient's illness(es). This type of relationship emphasizes shared responsibility for identifying the causes of the patient's condition and achieving insight about enduring solutions. The healing partnership is critical to the delivery of personalized systems of medicine and to managing the uncertainty (choices under risk) inherent in clinical practice. In the healing partnership, the appropriate utilization and integration of left-brain and right-brain functions are found.

In language, we have the fullest expression of the integration of left- and right-brain function. Language is so complex that the brain has to process it in different ways simultaneously—both denotatively and connotatively. For complexity and nuance to emerge in language, the left brain needs to see the trees, and the right brain helps us see and understand the forest.[33,34]

The starting point for creating a healing partnership is the patient's experience. People, not diseases, can heal. Mindful integration of brain function is at the heart of a healing partnership. Some of the basic steps for establishing a healing partnership include the following:

1. Allowing patients to express, without interruption, their story about why they have come to see you. (Research focused on the therapeutic encounter has repeatedly found that clinicians interrupt the patient's flow of conversation within the first 18 seconds or less, often denying the patient an opportunity to finish.[35]) The manner in which the patient frames the initial concerns often presages later insight into the root causes. Any interruption in this early stage of narrative moves the patient back into left-brain processing and away from insight.[36]
2. After focusing on the chief concerns, encouraging the patient's narrative regarding the present illness(es). Clarifications can be elicited by further open-ended questioning (e.g., "Tell me more about that"; "What else do you think might be going on?"). During this portion of the interview, there is a switching back and forth between right- and left-brain functions.
   - During this conversation, signs and symptoms of the present illness are distributed by the practitioner into the Functional Medicine Matrix Model form as previously described.
   - Analysis of the data thus collected proceeds by assessing probable underlying causes—based on evidence about common underlying mechanisms of disease—and ongoing mediators of the disease.
3. Next, conveying to the patient in the simplest terms possible that to achieve lasting solutions to the problem(s) for which the patient has come seeking help, a few fundamental questions must be asked and answered to understand the problem in the context of the patient's personal life. This framing of the interview process moves the endeavor from a left-brain compilation to a narrative that encourages insight—based on complex pattern recognition—about the root causes of the problem.
4. At this stage, control is shared with the patient: "Without your help, we cannot understand your medical problem in the depth and breadth you deserve." Implementing this shared investigation can be facilitated by certain approaches:
   a. For determining antecedent conditions, the following questions are useful:
      - When was the last time you felt well? When were you free of this problem?
      - What were the circumstances surrounding the appearance of the problem?
      - Have similar problems appeared in family members?

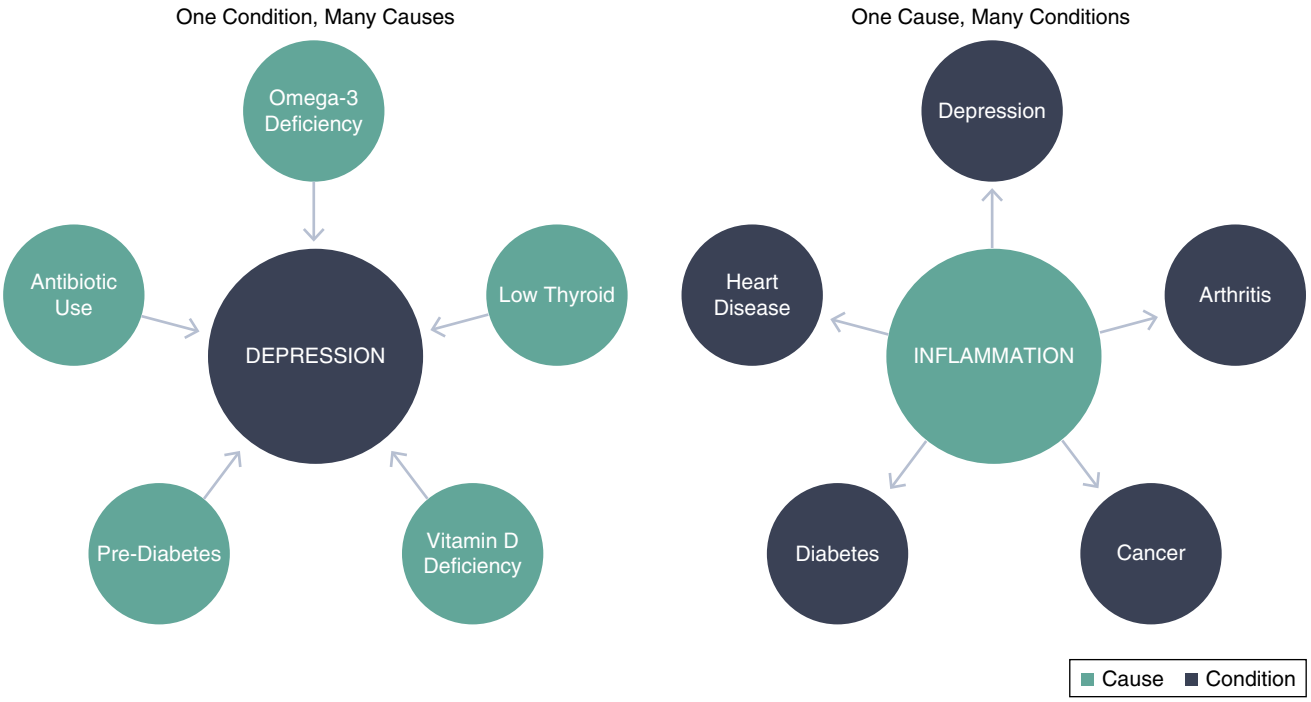

Fig. 1.5 Overview of the functional medicine (FM) model. (Courtesy the Institute for Functional Medicine.)

b. For triggers, the following question is critical:
   - What conditions, activities, or events seemed to initiate the problem? (Microbes and stressful personal events are examples but illustrate quite different categories of triggers. Triggers by themselves are usually insufficient for disease formation, so triggers must be viewed within the context of the antecedent conditions.)

c. Mediators of the problem are influences that help perpetuate it.
   - There can be specific mediators of diseases in the patient's activities, lifestyle, and environment. Many diverse factors can affect the host's response to stressors.
   - Any of the core clinical imbalances, discussed previously and shown on the Functional Medicine Matrix Model, can transform what might have been a temporary change in homeostasis into a chronic allostatic condition.

It helps at this juncture to emphasize again that the following issues are elemental in forming a healing partnership:

- Only the patient can inform the partnership about the conditions that provided the soil from which the problem(s) under examination emerged. The patient literally owns the keys to the joint deliberation that can provide insight into the process of achieving a healing outcome.
- The professional brings experience, wisdom, tools, and techniques and works to create the context for a healing insight to emerge.
- The patient's information, input, mindful pursuit of insight, and engagement become "the horse before the cart." The cart carries the clinician—the person who guides the journey using evidence, experience, and judgment and who contributes the potential for expert insight.

The crux of the healing partnership is an equal investment of focus by both clinician and patient. They work together to identify the right places to apply leverage for change. Patients must commit to engage both their left-brain skills and their right-brain function to inform and guide the exploration to the next steps in assessment, therapy, understanding, and insight. Clinicians must also engage both the left-brain computational skills and the right-brain pattern-recognition functions that, when used together, can generate insight about the patient's story. An overview of the functional medicine model is given in Fig. 1.5.

INTEGRATION OF CARE

Functional medicine explicitly recognizes that no single profession can cover all the viable therapeutic options. Interventions and practitioners will differ by training, licensure, specialty focus, and even by beliefs and ethnic heritage. However, all health care disciplines (and all medical specialties) can—to the degree allowed by their training and licensure and assuming a good background in Western medical science—use a functional medicine approach, including integrating the matrix as a basic template for organizing and coupling knowledge and data. Consequently, functional medicine can provide a common language, a flexible architecture, and a unified model to facilitate integrated and integrative care. Regardless of the discipline in which the clinician has been trained, developing a network of capable, collaborative practitioners with whom to comanage challenging patients and to whom referrals can be made for therapies outside the primary clinician's own expertise will enrich patient care and strengthen the clinician–patient relationship.

A Hierarchy of Healing: The Therapeutic Order

A Unifying Theory of Naturopathic Medicine

Stephen P. Myers, ND, BMed PhD, Pamela Snider, ND, Jared Zeff, ND, and *Zora DeGrandpre*, MS, ND*

OUTLINE

A BRIEF HISTORY OF NATUROPATHIC MEDICINE[1]

In 1900 Benedict Lust "invented" naturopathy, as an eclectic practice that combined many natural therapies and therapeutic systems under the umbrella of a comprehensive philosophy and system of practice based on the European nature cure movement that flourished in the 1800s. At the core of this philosophy was the *vis medicatrix naturae* (healing power of nature) and the naturalistic concept of vitalism. As such, naturopathic medicine has deep historical roots and represents a lineage of Western natural medicine that can be traced back to the Roman, Greek, Egyptian, and Mesopotamian cultures and, conceptually, to many traditional and indigenous world medicines.

The modern naturopathic profession originated with Lust, and it grew under his tireless efforts. He crisscrossed the United States, lecturing and lobbying for legislation to license naturopathy, testifying for naturopaths indicted for practicing medicine without a license, and traveling to many events and conferences to help build the profession. He also wrote extensively, including two monthly newspapers (*The Naturopath* and *Herald of Health*) for nearly 40 years, to foster and popularize the profession, and through his efforts, the naturopathic profession grew rapidly.[2–4] By the 1940s, naturopathic medicine had developed a number of 4-year medical schools and had achieved licensure in about one third of the United States, the District of Columbia, four Canadian provinces, and a number of other countries.[3,5]

*Previous edition contributor

The profession went through a period of decline, marked with internal disunity and paralleled by the rise of biomedicine and the promise of wonder drugs. By 1957, there was only one naturopathic college left. By 1975, only eight states still licensed naturopathic physicians, and by 1979, there were only six. A survey conducted in 1980 revealed that there were only about 175 naturopathic practitioners still licensed and practicing in the United States and Canada.[6] In contrast, in 1951, the number was approximately 3000.[7]

The decline of naturopathic medicine after a rapid rise was due to several factors. By the 1930s, a significant tension developed within the profession regarding clinical naturopathic practice based on traditional principles; the development of unified standards; and the role of experimental, reductionist science as an element of professional development.[8,9] Many naturopathic doctors questioned the capacity for the reductionist scientific paradigm to research naturopathic medicine objectively in its full scope.[8,10,11] This tension split the profession of naturopathic physicians from within after the death of Lust in the late 1940s, at a time when the profession was subject to both significant external forces and internal leadership challenges.

This perception created a mistrust of science and research. Science was also frequently used as a bludgeon against naturopathic medicine, and the biases inherent in what became the dominant paradigm of scientific reductionism made a culture of scientific progress in the profession challenging. The discovery of effective antibiotics elevated the standard medical profession to dominant and unquestioned stature by

a culture that turned to mechanistic science as an unquestioned authority. The dawning of the atomic age reinforced a fundamental place for science in a society increasingly dominated by scientific discovery. In this culture, standard medicine, with its growing political and economic strength, was able to force the near elimination of naturopathic medicine through the repeal or "sunsetting" of licensure acts.[2,3,12]

In 1956, as the last early doctor of naturopathy (ND) educational program ended (at the Western States College of Chiropractic), several doctors, including Drs. Ralph Weiss, Charles Stone, W. Martin Bleything, and Frank Spaulding, created the National College of Naturopathic Medicine in Portland, Oregon, to keep the profession alive. However, that school was nearly invisible as the last vestige of a dying profession and rarely attracted as many as 10 new students a year. The profession was considered dead by its historical adversaries.

The culture of America, dominated by standard medicine since the 1940s, however, began to change by the late 1960s. The promise of science and antibiotics was beginning to seem less than perfect. Chronic disease was increasing in prevalence as acute infection was becoming less predominant, and standard medicine had no "penicillin" for chronic diseases. In the late 1970s, scholars in family medicine proposed a biopsychosocial model of care in response to a prevailing perception of a growing crisis in standard medicine.[13] The publication of Engel's "The Need for a New Medical Model" in April 1977 signaled the founding of the field of family medicine based on a holistic philosophy. This shifting culture within standard medicine paralleled a broader social movement in support of alternative health practices and environmental awareness. Elements of the culture were rebelling against plastics and cheap synthetics, seeking more natural solutions. The publication of Rachael Carson's *Silent Spring* in 1962, an indictment of chemical pesticides and environmental damage, marked a turning point in cultural thinking. In *Silent Spring,* Carson challenged the practices of agricultural scientists and the government and called for a change in the way humankind viewed the natural world.[14] New evidence of the dangers of radiation, synthetic pesticides, and herbicides and environmental degradation from industrial pollution was creating a new ethic. Organic farming, natural fibers, and other similar possibilities were starting to capture attention. A few began seeking natural alternatives in medicine. By the late 1960s and early 1970s, enrollments at the National College of Naturopathic Medicine began to reach into the 20s. The 1974 class numbered 23 students. In 1975 the National College enrolled a class of 63 students.[15] The profession was experiencing a resurgence.

In 1978, with a desire to create a college based on science-based natural medicine, Joseph E. Pizzorno, ND, LM, and his colleagues—Les Griffith, ND, LM; Bill Mitchell, ND; and Sheila Quinn—created the John Bastyr College of Naturopathic Medicine in Seattle, Washington. With the creation of Bastyr, named after the eminent naturopathic physician Dr. John Bartholomew Bastyr (1912–1995), the profession entered a new phase. Not only did this new college double the profession's capacity to produce new doctors, but it also firmly placed the profession on the ground of scientific research and validation. "Science-based natural medicine," coined by Dr. Pizzorno, was a major driving force behind the creation and mission of Bastyr. Both Drs. Bastyr and Pizzorno had significant influence and leadership in achieving this focus.

One of Dr. Bastyr's important legacies was to establish a foundation and a model for reconciling the perceived conflict between science and the deeply established healing practices and principles of naturopathic medicine. Kirchfeld and Boyle[4] described his landmark contribution as follows:

> *Although naturopathic colleges in the early 1900s did include basic sciences training, it was not until Dr. John Bastyr (1912–1995) and his firm, efficient and professional leadership that science and research-based training in natural medicine was inspired to reach its fullest potential. Dr. Bastyr, whose vision was one of "naturopathy's empirical successes documented and proven by scientific methods," was himself the prototype of the modern naturopathic doctor, who culls the latest findings from the scientific literature, applies them in ways consistent with naturopathic principles and verifies the results with appropriate studies.*

Bastyr also saw a tremendous expansion in both allopathic and naturopathic medical knowledge, and he played a major role in making sure the best of both were integrated into naturopathic medical education.[4,16]

Bastyr met Lust on two occasions and was closely tied to the nature cure tradition of Kneipp through two influential women: his mother, and his mentor, Dr. Elizabeth Peters, who studied with Father Kneipp. He effortlessly integrated the clinical theories and practices of naturopathy with the latest scientific studies and helped create a new and truly original form of modern primary clinical care within naturopathic medicine. He spent the 20th century preparing the nature cure of the 19th century for entry into the 21st century.[2,16] Today's philosophic debates within the profession are no longer about science. They now tend to center on both sides of the earlier debate and include challenges to the nature cure tradition. A current debate, for instance, is about the role of "green allopathy" within the profession: the tendency to use botanical medicine or nutritional supplements as a simple "green drug" or pharmaceutical replacement therapy. This is in contrast to implementing the full range of healing practices derived from the nature cure tradition and within the framework of the therapeutic order construct to stimulate health restoration as the foundation for reversing disease, alongside, or instead of, botanical medicine or nutritional supplements. Professional consensus appears strong that the full range of naturopathic healing practices must be retained, strengthened, and engaged in the process of education and scientific research and discovery in the 21st century.[17–19]

ORIGINAL PHILOSOPHY AND THEORY

Through the initial 50-year period of professional growth and development (1896–1945), naturopathic medicine had no clear and concise statement of identity. The profession was whatever Lust said it was. He defined "naturopathy" or "nature cure" as both a way of life and a concept of healing that used various natural means of treating human infirmities and disease states. The "natural means" were integrated into naturopathic medicine by Lust and others based on the emerging naturopathic theory of healing and disease etiology. The earliest therapies associated with the term involved a combination of American hygienics and Austro-Germanic nature cure and hydrotherapy. Leaders in this field included Kuhne, Lindlahr, Trall, Kellogg, Holbrook, Tilden, Graham, McFadden, Rikli, Thomson, and others who wrote foundational naturopathic medical treatises or developed naturopathic clinical theory, philosophy, and texts to enhance, agree with, and diverge from Lust's original work.[20–28]

The bulk of professional theory was found in Lust's magazines, *Herald of Health* and *The Naturopath.* These publications displayed the prodigious writings of Lust but did not contain a comprehensive and definitive statement of either philosophy or clinical theory. Lust often stated that all natural therapies fell under the purview of naturopathy. Several texts were considered as somewhat definitive by various aspects of the profession at different times. These texts included Adolph Just's *Return to Nature* (1896), Louis Kuhne's *The New Science of Healing* (1899), and the seven-volume *Natural Therapeutics* by Henry Lindlahr, MD, which was published in the early 1900s. Lindlahr's *Nature Cure* (1913) was considered a seminal work in naturopathic theory, laying

the groundwork for a systematic approach to naturopathic treatment and diagnosis. Lindlahr ultimately presented the most coherent naturopathic theory extant, summarized in his *Catechism of Nature Cure,* which presented a five-part therapeutic progression:

1. "Return to nature"—attending to the basics of diet, dress, exercise, rest, etc.
2. Elementary remedies—water, air, light, electricity
3. Chemical remedies—botanicals, homeopathy, etc.
4. Mechanical remedies—manipulations, massage, etc.
5. Mental/spiritual remedies—prayer, positive thinking, doing good works, etc.[29]

Lindlahr's five-step therapeutic progression follows the *Catechism's* disease causation model: "The primary cause of disease, barring accidental or surgical injury to the human organism and surroundings hostile to human life, is violation of Nature's Laws." The effects of violation of nature's laws on the physical human organism are also the primary causes of disease because they inhibit normal function, lower vitality, and result in tissue destruction:

Primary
- Lowered vitality
- Abnormal composition of blood and lymph
- Accumulation of waste, morbid matter, and poisons in the system

Secondary
- Hereditary/constitutional
- Fevers, inflammation
- Mechanical luxations
- Weakening and loss of reason, will, etc.[29]

In 1948 Spitler wrote *Basic Naturopathy, a Textbook,*[10] and in 1951 Wendel wrote *Standardized Naturopathy.*[11] These texts presented somewhat different approaches; Spitler's text emphasized theory and philosophy, whereas Wendel's text was written, as evidenced by the title, to emphasize the standard naturopathic practices of the day, with an eye toward regulatory practice. In contrast, Kuts-Cheraux's *Naturopathic Materia Medica,* written in 1953, was produced to satisfy a statutory demand by the Arizona legislature but persisted as one of the few extant guides of that era. Practitioners relied on a number of earlier texts, many of which arose from the German hydrotherapy practitioners[30–35] or the eclectic school of medicine (a refinement and expansion of the earlier "Thomsonian" system of medicine)[36–40] and predated the formal American naturopathic profession (1900). However, by the late 1950s, publications diminished. The profession was generally considered on its last gasp, an anachronism of the pre-antibiotic era.

During the process of winning licensure, naturopathic medicine was defined formally by the various licensure statutes, but these definitions were legal and scope-of-practice definitions, often in conflict with each other, reflecting different standards of practice in different jurisdictions. In 1965 the U.S. Department of Labor's *Dictionary of Occupational Titles*[41] presented the most formal and widespread definition. The definition was not without controversy because it reflected one of the internally competing views of the profession, primarily, the nature cure perspective:

> *Diagnoses, treats and cares for patients using a system of practice that bases treatment of physiological function and abnormal conditions on natural laws governing the human body. Utilizes physiological, psychological and mechanical methods such as air, water, light, heat, earth, phytotherapy, food and herbs therapy, psychotherapy, electrotherapy, physiotherapy, minor and orificial therapy, mechanotherapy, naturopathic corrections and manipulations, and natural methods or modalities together with natural medicines, natural processed food and herbs and natural remedies. Excludes major surgery, therapeutic use of x-ray and radium, and the use of drugs, except those assimilable substances containing elements or compounds which are components of body tissues and physiologically compatible to body processes for the maintenance of life.*[41]

This definition did not list drugs or surgery within the scope of modalities available to the profession. It defined the profession by therapeutic modality and was more limited than most of the statutes under which naturopathic physicians practiced,[42] even in 1975, when there were only eight licensing authorities still active.

MODERN NATUROPATHIC CLINICAL THEORY: THE PROCESS OF DEVELOPMENT

> *Medical philosophy comprises the underlying premises on which a health care system is based. Once a system is acknowledged, it is subject to debate. In Naturopathic medicine, the philosophical debates are a valuable, ongoing process which helps the understanding of health and disease evolve in an orderly and truth-revealing fashion.*
>
> ***Randall Bradley, ND***[43]

After the profession's decline in the 1950s and 1960s, a rebirth was experienced, more grounded in medical sciences and fueled by a young generation with few teachers. The profession's roots were neglected out of ignorance, for the most part, along with a youthful arrogance. By the early 1980s, it was apparent that attempts to regenerate the progress made by Lust would require the creation of a unified professional organization and all which that entailed: accreditation for schools, national standards in education and licensure, clinical research, and the articulation of a coherent definition of the profession for legislative purposes, as well as for its own internal development. These accomplishments would be necessary to be able to demonstrate the uniqueness and validity of the profession, guide its educational process, and justify its status as a separate and distinct medical profession.

In 1987 the newly formed (1985) American Association of Naturopathic Physicians (AANP) began this task of developing a unified professional organization under the leadership of James Sensenig, ND (president), and Cathy Rogers, ND (vice president). Four tasks were developed, and committees with specific chairs were delegated. One task was to pursue accreditation of our schools through governmental accreditation bodies, headed by Joe Pizzorno, ND. Another was to create a standard, national licensure examination, independent of the profession, headed by Edwin Smith, ND. A third was to create a peer-reviewed journal that the profession could use to demonstrate its rational basis, headed by Peter D'Adamo, ND. The fourth was a committee to head the creation of a new definition of naturopathic medicine headed by Pamela Snider, ND, and Jared Zeff ND, LAc. The "Select Committee on the Definition of Naturopathic Medicine" succeeded in its 3-year project, which culminated in the unanimous adoption by the AANP's House of Delegates (HOD) of a comprehensive, consensus definition of naturopathic medicine in 1989 at the annual convention held at Rippling River, Oregon.[44–46] The unique aspect of this definition was its basis in definitive principles, rather than therapeutic modalities, as the defining characteristics of the profession. In passing this resolution, the HOD also asserted that the principles would continue to evolve with the progress of knowledge and should be formally reexamined by the profession as needed, perhaps every 5 years.[44–49]

In September 1996 the AANP HOD passed a resolution to review three proposed principles of practice that had been recommended as

additions to the AANP definition of naturopathic medicine originally passed by the HOD in 1989. These three new proposed principles were rejected, and the AANP HOD reconfirmed the 1989 AANP definition unanimously in 2000. The results of a profession-wide survey conducted from 1996 to 1998 on these three new proposed principles demonstrated that although there was lively input, the profession agreed strongly that the original definition was accurate and should remain intact. The HOD recommended that the discussion be moved to the academic community involved in clinical theory, research, and practice for pursuit through scholarly dialogue.[50–54] This formed the basis for further efforts to articulate a clinical theory. AANP members stated in 1987 to 1989 during the definition process: "These principles are the skeleton, the core of naturopathic theory. There will be more growth from this foundation."[46] By 1997, this growth in modern clinical theory was evident.

The first statement of such a theory was published in the AANP's *Journal of Naturopathic Medicine* in 1997 in an article titled "The Process of Healing, a Unifying Theory of Naturopathic Medicine."[55] This article contained three fundamental concepts that were presented as an organizing theory for the many therapeutic systems and modalities used within the profession and were based on the principles articulated in the consensus AANP definition of naturopathic medicine. The first of these was the characterization of disease as a process rather than a pathological entity. The second was the focus on the determinants of health rather than on pathology. The third was the concept of a therapeutic hierarchy.

This article also signaled the emergence of a growing dialogue among physicians, faculty, leaders, and scholars of naturopathic philosophy concerning theory in naturopathic medicine. The hope and dialogue sparked by this article were the natural next step of a profession redefining itself both in the light of today's advances in health care and with respect to the foundations of philosophy at the traditional heart of naturopathic medicine. This dialogue naturally followed the discussions of the definition process and created a vehicle for emerging models and concepts to be built on the bones of the principles. The essence and inherent concepts of traditional naturopathic philosophy were carried in the hearts and minds of a new generation of naturopathic physicians into the 21st century—these modern naturopathic students and naturopathic physicians began to gather to articulate, redefine, and reunify the heart of the medicine.

This new dialogue was formally launched in 1996, when the AANP Convention opened with the plenary session "Towards a Unifying Theory of Naturopathic Medicine," with four naturopathic physicians presenting facets of emerging modern naturopathic theory. The session closed with an open microphone. The impassioned and powerful comments of the naturopathic profession throughout the United States and Canada engaged in the vital process of deepening and clarifying its unifying theory. Dr. Zeff presented "The Process of Healing: The Hierarchy of Therapeutics"; Dr. Mitchell presented "The Physics of Adjacency, Intention, Naturopathic Medicine, and Gaia"; Dr. Sensenig presented "Back to the Future: Reintroducing Vitalism as a New Paradigm"; and Dr. Snider announced the Integration Project, inviting the profession to engage in it by "sharing a beautiful and inspiring anguish—the labor pains of naturopathic theory in the twenty-first century. We know what we have done, and we know there is much more…The foundation is laid. We are ready now for development and integration."[56]

Days later, in September 1996, the Consortium of Naturopathic Medical Colleges (now the American Association of Naturopathic Medical Colleges [AANMC]) formally adopted and launched the Integration Project, an initiative to integrate naturopathic theory and philosophy throughout all divisions of all naturopathic college curricula, from basic sciences to clinical training. A key element of the project engaged the further development and refinement of naturopathic theory. The project was cochaired by Drs. Snider and Zeff from 1996 to 2003. Steering members from all North American naturopathic colleges participated and contributed.[46] Methods included professional and scholarly research, expert teams, symposiums, and training. The result was the fostering of systematic inquiry among academicians, clinicians, and researchers concerning the underlying theory of naturopathic medicine, bringing the fruits of this work and inquiry into the classroom and into scientific discussion.[57]

The Integration Project sustained both formal and informal dialogue since its inception in 1996, which continues today through the Foundations of Naturopathic Medicine Institute. The work has engaged faculty and scholars of naturopathic philosophy in the United States, Canada, the United Kingdom, Australia, and many other countries where naturopathy is established or is professionalizing. It has also engaged institutional leaders and practicing doctors and faculty in all areas of the profession. Why? Naturopathic philosophy is deeply felt as the "commons" of naturopathic medicine: a place where the profession meets—one that is owned by all naturopathic physicians—that reflects, holds, and deepens the heart of naturopathic medicine. The philosophy of naturopathic medicine *is* the foundation and heart of naturopathic medicine and consists of its heritage, knowledge base, concepts, and knowledge codification; its clinical decision making; its integration and initiation of scientific research; and its public policy positions. The philosophy remains valid by evolving with the progress of knowledge, the progress of science, and the progress of the human spirit. It is for this reason medicine is seen as an art and a science. Because naturopathic philosophy engages the intuitively felt mission of nature doctors, it is vital that the profession periodically gathers to renew and revitalize progress regarding its unifying foundations.

The Integration Project sparked a wide range of activities in all six ND colleges at that time, resulting in all-college retreats to share tools, retreats for training of non-ND faculty in naturopathic philosophy, integration of a basic sciences curriculum, expert-team revision of core competencies across departments ranging from nutrition to case management and counseling, development of clinical tools and seminars for clinic faculty, creation of new courses, and the integration of important research questions derived from naturopathic philosophy into research studies and initiatives.[58] The latest effort, the Foundations of Naturopathic Medicine Institute and Project (textbook codification and symposia series; see www.foundationsproject.com) includes its development and presentation of the founding educational module on emunctorology, an essentially naturopathic science, during 2009 and 2010. This is a joint effort of faculty from several of our schools, led by Drs. Thom Kruzel, Rita Bettenberg and Stephen Myers.

North American core competencies for naturopathic philosophy and clinical theory were developed by faculty representing all accredited ND colleges in a landmark AANMC retreat in 2000. The AANMC's Dean's Council formally adopted these competencies in 2000 and recommended that they be integrated throughout curricula in all ND colleges. These national core competencies included the process of healing theory, Lindlahr's model, and the hierarchy of therapeutics (the therapeutic order).[59,60]

Finally, many meetings with scholars and teachers of naturopathic theory and other faculty and leaders—formal and informal—resulted in the further development and refinement of the hierarchy of therapeutics developed by Dr. Zeff in 1997.

Drs. Snider and Zeff and worked closely with each other and then with other naturopathic theory faculty from AANMC colleges in a

BOX 2.1 Working Definition of Naturopathic Nutrition

Consensus Statement from Naturopathic Nutrition Faculty Retreat, Naturopathy and Nutrition Panel and Southern Cross University, June 2003, Preamble

Naturopathic medicine is a distinct system of primary health care—an art, science, philosophy and practice of diagnosis, as well as treatment and prevention of illness. Naturopathic medicine is distinguished by the principles that underlie and determine its practice. These principles include the healing power of nature *(vis medicatrix naturae),* identification and treatment of the causes *(tolle causam),* the promise to first do no harm *(primum non nocere),* doctor as teacher *(docere),* treatment of the whole person, and emphasis on prevention. These principles give rise to a practice that emphasizes the individual and empowers him or her to greater responsibility in personal health care and maintenance.

Definition

Naturopathic nutrition is the practice of nutrition in the context of naturopathic medicine.

Naturopathic nutrition integrates both scientific nutrition and the principles of naturopathic medicine into a distinct approach to nutritional practice.

Core components of naturopathic nutrition are:

Respect for the traditional and empirical naturopathic approach to nutritional knowledge

The value of food as medicine

An understanding that whole foods are greater than the sum of their parts and recognition that they have vitality (properties beyond physiochemical constituents)

Individuals have unique interactions with their nutritional environments

Practice

In the context of the definition, and with respect to the therapeutic order, the practice of naturopathic nutrition may include the appropriate use of the following:

Behavioral and lifestyle counseling

Diet therapy (including health maintenance, therapeutic diets, and dietary modification)

Food selection, preparation, and medicinal cooking

Therapeutic application of foods with specific functions

Traditional approaches to detoxification

Therapeutic fasting strategies

Nutritional supplementation

series of revisions. Drs. Snider and Zeff collaborated in 1998 to develop the hierarchy of therapeutics into the "therapeutic order." The therapeutic order was subsequently explored and refined through a series of faculty retreats and meetings, as well as through experience with students and through student feedback. A key finding of the clinical faculty at Bastyr University was the emphasis on the principle "holism: treat the whole person" and respect for the patient's own unique healing order and his or her values as a context for applying the therapeutic order to clinical decision making.[61] The therapeutic order, or hierarchy of healing, is now incorporated into ND college curricula throughout the United States, Canada, Australia, and New Zealand. For example, an important international outgrowth of the profession's development of theory is the adoption of the unified "Working Definition of Naturopathic Nutrition" in June 2003 by the Australian naturopathic profession (Box 2.1). The 3-year project, fostered by Dr. Stephen Myers, brought together nutrition faculty from naturopathic medicine colleges throughout Australia. The project was cohosted by the Naturopathy and Nutrition Panel, an independent group of naturopaths and nutrition educators whose mission is to foster and support the development of the science, teaching, and practice of naturopathic nutrition, and the School of Natural and Complementary Medicine at Southern Cross University. The definition evolved over two retreats attended by more than 40 faculty members involved in teaching nutrition as part of a naturopathic medicine education. It commenced as a general agreement within the group that there was a real and distinct difference between conventional nutritional concepts and naturopathic nutritional theory. The general agreement was that the distinction between the two had been poorly defined to date and had been the source of dissonance between the naturopathic and science faculty within the colleges. The obvious next step was to define that difference to ensure that nutrition curriculum within naturopathic medicine colleges reflected the core elements of naturopathic nutrition. At the second retreat held in June 2003, the working definition was adopted with a recommendation that it be widely circulated within the naturopathic medicine profession to commence a dialogue aimed at both appropriate revision and broad adoption. This process created a much-needed consensus definition of naturopathic nutrition. This definition is based on the AANP defining principles and incorporates the therapeutic order theory.

The AANP Definition of Naturopathic Medicine position paper was reviewed again in 2010 and reratified unanimously in 2011 by the AANP House of Delegates. "Prescription medications" were added to the single Treatment and Care section and both Naturopathic Practice sections in the 5-page paper (see www.naturopathic.org).

In 2015 the World Naturopathic Federation, founded in 2015, published its first international survey results on naturopathic medicine's core concepts and education in two white papers: *The World Naturopathic Federation Report: Findings From the 1st World Naturopathic Federation Survey* (2015) and *WNF White Paper: Philosophies, and Principles, Theories* (2017). The therapeutic order was reported in the top three (2015) and top five (2017) theory concepts utilized by the profession across the world. The results of the 2015 report stated that the AANP Definition of Naturopathic Medicine position paper and its six principles were widely accepted as written by professionalizing naturopaths in countries responding to the survey, at an average rate of 95%.[62–65]

A THEORY OF NATUROPATHIC MEDICINE

Standard medicine, or biomedicine, has a simple and elegant paradigm. Simply stated, it is "the diagnosis and treatment of disease." In practice, this statement contains several assumptions. One assumption is that illness can be understood in terms of discrete diseases (i.e., human illnesses can be divided into identifiable entities, such as measles or specific forms of cancer, etc.). The next assumption is that "cure" is the elimination of the disease entity. The third assumption is that this is accomplished by the evidence-based application of pharmaceuticals, surgeries, or similar treatments to eliminate, palliate, or suppress the entity and its symptomatic expressions. These are so obvious that they are not commonly considered. They form the background thinking in medical decision making: "identify and treat the disease."

The elegance of this model, and the science behind it, has taken standard medicine to its highest point in history as a reliable vehicle to ease human illness, and its application has saved countless lives. The understanding of the physician, at least about the nature of pathology, has never been as complete as now. However, illness has a near-infinite capacity to baffle the physician. New diseases arise, such as Legionnaire's disease, human immunodeficiency virus/acquired immune deficiency syndrome, and Lyme disease, and shifts occur in disease focus, such as the shift between 1900 and 2000 from acute infection to chronic illness as the predominant cause of death.[66]

Beyond these obvious changes, even with the current depth of understanding, the standard medical world often lacks the ability to effectively understand and cure chronic disease, and treatment tends to become a task of the management of symptoms and the attempt to reduce long-term damage and other consequences rather than actual cure of the illness. So, even representing an apex of human achievement as it does, standard medicine is not without its weaknesses. Its greatest weaknesses include its relatively high cost,[67] its tendency to create iatrogenic disease,[67] and its inability to cure chronic illness as easily as it once cured pneumonia with penicillin or tuberculosis with streptomycin. Compounding the problem is the growing prevalence of antibiotic-resistant infections.[68,69] Part of the reason for the failures within biomedical science is its mechanistic basis. Breaking the body down to its constituent parts has led to a fundamental ignorance of and disrespect for the wholeness of the individual, the natural laws of physiology governing health and healing, and particularly for all things spiritual (the transpersonal domains). Inherent in the dictum—diagnose and treat the disease—is the general neglect of the larger understanding that disease is a process conducted by and within an intelligent organism that is constantly attempting to heal itself, with disease manifestations often being expressions of this self-healing endeavor. As noted by Pizzorno et al.,[70] this intelligent organism strives for optimal function and health. Human beings "are natural organisms, our genomes developed and expressed in the natural world. The patterns and processes inherent in nature are inherent in us. We exist as a part of complex patterns of matter, energy, and spirit. Nature doctors have observed the natural processes of these patterns in health and disease and determined that there is an inherent drive toward health that lives within the patterns and processes of nature."

The uniqueness of naturopathic medicine is not in its therapeutic modalities or the "natural" alternatives to the drugs and surgeries of standard medicine. It is the clinical theory that governs the selection and application of these modalities, captured in the unifying definition adopted in 1989 and expressed more specifically in the continuing articulation of clinical theory. That is, it is the way the naturopathic physician thinks about illness and healing.

The first element of this theory is based on the first defining principle: *vis medicatrix naturae.* It is based on the understanding that disease can be seen as a process and an entity. One can analyze the process of illness and derive some understanding. However, to do this, one needs to examine the assumptions underlying this concept. The governing assumptions of standard medicine are principally that diseases are entities and that drugs and surgery can eliminate these entities from the suffering person. These are not the governing assumptions of naturopathic medicine.

Illness and Healing as Process

Naturopathic medicine can be characterized by a different model than "identify and treat the disease." "The restoration of health" would be a better characterization. Naturopathic physicians adopted the following elegantly brief definition of naturopathic medicine in 1989 in an AANP position paper: "Naturopathic physicians treat disease by restoring health."[45] Immediately, a significant difference is made clear: standard medicine is disease based; naturopathic medicine is health based. Although naturopathic medical students study pathology with the same intensity and depth as standard medical students, as well as its concomitant diagnoses, the naturopathic medical student learns to apply that information in a different context. In standard medicine, pathology and diagnosis are the basis for the discernment of the disease "entity" that afflicts the patient, the first of the two steps of identifying and destroying the entity of affliction. In naturopathic medicine, however, disease is seen much more as a process than as an entity. Rather than viewing the ill patient as experiencing a "disease," the naturopathic physician views the ill person as functioning within a process of disturbance and recovery, in the context of nature and natural systems. Various factors disturb normal health. If the physician can identify these disturbances and moderate them (or at least some of them), the illness and its effects abate. As disturbances are removed, the body can improve in function, and in doing so, health naturally improves. The natural tendency of the body is to maintain itself in as normal a state of health as is possible—this is the basis of homeostatic principles.[71] The role of the physician facilitates this self-healing process.

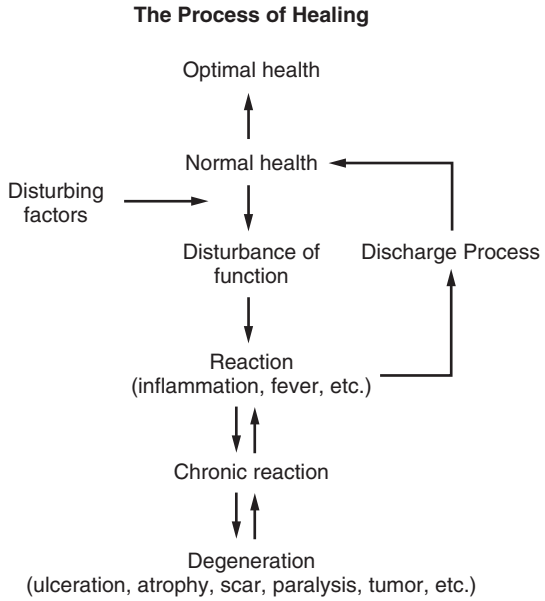

Fig. 2.1 The process of healing. Copyright 1997. (Used by permission. Jared L. Zeff, ND, LAc.)

The obvious first task of the naturopathic physician, therefore, is to determine what is disturbing the health so that these causative elements may be ameliorated. Disease is the process whereby the intelligent body reacts to disturbing elements. It employs such processes as inflammation and fever to help restore its health. In general, one can graph this process simply, as in Fig. 2.1.

The Naturopathic Model in Acute Illness

One can see "illness as process" most easily in the common cold. Within standard medical understanding, the common cold is caused by a virus, from among a family of pathological viruses that can infect a person. The immune system responds, developing appropriate antibodies, which eventually neutralize the virus. There is no "cure" yet discovered, except time. Medications are used to ameliorate the symptomatic experience: aspirin or acetaminophen for fever, decongestants to dry the mucus discharge, and so forth. These measures are not cures; they reduce the symptomatic expression of the "cold" but often lengthen the process. In naturopathic medicine, the cold is seen not as a disease entity but as part of a fundamental process whereby the body restores itself to health.

If the virus were the sole cause of the common cold, then everyone who came into contact with a sufficient dose of the virus would get the cold. Obviously, this does not happen. Susceptibility factors include immune competence, fatigue, vitality, genetics, and other host factors.[72] The virus enters a milieu in which all these factors affect the process. Once the virus enters the system, and if it overcomes resistance factors (Box 2.2), one begins to see disturbance of function, as illustrated in Fig. 2.1. One does not feel quite right. One may

BOX 2.2 Scientific Considerations: The Immune Response and Resistance Factors

Once inside the body, the rhinovirus binds to cellular receptors (primarily the intercellular adhesion molecule-1 [ICAM-1]) or to the low-density lipoprotein (LDL) receptor. The viral particles are then internalized and begin to take over the cellular machinery to produce intact virions.[72,103] At this stage, the body can sometimes mount an adequate defense via cell-mediated immunity to overcome the viral incursion. If we have been previously exposed to the virus, the body's humoral immune response will rapidly produce antibodies to the viral protein, which can also lead to eradication of the microbe. These two immune responses explain why some individuals may develop the full condition, whereas others will shake off the exposure within a few hours. If the viral load overcomes the body's innate defenses, the virus replicates unabated. In the process of replication, the virus not only disrupts the cellular mechanisms but also damages them as well by infecting the surface epithelium and the macrophages[104] and fibroblasts.[105] Naturopathic physicians are interested in the factors that lead to greater immune competence and health restoration through the process of healing and the health practices that support it. French physiologist Claude Bernard (1813–1878) said that the inner terrain or "milieu interieur" was the cause of disease, not the microbes; this concept underpins the naturopathic approach.

BOX 2.3 Scientific Considerations: Consequences of Suppressing the Body's Response

Current research shows that future pathologies may be linked to "suppression" of early rhinovirus infection. These include childhood asthma, adult asthma, and chronic obstructive pulmonary disease (COPD).[106,107] Individuals with asthma are known to have subtle deficiencies in production of type I and type III interferon (IFN),[108,109] indicating that for some asthma patients, early exposure to the rhinovirus predisposes them to asthma, and that the suppression of the normal response may be critical in the future development of asthma. With these effects in mind, the naturopathic physician does not look solely at the virus as a pathogenic entity but also seeks to determine how the patient responds to the virus, thereby determining the most reasonable approach to aiding the patient's natural responses and moderating the patient's long-term health strategies. Suppression of the body's natural responses is avoided. The long-term use of corticosteroids is a prime example of suppression and its consequences.[137,140]

begin to get a sore throat, the first inflammatory reaction, occurring at the point of entry of the virus into the body. The immune factors described may overcome the virus at this point, may be insufficient, or may be suppressed. All of this is mutable to some extent and is affected by host factors, such as nutritional status and fatigue, and can be influenced by taking immune tonics, vitamin C, and other supplements.

To the individual with the condition, the "cold" may proceed into a general state of fatigue and inflammation, possibly fever followed by mucus discharge, cough, and other symptoms, as the body processes and responds to the virus and its effects; eventually, the body overcomes it and eliminates the results.

In the naturopathic model, the cold is not understood so much to be a separate disease entity but a general and fundamental process of disturbance and recovery within the living body. It is a method whereby the body restores itself after a sufficient amount of disturbance accumulates within the system. This is why the cold has no "cure." It is the *cure* for what ails the body. In the naturopathic model of health, it is the support of this "adaptive response"—the restoration of balance that is the central point—through which the process is the "cure" (Box 2.3).

BOX 2.4 Scientific Considerations: The Role of Environment in Chronic Illness

Environmental and lifestyle disturbances are a profound driver in the naturopathic model of health. The scientific evidence is now irrefutable that the national and global burden of chronic disease is highly dependent on modifiable behavioral factors. In a recent study of the causes of death, it was found that tobacco, poor diet and lack of physical activity, alcohol and drug use, toxic agents, and vehicular and firearm incidents were the leading actual causes of death.[76] Other factors included frank malnutrition (as opposed to poor nutrition), unsafe sexual practices, and poor sanitation.[77,78] It has been definitively shown, for example, that diet and lifestyle changes can prevent some forms of diabetes[101,102] and other chronic diseases[142,143] that are leading causes of death in the United States.[76,101,102]

The early naturopathic philosophers and clinicians predicted that the treatment of acute disease by suppressing symptoms (discussed in more depth later in the chapter) would result in more chronic disease. The current disease burden in the Western world certainly confirms this century-old prediction.

The Naturopathic Model in Chronic Illness

Chronic illness arises, in general, when any or all of three factors occur:

1. The disturbing factors persist, such as a chronically improper diet, which continues to burden the body cumulatively, as the digestive processes slowly weaken under the stress of the improper or inadequate diet.
2. The reactive potential is blocked or suppressed, often by drugs, which interfere with the capacity of the body to process and remove its disturbances.
3. The vitality of the system is insufficient, or has become too overwhelmed, to mount a significant and sufficient reaction.

Again, as Lindlahr stated in *Nature Cure,* Chapters 2 and 4, disease is caused by one or more of the following as a result of violating nature's laws of healthy living:

Lowered vitality
Abnormal composition of blood and lymph
Accumulation of morbid matter and poisons

As any of these factors either continue to accumulate and disturb function or reduce the ability of the body to purge the disturbance, the body slides into a chronic, weakened reactive state, with possible episodes of intermittent reaction, and is perceived to be in a persistent chronic illness. Ultimately, as function is sufficiently disturbed, structures or functions are damaged, and chronic inflammation becomes ulceration or scar tissue formation. In terms of the allostatic model, the balance has been disrupted, and there is no more adaptive potential. Atrophy, paralysis, or even tumor formation[73–75] may occur. All of this is the body manifestly doing the best it can for itself in the presence of persistent disturbing factors and with respect to the limitations and range of vitality influenced by the constitution, psycho-emotional/spiritual state, and genotype of the person and his or her surrounding environment (Boxes 2.4 and 2.5).

Reversal of this overwhelmed condition is rarely accomplished by medicating the pathological state. This often results in the control of symptoms but with the persistence of the illness while ideally controlling its more dangerous aspects using higher force interventions, such as pharmaceutical drugs and surgical intervention. Reversal is more likely accomplished by identifying and ameliorating the disturbance and, as necessary, strengthening or supporting the individual response or reactive potential. The first step in this process is to identify and reduce disturbing factors.

BOX 2.5 Scientific Considerations: Chronic Illness and the Adaptive Response

Regarding the responses of an overwhelmed or chronically disturbed organism, it has been argued recently that the anemia of chronic disease is an adaptive biological response rather than a harmful disorder and is associated with a number of chronic states.[92] Citing a number of studies, it was also argued that it was the treatment of the anemia of chronic disease among critically ill patients and those with renal failure and cancer (e.g., breast cancer and head and neck cancers) that was associated with the greater mortality. The U.S. Food and Drug Administration issued a warning against the use of erythropoiesis-stimulating agents in those cancer patients not undergoing chemotherapy or radiation therapy.[143]

States where the normal compensatory mechanisms become overwhelmed or suppressed (reducing the reactive potential of the body) include states of chronic oxidative stress[144] and inflammatory processes.[145,146] It is not, however, solely a matter of an overwhelmed or chronically disturbed organism that is critical to the process of disease progression. Adaptive responses are also of vital importance to the development of chronic disease. Research has shown that these evolutionarily preserved adaptive mechanisms of physical activity, insulin sensitivity, and fat storage are essential in the prevention of chronic disease states.[141,142] In the development of type 2 diabetes, for example, there is increasing evidence that it is the individual's maladaptation to lack of physical activity that appears to lead to decreased insulin sensitivity and increased fat storage, which can then lead to a plethora of chronic diseases, many characterized by states of chronic inflammation[147] and oxidative stress. Continuing basic and clinical studies indicate that many of the processes currently regarded in mainstream medicine as harmful have been evolutionarily retained to provide an adaptive advantage.[148,149] The *Harvard Health Letter* recently published an article describing inflammation as part of the "Unifying Theory of Disease"[150] giving support to the argument that inflammation is crucial in both health and disease and that chronic diseases arise when the inflammatory process occurs without appropriate control. The allostatic model also provides a theoretical basis for naturopathic clinical theory. The allostatic model describes the process of achieving stability (homeostasis) through changes in the homeostatic "set points" or control boundaries.[82–85] Homeostasis, the maintenance of stability in biochemical and physiological processes, is essential for life—and allostasis, the "resetting" of the homeostatic "set points," is essential for the maintenance of homeostasis. As it develops through the various iterations of researchers and clinicians, the model emphasizes the need to look beyond the current linear-reductionist model of disease and toward a more holistic and balanced approach to disease conditions.

The adaptive response of the organism to insult or frank structural damage is a concept that also has support outside naturopathic medicine. For example, Schnaper et al.[151] described a conceptual framework for progressive kidney disease where the initial disease develops through an injury of some nature that provokes a cellular response as an adaptation to the original injury. Where this cellular response is effective, no progressive kidney disease may ensue. If, however, there is a maladaptation, these attempts at self-repair may lead to progressive loss of nephrons and chronic kidney disease.

THE DETERMINANTS OF HEALTH

To reduce the disturbance, one must identify the disturbance. In standard medicine, the first step is to identify the pathology, which is then treated. In naturopathic medicine, one must come to understand what is disturbing the health. To do this, the physician needs to understand what determines health in the first place. The physician can then evaluate the patient in these terms and come to understand what is disturbing the natural state of health. Such a list could be created by any doctor, certainly any naturopathic physician. The authors propose the use of the list in Box 2.6.

Some of these determinants have been discussed—those modifiable behavioral factors such as drug and alcohol use, poor diet or frank malnutrition, lack of physical exercise, environmental and socioeconomic factors, and unsafe sexual practices[76–79] (Box 2.7). Many of these behavioral factors have major psychological and spiritual components, and the effect can be increased stress on both the individual and the family, with all its attendant consequences.[79–81] The naturopathic physician evaluates the patient with these areas in mind, looking for aspects of disturbance, first in the spirit and most generally in diet, digestion, and stress in its various aspects. In this evaluation, the naturopathic physician brings to bear a body of knowledge somewhat unique to naturopathic medicine to evaluate not solely in terms of pathological entity but also in terms of normal function and subclinical functional disturbance (Box 2.8). By locating areas of abnormal function or disturbance, the naturopathic physician acts or recommends ways to ameliorate the disturbance.

As disturbing factors or insults to the system are reduced, the natural tendency of the system is to improve and optimize its function, directing the system back toward normalcy, or homeostasis. In more conventional medical terms, this is one of the fundamental concepts of the allostatic model.[80,82–85] In naturopathic thinking, this is the removal of the obstacles to cure, which allows the emerging action of the *vis medicatrix naturae*, the vital force, the healing power of nature. This is the first step in the hierarchy of healing and what naturopathic physicians may call the overarching model in the clinical theory (the process of healing) of naturopathic medicine: the therapeutic order. This process can be seen in the naturopathic model of healing in Fig. 2.1.

THERAPEUTIC ORDER AND NATUROPATHIC ASSESSMENT

The Assessment Order: Components of a Vitalistic Assessment of Illness, Healing, and Health

> *One thing I have learned in TCM, is that the assessment part implies the treatment, because the treatment is to balance what is imbalanced.*
>
> ***Christy Lee Engel ND, Lac, Bastyr University, 2014***

The assessment order is a set of prioritized components of a vitalistic naturopathic assessment of the patient based on, or dictated by observations of the

- nature,
- locus, or
- center of gravity of the degenerative (disease) process.

This degenerative disease process is evaluated in the context of natural health and healing systems, which interconnect

- mind, body, and spirit;
- the natural, cultural, and socioeconomic environments;
- our heredity, and
- how we live.

These components have been recognized from ancient times through the present.[86] Inclusive of conventional pathological evaluation, the naturopathic assessment order is a guideline to identifying and assessing various types, levels of, and priorities in the underlying causation of degenerative and dysfunctional conditions. The assessment order provides an ordered, nonrigid, dynamic framework (leading to the *therapeutic* order) for gauging the "center of gravity" of the disease process (the most efficient level at which to intervene to engage the patient's healing response). By carefully assessing the status of the patient's health and vitality and identifying components currently contributing to the disease process, the underlying causes become evident. These components

BOX 2.6 Naturopathic Medicine Determinants of Health, Factors That Influence Health

Inborn Determinants
Genetic makeup (genotype)
Intrauterine/congenital factors
  Intrauterine influences: maternal nutrition, health, and lifestyle
  Maternal exposures: drugs, toxins, illnesses, viruses, psycho-emotional
Constitution: determines susceptibility

Disturbances/Disturbing Factors
Illnesses: Patho-biography
Medical interventions (or lack of)
Physical and emotional exposures, stresses and trauma
Toxic and harmful substances
Trauma (physical/emotional)
Toxemia
Addictions
Environmental disturbances, stress: environmental, physical, emotional

How We Live—Hygienic, Lifestyle, Psycho-emotional, Spiritual, Socioeconomic, and Environmental Factors

Spirit
Spiritual life/practice
Self-assessment
Relationship to larger universe (trust, consciousness, compassion)

Exposure to Nature/Environment
Fresh air
Clean water
Natural light
Geography and ecosystem
Exposure to natural systems, wild places, cycles

Diet, Nutrition, and Digestion
Unadulterated food
Optimal nutrition

Rest and Exercise
Rest and sleep
Recreation
Exercise and movement
Breath
Vital force, vital reserve, energy
Structural integrity

Socioeconomic Factors
Loving and being loved
Meaningful work
Culture
Community
Government/public policy
Environment
Income and economic
Health care (quality and access)
Education

BOX 2.7 Scientific Considerations: Subclinical Inflammation and Chronic Illness

It is becoming increasingly evident that many chronic diseases may have a long subclinical phase, most involving the inflammatory process. As mentioned, a chronic, subclinical inflammatory state has been linked to a number of disorders, including insulin resistance,[152] obesity,[153] vascular disease,[154–157] hypertension,[158] and aging.[159]

BOX 2.8 Scientific Considerations: Determinants of Health Within Public and Community Health Concerns

There exists an increasing consensus that Crohn's disease and ulcerative colitis result from the combined effects of four important factors, none of which is individually sufficient to cause the disease. These four factors are the global changes in the environment, alterations in the microbiome of the intestine, multiple genetic factors, and aberrations or maladaptations in both the innate and adaptive immune systems.[160–163] These four factors, considered to be vital to the development and the increased rates of irritable bowel disease, are quite similar to the determinants of health described in Box 2.6. This serves as a further example of the growing appreciation for the similarities (with important differences) between naturopathic medicine and public and community health.

are assessed for presence, absence, onset, triggers, depth, duration, and modalities and for physiological, psychospiritual, mental, biofield, organ system, and tissue targets. Components to be assessed include (1) determinants of health; (2) vitality; psychospiritual, mental, and energetic availability; and vital force; (3) physiological and energetic systems; (4) structure and musculoskeletal components; (5) the pathology itself, its biochemistry, histology, and pathophysiology; and (6 and 7) the level and strength of specific, targeted, managerial, and higher-force interventions necessary for patient safety and reduction of suffering.

Using the assessment order also engages the power of the patient–physician relationship: *docere*. "If the whole reason for the assessment is to develop a treatment plan [suitable to the patient's safety and health recovery], that is one way to look at it. When we add the *docere* experience between physician and patient, then we add the complexity of the two systems, the intention of the physician, the energetic of the *Vis*—and we have a whole new dynamic in the assessment process, which itself begins to be the treatment process," notes Christy Lee Engel ND, LAc.

The case-taking and evaluation process thus begins the treatment process. It is the foundation of the doctor–patient relationship. Subjective and objective data contribute to both the pathological and the vitalistic assessment. The pathological assessment is viewed as partial although valuable information within the context of the entire vitalistic naturopathic assessment. The naturopathic assessment, in effect, places the disease process, its specific pathophysiology, and its staging within the broader context of the patient's vitality, constitution, etiologic factors (never been well since), and underlying or root causes and leads to the level of intervention suggested by the therapeutic order.

The patient's story or patho-biography (Box 2.9) is an essential and powerful tool for making a complete naturopathic assessment. All information, subjective and objective (S, O), leads to the diagnosis and naturopathic assessment summary using the naturopathic assessment order (A) and to the treatment plan using the naturopathic therapeutic order (P).

The Naturopathic Medicine Assessment Order

Components of a vitalistic assessment of illness, healing, and health

I. Evaluate Conditions for Health—Assess Naturopathic Medicine Determinants of Health

Identify/assess inborn and constitutional factors (innate vitality and susceptibility)—genetics, epigenetics, constitution, elements, and individual perceptions and values.
Identify/assess disturbing factors (obstacles to healing)—behavioral, hygienic, socioeconomic, environmental, psycho-spiritual, and cultural determinants.
Identify/assess health-promoting factors—behavioral, hygienic, socioeconomic, environmental, psycho-spiritual, and cultural determinants.

II. Evaluate *Vis Medicatrix Naturae*: The Healing Power and Processes of Nature

Assess vital force, vitality, energetic/biofield, and stage and status of healing/illness processes.
Assess vital reserve and vitality.
Assess spiritual state.
Assess awareness, energy, and biofield.
Assess vital force, direction, and intensity in healing versus illness process simillimum, signature, dual effect, chronobiology, minimum dose
- suppression, return of old symptoms/retracing
- Hering's rules—direction of symptom progression
- Felt sense by patient of trust, energy, awareness, ability to love

Assess impact of intention, healing practices, and healing interaction on healing response.
Assess healing response—strength, direction, response versus reaction or crisis.

III. Conduct a Functional Assessment of Physiological and Bioenergetic Systems

Assess disturbances in physiological, energetic, and organ and cellular system functions and interrelationships—over-/underactivity, burden, obstruction, disorder, nourishment. Examples include neuroendocrine, digestive, emunctories, psycho-spiritual, and so forth.

IV. Evaluate Structural Obstacles to Health

Assess musculoskeletal and structural integrity.
Assess need for nutrients, movement, and exercise to support musculoskeletal integrity.

V. Conduct Pathological Assessment

Assess symptoms, urgency, suffering, and potential for damage.

VI. Assess Need, Risks, and Benefits of Highest-Force Interventions

Patho-biography, follow-up, physical examination, signs, symptoms, lab imaging

BOX 2.9 The Pathobiography

In spite of the organic roots of our medical genesis, any [physician] must [not] consider... illness purely as a material process of organic alteration. The integration of this illness in its anatomo-clinical aspect in the patient as a person enables us to discover the morbid dynamics underlying the pathological process. The "patho-biographic" case history assumes particular interest as it involves the entire psychic, emotional, affective life of the patient, his cravings, frustrations, achievements, anxiety to succeed, his perspectives. His patho-biographic past is no more than the process of psycho-physical adaptation of the individual to his circumstances and where physiopathological alterations are no more than the objective expression and the ultimate result of such adaptation."

THERAPEUTIC ORDER

The naturopathic medicine therapeutic order is a natural hierarchy of therapeutic intervention based on or dictated by observations of the nature of the healing process from ancient times through the present.[86]

The therapeutic order is a systematic approach to engaging the patient's healing response by working with the order of effective intervention inherent in the healing power and processes of nature. This order is simultaneously linear, holarchical, and recursive and functions as a multilayered, complex system powered by the vital force. It is either limited or increased in its efficiency by the level of the patient's vitality. By removing obstacles to healing, establishing health-promoting factors (giving the body and spirit what it needs), and stimulating the vital force, vitality is increased, igniting the orderly self-healing processes of *vis medicatrix naturae.*

Naturopathic physicians have long recognized (Box 2.10) that (1) the healing process is observable—a natural phenomenon (law of nature) seen consistently in health, healing, and illness (e.g., similar to laws of biology, physics, and regularities of other natural sciences); (2) "Naturopathic medicine recognizes this healing process to be ordered and intelligent" (Snider and Zeff et al., AANP House of Delegates, 1989, 2001, 2011). The principle *vis medicatrix naturae* guides the physician to ignite this ordered process by removing obstacles to healing (disturbing factors) and establishing a healthy internal and external environment (AANP 1989). This is accomplished by establishing individualized global health determinants that "treat disease by restoring health." Less detailed therapeutic orders also exist in traditional Chinese, Tibetan, Ayurvedic, and Unani medicine theories.

The therapeutic order is a natural ordering of the modalities of naturopathic medicine and their application. The concept is somewhat

BOX 2.10 Nature's Healing Order—Lindlahr

Lindlahr referred to the *vis medicatrix naturae* as "the constructive principle in nature." In 1914 he described the healing order this way: "The underlying causes of disease must be removed before we can cure chronic disease and bring about a normal condition of the organism…" the true healer is … the *vis medicatrix nature* which ... endeavors to repair, to heal and to restore all that the physician can do is to remove obstructions and to establish normal conditions within and around the patient, so that the healer within can do his work to the best advantage. . . . Though we cannot heal and give life, we can in many ways assist the healer within. We can teach and explain Nature's Laws, we can remove obstructions and we can make the conditions within and around the patient more favorable for the action of Nature's healing forces."

Lindlahr, H. *Nature Cure*. http://www.fulltextarchive.com/pdfs/Nature-Cure.pdf. Nature Cure. 1913; 460, 532.

BOX 2.11 The Therapeutic Order: Hierarchy of Healing

1. Establish the conditions for health.
   Identify and remove disturbing factors.
   Institute a more healthful regimen.
2. Stimulate the healing power of nature *(vis medicatrix naturae):* the self-healing processes.
3. Address weakened or damaged systems or organs.
   Strengthen the immune system.
   Decrease toxicity.
   Normalize inflammatory function.
   Optimize metabolic function.
   Balance regulatory systems.
   Enhance regeneration.
   Harmonize with your life force.[2]
4. Correct structural integrity.
5. Address pathology: Use specific natural substances, modalities, or interventions.
6. Address pathology: Use specific pharmacological or synthetic substances.
7. Suppress or surgically remove pathology.

The actual therapeutic order may change, depending on the individual patient's needs for safe and effective care. The needs of the patient are primary in determining the appropriate approach to therapy.

Acute and chronic concerns are both addressed using the therapeutic order.[91] Acute concerns are addressed first to avoid further damage, risk, or harm to the patient. The point of entry for assessment and therapy is dependent on each patient's need for effective and safe care, healing, and prevention of suffering or degeneration.[2,91]

From Zeff J, Snider P. Course syllabus: NM5131, Naturopathic clinical theory. Seattle, WA: Bastyr University; 1997–2005.

plastic, in that one must evaluate the unique needs, and even the unique healing requirements, of the specific patient or situation.[87] However, the nature of healing dictates a general approach to treatment. In general, this order is listed in Box 2.11.

An analogy for the therapeutic order in Australian integrative medicine is what is called the "softer option" model of patient care.[88] This model recognizes that, given a choice, the patient will generally choose the softer option, provided that this does not limit a harder option if the softer option fails. By way of example, given a choice between an antibiotic and amputation for a minor cut finger, most people would choose the softer option. Expanding this range of choice to an herbal cream, antiseptic (herbal or nonherbal), and a Band-Aid; an antibiotic; or amputation, we develop a therapeutic order ranging from the softest option (the least force) to the hardest option (the higher-force intervention). The therapeutic order can be seen as a progression of therapeutic interventions that begins with this "softer option."

Acute and Chronic Concerns

As discussed previously, there is an inherent drive toward health that is observable within the patterns and processes of nature. The drive is not perfect. There are times when, unguided, unassisted, or unstopped, the drive goes astray, causing preventable harm or even death in patients; the constructive healing intention[89] becomes destructive pathology. The ND is trained to know, respect, and work with this drive in both acute and chronic illness, using the therapeutic order, and to know when to wait or do nothing, act preventively, assist, amplify, palliate, intervene, manipulate, control, or even suppress using the principle of the least force.[90] Acute and chronic concerns are both addressed and managed using the therapeutic order.[91] Acute concerns are addressed first to avoid further damage, risk, or harm to the patient. The point of entry for assessment and therapy is dependent on each patient's need for effective and safe care, healing, and prevention of suffering and degeneration.[70,91]

Naturopathic physicians avoid suppression of symptoms in acute circumstances unless necessary for patients' well-being and safety. Instead, wherever possible, therapies for acute concerns use the least force (minimizing toxic side effects, suppression of natural functions, and physiological burdens) available to intervene effectively, healing or palliating as needed. The full range of modalities, from nutrition to homeopathy, botanical and physical medicine, hydrotherapy, counseling, prescriptive medication, and surgery, is available to the patient as the naturopathic physician works to apply the least force in providing effective preventive, acute, and chronic care.[91]

Establish the Conditions for Health

Identify and Remove Disturbing Factors

If one understands health to be the natural state and "disturbance" the original culprit, then identifying and reducing disturbance is the obvious first step, unless there is immediate danger to life or limb, in which case acting to reduce suffering and preserve life or limb is paramount. In most chronic disease, neither is immediately threatened. This understanding dictates the primary treatment goal the physician must attend to: the identification and amelioration of those factors disturbing health, especially factors that most disturb health (inappropriate diet, excessive stress, and spiritual disharmony). To understand what disturbs health, one must understand what determines health. The naturopathic physician evaluates a patient with reference to the determinants of health to discover wherein the patient's health is disturbed. In this step, the physician is essentially removing the obstacles to cure and allowing the *vis medicatrix naturae* to do its work.

Among these many possibilities, the most significant are attitude, diet, digestion, psychological and other stressors, and what might be called "spiritual integrity." Humans have a transpersonal dimension and can be seen as spiritual beings. *Spiritual* here is not defined by religion or belief in a deity or deities; it is that component of individuals that gives rise to their inner compass, their "joie de vivre" and their internal meaning of life, their core beliefs, and their values. Perceived in this way, it can be seen that many people in society are experiencing "spiritual crises."[92] Although the general purview of the physician is the body, that instrument cannot be separated from the spirit that animates it. If the spirit is disturbed, the body cannot be fundamentally healthy. Hahnemann, the brilliant and insightful founder of homeopathy, instructed physicians to attend to the spirit.[93] Disturbance in the spirit permeates the body and eventuates physical manifestation. Physicians are responsible

BOX 2.12 Scientific Considerations: Toxemia Today

Using conventional medical terminology, disorders derived from environmental, dietary, and lifestyle factors are termed *idiopathic environmental intolerances, multiple chemical sensitivities,*[98,164–166] *or sometimes oxidative stress disorders.*[167–171] The terminology may be different, but each term describes the same symptomatology. Environmental toxins accumulate, and chronic inflammation increases. These exogenous and endogenous toxins and the lack of exercise stress the system further. The ketogenic diet to control epilepsy may be considered one example of the successful application of diet to control symptoms.[172]

for perceiving such disturbances and addressing them. At colleges of naturopathic medicine in Australia, the United Kingdom, and North America, faculty work with naturopathic medicine students to develop their ability to perceive the spiritual nature of an individual as a foundational skill in addressing the spiritual crises or fundamental needs that have a profound effect on health and well-being. Using this definition, both atheists and agnostics can be seen to have a spiritual aspect. This definition also removes spirituality from religiosity in a way that does not denigrate any individual religious belief, allowing the naturopathic clinician to explore this aspect as part of routine care.

One of the oldest concepts in naturopathic medicine is the concept of toxemia. Toxemia is the generation and accumulation of metabolic wastes and exogenous toxins within the body. These toxins may be the results of maldigestive processes, intermediate metabolites, environmental xenobiotics, and colon bacterial metabolites, for example. These toxins become irritants within the body, resulting in the inflammation of tissues and the ultimate interference with normal biochemical processes.[94] The maldigestive and dysbiotic[95,96] origin of these internally and externally derived toxins is the result of an inappropriate diet, broad-spectrum antibiotics, and the effects of excessive stress on digestion.[97] Eating a diet that cannot be easily digested or that is out of appropriate nutrient balance for the individual results in the creation of metabolic toxins in the intestines.[95–98] Stress, causing the excessive secretion of cortisol and adrenaline, results in the decrease of blood flow to the digestive process, among other effects,[80,82–85] which decreases the efficient functioning of digestion and increases the tendency toward maldigestion, dysbiosis, and toxemia. Physicians can now easily measure the degree of toxemia in various ways (urinary indican or phenol[98]). The older concept of toxemia,[99,100] with scientific advances in its understanding[91,99] (Box 2.12), may now be productively combined with an understanding of the newer concept of allostasis[82–85] and the historical[89,100] and reemerging discussion on the inflammatory component of many, if not most, chronic diseases. Spiritual disharmony, inappropriate diet, digestive disturbance, stress, and toxemia (leading to inflammation) are considered primary causes of chronic illness and must be addressed if healing is to occur. Beyond these, other disturbing factors must be discerned and addressed, whichever pertain to the individual patient.[101,152–154,158,159,165–171]

Institute a Healthier Regimen

As a corollary of the first step, once physicians have determined major contributing factors to illness, they construct a healthier regimen for the patient. Some disturbing factors can be eliminated, like inappropriate dietary elements.[110,111] Others are a matter of different choices or living differently. The basics to consider are appropriate diet, appropriate rest and exercise, stress moderation, a healthy environment, and a sense of spiritual fulfillment.[82,92,141,142,145,146,148]

If this model is correct, these measures alone should result in enhanced health. The problem arises in knowing how to do these things. What is an appropriate diet? This is an area of considerable controversy. Physicians think about diet in many different ways. The goal of dietary improvement is to reduce the symptomatic consequences of the patient's diet and provide optimal nutrition to the patient. The point here, regardless of how this is done, is that it is central and essential for fundamental health improvement. If the diet is not correct, if digestion is not appropriate, if nutrition is not adequate, the patient cannot appropriately function or improve, and the scene is potentially set for chronic inflammatory conditions and the resetting of the adaptive allostatic and homeostatic set points. If the diet and digestion are appropriate, the basis for improvement in other areas is enhanced.

The same is true with these other fundamental elements, to which Lindlahr referred in the first element of his catechism, "return to nature": exercise, rest, dress, and so forth.[29] These have been expanded in the "determinants of health." They create the basis for improvement. What this really means is to change the "terrain," the conditions in which the disease has formed—not only to change but to improve the conditions so that there is less basis for the disease. Hahnemann addresses this on the first page of his *Organon of Medicine*.[93] He identified four tasks for the physician: to understand the true nature of illness, "what is to be cured"; to understand the healing potential of medicines (whether they enhance or suppress function); to understand obstacles to recovery and how to remove them (the determinants of health); and to understand the elements that derange health and how to correct them so that recovery may be permanent.[93] Changing and improving the terrain in which the disease developed is the obvious first step in bringing about improvement. This sets up the basis for the following elements to have the most beneficial effects.

Stimulate the Self-Healing Mechanisms

A certain percentage of patients will improve sufficiently simply by removing disturbing factors and establishing a healthier regimen. Most require more work. Once the patient is prepared, once the terrain is beginning to clear of disturbing factors, then one begins to apply stimulation to the self-healing mechanisms. The basis of this approach is the underlying recognition of the *vis medicatrix naturae,* the tendency of the body to be self-healing, the wisdom and intelligence within the system that constantly tends toward the healthiest expression of function, and the healing "forces" in the natural environment (air, water, light, etc.). The body heals itself. The physician can help create the circumstances to promote this. Then, as necessary, the physician stimulates the system. This also requires that attention be given to the patient's emotional state of mind because the psychological condition of the patient is often of major importance.[113,114]

One of the best ways to do this is through constitutional hydrotherapy, as developed by Otis G. Carroll, ND, early in the past century. This procedure is simple, involving the placement of hot and then cold towels on the trunk and back, in a specific sequence (depending on the patient), usually accompanied by a sine-wave stimulation of the digestive tract. This is a dynamic treatment, simple, inexpensive, and universally applicable. It helps recover digestive function, stimulates toxin elimination, "cleanses the blood," enhances immune function, and has several other effects. It moves the system along toward a healthier state.[115] Exercise often achieves similar results. Many naturopathic modalities can be used to stimulate the overall vital force.

More specific approaches to stimulation, although general in effect, are applied differently to each patient and have a less general effect than those previously mentioned. Homeopathy and acupuncture[116–118] are often the primary methods of such stimulation. They add little to the system; they are not gross chemical treatments. They work with what is there, stimulating a reaction, stimulating function, and correcting disturbed patterns.

Each method helps move the system out of its disturbed state and, with the reduction of encumbrance, helps move it toward health.

Finally, exposure to the patterns, rhythms, and forces of nature is a traditional part of naturopathic medicine and the tradition of nature doctors throughout the world. As previously noted, "We exist as part of complex patterns of matter, energy, and spirit,"[2] and the natural progression of these patterns, and the drive toward health inherent in them, is a natural ally for the physician. Exposure to appropriate rhythms, patterns, and forces of nature strengthens vitality and stimulates the healing power of nature.

Support Weakened or Damaged Systems or Organs

Some systems or functions require more than stimulation to improve. Some organs are weakened or damaged (e.g., adrenal fatigue after prolonged stress), and some systems are blocked or congested (e.g., the hepatic detoxification pathways) and require extra help. This is where naturopathic physicians use their vast natural medicinary. Botanical medicines can affect any system or organ, enhancing its function, improving its circulation, providing specific nutrition, and stimulating repair. Glandular substances can be applied to a similar purpose. Plus, there are a growing number of evidence-based "nutraceuticals"—biological compounds that enhance metabolic pathways and provide specific substances to enhance metabolic function.[119–130]

Naturopathic physicians can also apply specific homeopathic medications, usually in the lower potencies, which act nutritively and can stimulate specific organs or functions. This method, generally referred to as *drainage,* can be used to stimulate detoxification of specific substances from the body in general or of specific organ systems or tissues. Dr. Pizzorno's work in *Total Wellness* and *The Toxin Solution*[131,132]*;* the work of "functional medicine" leader Jeffrey Bland, PhD; and the *Textbook of Functional Medicine* by Jones[90] exemplify the clinical strategies applied at this level of the therapeutic order. These strategies are used to restore optimal function to an entire physiological system (immune, cardiovascular, detoxification, life force, endocrine).[131,132]

One can also use specific exercises to stimulate or enhance organ health. Some systems of yoga and qi gong are organ specific. Specific applications of hydrotherapy and other physiotherapy systems can be applied to enhance the function of organs or tissues.

It has been the clinical experience of many naturopathic physicians that these methods, combined with an appropriate diet and a healthier regimen, along with constitutional hydrotherapy, appropriate homeopathy, and acupuncture, bring most health problems back to normal, without negative consequence, rapidly, efficiently, and permanently.

Address Structural Integrity

Many structural problems result from generalized stress of some kind on internal systems. For example, midback misalignment or discomfort (T1–T12) is often found associated with a history of underlying stress on the digestive organs, the enervation of which originates at those spinal segments. One can manipulate the vertebra back into proper alignment or massage contracted musculature, but until one corrects the underlying functional disturbance, there will be a tendency to repeated structural misalignment. In some circumstances, the singular problem may be simply structural disintegrity. One may have fallen or been hit in some fashion and simply needs the neck manipulated back into proper alignment and the surrounding soft tissue relaxed. There may be no dietary error or other disturbance aside from the original injury, and correction requires only simple manipulation or therapeutic massage. This is an example of the flexibility of the therapeutic order concept. In this case, first-order therapeutics manipulate the cervical spine or relax chronically contracted muscles. Usually, however, the problem of structure is part of the larger problem, and such intervention becomes a fourth-order therapeutic.[70]

Reintegrating structure can occur in many ways, one of which is the method of "bone cracking" known to the ancient Greeks and Chinese and probably all other ancient healing cultures. However, there are nonforce manipulative systems that include many modalities of therapeutic massage. Some systems of exercise are designed to reintegrate and maintain normal structural relationships. Any of these might be appropriate to a specific patient. By approaching the problem in the context of the therapeutic order, one can expect structural corrections to be required only occasionally and for the results to be more or less permanent.

Address Pathology: Use Specific Natural Substances, Modalities, or Interventions

Having gone through the first four steps of this therapeutic hierarchy, most patients improve. The improvement is based on the sound footing of the underlying correction or removal of fundamental causative elements. It is also based on the intrinsic nature of the body to heal itself using the least possible force. Most pathology improves or disappears under these circumstances, but sometimes it is necessary to address pathology. This may be the case because the particular pathology may be threatening to life or limb. Acting on this threat is imperative. It can often be done with naturopathic means, directed specifically against the pathology. Biochemical or genetic individuality also can demand an emphasis at this level of intervention.

One of the major conflicts in naturopathic medicine is that some practitioners find it expedient to diagnose and treat pathology (the standard medical model) rather than pursue a naturopathic model of practice. This approach tends to be less satisfying and less productive of the most elegant outcomes and the long-term continued health of the patient. It also reduces the capacity of the physician to treat, such as in cases where there is no evidence-based treatment for the pathology in question, or where there is no clear diagnosis (i.e., no distinct pathology to treat). This approach is increasingly referred to as "green allopathy." However, the vast body of knowledge that naturopathic education presents in this arena makes such an approach seductive, especially in a culture that more or less expects, supports, reinforces, and pays for a biomedical ("allopathic") approach to diagnosis and treatment.

It is easy to do this. The culture is accustomed to this model and often expects to encounter this in the naturopathic physician's office. In some states, such as Oregon, Washington, and Arizona, where the naturopathic formulary includes most antibiotics and many pharmaceutical drugs, one can practice almost without distinction from a medical doctor. The typical naturopathic formulary is often sufficient to prescribe on a strictly pathological basis.

The problem with this is that it is generally not as effective, especially in the treatment of chronic disease. The value of naturopathic medicine in our culture is not that naturopathic physicians can function almost like medical doctors, with a "natural" formulary instead of drugs. It is that they offer a fundamentally different approach, one based on the restoration of health rather than the treatment of disease.

Given all of this, it still may be useful to directly address the pathological entity or its etiology.[112,133-136] When treating an antibiotic-resistant infection, for example, it may be useful to apply botanical medicines with specific antibiotic properties, along with immune tonics and the more fundamental steps of this therapeutic hierarchy. In difficult cases, such as many cancers, using agents that have specific, pathology-based therapeutics may be an essential element of comprehensive treatment. The naturopathic formulary provides a vast and increasing number of such options. One advantage of such treatment

is that, in general, when applied by a knowledgeable practitioner, it rarely adds more burden or toxicity to the system. Naturopathic pathology-based treatments still follow the dictum "do no harm."

Address Pathology: Use Specific Pharmacological or Synthetic Substances

About 800,000 medical doctors and osteopathic physicians in the United States are trained in the science of pathology-based treatment, using pharmaceuticals and surgery, for example. There are times when such an approach is necessary to preserve life, limb, or function. Although some naturopathic physicians, by training and by statute, may prescribe pharmaceuticals or perform minor office procedures and surgeries, naturopathic physicians may also refer patients in need of such services to appropriate standard medical doctors (MDs) or medically trained osteopaths (DOs). In a growing number of states, NDs can legally provide an expanding range of prescription drugs. Although this is an important tool for the naturopathic primary caregiver, this privilege requires enhanced responsibility for the ND to prescribe those substances only as needed—and to thoroughly rely on applying the least force appropriate to effect recovery and protect patient safety. Both Dr. Lust (at the end of his life) and Dr. Bastyr recognized the need for NDs to have the ability to access, as needed, prescriptive medications and perform minor office procedures to function as primary caregivers. However, both admonished that the philosophy and principles of the medicine guide their judicious use—only as truly needed, based on the least force necessary to restore the patient to health.

Naturopathic physicians are well trained in this regard and respect the necessity and utility of standard medical practice in appropriate situations. Some disagreement exists regarding which situations may be appropriate. The AANP has developed position papers to resolve some of these questions.

In general, although recognizing the necessity of such treatment, most naturopathic physicians also recognize that such treatment often carries consequences that also must be addressed.

Suppress Pathology

Sometimes it is necessary, when there is a risk of harm to the patient's health or tissue or to relieve suffering, to suppress pathology. Medical doctors are especially trained in this art and have powerful and effective tools with which to do this. Unfortunately, suppression, because it does not fundamentally remove or address essential causative factors (e.g., dietary error) often results in the development of other, often deeper disturbance or pathology. Because much pathological expression is the result of the actual self-healing mechanisms (e.g., inflammation), suppressive measures, in general, work in opposition to the *vis medicatrix naturae.* The result of suppression is that the fundamental disturbing factors are still at play within the person, still disrupting function to some extent, whereas the suppression reduces the symptomatic expression and resolution of disturbance. One simple example of this is the overuse of oral corticosteroidal anti-inflammatory and antihistaminic drugs in the treatment of acute asthma. This usually effectively opens the airways. However, prolonged use weakens the patient. If the treatment persists, the patient may become immune compromised or osteoporotic or can develop psychological disorders. These symptoms are part of the long-term effects of steroids.[137] It may, of necessity, maintain breathing, but the long-term cost to the organism can be high.

Suppression, although it may be lifesaving, often has serious consequences. With standard medical methods of care, the cure of chronic illness is often elusive. This is the benefit of the naturopathic approach: by taking a nonsuppressive course of action, based on sound physiological principles, one can often restore health without recourse to the potential damage of suppression. Naturopathic physicians, although recognizing the occasional necessity of suppressive approaches, generally avoid suppression, which is a primary way in which physicians can inflict harm, even with the best of intentions.

THEORY IN NATUROPATHIC MEDICINE

The therapeutic hierarchy is based on the observation of the nature of healing and the inherent order of the healing process. It is part of a unifying theory of naturopathic medicine, an outgrowth of the principles that underlie naturopathic thinking. It provides the physician with instructions that order the many therapeutic modalities used by the practice.

The consensus definition of naturopathic medicine, adopted by the AANP in 1989, is a statement of identity, distinguishing naturopathic medicine from other systems of medical thought. Contained within it is a set of instructions regarding the practice of the medicine. The three concepts discussed here—"disease as process," "the determinants of health," and "the therapeutic order"—are an articulation of these instructions. They are presented as a clinical theory of naturopathic medicine. They have been crystallized, as is the definition, from the observation by nature doctors throughout time and across many traditions of the nature of health, disease, and healing. They provide the physician with instructions. These instructions include a procedure for thinking about human illness in such a way that one can approach its cure in an ordered fashion by understanding its process as an expression of the *vis medicatrix naturae.* It provides the framework for truly evaluating the patient as a whole being: spiritual, mental/emotional, and physical, rather than as a category of pathology. Plus, the theory of naturopathic medicine provides the physician a system for organizing and efficiently integrating the vast therapeutic array provided in naturopathic medicine. Ultimately, it satisfies Hahnemann's observation of the ideal role of medicine, that "the highest ideal of cure is rapid, gentle and permanent restoration of the health … in the shortest, most reliable and most harmless way, upon easily comprehensible principles."[93] The roots of the observations that form this theory are traceable through the mid- and early 20th century, to the traditional theory of the 19th-century European nature cure, and to the roots and theories of traditional world medicines. Hippocrates's writings on the *vis medicatrix naturae* form a foundation that historically underpins the development of this theory.[138,139]

Finally, it is observable across many traditional world medicines that various healing orders are described. Such structures hold implications for public and community health priorities and suggest the reprioritization of healthcare priorities and financing. Implications for public policy and the growing national disease debt invite exploration.

Although this presentation is not comprehensive, the attempt has been made to demonstrate these roots, at least in some of their major articulations. The work presented here is a continuation of this historical process, which ultimately is driven by the true mission of the physician: to ease suffering and to preserve life.

> *What Methods of Cure Are in Conformity with the Constructive Principle in Nature? Those methods which: Establish normal surroundings and natural habits of life in accord with Nature's Laws. Economize vital force. Build up the blood on a natural basis, that is, supply the blood with its natural constituents in right proportions. Promote the elimination of waste matter and poisons without in any way injuring the human body. Arouse the individual in the highest possible degree to the consciousness of personal accountability and the necessity of intelligent personal effort and self-help.*[29]

The History of Naturopathic Medicine: Origins and Overview

George W. Cody, JD, MA, and *Heidi Hascall*, MA*

OUTLINE

Editors' Note: This is the first of two chapters comprehensively presenting the origins and evolution of naturopathic medicine. Quotes from key historical figures are used extensively in both chapters to illustrate how the ideas of naturopathic medicine originated and evolved. One challenge with this approach is that the language use and terminology more than a century ago are somewhat different from the current vocabulary. In addition, these pioneers were limited by the very early stages of the biological sciences because rigorous research into physiology and pathology was just beginning. Thus, from the modern perspective, some ideas may seem quaint, awkward, or "unscientific" based on our current understanding. Nonetheless, the concepts of health and disease they developed, despite the limited biological research, were remarkably insightful and, as well demonstrated by the more than 200 chapters in this textbook, have almost all now been fully validated. In fact, a number of their dire predictions of increased incidence of chronic disease if conventional medicine practices became dominant have now been conclusively demonstrated to have been correct. We urge the reader to focus on the evolution of the concepts and not be distracted by the antiquated terminology.

INTRODUCTION

Naturopathy, as a generally used term, emerged in America from the writings and promotion of Benedict Lust. Naturopathy, or "nature cure," is both a way of life and a concept of healing that employs various natural means of treating human infirmities and disease states. The earliest mechanisms of healing associated with the term, as used by Lust, involved a combination of hygienics and hydropathy (hydrotherapy). The term itself was coined in 1895 by Dr. John Scheel of New York City to describe his method of health care. However, earlier forerunners of these concepts already existed in the history of natural healing, both in America and in the Austro-Germanic European core.

Lust came to this country from Germany in the 1890s as a disciple of Father Sebastian Kneipp, a Dominican priest, and as an emissary dispatched by Father Kneipp to bring hydrotherapy to America. Lust purchased the term *naturopathy* from Scheel in 1902 to describe the eclectic compilation of doctrines of natural healing that he envisioned to be the future of natural medicine. In January 1902, Lust, who had been publishing the *Kneipp Water Cure Monthly* and its German-language counterpart in New York since 1896, changed the name of the journal to *The Naturopath and Herald of Health* and evoked the dawn of a new health care era with the following editorial:

> *Naturopathy is a hybrid word. It is purposely so. No single tongue could distinguish a system whose origin, scope and purpose is universal—broad as the world, deep as love, high as heaven. Naturopathy was not born of a sudden or a happen-so. Its progenitors have for eons been projecting thoughts and ideas and ideals whose culminations are crystallized in the new Therapy. Connaro, doling out his few fixed ounces of food and drink each day in his determined exemplification of Dietotherapy; Priessnitz, agonizing, despised and dejected through the long years of Hydropathy's travail; the Woerishofen priest, laboring lovingly in his little parish home for the thousands who journeyed Germany over for the Kneipp cure; Kuhne, living vicariously and dying a martyr for the sake of Serotherapy; A.T. Still, studying and struggling and enduring for his faith in Osteopathy; Bernarr Macfadden, fired by the will to make Physical Culture popular; Helen Willmans, threading the mazes of Mental Science, and finally emerging triumphant; Orrison Sweet Maraden, throbbing in sympathy with human faults and failures, and longing to realize Success to all mankind—these and hosts of*

* Previous edition contributor

others have brought into being single systems whose focal features are perpetuated in Naturopathy.

Jesus Christ—I say it reverently—knew the possibility of physical immortality. He believed in bodily beauty; He founded Mental Healing; He perfected Spirit-power. And Naturopathy will include ultimately the supreme forces that made the Man of Galilee omnipotent.The scope of Naturopathy is from the first kiss of the new-found lovers to the burying of the centenarian whose birth was the symbol of their perfected one-ness. It includes ideally every life-phase of the id, the embryo, the foetus, the birth, the babe, the child, the youth, the man, the lover, the husband, the father, the patriarch, the soul.

We believe in strong, pure, beautiful bodies thrilling perpetually with the glorious power of radiating health. We want every man, woman and child in this great land to know and embody and feel the truths of right living that mean conscious mastery. We plead for the renouncing of poisons from the coffee, white flour, glucose, lard, and like venom of the American table to patent medicines, tobacco, liquor and the other inevitable recourse of perverted appetite. We long for the time when an eight-hour day may enable every worker to stop existing long enough to live; when the spirit of universal brotherhood shall animate business and society and the church; when every American may have a little cottage of his own, and a bit of ground where he may combine Aerotherapy, Heliotherapy, Geotherapy, Aristophagy and nature's other forces with home and peace and happiness and things forbidden to flat-dwellers; when people may stop doing and thinking and being for others and be for themselves; when true love and divine marriage and pre-natal culture and controlled parenthood may fill this world with germ-gods instead of humanized animals.In a word, Naturopathy stands for the reconciling, harmonizing and unifying of nature, humanity and God.

Fundamentally therapeutic because men need healing; elementally educational because men need teaching; ultimately inspirational because men need empowering, it encompasses the realm of human progress and destiny.

Perhaps a word of appreciation is due Mr. John H. Scheel, who first used the term "Naturopathic" in connection with his Sanitarium "Badekur," and who has courteously allowed us to share the name. It was chosen out of some 150 submitted, as most comprehensive and enduring. All our present plans are looking forward some five or ten or fifty years when Naturopathy shall be the greatest system in the world.

Actually the present development of Naturopathy is pitifully inadequate, and we shall from time to time present plans and ask suggestions for the surpassing achievement of our world-wide purpose. Dietetics, Physical Culture and Hydropathy are the measures upon which Naturopathy is to build; mental culture is the means, and soul-selfhood is the motive.

If the infinite immensity of plan, plea and purpose of this particular magazine and movement were told you, you would simply smile in your condescendingly superior way and straightway forget. Not having learned as yet what a brain and imagination and a will can do, you consider Naturopathy an ordinarily innocuous affair, with a lukewarm purpose back of it, and an ebbing future ahead of it. Such is the character of the average wishy-washy health movement and tumultuous wave of reform.

Your incredulous smile would not discomfit us—we do not importune your belief, or your help, or your money. Wherein we differ from the orthodox self-labeled reformer, who cries for sympathy and cringes for shekels.

We need money most persistently—a million dollars could be used to advantage in a single branch of the work already definitely planned and awaiting materialization; and we need co-operation in a hundred different ways. But these are not the things we expect or deem best. Criticism, fair, full and unsparing is the one thing of value you can give this paper. Let me explain. Change is the keynote of this January issue—in form, title, make-up. If it please you, your subscription and a word to your still-benighted friends is ample appreciation. But if you don't like it, say so. Tell us wherein the paper is inefficient or redundant or ill-advised, how it will more nearly fit into your personal needs, what we can do to make it the broadest, deepest, truest, most inspiring of the mighty host of printed powers. The most salient letter of less than 300 words will be printed in full, and we shall ask to present the writer with a subscription-receipt for life.

By to-morrow you will probably have forgotten this request; by the day after you will have dropped back into your old ways of criminal eating and foolish drinking and sagged standing and congested sitting and narrow thinking and deadly fearing—until the next progress paper of New Thought or Mental Science or Dietetics or Physical Culture prods you into momentary activity.

Between now and December we shall tell you just how to preserve the right attitude, physical and mental, without a single external aid; and how, every moment of every day, to tingle and pulsate and leap with the boundless ecstasy of manhood consciously nearing perfection.

A BRIEF HISTORY OF EARLY AMERICAN MEDICINE WITH AN EMPHASIS ON NATURAL HEALING

To understand the evolutionary history of naturopathic medicine in this country, it is necessary to view the internal development of the profession against the historical, social, and cultural backdrop of American social history.

Medicine in America: 1800–1875

In the America of 1800, although a professional medical class existed, medicine was primarily domestically oriented. An individual who fell ill was commonly nursed by a friend or family member who relied upon William Buchan's *Domestic Medicine* (1769), John Wesley's *Primitive Physic* (1747), or John Gunn's *Domestic Medicine* (1830).[1]

Professional Medicine

Professional medicine transferred from England and Scotland to America in prerevolutionary days. However, 18th- and early-19th-century America considered the concept of creating a small, elite, learned profession to run counter to the political and institutional concepts of early American democracy.[1]

The first medical school in the American colonies opened in 1765 at what was then the College of Philadelphia (later the University of Pennsylvania), and the school was dominated by revolutionary leader and physician Benjamin Rush, a signatory to the Declaration of Independence. The proliferation of medical schools to train the new professional medical class began seriously after the war of 1812. Between 1810 and 1820, new schools were established in Baltimore, Lexington, Cincinnati, and even in rural communities in Vermont and Western New York. Between 1820 and 1850, substantial numbers of schools were established in the western rural states. By 1850, there were 42 medical schools recognized in the United States, although there were only 3 in all of France.

Generally, these schools were started by a group of five to seven local physicians approaching a local college with the idea of establishing a medical school in conjunction with the college's educational facilities. The schools were largely apprenticeship based, and the professors received their remuneration directly from fees paid by the students.

The requirements for a doctor of medicine (MD) degree in late-18th- and early-19th-century America were roughly as follows:

- Knowledge of Latin and natural and experimental philosophy
- Three years of serving an apprenticeship under practicing physicians
- Attending two terms of lectures and passing of attendant examinations
- A thesis

Additionally, graduating students had to be at least 21 years of age.[1]

The rise of any professional class is gradual and marked by difficulties, and varying concepts existed as to the demarcation of a "professional" physician. Contrasts included graduates of medical school versus nongraduates, medical society members versus nonmembers, and licensed physicians versus unlicensed "doctors." Licensing statutes came into existence between 1830 and 1850 but were soon repealed because they were considered "undemocratic" during the apex of Jacksonian democracy. [1]

Thomsonianism

In 1822 the rise in popularity of Samuel Thomson and his publication of *New Guide to Health* helped frustrate the creation of a professional medical class. Thomson's work was a compilation of his personal view of medical theory and American Indian herbal and medical botanical lore. Thomson espoused the belief that disease had one general cause—"cold" influences on the human body—and that disease therefore had one general remedy: "heat." Unlike the followers of Benjamin Rush and the American "heroic" medical tradition who advocated blood-letting, leeching, and the substantial use of mineral-based purgatives such as antimony and mercury, Thomson believed that minerals were sources of "cold" because they came from the ground and that vegetation, which grew toward the sun, represented "heat." [1]

As noted in Griggs's *Green Pharmacy* (the best history of herbal medicine to date), Thomson's theory developed as follows[2]:

> *Instead, he elaborated a theory of his own, of the utmost simplicity: "All diseases … are brought about by a decrease or derangement of the vital fluids by taking cold or the loss of animal warmth … the name of the complaint depends upon what part of the body has become so weak as to be affected. If the lungs, it is consumption, or the pleura, pleurisy; if the limbs, it is rheumatism, or the bowels, colic or cholera morbus … all these different diseases may be removed by a restoration of the vital energy, and removing the obstructions which the disease has generated …"*
>
> *Thus the great object of his treatment was always to raise and restore the body's vital heat: "All … that medicine can do in the expulsion of disorder, is to kindle up the decaying spark, and restore its energy till it glows in all its wonted vigor."*

Thomson's view was that individuals could be self-treating if they had a sincere "guide to health" philosophy and a copy of his book, *New Guide to Health*. The right to sell "family franchises" for the use of the Thomsonian method of healing was the basis of a profound lay movement between 1822 and Thomson's death in 1843. Thomson adamantly believed that no professional medical class should exist and that democratic medicine was best practiced by laypersons within a Thomsonian "family" unit.

By 1839, Thomson claimed to have sold some 100,000 of these family franchises called "friendly botanic societies." Although he professed to have solely the interests of the individual at heart, his system was sold at a profit under the protection of a patent he obtained in 1813.

The Eclectic School of Medicine

Some of the "botanics" (professional Thomsonian doctors) wanted to separate themselves from the lay movement by creating requirements and standards for the practice of Thomsonian medicine. Thomson, however, was adamantly against a medical school founded on his views. Thus it was not until the decade after Thomson's death that independent Thomsonians founded a medical college (in Cincinnati) and began to dominate the Thomsonian movement. These Thomsonian botanics were later absorbed into the medical sectarian movement known as the "eclectic school," which originated with the New Yorker Wooster Beach.

Beach was another of medical history's fascinating characters. From a well-established New England family, he started his medical studies at an early age, apprenticing under an old German herbal doctor, Jacob Tidd. After Tidd died, Beach enrolled in the Barclay Street Medical University in New York. Griggs[2] described the following:

> *Beach's burning ambition was to reform medical practice generally—not to alienate the entire profession by savage attacks from without—and he was convinced that he would be in a stronger position to do so if he were himself a diplomatized doctor. The faculty occasionally listened to criticism from within their own number: against onslaughts of "illiterate quacks" like Samuel Thomson, they simply closed ranks in complacent hostility.*

After opening his own practice in New York, Beach set out to win over fellow members of the New York Medical Society (into which he had been warmly introduced by the screening committee) to his point of view that heroic medicine was inherently dangerous to mankind and should be reduced to the gentler theories of herbal medicine. He was summarily ostracized from the medical society.

To Beach, this was a bitter blow, but he soon founded his own school in New York, calling the clinic and educational facility the "United States Infirmary." However, because of continued pressure from the medical society, he was unable to obtain charter authority to issue legitimate diplomas. He then located a financially ailing but legally chartered school, Worthington College, in Ohio. He opened a full-scale medical college; out of its classrooms, he launched what became known as the *Eclectic School of Medical Theory*. Griggs related the following[2]:

> *Beach had a new name for his practice: While explaining to a friend his notions of combining what was useful in the old practice with what was best in the new, the friend exclaimed, "You are an eclectic!" to which, according to legend, Beach replied, "You have given me the term which I have wanted: I am an eclectic!"*

Cincinnati subsequently became the focal point of the eclectic movement, and the E. M. Institute medical school remained until 1938 (the last eclectic school to exist in America).[3] The concepts of this sect helped form some of the theoretical underpinnings of Lust's naturopathy. Lust himself graduated from the Eclectic Medical College of the City of New York in the first decade of the 1900s.

Despite his criticism of the early allopathic movement (although the followers of Rush were not yet known as *allopaths*, a term reputed to have been coined by Samuel Hahnemann) for their "heroic" tendencies, Thomson's medical theories were "heroic" in their own fashion. Although he did not advocate blood-letting, heavy metal poisoning, and leeching, botanic purgatives—particularly *Lobelia inflata* (Indian tobacco)—were a substantial part of the therapy.

The Hygienic School of Thought

One other forerunner of American naturopathy, also originating as a lay movement, grew into existence at this time. This was the "hygienic" school, which had its genesis in the popular teachings of Sylvester Graham and William Alcott.

Graham began preaching the doctrines of temperance and hygiene in 1830. In 1839 he published *Lectures on the Science of Human Life,*

two hefty volumes that prescribed healthy dietary habits. He emphasized a moderate lifestyle, recommending an antiflesh diet and bran bread as an alternative to bolted or white bread.

Alcott dominated the scene in Boston during this same period and, together with Graham, saw that the American hygienic movement—at least as a lay doctrine—was well established.[4]

Homeopathy

By 1840, the profession of homeopathy had also been transplanted to America from Germany. Homeopathy, the creation of an early German physician, Samuel Hahnemann (1755–1843), had three central doctrines:

- The "law of similars" (that like cures like)
- That the effect of a medication could be heightened by its administration in minute doses (the more diluted the dose, the greater the "dynamic" effect)
- That nearly all diseases were the result of a suppressed itch, or "psora"

The view was that a patient's natural symptom-producing disease would be displaced after homeopathic medication by a similar, but much weaker, artificial disease that the body's immune system could easily overcome.

Originally, most homeopaths in this country were converted orthodox medical men, or "allopaths." The high rate of conversion made this particular medical sect the archenemy of the rising orthodox medical profession. (For a more detailed discussion of homeopathy, see Chapter 39.)

The first homeopathic medical school was founded in 1850 in Cleveland; the last purely homeopathic medical school, based in Philadelphia, survived into the early 1930s. [1]

The Rise and Fall of the Sects

Although these two nonallopathic sects were popular, they never comprised more than one fifth of the professional medical class in America. Homeopathy at its highest point reached roughly 15% and the eclectic school roughly 5%. However, their very existence for many years kept the exclusive recognition desired by the orthodox profession from coming within its grasp. Homeopathy was distasteful to the more conventional medical men not only because it resulted in the conversion of a substantial number of their peers but also because homeopaths generally also made a better income. The rejection of the eclectic school was more fundamental: it had its roots in a lay movement that challenged the validity of a privileged professional medical class.

The existence of three professional medical groups—the orthodox school, the homeopaths, and the eclectics—combined with the Jacksonian view of democracy that prevailed in mid-19th-century America, resulted in the repeal of virtually all medical licensing statutes existing before 1850. However, by the 1870s and 1880s, all three medical groups began to voice support for the restoration of medical licensing.

Views differ as to what caused the homeopathic and eclectic schools to disappear from the medical scene in the 50 years after 1875. One view defined a sect as follows[5]:

> *A sect consists of a number of physicians, together with their professional institutions, who utilize a distinctive set of medically invalid therapies which are rejected by other sects.*

By this definition, the orthodox or allopathic school was just as sectarian as the homeopathic and eclectic schools. Rothstein's view was that these two 19th-century sects disappeared because, beginning in the 1870s, the orthodox school grasped the European idea of "scientific medicine." Based on the research of such men as Pasteur and Koch and the "germ theory," this approach supposedly proved to be the medically proper view of valid therapy and gained public recognition because of its truth.

Another view was that the convergence of the needs of the three sects for professional medical recognition (which began in the 1870s and continued into the early 1900s) and the "progressive era" led to a political alliance in which the majority orthodox school was ultimately dominant by sheer weight of numbers and internal political authority. Starr[1] noted the following:

> *Both the homeopaths and eclectics wanted to share in the legal privileges of the profession. Only afterward did they lose their popularity. When homeopathic and eclectic doctors were shunned and denounced by the regular profession, they thrived, but the more they gained an access to the privileges of regular physicians, the more their numbers declined. The turn of the century was both the point of acceptance and the moment of incipient disintegration.*

In any event, this development was an integral part of the drive toward professional authority and autonomy established during the progressive era (1900–1917). It was acceptable to the homeopaths and the eclectics because they controlled medical schools that continued to teach and maintain their own professional authority and autonomy. However, it was after these professional goals were attained that the lesser schools of medical thought went into rapid decline. [1]

The American Influence

From 1850 to 1900, the medical counterculture continued to establish itself in America. From its lay roots in the teachings of the hygienic movement grew professional medical recognition, albeit a small minority and "irregular" view, that hygiene and hydropathy were the basis of sound medical thought (much like the Thomsonian transition to botanic and eclectic medicine).

Russell Trall

The earliest physician who had a significant effect on the later growth of naturopathy as a philosophic movement was Russell Trall, MD. As noted in James Whorton's *Crusaders for Fitness*,[4] he "passed like a meteor through the American hydropathic and hygienic movement":

> *The exemplar of the physical educator-hydropath was Russell Thatcher Trall. Still another physician who had lost his faith in regular therapy, Trall opened the second water cure establishment in America, in New York City in 1844. Immediately he combined the full Preissnitzian armamentarium of baths with regulation of diet, air, exercise and sleep. He would eventually open and or direct any number of other hydropathic institutions around the country, as well as edit the Water-Cure Journal, the Hydropathic Review, and a temperance journal. He authored several books, including popular sex manuals which perpetuated Graham-like concepts into the 1890s, sold Graham crackers and physiology texts at his New York office, was a charter member (and officer) of the American Vegetarian Society, presided over a short-lived World Health Association, and so on. His crowning accomplishment was the Hygeian Home, a "model Health Institution [which] is beautifully situated on the Delaware River between Trenton and Philadelphia." A drawing presents it as a palatial establishment with expansive grounds for walking and riding, facilities for rowing, sailing, and swimming, and even a grove for open-air "dancing gymnastics." It was the grandest of water cures, and lived beyond the Civil War period, which saw the demise of most hydropathic hospitals. True, Trall had to struggle to keep his head above water during the 1860s, but by the 1870s he had a firm financial footing (being stabilized by tuition fees from the attached Hygeio-therapeutic College). With Trall's death in 1877, however, the hydropathic phase of health reform passed.*

As made evident later in this chapter, this plethora of activity was similar to that engaged in by Benedict Lust between 1896 and his death in 1945, when he worked to establish naturopathy. The Hygeian Home and later "Yungborn" establishments at Butler, New Jersey, and Tangerine, Florida, were similar to European nature cure sanitariums, such as the original Yungborn founded by Adolph Just and the spa/sanitarium facilities of Preissnitz, Kneipp, and Just.

Trall gave a famous address to the Smithsonian Institution in Washington, DC, in 1862, under the sponsorship of the Washington Lecture Association. "The true healing art: or hygienic vs drug medication," a 2.5-hour lecture purported to have received rapt attention, was devoted to Trall's belief in the hygienic system and in hydropathy as the true healing art. The address was reprinted by Fowler and Wells (New York, 1880) with an introduction written by Trall, before his death in 1877.

Trall also founded the first school of natural healing arts in this country to have a 4-year curriculum and the authorization to confer the degree of MD. It was founded in 1852 as a "hydropathic and physiological school" and was chartered by the New York State Legislature in 1857 under the name "New York Hygio-Therapeutic College," with the legislature's authorization to confer the MD degree.

In 1862 Trall went to Europe to attend the International Temperance Convention. He took a prominent part at this meeting of reformers, specifically related to the use of alcohol as a beverage and as a medicine. He eventually published more than 25 books on the subjects of physiology, hydropathy, hygiene, vegetarianism, and temperance, among many others.

The most valuable and enduring of these was his *Hydropathic Encyclopedia,* a volume of nearly 1000 pages that covered the theory and practice of hydropathy and the philosophy and treatment of diseases advanced by older schools of medicine. At the time of his death, according to the December 1877 *Phrenological Journal* cover article featuring a lengthy obituary of Trall, this encyclopedia had sold more than 40,000 copies since its original publication in 1851.

For more than 15 years, Trall was editor of the *Water-Cure Journal* (also published by Fowler and Wells). During this period, the journal went through several name changes, including the *Hygienic Teacher* and *The Herald of Health.* When Lust originally opened the American School of Naturopathy, an English-language version of *Kneipp's Water-cure* (or *Meine Wasser-kurr* in German) being unavailable, he used only the works and writings of Trall as his texts.

Martin Luther Holbrook

By 1871, Trall moved from New York to the Hygeian Home on the Delaware River. His water-cure establishment in New York became the New Hygienic Institute. One of its coproprietors was Martin Luther Holbrook, who later replaced Trall as the editor of *The Herald of Health.* Professor Whorton noted the following[4]:

> *But Holbrook's greatest service to the cause was as an editor. In 1866 he replaced Trall at the head of The Herald of Health, which had descended from the Water-Cure Journal and Herald of Reforms (1845–1861) by the way of the Hygienic Teacher and Water-Cure Journal (1862). Under Holbrook's direction the periodical would pass through two more name changes (Journal of Hygiene Herald of Health, 1893–1897, and Omega, 1898–1900) before merging with Physical Culture.*

Trall and Holbrook both advanced the idea that physicians should teach the maintenance of health rather than simply providing a last resort in times of health crisis. Besides providing a strong editorial voice espousing vegetarianism, the evils of tobacco and drugs, and the value of bathing and exercise, dietetics and nutrition, along with personal hygiene, were strongly advanced by Holbrook and others of the hygienic movement during this era. Whorton described the idea as follows[4]:

> *The orthodox hygienists of the progressive years were equally enthused by the recent progress of nutrition, of course, and exploited it for their own ends, but their utilization of science hardly stopped with dietetics. Medical bacteriology was another area of remarkable discovery, bacteriologists having provided, in the short space of the last quarter of the 19th century, an understanding, at long last, of the nature of infection. This new science's implications for hygienic ideology were profound—when Holbrook locked horns with female fashion, for example, he did not attack the bulky, ground-length skirts still in style with the crude Grahamite objection that the skirt was too heavy. Rather he forced a gasp from his readers with an account of watching a smartly dressed lady unwittingly drag her skirt "over some virulent, revolting looking sputum, which some unfortunate consumptive had expectorated."*

Holbrook expanded on the work of Graham, Alcott, and Trall and, working with an awareness of the European concepts developed by Preissnitz and Kneipp, laid further groundwork for the concepts later advanced by Lust, Lindlahr, and others[4]:

> *For disease to result, the latter had to provide a suitable culture medium, had to be susceptible. As yet, most physicians were still so excited at having discovered the causative agents of infection that they were paying less than adequate notice to the host. Radical hygienists, however, were bent just as far in the other direction. They were inclined to see bacteria as merely impotent organisms that throve only in individuals whose hygienic carelessness had made their body compost heaps. Tuberculosis is contagious, Holbrook acknowledged, but "the degree of vital resistance is the real element of protection. When there is no preparation of the soil by heredity, predisposition or lowered health standard, the individual is amply guarded against the attack." A theory favored by many others was that germs were the effect of disease rather than its cause; tissues corrupted by poor hygiene offered microbes, all harmless, an environment in which they could thrive.*

In addition to introducing the works of Kneipp and his teachings to the American hygienic healthcare movement, Holbrook was a leader of the fight against vivisection and vaccination[4]:

> *Vivisection and vaccination were but two of the practices of medicine criticized in the late 19th century. Therapy also continued to be an object of protest. Although the heroism of standard treatment had declined markedly since mid-century, a prescription was still the reward of any visit to the doctor, and drugless alternatives to healing were appearing in protest. Holbrook published frequent favorable commentaries on the revised water cure system of Germany's Kneipp. A combination of baths, herbal teas, and hardening exercises, the system had some vogue in the 1890's before flowering into naturopathy. Holbrook's journal also gave positive notices to osteopathy and "chiropathy" [chiropractic], commending them for not going to the "drugstore or ransack[ing] creation for remedies nor load[ing] the blood with poison." But though bathing and musculoskeletal manipulation were natural and nonpoisonous, Holbrook preferred to give the body complete responsibility for healing itself. Rest and proper diet were the medicines of this doctor who billed himself as a "hygienic physician" and censured ordinary physicians for being engrossed with disease rather than health.*

The Beginnings of "Scientific Medicine"

While the hygienic movement was making its effect, the orthodox medical profession, in alliance with the homeopaths and eclectics, was making significant advances. The orthodox profession, through the political efforts of the American Medical Association (AMA), first tried to remove sectarian and irregular practitioners by segregating them from the medical profession altogether. It did so by formulating and publishing its first national medical code of ethics in 1847. (In 1846 the orthodox profession formed the AMA to represent its professional views.) The code condemned proprietary patents (even carrying over into a physician's development of surgical or other medical implements, which led to its greatest criticism); encouraged the adoption of uniform rules for payment in geographic areas; condemned the practice of contract work; prohibited advertising and fee-sharing even among specialists and general practitioners; eliminated blacks and women; and, most significantly, prohibited any consultation or contact with irregulars or sectarian practitioners. The code stated the following[6]:

> *No one can be considered as a regular practitioner, or a fit associate in consultation, whose practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry.*

In the late 1870s and into the 1880s the major sects—the orthodox or allopathic school, the homeopaths, and the eclectics—began to find more reason to cooperate to obtain common professional goals. These included the enactment of new licensing laws and the creation of a "respectable" medical educational system. Also at this time, the concept of "scientific medicine" was brought to America. (Although Starr differed from Rothstein regarding the causes of the decline of the homeopathic and eclectic sectarian schools, he noted that Rothstein clearly documented the 19th-century transition of medicine into a recognized professional class composed of both the minority sects and the orthodox school.)

This transition from conflict between the major sects resulted in the erosion of the implementation of the code of ethics; the cooperation among the sects to revive medical licensing standards; the admission of sectarian physicians to regular medical societies; and ultimately, a structural reorganization of the AMA, which occurred between 1875 and 1903.[15]

Once the cooperation among the three medical views began, the medical class dominated by the regular school came fully into power. The homeopathic and eclectic schools of thought met their demise finally because of two significant events: (1) the rapid creation of new medical educational standards between 1900 and 1910, culminating in the publication of the famous "Flexner Report" (1910), and (2) the effective infusion of millions of dollars into selected allopathic medical schools by the newly created capitalistic philanthropic foundations, principally the Carnegie and Rockefeller Foundations.

The Foundations

The effect of the monies from the Carnegie and Rockefeller Foundations was clearly documented[7] and described in detail in Brown's *Rockefeller Medicine Men*.[8] The effect of the monies from these foundations, contributed to medical schools that met the AMA's views on medical education and philosophy, cannot be underestimated.

This process has been well documented.[1,7,9,10] As discussed by Burrows,[10] these educational reforms allowed the AMA to forge a new alliance with state legislators and push quickly for medical licensing designed to reward the educational and medical expertise of the newly orthodox "scientific medicine" and to the exclusion of all others.

Medical Education in Transition

Based on the rising example of scientific medicine and its necessary connection to research, the educational laboratory, and a more thorough scientific education as a preamble to medical practice, Harvard University (under the presidency of Charles Elliott) created a 4-year medical educational program in 1871. The primal modern medical educational curriculum was devised and set in motion more than 20 years later at Johns Hopkins University under the leadership of William Osler and William Welch, using the resources from the original endowment of the hospital and university from the estate of Johns Hopkins.[1]

Other schools followed suit. By the time the AMA set up its Council on Medical Education in 1904, it was made up of five members from the faculties of schools modeled on the Johns Hopkins prototype. This committee set out to visit and rate each of the 160 medical schools then in operation in the country. The ratings used were class A (acceptable), class B (doubtful), and class C (unacceptable).

Eighty-two schools received a class A rating, led by Harvard, Rush (Chicago), Western Reserve, the University of California, and notably, Johns Hopkins. Forty-six schools received a class B rating, and 32 received a class C rating. The class C schools were mostly in rural areas, and many of them were proprietary in nature.

Flexner Report

Subsequent to the AMA ratings, the Council on Medical Education applied to the Carnegie Foundation to commission an independent report to verify its work. Abraham Flexner, a young, energetic, and noted educator, was chosen for this task by the Carnegie Foundation and accompanied by the secretary (Nathan Colwell, MD) of the Council on Medical Education, who participated in all of the committee site visits.

Flexner visited each of the 162 operating U.S. medical schools. The widely publicized *Flexner Report* put the nails in the coffins of all schools with class C ratings and many with class B ratings. Significantly, the educational programs of all but one eclectic school (in Cincinnati) and one homeopathic school (in Philadelphia) were eliminated by 1918.

The eclectic medical schools, in particular, were severely affected by the report. Griggs explained this effect as follows[2]:

> *Of the eight Eclectic schools, the Report declared that none had "anything remotely resembling the laboratory equipment which is claimed in their catalogs." Three of them were under-equipped; the rest "are without exception filthy and almost bare. They have at best grimy little laboratories … a few microscopes, some bottles containing discolored and unlabeled pathological material, in an incubator out of commission, and a horrid dissecting room." The Report found them more culpable than a regular school for these inadequacies: "… the Eclectics are drug-mad; yet, with the exception of the Cincinnati and New York schools, they are not equipped to teach the drugs or drug therapy which constitutes their sole reason for existence."*

The other regular schools that conducted homeopathic or eclectic programs had by that time phased them out in the name of "scientific medicine" (see also Haller[3]).

Pharmaceutical Industry

During this same time, the AMA, through several of its efforts, began a significant alliance with the organized pharmaceutical industry of the United States, shaping it in a manner acceptable to the allopathic profession.[1,9,11]

The New "Sects"

The period from 1890 to 1905 saw the rise of three new medical sects and several other smaller "irregular" schools that replaced those soon to pass from the scene. In Missouri, Andrew Taylor Still, originally trained as an orthodox practitioner, founded the school of medical thought known as "osteopathy" and in 1892 opened the American School of Osteopathy in Kirksville, Missouri. In 1895 Daniel David Palmer, originally a magnetic healer from Davenport, Iowa, performed the first spinal manipulation, which gave rise to the school he termed "chiropractic." He formally published his findings in 1910, after having founded a chiropractic school in Davenport, Iowa. In 1902 Lust founded the American School of Naturopathy in New York.

Although some of the following discussions are devoted to the schools of healing called *osteopathy* and *chiropractic,* only that portion of their histories related to the history of naturopathy is mentioned.[12] (A full study of osteopathic medicine in America may be found in *The D.O.'s* by Gevitz,[13] and a reasonable sketch of chiropractic medicine may be found in Kapling's chapter in *Alternative Medicine.*[12])

As noted by Starr,[1] these new sects, including Christian Science, formulated by Mary Baker Eddy,[14] either rose or fell on their own without ever completely allying with orthodox medicine. Starr theorized that these sects arose late enough that the orthodox profession and its political action arm, the AMA, had no need to ally with them and would rather battle with them publicly. This made these sectarian views separate and distinct from the homeopathic and eclectic schools.

THE FOUNDING OF NATUROPATHIC MEDICINE

Benedict Lust

Lust came to the United States in 1892 at the age of 23. He suffered from a debilitating condition in his late teens while growing up in Michelbach, Baden, Germany, and was sent by his father to undergo the Kneipp cure at Woerishofen. He stayed there from mid-1890 to early 1892; not only was he "cured" of his condition, but he also became a protégé of Kneipp. Dispatched by Kneipp to bring the principles of the Kneipp water cure to America, he emigrated to New York City.

By making contact in New York with other German Americans who were also becoming aware of the Kneipp principles, Lust participated in the founding of the first "Kneipp Society," which was organized in Jersey City, New Jersey, in October 1896.

Lust also attended the first organizational meeting (in mid-October 1896) of the Kneipp Society of Brooklyn. Subsequently, through Lust's organization and contacts, Kneipp Societies were founded in Boston; Chicago; Cleveland; Denver; Cincinnati; Philadelphia; Columbus; Buffalo and Rochester, New York; New Haven, Connecticut; San Francisco; New Mexico; and Mineola on Long Island, New York.

The members of these organizations were provided with copies of the *Kneipp Blatter* and a companion English publication Lust began to put out called *The Kneipp Water Cure Monthly.*

The first "sanatorium" using Kneipp's principles was organized in this country shortly before Lust's arrival. Charles Lauterwasser, an earlier student of Kneipp's who called himself a hydrothic physician and natural scientist, opened the Kneipp and Nature Cure Sanatorium in Newark, New Jersey, in 1891.

In 1895 the Brooklyn Light and Water-Cure Institute was established in Brooklyn, New York, by L. Staden and his wife Carola, both graduates of Lindlahr's Hygienic College in Dresden, Germany. According to their advertising, they specialized in natural healing, Kneipp water treatment, and Kuhne's and Preissnitz's principles (including diet cure, electric light baths [both white and blue], electric vibration massage, Swedish massage and movements, and Thure Brandt massage).

In 1895 Lust opened the Kneipp Water-Cure Institute in New York City, listing himself as the owner and Dr. William Steffens as the residing physician. At the same address (on 59th Street) in October of that year, Lust opened the first "Kneipp store." In the originating November 1896 edition of *The Kneipp Water Cure Monthly* and *Kneipp Blatter,* he advertised his store and sanitarium as personally authorized by Kneipp. In the first part of 1896, just before his organizing of various Kneipp Societies around the New York area, Lust returned to Woerishofen to study further with Kneipp.

Kneipp died in Germany, at Woerishofen, in June 1897. With his passing, Lust was no longer bound strictly to the principles of the Kneipp water cure. He had begun to associate earlier with other German American physicians, principally Dr. Hugo R. Wendel (a German-trained *Naturarzt*), who began, in 1897, to practice in New York and New Jersey as a licensed osteopathic physician. In 1896 Lust entered the Universal Osteopathic College of New York, graduated in 1898, and became licensed as an osteopathic physician. In 1897 Lust became an American citizen.

Once he was licensed to practice as a healthcare physician in his own right, Lust began the transition toward the concept of "naturopathy." Between 1898 and 1902, when he adopted the term *naturopath,* Lust acquired a chiropractic education and changed the name of his Kneipp store to the Health Food Store (the original facility to use that name and concept in this country), specializing in providing organic foods and the materials necessary for drugless cures. He also began the New York School of Massage (listed as established in 1896) and the American School of Chiropractic, all within the same facility—Lust's Kneipp Institute.

Photographs of this facility taken between 1902 and 1907, when the facility moved to another location, show a five-story building listing "Benedict Lust—Naturopath, Publisher, Importer."

He returned to Germany in 1907 to visit with Dr. Baumgarten, Kneipp's medical successor at the Woerishofen facility, which was then run, in cooperation with Baumgarten, by the Reverend Prior Reily, the former secretary to Kneipp and his lay successor at Woerishofen. As directed by Kneipp, Reily had completed, after Kneipp's death, Kneipp's masterwork *Das grosse Kneipp—Buch.* Lust maintained contact with the partnership of Reily and Baumgarten throughout the early part of the 20th century.

In 1902 when he purchased and began using the term *naturopathy* and calling himself a "naturopath," Lust, in addition to his New York School of Massage and American School of Chiropractic, his various publications, and his operation of the Health Food Store, began to operate the American School of Naturopathy, all at the same 59th Street New York address.

By 1907 Lust's enterprises had grown sufficiently large that he moved them to a 55-room building. It housed the Naturopathic Institute, Clinic, and Hospital; the American Schools of Naturopathy and Chiropractic; the now-entitled Original Health Food Store; Lust's publishing enterprises; and the New York School of Massage. The operation remained in this four-story building, roughly twice the size of the original facility, from 1907 to 1915.

From 1912 to 1914, Lust took a "sabbatical" from his operations to further his medical education. By this time, he had founded his large estate-like sanitarium in Butler, New Jersey, known as "Yungborn" after the German sanitarium operation of Adolph Just.

In 1912 he attended the Homeopathic Medical College in New York, which, in 1913, granted him a degree in homeopathic medicine, and in 1914, he received his degree in eclectic medicine. In early 1914 Lust traveled to Florida and obtained an MD's license on the basis of his graduation from the Homeopathic Medical College and the Eclectic Medical College of New York City.

He founded another "Yungborn" sanitarium facility in Tangerine, Florida, and for the rest of his life, while continuing his publications, he engaged in active public lecturing. He also continued to maintain a practice in New York City and operated the sanitariums in Florida and New Jersey. His schools were operated primarily by Hugo R. Wendel.

From 1902, when he began to use the term *naturopathy,* until 1918, Lust replaced the Kneipp Societies with the Naturopathic Society of America. Then, in December 1919, the Naturopathic Society of America was formally dissolved because of its insolvency, and Lust founded the American Naturopathic Association (ANA). Thereafter, 18 states incorporated the association.

In 1918, as part of his effort to replace the Naturopathic Society of America (an operation into which he invested a great deal of his funds and resources in an attempt to organize a naturopathic profession) and replace it with the ANA, Lust published the first *Universal Naturopathic Directory and Buyer's Guide* (a "yearbook of drugless therapy").

Although a completely new version was never actually published, despite Lust's announced intention to make this volume an annual publication, annual supplements were published in either *The Naturopath and Herald of Health* or its companion publication *Nature's Path* (which commenced publication in 1925). The *Naturopath and Herald of Health,* sometimes printed with the two phrases reversed, was published from 1902 to 1927 and from 1934 until after Lust's death in 1945.

This volume documented the merging of the German and American influences that guided Lust in his development of the practice of naturopathy. The voluminous tome, which ran to 1416 pages, was dedicated to:

> *The memory of all those noble pioneers and discoverers who have died in the faith of Naturopathy, and to their courageous successors in the art of drugless healing, all of whom have suffered persecution for saving human lives that medical autocracy could not save, this work is respectfully dedicated by its editor Benedict Lust, N.D., M.D., "The Yungborn," Butler, New Jersey, U.S.A., April 1, 1918.*

Lust's introduction is reprinted here in its entirety to show the purpose of the directory and the status of the profession in the early 1900s:

Introduction

To the Naturopathic Profession, the Professors of Natural Healing in all its branches, the Professors of Scientific Diet, Hydrotherapy, Heliotherapy, Electrotherapy, Neuropathy, Osteopathy, Chiropractic, Naprapathy, Magnetopathy, Phytotherapy, Exercise, Swedish Movements, Curative Gymnastics, Physical and Mental Culture, Balneopathy, and all forms of Drugless Healing, the Faculties of all Drugless Colleges, Institutions, Schools, and all Professors of Hygiene and Sanitation; Manufacturers of Naturopathic Supplies; Publishers of Health Literature, and Natural Healing Societies, GREETINGS: I have the honor to present to your consideration and goodwill, this Volume, No. 1, Year 1918–1919, of the Universal Naturopathic Directory, Year Book of Drugless Healing, and Buyers' Guide.

For twenty-two years past, the need of a directory for Drugless Therapy has been felt. The medical world is in a condition of intense evolution at the present time. It is evolving from the Drugging School of Therapy to the Drugless School. People by the million have lost confidence in the virtues of Allopathy and are turning with joyful confidence to the Professions of Natural Healing until it has been estimated that there are at least forty thousand practitioners of Naturopathic healing in the United States.The motto that IN UNITY THERE IS STRENGTH is the foundation of the present enterprise.

Hitherto, the drugless profession has lacked that prestige in the eyes of the public, which comes from the continuous existence of a big institution, duly organized and wielding the immense authority which is derived no less from organization and history than from the virtues of the principles that are held and practiced by such institutions. The public at large instantaneously respects an institution that is thoroughly organized and has its root earthed in history.

The time has fully arrived when the drugless profession should no longer exist in the form of isolated units, not knowing one another and caring but little for such knowledge. Our profession has been, as it were, as sheep without a shepherd, but the various individuals that constitute this movement so pregnant with benefits to humanity, are now collected for the first time into a Directory and Year-Book of Drugless Healing, which alone will give immense weight and dignity to the standing of the individuals mentioned therein.Not only will the book add to the prestige of the practitioner in the eyes of his patients, but when the scattered members of our profession in every State desire to obtain legislative action on behalf of their profession and themselves, the appeal of such a work as our directory will, in the eyes of legislators, gain for them a much more respectful hearing than could otherwise be obtained.

Now, for the first time, the drugless practitioner finds himself one of a vast army of professional men and women who are employing the most healthful forces of nature to rejuvenate and regenerate the world. But the book itself throws a powerful light upon every phase of drugless healing and annihilates time and distance in investigating WHO IS WHO in the realm of Drugless Therapy.

A most sincere effort has been made to obtain the name and address of every adherent of the Rational School of Medicine who practices his profession within the United States, Canada and the British Isles. It is impossible at this stage of Naturopathic history, which is still largely in the making, to obtain the name and address of every such practitioner. There were some who, even when appealed to, refused to respond to our invitation, not understanding the object of our work. Many of even the most intelligent members have refused to advertise their professional cards in our pages. But we can only attribute these drawbacks to the fact that every new institution that has suddenly dawned upon human intelligence will find that a certain proportion of people who do not understand the nature of the enterprise because the brain cells that would appreciate the benefits that are sought to be conferred upon them, are undeveloped, but a goodly proportion of our Naturopaths have gladly responded to the invitation to advertise their specialty in our columns. These, of course, constitute the brightest and most successful of our practitioners and their examples in this respect should be followed by every practitioner whose card does not appear in this book.We take it for granted that every one of the forty thousand practitioners of Naturopathy is in favor of the enterprise represented by this Directory. This work is a tool of his trade and not to possess this book is a serious handicap in the race for success.

Here will be found an Index of by far the larger number of Naturopaths in the country arranged in Alphabetic, Geographic and Naturopathic sections. Besides this, there is a classified Buyers' Guide that gives immediate information regarding where you can find special supplies, or a certain apparatus, or a certain book or magazine, its name, and where it is published. The list of Institutions with the curriculum of each will be found exceedingly useful.

Natural healing, that has drifted so long, and, by reason of a lack of organization, has been made for so many years the football of official medicine, to be kicked by any one who thought fit to do so, has now arrived at such a pitch of power that it has shaken the old system of bureaucratic medicine to its foundations. The

professors of the irrational theories of life, health and disease, that are looking for victims to be inoculated with dangerous drugs and animalized vaccines and serums, have begun to fear the growth of this young giant of medical healing that demands medical freedom, social justice and equal rights for the new healing system that exists alone for the betterment and uplifting of humanity. I want every Professor of Drugless Therapy to become my friend and co-worker in the great cause to which we are committed, and those whose names are not recorded in this book should send them to me without delay. It will be of far greater interest and value to themselves to have their professional card included amongst those who advertise with us than the few dollars that such advertisement costs.

It will be noted that there are quite a number of Drugless Healers belonging to foreign countries (particularly those of the Western Hemisphere) represented in this Directory. The profession of medicine is not confined to any race, country, clime or religion. It is a universal profession and demands universal recognition. It will be a great honor to the Directory, as well as to the Naturopathic profession at large to have every Naturopathic practitioner, from the Arctic Circle to the furthest limits of Patagonia, represented in the pages of this immense and most helpful work.

I expect that the Directory for the year 1920 will be larger and even more important than the present Directory and that it will contain the names of thousands of practitioners that are not included in the present work.

The publication of this Directory will aid in abolishing whatever evils of sectarianism, narrow-mindedness and lack of loyalty to the cause to which we are devoted, that may exist. That it will promote a fraternal spirit among all exponents of natural healing, and create an increase of their prestige and power to resist the encroachments of official medicine on their constitutional rights of liberty and the pursuit of happiness, by favorably influencing Legislators, Law courts, City Councils and Boards of Health everywhere, is the sincere belief of the editor and publisher.

Having introduced the volume, Lust leads off with his article entitled "The principles, aim, and program of the nature cure system."

Again, this relatively brief article is reproduced here in its entirety so that one can see the merging of influences:

The Principles, Aim, and Program of the Nature Cure System

Since the earliest ages, Medical Science has been of all sciences the most unscientific. Its professors, with few exceptions, have sought to cure disease by the magic of pills and potions and poisons that attacked the ailment with the idea of suppressing the symptoms instead of attacking the real cause of the ailment.

Medical science has always believed in the superstition that the use of chemical substances which are harmful and destructive to human life will prove an efficient substitute for the violation of laws, and in this way encourages the belief that a man may go the limit in self indulgences that weaken and destroy his physical system, and then hope to be absolved from his physical ailments by swallowing a few pills, or submitting to an injection of a serum or vaccine, that are supposed to act as vicarious redeemers of the physical organism and counteract life-long practices that are poisonous and wholly destructive to the patient's well-being.

From the earliest ages to the present time, the priests of medicine have discovered that it is ten times easier to obtain ten dollars from a man by acting upon his superstition, than it is to extract one dollar from him, by appealing to reason and common sense. Having this key to a gold mine within their grasp, we find official medicine indulging at all times in the most blatant, outrageous, freakish and unscientific methods of curing disease, because the methods were in harmony with the medical prestige of the physician.

Away back in pre-historic times, disease was regarded as a demon to be exorcized from its victim, and the medicine man of his tribe belabored the body of his patient with a bag in which rattled bones and feathers, and no doubt in extreme cases the tremendous faith in this process of cure that was engendered in the mind of the patient really cured some ailments for which mental science and not the bag of bones and feathers should be given credit.

Coming down to the middle ages, the Witches' Broth—one ingredient of which was the blood of a child murderer drawn in the dark of the moon—was sworn to, by official medicine, as a remedy for every disease.

In a later period, the "docteur a la mode," between his taking pinches of snuff from a gold snuff box, would order the patient bled as a remedy for what he denominated spirits, vapors, megrims, or miasms.

Following this pseudo-scientific diagnosis and method of cure, came the drugging phase in which symptoms of disease were unmercifully attacked by all kinds of drugs, alkalis, acids and poisons which were supposed, that by suffocating the symptoms of disease, by smothering their destructive energy, to thus enhance the vitality of the individual. All these cures have had their inception, their period of extensive application, and their certain desuetude. The contemporary fashion of healing disease is that of serums, inoculations and vaccines, which, instead of being an improvement on the fake medicines of former ages are of no value in the cure of disease, but on the contrary introduce lesions into the human body of the most distressing and deadly import.

The policy of expediency is at the basis of medical drug healing. It is along the lines of self-indulgence, indifference, ignorance and lack of self-control that drug medicine lives, moves and has its being. The sleeping swineries of mankind are wholly exploited by a system of medical treatment, founded on poisonous and revolting products, whose chemical composition and whose mode of attacking disease, are equally unknown to their originators, and this is called "Scientific medicine."

Like the alchemist of old who circulated the false belief that he could transmute the baser metals into gold, in like manner the vivisector claims that he can coin the agony of animals into cures for human disease. He insists on cursing animals that he may bless mankind with such curses.

To understand how revolting these products are, let us just refer to the vaccine matter which is supposed to be an efficient preventive of smallpox. Who would be fool enough to swallow the putrid pus and corruption scraped from the foulest sores of smallpox that has been implanted in the body of a calf? Even if any one would be fool enough to drink so atrocious a substance, its danger might be neutralized by the digestive juices of the intestinal tract. But it is a far greater danger to the organism when inoculated into the blood and tissues direct, where no digestive substances can possibly neutralize its poison.The natural system for curing disease is based on a return to nature in regulating the diet, breathing, exercising, bathing and the employment of various forces to eliminate the poisonous products in the system, and so raise the vitality of the patient to a proper standard of health.

Official medicine has in all ages simply attacked the symptoms of disease without paying any attention to the causes thereof, but natural healing is concerned far more with removing the causes of disease, than merely curing its symptoms. This is the glory of this new school of medicine that it cures by removing the causes of the ailment, and is the only rational method of practicing medicine.

It begins its cures by avoiding the uses of drugs and hence is styled the system of drugless healing. It came first into vogue in Germany and its most famous exponents in that country were Priessnitz, Schroth, Kuhne, Kneipp, Rickli, Lahmann, Just, Ehret, Engelhardt, and others.

In Sweden, Ling and others developed various systems of mechano-therapy and curative gymnastics.

In America, Palmer invented Chiropractic; McCormick, Ophthalmology. Still originated Osteopathy; Weltmer, suggestive Therapeutics. Lindlahr combined the essentials of various natural methods, while Kellogg, Tilden, Schultz, Trall, Lust, Lahn, Arnold, Struch, Havard, Davis, Jackson, Walters, Deininger, Tyrell, Collins and others, have each of them spent a lifetime in studying and putting into practice the best ideas of drugless healing and have greatly enlarged and enriched the new school of medicine.

Life Maltreated by Allopathy

The prime object of natural healing is to give the principle of life the line of least resistance, that it may enable man to possess the most abundant health.

What Is Life?

The finite mind of man fails to comprehend the nature of this mysterious principle. The philosopher says "Life is the sum of the forces that resist death," but that definition only increases its obscurity. Life is a most precious endowment of protoplasm, of the various combinations of oxygen, hydrogen, carbon and nitrogen, and other purely mineral substances in forming organic tissues. As Othello says, referring to Desdemona's life, which he compares to the light of a candle—

"If I quench thee thou flaming minister,
I can thy former light restore
Should I repent me; but once put out THY light,
I know not whence is that Promethean heat
That can thy light relume."

The spark of life flickers in the sockets of millions and is about to go out. What system of medicine will most surely restore that flickering spark to a steady, burning flame?

Will [it be] the system that employs poisonous vaccines, serums and inoculations, whose medical value has to be supported by the most mendacious statements, and whose practitioners are far more intent on their emoluments and fame, than they are in the practice of humanity?

The Allopathic system, which includes nine tenths of all medical practitioners, is known by its fruits, but it is an appalling fact that infant mortality, insanity, heart disease, arteriosclerosis, cancer, debility, impoverished constitutions, degeneracy, idiocy and inefficiency have enormously increased, particularly during the last twenty-five years, that is, during the regime of inoculations, serums and vaccines.

Naturopathy, on the other hand, so far as it has been developed, and so far as official medicine will allow it to act, leaves no such trail of disease, disaster and death behind it. Natural healing is emancipation from medical superstition, ignorance and tyranny. It is the true Elixir of Life.

The Allopaths have endeavored to cure sick humanity on the basis of the highly erroneous idea that man can change the laws of nature that govern our being, and cure the cause of disease by simply ignoring it. To cure disease by poisoning its symptoms is medical manslaughter.

Dr. Schwenninger of Germany says: "We are suffering under the curse of the past mistakes of our profession. For thousands of years medical doctors have been educating the public into the false belief that poisonous drugs can give health. This belief has become in the public mind such a deep-seated superstition, that those of us who know better and who would like to adopt more sensible, natural methods of cure, can do so only at the peril of losing practice and reputation.

"The average medical man is at his best but a devoted bigot to this vain school-craft, which we call the Medical Art and which alone in this age of science has made no perceptible progress since the days of its earliest teachers. They call it recognized science! Recognized ignorance! The science of to-day is the ignorance of to-morrow. Every year some bold guess lights up as truth to which but the year before the schoolmen of science were as blind as moles."

And Dr. O.W. Holmes, Professor of Anatomy in Harvard University, states: "The disgrace of medicine has been that colossal system of self-deception, in obedience to which mines have been emptied of their cankering minerals, entrails of animals taxed for their impurities, the poison bags of reptiles drained of their venom, and all the inconceivable abominations thus obtained thrust down the throats of human beings, suffering from some fault of organization, nourishment, or vital stimulation."

And these misguided drug doctors are not only not ashamed of their work, but they have induced subservient legislators to pass laws that perpetuate the age-long scandal of allopathic importance, and the degenerative influence of the poisons, and to actually make it a crime on the part of nature doctors to cure a man of his ailment. The brazen effrontery of these medical despots has no limits. They boast of making the State legislators their catspaw in arresting, fining and imprisoning the professors of natural healing for saving human life. Legislators have no right to sit in judgment over the claims of rival schools of healing. They see tens of thousands of sick people go down to their graves by being denied the cures that the employers of nature's forces alone can give them. It is their business to provide for the various schools of medicine a fair field and no favor.

A citizen has an inalienable right to liberty in the pursuit of happiness. Yet the real saviors of mankind are persecuted by the medical oligarchy which is responsible for compulsory vaccination, compulsory medical inspection of public school children, and the demands for State and Federal departments of health, all for the ostensible good of the people, but in reality for the gain of the Medical Trust.

The Naturopaths

The Naturopaths are desirous of freedom for all schools of medicine. They are responsible practitioners who are willing to be examined by an impartial council, appointed by and acting for the State, who will testify to the life and character of every drugless physician before he is entitled to practice medicine. Not one invidious discrimination should be made between the different schools of medicine. The state should see to it that each school should have a full opportunity to do its best for the up-lifting of its citizens.

The Program of Naturopathic Cure

1. ELIMINATION OF EVIL HABITS, or the weeds of life, such as overeating, alcoholic drinks, drugs, the use of tea, coffee and cocoa that contain poisons, meat eating, improper hours of living, waste of vital forces, lowered vitality, sexual and social aberrations, worry, etc.
2. CORRECTIVE HABITS. Correct breathing, correct exercise, right mental attitude. Moderation in the pursuit of health and wealth.
3. NEW PRINCIPLES OF LIVING. Proper fasting, selection of food, hydropathy, light and air baths, mud baths, osteopathy, chiropractic and other forms of mechano-therapy, mineral salts obtained in organic form, electropathy, heliopathy, steam or Turkish baths, sitz baths, etc.

Natural healing is the most desirable factor in the regeneration of the race. It is a return to nature in methods of living and treatment. It makes use of the elementary forces of nature, of chemical selection of foods that will constitute a correct medical dietary. The diet of civilized man is devitalized, is poor in essential organic salts. The fact that foods are cooked in so many ways and are salted, spiced, sweetened and otherwise made attractive to the palate, induces people to over-eat, and over eating does more harm than under feeding. High protein food and lazy habits are the cause of cancer, Bright's disease, rheumatism and the poisons of auto-intoxication.

There is really but one healing force in existence and that is Nature herself, which means the inherent restorative power of the organism to overcome disease. Now the question is, can this power be appropriated and guided more readily by extrinsic or intrinsic methods? That is to say, is it more amenable to combat disease by irritating drugs, vaccines and serums employed by superstitious moderns, or by the bland intrinsic congenial forces of Natural Therapeutics, that are employed by this new school of medicine, that is Naturopathy, which is the only orthodox school of medicine? Are not these natural forces much more orthodox than the artificial resources of the druggist? The practical application of these natural agencies, duly suited to the individual case, are true signs that the art of healing has been elaborated by the aid of absolutely harmless, congenial treatments, under whose ministration the death rate is but five per cent of persons treated as compared with fifty per cent under the present allopathic methods.

The Germanic Influence

The philosophic origins of naturopathy were Germanic. The most significant influences, except those of Russell Trall, the osteopathic concepts of A.T. Still (at this time, strictly the correction of spinal lesions by adjustment), and the chiropractic principles of D. D. Palmer, were originally Germanic. (This was well established in the January 1902 editorial in *Water Cure Monthly*.)

The specific influences on which Lust drew for his work, in order of their chronologic contributions to the system of naturopathy, are the following:

1. Vincent Preissnitz (1799–1851)
2. Johann Schroth (1798–1856)
3. Father Sebastian Kneipp (1821–1897)
4. Arnold Rickli (1823–1926)
5. Louis Kuhne (c. 1823–1907)
6. Henry Lahman (no dates known)
7. F. E. Bilz (1823–1903)
8. Adolph Just (1859–1939).

Also of note were Theodor Hahn and T. Meltzer, who, in the 1860s, were well known for their work in the movement called, in German, *Naturatz* or "naturism."

In photographs accompanying his article "The principles, aim and program of the nature cure system," Lust described each of these thinkers as follows:

1. VINCENT PREISSNITZ, of Graefenberg, Silesia. Founder of Hydropathy. Born October 4, 1799. A pioneer Naturopath, prosecuted by the medical authorities of his day, and convicted of using witchcraft, because he cured his patients by the use of water, air, diet and exercise. He took his patients back to Nature—to the woods, the streams, the open fieldstreated them with Nature's own forces and fed them on natural foods. His fame spread over the whole of Europe, and even to America. His cured patients were numbered by the thousands. The Preissnitz compress or bandage is in the medical literature. Preissnitz is no more, but his spirit lives in every true Naturopath.

2. JOHANN SCHROTH, a layperson, not described in Lust's directory but often talked of in later works and prominently mentioned for his curative theories in Bilz's master work, The Natural Method of Healing. Schroth smashed his right knee in an accident with a horse and it remained stiff in spite of repeated medical treatment. At last, a priest told Schroth that Preissnitz's methods might help, and Schroth decided to give them a try. In order to avoid frequent changing of the packs that were directed by Preissnitz, he placed several packs on top of one another, wrapping the whole portion with a woolen cloth. He left this pack on the injured knee for several hours and produced a moist heat which he theorized to cause the poisonous toxins to dissolve and be swept away. These packs are still used as part of the "Schroth cure" and have reportedly become famous for their blood-cleansing effect. (From an article in the March 1937 Naturopath and Herald of Health by Dr. T.M. Schippel.) As noted by Bilz, the Schroth cure, called by Bilz "the regenerative treatment," was developed for treatment of chronic diseases through the use of an extreme diet following total fasting by withdrawing of all food and drink and then the use of totally dry grain products and the eventual reintroduction of fluids.

3. FATHER SEBASTIAN KNEIPP, of course, is much described and the photos include one of Kneipp lecturing to the multitudes at Wandelhale at Woerishofen, attending Pope Leo XIII in 1893, noting this is the only consultation on health care matters that Kneipp ever consented to outside of Woerishofen, though many famous and aristocratic individuals desired his counsel, and a picture of Kneipp with the Archdukes Joseph and Francis Ferdinand of Austria walking barefoot in new-fallen snow for purposes of hardening the constitution. It was noted that the older Archduke was cured by Kneipp of Bright's disease in 1892, and it noted that the Archduke Joseph, in appreciation of this cure, donated a public park in the town of Woerishofenat a cost of $150,000 florens. The Archduke Francis Ferdinand, the son of Archduke Joseph, was the individual whose murder precipitated World War I. There is a further picture of Kneipp surrounded consultation to numerous patients.

4. ARNOLD RICKLI, founder of the light and light and aircures (atmospheric cure). Dr. Rickli was one of the foremost exponents of natural living and healing. In 1848, he established at Veldes, Krain, Austria, the first institution of light and air cure or as it was called in Europe the "atmospheric cure." In a limited way (rather very late) his ideas have been adopted by the medical profession in America for the cure of consumption. He was an ardent disciple of the vegetarian diet and exemplified the principles of natural living in his own life. The enclosed photo shows him at the age of 97, when he was still active and healthy. He has since passed on, but his work still lives as a testimonial of his untiring efforts. He was the founder and for over 50 years the President of the National Austrian Vegetarian Association.

5. LOUIS KUHNE wrote, in 1891, The New Science of Healing, the greatest work of basic principles in natural healing. In the tradition of Natural Healing and prevention, Kuhne has been described as one who "… advocated sun, steam baths, a vegetarian diet, and whole-wheat bread … in these relatively early days." His renowned work constitutes the only true scientific philosophy for the application of all Drugless Methods. He was the first to give to the world the comprehensible idea of pathology and the first to proclaim the doctrine of the "unity of cure." His book Facial Expression gives the means of diagnosing a patient's pathological condition and determining the amount and location of the systemic encumbrance. He is the founder and first Master of Naturopathy.

6. DR. H. LAHMAN. When the University of Leipzig expelled H. Lahman for his spreading medical sedition among the students, it added a staunch advocate to natural healing. Dr. Lahman finished his medical education in Switzerland and returned to Germany to refute in practice the false ideas of medical science. He later founded the largest Nature Cure institution in the world at Weisser Hirsch, near Dresden, Saxony. He was a strong believer in the "Light and Air" cure and constructed the first appliances for the administration of electric light treatment and baths. He was the author of several books on Diet, Nature Cure and Heliotherapy. As noted in Other Healers, Other Cures: "Heinrich Lahmann came along to stress no salt on foods and no water with meals …" His works on diet are authoritative and his "nutritive salts theory" forms the basis of rational dietetic treatment. This work has but recently come to light in America, and progressive dietitians are forsaking their old, worn-out, high protein, chemical and caloric theories for the "organic salts theory." Carque, Lindlahr, McCann, and other wide awake food scientists have adopted it as a basis for their work. Dr. Lahman was a medical nihilist. He denounced medicine as unscientific and entirely experimental in its practice and lived to prove the saneness of his ideas as evidenced by his thousands of cured patients.

7. PROFESSOR F.E. BILZ. That real physicians are born, not made, is well illustrated in the case of Dr. Bilz, who achieved his first success in healing as a lay practitioner. As a mark of gratitude, a wealthy patient presented him with land and a castle in which to found a Nature Cure anitarium.… The Bilz institution at Dresden-Rdebeul, Germany, became world renowned and was long considered the center of the Nature Cure movement. Professor Bilz is the author of the first Naturopathic encyclopedia, The Natural Method of Healing, which has been translated into a dozen languages, and in German alone has run into 150 editions. He has written many works on Nature Cure and Natural Life, among them being The Future State, in which he predicted the present World War, and advocated a federation of nations as the only logical solution of international problems.

8. ADOLPH JUST, famous author of Return to Nature and founder of original "Yungborn" in Germany.

Both Adolph Just's *Return to Nature* and Louis Kuhne's *The Natural Science of Healing* were translated into English by Lust and released through his publication house.

The Convergence With American Influences

The Universal Naturopathic Directory was truly eclectic in its compilation and composition. Besides the Lust articles, the volume included "How I became acquainted with nature cure" by Henry Lindlahr, MD, ND (which was reproduced in large part in the introduction to volume 1 of Lindlahr[15]); "The nature cure" by Carl Strueh, MD, ND; "Naturopathy" by Harry E. Brook, ND; "The present position of naturopathy and allied therapeutic measures in the British Isles" by Allen Pattreiouex, ND; "Why all drugless methods?" by Per Nelson; and "Efficiency in drugless healing" by Edward Earle Purinton (a reprint of the 1917 publication, referred to earlier, which was composed of a series of articles published in *The Herald of Health and Naturopath* between August 1914 and February 1916).

The volume also contained Louis Kuhne's "Neo-naturopathy (the new science of healing)," in the first publication of the translation by Lust, and articles on electrotherapy, neuropathy, dietology, chiropractic, mechanotherapy, osteopathy, phytotherapy, apyrtropher, physical culture, optometry, hydrotherapy, orthopedics, pathology, natural healing and living, astroscopy, phrenology, and physiology—all of which were specially commissioned for the directory from practitioners and authors considered expert in these subjects.

Also included was a national directory of drugless physicians in alphabetical order, geographically arranged and itemized by profession; biographic notes on American contributors of note; the naturopathic book catalog; a guide to natural healing and natural life books and periodicals; a classified list of medical works; a series of book reviews; a buyer's guide for naturopathic supplies; and, in addition to extensive indexes, a "parting word" by Lust.

The volume contained numerous advertisements for naturopathic schools, sanitariums, and individual practices, and it closed with the following note:

> *This, then, completes Volume 1 of the Naturopathic Directory, Drugless Yearbook and Buyer's Guide for the years 1918 and 1919. Into it, has been placed the conscientious labor of many willing hearts, hands and minds. It is their contribution to the noble cause of natural healing. It will stand as a monument to their endeavors, as well as a memorial to the great souls, the fathers of natural healing, who have passed on.*
>
> *Let this, then, herald a new era—the era wherein man shall recognize the omniscience of Nature, and shall profit through conforming to her laws.*

In the biographic sections, it is apparent that Lust owed a great deal of the feeling of camaraderie in the nature cure movement to some varied American practitioners. The most prominent of these had their biographic sections contained in the 1918 directory. Two of them deserve specific note and attention: Palmer and Still.

Lust met A. T. Still in 1915 in Kirksville, Missouri, shortly before Still's death. From their meetings, Lust noted later in the *Naturopath and Herald of Health* (June 1937) that Still believed that osteopathy by "compromising with medicine is doomed as the school that could have incorporated all the natural and biological healing arts." Lust wanted naturopathy to fill this void.

Lust also had a lengthy acquaintance with B. J. Palmer (the son of D. D. Palmer, the founder of chiropractic), who, following in his father's footsteps, put Davenport, Iowa, and the Palmer Chiropractic College on the map.

Lust also became connected with Henry Lindlahr, MD, ND, of Chicago (as noted in the autobiographical sketch contained in the directory[16] and reprinted in volume 1 of Lindlahr[15]). Lindlahr was a rising businessman in Chicago with all the bad habits of the "gay nineties" era. In his 30s, he became chronically ill. He had gone to the orthodox practitioners of his day and received no relief.

Then he was exposed to Schroth's works, and in following them began to feel somewhat better. Subsequently, he liquidated all his assets and went to a German sanitarium to be cured and to learn nature cure. He returned to Chicago and enrolled in the Homeopathic/Eclectic College of Illinois. In 1903 he opened a sanitarium, which included a residential sanitarium, located in Elmhurst, Illinois; a "transient" clinic (office) on State Street in Chicago; and "Lindlahr's Health Food Store."

Shortly thereafter, he founded the Lindlahr College of Natural Therapeutics, which included hospital internships at the sanitarium. The institution became one of the leading naturopathic colleges of the day. In 1908 he began to publish *Nature Cure Magazine* and began publishing his series of *Philosophy of Natural Therapeutics,* with volume 1 ("Philosophy") in 1918. This was followed by volume 2 ("Practice") in 1919; volume 3 ("Dietetics"; republished with revisions as originally published in 1914); and, in 1923, volume 6 ("Iridiagnosis"). The intended volumes 4 and 5 were in production at the time of Lindlahr's death in 1927. As described in *Other Healers, Other Cures*[17]:

Henry Lindlahr, another American, is remembered for his conviction that disease did not represent an invasion of molecules, but the body's way of healing something. In other words, he viewed symptoms as a positive physiological response—proof that the body is fighting whatever's wrong. Accordingly, a fever is a "healthy" sign and one should be let alone, unless it is dangerously high, of course.

The effect of all these gentlemen on the development of naturopathy in America, under Lust's guidance, was profound.

From these beginnings, the naturopathic movement gathered strength and continued to grow through the 1920s and 1930s, having a major effect on natural healing and natural lifestyles in the United States.

Along the way, Lust was greatly influenced by the writings of John H. Tilden, MD (largely published between 1915 and 1925). Tilden was originally a practicing physician in Denver who became disenchanted with orthodox medicine and began to rely heavily on dietetics and nutrition, formulating his theories of "auto-intoxication" (the effect of fecal matter remaining too long in the digestive process) and "toxemia."

Lust was also greatly influenced by Elmer Lee, MD, who became a practicing naturopath around 1910 and whose movement was called the "hygienic system," following the earlier works of Russell Trall. Lee published *Health Culture* for many years.

In addition to John Tilden, MD, and Elmer Lee, MD, another medical doctor, John Harvey Kellogg, MD, who turned to more nutritionally based natural healing concepts, was greatly respected by Lust. Kellogg was renowned through his connection with the Battle Creek Sanitarium. The sanitarium itself was originally founded in the 1860s as a Seventh-Day Adventist institution designed to perpetuate the Grahamite philosophies of Sylvester Graham and William Alcott. The sanitarium was on the verge of being closed, however, because of economic failure, when, in 1876, Kellogg, a new and more dynamic physician-in-chief, was appointed.

Kellogg, born in 1852, was a "sickly child" who, at the age of 14, ran across the works of Graham and converted to vegetarianism. At the age of 20, he studied for a term at Trall's Hygio-Therapeutic College and then earned a medical degree at New York's Bellevue Medical School. He maintained an affiliation with the regular schools of medicine during his lifetime, due more to his practice of surgery than his beliefs in the area of health care.[4]

Kellogg designated his concepts, which were basically the hygienic system of healthful living, "biologic living." Principally, Kellogg defended vegetarianism, attacked sexual misconduct and the evils of alcohol, and was a prolific writer throughout the late 19th century and early 20th century. He produced a popular periodical, *Good Health,* which continued in existence until 1955. When Kellogg died in 1943 at the age of 91, he had had more than 300,000 patients through the Battle Creek Sanitarium (which he had renamed from the Western Health Reform Institute shortly after his appointment in 1876), including many celebrities, and the "San" became nationally well known.

Kellogg, along with Tilden and Elie Metchnikoff (director of the prestigious Pasteur Institute and winner of the 1908 Nobel Prize for a contribution to immunology), wrote prolifically on the theory of auto-intoxication. Kellogg, in particular, felt that humans, in the process of digesting meat, produced various intestinal self-poisons that contributed to auto-intoxication.

As a result, Kellogg became a near fanatic on the subject of helping humans return to a more healthy, natural state by returning to the naturally designed usage of the colon. He felt that the average modern colon was devitalized by the combination of sedentary living, the custom of sitting rather than squatting to defecate, and the modern civilized habit of ignoring "nature's call" out of an undue concern for politeness. Further, Kellogg concentrated on the fact that the modern diet had insufficient bulk and roughage to stimulate the bowels to proper action.

Kellogg was also extremely interested in hydrotherapy. In the 1890s he established a laboratory at the San to study the clinical applications of hydrotherapy. This led, in 1902, to his writing *Rational Hydrotherapy.* The preface espoused a philosophy of drugless healing that came to be one of the bases of the hydrotherapy school of medical thought in America.

Tilden, as mentioned, was of a similar mind. He must have been to have provided natural healthcare literature with his 200-plus-page dissertation entitled "Constipation," with a chapter devoted to the evils of not responding when nature called.

This belief in the "evils" drawing away from the natural condition of the colon was extremely important to Kellogg's work.[4] Because of Lust's interest, Kellogg's *The New Dietetics* (1921) became one of the bibles of naturopathic literature.[18]

Lust was also influenced by the works of Sidney Weltmer, the father of "suggestive therapeutics." The theory behind Professor Weltmer's work was that whether it was the mind or the body that first lost its grip on health, the two were inseparably related. When the problem originated in the body, the mind nonetheless lost its ability and desire to overcome the disease because the patient "felt sick" and consequently slid further into the diseased state. Alternatively, if the mind first lost its ability and desire to "be healthy" and some physical infirmity followed, the patient was susceptible to being overcome by disease.

Weltmer's work dealt specifically with the psychological process of desiring to be healthy. Lust enthusiastically backed Weltmer's work and had him appear on the programs at various annual conventions of the American Naturopathic Association (which commenced after its founding in 1919).

Lust was also personal friends with and a deep admirer of Bernarr MacFadden.[19] MacFadden was the founder of the "physical culture" school of health and healing, also known as "physcultopathy." This school of healing gave birth across the country to gymnasiums at which exercise programs, designed to allow the individual man or woman to maintain the most perfect state of health and human condition possible, were developed and taught.[4] *Other Healers, Other Cures* described it as follows[15]:

The next Naturopathic star, after Kellogg, was Bernarr MacFadden, the physical culturist who built a magazine-publishing empire (his first magazine was Physical Culture founded in 1898). MacFadden proselytizes for exercise and fresh vegetables, hardly eccentric notions. But his flamboyant efforts to publicize them and his occasional crack-pot ideas (like freezing the unemployed, then thawing them out when the Depression was over) alienated many people. Still, he was his own best advertisement. He fathered nine children by four wives and was parachuting from planes in his 80s. One of MacFadden's admirers was that arch-foe of the medical profession, George Bernard Shaw, the longevous eccentric in his own right.

Lust was also interested in, and helped publicize, "zone therapy," originated by Joe Shelby Riley, DC, a chiropractor based in Washington, DC, and one of the early practitioners of "broad chiropractic." Zone therapy was an early forerunner of acupressure as it related "pressures and manipulations of the fingers and tongue, and percussion on the spinal column, according to the relation of the fingers to certain zones of the body."[17]

Several other American drugless healers contributed to a broad range of "-opathies" that Lust merged into his growing view of naturopathy as the eclectic compilation of methods of natural healing. The

Universal Directory also contained a complete list of osteopaths and chiropractors as drugless healers within the realm of Lust's view of naturopathic theory. His other significant compatriots at the time of the publication of the directory were Carl Stueh, described by Lust as "one of the first medical men in this country who gave up medicine and operation for natural healing"; F. W. Collins, MD, DO, DC, an early graduate of the American School of Naturopathy (1907) who went on to graduate from the New Jersey College of Osteopathy (1909) and the Palmer School of Chiropractic (1912); another "broad chiropractor," Anthony Matijaca, MD, ND, DO, the naturopathic resident expert in electrotherapy and an associate editor of the *Herald and Health Naturopath* (the inverted name of the Lust journal at the time of the directory); and Carl Schultz, ND, DO, MD, president and general manager of the Naturopathic Institute and Sanatorium of California, essentially the second school in the country to pursue the education of physicians under the name of "naturopathy."

In *Inner Hygiene: Constipation and the Pursuit of Health in Modern Society,* Whorton[20] offered his first assessments of the work of Lust as it related to the emergence of naturopathy in the early 20th century:

> *Most of the drugless clan also identified themselves as practitioners of naturopathy, a system of practice that grew out of hydropathy, as well as German water-cure and nature-cure traditions. Organized in the late 1890s under the leadership of German immigrant Benedict Lust, naturopathy sought to cure the full scope of human ills with natural agents (herbs, water, air, sunlight, electricity, massage, and others), agents that supported and stimulated the body's own healing mechanisms.*

In his extensive assessments of Lust's work and writings in *Nature Cures: The History of Alternative Medicine in America,* Whorton[21] attempted to put the philosophic development of naturopathy in a reasonable historical context:

> *However much a dreamer Lust was in some respects, he was an insightful realist in others. He was correct in believing that simply giving nature support as it ran its course was the best one could do with many diseases in his day. He was correct in seeing self-abuse as the source of much physical, and emotional, suffering and attacked it with an ardor that MDs could not bring to the task until nearly a century later. Recent medical lamentations over the evils of smoking, sexual promiscuity, and other risky behaviors adopted in the thoughtless chase after pleasure have nothing on Lust's jeremiads …*
>
> *Lust was right in reprimanding allopaths for focusing so strongly on disease as to lose sight of the importance of promoting health. He was right in appreciating the need to "individualize" the treatment of each patient—and in seeing patient self-responsibility as part of that individualization.*

EARLY-20TH-CENTURY MEDICINE

The Metamorphosis of Orthodox Medicine

Naturopathy's formative years, and in some respects its halcyon days, were from 1900 to 1917. In many jurisdictions, modern licensing laws were not yet in effect, so varied schools of healing were openly practiced. By 1920, however, the American world of medicine had undergone a sharp transition, culminating in four decades of change.

A look at the structure of early medical care in the United States is instructive, even as practiced and dominated by the orthodox school, when noting the changes that occurred between 1875 and 1920.

In 1875 the following was descriptive of American medical practice:

- The practice, even in urban areas, sent the doctor to the patient; the "house call" was the norm.
- There was little modern licensing regulation.
- Hospitals were charitable institutions where persons too poor to otherwise receive health care were usually sent when ill.
- The AMA, although formed in 1846 and generally representative of the professional goals of the regular or orthodox school of medicine, had scarcely begun to make any political inroads at all.
- Medical schools required little or no college education for entrance and were largely apprenticeship based and proprietary in nature, having changed little throughout the century.
- Although some doctors had begun to specialize, to do so was far from the norm. The major recognized specialties were surgery, obstetrics, and gynecology.
- Many different types of doctors existed, and society's reaction to the profession neither recognized specific expertise nor necessarily rewarded professionals in medical practice well.
- Although the orthodox school made up roughly 80% of professional medical practitioners, the homeopaths and the eclectics were visible and respected in their own communities for their abilities and expertise, and much of the public relied on other "irregular" practitioners.

By comparison, in 1920, a total metamorphosis of the medical profession had occurred:

- By 1920, practices had become office oriented and clinic oriented.
- Modern licensing principles had become fully developed, and physicians and surgeons were licensed in all jurisdictions. Most other healthcare providers had some licensing restrictions placed on them, if they were recognized at all.
- Due largely to the introduction into surgery of the practice of antiseptic techniques and aseptic procedures and a correspondent decline in operative mortality, institutional care in the hospital became increasingly accepted. Also, clinical pathology and diagnostic laboratory procedures had become well developed, and the hospital had become a major training and clinical research facility that was generally more acceptable to the patient.
- The AMA was approaching the peak of its political power, having exercised, through its Council on Medical Education and its Council of Pharmacy and Chemistry, major effects on medical schools and the pharmaceutical industry.
- The transition to research- and education-based medical schools, instead of practitioner apprenticeships and proprietary education, had become complete. All recognized medical schools had a 4-year curriculum, with an undergraduate degree or substantial undergraduate study required as a prerequisite. In addition, most schools, in conjunction with most licensing statutes, required a year's internship.
- Specialization was becoming well developed, and the number of specialty groups had increased considerably. This would continue throughout the 1930s and into the early 1940s.
- Professional authority and autonomy had undergone a substantial transition, and the allopathic physician was now recognized as a medical expert.
- By 1922, the last eclectic school was on the verge of closure, and in the early 1930s, the last of the homeopathic schools in the United States was also on the verge of closure. The influence of these sects on orthodox medicine had dwindled to almost nothing. Naturopaths and other alternative healthcare practitioners had adopted the areas of expertise previously considered the territory of homeopaths and eclectics.

The Halcyon Years of Naturopathy

In 1924 Morris Fishbein succeeded George Simmons as editor of the *Journal of the American Medical Association (JAMA).* Fishbein had

joined the editorial staff of *JAMA* under Simmons immediately after his graduation from Chicago's Rush Medical School in 1913. Campion pointed out the following[9]:

> *Over the years, Fishbein not only established himself as the gifted editor of the most widely read medical journal in the United States; he also learned how to extend his editorial position, how to project his opinions nationwide. He became, as the saying went in those years, a "personality." TIME referred to him as "the nation's most ubiquitous, the most widely maligned, and perhaps most influential medico."*

In addition to his development of *JAMA* as an editorial and personal voice, Fishbein also continually railed against "quackery." Lust, among others, including MacFadden, became Fishbein's epitome of quackery. When MacFadden became a wealthy man, after his publishing company included popular magazines like *True Confessions* and *True Detective,* he began campaigning for the 1936 Republican presidential nomination. In response, a physician submitted, under the initials "K.G.," a tongue-in-cheek listing of the cabinet that would exist under MacFadden, including the newly created "Secretary of Aviation" for Lust. Lust was a popular figure by this time who conducted such a busy lecture schedule and practice, alternating between the "Yungborns" in Butler, New Jersey, and Tangerine, Florida, that he had become almost as well known as an airline traveler. Lust devoted a complete editorial in *Nature's Path* to a response.

Although Fishbein had *JAMA* as a personal editorial outlet, Lust had his own publications. Commencing with the *Naturopath and Herald of Health* in 1902 (which changed its name to *Herald of Health and Naturopath* in 1918), Lust continually published this and other monthly journals. In 1919 it became the official journal of the ANA, mailed to all members. Each edition contained the editorial column "Dr. Lust Speaking."

In the early 1920s, the "health fad" movement was reaching its peak in terms of public awareness and interest. As described, somewhat wistfully, in his June 1937 column, Lust announced the approach of the 41st Congress of Natural Healing under his guidance:

> *The progress of our movement could be observed in our wonderful congresses, in 1914 Butler, N.J., 1915 Atlantic City, 1916 in Chicago, 1917 Cleveland, 1918 New York, 1919 Philadelphia, 1920 and 1921 again New York, and 1922 in Washington, D.C., where we had the full support and backing of the Congress of the United States. President Harding received the president and the delegates of our convention and we were the guests of the City of Washington. Through the strenuous efforts of Dr. T.M. Schippel, Hon. Congresswoman Catherine Langley of Kentucky, and eight years of hard work financed and sustained by Dr. Schippel and her powerful friends in Congress, Naturopathy was fully legalized as a healing art in the District of Columbia and the definition was placed on record and the law affirmed and amended by another act which has been fully published over and over again in the official journal of the A.N.A., Naturopath.*
>
> *In 1923 in Chicago, with the help and financing of the great and never-to-be forgotten Dr. Henry Lindlahr, we had a great convention. Not only were all the Naturopaths there but even to an extent our congress was recognized and acknowledged as official and of great importance by the medical people, particularly by the Health Commissioner of Chicago. We held a banquet, and there were discussions covering all platforms of the healing art. It was the first congress in the United States where medicine and Naturopathy in all its branches such as the general old-time Nature Cure, Hydrotherapy and Diet, Osteopathy, Naprapathy, Chiropractic, Neuropathy and Physiotherapy were represented on the same platform. The speakers represented every modern school of healing and the movement at that time was in the direction of an entirely recognized and independent school of healing. There were two camps, official medicine and official Naturopathy, the medical camp having all that is good and bad in medicine and surgery and all the other schools of healing that had sold their birthright and trusted to the allurement of organized medicine, such as Homeopaths, Eclectics, Physio-medics, and the Osteopaths to a large extent. The Osteopaths were always in the wrong camp when they went on mixed boards and Dr. Andrew Taylor Still, the father of Osteopathy, told me in 1915 that by compromising with medicine Osteopathy is doomed as the school that could have incorporated all of the natural and biological healing arts.*
>
> *The year following we had the great congress in Los Angeles which has never been duplicated. We had to meet in two hotels because the crowds ran over 10,000. The glorious banquet will never be forgotten and the congress celebrated and demonstrated that the initial and first intent of the A.N.A. to teach the public Natural Living and Nature Cure was realized. We will never forget the glorious week in Los Angeles where the authorities and the whole city joined us. The success of that congress was largely due to the talent of Dr. Fred Hirsch, the successor to Prof. Arnold Ehret and the noble and generous Naturopaths of the A.N.A. of Cal. There was never a second congress like that.*
>
> *Then we had the great congresses of New York in 1925, Indianapolis 1926, Philadelphia 1927, Minneapolis 1928, Portland, Oregon 1929, New York 1930, Milwaukee 1931, Washington, D.C., 1932, Chicago 1933, Denver 1934, San Diego 1935, and Omaha 1936.*

In 1925 Lust began to try to reach more of the general populace through the lay publication *Nature's Path. The Naturopath* and *Nature's Path* were later merged because the self-supporting advertising and subscription monies were more available by publication to the general populace than to the members of the association (*The Naturopath,* 1902–1927; *Nature's Path,* 1925–1927; merged 1927–1933; separated 1934–1938; *Nature's Path,* 1939–1945).

How large a professional movement Lust inspired during this period of naturopathy's emergence is difficult to gauge. An extensive government survey was not undertaken until 1965. However, as Whorton described in *Nature Cures,*[21] naturopathy had an effect:

> *Those were messages that had enough appeal, evidently, to allow naturopathy to expand steadily through the first decades of the century until by 1923 Lust could estimate that there were nine thousand naturopaths, a "vast army of professional men and women" working on all continents to "rejuvenate and regenerate the world." His figures were undoubtedly inflated. An independent study [the work of the CCMC discussed later] put the number of naturopaths at "possibly 1500," allowing that if the "allied groups" that advocated drugless healing under other names [physiotherapy, sanipractic] were added on the total may reach 2500. Yet whatever their numbers, naturopaths had grown into a force not to be ignored.*

Although Lust's claim of 9000 naturopaths worldwide is impossible to assess, 5000 practitioners may be a reasonable estimate of the reach of his naturopathy in the United States by the late 1920s and into the 1930s. As Whorton[21] reported, the mixer orientation within chiropractic was also becoming a growing presence. This orientation was a philosophy that tended to merge chiropractic and naturopathy in education and practice.[22] Although homeopathy has undergone a small revival in recent years, very few MDs now practice it. It is currently mainly of interest to naturopaths, who earn doctor of naturopathy (ND) degrees, and to a few chiropractors. Naturopaths closely resemble

chiropractors in that they use spinal manipulative therapy and because so-called mixer chiropractors also use naturopathic methods such as heat, cold, hydrotherapy, physiotherapy, dietary supplements, and even some herbal and homeopathic remedies, which is why the traditional, or "straight," chiropractors disparagingly call them "medipractors." Until the middle of the 20th century, a few mixer schools offered both DC and ND degrees, either as alternatives or together after an additional semester of study. Whorton noted a "1930 survey in which some 1,800 chiropractors participated, found, for example, that 1,124 employed hydrotherapy, 1,173 used light therapy, 1,257 provided electrotherapy, and a full 1,352 trusted vibration therapy."[21]

In January 1934 Lust commenced republication of the title *Naturopath and Herald of Health* in addition to *Nature's Path.* Each volume opened with his personal column, different for each publication. Both publications were issued through 1938, when the *Nature's Path* again became the sole publication until Lust's death in 1945.

After the *Universal Directory,* Lust continued to write volumes on naturopathic principles, although he was more of a synthesizer, organizer, lecturer, and essayist than a scientific documenter of naturopathic principles. His most enduring contributions may remain his early translations of Kuhne's and Just's works.

During the 1920s and up until 1937, Lust's brand of "quackery," so labeled by Fishbein, was in its most popular phase. Although the institutional markings of the orthodox school had gained ascendancy, before 1937, it had no real therapeutic success in the treatment of disease outside of the broad advancements in public health.

Lust's naturopathy, together with chiropractic and osteopathy, continued to be on the outside looking in, this lack of therapeutic advancement notwithstanding. Practitioners of all three movements were continually prosecuted for practicing medicine without a license, although they often won their cases by establishing to juries that their practices were (even according to the testimony of medical men) not the same as medicine at all. At the time, orthodox practitioners could offer little or no expectation of cure for many diseases, and the "health food and natural health" movement was generally popular.

During the 1920s Gaylord Hauser, later to become the health food guru of the Hollywood set, came to Lust as a seriously ill young man. Lust, through the application of the nature cure, removed Hauser's afflictions and was rewarded by Hauser's lifelong devotion. His regular columns in *Nature's Path* became widely read among the Hollywood set.

As noted in *Other Healers, Other Cures*[15]:

> *The last big name in Naturopathy was Gaylord Hauser, a Viennese-Born food scientist (as one of his early books identified him) turned to Naturopathy in his later years. He is best remembered for advising the eating of living foods, not dead foods, and for escorting Greta Garbo around. In addition to fresh fruits and vegetables, Hauser's "Wonder Foods" were skimmed milk, brewer's yeast, wheat germ, yogurt, and blackstrap molasses.*

The naturopathic journals of the 1920s and 1930s are instructive. Much of the dietary advice focused on poor eating habits, including the lack of fiber in the diet and an overreliance on red meat as a protein source. More than half a century later in the 1980s, the pronouncements of the orthodox profession, the National Institute of Health, and the National Cancer Institute finally accepted the validity of these early assertions by naturopaths that poor dietary and living habits (particularly smoking) would lead to degenerative diseases, including cancers associated with the lungs, the digestive tract, and the colon.

The December 1928 volume of *Nature's Path* was the first American publication of the works of Herman J. DeWolff, a Dutch epidemiologist who was one of the first individuals to assert, based on studies of the incidence of cancer in the Netherlands, that there was a correlation between exposure to petrochemicals and various types of cancers. He saw a connection between chemical fertilizers and their usage in some soils (principally clay) that led to poisons remaining in vegetables after they had arrived at the market and were purchased for consumption. Again, it was 50 years before orthodox medicine began to accept the wisdom of such concerns.

As Whorton noted in *Nature Cures,* naturopaths were less successful than osteopaths and chiropractors in accomplishing professionalization by the elevation of professional standards, including professional education. This occurred despite the formation of a National Board of Naturopathic Examiners of the ANA in 1940. There was constant internal bickering, which "by the 1940s had taken on a more ominous tone." Although "standards at naturopathic schools were steadily raised from the 1940s on, thanks to both professional idealism and the requirements of state licensing laws," based on "a perusal of the statutes of the dozen states in which naturopaths were licensed in the late 1940s," the divisive trends within naturopathy "would not begin to be reversed until the 1970s."

Whorton[21] observed that there was no misunderstanding where Lust himself stood on the need for professional standards:

> *Obtaining their own licensing statutes was perceived by alternative practitioners as a critical measure for purging incompetence and quackery from their own rank. "Where there is no official recognition and regulation," the founder of naturopathy, Benedict Lust maintained, "you will find the plotters, the thieves, the charlatans … [The] riff-raff opportunists bring the whole art into disrepute." By the time Lust said this, shortly before his death in 1945, frustrating experience had demonstrated that "that is the fate of any science—any profession—which the unjust laws have placed beyond the pale." In following the evolution of alternative medicine over the first third of the twentieth century, it is essential to keep in mind that constant battle of each system to bring itself within the pale.*

The Emerging Dominance of American Medical Association Medicine

In 1937 the status of conventional (allopathic) medicine began to change. The change came with the beginning of the era of "miracle medicine." Lewis Thomas, in his interesting work *The Youngest Science,*[23] compared his education and internship as a physician with his father's life as a physician. His father believed that bedside manner was more important than any actual medication offered by the physician. His father went into general surgery so that he could offer some service to his patients that actually made some change in their condition. Thomas pointed out that the major growth of "scientific medicine" until 1937 advanced diagnosis rather than offering any hope of cure.

This introduction of "miracle medicine," the social effects of World War II on health care, and the death of Lust in 1945 all combined to contribute a precipitous decline for naturopathy and natural healing in the United States. (During the war, the necessity for crisis surgical intervention techniques for battlefront conditions encouraged the use of morphine, sulfa drugs, and penicillin for diseases not previously encountered in civilian life by American combat soldiers. This resulted in the rapid development of higher-technology approaches to medicine and highly visible successes.)

Lust recognized this, and his editorializing became, if anything, even more strident. From the introduction of sulfa drugs in 1937 to the Salk vaccine's release in 1955, the American public became used to annual developments of miracle vaccines and antibiotics.

Lust died in September 1945 at the Yungborn facility in Butler, New Jersey, preparing to attend the 49th Annual Congress of his American ANA. In August 1945, for the official program of that congress held in October 1945 just after his death, he dictated the following remarks:

> *What is the present condition of Naturopathy? What is its future? I can give my opinion in a very few words. For fifty years I have been in the thick of the fight to bring to the American people the Nature Cure. During that period I have had an opportunity to judge what Naturopathy has done, and can accomplish and the type of men and women, past and present, who make up the Naturopathic ranks.*
>
> *Let us take the present situation first. What is Naturopathy accomplishing? The answer to that is: "Everything." Naturopathy holds the key for the prevention, alleviation and cure of every ailment, to man and beast alike. It has never failed in the hands of a competent Naturopath. Whatever the body can "catch"—that same body, with proper handling, can eliminate. And that takes in cancer, tumors, arthritis, cataract and the whole gamut of "incurable medical" disease and ailments. During my years of practice I, personally, have seen every type of human ailment and so-called serious "disease" give way to the simple, proven Naturopathic methods. I make no exception to that statement.*
>
> *Now let us see the type of men and women who are the Naturopaths of today. Many of them are fine, upstanding individuals, believing fully in the effectiveness of their chosen profession—willing to give their all for the sake of alleviating human suffering and ready to fight for their rights to the last ditch. More power to them! But there are others who claim to be Naturopaths who are woeful misfits. Yes, and there are outright fakers and cheats masking as Naturopaths. That is the fate of any science—any profession—which the unjust laws have placed beyond the pale. Where there is no official recognition and regulation, you will find the plotters, the thieves, the charlatans operating on the same basis as the conscientious practitioners. And these riff-raff opportunists bring the whole art into disrepute. Frankly such conditions cannot be remedied until suitable safeguards are erected by law, or by the profession itself, around the practice of Naturopathy. That will come in time.*
>
> *Now let us look at the future. What do we see? The gradual recognition of this true healing art—not only because of the efforts of the present conscientious practitioners but because of the bungling, asinine mistakes of orthodox medicine—Naturopathy's greatest enemy. The fiasco of the sulpha drugs as emphasized disastrously in our armed forces is just one straw in the wind. The murderous Schick test—that deadly "prevention" of diphtheria—is another. All these medical crimes are steadily piling up. They are slowly, but inevitably, creating a public distrust in all things medical. This increasing lack of confidence in the infallibility of Modern Medicine will eventually make itself felt to such an extent that the man on the street will turn upon these self-constituted oppressors and not only demand but force a change. I may not be here to witness this revolution but I believe with all my soul that it is coming. Yes, the future of Naturopathy is indeed bright. It merely requires that each and every true Naturopath carry on—carry on—to the best of his and her abilities. May God bless you all.*

The effects of postwar events on osteopathy and chiropractic were completely different from the effect on naturopathy. In the early days of osteopathy, there was a significant split between the strict drugless system advocated by A. T. Still (osteopathy's originator) and the beliefs of many MDs who converted to osteopathy because of its therapeutic value. The latter group did not want to abandon all of the techniques they had previously learned and all of the drugs they had previously used when those therapy techniques were sometimes effective. Ultimately, most schools of osteopathy, commencing with the school based in Los Angeles, converted to more of an imitation of modern orthodox medicine. These developments led to more of an accommodation between the California osteopaths and the members of the California Medical Association. (This developing cooperation between the California Osteopathic and Medical Association was one of the major issues leading to the downfall, in 1949, of Fishbein's editorial voice in *JAMA*.) Thus osteopathy found a place in professional medicine, at the cost of its drugless healing roots and therapies.[9]

Naturopathy had become an element of chiropractic education and practice at least as early as 1910 with the founding of the Peerless College of Chiropractic and Naturopathy in Portland, Oregon.[22] From this point on, naturopathic education developed in two tracks: schools of naturopathy owned and operated by naturopaths and chiropractic schools that had naturopathic curricula in addition to the core chiropractic programs. These latter schools were a central part of the mixer orientation within chiropractic.[22,24]

Initial assessments of schools of naturopathy occurred in the 1920s and 1930s. These assessments came from those within, or allied with, allopathy and were therefore hardly unbiased, but much of the information in these assessments seemed credible. The progression of education in naturopathy would be expected to have been similar to that of chiropractic, if somewhat smaller in scale. In this regard, Wardwell noted[22]:

> *Wiese and Ferguson[25] identified 392 different chiropractic schools as having existed in the United States. When those for which there is no evidence of more than a year of operation are eliminated, the number is reduced to 188. Most of them probably produced few graduates—the number of schools increased rapidly to their largest between 1910 and 1926, and then contracted, particularly during the depression of the 1930s and World War II.*

The history of schools of naturopathy followed much the same pattern. Whorton[21] noted in *Nature Cures* that this was the case. The operators of these schools seemed, at least on the surface, aware of the kind of criticisms to which proprietary trade and professional schools were subjected: limited facilities, limited resources, and an emphasis on collecting revenue versus providing a full professional education.[22,24] The leading operators of schools of naturopathy sought, at least on paper, to respond to these criticisms. By letter agreement dated October 7, 1922, four of the most identifiable leaders of naturopathy—Benedict Lust, Joe Shelby Riley, F. W. Collins, and Henry Lindlahr—committed to the formation of the Associated Naturopathic Schools and Colleges of America and committed themselves, as "the Presidents of Naturopathic Schools in the United States of America," to specific educational minimums "on and after January 2, 1923": "all matriculants must have a primary school education[26] and all naturopath courses must be composed of 4 years of 6 months each." Additionally, the letter provided that "time allowance or credits may be given to practitioners in the field who desire to take up the naturopathic courses, and to licensed physicians of other methods of healing," with the amount of such credit being left to each school's discretion.

In the summer and fall of 1927 representatives of the AMA's Council on Medical Education and Hospitals conducted inspections—unannounced and incognito—of schools of "chiropody, chiropractic, naturopathy, optometry, osteopathy, physical therapy, as well as a large number of institutions." From these inspections, several reports were generated, including the Council's report on "Schools of Chiropractic and Naturopathy in the United States,"

which appeared first as part of the Council's *Annual Report, 1928,* and later as reprinted in *JAMA*. The report identified 40 schools of chiropractic and 10 schools of naturopathy and detailed the inspections of "some schools of Chiropractic and of Naturopathy": Palmer School of Chiropractic (a straight school); National College of Chiropractic (a mixer school that was reported as having recently purchased and assimilated Lindlahr College of Natural Therapeutics); Los Angeles College of Chiropractic (another leading mixer school); the combined American School of Naturopathy, Inc. and American School of Chiropractic, Inc. (Lust's own New York City schools, although Lust was observed to have been "in Florida" at the time of the inspections); and the Naturopathic College and Hospital of Philadelphia. The reports were predictably negative with regard to facilities, resources, and the clearly proprietary nature of the establishments.

Louis Reed of the Committee on the Costs of Medical Care (CCMC), in discussing "naturopathic schools,"[24] relied heavily on this report from the AMA's Council and observed that "in 1927, according to the American Medical Association, there existed twelve naturopathic colleges with not over 200 students. These figures would probably hold good for the present time." Reed also concluded that there were "a considerable number of miscellaneous drugless healers of a type similar to chiropractors practice in this country" as of 1932 and that "the naturopaths form the largest group of these practitioners.… Of these various cults, only the naturopaths and the sanipractors have any considerable membership. Many of the (other) cults are really part of the naturopathic group."[24]

As to numbers of drugless practitioners, Reed observed that "only the roughest estimate can be made—probably there are about 2500," of which naturopaths "number possibly 1500," and sanipractors—"only the name distinguishes sanipractors from the naturopaths"—numbered some 500 in their Washington state "stronghold." Reed also observed that as of 1932: "A few states—Connecticut, Florida, Oregon, South Carolina, Utah, Washington and the District of Columbia—provide for licensing of naturopaths as limited practitioners.… In addition to those mentioned, certain states (Alabama, Colorado, Illinois, Indiana, Michigan, Ohio, Pennsylvania, New Jersey, and Wyoming) make (other) provision for the licensing of drugless or limited practitioners."[24]

Reed's work for the CCMC, although clearly biased against all of the healing philosophies he identified as "medical cults" (a la Fishbein), principally osteopathy, chiropractic, and naturopathy, was the only work that attempted to survey the presence and effect of these schools of healing in the United States in the 1920s and 1930s.[27] A decade later, in April 1945, another work of this kind appeared in the *Rhode Island Medical Journal.* The article, "Naturopathic Legislation and Education," was written by the Rhode Island Medical Society's executive secretary, John E. Farrell, to set out some of the society's reasons for opposing legislation that would license naturopathy in Rhode Island. The article noted that according to the 1942–1943 Report of the Committee on Education of the ANA, 13 schools of naturopathy in the United States met the criteria of the ANA; the article went on to make a lengthy "Report on Schools" through visits to most of the identified schools.[28] The predictable criticisms of these schools as underfinanced, underresourced, and proprietary in nature appeared once again, although by actual detail of description, National College (Chicago) and Western States (Portland) seemed to be well-established, functioning mixer schools of chiropractic and naturopathy.

The effect on chiropractic of the post–World War II years was somewhat different. Because of educational recognition under the G.I. Bill, the number of chiropractors in the country grew substantially, and their effect on the populace grew accordingly. The sect eventually grew powerful enough in terms of numbers and economic clout that it could pose a legal challenge to the orthodox monopoly of the AMA. However, in the immediate postwar years, the AMA gained tremendous political clout. Combined with the American Legion and the National Board of Realtors,[29] these three groups posed a powerful political triumvirate before the U.S. Congress.

These years, called the years of the "great fear" in Caute's book by that name,[30] were the years during which to be unorthodox was to be "un-American."

Across the country, courts began to take the view that naturopaths were not truly doctors because they espoused doctrines from "the dark ages of medicine" (something American medicine had apparently come out of in 1937) and that drugless healers were intended by law to operate without "drugs" (which became defined as anything a person would ingest or apply externally for any remedial medical purpose). In this regard, the Washington State Supreme Court case of *Kelly v. Carroll*[31] and the Arizona State Supreme Court case of *Kuts-Cheraux v. Wilson* document how significant limitations were placed on naturopaths under the guise of calling them "drugless healers."

In the state of Tennessee, as a reaction to the 1939 publication of the book *Back to Eden* by herbalist Jethro Kloss, court action initiated by the Tennessee State Medical Association led first to the publishers being forbidden to advertise the book for any therapeutic purpose. They were allowed only to acknowledge that it was in stock. Then, after a serious licensing scandal during the war years, the Tennessee State Legislature declared the practice of naturopathy in the state of Tennessee to be a gross misdemeanor, punishable by up to 1 year in jail.

Although it was under considerable public pressure in those years, the ANA undertook some of its most scholarly work, coordinating all the systems of naturopathy under commission. This resulted in the publication of a basic textbook on naturopathy (*Basic Naturopathy,* published in 1948 by the ANA[32]) and a significant work compiling all the known theories of botanical medicine (as commissioned by the ANA's successor after its 1950 name change to the American Naturopathic Physicians and Surgeons Association), the *Naturae Medicina,* published in 1953.[33] Naturopathic medicine began splintering when Lust's ANA was succeeded by six different organizations in the mid-1950s.

The primary organizations among these were the successor to the ANA, which underwent a name change in 1950 to the American Naturopathic Physician and Surgeon's Association and subsequently changed to the American Association of Naturopathic Physicians (AANP) in 1956, and the International Society of Naturopathic Physicians formed under the leadership of M. T. Campenella of Florida shortly after Lust's death, with its American offshoot, the National Association of Naturopathic Physicians.

In the face of the AMA's determination to eliminate chiropractic, and with it, naturopathy—healing philosophies that were linked through the mixer orientation within chiropractic (during the 1930s and through the 1960s the majority camp within a divided chiropractic)—naturopathy went through a period of decline described by Hans Baer (see Bibliography).

Walter Wardwell was a sociology professor who became an early leader in what developed as a subspecialty in the 1950s: medical sociology. His earliest work, starting with his doctoral dissertation (1951) at Harvard, focused on chiropractic as an example of a marginalized health profession (see Bibliography). As early as his doctoral dissertation, Wardwell discussed naturopathy as an adjunct discipline to

chiropractic in the context of the continuing division of chiropractic into mixers and straights. As he later noted[34]:

> *Comparison of the survival of chiropractic with that of osteopathy and naturopathy is a quite different matter which does not involve metaphysical or epistemological differences between them. Furthermore, the overlap in theory between chiropractic, osteopathy and naturopathy is very great. Differences between osteopathic and chiropractic manipulative treatment appear to be more a matter of who applies the technique rather than differences in technique itself. The distinction between chiropractors and naturopaths is even more blurred because they often trained at the same schools and sometimes they studied both fields simultaneously. As recently as 1948, three of the currently accredited chiropractic colleges offered N.D. (Doctor of Naturopathy) and D.C. (Doctor of Chiropractic) degrees.*

In this context he described naturopathy as a school of healing that became extinct as two historical factors converged: the death of Lust in 1945, leaving naturopathy without its "founder," and the mandate in the early 1950s by the major mixers' professional group, the National Chiropractic Association (NCA), that it would no longer accredit chiropractic schools that granted degrees in naturopathy:

> *In the case of naturopathy, chiropractic's victory is nearly complete. Although there may still be up to 2000 naturopaths in practice[35] with naturopaths licensed in a few states, and one small school in Portland, Oregon, still offers naturopathic degrees, none of the schools that formerly offered both chiropractic and naturopathic degrees currently does so. With practically no new recruits entering the profession, naturopathy must disappear.*

By the late 1970s, Wardwell had learned of efforts in the Pacific Northwest to keep naturopathy alive. In his chapter in the *Handbook of Medical Sociology,* Wardwell noted this presence in the Northwest (which had received no mention in the first two editions in 1963 and 1972)[36]:

> *The accrediting of chiropractic colleges is encouraging uniformity, not only in curricula but in scope of practice. Those colleges that formerly offered the Doctor of Naturopathy (N.D.) as well as the D.C. degree have ceased doing so, leaving naturopathy with only one remaining small college in Portland, Oregon.*

In his masterwork, *Chiropractic: History and Evolution of a New Profession* (1992),[22] Wardwell devoted substantial attention to the effect of naturopathy on the mixer orientation within chiropractic and traced naturopathy's final educational decline to the untimely death in 1954 of William A. Budden, DC, ND, the president of the Western States Chiropractic College (WSCC; Portland, Oregon). After Budden's death, the WSCC continued to teach naturopathy until 1958 but dropped its ND degree program in 1956. This was the last resistance to the position of the accrediting committee of the NCA, and no chiropractic ND programs remained. Wardwell observed, though, that the seeds of a naturopathic reemergence had been planted in the Northwest after Budden's death and that naturopathy might survive.

The last ND diplomas were granted at the WSCC in 1958 to students who were enrolled in the ND program at the time of Budden's death. Brinker[37] noted the following:

> *Political pressure from the chiropractic profession had begun in the late 1940s to force chiropractic schools to relinquish programs granting naturopathic degrees. After threatening loss of accreditation, the National Chiropractic Association finally forced Western States College to drop its School of Naturopathy in 1956, and it became exclusively Western States Chiropractic College.*

Efforts to keep naturopathy alive through education and licensure were examined by two reports prepared in 1958, a time when the Utah legislature was reexamining naturopathy's licensure in the aftermath of a case from the Utah Supreme Court that had dealt its practicing NDs a crippling blow. The first was *A Study of the Healing Arts With a Particular Emphasis Upon Naturopathy* (November 1958), prepared as "A Report to the Utah Legislative Council" by legislative council staff. As part of its work, the staff conducted inquiries of and site visits to seven schools accredited by the Utah Naturopathy Examining Board as of August 1957.

Separately, the Bureau of Economic and Business Research[38] of the University of Utah (BEBR) undertook a study focusing on schools that had granted naturopathy degrees and produced *Survey of Naturopathic Schools* ("Prepared for the Utah State Medical Society," December 1958). Preparation of the study was, as noted in the title, undertaken by the university research program at the request of the state medical society, but the preparation of the study was independent, and "no attempt was made by that group to influence the results of the study" (Foreword and Acknowledgements).

The BEBR study, done with the requested cooperation of investigators from five other universities located in various sections of the United States, surveyed all of the schools listed by Utah licensees as schools of graduation or schools attended, using records maintained by the Utah Department of Business Registration.[10] Because the state of naturopathic education in the 1950s is relevant, some observations from this study are worth noting[39]:

> *One of the most important results to emerge from this study is that there are virtually no schools now teaching naturopathy.*

Of the 26 schools investigated during this study, only 9 were still in existence in the fall of 1958. Of these nine, only three are now granting naturopathic degrees, and two others are teaching naturopathy.

Of the three schools granting ND degrees, the study found that one school, Sierra States University in California, began offering a "postgraduate" ND degree after the most highly respected chiropractic program in the country, Los Angeles College of Chiropractic, had discontinued its ND degree program in 1948. National College of Naturopathic Medicine (NCNM), the Oregon school, had—in 1957, its first year of operation—four ND students who were starting at NCNM and 60 enrolled "postgraduate" DCs pursuing ND degrees. The school had been recognized by the Utah examining board but had not yet granted degrees. The third school granting ND degrees as of 1957 to 1958 was the Central States College of Physiatrics in Eaton, Ohio, essentially the one-man operation of H. Riley Spitler, author of *Basic Naturopathy* (published by the ANA in 1948). This school granted a doctor of mechanotherapy (DM) degree, recognized in only Ohio and Alabama by law, or an ND degree to anyone who sought licensure in a state where an ND degree would qualify a graduate for licensure. The course of study for both degrees was the same, and the school had graduated 10 students in the previous 2 years. Its ND degrees were recognized in Utah.

By 1955, the AANP, as it ultimately became known, had recognized only two schools of naturopathic medicine, the Central States College of Physiatrics in Eaton, Ohio, under the leadership of H. Riley Spitler, and Western States College of Chiropractic and Naturopathy located outside Portland, Oregon, under the leadership of W. A. Budden. Budden was a Lindlahr graduate and among the group that took over control of the Lindlahr College after Lindlahr's death in the 1920s. He moved west in 1929 when the northwestern states, including Oregon, became a bastion for naturopaths in this country.

This state of affairs was accurately described by Homola[40] in his book on the history and evolution of chiropractic:

> *As of 1958, only five states (Arizona, Connecticut, Oregon, Virginia and Utah) separately classified and provided licensing provisions for the naturopath. A few states, however, did permit licensing of drugless healers following examination by [a] board. (A good number of states have repealed their laws licensing naturopaths in recent years.) Chiropractic schools that employ the use of physiotherapy teach a course that is very similar to the practice of naturopathy. Likewise, the three or four naturopathic schools still operating today have a curriculum similar to that of many chiropractic colleges. In fact, at least four chiropractic colleges awarded naturopathic degrees along with the chiropractic degree before they came under the jurisdiction of the national Chiropractic Association. With the approval of this organization, the schools were prohibited from issuing naturopathic degrees. This practically amounted to a death-dealing blow to the profession of naturopathy.*[40]

In 1967 the U.S. Department of Health, Education, and Welfare; the Public Health Service; and the National Center for Health Statistics (NCHS) published Public Health Service Publication No. 1758, *State Licensing of Health Occupations.* With the assistance of the Council of State Governments, the NCHS collected data regarding the licensure of health professionals at the state level. "Chapter 8: Naturopaths" recorded the available data for the naturopathic profession as of the mid-1960s. In summary, the NCHS identified five states and the District of Columbia as licensing naturopaths as of 1967: Arizona, Connecticut, Hawaii, Oregon, and Utah. California and Florida were identified as renewing existing licenses but granting no new licenses. The publication reported that by 1965, California had renewed 66 licenses and Florida, 136. Licenses in effect by state were as follows: Arizona (100), Connecticut (47), Hawaii (14), Oregon (148), and Utah (42). No numbers were provided for the District of Columbia. The report stated the following[41]:

> *In addition to Doctors of Naturopathy (ND) there are other limited branches of medicine; these have not been included in the study. In the State of Washington the Drugless Therapeutics Examining Committee functions (for such licensure). The Ohio law states which branches are to be specified on certificates issued by the State Medical Board to limited practitioners. No attempt has been made to collect information on these drugless healers who are few in number.*

Active state practitioners were also numbered (although the reason for the differentiation is not clear), as follows: Arizona (53), Connecticut (29), Hawaii (13), and Oregon (121). Given the existence of approximately 50 practitioners at the time in Washington, and some practicing in Idaho under a decision of the Idaho Supreme Court, there appear to have been perhaps as many as 600 to 700 remaining naturopaths practicing at the end of the 1960s.[42]

According to documentation provided to the federal Department of Health, Education, and Welfare in 1968 by the again-remaining professional association—the National Association of Naturopathic Physicians—only 17 degrees were granted from 1960 to 1968. By 1968, this association had 168 members and estimated that there were perhaps 500 "active" naturopaths in the United States. Congress adopted Medicare in 1965. The legislation covered payment for the services of physicians (essentially MDs and DOs), hospital services, and "other therapeutic services" that would commonly be provided through these conventional means. As Wardwell reported,[22] in 1967, Congress directed the secretary of the Department of Health, Education, and Welfare (HEW), Wilbur Cohen, to study the inclusion services of "additional types of licensed practitioners." The surgeon general and other HEW staff prepared the resulting *Independent Practitioners Under Medicare* using advisory committees only (Wardwell served on the Expert Review Committee for Chiropractic and Naturopathy), which actually had little input. This report documented the ebb tide of naturopathy's "period of decline," as Baer later labeled it.[43] The section of the report *Naturopathy* concluded that as of 1968:

> *Naturopathic theory and practice are not based on the body of basic knowledge related to health, disease, and health care which has been widely accepted by the scientific community. Moreover, irrespective of its theory, the scope and quality of naturopathic education do not prepare the practitioner to make an adequate diagnosis and provide adequate treatment.*

Considering the state of the profession in 1968, these negative assessments were hardly unexpected.

THE MODERN REJUVENATION

After the counterculture years of the late 1960s and feeding of an American disenchantment with organized medicine that began after the miracle-drug era faded, exposing some of orthodox medicine's limitations, alternative medicine began to gain new respect. Naturopathic medicine underwent an era of rejuvenation as a late-1970s consumer interest in more "holistic" medicine began to emerge.

As succinctly described in Cassedy's[44] *Medicine in America: A Short History,* this phenomenon, which was not limited to naturopathic medicine, was consistent with the modern and continuing "search for health beyond orthodox medicine":

> *It should not have been surprising to anyone that certain organized therapeutic sects continue to exist in mid–twentieth century America as successful and conspicuous alternatives to regular medicine. This is not to say that they offer the same threats to the medical establishment or play the same roles as their nineteenth-century counterparts had, as complete therapeutic systems. But they do continue to hold a strong collective appeal for individuals who mistrust or are somehow disenchanted with mainline medicine. They have appealed also to antiauthoritarian sentiments that flourish throughout society. Moreover, as earlier, they satisfy various needs that regular medicine continues to neglect or ignore.*

The same author, in describing the post–World War II decades and the changing fortunes of such healing theories as naturopathic medicine, observed as follows:

> *The period also brought about the renewal or updating of certain previously widely used therapies and considerable experimentation with others, some of them exotic. To an extent this trend represented the rediscovery by trained physicians, nurses, and other regular health professionals of certain values and older styles of therapy. The participation of such professionals proved to be an essential ingredient in the rebirth of several such therapies. However, the major reason for the new successes was the wide-spread active interest and involvement of America's literate lay people in the search for more personal or humane forms of treatment.*

As another author, John Duffy,[45] observed in *From Humors to Medical Science:*

Since health is too closely related to cultural, social, and economic factors to be left exclusively to doctors, American lay people have always engaged in do-it-yourself medicine, resorted to "irregulars and quacks," and supported health movements. As a result of the current fad for physical fitness, our streets are beset by sweat-suited individuals of all ages doggedly jogging their way to health and long life. In addition, stores selling "natural" foods are flourishing, physical fitness salons have become a major business, and anti-smoking and weight-loss clinics and workshops are attracting thousands of individuals bent on leading cleaner and leaner lives. And those for whom physical activity in itself is not enough are seeking physical and mental well-being through faith healing, yoga, and a host of major and minor gurus.

When neither mental effort nor physical exercise can solve medical problems, the sceptics of modern medicine can always turn to the irregulars. A recent estimate places a number of Americans who have relied on an irregular practitioner at some time in their lives at 60 million, and, aided by the high cost of orthodox medicine, irregular medical practice appears to be on the rise.

At the beginning of this period of rejuvenation, the profession's educational institutions had dwindled to one, the National College of Naturopathic Medicine (which had branches in Seattle, Washington, and Portland, Oregon), which was founded after the death of R. A. Budden and the conversion of Western States College to a straight school of chiropractic. Kruger's[15] book *Other Healers, Other Cures* described it as follows in 1974:

Today, Naturopaths in seventeen states are licensed to diagnose, treat, and prescribe for any human disease through the use of air, light, heat, herbs, nutrition, electrotherapy, physiotherapy, manipulations, and minor surgery. At present, one can earn an D.N. [a misnomer, actually—N.D.] degree at the National College of Naturopathic Medicine in Seattle and Emporia, Kansas, [where, by contract, the first 2 years of the 4-year medical education were then taught], or the new North American Naturopathic Institute in North Arlington, New Jersey [there is also a school in Montreal]. The four-year curriculum covers many standard medical courses—anatomy, bacteriology, urology, pathology, physiology, X-ray reading etc.—but also includes botanical medicine, hydrotherapy, electrotherapy, and manipulative technique.

The public, by the late 1970s, was particularly ripe for another rejuvenation of naturopathy's brand of "alternative" health care. As described in Murphy's *Enter the Physician: The Transformation of Domestic Medicine, 1760–1860,* when discussing this cyclical rejuvenation in the mid-20th century[46]:

Contemporary crusaders still stress prevention as the layperson's primary duty, but a growing chorus is calling for every person to assume the newly proactive role in his or her own health care.

What would this entail? There are probably as many answers to this question as there are respondents, but it is striking to note how many of the solutions would have been familiar to our ancestors who lived between 1760 and 1860. One recurring idea, for instance, is that each person knows his or her own constitution history the best and therefore has a duty to communicate that knowledge to medical personnel. Another is a refurbished concept of *vis medicatrix naturae,* the belief that many diseases are self-limiting and therefore do not require much medical intervention—and certainly not the amount or the sort to which contemporary Americans are accustomed. Most significantly, today's analysts are calling on professionals and nonprofessionals to build and nurture a healthcare partnership very much like that envisioned by 19th-century health publicists: a partnership based on mutual respect, clear understanding, and faithful execution. In that scenario, both as it originally evolved and in its updated version, it is the doctor who directs treatment, but crucial to a successful outcome are the informed and responsible actions of the patients, other caregivers, and the patient's family and friends.

In 1978 the John Bastyr College of Naturopathic Medicine was formed in Seattle, Washington, by Joseph E. Pizzorno, ND (founding president), Lester E. Griffith, ND, and William Mitchell, ND (all graduates of the National College of Naturopathic Medicine), and Sheila Quinn, who felt that it was necessary to have more institutions devoted to naturopathic care and the teaching of naturopathic therapeutics. To differentiate Bastyr from the other "irregular"[45] schools, Pizzorno coined the term *science-based natural medicine* and developed the curriculum to implement it. Bastyr's cofounder and first president, Joseph Pizzorno, recognized that "anecdotal and unverified 'cures', particularly when associated with unusual therapies do our cause little good." Consequently, instruction at the school "concentrated more on the scientifically verifiable aspects of natural medicine and less on the relatively anecdotal nature cure aspects."[21]

In *Other Healers, Unorthodox Medicine in America,*[47] a volume written to provide "a scholarly perspective on unorthodox movements and practices that have arisen in the United States" (from the editor's preface), author Martin Kauffman, a modern expert in homeopathy from the Department of History at Westfield State College, detailed Bastyr's homeopathic requirements to graduate:

In 1978, three naturopathic practitioners in Seattle founded the John Bastyr College of Naturopathic Medicine. During the sixth quarter all students at that school are required to take 44 hours of course work in homeopathy, after which they may elect another 66 hours and up to 238 hours of clinical homeopathic instruction. The significance of the naturopathic schools to the resurgence of homeopathy is demonstrated by the fact that "about one third of the graduating class specialized in homeopathic practice, a total of about 50 each year in all."[47]

During the late 1970s, other naturopathic doctors also recognized the need to establish educational institutions for students of naturopathic medicine; subsequent efforts included colleges in Arizona (the Arizona College of Naturopathic Medicine), Oregon (the American College of Naturopathic Medicine), and California (the Pacific College of Naturopathic Medicine). Unfortunately, none of these three survived.

As public demand for natural healing grew in the 1980s and 1990s, the emerging profession continued to grow a breadth and quality of educational opportunity for those seeking accredited doctorate-level programs in naturopathic medicine.

With thriving enrollments at Bastyr and National College, the Council on Naturopathic Medicine was founded in 1978 to establish and oversee educational standards, and today it is recognized by the U.S. Secretary of Education as the national accrediting agency for programs leading to the doctor of naturopathic medicine (ND or NMD) or doctor of naturopathy (ND) degree. To further build on the cornerstone of accredited education and ensure educational quality, in 1986 the Naturopathic Physician Licensing Examination became the first national board examination for graduates; today, graduates must pass a two-part medical examination in biomedical and clinical sciences before they are eligible to use the title "ND." This examination is modeled after the conventional medical board examination for allopathic graduates, the U.S. Medical Licensing Exam, which assigns the "MD" license. This training was described in detail in a report

from 2001 by the University of California San Francisco Center for Health Professions: "Naturopathic physicians are typically trained in a wide array of alternative therapies including herbology, homeopathy, massage, hydrotherapy, physical medicine, behavioral medicine, Traditional Chinese medicine, Ayurvedic medicine, acupuncture, and nutrition therapy, as well as clinical practices such as minor surgery, pharmacology and obstetrics."[48]

With educational standards set, throughout the 1990s and 2000s, a select group of new programs and institutions attained accreditation status with the Council on Naturopathic Medicine: Southwest College of Naturopathic Medicine and Health Sciences, Tempe, Arizona; the College of Naturopathic Medicine at the University of Bridgeport, Connecticut; the Canadian College of Naturopathic Medicine, Toronto, Ontario; and, in 2011, the Boucher Institute of Naturopathic Medicine, British Columbia, Canada. The establishment of multiple geographic locations for this type of education paves a solid future for the profession, providing hundreds of newly graduated naturopathic doctors every year in the United States and Canada.

There are favorable commentaries on the current state of naturopathic medicine. *Other Healers, Unorthodox Medicine in America*[47] is a volume written to provide "a scholarly perspective on unorthodox movements and practices that have arisen in the United States." As described in the *Encyclopedia of Alternative Health Care* by Olsen[49]:

> *While naturopathic medicine is now legal (in several states), many naturopaths practicing in other states are old-timers, practicing under their original "drugless therapy" licenses, issued before laws prohibiting new naturopathic practices went into effect.*

In cooperation with regional associations, the AANP has won licensure and scope-of-practice protection at a steady rate on par with the growth of schools accredited by the Association of Accredited Naturopathic Medical Colleges. As of 2011, 15 U.S. states, the District of Columbia, five Canadian provinces, and the U.S. territories of Puerto Rico and the U.S. Virgin Islands regulate the naturopathic profession (Box 3.1).

Baer's interest in the evolution of chiropractic as a philosophy of healing led him to Wardwell's work and to Wardwell's earlier scholarship, which had been tied to the mixer orientation within chiropractic. Baer took note of his descriptions of naturopathy as a near-extinct philosophy. Predictions of extinction were consistent among the assessments of social scientists in the 1970s and continued into the mid-1980s. Twaddle and Hessler, Rosengren, Whorton, and most notably, Wardwell all discussed naturopathy as a once-observable but marginalized philosophy of health and healing at odds with the conventional medical claims of a scientific medicine (see Bibliography). These social scientists placed naturopathy's demise sometime in the 1950s when chiropractic severed its open naturopathic link by terminating ND programs.

Baer, before Wardwell, took special note of Bastyr and the professionalization represented by its scientific medicine–based curriculum and the publication of a John Bastyr College of Naturopathic Medicine project, *The Textbook of Natural Medicine.*

In his 1992 *Medical Anthropology* article[43] "The Potential Rejuvenation of American Naturopathy as a Consequence of the Holistic Health Movement," Baer detailed his own view of Naturopathy's "three stages of development" noted at the outset of this chapter. Besides relying on material covered in the original chapter of "The History of Naturopathic Medicine," which first appeared in 1985, Baer covered much of the new material regarding the emerging (1900–1930s) and declining (1940–1970s) stages of naturopathy.

Baer particularly broke new ground with his recognition of a "potential rejuvenation" of naturopathy as naturopathic medicine and his recognition that the profession had knowingly or unknowingly adopted a recognized survival strategy as a matter of organizational policy: professionalization. Baer also advanced a theory regarding the "potential rejuvenation" as tied to the emergence in the 1970s of holistic medicine. Holistic medicine, as a philosophy of healing, had a cultural affinity with the eclecticism inherent in naturopathic philosophy. In his 2001 book[50] *Biomedicine and Alternative Healing Systems in America,* Baer updated this view of the status of naturopathic medicine in a chapter entitled "Naturopathy and Acupuncture as Secondary Professionalized Heterodox Medical Systems." With the passage of the additional 10 years, Baer observed[50]:

> *Unlike chiropractic, which no longer poses a serious threat to biomedicine because of its status as a specialty emphasizing spinal manipulation, a rejuvenated naturopathy finds itself in direct competition with biomedicine because both systems claim to provide a comprehensive approach to health care.*
>
> *As osteopathy and chiropractic did earlier, naturopathy … [is] increasingly incorporating the theory and social organization of biomedicine.*
>
> *[N]aturopathy with [its] reductionist philosophy and [its] focus on individual responsibility for healthy living may well undergo further growth in an era of growing health costs.*

BOX 3.1 States/Districts/Provinces That Regulate the Naturopathic Profession (updated 2018)

States
Alaska
Arizona
California
Colorado
Connecticut
Hawaii
Idaho
Kansas
Maine
Massachusetts
Minnesota
Montana
New Hampshire
North Dakota
Oregon
Pennsylvania
Rhode Island
Utah
Vermont
Washington

Districts and Territories
District of Columbia
Puerto Rico
U.S. Virgin Islands

Provinces
Alberta
British Columbia
Manitoba
Nova Scotia
Ontario
Saskatchewan

THE 21ST CENTURY AWAITS

Baer carried his examination of the sociopolitical aspects forward in his 2001 article "The Sociopolitical Status of U.S. Naturopathy at the Dawn of the 21st Century,"[51] which examined the state of naturopathic medicine as it prepared to enter the 21st century. Although "professionalized naturopathy has undergone tremendous growth and legitimization since the late 1970s, nevertheless, it finds itself in a tenuous situation at the dawn of the twenty-first century in that its strength is confined primarily to the Far West and New England; it faces increasing competition from the partially professionalized and lay naturopaths; and it faces the danger of being overshadowed by a powerful biomedical system that is increasingly incorporating aspects of holistic health into its own practice."

He offered no definitive answers to these questions of naturopathic medicine's future, but he also highlighted areas needing further attention by social scientists: continued exploration of the reasons for naturopathy's decline and rejuvenation and continued study of the naturopathic profession in recognition of its state of professionalization.

In closing, Baer observed: "In sum, while changes in the popular ideas about health and healing unleashed the social forces that enabled professional naturopathy to get back on its feet, those same social forces may overwhelm its core claim to being a unique, natural approach to healing."

Whorton expressed the view that in many respects the transition from the marginalized naturopathy to the professionalized naturopathic medicine has now been accomplished.[52] He traced his view of this transformation as part of the larger transformation "from alternative medicine to complementary medicine" on the part of osteopathy, chiropractic, and naturopathy. Whorton described the factors that allowed this transformation even after the death of Lust in 1945: the issue of the "field's lack of a scientific basis" was determined internally when the "died-in-the-wool believers in 'nature cure'" were outlasted by the "liberal practitioners belonging to the so-called western group, naturopaths concentrated in the western states who recognized the validity of mainstream medicine's scientific foundation and sought to incorporate biomedical science into their own system and apply it under the guidelines of naturopathic philosophy."

As Whorton noted, "a key figure among the pseudomedicals was John Bastyr—a practitioner in Seattle since the 1930s, and particularly well-known for his advocacy of natural childbirth." Bastyr, Whorton noted, "recognized the necessity of naturopathy staying abreast of advances in biomedical science and applying those advances 'in ways consistent with naturopathic principles.'"[21] Bastyr was directly involved with the formation and maintenance of the NCNM during the years of naturopathy's decline and lived to see much of "the short history of John Bastyr College [of Naturopathic Medicine] ... the most compelling illustration of the triumphant rebirth of naturopathy as naturopathic medicine."[21]

Bastyr has been called the "father of modern naturopathic medicine" by Pizzorno, ND,[52] the moving spirit behind the professionalization of naturopathic medicine and the founding president of Bastyr University. No individual has carried the practice of NDs in the United States in the way that Lust did, but Bastyr and the others profiled by Kirchfeld and Boyle in *Nature Doctors* kept naturopathy alive during its decline in the 1950s and 1960s so that it could, in time, reemerge.

The movement continues to grow, and thus the effect of natural healing has come full circle. In an era where the statistical number of persons born who are expected to contract cancer, now recognized as a degenerative disease, has increased rather than declined and where the incidence of other degenerative diseases (arthritis, arteriosclerosis, atherosclerosis, etc.) has increased in direct relation to the lengthening of life expectancies produced by improved sanitation and nutrition (although speciously claimed by AMA medicine to be the result of their therapies), the early teachings of Lust, Lindlahr, and others appear to have more validity than ever.

42. The State Licensing of Health Occupations; U.S. Department of Health, Education, and Welfare; and the National Center for Health Statistics Public Health Service Publication No. 1758 (1967) reported: "Naturopaths are specifically licensed in at least five States and the District of Columbia. The absence of a State from this list does not imply that there are no licensed naturopaths. Illinois, for example, could be covered by the medical practice act. Texas and Virginia provide for naturopaths on examining boards but no information is available on licensing practices. Elsewhere licensing powers have been abolished and no new licenses have been issued; for example, in 1965 naturopathic licenses renewed in California numbered 66 and in Florida, 136."

The History of Naturopathic Medicine

A New and Revisionist Perspective: The Lost Years of the 20th Century

George W. Cody, JD, MA

OUTLINE

INTRODUCTION AND AUTHOR'S NOTE

When earlier chapters on natural healing in the United States were researched and written, the available sources were primarily the extensive publications of Benedict Lust and the works of other historians. When other historians had looked extensively at naturopathy—historians such as James Whorton, Hans Baer, or (recently) Susan Cayleff—they also relied on primarily on Benedict Lust.

This has left a historical gap between Lust's death in 1945 and the 1970s when a modern naturopathic medicine emerged and began making its own historical record. But there is a hidden history of natural healing between 1945 and 1975 that this chapter will seek to explore and document—a history that is surprisingly rich and deep.

Discovering and documenting the history of this period had to wait until resources became available for research. Five new resources that became available in the past 10 to 15 years are at the heart of this new chapter. All of these resources have become available—accessible for research—due to modern technology.

The first is the library resources of the modern naturopathic colleges, primarily Bastyr University and what is today the National University of Natural Medicine (NUNM). These resources, though, have largely not been digitized and required old-fashioned "shoe leather" research.

This work is greatly indebted to the "shoe leather" of Eric Blake, ND, of Portland, Oregon (and to Mitchell Stargrove, ND, also of the Portland area, who introduced this author to Eric's work). Eric had spent many hours about 15 years ago researching the stacks of material in the NUNM "rare book" room with an eye to what Benedict Lust either did not tell us or any off-track items that were buried in Lust's publications. This led to many hours of conversation and correspondence between this author and Eric that led down the path of a new historical synthesis.

Second, the John Bastyr archives at Bastyr University then opened up material that Dr. Bastyr had saved from this era that had been in boxes, unexplored. Chief among these was a collection (not complete) of the publications of the Western American Naturopathic Association (ANA)/American Naturopathic Physicians and Surgeons Association/ American Association of Naturopathic Physicians from 1947 to 1954. Dr. Bastyr was a protégé of Dr. Robert V. Carroll Sr., who had brought Bastyr into the world and practice of naturopathy, as these records documented. (Thanks are owed to the staff of the library at Bastyr University, especially Jane Saxton and Linda Tally.)

Third is the archive materials at the W.A. Budden Library of the University of Western States (UWS) in Portland, Oregon. The UWS is the modern successor to Dr. Budden's Western States College where Dr. Budden was president from 1929 to 1954. What was not already digitized and accessible on the UWS website was scanned and made available to this author by the archive librarian, Katie Lockwood. She also deserves a large credit for advancing this historical work product.

Fourth is two resources on the history of the UWS and of chiropractic: the history of the UWS by Lester Lamm, DC, and the history of chiropractic education by Keating, Rehm, and Callender, which includes the detailed minutes of the Council on Education of National Chiropractic Association, within which Dr. Budden participated, operated, and influenced.[1]

Fifth, and finally, a massive amount of newspaper archive material has been digitized and made available. Coupled with search-engine capacities, a completely buried panorama of natural healing history has gone through a supernova process. Armed with these voluminous materials, the questions "Who were the naturopaths?" and "What happened to them?" can at last start to be answered.

Editors' Note: This is the second of two chapters documenting the origins and evolution of naturopathic medicine. Although these were written to stand alone, a full understanding requires reading both chapters.

PART ONE: WHO WERE THE NATUROPATHS?

Natural healing advanced a science-based alternative to the American medical profession of the 20th century; this alternative philosophy started first as naturopathy as promulgated by Benedict Lust, and then its concepts and practice evolved into naturopathic medicine primarily through the work of three early pioneers: Henry Lindlahr, William C. Schulze, and Walter B. Cannon, all medical doctors disenchanted by conventional medicine moving in what they considered the wrong direction. By the early 1950s, natural healing—an alternative to conventional medicine practiced by chiropractors and naturopaths—reached its peak. Practitioners were spread across the United States, and their common philosophy was based on a belief in the *vital force*—the inherent healing power within all of us. The leadership of W.A. Budden and Robert V. Carroll was critical to the professional growth of natural healing from the mid-1930s to the early 1950s. They led a professionalization movement within natural healing that brought these practitioners to the peak that was reached in the post-WWII United States.

IN THE BEGINNING

In the early 20th century there was medicine as practiced by medical doctors ("MDs") and as represented in the United States by the American Medical Association (AMA). The AMA became, over the first 75 years of the 20th century, one of the most powerful political interest groups in US history and became known as "organized medicine."[2]

There were alternatives that emerged early in the 20th century, primarily in the form of chiropractic, naturopathy, and other "drugless' schools of healing as well as in the work of MDs who diverged from the AMA's concept of "scientific medicine." Scientific medicine was based on Louis Pasteur's "germ theory."

Germ Theory and Conventional Medicine

At the turn of the 20th century, as Howard Berliner (1985) has documented, straight germ theory (germ *x* causes disease *y*) became established as the core concept of "scientific medicine" in American allopathic medical education. At the time, the major rivalry in American medicine was between allopaths (about 60% of medical practitioners) and homeopaths (about 30%, the balance being Eclectics and physio-medicalists).

Once the substantial resources of the Rockefeller philanthropies were put behind scientific medical education based on germ theory—with the full consent of the AMA—American medicine became synonymous with the germ theory. This, the Flexner Report (1910), and medical research devoted to finding pharmaceuticals to defeat germs to "cure" disease were all funded by Rockefeller philanthropies and led to what is considered to be the dominant paradigm in American medicine.[3]

As Berliner documents, this was largely the result of a determination to put the Rockefeller philanthropic resources behind this concept of "scientific medicine" not, at the time, any clear clinical superiority on the part of the allopathic philosophy. As of the period in which this took place, largely 1900 to 1920, there was no clinical validation for scientific medicine in terms of the discovery of specific pharmaceuticals of demonstrated efficacy.

Be'champ, Bernard, and the Alternatives to Germ Theory

The concept of an alternative to the germ theory of disease traces to two French contemporaries of Louis Pasteur: Augustine Be'champ and Claude Bernard. Pasteur's work asserting microbes as the cause of disease has been well documented and lauded and does not need to be reproduced here.

Be'champ's theory was, put as simply as possible in the biological sense, that "germs" are always present in our environment and do not "cause" disease. Disease is related, rather, to the physiology of the host, the human (or mammalian) body, not to the germs per se. What we observe in microbiology relative to disease is the resultant by-product of the body's failed attempt to reject a pathogenic microbe, a function that a healthy body's autoimmune system should accomplish.[4]

Bernard's work in physiology was much celebrated in the 19th century. As noted by Charles Gross (1998): "Today the fame of Claude Bernard rests primarily (if not entirely) on his idea that the maintenance of the stability of the internal environment *(milieu interieur)* is a prerequisite for the development of a complex nervous system." But as noted by Gross and others, although Bernard advanced this idea between 1854 and his death in 1874, it "had no impact for over 50 years after its formulation." Why did this "insight that the 'constancy of the internal environment is the condition for the free life' (have) no significance (indeed no meaning) for biologists for more than 50 years?" One major reason was that "Pasteur's new bacteriology and its omnipresent, omnipotent germs, were dominating the biomedical Zeitgeist."[5]

The Early Integrators

In the pre-WWII years, the work of three MDs that diverged from germ-theory orthodoxy became central to the emergence of integrative medicine. These three MDs are Henry Lindlahr, William Charles Schulze, and Walter B. Cannon.

Henry Lindlahr and Integration in Clinical Practice

The standard biography of Lindlahr is that of Kirchfeld and Boyle in *Nature Doctors.*[6] His own therapeutic philosophy is set out in his four-volume work *Natural Therapeutics*, published in 1923 and republished in 1975 as edited by Jocelyn Proby, DO.[7] The four volumes are *Philosophy, Practice, Dietetics,* and *Iridiagnosis.*

Lindlahr started his own school in Chicago in 1914 and built a substantial sanitarium, clinic, and college operation as well.[8] A central tenet of Lindlahr's work, in spite of his medical training, was that the allopathic approach to healing was wrong. There were, he said, "two principal methods of treating disease. One is the combative, the other the preventive… The slogan of modern medical science is, 'Kill the germ and cure the disease'… The combative method fights disease with disease, poison with poison, and germs with germs."[9]

On the other hand, "The preventive method does not wait until disease is fully developed and gained ascendancy in the body, but concentrates its best endeavors on preventing, by hygienic living and natural methods of treatment, the development of disease."[10]

In *Philosophy*, he states: "It is the intent of this volume to warn against the exploitation of destructive combative methods to the neglect of preventive constructive and conservative methods. If these teachings contribute something toward this end they will have fulfilled their mission."

His work is consistent with Walter Cannon's physiological insights, and a decade before Cannon's *Wisdom of the Body* was published, he wrote in *Philosophy:*

> *The diet expert, the hydrotherapist, the physical culturist, the adjuster of the spine, the mental healer and the Christian Scientist, pay little attention to the pathological conditions or the symptoms of disease. Each of these, in accordance with his theory of disease and cure, regulates the diet and habits of living on a natural basis, promotes elimination, teaches correct breathing and wholesome exercise, corrects the mechanical lesions of the body, or establishes the right mental and emotional attitude, and, in so far as he succeeds in doing this, builds health and so diminishes the possibility of disease. The successful doctor of the future will have to fall in line with the procession and do more teaching than prescribing.*[11]

Lindlahr strongly advocated for Be'champ's theories, especially in his *Philosophy* volume. He had discovered Be'champ's work, he said, through the earliest work of Ethel Douglas Hume.[12] Specifically, Lindlahr noted that he had then "made a careful study of [Be'champ's] last work, entitled *The Blood,* in which he summarizes the mycrozymian theory of cell life." From this study, Lindlahr found "a rational, scientific explanation of the origin, growth and life activities of germs and of the normal living cells of vegetable, animal and human bodies."[13] At two points in *Philosophy,* Lindlahr discusses at length the understanding of Be'champ's work that he has gained from his own intense study of Be'champ's writings and how from his own clinical observations and experience, and from Be'champ's work, he comes to advance three primary manifestations of disease. These manifestations of disease are (1) lowered vitality (vitality is the body's strength of positive resistance and recuperative power, the "vital force" of cellular function); (2) abnormal composition of blood and lymph; and (3) accumulation of waste, morbid matter, and poisons in the system.[14]

William Charles Schulze and Integration in Medical Education

Schulze was an MD (of Rush Medical College) who, in 1914, purchased the National School of Chiropractic and broadened its curriculum to include the basic sciences as well as "physiological therapeutics" and mechano-therapy.[15] The name was changed in 1920 to the National College of Chiropractic (NCC). His most enduring influence may have come from acquiring and merging Lindlahr's school after Lindlahr's untimely passing in 1924 and in his mentoring influences on W.A. (Alfred) Budden, DC, ND, of Portland's Western States College and, later on, Joseph Janse, DC, ND, the postwar president of National College (1945–1983).[16]

As Keating and Rehm noted about Schulze:

> *Part of the Schulze legacy is the tradition of broad-scope, "rational chiropractic," or what Palmer called "mixing." As an MD, Schulze had been trained in medical and presumably some minor surgical procedures, but he had apparently committed himself to "drugless healing" early in his career. However, drugless healing, which involved a variety of naturopathic methods, was anathema to the Palmer branch of the profession. The physician-chiropractor would quickly run afoul of the adiagnostic, nontherapeutic, subluxation-only forces in the profession.*[17]

Schulze sought "to promote a professionalism among students and doctors which could rival that of medical competitors," and under Schulze, the NCC introduced laboratory courses in pathology, biochemistry, bacteriology, and toxicology, together with a "strong commitment to diagnostic training," all in response to the adoption in the late 1920s of the Basic Science Law. The NCC adopted the motto "four ways to beat the basic science law": (1) Study basic science. (2) Study basic science. (3) Study basic science. (4) Study basic science. Schulze came under much criticism from the "straights" in chiropractic, and this only increased after he purchased the Lindlahr School of Natural Therapeutics from Henry Lindlahr's estate and transferred "the entire student body and the better part of the faculty" to the NCC.[18] In 1928 this part of the National school was formed into the National College of Drugless Physicians, which was National's ND degree program.

The *National College of Chiropractic Journal* became a voice that extended beyond the NCC itself by the early 1920s, becoming a professional voice as well, challenging B.J. Palmer's "straight" chiropractic philosophy as well as the antagonism of Morris Fishbein, MD, the editor of the *Journal of the American Medical Association (JAMA).* This voice was first found under the NCC secretary, A.J. Forster, MD, DC, and then "under the editorship of William Alfred Budden, DC, ND, an English immigrant and former economics instructor at the University of Alberta who graduated from the NCC in 1923."[19]

From the mid-1920s, Schulze was involved more in the professional activities than in the day-to-day operations of the NCC, and always in the "mixer" camp—first in the American Chiropractic Association (ACA) and then starting in 1930 in the successor National Chiropractic (NCA). Schulze then followed a busy, nationwide speaking schedule in the early 1930s, advocating consistently for the broad-scope professional values of the NCA as taught at the NCC/NCDP. At the 1934 annual meeting of the NCA (May 1934), Schulze—a regular speaker at these annual meetings—noted in his speech that at the time, "harmony among Chiropractors and Drugless practitioners, especially the Naturopaths, was good to look upon."[20]

In 1934 Dr. Schulze joined a convention tour coined "the Northwest Circuit" organized by C.O. Watkins, DC, of Montana that had its speakers speak at NCA-affiliated conventions held in Minnesota, North Dakota, Montana, Washington, British Columbia, Idaho, Utah, Wyoming, and Colorado. The Washington stop was for the meeting of the Northwest Chiropractors Association and was a gathering of 300 attendees from Oregon, Washington, Idaho, Northern California, and British Columbia in September.[21]

The last full year that Dr. Schulze was actively engaged was 1934; he was in ill health for much of 1935 and passed away in September 1936. When he passed away, one of the very many appreciation letters honoring his productive life was sent by Dr. Robert Carrol as the president of the Washington State Naturopathic Association, saying, "The entire drugless profession has lost a friend and teacher."[22]

In 2002 Rehm and Keating noted as Dr. Schulze's great accomplishment, "Schulze created an intellectual environment that would be

rivalled in the middle age of the profession only at Budden's Western States College."[23]

Walter B. Cannon and Integration in Medical Research

Cannon did extensive research in physiology, his area of teaching at Harvard. He concurred with Bernard's concept of the "internal environment" of the human body and coined the term *homeostasis* to describe the body's need to respond physiologically to the external environment to maintain a stable internal environment, which he described as a primary function of the central nervous system.[24] His concept was that through what he called the "wisdom of the body," mammalian forms such as the human body "may be confronted by dangerous conditions in the outer world and by equally dangerous possibilities within the body, and yet continue to live and carry their functions with relatively little disturbance," something that Hippocrates had called *vis medicatrix naturae.*

In a distinctive passage in *The Wisdom of the Body,* Cannon set forth a concept that became central to the postwar chiropractor-naturopaths:

> *The fathers of medicine made use of an expression, "the healing forces of nature," the vis medicatrix naturae. It indicates, of course, recognition of the fact that processes of repair after injury, and of restoration to health after disease, go on quite independent of any treatment that the physician may give …*
>
> *In the first place, the well-trained physician is acquainted with the possibilities and limitations of self-regulation and self-repair in the body. He is instructed in that knowledge and employs it not only for his own intelligent action but also as a means of encouragement for the patient who looks to him for counsel …*
>
> *Again, the physician realizes better than the layman that many of the remarkable capacities of the organism for self-adjustment require time—all of the processes of repair belong in that class—and that they can play an important role in restoring the organism to efficiency only if they are given the chance that time provides …*
>
> *Furthermore the physician realizes that he has at his command therapeutic with which he can support or replace the physiological self-righting or self-protective processes we have been considering …*
>
> *Finally a great service which the physician renders is the bringing of hope and good cheer to his patients. He has seen at work in many cases the restorative processes of the organism … When we are afflicted and our bodily resources seem low, we should think of these powers of protection and healing which are ready to work for the bodily welfare.*[25]

Lindlahr was the greatest *direct* influence on the post-WWII philosophy of natural therapeutics, the central core of "drugless" or "nonmedical" philosophy. Lindlahr's and Cannon's work have a remarkable consistency between them, although Lindlahr was largely influenced by Be'champ and Cannon by Bernard. Together they advanced the work of these two 19th-century French scientists into the 20th century, and in doing so, they advanced a scientific basis for an "alternative" to the germ theory that was at the core of conventional "scientific medicine." Schulze pioneered the education of physicians in a professional "drugless" therapeutics consistent with the theoretical work of Lindlahr and Cannon.

THE EARLY 20TH CENTURY

The shaping of America's modern healthcare landscape began in what historians call the Progressive Era—roughly 1900 through the end of World War II in 1919. At the turn of the 20th century, the AMA had begun the elevation of allopaths over homeopaths and Eclectic physicians—all MDs—and had completed this process by the end of the Progressive Era, aided by the 1910 Flexner Report and the efforts of the Rockefeller and Carnegie Foundations (see previous discussion). By the early 1920s, what had become the AMA's monopoly structure within the medical profession was in place.[26]

Drugless Healing

But as homeopaths and eclectics disappeared, a wide range of practitioners known as "drugless healers" emerged. In this period the licensing structure that became a critical part of the AMA's monopoly structure had not been fully adopted across the United States, and these drugless healers, probably several thousand of them, were to be found in practice. The practitioners of manipulation modalities—including osteopaths and chiropractors, but others as well, such as mechanotherapists and naprapaths—were "drugless." So were myriad others, including practitioners of neuropathy, physcultopathy (physical culture), sanipractic, food science, suggestive therapeutics, and Swedish movement. Some of these drugless healing practitioners were specifically regional; naprapaths were almost exclusively found in Illinois, where D.J. Palmer protégé Simon Oakley had founded his school, and sanipractors were originally exclusive to the state of Washington before advancing their presence into British Columbia in Canada.[27]

Benedict Lust

In 1902 Lust originated his use of the term *naturopathy* and began his development of a theory and philosophy of health and healing "to describe the eclectic compilation of doctrines of natural healing that he envisioned was to be the future of natural medicine." Lust launched his career as the progenitor of naturopathy, adopting that name for his eclectic brand of natural therapeutics and placing the term *naturopath* firmly in the title of his monthly publications, which continued under his status as editor and publisher until his death in 1945.[28] One of the anomalies of Lust's work was that for at least 30 years, there was no firm definition of *naturopathy*; rather, Lust clearly attempted to incorporate all methods of "drugless healing" and "natural therapeutics" into his philosophy of naturopathy. This included the original concept of osteopathy devised by Dr. Still and chiropractic as devised by D.D. Palmer. In Lust's view, these were all pieces of naturopathy, linked together by not being "allopathic medicine."[29]

This "drugless" label could only incorporate Still's osteopathy in its original form, which did not incorporate a *materia medica,* as described, for instance, in Charles Hazzard's *Principles of Osteopathy* (3rd edition, 1899).[30] Where chiropractic was concerned, Lust's naturopathy became clearly allied with the "mixer" philosophy, and both Lust and the mixers were in conflict at the time with the "straights" led by B.J. Palmer.[31]

Naturopathy and Chiropractic

Precisely when chiropractic and naturopathy first became melded into a symbiotic relationship is historically murky. D.D. Palmer did not—at least as historically reported—practice or teach naturopathy or openly associate himself with it. His son, B.J., was adamantly opposed to anything that would dilute the purity of "straight" chiropractic. Benedict Lust, the historical progenitor of naturopathy in America, taught and endorsed chiropractic very early in the 20th century, but it was Solon Langworthy, an early student of D.D.'s, who opened the second identifiable school of chiropractic in 1903 and based its curriculum on mixing nature cure with chiropractic.

Palmer was the originator of chiropractic, of course, but he adopted a kind of "Johnny Appleseed" approach to his spinal manipulation insights, "planting" the concept of chiropractic adjustment more than

anything else. He was traveling constantly after 1902 and granting the right to practice and to educate others in his methods to recipients of his written "diplomas."

It was B.J. Palmer, the son, who adopted a proprietary interest in chiropractic after his graduation from D.D.'s instruction in 1902, much as Lust did in naturopathy. Both chiropractic and naturopathy could best be described as social movements in the field of health and healing in their first two decades of evolution. It was not until the 1920s that others began to work at the professionalization of chiropractic and naturopathy, and many of the most influential of these who became connected with naturopathy were chiropractic "mixers," becoming known in time as the chiropractor-naturopaths or "DC, NDs."

Nature Cure and the Vital Force

Benedict Lust's vision of drugless healing, although it continued to "expand," as noted by Susan Cayleff, was always intended to be consistent with Germanic 19th-century "nature cure." As noted by Henry Lindlahr is his 1915 book *Nature Cure,* the original concepts were credited to Vincent Preissnitz.[32] As noted by Lindlahr, nature cure became "the idea of drugless healing [which] spread over Germany and over the civilized world."[33]

Citing Lindlahr, Susan Cayleff summarized American nature cure's idea of human sickness this way:

> *Henry Lindlahr, MD, a leader in naturopathic philosophy, explained the five specific conditions that caused disease; lowered vitality; abnormal composition of blood and lymph, resulting mainly from wrong eating and drinking; accumulation of waste, producing morbid matter and poison in one's system; mechanical lesions, that is pressure, tension or strain on nerves and nerve centers caused by luxations (dislocations) of bony structures or straining of muscles and ligaments; and discordant or destructive mental and emotional attitude. These conditions more or less remained the core of naturopathy for decades.*[34]

Treatment by means of nature cure theory relied on the body's own drive to maintain health—to achieve what Walter Cannon later called "homeostasis"—by recognition of what was labeled the "vital force." The work of F.E. Bilz, a German MD, was very influential in this regard. Bilz first published his synthesis of German nature cure in Germany in 1898, and in 1901 he published *Natural Method of Healing: A Complete Guide to Health (translated from the latest German edition)* as the English language version of his work.[35]

Bilz noted: "[I]t is known that we cannot heal a disease with the remedy we apply, but that it is the vital force within us which heals, and that we need but aid it, [and] our position becomes a far easier one."[36] This "vital power," the "power of healing," Bilz said, "resides in man himself … divine nature placed it there at the creation of each being.'' Adopting this concept, Lindlahr noted that all healing must "economize vital force" because it is the vital force that "is the Supreme power and intelligence, acting in and through every atom, molecule and cell in the human body which is the true healer, the *vis medicatrix nature* which always endeavors to repair, to heal and to restore …"[37]

GENESIS OF POST–WWI PROFESSIONALISM

To understand the DC, NDs and their professionalization requires going beyond the career of Benedict Lust and the natural living and healing movement that he founded. It also requires more historical background.

The committed professionalization process that followed began in the late 1920s and continued through the first years after WWII. The focus was on moving the educational process and the clinical practice of both naturopathy and chiropractic past the "founder's grip" of Benedict Lust and B.J. Palmer by means of the creation of stable residential colleges and stable state and national professional organizations.

This task was compounded with regard to both of these professions by the committed drive by organized medicine in the United States (primarily in the form of the AMA and its state and local constituencies) toward medical dominance. To respond to the determination of medicine to achieve this dominance, a resistance based on the core values of "Americanism" was required, along with personal resilience and tenacity.

A Short Course in Medical Dominance

Medical dominance is best understood by reference to the book of this same name by Australian sociologist Evan Willis.[38] The subject can be supplemented by a very useful work by another sociologist, Saul Rosenthal, *A Sociology of Chiropractic.*[39]

These sociologists argue that organized medicine has had as a goal since at least 1900 the achievement of medical dominance in domains: achievement of complete control over its own work (autonomy), achievement of complete control over the work of others in health care (dominion), and achievement of complete control over all matters of public policy within the health domain (medical sovereignty).

Willis's argument is sophisticated and extensive; indeed, his discussion of the subject is a book-length treatise. But the short version as it relates to the "exclusion" of "alternative" practices like chiropractic and naturopathy can be summarized. Relying on earlier work by Howard Berliner and others, he demonstrates that medicine's dominance was achieved through the allopathic claiming of the mantle of "science" for its work. This was done through the adoption of the germ theory of disease.[40]

This, in turn, had two advantages, as Willis argues: first, individual clinical skill became less important than extensive schooling within a laboratory and hospital-based system ("clinical skill" versus "clinical science"), and second, health became an individual scientific problem, not a social, environmental or lifestyle problem.

The "Great Trade"

In the United States, this manifested itself in the early 20th century as "the Great Trade" described by Fredric Wolinsky: "[B]y 1925, the AMA had gained a monopoly over the production and licensing of physicians. This included the power to determine what the curriculum should be, how many students should be admitted, which students should be admitted, and how many faculty there should be for each student. Thus 1910 marked a trade of importance between society (as represented by state and federal governments) and the AMA. The trade gave the AMA the exclusive right and sole power to regulate the medical profession. In return, the AMA was to give society the best and most efficient medical care system possible. Society has clearly lived up to its part of the bargain …"[41]

American Exceptionalism

"American exceptionalism" or "Americanism" has been analyzed extensively in the book of the same name by Professor Seymour Martin Lipset, one of the most distinguished US academicians. Professor Lipset gives this synopsis of Americanism: "The American Creed can be described in five terms: liberty, egalitarianism, individualism, populism and *laissez-faire.*"[42]

Medical dominance strikes at each of these five values, all in the name of "scientific medicine." It is based on using the power of the state to enforce the "great trade" as public policy, the antithesis of populism. It is corporatist, not individualist and *laissez-faire.* It creates a

favored class of medical professionals over serving egalitarianism, and by the exercise of the power of the state, it constrains the liberty of the patient as a consumer.

A Time to Build a Profession: The 1930s

The drugless healing concepts of nature cure became, by the 1930s, the philosophical basis for a professional alternative to conventional medicine in the form of the chiropractor-naturopaths, the "DC, NDs." By the mid-1930s, as Susan Cayleff notes, Benedict Lust came to abandon "therapeutic inclusivity" and declared that a clear and fixed professional identity was necessary.[43] For some others who had already formed a professional identity and founded schools and colleges, this moment of self-reckoning came not a moment too soon. It was time to bring all of this into focus as a professional identity once and for all.

The Move Toward Professionalization

By the 1930s, the concept of "drugless healing" began to change, and significantly. The majority within osteopathy was moving to add *materia medica* to osteopathic manipulation and prescribing in line with allopathic thinking and the germ theory.[44] The majority within chiropractic were "mixers," perhaps 70% of chiropractors.[45] And within naturopathy, the amalgamation period of the previous 30 years was giving way to identification as naturopaths and abandonment of other drugless labels.[46]

In the case of osteopathy, the conflict between the originalists and the modernists played out within the American Osteopathic Association (AOA) in the form of battles over "standards" applicable to the osteopathic colleges. Among chiropractors, two professional associations emerged by the early 1930s, the National Chiropractic Association (NCA), which was the association for the "mixers" within chiropractic, and the B.J. Palmer–led Chiropractic Health Bureau, which in 1941 became the International Chiropractic Association—the organization of the "straights."

From the AMA's perspective, the "straights" were the most easily labeled as a "healing cult." The straights stood politically for 18-month schooling directed toward identifying "subluxations" of the spine and resolution by manual spinal adjustment as the treatment for all human ailments. A high school education was considered sufficient as a prerequisite for a "straight" chiropractic education.

The NCA had adopted a 4-year residency education requirement by the end of the 1930s, led by the Metropolitan Chiropractic College, Western States College (WSC or Western States) and the National Chiropractic College. A leader in consistently upgrading educational standards within the NCA was W.A. Budden of Western States.

Within naturopathy, the transition in the 1930s was more complex. As pointed out by Susan Cayleff, by 1935 Benedict Lust moved away from considering all drugless healers part of naturopathy, regardless of how they identified themselves. After three decades, he instead declared that all naturopaths needed to identify as such, encouraging all remaining drugless healers to openly join the naturopathic movement.[47] Kirchfeld and Boyle assert that Lust had gone beyond the establishment and popularization of the American naturopathic movement by the end of the 1920s and "must be credited with four other accomplishments." These were founding the American School of Naturopathy, founding the ANA, his publications, and "the legal status of naturopathy attained as a result of his efforts," which they call "the most tangible of his efforts." They note that "it is difficult to separate the success of Lust's organizations from that of his publications."[48]

By the early 1930s, the success of Lust's efforts must be deemed "qualified."

A 1927 survey by a committee of the AMA of all "schools of chiropractic and naturopathy" found Lust's combined American School of Chiropractic and American School of Naturopathy to be a night school program operating classes for 3 hours each weeknight for a 4-year, 9-months-per-year course. No catalog was published due to expense, but the school was described in Lust's monthly publications. The school as of 1927 and forward was not established to function in the era of the Basic Science Law, and moreover, neither chiropractic nor naturopathy was licensed in New York. In 1935 Lust was found guilty of illegally (under New York law) issuing diplomas awarding a "doctor" degree without a lawful state charter.

It is true that Lust's ongoing influence was from his publications and from his continued popularization of naturopathy through his travels and his speeches. Through this popularization, others were able to obtain legal status for naturopaths in several states, but this was largely accomplished by others in the movement. Lust's own operations were in New York (school and publications), New Jersey (his first Yungborn Sanitarium) and Florida (second Yungborn Sanitarium). Of these states, only Florida granted naturopaths recognized legal status, and this was accomplished by others in the movement.

By the 1930s, an alternate vision formed within the ANS and within some of the NCA schools that offered ND degrees in addition to DC degrees. As Lust's influence declined during WWII and after his passing in 1945, others came forward with a competing vision of the relationship between chiropractic and naturopathy, of naturopathic education, and of nonmedical clinical practice. How this came about is a piece of history that has not been well documented before. The story centers on a few men and women, the most prominent of whom are W.A. (Alfred) Budden of Western States College, with its Schools of Chiropractic and Naturopathy, and Robert V. Carroll of the ANA.

Dr. Budden and Evolution of the Profession in the Pacific Northwest

Budden's Early Career and Arrival in Oregon

W.A. Budden, DC, ND, educated at Schulze's National College and later a Pacific Northwest (NW) transplant, was a leader in the professional development movement of drugless physicians. Over time, Budden acquired several staunch allies in this effort.

The alliance of DCs and NDs in the Pacific NW began through the efforts of Dr. Budden and took root during the remarkable Oregon ballot campaign of 1934. This alliance continued to grow in the aftermath of the ballot fight, as Dr. Budden lived by what he considered to be the lessons of this formative campaign.

This ballot campaign of 1934 was Dr. Budden's brainchild. Budden himself had come west from Chicago to Portland, Oregon, steeped in a "mixer's" amalgam of core chiropractic, physiotherapy, and Lindlahr's natural therapeutics. Budden attended Schulze's National College from 1922 to 1924. Upon graduation as a DC, he joined the faculty and in 1925 succeeded the college's previous dean and school journal editor.[49]

It was at this time that National purchased and absorbed Lindlahr's College of Natural Therapeutics, the premier drugless school of the time. Budden was integrally involved in the integration of the Lindlahr programs into national as the college's ND degree program. As an educator and administrator at National through the 1920s, Budden also authored a textbook for use at National: *Physiotherapy: Technique and Treatment.*[50] In 1929 Budden moved to Portland, and his career as an educator began in earnest.

When Budden arrived in Portland in 1928, he purchased the Pacific Chiropractic College for cash; in 1933 the Pacific College was reincorporated and renamed the Western States College. Western States' core mission was "for the purpose of operating a college that would offer

DC and ND degrees together with training nurses and health technicians and maintain clinics and hospitals."[51]

When he arrived, Budden also networked with both Oregon's chiropractors and naturopaths. Chiropractic had been licensed first in Oregon in 1915; licensure for naturopathy was more recently established, in 1927.[52] He spoke at the Oregon Chiropractic Association's 22nd Annual Meeting in July of 1929, and then in July of 1930, he spoke at the annual meetings of both the Oregon Chiropractic Association and the Oregon Naturopathic Association. These speaking appearances became a tradition carried out many times with each group over the years until his death in 1954.[53]

Oregon adopted a Basic Science Law in 1933.[54] Dr. Budden's initial view was that the Basic Science Law was the medical profession's creation intended specifically to blunt the rise of any competition to MDs, specifically that of DOs, DCs, and NDs.

But Budden's first effort was to try to craft a political response to a political problem. As Budden later related the history of this effort, "October, 1933, saw the formulation of a joint legislative committee to manage the drafting of and the campaign for an amendment to the constitution of Oregon regulating the practice of the healing arts." The Joint Legislative Committee (JLC) was the joint committee of the Oregon Association of Chiropractic Physicians and the Oregon Naturopathic Association, and as Dr. Budden described, it was "composed of an equal number of chiropractors and naturopaths."[55]

The first action of the JLC was to work with legal counsel to draft what became known as the "Healing Arts Amendment," a proposed amendment to the Oregon Constitution by citizen's initiative.[56] As the news report in *The Oregonian,* Portland's and Oregon's largest newspaper, reported, "petitions for this measure contained approximately 47,000 signatures against the 26,667 required by law. The completed petitions were brought to Salem [Oregon's capital] by a caravan of 14 automobiles."[57]

On Election Day, after an exhaustive 6-month effort, the ballot measure went down by a 3-to-1 margin. This attempt to curtail medical dominance in Oregon was, on the surface, not successful. Nonetheless, Dr. Budden, over time, took heart from what he considered to be the "lessons learned" from the campaign.[58] Moreover, he gained some considerable respect for his willingness to engage in politics and the tenacity with which he could wage a political campaign even with limited resources, and this would be to his advantage over the years.[59]

These were lessons that he seemed to take to heart and that animated him for the next 20 years of his career as an educator and a consummate professional. From these "lessons learned," Dr. Budden committed himself to several things. He accepted the basic sciences as a necessary part of a "nonmedical" physician's education, although he continued to argue that professional examinations were best given to candidates by each profession's licensing board. He actually, in time, came to view the Oregon examinations as quite fairly conducted, and his students gained a high passing rate as the curriculum focused on these subjects as part of the core education in both chiropractic and naturopathy.[60]

He continued an extensive public-speaking schedule, regularly appearing through the 1930s, the war years, and in the postwar era before lay audiences like the HEL and the Biochemistry League as well as holding speaking events at Western States and giving weekly radio talks.

He continued at all times to commit his WSC programs to provide a sound and thorough education to his students in both the School of Chiropractic and the School of Naturopathy. He worked tirelessly to improve the standards for all similar colleges and took the lead at every turn in increasing the coursework and prerequisites required.[61]

These alliances and friendships were important to the WSC and to professional development in the Pacific NW. Dr. Budden, and his DC, ND allies, built stability into the education and organization of chiropractic and naturopathy, especially in the western United States and the Pacific NW, but much of their work is forgotten today.

One of these alliances will be discussed here as part of Dr. Budden's efforts to secure strength and stability for both chiropractic and naturopathy in the Pacific NW and at WSC: that with Robert Carroll, DO, ND, of Seattle.

Robert V. Carroll, ND—Leader of NDs in Washington

One of the strongest leaders and professional organizers in his own right was Robert V. Carroll Sr., DO, ND. Dr. Carroll had built the naturopathic profession in Washington. Licensing in Washington was granted under the Drugless Healing Act of 1919. Licenses were actually issued for the practice of sanipractic, a drugless school unique to Washington.[62] But Carroll, although his license said "Sanipractic," was determined to build a distinct identity professionally and allied early with Benedict Lust's ANA.[63]

Robert V. Carroll (Sr.) was also educated in Chicago after WW I, graduating from the American College of Osteopathy and the Lindlahr College of Natural Therapeutics (both Lindlahr schools) in 1923. Carroll finished his studies with Lindlahr and his school faculties just a year before Lindlahr's sudden death from an infection in late March of 1924. Lindlahr's signature is on Carroll's Doctor of Natural Therapeutics diploma,[64] and Carroll spoke often in later years of having been a student of Lindlahr himself.

Carroll moved west to Washington right after graduation, stopping for a year to practice with his brother, O.G., in Spokane before moving on to Seattle.[65] By 1930 he had begun the process of professional organization in Washington, founding the Washington Association of Drugless Physicians and serving as its president for 8 years, with the organization's name changing to the Washington State Naturopathic Association in 1934.[66]

The Beginning of the Budden–Carroll Alliance

The complete origin of Carroll's association with Dr. Budden and his support for Western States is unclear. Both Drs. Carroll and Budden studied in Chicago at about the same time. Dr. Budden made an alliance with the DCs and NDs in Oregon in the early 1930s and as a leader in the drugless professions in Washington. Dr. Carroll had his own connections with the Oregon NDs. Yet still, any connection that they had before the 1934 Ballot Campaign is not yet documented.

But in the immediate aftermath of the campaign, they joined forces, as reported by Benedict Lust. In February 1935, the same month that the *Chiropractic Journal* published Dr. Budden's "Medical Propaganda" article detailing B.J. Palmer's efforts to defeat the Oregon Ballot Campaign, Lust used his "Dr. Lust Speaking" platform in the *Naturopath and Herald of Health*[67] to similarly interfere in professional efforts in the Pacific Northwest (subtitled "Schisms"):

> *Word has come to us of a meeting that was called for Portland, Ore., in December last for the purpose of the "unification and coordination of Naturopathy and Chiropractic." This went out on the letterhead of the Washington Naturopathic Association with headquarters in Seattle and was signed by the president, Dr. Robert V. Carroll.*

Another letter from the Western States College of Portland signed by Dr. A. Budden, calls for a meeting to be held in Seattle on January 12th to put the "finishing touches" on an organization to be known as the International non-Medical Alliance.

Let us say right here and now that we are against any alliance between Naturopaths and Chiropractors. (Naturopath and Herald of Health, February 1935, p. 34)

Lust went on to say that alliances with the chiropractors in California and elsewhere had helped chiropractors and hurt naturopaths and that furthermore, there should only be the ANA to speak for naturopaths and no other associations or groups that purport to represent naturopaths.

"We have no fault to find with Dr. Carroll or Dr. Budden. We are however utterly opposed to the formation of other organizations that would usurp the prerogatives and program of the A.N.A. This organization has stood the test of time."

NATURAL HEALING AT ITS PEAK

In March 1952 Henry J. Schlichting Jr., ND, appeared before the 42nd annual convention of the Oregon Association of Naturopathic Physicians in Portland, Oregon. At the time, Schlichting was the president of the American Naturopathic Physicians and Surgeons Association (ANPSA).[68] Schlichting was quoted as saying that two major national issues facing naturopaths were that alternative schools got no tax support and that naturopaths could not be admitted to tax-supported hospitals. This created "a heavy demand on our profession and the lay public to meet rising … costs."

Schlichting was reported to have told the convention, "Despite these problems the profession 'is making definite progress on a national scale as evidenced by licensing in over 20 states,' [and] insurance companies are recognizing naturopaths 'because they are getting satisfactory results.'"[69]

Although the "licensing in over 20 states" was a generous count, there was no question that at the time Schlichting was speaking, the natural healing alternative was at its peak. Schlichting was from Midlands, Texas, a West Texas city where all major oil companies had a presence in a state where there were almost 500 licensed naturopaths.[70] Specific licensing of naturopathy was in place in 8 states (out of 48); 2 states had naturopaths practicing under drugless licensing, and about a dozen other states had broad, "mixer" licensing of chiropractors. In other states, naturopaths were fairly openly practicing without licensing but consistently pursuing legislation. Natural healers were practicing in about 40 of the 48 states.[71]

What Is the Vital Force?

What bound this natural healing profession together was a belief in the vital force and a resistance to "suppressive drugs," those pharmaceuticals that relieved symptoms without treating the underlying disease state. Between the mid-1930s and the early 1950s—separate from Benedict Lust and his publications—this doctrine of the vital force became central to natural healing in a manner most consistent with Walter Cannon's concept of *homeostasis:*

Yet, we must ever keep in mind that there is no disease to be cured; there are only sick people to be healed…

The physician must support the inherent nature of the patient by whatever means…By supporting the inherent power—the vital force—we re-establish a harmonious functioning of the disordered parts or functions.

It is not the physician that cures, but the indwelling vital force that heals.

Since it is the vital force that heals, we must seek those methods and do for the patient those things which will best support the natural healing powers of the particular person; we must be careful to do nothing that would interfere with that healing force.

If we are not to interfere with the workings of the vital force in its attempt to heal, then we must carry on our practice in conformity with … the laws of nature.

The mere use of a naturopathic method or modality does not mean you are practicing Naturopathy in conformity with its principles and philosophy. If such methods are used as a suppressive treatment, the physician is practicing Allopathic and not Naturopathic medicine.

As naturopathic physicians we must work … in accordance with natural law.

("Editorial" by A.R. Hedges, DC, ND,[72] Journal of the ANA, May 1950)

Credit to Budden and Carroll

The leadership of W. A. Budden and Robert V. Carroll was critical to the professional growth of natural healing from the mid-1930s to the early 1950s. Their alliance had begun formally in late 1934.[73] From 1935 forward, Budden was *the* trailblazer in natural healing education. Robert Carroll became a trailblazer in the professional organization of natural healers, and through a network of common associates, they each supported the work of the other.

Budden accepted the basic sciences as a necessary part of a "nonmedical" physician's education, although he continued to argue that professional examinations were best given to candidates by each profession's licensing board. He actually, in time, came to view the Oregon examinations as quite fairly conducted, and his students gained a high passing rate as the curriculum focused on these subjects as part of the core education in both chiropractic and naturopathy.[74]

Education

He continued at all times to commit his WSC programs to provide a sound and thorough education to his students in both the School of Chiropractic and the School of Naturopathy. He worked tirelessly to improve the standards for all similar colleges and took the lead at every turn in increasing the coursework and prerequisites required.[75]

But it must be understood that Dr. Budden considered chiropractic and naturopathy as complementary, as part of a complete package, and his friends and allies were like-minded; they were "DC, NDs." Emblematic of this view are two events that took place in the mid-1930s: WSC joined in the school alliance known as the "Affiliated Universities of Natural Healing," and Dr. Budden recommitted Western States to a broad natural healing, drugless, progressive curriculum.

The first of these, the affiliation, was the brainchild of Homer G. Beatty, DC, ND, the president of the University of the Natural Healing Arts (UNHA) in Denver, Colorado. The four schools that were advertised in 1935 as being "affiliated" were Western States and the UNHA, joined by the Metropolitan College of Chiropractic and Physiotherapy of Cleveland, Ohio, and the University of the Healing Arts of Hartford, Connecticut. These schools were affiliated in recognizing that the goal of "a regular standard, four years of nine months each, course in Chiropractic and allied subjects is warranted by our profession and offered by the … school members of this affiliation."[76]

The commitment to curriculum was significant, and WSC was a leader in this area, *especially* in naturopathy. Western States was, as of 1933, located at 538 S.E. Alder Street, Portland, and remained at this location until late 1939. The WSC Schedule of Classes and Hours, first printed in May 1933 and in use throughout the college's stay at the S.E. Alder location, set out a curriculum for both the chiropractic and naturopathy programs of 4000 hours of total study over 4 school years, each consisting of 8 months of residential attendance. The school year was September through July of the following year.[77]

The programs had 2750 hours of common study, starting with the basic sciences, and then "upper-class" requirements of 1250 hours specific to each program. Both courses of study had coursework in physiotherapy, electrotherapy, and hydrotherapy, with the major differences between the programs being the chiropractic coursework in clinical neurology versus the naturopathy coursework in herbology and biochemistry.

In actual practice, students enrolled in the chiropractic program and then added the naturopathy program as provided for in the schedule: "After receiving either the D.C. degree or the N.D. degree, the other degree may be secured by an additional 4 months' work; both degrees cannot be awarded within the regular course." The graduating class of July 1937 was typical, with seven DC graduates, four of whom also received the ND degree.[78]

And Dr. Budden was firm in his commitment to a broad natural healing education and a corresponding view of the DC and ND professions. In 1935 he wrote to the *Chiropractic Journal* to object to the idea that "coagulation of tonsils and dehydration of hemorrhoids" were construed as surgery and therefore not defensible as part of chiropractic. He said, "Western States College stands foursquare behind the members of the profession who are engaged in the practice of electrotherapy as a part of chiropractic."[79] As the Schedule of Classes and Hours noted, under Oregon law, chiropractic was "that system of adjusting with the hand or hands the articulation of the bony framework of the human body, and the employment and practice of physiotherapy, electrotherapy and hydrotherapy." As Dr. Budden's letter went on to say: "There is no reason to back down or retreat from the position we have already established." And he did not, either in the classroom, in clinical practice, or in any public forum.

And finally, he made friendships and alliances deeply within both the chiropractic and naturopathic professions of his day. His chiropractic contributions and their effects on the DC profession have been written about elsewhere, but his naturopathic contributions and their effects have not been written about, and so some attention to his efforts in naturopathic education and professionalism will be paid here. He is known as a great chiropractic educator, one of the classic "schoolmen," but he is also remembered "as a great naturopath."[80]

A Profession

When Benedict Lust criticized the alliance formed by Budden and Carroll in late 1934, he was well aware of the Oregon Ballot Campaign and how hard the DC, ND alliance had fought in that 1934 effort. To emphasize the "push" that was necessary in that fight, Budden had addressed the 1934 Oregon Naturopathic Association annual meeting in June on the fight ahead. And through A.R. Hedges, DC, ND, and others in the ND community (which may have included Washington's Carroll) and to boost interest, the ONA had Lust come out from New York for the meeting.[81]

Carroll, by all accounts of the events of the next 15 years of activities within the naturopathic profession, was frustrated by Lust's interference in the political situation in the Pacific NW. What Lust had said struck at the very philosophy of the WSC with its School of Chiropractic and School of Naturopathy. Over the next 15 years, Carroll did three things: he wrested control of the ANA out of the hands of Lust, the "president for life," he made it a much more professional organization, and he backed Dr. Budden and Western States at every turn in the process.[82]

At the 1935 ANA convention in San Diego, Carroll pushed through a new constitution and supporting bylaws modeled on those perfected by the AMA. The state associations would have House of Delegates members based on the membership size of each state. The Board of Directors and Officers would be elected annually, and the Board would conduct much of the business of the ANA, primarily through its Executive Committee. Lust was elected again as president, but the "president-for-life" status was effectively rescinded.[83]

From this point forward, there were more voices within the ANA.

Gradually, Robert Carroll took control of the reins of the naturopathic profession. The final split from the personal grip of Benedict Lust occurred in 1942. The annual convention of the ANA was scheduled for June 1942 in Chicago. The news of this location for the annual meeting had been released at the 1941 annual convention in St. Louis and continually publicized since November of that year.[84] By the spring of 1942, Lust came to realize that he was to be challenged for the presidency of the ANA by a group led by Carroll that was seeking a more committed professional development within naturopathy. This group was largely from states that had licensing laws of some kind in place for naturopaths.[85]

As these naturopaths met in Chicago and elected Frederick Dugdale of Portland, Maine, as their president, Lust and his close associates, Jesse Mercer Gehman of New Jersey and T.M. (Teresa) Schippell of Washington, D.C., hurriedly convened their own meeting in Atlantic City, New Jersey. This meeting of about 70 naturopaths from the eastern United States, almost entirely from unlicensed states, was declared the convention of "the real ANA."[86]

Even though Lust would contest the validity of what he called the "pseudogroup" of "pseudo Naturopaths," until he passed away in the late summer of 1945—and his eastern followers would continue this even longer—it is clear that Dr. Carroll and the Western group acted within the full authority of the constitution and bylaws of the association and were in the "right" in this dispute.

In any event, as Schippell wrote at the time, the western "insurgents" led by Robert Carroll had been working to "attract many outstanding naturopaths to their ranks, (and bring) in many state organizations to their membership" and had many "well-known practitioners."[87] Carroll assumed the presidency of the western ANA at the July 1946 convention and held the office for 3 years, until July 1949.

The Merging of Efforts

Carroll was a friend of Western States as president of the ANA and afterward as the group's past president. In many ways, Western States came to have a favored status among schools that were connected with the teaching of naturopathy where Dr. Carroll and the western ANA were concerned. As the western ANA grew in stature, it began to make three goals clear: to unify all naturopaths in one professional organization (which meant unity with the smaller eastern group left after the death of Benedict Lust in 1945), to advance the goal of a naturopathic profession based in licensed states, and to develop its own clear educational standards. Unity was supposed to take place at the strong and successful Salt Lake City convention in July 1948, during Carroll's presidency. It did not. But professionalism was much advanced by the creation of a strong committee and organizational structure that Carroll ushered in and by the enlistment of quality professionals like Alton C. Johnson, DC, ND, of California—the author of *Principles and Practice of Drugless Therapeutics*—into the western ANA membership.

And the ANA adopted Budden's model of a 4-year, 36-month residence course of study as its educational standard, passing a resolution at its July 1949 convention in Houston, Texas, against recognizing any school that (1) offered any of its instruction by correspondence; (2) offered diplomas rather than a course of instruction; (3) offered to grant multiple degrees for the same course of instruction; (4) granted any advanced standing or transfer credit that was based on study at schools not recognized by the ANA, the American Osteopathic Association, or the National Chiropractic Association.[88]

This was done as some of the last business conducted under Carroll's presidency. In December 1949, the *Journal of the American Naturopathic Association* first published its list of approved schools, listing three schools that would require basic science credits from an outside institution of higher education and Western States as the only school offering residency education in all 4 years of the required curriculum.

Moreover, Carroll strengthened the connections between the Oregon DC, ND community and Western States with the western ANA. Carroll personally quelled unrest among some of the ND community and Western States in the postwar years. He visited a regular meeting of the Oregon Naturopathic Association in December 1947 while ANA president, together with his successor as president of the Washington State Naturopathic Association (Dr. Helena Winters of Kelso, Washington). He then made another visit to the ONA monthly meeting a year later in December 1948. As reported in *Oregon Pioneer,* unrest began in the fall of 1948 within the ND community around Western States that the school was becoming known more as a chiropractic school, or a school of "chiropractic and drugless physicians," outside of the college. Carroll made the purpose of his 1948 visit as ANA president to express his support for Dr. Budden and Western States as Budden saw fit to operate the college.[89]

After leaving the presidency in July 1949, Carroll remained active—somewhat more behind the scenes—in matters of the ANA and the Pacific Northwest. The largest issue for the Western ANA for 1950 was the unfinished business of unification with the remaining naturopaths in the eastern group, and for the year between the annual conventions of 1949 and 1950, this was almost all-consuming. Additionally, legal issues arose in Washington State in 1950 regarding the 1919 Drugless Healing Act under which the naturopaths in that state were licensed. These legal issues threatened to do severe damage to the profession's legal status.[90]

Unification under the Western group's national structure was achieved in St. Louis in 1950, although the amalgamation remained messy until the very end. Then, Dr. Robert V. Carroll, a true giant within the naturopathic profession and a friend of Western States College until the end, passed away suddenly in April 1951.[91]

Firming Up the Curriculum—Chiropractic and Naturopathy

From the time that Dr. Budden opened the "new" or "converted" Western States College in 1934, the curricula in both the School of Chiropractic and the School of Naturopathy showed his imprint.[92] The primary philosophy-of-practice texts were Joy Loban's *Technic and Practice of Chiropractic,* a text authored in 1915 by a leading faculty member from the National College program, and in naturopathy, Otto Juettner's *A Treatise on Medical Practice (the Art and Science of Non-Medical Therapeutic Methods),* a text by a leading Eclectic and physio-medical practitioner. Juettner's work was first published in 1916 and republished by Benedict Lust's New York publishing house.[93]

The other practice texts in use for the 1930s were Goldthwaite's *Body Mechanics and* Marlin's *Manipulative Treatment* for nonspinal adjustive technique, Grieve's *Modern Herbal* for knowledge of herbal remedies, Luke's *Manual of Natural Therapy* for hydrotherapy, Kovac's *Electrotherapy and Light Therapy* for electrotherapy, Sherman's *Chemistry of Food and Nutrition* for dietetics, and Boyd's *Preventive Medicine* for hygiene and public health. The eclectic nature of these texts shows Budden's wide knowledge of the subject areas included in the Western States curricula, but the use of Loban and Juettner's works also reflects the fact that although the professions had grown significantly since WWI, the available scholarship had not.

This began to change at the end of the 1930s with the publication in 1939 of Homer G. Beatty's (of the University of the Natural Healing Arts in Denver) *Anatomical Adjustive Technique* and Alton Johnson's first edition of *The Principles and Practice of Drugless Therapeutics.* Also published in 1939 by the National College of Chiropractic was *Chiropractic Principles and Technic* by Biron, Wells, and Houser of the NCC faculty; this was the first real advancement of the work begun at NCC by Joy Loban in the much earlier days of the profession. And in the late 1930s, John Robinson Verner's *The Logic and Science of Chiropractic* first appeared.

However, the onset of WWII not only slowed the progress of the colleges, but also the rationing of all materials, including paper, made the widespread use of these new works of scholarship problematic. For 1940 to 1941, the 1938 to 1939 WSC catalog simply had the additional date "1940 & 1941" stamped on the cover; no new catalog appears to have been printed until 1944, and no changes were made to the curricula for the duration of wartime.[94]

The 1944 catalog, which was used through 1947, included as new texts added to the curricula those by Beatty (added in anatomical adjustment); Biron, Wells, and Houser (added in palpation); and Johnson (1st edition; added in electrotherapy).[95] Also, *Rational Bacteriology* by chiropractic scholars Verner and Weiant was added to the more standard text by Zimmer in bacteriology.

New Developments in Postwar Scholarship

It was not until the fall term of 1947 that new scholarship began to appear in use at an accelerated pace at Western States. *The Logic and Science of Chiropractic* by Verner (3rd edition, 1946) was added to the curriculum in chiropractic; in naturopathy, Thomas Lake, DC, ND's *Treatment by Neuropathy and the Encyclopedia of Physical and Manual Therapeutics* was added. This latter work was a lengthy treatise published in 1946 on what was more generally known as mechanotherapy by a chiropractor-naturopath of some substantial reputation based in southeastern Washington State.[96]

Dr. Budden on Chiropractic and Naturopathy

The first postwar catalog published was entitled "Bulletin of the Western States College, Announcement of the School of Chiropractic and School of Naturopathy." The college symbol was now a hand holding a torch with the peroration *fiat lux,* or "let there be light."

For this first postwar catalog, Dr. Budden penned his own descriptions of chiropractic and naturopathy, both as to Pacific NW history and as to philosophy. This material became a constant in WSC's postwar catalogs into the mid-1950s.[97]

Prospective students and interested parties were given this introduction to the WSC School of Chiropractic:

> *School of Chiropractic, Founded 1908.*
>
> *The history of Chiropractic is largely the history of its schools. This is particularly true in the Northwest, where the energy and vision of the founder brought forth the D.D. Palmer School of Chiropractic in Portland, Oregon.*

As early as 1908 Dr. Palmer, together with Dr. LaValley, opened the doors of this pioneer institution.

Since that day Portland has been the seat of Chiropractic learning in the Northwest. Always an institute devoted to this purpose has stood in the Rose City. The Western States College is therefore the lineal descendant and beneficiary of all that has gone before. It is carrying on the work of the founder as he would have desired it, in this modern manner.

Chiropractic literature also found its birthplace in Oregon. The original text, "The Chiropractic Adjuster," by D.D. Palmer, was published in Portland."

This was the introduction to the School of Naturopathy:

School of Naturopathy, Founded 1930

The Latins spoke of it as the Vis Medicatrix Naturae—a remedial force or impulse. The Germans called it Natur Heiling, the remedial impulse of Nature, the self-recuperative power of the bodily system, independent of medicine.

It has been described, also, as the capability of living tissue, animal or vegetable, to remedy and remove disease, or to repair the healing power of nature.

United in man with the dynamics of the mind, this matchless force constitutes the basis of naturopathic therapy.

To intelligently enlist it in the fight against disease is the whole art of non-medical healing.

These two short pieces, authored by Dr. Budden, contain his synopses of chiropractic and naturopathy and present the central core of his nonmedical philosophy.

More Curriculum and Postwar Scholarship

By the fall term of 1949, as the Western States Class of 1953 was entering school, the full flowering of postwar scholarship in both chiropractic and naturopathy was available, and Dr. Budden took advantage of the newest works in crafting his curriculum for each program. Through the course of the college terms from fall 1949 to spring 1953 when the class of 1953 was in attendance at WSC, the chiropractic and naturopathy students were educated in two additional new works of nonmedical scholarship: Janse et al., *Chiropractic Principles and Technic,* 2nd edition, and H. Riley Spitler's newly published *Basic Naturopathy*. This latter text was commissioned and published by Carroll's western ANA with the intention of providing a definitive text in naturopathy. The scholarship is thorough and sound, and it holds up well today as "cutting-edge" work in its time.[98]

Budden paired Spitler's text with a classic from the Eclectic–physio-medical school of medical philosophy, Clymer's *Nature's Healing Agents: The Medicines of Nature* (2nd edition, 1926) based on an adaptation of the Thomsonian System. This combination of Verner, Janse, Spitler, and Clymer plus the coursework in dietetics, physical fitness, body mechanics, electrotherapy, physiotherapy, and hydrotherapy demonstrated the clear imprint of Schulze and Lindlahr on Budden's conception of the nonmedical physician.[99]

It cannot be overstated that Budden's students were the broad-scope chiropractors and naturopaths of the postwar era. The WSC students Budden produced kept these professions alive, especially in the Northwest, for the next 30 years, into the mid-1970s.

This postwar era was the zenith of the period when WSC was *the* pacesetting educational and scholarship beacon in chiropractic and naturopathy. This postwar period was the WSC era when WSC was the intellectual environment that would be rivaled in the middle age of the professions perhaps only at National College.[100]

A.R. Hedges, DC, ND, and W. Martin Bleything, DC, ND—First Connections

Another of the friends and allies Dr. Budden first grew close to professionally during the 1930s was A.R. Hedges, DC, ND, of Medford, Oregon. Medford is a smaller city about 275 miles due south of Portland, located just north of the Oregon–California state line. In 1930 when Portland's population was just over 30,000, Medford's population was just over 11,000, and the "greater Medford" population (within a 5-mile radius of the city center) was just under 17,000.[101]

A.R. Hedges had been practicing as a drugless physician in Medford since 1911. His advertisements for his practice with his wife Louisa for their "chiropractic-naturopathic" offices had appeared in the *Medford Mail-Tribune* as early as 1913.[102] Both A.R. and Louisa appeared in Benedict Lust's *Universal Encyclopedia Directory and Buyer's Guide—Year Book of Drugless Therapy for 1918–1919* as active drugless healers in Oregon.

Whether by coincidence or not, Dr. Hedges did not appear on the statewide Oregon scene as a leader in either chiropractic or naturopathy until 1929, just as Dr. Budden was arriving on the scene as well. From here on, the professional arc of these two DC, NDs intersected continually.

At the June 1929 annual meeting of the Oregon Chiropractic Association (OCA), the forerunner of the OACP, Hedges was named by the OCA president to the convention's resolutions committee. This is the first time he appears in any news coverage of OCA affairs. It was at this conference that Dr. Budden gave his first of many addresses to the Oregon profession. Although it is not clear that the two first met each other at this meeting, Dr. Budden drove down to Medford in March 1930 for a Saturday evening meeting of the Southern Oregon Branch of the OCA held at Dr. Hedges's home in Medford. The Southern Oregon Branch was the professional business section for the southwestern region of the state between annual meetings of the OCA.[103]

Budden was in the company of the OCA's president and the secretary of the state Board of Examiners, both doctors from Portland. Plans were being made for the next annual meeting, which was to be held in Medford for the first time. The upcoming legislative session and legislative planning were also discussed.[104] Dr. Budden would attend meetings of the Southern Oregon Branch many more times over the years.

By the next summer, Hedges was named to his first 3-year term on the Oregon Board of Naturopathic Examiners, serving from 1930 to 1933. Over the course of the 1930s, Dr. Budden and Dr. Hedges crossed paths many times during the professional activities of both the OCA/OACP (the progressive "mixer" group of the state) and the naturopaths of Oregon. This was particularly true during the 1934 Ballot Campaign, in which Dr. Hedges actively participated.[105]

It would be during the war and postwar years that the association of Drs. Budden, Carroll, and Hedges would have its greatest import for Western States College. But before moving the story forward into the war years, it is necessary to introduce W. Martin Bleything.

Dr. Wallace Martin Bleything

Dr. Wallace Martin Bleything first appeared on the Oregon scene in 1937 when he was on the speaker's roster for the 1937 annual meeting of the Oregon Association of Chiropractic Physicians, the successor to the Oregon Chiropractic Association. This was a meeting held at WSC that also featured Dr. Carroll as a speaker, and the 1937 WSC commencement was held in conjunction with this event.

The subject of Bleything's speech on this occasion is not known from the news clip available, but at the time, Bleything was working for a research laboratory in Los Angeles. In 1941, just before the United States entered WWII, Bleything appeared as a speaker before an osteopathic postgraduate meeting in Amarillo, Texas, giving a series of talks on endocrinology, a subject for which he was listed as a "nationally-known expert."[106] Just after war broke out, he was awarded his Master of Chiropractic degree from the California Chiropractic College of Oakland, California.[107]

Hedges and Bleything—the War and After

As America went to war, Hedges's professional profile continued to rise as a physician who had been in practice for 30 years. In July 1942 he was elected vice president of the Oregon Association of Chiropractic Physicians, and in December of that year he was named once again to the Oregon Board of Naturopathic Examiners to finish a term (through July 1, 1943) for a member of the Board who had passed away.[108]

In July 1944 he was elected the OACP president at the annual meeting, and he served as president until July 1946. The vice president elected with him in 1944 was another DC, ND, J. W. Sargent, who had worked with Hedges and Budden going back to the 1934 Ballot Campaign if not longer.[109] In fact, there was clearly considerable overlap in the 1930s and 1940s between the OACP and the Oregon Naturopathic Association. In 1946 as his successor as OACP president was being elected, Hedges was reappointed to a full 3-year term on the Oregon Board of Naturopathic Examiners.[110]

In 1949 at the July convention of the ANA in Houston, Hedges was elected second vice president (VP), taking office as Carroll stepped down as president. By November 1949, his hometown Medford newspaper was reporting on his travels across the country in his national position.[111] Hedges was now positioned to protect the interests of WSC with the national ANA as well as Carroll, and he continued to do so.

Hedges served as second VP of the western ANA for 1 year until July 1950; then, as part of the newly unified ANA, he was elected first VP and twice reelected, serving as first VP from 1950 to 1953. At the 1951 annual meeting, the association had gone through a name change to the American Naturopathic Physicians and Surgeons Association. Hedges wrote the editorial in what was now the *Journal of the ANPSA* explaining the long story behind the earlier schism, unification, and the reason for the name change.[112]

He also wrote a series of editorials in the association journal eloquently explaining the difference in core philosophy between the allopaths on one hand and naturopaths and chiropractors on the other; the difference between viewing the physical organism as operating in "conformity with the laws of chemistry" versus the view that the body "is in a vital realm, presided over by a vital force" that maintains life; and the difference between treating symptoms with suppressive means versus "supporting the vital force" to "regain harmonious function" and "to do nothing that would interfere with that healing force."[113]

In July 1953 he was elected president, and he was reelected July 1954, serving until mid-1955. This was all capped off for Dr. Hedges when he appeared before the Oregon Naturopathic Association annual meeting in March 1954 as national president.[114] Throughout these years, Hedges succeeded Carroll in guarding the interests of the Western States program at both the state and national levels. In 1947 the Los Angeles College of Chiropractic dropped its ND degree program. In 1949 the Metropolitan College of Chiropractic closed. Then in 1950, Homer Beatty of Denver's University of the Natural Healing Arts suddenly passed away, and the National College of Chiropractic dropped its ND degree program. Through these events, the other legitimate, 4-year residency programs were lost. As the largest and strongest organization of naturopaths, the ANPSA had a vested interest in the existence and success of WSC.

That brings matters back to Dr. Budden and WSC as the war ended in 1945. Dr. Wallace Martin Bleything, known most often as W. Martin Bleything or Martin Bleything, appears to have been linked primarily to Western States in the postwar era. As the war came to a close, Western States was hanging together but uneasily, as already described. With peace came the wave of returning veterans and a postwar boom of interest fueled by the Servicemen's Readjustment Act of 1944, or the "G.I. Bill." About 2.2 million returning veterans used their G.I. Bill benefits to attend colleges or universities, the classification attained by Western States through the Veteran's Administration, which certified institutions of higher education.[115]

As Lester Lamm described the circumstances of Western States in *Oregon Pioneer:*

> *The shortage of students produced by the Great Depression and made worse by World War II disappeared almost overnight, leaving the college with a completely new challenge: what to do with more applicants than the institution could manage.*
>
> *The G.I. Bill filled college and university classrooms across the nation, and the Western States College was the fortunate beneficiary of escalating applications and enrollment numbers. The explosion of growth was unanticipated and the college was not prepared for the magnitude of the student influx it experienced.*
>
> *The makeup of the student population was also challenging. Students demanded the administration provide them with a higher quality education, in a more appropriate facility.*[116]

The school resolved the facilities space problem in late 1946 by purchasing a building on S. E. Alder in Portland, a former lodge building. As A.E. Homewood described it, "this was far from ideal, or a place of beauty, but did offer the necessary space for expansion."[117] Qualified faculty was another matter. The size of the new student population surpassed the method of Dr. Budden doing a lot of instruction supplemented by local practitioners. Enter, among others, Dr. Bleything.

Bleything had a varied and colorful background, but most relevant to Western States, he had grown up in Portland, then moved to Seattle shortly before World War I. Interrupted by service during the first war, he had studied chemistry and then worked and studied at Grace University Hospital, a homeopathic and drugless physician training program combined with a sanitarium maternity ward run largely by a homeopathic, fully licensed MD. John Bastyr, DC, ND, after whom Bastyr University is named, had interned there, and Dr. Robert Carroll had been on the sanitarium staff, both during the 1930s. Between 1932 and 1942, Bleything had worked at a research laboratory in Los Angeles as a colloidal chemist, as well as graduating from chiropractic college.[118]

Bleything arrived at WSC in 1947 and joined the faculty in first- and second-year basic sciences and in third- and fourth-year practice courses in chiropractic. He got licensed in Oregon as a DC and became a member of the OACP. Within another year, he got licensed as an ND and joined the ONA. By 1951 he had been recruited by A.R. Hedges to take over as editor of the *Journal of the American Naturopathic Association* and had become the lead faculty member in instruction in the naturopathy program at Western States (while still continuing with the basic sciences). Again, Western States had connections deep into the national affairs of naturopathy and was the example naturopaths always turned to when the education of NDs was challenged.[119]

The Western State College Class of 1953

By 1946 the way was now clear for the Western States programs and the chiropractic and naturopathic professions to establish themselves in peacetime. In the fall quarter of 1949, the Western States class of 1953 entered the college. By the time the class of 1953 graduated, the majority had finished with both DC and ND degrees, and the graduating class of the School of Naturopathy was the largest class of ND degree holders ever at WSC. It was also the largest such class anywhere for another 30 years—until the John Bastyr College of Naturopathic Medicine in Seattle graduated its first full class in 1982. The class of 1953 would make its mark in keeping alive both broad-scope chiropractic in Oregon and elsewhere and naturopathy in Oregon, Washington, and the Canadian province of British Columbia for that same 30-year period.

In the immediate postwar period, 1946 to 1952, the AMA—or organized medicine—was consolidating its power within the US healthcare system. Medical dominance was present, but as a threat to alternative practitioners, it was not yet at full throttle. This was, looking back historically, because of the AMA's obsession with the threat that organized medicine called "socialized medicine"—a healthcare system controlled by the federal government.[120]

The AMA and President Truman

Universal health care—a totally government-funded healthcare system—was a pronounced political goal of President Harry Truman. The political and public relations machinery of the AMA was almost entirely directed at this "threat" to the "American Way" for all of President Truman's postwar term in office. While organized medicine was politically preoccupied, chiropractic and naturopathy were able to advance. President Truman left office in January 1953, and by the summer of 1953, the AMA was starting a national campaign to eliminate chiropractors and naturopaths as competitors, but until then, battles were fought on a state-by-state basis.[121]

As previously discussed, the National Chiropractic Association (NCA)—the chiropractic "mixer" group—was directing its accredited colleges to shut down any of their nonchiropractic degree programs, specifically any ND degree programs. After National Chiropractic College complied in 1950, Dr. Budden was the lone holdout in maintaining a naturopathy program. The push in this direction was led by John Nugent, the "Flexner of Chiropractic." In meetings of the education council of the NCA, Dr. Budden was merely resistant; behind closed doors, Dr. Budden and Dr. Nugent had loud, if personally respectful, disagreements about this subject. Dr. Budden was unyielding.[122]

And so the postwar period of 1946 to 1952 was a period of professional development in natural healing and of advances in clinical science and in serious scholarship. But in DC, ND education, Western States was alone after 1950. This was, at the same time, WSC's most fruitful period under Dr. Budden fueled by the G.I. Bill—the only public funding program for DC and ND education until the rise in the 1980s of student loan and Pell Grant funding.

Enter the Class of 1953

By the fall quarter of 1949, the college had settled into a former lodge building at 4535 S. E. 63rd Street. The curriculum was set as well, and the students were expected to attend straight through for three quarters plus summer term in each of the first 3 years of attendance, and two quarters in the fourth year. The schedule started the first week of October and went through the end of July of the following year; the fall, winter, and spring quarters were each 3 months long, and summer term was the month of July. Each regular term was 300 classroom hours of instruction, and summer term was 100 hours, for a total of 1000 hours the first year. This increased to 1160 for the second year, 1260 for the third year, followed by a fall and winter term fourth year of 940 hours. Degree completion for either the chiropractic or naturopathic degree came at the end of the spring quarter the fourth year.[123]

The first 2 years were intense with the basic sciences curriculum (as such programs are today) together with either Introduction to Chiropractic or to Introduction to Naturopathy, followed by Principles of either discipline included in the first 2 years. The students largely lived and breathed this coursework for 4 years, with most of the social activities that the students had being activities like clubs and dances at the college. This class of 1953 was mostly veterans, a bit older, a bit more ready to get to work and on with life, and mostly married. And they were from throughout the country and from British Columbia, Canada. There were eight each from Oregon and Washington; three from California; two each from Missouri, North Dakota, Minnesota, and British Columbia; and one each from Nebraska, Illinois, Michigan, Colorado, Montana, and Ohio. There were five women in the class and two African Americans, one of whom, being from Miami, had come the farthest from home to study at Western States.

Emblematic of the initiative of this class of 1953, class members started a monthly news publication entitled *The Synergist: Western States College Voice of the Student Body,* "published in the interest of UNITY among all interested drugless healing arts."[124] This monthly publication is virtually a journal of this class of 1953, disappearing as a monthly when the class of 1953 graduated and surviving as a bimonthly only for another year or so. But while this class was enrolled at WSC, it was their voice.

Another aspect of the quality of WSC and its student body, and the class of 1953, particularly, was its racial integration. Two members of this class that entered in the fall of 1949 were male African American students who graduated with the class of 1953. One of these students came completely across the country, from Miami, Florida. Jackie Robinson "broke the color barrier" in baseball in 1947. President Truman desegregated the American Armed Forces by Executive Order in 1948. The Warren Court did not strike down the segregation concept in public education until 1954. The enrollment of these two students and their integration into the graduating class of 1953 speaks volumes about the progressiveness of Dr. Budden, of WSC, of the students of the class of 1953, and of the city of Portland in general.

The members of the class participated in two designated "fraternities," Sigma Phi Kappa, a chiropractic fraternity founded in 1912 and chartered at Western States in 1948, and Phi Nu Sigma, a naturopathic fraternity started at Western States modeled on Sigma Phi Kappa. Phi Nu Signa announced in *The Synergist* for February 1953 that it was starting the process of "expanding its sphere of influence by providing for and inviting practicing Naturopathic Doctors to join its ranks to help promote Naturopathy and naturopathic principle and practice." This last item seemed to be a parting gift from the leaders of the class of 1953 to the fraternity and also a way to stay involved themselves as new NDs.

As Reported in *The Synergist*

The initiative of the class of 1953 becomes clear in looking at its own documentation of itself and of the larger WSC student body in *The Synergist.* By the time of the class of 1953 commencement ceremonies in March and July of 1953, *The Synergist* was publishing regular news submitted for publication by both the OACP and the ONA. This provided the student body with a regular source of professional news, and *The Synergist* became a publication subscribed to by the professions as well.

In the postwar era, Western States became a fixture of natural healing under Dr. Budden. *The Synergist* captured this in documenting the professional activities and meetings that took place at the college and the participation of Dr. Budden, the faculty, and student body in these events. As an example, *The Synergist* for May 1952 recapped the annual OANP meeting that had been held at WSC in March 1952, at which the featured keynote speaker had been Henry J. Schlichting Jr., ND, national president of the ANPSA.[125] The same edition of *The Synergist* reported the complete program for the annual meeting of the Oregon Association of Chiropractic Physicians to be held at WSC the first week of June that year.

Dr. Schlichting, it was reported, had given an open speech to WSC students and staff, to physicians, and to the public, as well as a speech to the convention banquet. *The Synergist* reported in the column "Naturo-News" authored by Dr. R.A. Rombaugh of Independence, Oregon, that Dr. Schlichting "lauded the pioneers and early educators and complimented Dr. W.A. Budden, Western States College Director on the fine job in building the College to today's high level of standards." The schools Dr. Schlichting said, were "the life blood of any profession."

Another initiative of the class of 1953 was an annual WSC picnic. The first reported "WSC Annual Picnic" was to be held Sunday, June 15, 1952, but was postponed a week due to inclement weather. But when it was held on June 22, 1952, as reported in *The Synergist* for July 1952, it left all attendees and participants "looking forward to the picnic next year." More impressively, the picnic was attended by both members of the Oregon Association of Naturopathic Physicians and the Washington Association of Naturopathic Physicians, as reported in the *Journal of the American Naturopathic Physicians and Surgeons Association* (vol. 5, no. 2, June 1952).

More Professional Matters for Dr. Budden

Three other events of interest occurred during 1953 that affected the class and were noted in *The Synergist.* First, the Oregon chiropractic scope of practice came under assault again, from the medical profession on one side and the "straight" chiropractic group on the other. A breakfast meeting of the Oregon Joint Legislative Council held Saturday, March 7, 1953, was broadcast on radio and moderated by radio commentator (and future Oregon governor) Tom McCall. The specific subject was pending Senate Bill 134, yet another bill to strip obstetrics and minor surgery from the Oregon chiropractic scope of practice.[126]

Dr. Budden appeared with another physician from the OACP representing the Joint Legislative Committee of chiropractors and naturopaths. The medical view was provided by representatives of the Multnomah County Medical Association, both of them clinical professors at the University of Oregon Medical School, one in OB/GYN and one in general surgery. When asked by McCall about the fact that Palmer College did not teach these subjects as "The Fountainhead" of chiropractic, Budden related some of the history of "straights" and "mixers" and told the audience that one major issue was that the Palmer school did not wish to go to the expense of teaching these subjects even though it had adopted a 4-year curriculum in 1953.

By the following Tuesday, the Oregon Chiropractic Research Association—the Oregon "straight" organization, a group in Oregon about one-fourth the size of the OACP—had issued a strongly worded communique to the radio station that broadcast the discussion and to *The Oregonian* newspaper.

The statement said that the OCRA had nothing to do with the pending legislation and no interest in it, but it took offense at Budden's characterization, noting that Palmer devoted 4485 class hours to "straight" adjustment technique and that Budden "attempted" to teach a laundry list: spinal adjustment, obstetrics, surgery, eye-ear-nose-throat practice, proctology, proctology, removal of tonsils (by electrotherapy), administering anesthetics, use of hypodermics, electrotherapy, hydrotherapy, physiotherapy, "and such" in 4240 class hours.[127]

In the long run, once again, no legislation was passed, altering the Oregon scope of practice.

Some Positive Developments

What did pass at the insistence of Dr. Budden and Western States College, and with the support of both professions, was House Bill 271 (NDs) and 272 (DCs) increasing the educational requirements to high school *plus* 2 years of college credit from an accredited college or university. This was noted in an approving editorial in *The Synergist* for February 1953, penned by Appa Anderson.

Finally, it was noted in *The Synergist* for March 1953 that as president, Dr. A.R. Hedges was bringing the American Naturopathic Physicians and Surgeons Association convention to Portland that summer, in July. The general chairman for the convention was WSC's Professor W. Martin Bleything.[128]

1953 for the Class of '53

The April 1953 issue of *The Synergist* contained a column by the editor of the *O.A.C.P. Journal;* this column had by now become a regular presence in *The Synergist.* The editor was A.C. Johnson, WSC class of 1951. He paid a special tribute to the class of 1953, saying "without reservation, I would like to praise a universally qualified and most ambitious group." He paid special tribute to those "from this group, (that) have become the working force that has published *The Synergist* during these past four years," and closed with: "To the class of '53, and with gratitude to you who have done so much to keep the college, the students, and the profession interested and united, we, the profession, wish you God speed in the gratifying endeavor that awaits you."

And then this remarkable class prepared to graduate and pass into the history of Western States. For some comparison, in June 1949, WSC graduated 36 DC degrees and 16 ND degrees, with 11 graduating with dual degrees. In March 1950, WSC graduated 29 DC degrees and 2 ND degrees. In March 1951, 21 DCs graduated and 4 ND degrees. In March 1952, 31 DCs and 1 ND graduated.

The class was scheduled to graduate in March 1953, and most were graduating as DCs. Because there was interest expressed among class members in receiving dual degrees, a special spring quarter schedule had been arranged, focused exclusively on ND therapeutics. *The Synergist* had reported this development from time to time over the 1952–1953 school year. It was noted in the March 1953 publication: "much of the class will be around after Graduation to take a post-graduate course in Naturopathy, so we really won't be saying our goodbyes for a while" This course for DCs required a full spring quarter of coursework in Cyriax's *Text-book of Orthopaedic Medicine, Volume II* on massage therapy, Mausert's *Herbs for Health,* and Spitler's *Basic Naturopathy* in a course designed by Drs. Budden and Bleything.

The class of 1953 had two commencement ceremonies, one in March and one in late June. In March, 33 DCs and 2 NDs graduated, with 7 DCs also receiving the BTS degree and 1 ND receiving the BTS degree. In July, at a special commencement at the end of the spring quarter, 33 NDs were graduated, and 1 received the BTS degree. Twenty-six of these degrees went to DC graduates from March 1953, three went to March 1952 DC graduates who returned for the spring quarter course, and six ND degrees were received by ND candidates who finished studies in June with the extra quarter's work.

The late-June ND degree ceremony was staged as an evening event on the second night of the ANPSA convention, as reported in the *Journal of the ANPSA* for September 1952 (vol. 6, no. 6). "The

commencement address was delivered by that outstanding authority on nutrition of the University of Missouri, William Albert Albrecht, Ph.D. Dr. Albrecht's address was indeed inspiring, not only to the graduates but to all in attendance." And, as the reporter noted: "It was indeed an inspiration to see this fine young group of naturopathic physicians entering the profession. The profession needs more young naturopathic physicians to assure its future."[129]

Some Stalwarts of 1953

Joseph Boucher, the ND degree graduate who had been student body president for 1952 to 1953, received the William J. Gallagher award as the outstanding graduate of the class of 1953, with Appa Anderson being noted by Dr. Budden in announcing the award as a close second. And then the class of 1953 left Western States to conquer the world. But this class was the fruition of all that Dr. Budden and the chiropractic and naturopathic professions had built at Western States in the face of challenges and opposition.

Dr. Budden died unexpectedly in August 1954, less than a week after returning from attending his last NCA meeting.[130] By the time the class of 1953 finished its first year at Western States, the ND program was the only remaining ND program in the United States.[131] Within 2 years of the death of Dr. Budden, the ND program at Western States was discontinued; courts had restricted the legal scope of practice in Washington and Arizona; and licensing of NDs was lost completely in Texas due to actions by the courts and in South Carolina, Utah, and Florida by legislative action. How this happened is another piece of history still to be told, but a great deal of it curbed broad-scope or "mixer" practices in those states, and a large factor was medical dominance, what the educators and physicians discussed here had battled for 25 years. Things did not improve until at least the 1980s, another part of the story yet to be told.

But that should in no way diminish what was done at Western States College and in *both* its School of Chiropractic and its School of Naturopathy. From the class of 1953, Joseph A. "Joe" Boucher, ND, BTS, became a giant of Canadian naturopathy in his own right,[132] Appa Anderson stayed at Western States for an impressive career of her own in chiropractic radiology,[133] and Professor W. Martin Bleything was one of the founders of today's National University of Natural Medicine, together with one of his fellow faculty members and a former Western States student from the class of 1952.[134] Ralph M. Failor, who—along with his wife Hazel—received a DC degree in March and an ND degree in July, would succeed Dr. Budden as president of WSC. He would in time become a big part of the history of WSC.[135]

What happened was remarkable and needs to be better known.

PART TWO: WHAT HAPPENED TO THEM?

Moving On

There may be no more exemplary story in the development of natural healing among chiropractor-naturopaths than the story of Henry J. Schlichting Jr., of Midland, Texas. Schlichting was trained as a chiropractor in Oklahoma and moved to Texas in 1941, setting himself up as a naturopath. At the time, neither chiropractors nor naturopaths were licensed in Texas. Schlichting became a leader within natural healing professionals, first within Texas and then nationally. He became a trusted ally of both Robert Carroll and of Dr. Budden at Western States College. He and his Texas naturopaths achieved licensed status in 1949. In the early 1950s, all looked bright, and then it all turned dark.

On the evening of July 17, 1953, the commencement for 37 recipients of the degree of doctor of naturopathy took place in the auditorium at Western States College in Portland, Oregon. This special commencement was scheduled as the Tuesday night program for the 1953 annual convention of the American Naturopathic Physicians and Surgeons Association, as the immediate past president of the ANPSA Henry J. Schlichting Jr. of Midland, Texas, was in attendance.[136]

As Schlichting had said a year earlier in a speech at WSC, the prospects for naturopaths seemed good as this WSC class of 1953 graduated, most of them as DC, NDs. But the forces of medical dominance were building, starting back home in Texas, even as Schlichting was attending the convention in Portland. Within 6 years, natural healing in the United States would be much diminished. No career demonstrates this as clearly as that of Schlichting, a remarkable man and physician who, by the end of the 1950s, had been barred by the State of Texas from practicing his chosen profession and who had lost almost everything.

When the class of 1953 graduated from Western States, the leadership of the naturopathic part of the natural healing professions was in Henry Schlichting's hands as the president of the ANA, with A.R. Hedges in line to become Schlichting's successor. There were headwinds, though, just beginning to be felt.

HEADWINDS

Some of these headwinds had been building within the naturopathic movement itself since the 1930s. Benedict Lust criticized Dr. Budden and Dr. Carroll in early 1935 for proposing a continuing alliance based in the Pacific NW between broad-scope chiropractors and naturopaths. The 1935 annual ANA convention a few months later in San Diego was a crossroads event for ND as a profession. Lust opened the convention with a presidential address that seemed to mark a "scofflaw" phase in Lust's career as the head of the naturopathic movement. He told the convention that he had been prosecuted—and persecuted—for issuing diplomas to "doctors" from the American School of Naturopathy without a New York State charter to do so. The State of New York, he charged, was operating as an arm of the AMA's "Medical Trust." Only naturopaths, he told the convention, could decide who deserved to be called naturopaths, not the state or the Medical Trust. Naturopathy needed to be accepted by the public to be legitimate, not by the state.

But for the first time, Robert Carroll brought a countervailing view to an ANA convention. These countervailing visions of the future of naturopathy were the visions that played themselves out over the next 10 years within the ANA. The ANA could not be a movement run by a permanent leadership but needed to truly be a professional organization seeking to advance a natural healing profession. In adopting a new constitution and bylaws proposed by Carroll, the ANA accepted Carroll's vision of the future over Lust's vision from the past.

By 1937 Carroll was comfortable that the ANA was in a good place; now it was time for the profession to accept that fact. At the end of 1937, as the chairman of the Executive Committee of the ANA, Carroll issued "An Appeal to All Naturopaths." He opened by saying that he for some time he had been "alarmed and rather disappointed with the seeming indifference of many of the Drugless Physicians to our National Association." "Progressive Naturopaths," he said, were committed to the goal, through the ANA, that "our profession will take its place as a scientific body of learned naturopaths." With science on its side, progressive naturopaths could, for example, "tell the world just why Sulfanilamide is detrimental to the human body, and in just what kind of cases it is fatal or contraindicated—This must be our objective if we ever hope to merit the respect of the public and our educational institutions." Changes had been made in the ANA in 1935 "to pull our profession out of the adolescent state, which we have seemingly been unable to pass."

As part of the change in ANA structure, the leadership of the ANA also gained some input into submission of ANA professional material in *Naturopath and Herald of Health* in exchange for ANA dues monies

being used to support Lust's costs of publication. Using this position, Carroll had an article by Dr. Budden on the effects of the Basic Science Laws published in *NHH*. The article also appeared in one of the leading chiropractic journals.

Revisiting Basic Science

This article was written in Budden's inimitable style and was written only a couple of years away from the Oregon 1934 ballot fight that marked Budden's initial response to Oregon adopting its Basic Science Law. In a classic Americanism argument, Budden pointed out that a "whole generation of college-bred men and women" would be good national policy as there "should be more and evermore of our youth attending institutes of higher learning, and provisions should be made to make this possible." But there were policies that were intended to work against "Americans who value democracy" and that had the "sinister objective, nothing less than the establishment of exclusive privileges in education."

This was where, Budden argued, the Basic Sciences Laws were directed. They were designed as a test of university-level sciences divorced from the application of the sciences to drugless, nonmedical professions. This was at a time when "the drugless world had developed its own schools and colleges; institutions of learning peculiar to human therapeutics from the non-medical standpoint, well-equipped and staffed by competent teachers."

"Drugless schools," he pointed out, "have no state support and few endowments; they must depend on contributions from alumni and upon tuition." And as "a great national magazine (had) brought to light the unpleasant truth [was] that more people gave allegiance to physiological and drugless methods than to purely medical treatments." If "the drugless schools continued to flourish and to increase in value to the community and the country at large, it soon be too late to attack them. Thus the basic science idea was born."

Budden went on to argue that "it is important to note that in most states, and in the state of Oregon in particular," the sciences called the basic sciences—anatomy, chemistry, physiology, pathology and public health—were already taught and tested on for chiropractic and naturopathy. The purpose of the "extra" examination seemed to Budden to be an attempt to raise a barrier to drugless, nonmedical students of chiropractic and naturopathy with a clear ulterior and undemocratic motive: to keep these practitioners out of the marketplace: "Proponents of the law maintain that by this arrangement, which they contend is fair to all alike, the public is assured of a higher grade of practitioner. The police power of the state should be wielded to protect the public: not one particular group of physicians. The way of safety for the citizen is not in uniformity of thought in the healing arts, but in diversity."

Dr. Budden had come to be recognized by Robert Carroll as one of the leading "schoolmen" in natural healing. Although Budden was very concerned about "a board composed of university lecturers or Deans, men who know nothing of drugless practice and care less, prejudiced even before they occupy positions on the basic science board," he came to believe within less than 10 years of dealing with the Oregon board that the examinations were fairly held—which will be addressed later in this chapter.

A similar set of countervailing visions to those playing out within naturopathy played out within the National Chiropractic Association. In 1939 the influential broad-scope (or "liberal") chiropractor from Montana, C. O. Watkins, DC, argued in an influential article[137] that chiropractors should not favor separate licensing and degree status for naturopathy; rather, chiropractic statutes should be sought legislatively, recognizing that naturopathy was incorporated within a broad conception of "liberal" chiropractic and should be recognized as such.

In the article, Watkins noted that nationwide, there were "16,000 chiropractors, 95 per cent using other than straight Chiropractic" and "2000 naturopaths, many of them holding Chiropractic licenses who could also be considered liberal chiropractors." Furthermore, Watkins noted, the NCA had considered the issue of backing naturopathic legislation and decided on a different policy: "That the NCA oppose any plan that would cause the passage of separate physio-therapy laws or naturopathic laws to cover liberal chiropractors, but rather favor liberalization of Chiropractic legislation where it desirable to legalize liberal practice."

Looking back through the lens of historical hindsight, it seems that these policy differences fostered a diffusion of energies that would have been better spent seeking recognition for natural healing in the most expansive way possible, wherever possible.

And Scandals

Although most developments that have been discussed thus far were positive, in the 1940s, there were scandals involving practitioners identified as "naturopaths" as well. In 1938 a group of liberal chiropractors that identified themselves as chiropractor-naturopaths had formed the American Naturopathic Association of Michigan. Their leaders were charged with bribing members of the Michigan state legislature during the 1939 and 1941 legislative sessions. The charges alleged that bribes had been paid in an effort to get a naturopathic law enacted, and reports of the investigation by an inquiry judge, including the charges brought and the trials and guilty pleas in the case, dominated upper Midwest headlines from late 1944 through the end of 1945.

A much bigger scandal—one that received much wider and more sensational coverage—emerged in Tennessee. By the time the events there had played out, the courts had laid the groundwork for the assault on naturopaths that took place 10 years later in the mid-1950s. Organized naturopathy came to Tennessee in December 1937 when the ANA of Tennessee was chartered. Guy W. Cheatham, DC, ND, had established the Nashville College of Chiropractic and Naturopathy earlier in the 1930s, and the school and the ANA of Tennessee operated in an unlicensed vacuum for several years while Cheatham was active in the NCA efforts on chiropractic education and in ANA national affairs. George A. Floden, DC, ND, of Los Angeles, California, was affiliated with Cheatham's college and lectured there on a regular basis.

Matters in Tennessee changed significantly and abruptly in 1943 when the Speaker of the Tennessee House of Representatives, backed by the Crump political machine based in Shelby County (Memphis), pushed through a naturopathic licensing law over the veto of the state's governor. A 1946 investigation suggested that two naturopaths who later were named to the naturopathic licensing board funneled several thousand dollars to the Speaker (one bookkeeping entry showed $7835 for "1943 legislature"), their golfing buddy, in the form of "friendly" golfing bets.

By 1946 the examining board, which by statute kept its own books and records of licenses issued, had issued 917 Tennessee licenses to "naturopaths" from as far away as California, Alaska, Mexico, Canada, and South Africa. The number could actually have been more than 1000 licenses issued, as the books and records of the examining board "disappeared" from the offices of one of the board's members while the records were under subpoena by state prosecutors. But investigation showed that some diplomas and licenses were sold as a package: $1500 for a diploma and $1500 for a license.

In December 1946, 27 indictments were issued by a grand jury in Nashville. Those charged included Guy Cheatham DC, ND, and his California associate George Floden, DC, ND, along with a California associate of Floden. Two Texas NDs who lectured at Cheatham's Nashville College were charged as well, and in the grand jury's 34-page

indictment, it was alleged that all schools of naturopathy in Tennessee were "diploma mills." Cheatham had, admittedly, issued "naturopathy" diplomas to earlier chiropractic graduates of his college so that they could apply for naturopathy licenses after the 1943 statute went into effect.

In all, 17 defendants submitted *nolo contendere* ("no contest") pleas and were fined between $100 and $1000. The largest fines of $1000 went to two of the three members of the licensing board that the prosecutor said were "to blame for the conspiracy." Charges against Flodden and his California associate were dropped when the State of California denied extradition to Tennessee on the charges.

More importantly in the long run, the 1947 Tennessee legislature repealed the naturopathy act, criminalized any future practice of naturopathy in Tennessee, and invalidated all existing licenses to practice naturopathy in that state as of January 1947. Ten practitioners—all members of the ANA of Tennessee and all "clean" of any taint from the indictments—filed suit, seeking a declaration by the courts that the repealer statute was constitutionally invalid because it deprived them of their valid property interest in their licenses to practice without due process and without any finding that naturopathy itself was a threat to the health and welfare of the citizens of Tennessee.

A chancery court (trial-level) judge agreed, holding that the legislature did not have the constitutional authority to rescind the right to practice a legalized profession and to revoke, *carte blanche,* an entire class of professional licenses from practitioners who were without fault. A request to enjoin *any* enforcement of the statute through prosecutions for practicing medicine without a license was denied as beyond the authority of the court.

But before 1947 was over, the Tennessee Supreme Court had reversed this judgment. The Supreme Court held that the allegations of massive fraud in issuing licenses were serious enough to justify a sweeping response under the state's constitutional police powers, without the necessity to review each license in question. Moreover, the Tennessee court held that it was well within the police power of the state legislature, under the same constitutional police powers, to repeal an entire class of professional licenses—especially in the healthcare domain—*at any time, within its reasonable discretion.* That is, where licensing was concerned, the legislature taketh, and the legislature taketh away.

The plaintiff naturopaths petitioned the US Supreme Court for review of the case and of the Tennessee Supreme Court's holding on these constitutional issues. Review was denied. The table was set for a later broad assault on the licensing of natural healers across multiple states in the 1950s.

And Repercussions

The mischief and the stain originating in Tennessee spread quite quickly as well. In early 1947 as the scope of the Tennessee scandal was emerging and as the Tennessee legislature was repealing the Tennessee licensing law, investigations of licensing of naturopaths began first in Connecticut and then in South Carolina. In Connecticut, the state health commissioner—by state law a position held by an MD—withheld licenses from 28 applicants who had been approved for licensing by the Connecticut Board of Naturopathic Examiners starting in 1942 because none of the applicants had passed state licensing examinations, neither the basic science examination nor the naturopathic licensing examination. All of the applicants had been approved based on a Connecticut healing arts licensing reciprocity statute. All of the applicants sought reciprocity based on licenses issued in South Carolina—a state with no basic science examination.

In 1946 three applicants brought suit in two actions against the health commissioner seeking a court order directing that their licenses be issued immediately (through a *writ of mandamus* or "mandate"). Both applicants had failed the basic science examination more than once and then presented South Carolina licenses to the Connecticut Board, which had approved reciprocity applications. The applicants prevailed first in chancery (trial) court, then in the Connecticut Supreme Court.

The courts—the chancery court in June 1946 and the Connecticut Supreme Court in April 1947—held that the health commissioner served in a ministerial capacity, that is, the health commissioner had no discretion in issuing licenses when the Naturopathic Board had approved the applications. The courts also found that the reciprocity statute allowed the approval without examination, but the Connecticut Supreme Court agreed with the trial court that the health commissioner was trying to protect the public interest. The Connecticut Supreme Court noted further that if evidence showed that the applications were fraudulent or the actions of the Board were taken in bad faith, members of the Board should be removed from office.

Based on the issues developed in the court proceedings, the Connecticut police—which had the responsibility for licensing background checks—began an investigation into the reciprocity applications that lasted 6 months. This led in turn to an overlapping investigation by the state police in South Carolina. A clear pattern was documented: applicants from schools not recognized by South Carolina (which recognized only the National College of Chicago and Metropolitan of Cleveland as of 1947), primarily applicants with diplomas from Lust's American College of New York, had obtained licenses in Tennessee between 1943 and 1946, and then been licensed in South Carolina without examination.

Twenty-four applicants had then applied for licensing in Connecticut, again based on reciprocity. An investigation done in South Carolina by two Connecticut police detectives disclosed that only four applicants had actually spent any time practicing in South Carolina, and no time had been spent in Tennessee. The South Carolina Board had suspended the practice of accepting reciprocity applications from Tennessee in February 1947 when the Tennessee legislature outlawed naturopathy, but in 1947 and 1948, legislative pressure built up on the Board, and ND licensing in the state was under threat of repeal. By 1949 the repeal threat had been survived—for the present.

Much of this was a result of Connecticut adopting a Basic Science Law when only National, Metropolitan, Western States, UNHA of Denver, and Los Angeles College—all chiropractic colleges with ND degree programs—had legitimate 4-year residency programs with a basic sciences curriculum. How had this been worked through by these colleges? By 1944 Dr. Budden's view of the Oregon Basic Sciences Examining Board had changed based on 10 years of experience with the Board and its examinations.

More Basic Science

In the October 1944 issue of *The National Chiropractic Journal,* Budden offered his updated assessment of the Oregon Basic Science Law in the article "Effects of Basic Science Law in Oregon." By this time, Budden noted that "we should like to make it clear … that we—the faculty and myself—have had some ten years of experience with the preparation of students for this test and, as a consequence, we feel that we make speak with some authority." This notwithstanding that "public and candid discussion of the merits and demerits of basic science legislation has been regarded as a species of treason to Chiropractic (and Naturopathy)."

But strictly directed to the Oregon experience, the Basic Science Law in general had shown his students to be ready join "one of the learned profession," passing an examination given by a board of college and university professors chosen by the Board of Higher Education that "conducts its affairs with equity and intelligence (with) examinations

that are fairly held and the papers fairly marked." From all the evidence Budden had observed—and from a success rate of 25 out of 30 students passing the examination the first time (83.33%)—Budden believed "that if a student follows the courses covering the required subjects as they are given in the accredited schools, faithfully and with diligence he will pass the test."

He still noted that the public health part of the examination was based totally on the medical approach to the subject, requiring that the faculty had to teach students both "traditional" public health and the nonmedical alternative thinking. But he felt this was a price to pay in order that a higher level of nonmedical education was achieved, medical propaganda about a low level of nonmedical education was "wiped out," success on the examinations favorably influenced the courts and the legislature, and there was more favorable treatment of the nonmedical professions by the outside the medical domain "all-around."

Finally, Budden noted that "of late efforts have been made to circumvent the law by setting up very dubious and possibly illegal 'reciprocity.'" This, he said, was self-defeating: "There is only one way; to qualify enough candidates to show that the level of education makes two [licensing] examinations for the right to practice the healing arts preposterous."

In this thinking, as in many respects, Dr. Budden was almost 40 years ahead of his time.

Dr. Schlichting

Henry J. (Hank) Schlichting Jr. was born in Fowler, Kansas, in 1915 and was raised—or, as he put it, "reared"—in Weatherford, Oklahoma. By 1938, at age 23, he had graduated from Oklahoma City's Carver Chiropractic College and relocated to Amarillo in the Texas Panhandle, where he joined "Dr. Roy G. Moore's Chiropractic Hospital—Serving the Entire Southwest" as "Assistant Specializing in Dislocations and Fractures." By the fall of 1941, he had relocated to Midland, Texas, and opened his own practice, the Modern Health Clinic. He advertised himself as "Dr. Henry Schlichting, Jr., Naturopathic Physician Specializing in Fractures and Dislocations."[138]

How Schlichting came to call himself a naturopath is somewhat unclear. In the mid-1930s there was no licensing in Oklahoma or Texas for either chiropractors or naturopaths. Carver Chiropractic College in Oklahoma City taught obstetrics, minor surgery, and a broader use of adjustive technique than "straight" chiropractic. Texas was mostly dominated by straights through the influence of the Texas Chiropractic College in San Antonio. Although Schlichting's early training was in chiropractic, and he was first in chiropractic practice in the Amarillo, Texas, area when he settled in Midland in 1941, he allied himself with the naturopaths in Texas and always called himself a naturopath.[139]

Also, by the fall of 1941, he had joined the newly formed ANA of Texas. At the organization's first statewide convention in Dallas—attended by more than 500 initial members—he was elected secretary-treasurer. This quick ascension into the leadership ranks of the naturopaths of Texas led in turn to his connection with the western ANA group and with Robert V. Carroll.[140]

Dr. Schlichting and the Western ANA

The 1942 convention of the ANA in Chicago was boycotted by Benedict Lust, Jesse Mercer Gehmann, T. J. Schippell, and their allies that became the eastern group. They held a "rump" convention of about 75 eastern naturopaths in Atlantic City in anticipation of the Chicago convention electing someone other than Lust as ANA president. In Chicago, Fredric Dugdale of Portland, Maine, was elected president. The president of the ANA of Texas, which since its formation in 1940 had delivered the biggest state representation to the ANA, was H. A. Brown of Canyon, Texas. He was elected first VP of the national ANA under Dugdale (Robert Carroll stayed as chairman of the Board of Directors), and in 1944 Brown was elected national president. When Carroll succeeded Brown as ANA president in 1946, he tapped Schlichting as his secretary.[141]

What made Schlichting stand out to Robert Carroll must be guessed at, but Carroll was a superb leader and organization man, and he recruited many significant naturopaths into the profession and into the western ANA. He recruited John Bastyr and many others in Washington State into naturopathy before moving on to the national stage. Schlichting had much to commend him: he became a strong ally of Harry Brown in the Texas ANA, an organization that grew to more than 400 members, most of whom also joined the national ANA; he was a talented writer and speaker; and he was a strong organization man.

Once he was placed as national secretary by Carroll, Schlichting brought all of these talents to the national ANA. He continued to advance naturopathy in Texas, and he built a busy, thriving practice in Midland. Throughout the 1940s he advertised specializing in fractures and dislocations. Midland was a western Texas oil town, and oil roughneck work was notorious for its physical toll. The Carver techniques emphasized minor surgery and a "structural" approach to chiropractic. This became known in chiropractic as the Carver Technique, and as it evolved, it became one of the roots of naturopathic physical medicine.[142]

More Background on Clinical Practice

Willard Carver "opened the Carver-Denny School of Chiropractic in Oklahoma City in 1906, which in 1908 became the Carver Chiropractic College Carver's philosophy gave equal importance to any anatomically produced 'nerve occlusion,' whether or not related to the vertebral column, while his *structural* approach to biomechanics became more 'holistic' than B.J.'s [Palmer] segmental one-bone-out-of-place approach."[143]

Carver established four chiropractic schools, in New York City; Washington, D.C.; and Denver in addition to Oklahoma City. It was the Denver school that became most significant to natural healing education and clinical technique. As Walter Wardwell described the relevant history: "Homer G. Beatty (1897–1951), who had graduated from Carver's Oklahoma school in 1922, became the dean of the Colorado school in 1923 and its president in 1924, serving until his death in 1951." In 1939 Beatty published *Anatomical Adjustive Technique.* By 1935 the school was reorganized as the nonprofit University of the Natural Healing Arts, which offered three doctoral degrees, D.C., N.D. and D.P.T. [Doctor of Physical Therapy], the last requiring 3 years of study rather than the 4 required for the others."[144]

Homer G. Beatty, DC, ND, is a part of the story of the professionalization of natural healing for several reasons. He was a part of the educational efforts of the National Chiropractic Association from its commencement in the early 1930s. He adopted the 4-year residency educational model for the UNHA DC and ND degree programs in lockstep with Budden at Western States. Although Colorado did not adopt licensure separately for NDs, his ND program at UNHA provided about half of the licensed NDs in the neighboring state of Utah by the mid-1950s. And perhaps most importantly, his book *Anatomical Adjustive Technique,* which described methods of treatment by manual adjustment for the entire anatomy, became a cornerstone for natural physical medicine.

It was this type of clinical technique that was used by Schlichting in his West Texas practice. These clinical techniques were supplemented by the treatment methods illustrated in Alton Johnson's *Principles and Practice of Drugless Therapeutics,* the first edition of which was also published in 1939. Johnson, another DC, ND, covered physiotherapy,

electrotherapy, and hydrotherapy—in addition to adjustive technique—in his book on clinical science for natural healers. Both of these works were integrated by Budden into the postwar curriculum at Western States, and both Beatty and Johnson became members of the western ANA after the war. In Johnson's case, he was recruited by Carroll and Schlichting to attend the 1948 western ANA convention in Salt Lake City and prevailed upon by them to accept the chairmanship of a new ANA committee on physiotherapy. In this position, Johnson wrote or edited a regular physiotherapy column in the journal of the association for several years (while also writing regularly for the journal *The Scientific Chiropractor*), and in the early 1950s he served a 3-year term on the national association's Board of Directors.[145]

These were the clinical techniques at the center of Schlichting's clinical practice during the 1940s when he established his practice and became a leader in the national movement of natural healers. He also became a civic leader in Midland, as a prototypical American joiner of voluntary civic associations: the Lions Club, the Jaycees, the Toastmasters, and various civic improvement efforts. Dr. Schlichting, or "Doc" to the citizens of Midland, practiced and lived very visibly in his adopted hometown, as many members of the western ANA did in the 1940s before natural healing came under assault by the AMA in the 1950s.

Back to the National Scene

As a national officer by 1946, Schlichting found himself in the middle of the dispute over control of the American Naturopathic Association, chartered in Washington, D.C. by Benedict Lust in 1919. After the "pseudo-group insurrection" of 1942, Lust remained embittered and denied the legitimacy of the "western ANA" until his death in August 1945.

But for these 3 years, the nation was at war, and many were diverted from much of civilian life. The westerners largely built a communication network, held annual meetings, and waited out the war. Peacetime would come, and by circumstance, when it did, Benedict Lust had died. Then in peacetime, internecine warfare broke out among the naturopaths, as both Carroll and his western group and the eastern group led by Jesse Mercer Gehmann, T.M. Schippell, and a new face, Paul Wendel, laid claim to the "ANA." Working with Carroll, Schlichting and a few others built up their Western "pseudo-group" while defending their right to being "the real ANA" and while constantly pushing the concept of unifying all naturopaths within one organization.[146]

Looking through the historical record, it seems clear that Robert Carroll had followed a methodical campaign to make the ANA into a true professional organization and that he had done so by amending the ANA constitution, bylaws, and governing structure. The western group had every right to be recognized as the legally constituted ANA organization as WWII ended, and Carroll's ANA represented the broad-scope practitioners from the urban areas of about 20 states, including all of the licensed states. The eastern group that survived Lust, though, continued his dispute of their claim of legitimacy from 1946 to 1950, and the issue was a constant distraction.[147]

Through 1946 and 1947 the western group, for various reasons—including a postwar paper shortage—struggled to produce a monthly publication for its membership. During this time the leadership communicated with members through a series of "Dear Doctor" newsletters that Schlichting sent out from his Midland, Texas, office as "American Naturopathic Association, Inc., Office of the Secretary." In January 1948, at long last the *Journal of the ANA* debuted, and the western ANA became a more established presence on the cultural, political, and professional scene. With much anticipation of a "Unity Convention," the group convened in July 1948 in Salt Lake City, Utah, for its annual meeting. Although the organization had grown in strength and presence—and more than 300 naturopaths attended the meeting from about 20 states—"unity" was not achieved, and Carroll passed the reins of the presidency to Schlichting.[148]

As of the summer of 1948, there were ND degree programs at National College of Chiropractic in Chicago, UNHA in Denver, Western States in Portland, and Metropolitan College in Cleveland, Ohio, that were legitimate 4-year residency colleges, as well as a program at the Los Angeles College of Chiropractic that was in a state of flux, although soon to be disbanded completely by the National Chiropractic Association. Schlichting took the presidency from Carroll at a time when the future for chiropractor-naturopaths looked promising.[149]

A historical note here is in order. Almost all of the naturopaths in the western group were chiropractors who had branched out in classic "mixer" fashion. With the exception of Robert Carroll himself, who had been a direct student of Henry Lindlahr and who had begun to call himself a "naturopath" instead of a drugless healer in the early 1930s, a historical tracking of every ND leader from the postwar era leads back to an early chiropractic college. As just two examples (Schlichting's education has been covered), Harry Riley Spitler (the lead editor of *Basic Naturopathy)* graduated from Ross Chiropractic College in Fort Wayne, Indiana, before WWI, and John Bastyr (after whom today's Bastyr University is named) graduated from the Seattle Chiropractic College in the early 1930s. Spitler was also on the faculty of the Metropolitan College from the mid-1930s until WWII. Also, in several states, "mixers" became identified as naturopaths because chiropractic "straights" took control of chiropractic licensing. Washington, South Carolina, Utah, and Texas were such states.[150]

Dr. Schlichting Becomes President

When Schlichting took over as president of the western ANA, things were at a critical juncture for natural healers, whether they identified as chiropractors or naturopaths both nationally or back home in Texas. Schlichting, while running a busy, growing practice and emerging as a civic leader in Midland, was up to the task of growing the ANA as an organization *and* achieving legal recognition for naturopaths in Texas. In doing so, he followed Robert Carroll's model: practice openly and proudly as an "ND" and "Dr.," be a civic leader, push constantly for recognition for naturopaths and legitimate ND school programs, and do everything possible to unify the profession within the ANA.[151]

As the incoming president in 1948, Schlichting had set the ANA 1949 convention for Houston, Texas, to take place coinciding with the opening of Houston's newest—and in keeping with the mottos of Texas "biggest and best"—luxury hotel. As 200 Texas naturopaths joined with 200 out-of-state naturopaths for the ANA's largest convention, Schlichting was able to announce to the attendees that the Texas legislature had passed a Texas licensing law as part of a legislative "deal," and the governor of Texas was signing off on the legislation. Within 2 years, Texas was the home to more than 400 licensed NDs—the largest licensed state in terms of numbers and the largest source of Western ANA members.[152]

The nature of the "deal" became critical within just a few years. The Texas State Medical Association wanted Texas to adopt a Basic Science Law. The Texas chiropractors wanted a licensing law for "straight" chiropractic. An earlier law had been struck down by the Texas Supreme Court for violating a provision of the Texas Constitution that prohibited giving preference to any "school of medicine." And the growing naturopathic group of 500 and counting wanted recognition. A group of legislators brokered a deal: a Basic Science Law would be adopted

first; then, subject to it, a chiropractic law crafted to withstand challenge would be adopted; and finally, a pending naturopathic bill would be adopted.[153]

The Basic Science Law passed both houses of the Texas legislature handily, the chiropractic law was adopted by slightly tighter margins, and then the naturopathic law passed the state House fairly comfortably. But then, in a harbinger of things to come and with its Basic Science Law in hand, the state medical association tried to kill the deal with a push against the ND bill in the state Senate. The bill, after much delay, passed the state Senate by one vote, 23-22, in July 1949, while the profession was in Houston for its convention.[154]

NATUROPATHS AT THEIR PEAK

The Late 1940s and Professional Growth

Under Schlichting's leadership as national and state leader—and soon as a member of the first naturopathic licensing board in Texas—the profession continued to grow. But as noted earlier, the number of schools started to decline. Los Angeles dropped its program, and Metropolitan closed up in 1949. National dropped its program in 1950 under pressure from the National Chiropractic Association. Suddenly in 1951, Homer G. Beatty, DC, ND, of the UNHA in Denver passed away and with him, in short order, so did another ND program; only Western States under Dr. Budden was left.[155]

In Memoriam—Robert V. Carroll, Sr.

And then suddenly in March 1951, Robert V. Carroll—Schlichting's mentor and the true "father" of the modern naturopathic profession passed away. As Schlichting and the editors of the *Journal of the ANA* memorialized Robert Carroll's life and career[156]

In MEMORIAM

Dr. Robert V. Carroll, Sr., died Friday, May 11th, of internal hemorrhage followed by coronary embolism. He died as he lived, suddenly and dramatically. There had been no prior illness. He went from excellent health to death in twenty-four hours.

The naturopathic field has lost one of its greatest fighters. His was not the fight for individual stature; his was the fight for rightful and legal recognition of Naturopathy. He did not aspire to a statue, a pedestal or plaque exhorting his name in superlatives; his desire was to see naturopathy reach its honored place in the sun and to be a proud member of that profession.

Now, his three score and ten has been completed. His earthly body has been laid away, but his spirit will march on. He has left a high mark on the wall. When we can measure up to it, his dream will have come true.

The world has lost a man, the nation, a citizen, and naturopathy, a leader. But in our hearts each of us knows that the loss cannot be described in words alone. He admired and respected the qualities in others that fired them to opposition. In his heart he had only friends, agreeing friends and disagreeing friends. All will miss him.

In the 1950s Henry Schlichting and the naturopaths faced challenging times that could not be foreseen in 1951. Robert Carroll's leadership and vision would be missed.

1947–1950 and Forward

When Robert V. Carroll passed away unexpectedly in May of 1951, the natural healing profession that he had helped build with 20 years of diligent work was trending upward. When Dr. Carroll passed from the scene, national leadership was then held by Henry J. Schlichting Jr., of Midland, Texas, and by A.R. Hedges of Medford, Oregon. Educational leadership was in the hands of W. A. Budden of Western States College, Portland, Oregon, and Joseph Janse of National College of Chicago, Illinois. Texas had licensed naturopaths and chiropractors in 1949 as part of a legislative "deal" in which the Texas legislature also adopted a Basic Science Law.

In 1950 the Georgia legislature had licensed naturopaths, and the Nevada legislature had also adopted licensing statutes in 1951. In the negative column at the time of Carroll's passing, National College had dropped its formal ND degree program in 1950 under pressure from the National Chiropractic Association's Council on Education, and the governor of the state of Nevada had vetoed the Nevada legislation just after the legislature adjourned. Joe Janse would proudly call himself a DC, ND, well into the 1960s and preside over a broad, "liberal" chiropractic curriculum at National, but the National College decision reduced legitimate, 4-year residency ND education to only Western States.[157]

In Texas, Henry Schlichting—"Doc" to the Midland, Texas, community—sat on a three-member naturopathic board that had processed and accepted more than 400 applications for licensing on a "grandfather" basis that was part of the 1949 legislation. Texas became both the largest state membership base for the western ANA and the largest licensed state in naturopathy. The natural healers seemed to have weathered the Tennessee scandal by 1951 and to have absorbed the lesson that H. Riley Spitler called "Remember Tennessee."[158]

Naturopathy in Connecticut[159] could have suffered much more than it did in the aftermath of the Tennessee scandal, but the Connecticut Supreme Court ruled in April 1947 that the Connecticut State Board of Naturopathic Examiners—not the state commissioner of health, a medical doctor—was the legal decision maker in licensing. As early as 1942 the health commissioner had delayed the issuing of licenses approved by the Board when the approval was under the licensing reciprocity statute and from South Carolina, a state with no Basic Science Law and that approved schools that were not on the Connecticut Board's approved schools list. The commissioner's position was that the reciprocity statue required licensing by a state with licensing requirements comparable to those in effect in Connecticut.

By 1946, when this issue emerged into public awareness, licenses issued in Tennessee—where the diploma mill and licensing fraud scandal was first coming to light—also started appearing in reciprocity applications. By the time two applicants, both with diplomas from Lust's American School in New York (which had lost its state charter in 1935) and with licenses from South Carolina and Tennessee, prevailed in the Connecticut Supreme Court, the legislature had repealed the reciprocity statutes at the urging of the governor, and the state attorney general had begun a review of all existing licenses to determine whether evidence of fraud existed in the application process.

The Board revoked 17 licenses on its own, and the attorney general revoked several more after a trial that focused on the scandal in Tennessee and the loose practices in South Carolina in its own handling of the reciprocity issue. Extensive testimony was introduced by the attorney general's office about the Tennessee licensing scandal from depositions taken in Tennessee, and also about the extent to which South Carolina "rubber stamped" reciprocity application in 1945 and 1946 supported by Tennessee licenses.

In the long run, the Connecticut Board emerged with its licensing authority intact for applicants who graduated from properly approved schools and after successful passage of licensing examinations. The same proved to be true in South Carolina but only after the Board there went through a major legislative scrutiny process and adverse publicity of its own.[160] During the 1947 South Carolina legislative session, the state House of Representatives passed a "concurrent resolution" asking

for an inquiry into "examinations and personal qualifications required of applicants to practice naturopathy in this state and the propriety of granting licenses therefore."

During the 1948 legislative session, the full resolution was addressed between the House and the Senate (which was more favorable to the naturopaths), instructing the state Naturopathic Board to clean up its own house and report to the legislature by the 1949 session. As reported in the press, "The assembly … asked the State Board of Examiners to look into this situation, remedy it if possible."

In February 1949, the Board reported to the legislature "that it had revoked a number of reciprocity licenses, giving the holders a chance to regain them by taking state examinations … Most did and were relicensed … But at least one holder of a license refused to accept the board's order and has brought court action against it." The Board requested stricter licensing laws and stronger disciplinary powers, and the legislature obliged.

After the Scandals

These two states were the most directly affected by the Tennessee scandal. Connecticut was "purged" by the actions of state authorities; South Carolina was purged by aggressive action of the State Naturopathic Board. Licensing in both states survived the Tennessee infection. As a reflection of post-Tennessee reality, the 1949 licensing of naturopaths in Texas included a specific reference in its "grandfather" provisions that provided that licenses issued in the state of Tennessee were not to be considered for any purpose, recognizing that the Tennessee legislature had acted to invalidate any licenses that had been issued.[161]

With a substantial base to work with in Texas, Schlichting decided that the naturopaths should address their own education issues by establishing a legitimate 4-year residency college within the state to be supported primarily by the Texas profession. Lack of "Class A naturopathic colleges," Schlichting wrote in announcing the founding of SCNM to the profession, "is a threat to the perpetuation of our profession." In 1951 the Southern College of Naturopathic Medicine (SCNM) was chartered, and an agreement was made with the newly named Texas Southmost College—a 25-year-old institution previously known as Brownsville Junior College and located in Brownsville, Texas, to serve as the home for SCNM.

The administrative offices for were located in a building on the Texas Southmost campus, and the premed and basic science courses for SCNM students were taken through cross-enrollment at Texas Southmost. The first major event sponsored by SCNM was a 2-week postgraduate seminar cosponsored with the Texas Naturopathic Physicians Association and held on the Texas Southmost campus.[162]

A Change of Identity

The summer of 1951 was eventful for the naturopaths for several reasons. Meeting in Miami Beach, Florida, the western ANA changed its name to the American Naturopathic Physicians and Surgeons Association (ANPSA), reelected Dr. Schlichting as its president, and established its corporate charter and located its headquarters in Des Moines, Iowa. The reasons behind this organizational restructuring were explained in articles by Schlichting and by A.R. Hedges in the September 1951 issue of what was now the *Journal of the ANPSA*. The changes were necessitated, they said, by the last resistance to the newly unified ANA continuing to lay claim to the name American Naturopathic Association. The group felt strong enough to take on a "post-Lustian" identity in representing the natural healing professions.

Robert Carroll would likely have never accepted this one step. He proudly carried the banner of the ANA and felt—correctly—that he was entitled to do so. But Schlichting and Hedges felt that the profession could use the new strength that came with licensed status for naturopaths in Texas, added to the existing licensed states, to support a modern profession, a reinvigorated educational system and a staunch commitment to the *vital force*. Carroll had always preached the value of science in explaining the theory of natural healing and the value of supporting work like Cannon's vision of *homeostasis*. Schlichting preached the value of a professional identity as "family physicians" in a general family practice that included minor surgery and obstetrics.

The new professional organization, he pointed out, was formed to "promote the public health and to perpetuate and advance the science, art and practice of the naturopathic school of medicine; to accomplish such objectives by attaining high standards of naturopathic education and by constantly stimulating and furthering the profession's interest in and knowledge of the diagnosis, treatment and prevention of … disease and ill health." As things trended upward for scientific natural healing in 1951, it was through this vision.[163]

Medical Dominance Arises

But all of this began to change dramatically in 1953, and what seemed so promising at the beginning of the 1950s was totally eroded by the end of the decade. No developments demonstrated this as much as the history of natural healing in Texas over just 10 short years. The force of medical dominance began to rear its head in 1953 at the annual convention of the AMA. A resolution was introduced by the Alabama delegation to the House of Delegates to attack chiropractic and naturopathy at their "weakest point," their school and colleges.

At the behest of AMA leadership, this topic was referred to the AMA educational committee rather than passed on by the House of Delegates. The educational committee felt that the AMA should refrain at the time from weighing in directly on the schools and colleges of other professions for political reasons, but the sentiment of the resolution was taken by AMA leadership as a strong interest by the medical profession in moving politically against these remaining "healing cults." The matter was passed back to the state medical societies to deal with at the state level, with the full support of the national association.[164]

Historian Monte Poen called the AMA "the country's richest and most influential post-World War II lobby." In assessing the powerful effect of the AMA's lobbying, Poen (from his research in the 1970s) noted that "As to the role played by organized medicine, I have become more impressed by the medical community's ability to influence public opinion" in the post-WWII 1940s and 1950s.[165]

At the state level, organized medicine used its ability to influence public opinion to sway the views of mainstream newspapers, government officials, and state legislators. This was important because professional legitimization is established in the United States on a state-by-state basis. This has been true since 1889 when the US Supreme Court decided *Dent v. West Virginia*. The history of this first medical licensing case is the subject of James Mohr's *Licensed to Practice: The Supreme Court Defines the American Medical Profession*.[166]

Dent, the petitioner in the case, was an Eclectic physician at a time in history when there were three schools of medicine: the Regulars (called "allopaths" according to Samuel Hahnemann), the homeopaths (as homeopathy was conceived by Hahnemann), and the Eclectics (which included the physio-medicalists). The Regulars in West Virginia founded the West Virginia Medical Society in 1867 and were the moving force behind the state licensing law adopted by the state legislature in 1882. By adopting legislation that required education at a Regular school, the licensing law barred practitioners from the two other schools of medicine from practicing in West Virginia.

As David Korostyshevsky summarized the key aspects of the situation in his review of Mohr's book in the *Journal of the History of Medicine*[167]:

Grounding his analysis in both legal and medical historiographies, Mohr argues that while the American public supported public health efforts to control epidemic disease, medical licensing was not a popular reform. It was instead "a consciously engineered policy, drafted and passed through the concerted efforts of a specific subset of physicians, the elite Regulars" of the Medical Society of West Virginia (156 of Mohr). Mohr also challenges the interpretation that medical licensing was a response to the growing complexity of scientific medicine. Because scientific medicine did not produce tangible results until the 1930s, the push for medical licensing is a consequence of economic and political factors, not strictly scientific ones. Finally, Mohr shows that the Supreme Court upheld a version of medical licensing that relied on the quality of a physician's education as the only measure of competence.

Because the Regulars were the largest of the three schools of medicine in 19th-century America, the *Dent* decision allowed the Regulars to achieve the elimination of the two other schools on a state-by-state basis, which, by the early 20th century, went a long way toward eliminating the other schools.

THE BEGINNING OF THE END

The Texas Medical Wars

All of this became relevant to events in Texas just as the naturopaths under Schlichting's leadership had begun to achieve success professionally and to create an educational institution that would fill the void left by the NCA decision to require chiropractic schools to abandon the training of naturopaths. As Schlichting transferred the presidency of the ANPSA to Hedges in 1952, he focused even more on his position as secretary of the Texas State Naturopathic Examining Board.[168] After Robert Carroll's unexpected passing, Budden and Hedges further advanced natural healing in Oregon—and tried to secure natural healing throughout the Pacific NW. Schlichting tried to do so in Texas at the same time, hoping to secure the Southwest (Texas in addition to Arizona) for natural healing as well.

The success of the naturopaths in Texas was targeted by the Texas Medical Association and the Texas Medical Board in 1953. The medical campaign against the naturopaths began in a remarkable way. When the 1949 legislature adopted the Texas Naturopathic Act (Article 4950d, Vernon Codified Statutes), its passage was during the term in office of Texas Attorney General Price Daniel (1947–1953). When Schlichting, as secretary of the Texas State Board of Naturopathic Examiners, sought guidance from the attorney general (AG) on the "grandfather clause" of the Naturopathic Act in 1952, that guidance was provided under AG Opinion V-1486, dated July 29, 1952, directed to Schlichting as a state official seeking a necessary interpretation of state law. Such guidance to state officials was—and is—a function of the AG's office under the Texas Constitution and Texas law.

In 1953 Price Daniel—later a US Senator (1953–1957), governor of Texas (1957–1963), and justice of the Texas Supreme Court (1971–1978)—was succeeded as AG by John Ben Shepherd. Shepherd's office received a letter requesting consideration of two questions challenging naturopathic validity under the Texas Constitution from the criminal district attorney of San Antonio, Texas.[169] That district attorney was considering bringing action against naturopaths in Bexar County, Texas, if the Naturopathic Act should be invalid. This action was being requested by the county medical society and state medical association.

In this situation, the Texas AG can—on a discretionary basis—serve a unique function, that of "an alternate Supreme Court."[170] This function is discretionary, but with the matter under consideration by a new AG, briefs were solicited by the AG's office and submitted on the issue. In spite of "three very able briefs" arguing in favor of the enforceability of the Naturopathic Act, G Opinion S-60, dated June 29, 1953, was issued, finding the act to violate the Texas Constitution: "SUMMARY: The Naturopathic Act, Article 4590d. V.C.S. violates the provisions of Art. XVI, Sec. 31 of the Constitution of Texas in that it gives a preference to one segment of the healing arts. To rule otherwise would require a holding that the Act is uncertain and indefinite and thus unconstitutional. *State Ex. Rel. Halsted,* 182 S.W. 2d 479 (Tex. Crim. 1944)."

The complete loss of naturopathy in Texas and the end of the Texas career of Henry J. ("Doc") Schlichting Jr., ND, would not be final for another 5 years. But this was the beginning of the end, and in the next 5 years Georgia, South Carolina, Florida, and Utah would be lost as well. Medical dominance as wielded by organized medicine was under way.

The fallout for naturopaths in Texas after the AG Opinion S-60 issued in July 1953 developed slowly at first. The 1953 session of the Texas legislature had just ended 2 months earlier, so there was no immediate opportunity to seek legislative relief. At the same time, although AG Opinion S-60 had considerable meaning, it was not the same as a decision by the courts. Schlichting and the Texas NDs worked quietly behind the scenes to take stock of the situation and to plan how to proceed. Judging by the material in the *Journal of the ANPSA* and the Texas newspapers, a decision was made by the Texas Naturopathic Physicians Association not to publicize the problems created for the Texas NDs by the attorney general's opinion.

Back to Education: WSC and *Natura Medicina*

Events for naturopaths for the rest of 1953 largely took place outside of Texas. After the very successful ANPSA convention in Portland and the Western States commencement for the ND class of 1953, the news at the end of the year was the 5-years-in-the-making publication of *Natura Medicina.* Within the first year of work on *Basic Naturopathy,* it became apparent to the primary editors—H. Riley Spitler and Pers Nelson of Connecticut—that inclusion of medicinal substances used in naturopathy would need to be reserved for later so that *Basic Naturopathy* would be focused on and confined to theory. President Robert Carroll of the ANA appointed a committee in April of 1947 to prepare a textbook on medicinal substances in use in naturopathy. The committee was formally designated the Natura Medica, Formulary, and Therapeutics Committee. The committee first convened to arrange committee assignments at the 1947 convention in Detroit; A.W. Kuts-Cheraux had been appointed committee chair. Originally the sections for inclusion were vitamins, cell salts, botanicals, and endocrines.[171] Correspondence was sent out by the committee to gather information from "the men in the field," as Kuts-Cheraux reported to the 1948 convention in Salt Lake City. Several complications that emerged from this survey of the profession were outlined by the committee chair in this report: (1) many of the botanicals in use had not been "subjected to the usual chemical analyses, alkaloid and glucoside determination … physiological properties and pharmacological action is very vague"; (2) many favorite botanicals had been identified by practitioners in "homely lay terms"; (3) "many agents endorsed by some practitioners were condemned by others as of no value"; and (4) a major issue that had not been "satisfactorily settled" had been the inclusion of Harrison Act narcotics that had been legalized by the Florida courts for use. Five more years would be required to bring all of the committee's work to its fruition.

The end product was worth the wait in general terms; the book was cutting edge in its contents and scope.[172] In addition to Kuts-Cheraux, there were major contributions to the work by Dr. Herbert Clough on the formulary of selected botanicals and by Dr. Helena Winters of Kelso, Washington, on vitamins and tissue cell salts (with assistance from Dr. H. Riley Spitler, chief author of *Basic Naturopathy*). Reinforced by the entirety of the book's approach to natural medicine was what had become the organizing philosophy of naturopaths in clinical practice: health and healing were emphasized rather than conventional medicine's prevention and treatment of disease, the vital force and homeostasis were a critical core element of the philosophy, and suppressive pharmaceuticals with their side effects were to be avoided.

But it arrived at an unfortunate time, just as the assault on naturopaths and chiropractors by organized medicine was getting under way.

The textbook, for instance, arrived too late to be put into use at Western States during the 1953–1954 school year. Dr. Budden's unexpected death in August 1954 kept the textbook from ever being incorporated into the curriculum. And as events would play out, this cutting-edge work arrived as the naturopathic profession was contracted severely by governmental action in the mid-1950s.

When Dr. Budden passed away, a remarkable force of nature, a remarkable liberal chiropractor, and a great naturopath was lost to the world and to natural healing. The *Journal of the National Chiropractic Association* for September 1954 had "A Tribute" by J.J. (John) Nugent, DC, director of education:

> *Dr. W. A. Budden, director of the Western States College of Chiropractic, Portland, Oregon, died suddenly in Portland on August 1, exactly one week after his return from a meeting of the Council on Education of the National Chiropractic Association.*
>
> *Dr. Budden was one of the pioneer leaders in chiropractic education …*
>
> *As much as any man in our profession, he espoused and introduced high educational standards in our schools.*
>
> *An important and forceful representative of our interests, his authoritative voice was respected and listened to in our legislative halls …*
>
> *To many, Dr. Budden's passing will mean that a great chiropractor, thinker, and educator has passed into history. And it is so! He was one of chiropractic's great …*
>
> *He was a vigorous and indomitable fighter for truth as he saw it for freedom of the individual, and, above all, for intellectual integrity …*
>
> *We will miss him sorely, the … profession has suffered an irreparable loss …*
>
> *Dr. Budden was born a gentleman, and lived and died by that high code.*
>
> *We shall not forget him!*

What was true for chiropractic was true for naturopathy as far as Dr. Budden's career and commitment were concerned. Both professions owe a deep debt to Dr. Budden that *should not* be overlooked and certainly not forgotten.

Events were building to a devastating outcome: the naturopaths were going to lose Western States College as an educational base and Texas as a professional base. When Dr. Budden died in August 1954, Western States itself was at a critical juncture. In the 6 months before Budden passed away, the three issues that would cause such trouble for Western States after his death had begun to appear on the horizon.

WSC and Hard Times

First, the postwar boom fueled by the G.I. Bill was coming to an end. It is difficult to overstate the effect on the chiropractic colleges generally, and Western States specifically, of the G.I. Bill adopted by Congress as the Serviceman's Readjustment Act of 1944. One of the main provisions of the act was the funding of higher education for those who elected this benefit. The funding available covered all of the costs of higher education: tuition, fees, and textbooks. This was true at public and private liberal arts universities and colleges but also true at WSC. By the time the act expired, almost 3 million veterans had attended institutions of higher education nationally, paid for by the federal government.[173]

Second, the new matriculation requirements that Budden had established at WSC and had convinced the Oregon legislature to put into law were taking effect. In an article entitled "The Aspects of Two Years Preprofessional Study as an Entrance Requirement," published in the *Journal of the National Chiropractic Association* in March 1954, Budden noted that "economically, the schools … that follow the two-year plan must expect to experience an, at least temporary, set back in revenue, and it would certainly be unwise … for an institution to venture in [this] direction unless its financial underpinning is of the caliber to absorb the shock through the lean years."

Third, the issue of Dr. Budden continuing the WSC of Naturopathy began to become a serious irritation within the Council on Education (COE) of the NCA. Indeed, there is every indication that only Dr. Budden's personal standing within the NCA and the COE kept the issue from becoming a more persistent matter while he was alive. At the semiannual meeting of the COE held February 11 to 13, 1954, in San Antonio, Texas, Budden raised the subject himself. The minutes for Friday afternoon, February 12, 1954, reflect that "Dr. Budden asked for a frank and open discussion on the Naturopathic issue."[174]

The conversation continued for the rest of the afternoon and again the next morning, as reflected in the minutes. Dr. John Nugent "reminded Dr. Budden that the Western States College was the only remaining school on the accredited list that still conducted a course in Naturopathy." Dr. Budden set out his position on the matter. It was better to "sustain a reputable school of naturopathy" to establish an educational standard that legislatures could look to. Legislation in both Idaho and South Dakota that would have diluted educational standards substantially had been defeated by pointing to Western States as the baseline for naturopathic education. On that note, the afternoon adjournment was taken.

When matters picked up the next morning, "Dr. Budden gave a complete review of the history of naturopathy and asked the Council to give him concise opinions and expression of decision" that he could share with the WSC Board of Directors so that "future policies of Western States College could be determined." Budden was reminded that at the midyear meeting in 1950, both Dr. Janse of National, together with his administrator, and Dr. Budden had been told to discontinue courses in naturopathy. Dr. Budden's Canadian protégé Dr. A.E. Homewood (dean of the Canadian Memorial College of Chiropractic [CMCC], chartered in 1945) "inquired as to the attitude of the Council" if the CMCC initiated courses in naturopathy "to accommodate those Provinces in Canada that sustained naturopathic laws?" Budden also inquired "whether the Council had the right to remove a college from the accredited list if it continued to conduct a naturopathic course?"

WSC and the NCA

The consensus of the council was stated as follows: (1) The Council "would frown on" the CMCC initiating any naturopathic courses, as

a degree or otherwise; (2) Dr. Budden was advised to tell the directors of the Health Resource Foundation as the governors of WSC that "recommended that the course and school of naturopathy as conducted at Western States College be discontinued as soon as obligations and commitments could be fulfilled or terminated"; and (3) the council "does have the right to remove a college from the accredited list if a naturopathic program was operated concurrently with the chiropractic program at an accredited school."

Three weeks later Dr. Budden presided over the 1954 commencement for a class of four ND degree recipients and 26 DC degree recipients, 13 of whom also received the BTS degree.[175] This was the state of matters when Dr. Budden passed away suddenly in August of that year—1954.

Back to Texas

In 1954 Schlichting left most of the national efforts to A.R. Hedges, who had the advantage of working from Oregon and so of having a stable licensing situation around him. The year was spent in Texas getting ready for the 1955 legislative session and weathering a summer of bad news that was beyond the profession's immediate control. Harry Hoxsey was a controversial figure before naturopathy was licensed in Texas in 1949, if not widely known outside the Southwest. After being pursued in the Midwest and charged with practicing medicine without a license for the use of his Hoxsey cancer treatment, Hoxsey opened his Dallas cancer clinic, which grew to a substantial patient volume by the early 1950s.[176]

The Texas Medical Wars

Relevant to naturopathy in Texas, Harry Hoxsey applied for licensing in 1950 under the grandfather provisions of the Texas law, and under the statute, he was deemed qualified to be licensed. First Carroll, and then Schlichting, kept Hoxsey away from the ANA/ANPSA, although Hoxsey had his supporters. But in 1954 when Hoxsey was in the national headlines and consistently reported on in the Dallas newspapers, he was called "the Dallas Naturopath who runs a cancer clinic," and headlines like "Dallas Naturopath Enjoined from Claiming Cancer Cure" appeared. Hoxsey, with the backing of a Pennsylvania state senator, had opened a cancer treatment clinic in the Miners Hospital in Spangler, Pennsylvania. The facility was run by the United Mineworkers Union, and the senator was the hospital's administrator. Convinced of Hoxsey's success in cancer treatment the full backing of the facility was arranged.

But at this point, the federal government moved in to bar the shipment of Hoxsey treatment preparations from Texas to Pennsylvania and the use of the "drugs" in that state. Several months of publicity about the legal dispute joined together "naturopath" and "fake cancer cure" in news coverage. None of this would prove helpful when the Texas legislature went into session in January 1955 and the Texas Naturopathic Physicians Association (TNPA) sought to have legislation passed that would overcome the AG's objection to the naturopathic law adopted in 1949.

The TNPA legislative committee under Schlichting's chairmanship hired a well-placed executive secretary who had been the executive director of the Texas American Legion to pursue a legislative fix to the licensing situation. New legislation was prepared with the assistance of former legislators who were practicing attorneys with an eye to resolving the AG's constitutional concerns. The legislation—House Bill 6—was introduced in the state House of Representatives in January at the start of the legislative session. It was quickly passed out of the House Public Health Committee, catching the medical profession off-guard. Then, just as quickly, members of the House started receiving a "flood of protests [that] began to pile up on legislators' desks." In mid-February, the bill was sent to the State Affairs Committee by a 92-46 vote of the House, where the legislation died.[177]

More Hard Times at WSC

After Dr. Budden's sudden passing, the leadership of the governing board of WSC—the Health Research Foundation (HRF)—fell to Dr. Milton Higgens of Couer d'Alene, Idaho. Dr. Higgens was himself a DC, ND, although Idaho had not licensed naturopaths. Dr. Higgens had been the Idaho representative to the NCA for several years and had been a friend and colleague of Dr. Budden and a director of the HRF for many years as well. Higgens realized in short order that the HRF would have to succeed Dr. Budden in setting WSC policy and that he would need to find someone to take over day-to-day management of WSC as well.[178]

In December 1954, Dr. Ralph Failor, DC, ND, a Portland-based alumnus of WSC (a class of 1953 member) signed on to do this job. As correspondence between Dr. Failor and Dr. Higgens demonstrates that Failor was established at WSC as more of a senior VP; he managed the college day to day on-site but with tightly constrained authority. He wrote full letters to Dr. Higgens once or twice a week and sought and accepted guidance from Dr. Higgens constantly. Dr. Higgens's guidance came in responsive correspondence, also once or twice a week.

The Failor–Higgens correspondence from December 1954 through April 1955, has three constant themes: on a day-to-day, week-to-week basis finances were very tight; the prospects for the future were very bleak; and the chiropractic and naturopathic professions were no help, although they were always "supportive"—lots of "thoughts and prayers."

The professions were particularly frustrating to Dr. Failor. As of April 1955, Dr. Failor had met with the "liberal" DCs of Oregon and Washington as well as the NDs from both states and the NDs from British Columbia. The DCs in Oregon were "supportive" but more concerned that the NCA needed to help the practicing profession more than anything. Legislative matters kept arising, and Dr. Budden was not around to address these anymore. The Washington NDs and "liberal," NCA-connected DCs needed WSC's structural appearance for their purposes, more than the actual institution; both professional groups needed to be able to cite WSC as the "model" for DC and ND education but took the existence of the college for granted.

Nothing highlighted this more than a proposal from the Oregon NDs when Dr. Failor met with their leadership to ask for financial help. As communicated by Dr. Failor to Dr. Higgens: "They asked if we would accept money sufficient to put out a Naturopathic catalogue. I said yes we would. Then, they said, well that is contingent on your [sic] writing the catalogue as we want it written." Meetings with the Washington NDs focused on the NDs submitting legislation that would use the WSC curriculum as an educational model.

Dr. Failor had received contact from both the Florida and South Carolina ND Boards asking for catalogs from WSC to document that an ND educational institution did exist. Dr. Failor wrote to Dwight James, the national executive secretary, to clarify the situation; on behalf the national AANP, Mr. James offered "that the word phytotherapy instead of Herbology, and Naturopathic Medicine instead of non-medical was to be almost a must in the new issue [of the catalogue]."

By the end of the spring term in 1955, Dr. Failor had become frustrated and dismayed by what he saw as WSC's financial status and even more so with what he saw as WSC's financial prognosis. As early as February 1955, Dr. Failor was recommending to the trustees of the Health Resource Foundation that governed WSC that the doors be closed, but the Board refused this assessment.

As Western State's historian Lester Lamm described the situation in the first academic year after Dr. Budden's death:

> *Unfortunately for Dr. Failor, he unknowingly accepted the leadership position at the beginning of one of the most troubling periods in the college's history. The deluge of postwar students that created the boom period dried up overnight, leaving the college to face almost insurmountable financial difficulties. In response to student demands for a better education in better facilities, the college had moved to a new campus in 1947. It had retooled its curriculum, increased its admission requirements, added new faculty and staff, and assumed additional obligations in anticipation of a financially robust future. In short, by 1955, the college was overextended.*

The peak year of G.I. Bill college enrollment nationally was 1947. Across the country. institutions of higher education scrambled to accommodate demand, adding and improving facilitates and faculty. As Lamm noted, WSC was part of this great national response to a newly created marketplace for higher education that became a core piece of the postwar American middle class. This cumulative effect on Western States was borne out by a March 1955 report by Dr. Failor to the HRF Board:

> *At a meeting of the board a month later, Dr. Failor shared a compilation of enrollment data from the previous four years. The trend was beyond alarming; it prognosticated doom.*

1.1.1.1.1.1.1.1 1950–51	*1.1.1.1.1.1.1.2 177*
1.1.1.1.1.1.1.3 1951–52	*1.1.1.1.1.1.1.4 151*
1.1.1.1.1.1.1.5 1952–53	*1.1.1.1.1.1.1.6 125*
1.1.1.1.1.1.1.7 1953–54	*1.1.1.1.1.1.1.8 99*
1.1.1.1.1.1.1.9 Spring 1955	*1.1.1.1.1.1.1.10 68*

> *Only 24 students were projected to enroll in the fall class.*

The declining enrollment through 1953 to 1954 was consistent with the G.I. Bill wave effect, and by the fall of 1954, it was known that the G.I. Bill benefits were scheduled to expire in June 1956 and were not expected to be further extended by the Congress. This meant that students who enrolled after the fall term in 1952 would at some point have to pay their own way. For the entering class of 1954–1955 (the class of 1958), the numbers were further depressed by the new 2-year college attendance prerequisite. Dr. Failor reported that of 49 solid applications for admission in the fall term of 1954, 30 were advised that they did not meet the entrance requirements, and only 19 students could be accepted.

Dr. Failor and WSC's School of Naturopathy

Some of this was undoubtedly foreseen by Dr. Budden, and it seemed like Dr. Budden had been forced to navigate the choppy seas of being a DC, ND "schoolman" for 25 years. What his plan might have been, though, no one seemed to know. The HRF Board was now two members who had worked with Dr. Budden for years plus Dr. Budden's replacement directly recruited by Dr. Nugent of the Council of Education of the NCA. They continually instructed Dr. Failor to stay the course and carry out Dr. Budden's vision. It was hard, though, for Dr. Failor to see the way.

As Dr. Lamm reports:

> *Dr. Failor met with a number of naturopathic trade organizations throughout the Pacific Northwest over the subsequent months to solicit support. Most in the naturopathic community voiced support of the college, but little in the way of direct financial backing ever materialized. What did materialize, however, was the naturopaths' growing resentment for the lack of representation on the HRF board and at the college. The naturopathic community had not gotten over being ignored when they first brought their concerns about equitable representation to Dr. Budden in 1948. Dr. Failor's appeal to the naturopaths for support only widened the rift between the two disciplines.*

Dr. Budden had always been in a position to speak to the naturopaths as one of them. This personal relationship earned over 25 years was gone. Unlike 1948, Robert Carroll was not around to tell the naturopaths to "buck up" and support the only school that they had. In May 1955, matters came to a head at a special meeting of the HRF Board with the naturopaths of WSC, plus members of the naturopathic and chiropractic professions from Oregon, Washington, and British Columbia—those most affected by developments at WSC.

This meeting followed a meeting on the evening of Thursday, May 12, 1955, of Dr. Failor, Dr. Higgens, and Dr. Williamson, the secretary of the HRF Board of Trustees. Also present by invitation were two well-placed DC, NDs, Drs. Ralph Hill and Ross Elliott. The discussion focused on the "paramount" financial issues: that monthly revenue was $4000, whereas expenses were $500; with faculty underpaid, fixed costs deemed "excessive," and "old, delinquent accounts" also deemed excessive. Further discussed was that the HRF trustees were constantly accused of falsifying the financial status (i.e., "crying poor"), carrying out a "silence campaign" (i.e., refusing to provide specifics publicly), and that "Dr. Higgens was trying to close the College."

Also, the various DC and ND professional interests in Oregon and Washington were discussed as they affected WSC. These interests were summarized in the meeting minutes: "Chiropractic: O.A.C.P. Liberals—want controls; Advertisers—want controls; Straights—want no part; Naturopaths: Nature Group—want no part; Medical Group—want shots and medicine included in the Naturopathic Curriculum at College (Not permissible under our Charter.)." In short, the professional groups either wanted much more say where the college was concerned or had no interest in the affairs of the college.

Drs. Higgens and Williamson decided, according to the minutes, to "call a meeting of the Full Board for Saturday, May 14th, 1955." In addition to the HRF Board, it was determined that the professional groups, specifically including the OACP and "officials of the naturopathic Physicians," would be invited to provide "council [sic] and suggestions."

On the afternoon of May 14, the meeting took place. Unfortunately, a reading of the minutes of the meeting can only be summarized as "things went badly."

Naturopathy in the Cross Hairs

Dr. A.R. Hedges—then finishing his third year as the president of the national naturopaths (now named the American Association of Naturopathic Physicians [AANP])—could not attend due to a family illness. This was unfortunate, as from the notes of the meeting, it appeared that Dr. Higgens and Dr. Hedges got along, but most tellingly, it appeared that Dr. Higgens and Dr. Bleything did not—or at least that Dr. Bleything was suspicious of Dr. Higgens's longtime membership in and connections with the NCA and Higgens's friendship with Dr. John Nugent of the NCA.

One of the issues that had the naturopaths most agitated was the attitude of the Council on Education of the NCA. As Dr. Lamm reports:

> *Sensitive information contained in correspondence and conversations between WSC and the Council on Education had been leaked to the naturopaths. Most alarming to the naturopaths was the suggestion that WSC would be denied accreditation from NCE if it didn't discontinue offering the ND degree … A letter from the CE was read to the attendees, which clearly described its position*

regarding the relationship between the two professions. Even though the letter contained no threat from the CE to deny WSC accreditation, it was clear a "divorce" was being encouraged.

The attitude that drove the Council on education—made up of the other NCA "schoolmen"—was summarized by Dr. Higgens as "[the] Association felt that WSC was taking too many Chiropractic students and making Naturopaths of them." Higgens told the naturopaths at the meeting that Dr. Nugent—even though as the director of education for the NCA he reported to the Council, and was therefore "the Messenger"—was "recommending against great pressure that we continue Naturopathy at WSC, is fighting the battle for us in the NCA." And in fairness, Dr. Budden did *not* take chiropractic students and make them into naturopaths; he took students and made them into chiropractic and chiropractic-naturopathic *physicians.* And as Higgens told the meeting, there "is no difference between Chiropractic and naturopathy, in this state [Oregon] where most men have two licenses—most do not know which they are practicing under."

Events over the next year would bear out what Higgens said about Dr. Nugent. Although Dr. Nugent generally did not favor dual-degree programs, he had been a staunch friend and admirer of Dr. Budden as a schoolman and honored Dr. Budden's vision after Budden was gone. The rest of the schoolmen on the NCA Council had tolerated Budden's position while he was alive, on the Council and in their midst. They were not inclined to be tolerant after Dr. Budden could no longer argue the case himself.

Bleything told Higgens at the meeting that if naturopaths were on the Board of the HRF and therefore had more say about the future of WSC, the naturopathic profession would contribute to the college. The overriding concern appearing in the meeting minutes was that the NCA Council would threaten to strip WSC's accreditation unless the naturopathy program was dropped and that because the HRF Board was three chiropractors now, they would abandon the ND program if the threat was made.

Higgens acknowledged that this could materialize as soon as the July NCA meeting. Bleything told the meeting, and Higgens, that if the HRF Board was expanded from three to five and the new seats were given to the naturopaths to fill, the naturopaths would commit financial resources to WSC, as the matter had been put before the Oregon Naturopathic Physicians Association, stating, "If Naturopathic profession gets representation on that Board you will get $10,000 without bowing to Nugent or anybody else." Higgens was openly resistant to expanding the Board, but when the meeting ended at 5:45 that afternoon, the HRF founders group convened to Dr. Failor's office, and by six they announced that they had voted to expand the HRF Board to five members, at least two DCs and two NDs.

Dr. Higgens had become the dominant player in the present and future of WSC since the passing of Dr. Budden. He was dedicated to the continuing existence of Western States as a chiropractic college, accredited by the National Chiropractic Association. From his correspondence with Dr. Failor, it is apparent that although he had his own dedication to the School of Naturopathy, he had no expectations that the naturopathic profession would be of any financial help in the effort to keep the school open. He had learned through Dr. Failor's efforts not to have expectations of the Oregon DCs as well. As an executive director of the NCA, he *did* have expectations of the NCA Council on Education and the NCA generally. Critical to him, as a result, was maintaining NCA accreditation.

On June 4, 1955, the 46th Annual Commencement of the Western States College of Chiropractic and Naturopathy was held. In spite of financial pressures, WSC was still open, and in spite of the critical observations by the Council of the NCA, 22 doctor of chiropractic degrees and 1 doctor of naturopathy were awarded (along with three X-Ray Technician Certificates and two Laboratory Technician Certificates).

The NCA met in early July, and although the Council minutes from that meeting reflect no on-the-record discussion of the WSC naturopathy program, immediately after the Council meeting, the HRF reversed itself and reinstated the three-member Board provision. For whatever reason, no financial commitment to WSC ever materialized from the naturopaths, and as of the 1955–1956 school year, the matter remained unresolved, with the naturopathy program under a cloud.

THE END

Things remained as dire as they had been during the main school year as the summer term was to begin. Dr. Failor had advised Dr. Higgens in correspondence that Dr. Bleything would organize and run the summer term on a no-pay basis. Bleything and others who similarly volunteered taught the summer term, and on September 27, 1955, 13 of the DC graduates from June received their ND degrees, and the lone ND graduate from June—Canadian Robert Fleming—received his DC degree.

But neither the school nor the naturopathy program was out of the woods. Dr. Lamm writes:

By the July 23, 1955, meeting of the HRF board, it was apparent to the trustees that continuing an affiliation with the naturopaths would be problematic if WSC was to achieve accreditation. At the meeting it was said, 'We are privileged to continue naturopathy… [until] we can gracefully work out a solution.' … It was clear by the reaction of the naturopaths that financial support for the college would not be found with them.

How or why this "was clear" based on events between May 19 and July 23 *does not* seem clear. It seems that before the addition of two new members to the Board could be implemented, and presumably based on issues that arose during the NCA meeting in Atlantic City, July 4–8, 1955, the Board withdrew the one condition that the naturopaths put on their financial support for WSC. (The minutes of the Council on Education meeting during this NCA annual convention do not reflect any on-the-record discussion of the naturopathy program. Dr. Failor *was* present and participated in the 3 days of Council meetings, which focused considerable attention to the 2-year college preparation admission requirement.)

How or why the naturopaths let the established WSC naturopathy program be discontinued is lost in the fog of history. It is clear that the naturopaths associated with Western States trusted Dr. Budden and worked well with the Oregon Association of Chiropractic Physicians, the Oregon NCA affiliate. Indeed, as Dr. Higgens observed, the professions in Oregon had substantial overlapping membership. But Dr. Failor, as a DC, ND, asked for help that was not forthcoming: "Dr. Failor met with a number of naturopathic trade organizations throughout the Pacific Northwest over the subsequent months to solicit support. Most in the naturopathic community voiced support of the college, but little in the way of direct financial backing ever materialized."

So the determination of whether to continue the naturopathy program or not was left to the HRF Board and its dealings with the NCA Council, which was hostile to the naturopathy program. Again, in fairness, Dr. Higgens told the Washington NDs in January and again in March that they should dispatch a representative or representatives of their own to the NCA Council to present the naturopathy program as an integral part of Western States and ask that both WSC's ND program *and* its accreditation be maintained as they had been during Dr. Budden's lifetime. But they never did so.

The End, Part 2

Matters came to a head during the midyear NCA Council meeting in Toronto, Canada, February 15–17, 1956, as reflected in the meeting minutes. In September 1955, as the 1955–1956 school year had begun, Dr. Higgens had stepped in to try to at least stabilize WSC's finances:

> *In response to a clearly desperate situation and in an effort to bring about financial stability, Dr. Higgens stepped forward on Sept. 8, 1955, and committed his personal assets by securing a $39,000 mortgage on behalf of the college and took out a $10,000 life insurance policy, naming the college as beneficiary. This was not the first time Dr. Higgens had reached for his checkbook to rescue the college, nor would it be the last. Regardless of the deteriorating situation at the college, and perhaps in spite of it, he was committed to doing everything possible to guarantee survival of WSC.*

If WSC had been Dr. Budden's school for 25 years, it was now firmly Dr. Higgens's school, governed by him and the two fellow chiropractors on the HRF Board. At the meeting in May 1955, Dr. Higgens had been openly questioned about his personal commitment to continuing WSC as a School of Chiropractic *and* Naturopathy. By the time of the February 1956 NCA Council meeting, it seems apparent that Dr. Higgens's commitment was to maintain an NCA-accredited School of Chiropractic, even—or perhaps especially—if that meant dropping the Naturopathy program at WSC. Although Dr. Failor, as the day-to-day manager of WSC in-the-trenches would have welcomed the financial support of the naturopaths and *could* have saved the Naturopathy program if support had been forthcoming, when support *never* materialized, the decision was really that of Dr. Higgens.

The minutes of the February NCA Council meeting tell the story. Dr. Failor had advised that he could not attend and represent WSC "because of pressing responsibilities at the college." And, one assumes, because of the cost of attending the meeting.

The meeting was scheduled for 3 days, Wednesday, February 8, through Friday, February 10, 1956. The "*first* point of consideration placed before the Council from the prepared agenda was the matter of the Western States College of Portland, Oregon, still conducting a course in naturopathy" (emphasis provided). The Chair of the Council (Dr. Thure Peterson) read an "extended statement" prepared by Dr. Nugent and sent to Dr. Higgens "in relation to the matter." The position set out in the statement was to advise Dr. Higgens and the HRF Board that the Council "considers it inopportune for any of the accredited colleges to seek to sustain a naturopathic course."

The Council further "encouraged the board to consider the *necessity* of discontinuing the course as soon as possible, *even at cost and sacrifice of certain advantages that it might represent*" (emphasis provided). Council member Dr. Hendricks noted that it was time for Western States to join Los Angeles and National and "discontinue its affiliations with the naturopathic profession." Failure to do so "would constitute an embarrassment to the Council."

Then Dr. Nugent spoke, and it was apparent that he—regardless of personal feelings on naturopathic programs—felt bound to try to honor the lifelong commitment of his friend and colleague Dr. Budden:

> *Dr. Nugent sought to advise the Council that relinquishing the naturopathic course by Western States College would impose on the college and its board of trustees tremendous economic problems and rob it of certain allegiance … It was the conviction of Dr. Nugent that a decision by Western States College to discontinue the naturopathic course would deal a severe blow to naturopathy and that unless the profession were to organize its own school it might well represent the demise of the profession …With Western States out of the picture of naturopathic education only two schools would be left that issued naturopathic degrees and these were institutions of minor quality and influence; namely the Great lakes College of Mechanotherapy and in Dayton, Ohio, and Spitler College of Naturopathy in Eaton, Ohio.*

These observations by Dr. Nugent came straight from Dr. Budden's long-stated positions expressed during many talks on the subject with Dr. Nugent and others in NCA leadership. In deference to Dr. Budden, Dr. Nugent set this entire argument out for the Council. He then communicated that these may not be the concerns of the current HRF Board governing WSC. Dr. Nugent told the Council that "upon the death of Dr. Budden, he [Dr. Nugent] had been asked by Dr. Higgens to help manage the Western States [College] and to help solve the naturopathic situation … that Dr. Higgens, personally, had invested thousands of dollars in the Western State College [because of his intimate friendship with Dr. Budden], yet he was ready to sacrifice the same if the naturopathic problem could be resolved; that he, Dr. Higgens, was anxious to have the Western States College sever its association with naturopathic education."

After all was considered "it was the general disposition of the Council that patience should be exercised in relation to the circumstances of Western State College," as through "the death of Dr. Budden … the present administration and board of trustees of the college had inherited many compromising and not readily solved problems." Dr. Nugent advised the Council that he was certain that before the Council meetings concluded, "he would obtain word that "a definite decision to eliminate the naturopathic course at Western States had been consummated."

And Naturopathy Is Finished at WSC

And so it was. As the Council convened on the morning of Friday, February 10, the Council was to hear the report of the Council on Educational Standards (Accrediting Committee). The Accrediting Committee proposed that the Council adopt a resolution that Western States "beginning September 1, 1956 … should seek to discontinue students for training in naturopathy" and "terminate its commitment to those naturopathic students enrolled." Dr. Nugent advised that he had spoken several times to Drs. Higgens and Failor since Wednesday morning, and that they understood that this step would be necessary "although it would involve extended financial loss and … the college might not be able to survive." Further that they had announced the day before during an all-school meeting that the decision had been made to discontinue the naturopathic course."

The Council meeting minutes note that the Council had received a copy of "A Statement of Policy on Western States College" that constituted the formal announcement of the decision to all concerned, and that the Council had responded through the Council secretary, Dr. Janse, acknowledging the "courage and integrity" that this decision had required. Within a short period of time, the naturopaths associated with Western States determined to start an independent naturopathy program, initially intended to provide an ND program for WSC's DC graduates who were desirous of an ND degree. In July, three NDs previously associated with WSC, Drs. Bleything, Spaulding, and Stone, chartered an Oregon not-for-profit corporation, the National College of Naturopathic Medicine (NCNM).

But this separation was the kind of "divorce" that left both parties worse off. Dr. Higgens had clearly hoped that the NCA would lend financial assistance to WSC with the "naturopathic issue" resolved. Instead, WSC suffered a severe enrollment decline and financial distress for almost 15 years, with average DC class sizes of 12 to 15 and a total enrollment of 50 to 60. The NCA responded with "hopes and

prayers," restricted accreditation, and suggestions that WSC should be merged with either Los Angeles or National—the two stronger programs with which they had a historical affinity.

Meantime, the NCNM proved to be a difficult proposition, as the ND profession of Oregon, Washington, and British Columbia tried to build a 4-year residency program. It was 15 years before the program—moved to Seattle in terms of actual facilities—began to have decent attendance in the early 1970s.

And all of this had taken its toll on Dr. Failor, DC, ND, as well. As Dr. Lamm reports:

> *Dr. Failor approached the Oregon Association of Chiropractic Physicians (OACP) with his doubts that the college could survive beyond July 1, 1956. The total student population was 73 and a number of disgruntled students announced their plans to transfer to the new naturopathic program starting in the fall. Dr. Higgins appealed to the National Chiropractic Association to support a policy compelling all chiropractic colleges to adopt a two-year, pre-professional college education admissions requirement. The NCA refused to budge.*
>
> *By summer 1956, frustration with lack of support from the NCA, CE, OACP, NDs and DCs; compounded by the student, staff and faculty discontent on campus and a worsening financial situation at the college was more than Dr. Failor was willing to tolerate any longer. He submitted his letter of resignation to the HRF. Even though he had repeatedly recommended closure of the college and left the institution saddened and disappointed, he was effective in instituting stopgap measures that kept the college solvent. Without Dr. Failor's efforts, the college would have closed.*

The educational structure of naturopaths had been severely damaged. And in Texas, the profession began to suffer damage as well.

Back to the Texas Medical Wars

The full story of the 1955 Texas legislative session where the naturopaths were concerned would not be told until the legislature reconvened in 1957, but by now, it had become well known that the AG had determined the old law unconstitutional.

After the legislature recessed without action, the state comptroller refused to pay any further warrants issued by the existing Naturopathic Examining Board given the AG's ruling, effectively putting the Board out of business.[179] In January 1956, using legal counsel retained by the TNPA, the Board filed suit against the comptroller asking the court to uphold the statute and order the comptroller to pay its bills. In May 1956, the district court judge hearing the case ruled in favor of the Naturopathic Examining Board and against the comptroller represented by the AG. The district court upheld the statute as constitutional as to the licensing and registration of naturopaths and directed the payment of warrants issued by the Board.

The comptroller's office filed an appeal, and the matter began working its way through the Texas appellate courts.

In 1957 matters played themselves out badly for the Texas naturopaths in a very public way.[180] The 1957 Texas legislative session began in late January 1957. At the time, the appellate case on the constitutionality of the 1949 statute was pending. Henry Schlichting had been succeeded as president of the TNPA by Howard Harman of San Antonio. The naturopaths were trying in this session to once again get legislation passed that would deal with the AG's opinion. At the end of February, Dr. Harmon went to the Speaker of the Texas House of Representatives with a tape recording on which a member of the Texas House appeared to solicit a bribe to withdraw legislation that would repeal the 1949 law and ban naturopaths from practicing in Texas.

This led to House investigative committee proceedings, a grand jury investigation, an indictment against the legislator, and the legislator's conviction. All of this played out between March 1957 and September 1957, with constant newspaper coverage throughout the state of Texas. It also had two unfortunate effects: few legislators wanted to have anything to do with the naturopaths while this was going on, and first the House investigative committee and then the grand jury dug up the story of the naturopaths' activities during the 1955 legislative session.

What emerged was that the naturopaths had raised a "war chest" of as much as $52,000 for the 1955 session and had spread around among members of the legislature perhaps as much as $37,000 or more to try to get legislation passed. In 2018 dollars, this would be $480,000 dollars raised and $345,000 passed out in legislative "cash gifts." It was rumors of this type of largesse that drew the interest of a young member of the House of Representatives to Harmon as TNPA president while he was in Austin—the state capital—for the 1957 session. The bribe solicited was $5000 total, $3000 for the representative and $2000 to share "with others." In 2018 dollars, this would be $45,000 total, $28,000 for the representative, and $17,000 to "share."

The naturopath caught up in the inquiry into the 1955 legislative activities of the Texas Naturopathic Physicians Association was Henry J. Schlichting Jr.

Texas Medical Wars Continued—1957

While the 1957 Texas legislative fireworks were playing out, the legal process was playing out at the same time.[181] In late January 1957, as the legislative session was getting under way, the Texas Court of Appeals upheld the AG's opinion and reversed the district court. The court held that the 1949 Naturopathic Act was unconstitutional, as the AG's opinion had concluded. The legal effect, as stated by the court, was to completely undo the legislative gains that the naturopaths had been granted under the 1949 "deal" that had given the medical profession a Basic Science Law: "The judgment of the Trial Court is reversed and judgment is here rendered declaring the Naturopathy Act, Art. 4590d V.A.C.S., *void*" (emphasis provided).

In February, Dr. Howard Harmon of the Texas Naturopathic Physicians Association tape-recorded House of Representatives member James Cox soliciting a bribe and took the recording to the Speaker of the House. In March, a legislative investigative committee was convened by the Speaker and—after an emotional "farewell" address to the House—Cox tendered his resignation, which was accepted by the governor. In April, a grand jury was convened, which took testimony about the bribe allegations and also about another matter that had emerged during the legislative hearing: allegations of a "slush fund" that had been used by the TNPA during the 1955 legislative session to "educate" House members with regard to legislation proposed by the TNPA after the AG's opinion had been issued in 1953.

If these assertions about the size of the "slush fund" and the extent of "educational" efforts were true, it had been for naught in 1955. The remedial legislation had been reported out of the House Public Health Committee early in the 1955 session—allegedly as a result of the TNPA "education" efforts—only to die before going any further. When the bill was quickly pushed through the committee process, the medical association took note, and before the matter could come to the House floor for a vote, a "flood of protests" from MDs "began to pile up on legislator's desks," and the bill stalled.

As the House investigation was proceeding in April, the statements of a "mystery witness" were produced by the Texas Department of Public Safety (DPS). The committee abruptly stopped its hearings and referred the matter to the grand jury. In mid-April, the grand jury heard from other NDs appearing before them about the "mystery witness," who was identified as Henry Schlichting Jr. Other NDs told the

press that "Schlichting was the only person who knew how the association's money was spent during past sessions of the legislature." On April 30, 1957, the grand jury heard from Schlichting, who had given a lengthy interview and sworn statement to the Texas DPS the week before.

After his appearance, Schlichting steadfastly gave "no comment" statements to the press, and never did he disclose what he testified to, nor the details of what the TNPA had done with its "slush funds" and "educational" efforts over many years. Another ND who appeared before the grand jury told the press that Schlichting "held his hand on the purse strings since 1943 and still does [in 1957]." But whatever Schlichting disclosed to DPS investigators and the grand jury in March and April of 1957, no indictments were ever issued against anyone accept Representative Cox for soliciting the bribe from Dr. Harmon.

But the entire Harmon–Cox–naturopaths bribery affair had a dampening effect on both the 1957 legislative session and the naturopaths as an interest group desperately needing legislative action. In an extensive two-part investigative report,[182] a reporter for the *El Paso Herald-Post* noted for the "Frantic Fifty-Fifth" legislative session that lobbyists had gone into hibernation when "the naturopaths got cute with their tape recorders" as the legislature began "shaking with a severe case of capital J jitters resulting from the naturopath tape recording in the Representative Cox bribery scandal." Just as significant for the naturopaths was the direct effect on them:

> *You won't find any naturopaths trying to influence legislation during these nervous days. They're now on the inactive list as far as lobbying is concerned—maybe because they figure they've raised their share of turmoil this session, or because they're too busy testifying before the Travis County Grand Jury, whose deliberations are being watched with such big interest by the legislators … Dr. Howard Harmon, the naturopath lobbyist whose tape recording brought about the Cox indictment, hasn't eased the situation any with his forecast that half a dozen lawmakers besides Representative Cox have ample reason to worry.*[183]

In so many ways, these developments could not have come at a worse time for the naturopaths in Texas. On May 1, 1957—the day after Schlichting appeared before the grand jury as the "mystery witness"—the Texas Supreme Court refused to hear the writ of error (appeal) by the Naturopathic Board of Examiners from the court of appeals decision against the 1949 Naturopathy Act. On June 12, 1957, the Texas Supreme Court rejected a request for rehearing of the application for a writ of error, leaving the naturopaths without any further relief at the state-court level. Within 60 days, the naturopaths applied for relief from the US Supreme Court; throughout these various legal steps, the Texas courts stayed enforcement of practicing medicine violations pending the final legal determination of the validity of the 1949 law.

In October, former representative Cox went on trial for bribery, and the newspapers throughout the state had the naturopaths on the front pages again. After the testimony of Dr. Harman and the playing of the recording that Harman had produced, Cox was found guilty as charged. On November 12, 1957 the US Supreme Court declined review of the Texas court decisions on the 1949 naturopathy law.

Texas—The End

On December 3, a massive statewide series of legal actions was taken across 27 Texas counties[184] coordinated by the Texas AG, who vowed to "run the naturopaths out of Texas." In the first "test case" arising out these actions taken in the name of the Texas State Board of Medical Examiners, an injunction was entered on December 9 against Henry Schlichting, enjoining him from continuing to practice naturopathy in the state of Texas without a license to practice medicine. Multiple other injunctions were entered against naturopaths in other counties across the state. For good measure, the AG asked for—and received—an injunction against the continued existence and activities of the Texas Naturopathic Physicians Association.[185]

The naturopaths in Texas—about 450 of them—were in fact out of business.

The case against Schlichting was appealed, and an accelerated review was granted by the Texas Supreme Court. Arguments were heard by the court in January 1958, and a decision was handed down on February 19, 1958. The Texas Supreme Court upheld the injunction against Schlichting. The US Supreme Court later denied review. The Texas career of Dr. Henry J. Schlichting Jr., naturopathic physician, was over.[186]

Schlichting stayed on in Midland, where he had built a solid reputation as a citizen, for another 7 years, practicing as an audiologist working for one of the largest hearing aid companies in the United States. His hearing clinics were regularly advertised, and his appearances at out-of-state gatherings of naturopaths were mentioned in the Midland and Pacific NW newspapers. Then, in 1965, he left his adopted home state of Texas and established a naturopathic practice in Phoenix, Arizona. In 1973 at the age of only 58, he died suddenly at home on a Sunday afternoon. He was taken back "home" to Midland as his resting place.[187]

Three More States Fall: 1955 to 1957

With both WDC and the state of Texas lost to naturopathy, the decline of natural healing accelerated. Licensing was lost in Georgia and in South Carolina, both in 1956. In Utah and Florida—after an extensive review of the profession and its lack of educational institutions—prohibitions were put in place against any further issue of licenses as of 1957. In Florida, after a successful court challenge to the initial action, new legislation was passed in 1959 reinstating the ban on further licenses. In all of these cases, three issues turned the tide against naturopaths: no legitimate school, declining numbers nationally (from no new graduates and 450 licenses gone in Texas), and intense opposition to natural healing by the AMA and its state constituencies.

Naturopaths were first licensed in Florida in 1927.[188] At that time, Benedict Lust had for some years operated his second Yungborn Sanitarium in Tangerine, Florida, in the Tampa Bay region of the state. The legislation adopted defined naturopathy as a "drugless" law, consistent with pre-1939 concepts of that term: "The use and practice of psychological, mechanical and material health sciences to aid in purifying, cleansing and normalizing human tissues for preservation or restoration of health … employs heat, light, water, electricity, psychology, diet, massage and other manipulative methods."

Naturopaths were licensed in South Carolina in 1937 under the leadership of M. S. Dantzler of Spartanburg. South Carolina was a state where the early chiropractic movement was dominated by "straights," and the "mixers" became naturopaths to achieve their own identity before the legislature. The original 1937 law was modeled directly after the Florida statute. ("The use and practice of psychological, mechanical and material health sciences to aid in purifying, cleansing and normalizing human tissues for preservation or restoration of health … employs heat, light, water, electricity, psychology, diet, massage and other manipulative methods").[189]

In 1941—on the eve of WWII—the statute was amended with this addition: "The use and practice of phytotherapy, minor surgery, obstetrics and gynecology, autotherapy and biologicals shall be a part of and included in the practice of naturopathy." The difficulties weathered by naturopaths in South Carolina from 1947 to 1949 after the Tennessee scandal have been discussed. Significantly, these problems were resolved by giving the state Board *more* enforcement powers so that the Board could better police the profession.

The Florida Saga Begins

In Florida, naturopaths in the greater Miami area of the state pushed to have the law interpreted to allow the right to prescribe drugs after the 1939 regulations were put in place at the federal level. Using the courts, this effort was successful in 1947 in convincing the Florida Supreme Court to interpret the reference to "phytotherapy" in the Florida statutes to include all drugs derived in any way from plant origins, including morphine and opium derivatives. In 1949 this created a significant—and predictable—backlash.[190]

In early April 1949, the State Board of Health, through its five-member governing body, adopted a resolution urging legislative action regarding "the licensing and practice of naturopathic physicians," with a finding that: "The board has information that the practice of naturopathy including the licensing of naturopathic physicians, and the treatment of patients of licensed naturopathic physicians is being conducted in such a manner as to be detrimental to the public health of Florida."

The next day, legislation was introduced in the Florida Senate to make the practice of naturopathy unlawful in the state, and the bill was referred to the Senate Committee on Public Health. Pending the hearing by the committee on the bill, the State Health Officer, a medical doctor, picked up the attack on licensed naturopaths, who at the time numbered 239. The concerns expressed were that naturopaths had been "drugless physicians" who opposed drugs as contrary to the natural maintenance of health and natural methods of healing, that naturopaths had no training in the use of *materia medica,* that no other state allowed such practices by naturopaths, and that the state of Tennessee had just determined that much of naturopathic education was a fraud, yet some Tennessee licensees were among the NDs in Florida now using drugs.

On April 19, 1949, the Florida Naturopathic Physicians Association ran a quarter-page ad in the *Miami Herald,* Florida's largest newspaper. The ad was entitled "NATUROPATHS ANSWER THE ATTACKS OF THE STATE BOARD OF HEALTH, An Open Letter to: Wilson T. Sowder, M.D., State Health Officer." In this "open letter," the NDs defended their record of having "used narcotic drugs under Federal Government regulation [for] several years during which they did not abuse or misuse the privilege." The letter further defended the way in which NDs designated their practices; conformed to the laws, including the court decisions on prescription authority and naturopathic educational standards established under the law; and questioned the good faith of an MD as "promoting monopolistic legislation … of the American Medical Association" rather than serving "the people of Florida."

The Senate committee held an all-day hearing the next day and heard a carefully marshaled presentation on these issues, including hearing the testimony of Harry Avery—the Tennessee investigator—as well as a state narcotics investigator and a regional federal narcotics inspector. The naturopaths were represented by legal counsel who was allowed to question the witnesses who appeared. More than 100 NDs attended the session. Although both narcotics inspectors argued against the NDs having prescription authority, both acknowledged under questioning that there had been no reported narcotic violations against Florida naturopaths.

As the hearing closed, the sentiment of the committee seemed to be that although tighter regulation would be in order, the bill outlawing naturopathy was too much. But the record was mixed. Most of the NDs had been licensed before the Basic Science Law had been adopted. Of the 239 licensees only 22—all from National College in Chicago—had passed the BSL examination. Many practitioners had diplomas from Lust's American College of Naturopathy; it was admitted into the record that Lust had been charged in 1934 with operating an unchartered school in New York. As the hearing closed, the committee chair put into the record a stack of 700 telegrams and 50 letters opposing the bill and 5 letters supporting the bill.

The committee voted at about 8 o'clock in the evening to not report the bill out to the Senate by a vote of two "for" and seven "against." One takeaway was important, though: one of the "for" votes was from State Senator Leroy Collins of Tallahassee. In the late 1950s, Collins was to become Florida's governor.[191]

The staff reporter who covered the hearings—indeed, the story of the Board of Health position on naturopaths—also contributed a lengthy four-part series on naturopaths in Florida. The one school represented in Florida among the licensed NDs that was clearly legitimate was the National College of Drugless Physicians—the Lindlahr school—founded in 1908 and part of the National College of Chiropractic. About 40 alumni were practicing in Florida, and "even the critical state medical societies that have commented on naturopathic schools don't charge that this college doesn't offer full four-year training, even though they do complain that it does not offer a four-year course devoted *exclusively* to naturopathy" (emphasis provided).[192]

At the conclusion of the reporting on the legislative matters and the general investigation of naturopaths in Florida, the reporter concluded the series with these observations: "Better regulation, rather than prohibition is probably the answer. If naturopaths were not permitted … drugs; … prominently identified themselves as naturopaths; if stricter examination of schools … [was] required—the public and naturopathy would be benefitted."

The Three-State Region

Geographically Georgia and South Carolina share a long common border, South Carolina to the east and Georgia to the west. The common border cuts a line through a common rural area. The Georgia newspapers covered the reports out of South Carolina through the 1947 to 1949 events, and in 1950, the Georgia naturopaths had general legislative support built up for establishing a licensing board that could "cull the quacks" from the state. The acceptance of this idea in South Carolina was noted, and the Georgia legislature followed suit.

Then in 1955, issues arose in both South Carolina and Florida. Geographically "in the middle," Georgia was affected as well. The South Carolina issues started when the state AG ruled that the law did not allow the naturopaths to prescribe drugs, specifically plant-based narcotics such as opium derivatives. The NDs frankly pushed things too far when they took the AG to court over the issue. Although they won the first rounds of the legal battle, the state medical association used the prospect of NDs claiming prescriptions rights, including to narcotics, to raise the issue of these practices being a threat to public safety.[193]

The prescription of such plant-related drugs had first arisen in Florida in the 1940s, and the courts in Florida had held that the NDs had these prescription rights.

But this issue raised conflict in Florida in 1955 as well through a series of investigative articles in the *Miami Daily News* entitled "Who Are the Naturopaths?" The articles—four in number—raised the same questions being raised in the South Carolina legislature: Where did these naturopaths go to school, and how has it come to pass that they can prescribe drugs and do minor surgery?[194]

In South Carolina and Florida, these questions in 1955 and 1956 provoked no acceptable answers. The National College program had been closed in 1950, the Western States program in early 1956. After the scare in 1949, the Florida NDs went on with business as usual. In fact, when the 1955 *Miami News* investigation was reported in November 1955, the only school pointed to by the Examining Board as approved was Western States. Then the program was discontinued in February 1956.

Leroy Collins was now the governor of Florida, and the *Miami News* investigation called him out by name for his legislative opposition to

naturopaths in Florida. Governor Collins commissioned a report from the State Bureau of Narcotics on the state of naturopathy. When the report documented that things had not seemed to have changed since 1949, he announced that one of his legislative priorities for 1957 was outlawing naturopathy in Florida.[195]

In 1955 South Carolina outlawed naturopathy; in 1956 Georgia outlawed naturopathy; in 1957 Florida outlawed the issuing of any new licenses to practice naturopathy. When the original legislation was struck down by the Florida courts, the 1959 legislature renewed the ban on issuing further licenses. Ultimately, the bans in these three states and Texas were upheld by the courts as within the police powers of state legislatures. In the meantime, things were not going well out West either.

Utah

The Early Days

In Utah the authorization to legally practice naturopathy first appeared in 1925 when the legislature passed legal authority for an examining board for physiotherapy and naturopathy under the Utah Department of Registration.[196] The governor at the time vetoed the measure on the basis that such practices were authorized to be licensed under the state medical board as treatment by a practitioner without the use of medicine or surgery. In October 1934, there were 15 naturopaths registered with the Department of Registration through the authorization of the medical board. Finally in 1937, a separate naturopathic board was authorized by the legislature, and the legislation was signed into law this time around. In 1939 legislation was passed into law raising the educational standards for naturopaths to require 4 years of post–high school education.

In each legislative session after 1939—1941, 1943, and 1945—legislation was proposed but not passed to allow for "practicing as a naturopathic physician and surgeon, including obstetrics." But in 1946, it emerged that the naturopathic examining board had been conducting a supplemental examination for obstetrics and minor surgery in addition to a basic naturopathy examination just as the medical board had done before the examination authority had been transferred. These supplemental licenses were then issued by the Department of Registration to license holders.

Utah Opens Up

This only became publicly known in September 1946, when a *second* AG opinion issued in May 1946, was publicly issued and reported by the Utah newspapers.[197] The story was this: In January 1946, a new department director had asked for an opinion from the AG whether naturopaths could be licensed to practice surgery and obstetrics. The AG's Letter of Opinion answered the question no, as both surgery and obstetrics were the practice of medicine, not naturopathy. In so answering, the opinion noted that there was no such thing as "minor surgery"; under Utah law, surgery was surgery.

In May, a *second* AG opinion letter was sent to the Department of Registration with the recognition that since 1939, naturopaths had been examined in "minor surgery and obstetrics," and upon successful passing of the tests, they had been issued licenses to practice. This opinion noted that the statutes "were not free of ambiguity," and therefore the practice of the Department would be deemed an existing "administrative interpretation" of the law, effective until either the legislature modified the statutes or the courts ruled otherwise. Moreover, the opinion went on to state that although licensed naturopaths could not use or prescribe drugs, those licensed to practice obstetrics and surgery *could* use and prescribe those drugs that "were recognized requirements in obstetrics or minor surgery." The opinion further stated that although naturopaths could not use drugs in general practice, they *could* keep on hand or prescribe drugs for communicable diseases or emergencies (e.g., antidotes for poisons) in practice.

And so, as a matter of statutory interpretation, Utah became a state that allowed very broad practices to naturopaths. The legislature never did adopt any statutory language that modified the statutes interpreted by the AG, and the courts never reviewed the matter; this was the status quo until September 1955. In 1955 the Utah Board of Health—not the Department of Registration—requested a *new* AG opinion on the same statutory issues. At the time, the Department of Registration listed 82 naturopaths, of whom 66 were authorized for obstetrics and minor surgery.[198]

And Shuts Down Again

The 1955 AG opinion reviewed the same licensing statutes as the 1946 opinions and came to a completely different conclusion. Naturopaths could not be licensed to do obstetrics and minor surgery nor prescribe drugs. Under this new opinion, the Department gave notice in November 1955 that it would be canceling all of the licenses issued to naturopaths to practice obstetrics and minor surgery, effective January 1, 1956. The naturopaths appealed to the courts but lost before the Utah Supreme Court in June 1956.[199] In the 1957 legislative session, legislation was passed that would have allowed the continued practice of obstetrics, minor surgery, and the prescription of drugs to "reinstate the status quo." This legislation was vetoed by the governor after the session ended.

Also, legislation was passed to fund and commission a study of the education and practices of naturopaths for the use of the 1959 legislative session. The report was devastating in its assessment of the state of naturopathic education in 1959. Essentially, the only school in existence was the National College of Naturopathic Medicine in Portland, Oregon, which at that time was in its early, rudimentary stage. Based on this assessment, no legislative relief was granted to licensed naturopaths in Utah, who were now firmly reduced to practicing without any obstetrics, minor surgery, or prescription rights.[200]

The 1959 legislature did pass a Basic Science Law. Naturopaths *were* authorized to take the midwifery examination and become licensed midwives as well as NDs but only after taking the BSL examinations. Also, naturopaths could take the obstetrics and minor surgery examinations as given by the medical board (not their own licensing board) but only after passing the BSL examination (this according to another AG opinion requested by the naturopathic board in 1961). And finally, from yet *another* 1961 AG opinion, naturopaths were not licensed to do spinal adjustment because by law, naturopaths were separate from chiropractic. From this point, naturopathy in Utah went into a long decline as existing practitioners retired from practice and new practitioners were scarce.[201]

Washington State Under Siege

In Washington, naturopaths had been in practice under the Washington Drugless Healing Act of 1919 since Robert V. Carroll had founded the Washington State Naturopathic Association in 1934. Before that time, all drugless practitioner licenses listed "Sanipractic," and practitioners either called themselves "drugless physicians" or "Sanipractors." Sanipractors used the initials "SP" for Sanipractic Physician. Licenses continued to be issued for "Sanipractic," but many practitioners demonstrated their alliance with Carroll—and through Carroll's WSNA, their alliance with the national ANA—by using the initials "ND" in practice.

After adverse court decisions in 1947 (drugless healers cannot practice surgery or obstetrics), 1950 (drugless healers are not "doctors" and are not allowed standard malpractice defenses), and 1957 (drugless healers can be prosecuted for practicing medicine without a license for using "Dr." or "physician," conducting physical examinations), the Washington naturopaths were completely unsuccessful in getting any legislative relief over the intense opposition of the medical profession. The NDs obtained 53 signatures on a petition submitted to

the Washington licensing department under the Drugless Healing Act and at least gained the right to be licensed to practice "Naturopathy" in Washington. For about 10 years, this obtained a little legal relief for them from some of the bad case law that applied to "Sanipractors."[202]

A Dismal State of Affairs: The 1960s

This once proud and vigorous natural healing movement that existed from after WWII for about 10 years had gone into such decline—as described here—that the naturopaths' self-reported state as of 1968 showed a professional movement almost gone.[203] In 1968 consideration was given by the US Department of Health and Human Services to the request by the National Association of Naturopathic Physicians to have naturopaths accepted as independent practitioners under Medicare. As part of this process, a lengthy questionnaire was completed and submitted by John W. Noble, DC, ND. Noble was a 1937 graduate of Western States College of both the School of Chiropractic and the School of Naturopathy. As of 1968, Noble was a licensed ND in Oregon, practicing in Portland. He was NANP president and also maintained the administrative offices of the National College of Naturopathic Medicine, which had recently moved its main instructional facilities to Seattle.

As of 1968, he reported that the NANP had 168 members from Washington (26), Idaho (26), Connecticut (24), Oregon (20), California (17), Kansas (16), and New York (7). Of these states, Washington, Idaho, Kansas, and New York were not considered licensed states, so almost half of the NANP membership came from unlicensed jurisdictions. Noble reported on behalf of NCNM that from 1960 to 1967, 16 students had graduated, and as of 1967/1968, 7 were enrolled.

According to the 1965 US government publication *State Licensing of Health Occupations,* there were 351 licenses in effect in Arizona, Connecticut, Hawaii, Oregon, Utah, and the District of Columbia—the states still issuing licenses.[204] Also, 202 licenses were renewed in Florida and California—states that were not issuing new licenses as of 1965. This was a total of 553 active licenses. Together with identifiable practitioners in the unlicensed states, there may have been 700 or so identifiable naturopaths, some practicing in extremely restrictive circumstances.

A Future Resurrection

It would not be until the mid-1970s that this serious decline of natural healing in the United States would begin to be reversed and not until the late 1980s that natural healing would return to an equivalency with the profession that was built between the mid-1930s and the early 1950s by Carroll, Budden, Schlichting, and the others discussed here. That was not, obviously, from lack of commitment or effort on their part.

Philosophy of Naturopathic Medicine

Rachelle S. Bradley, ND

OUTLINE

INTRODUCTION

This chapter examines the philosophical foundation of naturopathic medicine and its modern applications. Unlike most other health care systems, naturopathy is not identified by any particular therapy or modalities (e.g., conventional medicine, drugs and surgery; chiropractic, spinal manipulation). A wide variety of therapeutic styles and modalities are found within the naturopathic community (Box 5.1). For example, there are still practitioners who adhere to the strict "nature cure" tradition and focus only on diet, "detoxification," lifestyle modification, and hydrotherapy. There are also those who specialize in homeopathy, acupuncture, or natural childbirth. At the other end of the spectrum are naturopathic physicians who use botanical medicines, nutraceuticals, and pharmacology extensively to manipulate the body's biochemistry and physiology. Finally, there is the majority, who practice an eclectic naturopathic practice that includes a little of everything.

Since its inception 130 years ago, naturopathic medicine has been an eclectic system of health care. This characteristic has allowed it to adopt many of the more effective elements of natural and alternative medicine and to adopt conventional medicine's basic and clinical sciences, diagnostics, and pharmacology. Through all of this eclecticism, naturopathic medicine has always identified the Latin expression *vis medicatrix naturae* (the healing power of nature) as its philosophical linchpin.

However, the expression *vis medicatrix naturae,* by itself, does not provide a clear picture of naturopathic medical philosophy or an understanding of the practice of naturopathic medicine in all of its varied forms. With the profession's history of eclecticism, no two practitioners treat any individual patient exactly alike. This situation has its advantages (e.g., individualization of each patient's care, more therapeutic options) but also makes it difficult to perceive the profession's philosophical cohesiveness. Another major disadvantage of this eclecticism is the difficulty in developing consistent practice standards.

To attempt to solve this problem, the modern profession has articulated a general statement of naturopathic principles that expand on *vis medicatrix naturae* (Box 5.2). However, to gain a more in-depth understanding of naturopathic medicine, one must discuss medical philosophy in general.

MEDICAL PHILOSOPHY

The issues fundamental to a discussion of medical philosophy have changed little since naturopathy first appeared as a distinct profession at the end of the 19th century. What has changed is the level of understanding of the biological process and the language of science. Most people who study the early writers on naturopathic medical philosophy quickly get lost in the archaic language and arguments used to justify the theories. This chapter translates these concepts and issues into modern terms.

Vitalism Versus Mechanism

Historically, there have been two main medical philosophies, those of vitalism and mechanism. Their origins can be traced to the Hippocratic writings of ancient Greece. Throughout history, the line separating these two schools of thought has not always been clear, but their philosophical perspectives have generally been in opposition. The conflicting goals and philosophical foundations of these two concepts remain relevant as the modern practices of conventional and alternative physicians come into conflict. As will be seen, the foundations of naturopathic medical philosophy are found in vitalism. However, naturopathy also recognizes the practical value of the mechanistic approach to health care.

Mechanism

Up to the early part of the 20th century, there was considerable debate over the issue of vitalism versus mechanism in the field of biology. The mechanists, or materialists, maintained that the phenomenon of life could be explained exclusively as the product of a complex series of chemical and physical reactions. They denied the possibility that the animate had any special quality that distinguished it from the

BOX 5.1 Naturopathic Modalities

Naturopathic physicians are trained to use a number of diagnostic and treatment techniques. These modalities include the following:

- *Diagnosis.* All the conventional clinical laboratory, physical diagnosis, and imaging (e.g., radiography) techniques, as well as holistic evaluation techniques
- *Counseling.* Lifestyle, nutritional, and psychological
- *Natural medicines.* Nutraceuticals (i.e., all food constituents, constituents of biochemical pathways, etc.), botanical medicine, and homeopathy
- *Physical medicine.* Hydrotherapy, naturopathic manipulative therapy, physiotherapy modalities, exercise therapy, and acupuncture
- *Family practice.* Natural childbirth, minor surgery, natural hormones, biologicals, and pharmaceuticals

BOX 5.2 The Principles of Naturopathic Medicine

The Healing Power of Nature: *Vis Medicatrix Naturae*

Nature acts powerfully through healing mechanisms in the body and mind to maintain and restore health. Naturopathic physicians work to restore and support these inherent healing systems when they have broken down by using methods, medicines, and techniques that are in harmony with natural processes.

First Do No Harm: *Primum Non Nocere*

Naturopathic physicians prefer noninvasive treatments that minimize the risks of harmful side effects. They are trained to know which patients they can treat safely and which ones they must refer to other health care practitioners.

Find the Cause: *Tolle Causam*

Every illness has an underlying cause, often in aspects of the lifestyle, diet, or habits of the individual. A naturopathic physician is trained to find and remove the underlying cause of a disease.

Doctor as Teacher: *Docere*

A principal objective of naturopathic medicine is to educate the patient and emphasize self-responsibility for health. Naturopathic physicians also recognize and employ the therapeutic potential of the doctor–patient relationship.

Treat the Whole Person

Health or disease comes from a complex interaction of physical, emotional, dietary, genetic, environmental, lifestyle, and other factors. Naturopathic physicians treat the whole person, taking all of these factors into account.

Preventive Medicine

The naturopathic approach to health care can prevent minor illnesses from developing into more serious or chronic degenerative diseases. Patients are taught the principles with which to live a healthy life; by following these principles they can prevent major illnesses.

inanimate. It was their contention that the only difference between life and nonlife was the degree of complexity of the system.

Mechanism has several other distinctive characteristics. Its most obvious is that it is reductionistic. *Reductionism* is often used as a synonym for *mechanism.* Mechanistic science is also characterized by an emphasis on linear causality. Without this emphasis on reductionism and linear causality, Western science and medicine would probably have not been so successful. As the 20th century advanced, each new discovery in biological and medical science reinforced the arguments for mechanism, until, by the middle of the century, the biology community had almost exclusively embraced the philosophy of mechanism.

Mechanism is the philosophical foundation of biomedical science and conventional medicine. It is especially visible in the treatment modalities of surgery and most pharmaceuticals. Mechanistic medicine identifies disease and its accompanying signs and symptoms as simply the result of a disruption of normal chemical reactions and physical activities. Such disruptions are caused by the direct interference in these reactions and activities of a "pathogenic agent." (For the purposes of this discussion, the expression "pathogenic agent" refers to any known or unknown etiological agent, influence, or condition; examples are microbial agents, autotoxins, genetic defects, environmental toxins, non–end-product metabolites, and physical and emotional stress and trauma.) A living organism, then, is simply a very complex machine that, as a result of external agents and influences and "wear and tear," breaks down. Because the signs and symptoms of disease are thought to be caused only by these mechanical disruptions and interference with reactions, they are considered to be completely destructive phenomena and are therefore to be eliminated. Disappearance of the signs and symptoms indicates that the pathogenic agent and its resulting disease have been eradicated or, more likely, controlled. The goals of mechanistic medicine tend to be the quick removal of the signs, symptoms, and pathogenic agent.

Mechanistic medicine is being practiced in cases in which the intention of the therapy is to intervene in the perceived mechanism of the disease and/or to relieve the symptoms. Examples would be the use of antihistamines to relieve rhinitis, vitamin B_6 to help carpal tunnel syndrome, emergency care for traumatic injuries, coronary bypass surgery for blocked arteries, and insulin in juvenile-onset diabetes. Mechanism is also being used when an identified pathogenic agent is directly attacked or eliminated; for example, the use of antibiotics or the isolation of a patient from a particular allergen. Clearly, mechanistic medicine can be very effective in achieving its goals. In the presence of modern medical technology, it is easy to see how this philosophy came to dominate biology, medicine, and the attention of the public.

However, the unsolved problems of mechanistic medicine—particularly those of chronic degenerative disease; authoritarianism, which alienates patients from responsibility for their own health; and the rising cost of health care—suggest that there are limits to the mechanistic perspective and explain why vitalism has not disappeared and is in resurgence.

Vitalism

The philosophy of vitalism is based on the concept that life is too well organized to be explained simply as a complex assemblage of chemical and physical reactions (i.e., a living system is more than just the sum of its parts). This is in contrast to the mechanist's contention that "the only difference between life and non-life is the degree of complexity."

Throughout the 19th century, the debate between vitalism and mechanism was carried out mostly by biologists and, in medicine, between the "regular" doctors and those doctors who would now be called alternative. In the medicine of the 19th and early 20th centuries these would have been homeopathic, hydrotherapy, nature cure, and eclectic doctors—all medical doctors with equivalent credentials under the laws of the time. Although the specific terms of "vitalism" and "mechanism" were not necessarily the nomenclature of their debate, the perspectives were the same.

Interestingly, through most of the 19th century this debate within the medical community was distinctively not based on science as we currently think of it. The "regular" doctors of the era, as represented by the American Medical Association, were still strongly influenced by Galen's theory of disease of the four humors with its imaginary anatomy and physiology, bleeding, leeches, mercury, and other horrific treatments. Both the homeopaths and eclectic doctors argued based on

empirical evidence; on the other side, the regular doctors argued based on a dogmatic theory that was more than 1500 years old and unsupported by any evidence. Harris Coulter produced the seminal work on this debate in his three-volume book, *The Divided Legacy*.

The debate between vitalism and mechanism within the field of biology is well documented within the biology journals of the time. This was an era of amazing discoveries about how life functioned. Naturally, this is where the focus of this debate took place for biologists. As the secrets of cellular metabolism were revealed, this debate lurched from one specific argument to the next. The issue was where in the living organism did "God" have direct control. For example, at one point it was argued that the "seat of the soul" was the cell. As the cell was better understood, the place that was the point of God's intervention was postulated to be the nucleus. As research further revealed how the organelles functioned, the vitalistic biologists gave up ground until vitalism as a distinct philosophy in biology was finally abandoned.

The error that doomed the vitalistic-oriented biologists was that they were all reductionistic in the same way as the mechanistic biologists. Reductionistic science seems completely able to learn how life functions from a biochemical and biophysical perspective. Eventually, all of the individual chemical and physical reactions that are found in the processes of life will probably be identified. However, the vitalistic biologists missed the most essential aspect of vitalism: *holism*.

In naturopathy's early years there were few interactions between it and the academic and research worlds. The great authors and practitioners came to naturopathy through "conversion," in other words, most had been cured of some health problem by a natural cure and felt naturopathy and curing the sick was now their calling. There is no evidence that these naturopaths even knew that this debate between vitalism and mechanism was going on in the biology literature. Research in this early era of naturopathy consisted of observing nature and applying these observations to treating patients. This led to a deep appreciation of "nature's" desire for balance and order (what a physiologist would call homeostasis). This holistic perspective, combined with the results of the naturopathic treatments, was the empirical evidence that drove their understanding of health and disease. It was only in the latter half of the 20th century that the field of naturopathic medicine began to converge with the academic and research worlds. Since the 1970s this convergence has moved at breakneck speed, until today there is no longer any real distinction (although this is not evident in some of the politically motivated diatribes against the field of natural medicine). However, by this time the academic and research worlds had long since forgotten about vitalism.

An organism's unique complexity—as demonstrated by its ability to grow and develop, respond to stimuli, reproduce, and repair itself—requires a level of organization and coordination that suggests a distinct quality that is not readily explained by mechanism. This is studied extensively by all medical students in physiology class as the "normal" homeostatic process common to all living organisms. However, the tendency in conventional medical school is to put the concept aside when the student moves on to study pathology and the clinical sciences. Yet up to the point of death, maintaining homeostasis is a prime, if not the primary, driving force in all living organisms. To think that homeostasis is only an important factor in "normal" physiological processes and has no relevance in pathology is to ignore all of the basic sciences. All life is attempting to return to this ideal state whenever injured or ill. The only point in the life cycle that an organism is no longer "trying" to maintain homeostasis is death.

Reductionistic science has done a wonderful job elucidating the functions of the various components of life, but it tends to focus the researcher and the physician on the disease process as an isolated phenomenon rather than the result of a complex reaction of the whole organism to a pathological agent. Fortunately, the debate between the vitalistic and mechanistic perspectives in the modern era focuses on the more relevant and holistic general concepts. Although modern vitalism is inherently holistic in its view, there is no conflict with the findings of biomedical science. What is significant is not the individual biochemical or biophysical reactions, but the fact that they are all coordinated to such a degree as to produce the special activities of a living organism. Because there is no inanimate counterpart to this level of complexity and organization, homeostasis is the most dramatic general argument in favor of vitalism.

A less dramatic argument supporting the vitalistic perspective is the "problem of entropy." Entropy is the tendency of any closed system to find equilibrium, that is, the state of least organization. In other words, systems tend to run down and become less complex over time. In defiance of this universal rule, life, up until the point of death, consistently creates more complex systems out of simple ones. To do this, life actively pursues external matter and energy to incorporate into itself while also selectively eliminating byproducts from its use of this matter and energy.

When the problem of entropy is examined on the molecular level, the same individual chemical processes and elements may be found in both animate and inanimate systems. In the inanimate system, however, there is a constant move toward a state of chemical equilibrium. This type of system cannot maintain an unstable chemical state and always seeks stabilization. Even after the addition of external exciting energy, the system returns to the simplest, least reactive state possible. The animate system is virtually the opposite. It is continuously in a state of dynamic chemical instability, actively seeking energy to maintain this instability and consistently moving to more complex and more organized states (and back again). It is only at the onset of death that an animate system begins to move toward equilibrium, and, of course, then it is no longer animate.

The third general argument in favor of a vitalistic view of life is evolution. For evolution to exist as a force in nature, generations of living organisms have to survive long enough to grow, reproduce, and then evolve. For this survival to take place, the organisms' homeostatic and repair processes must be consistently directed toward maintaining a state of balance with the external environment (i.e., health). Any organism that does not behave biochemically and physiologically in this manner dies and cannot evolve. Thus the phenomenon of evolution, as the action of countless living organisms over eons, multiplies life's antientropic quality and is incompatible with a mechanistic view of living systems.

These easily observable examples of life's "special quality" suggest an "organizing force" that goes beyond what is possible from mere chemistry. This quality that makes life unique should not be mistaken as a metaphysical concept, although an argument for or against such concepts is not intended here. The point is only that vitalism is a medical philosophy based on observable scientific phenomena. Unfortunately, a definitive definition of this quality (in the old literature called the "vital force," defense mechanism, or simply "Nature") will have to wait for vitalistically or holistically oriented researchers. Reductionistic research has not provided much clarification of these special qualities of life—just ask a modern reductionistic biologist to explain how homeostasis works. They can describe what happens on a biochemical and biophysical level, but they cannot describe why it happens.

At this point in the discussion, not many mechanistic practitioners would have reason to be uncomfortable. However, the conflict becomes evident with examination of the premises on which the practice of vitalistic medicine is based. What truly separates vitalism from mechanism and makes it useful as a medical philosophy is its perspective on disease and its associated symptoms.

BOX 5.3 Cure, Suppression, Palliation, and Healing

Cure: A cure occurs when:
(a) a treatment is given to the person;
(b) the signs and symptoms of the disease go away;
(c) the treatment is removed and the signs and symptoms stay away; and
(d) the whole person is healthier and less likely to get sick than before the illness.

This is almost always going to occur only when the whole person was treated, and not just the disease or its symptoms. Palliation and suppression never lead to cure in and of themselves.

Palliation: Palliation occurs when:
(a) a treatment is given for the disease;
(b) the signs and symptoms of the disease go away; but
(c) when the treatment is removed the signs and symptoms return.

The symptoms of the disease are simply being controlled (not cured) as long as the treatment is continued.

It is a classic error of many practitioners and patients to equate palliation with moving toward cure. Palliation is on the opposite end of the spectrum as cure and is closer to suppression. Palliation can be useful but, in and of itself, never leads to cure—other more vitalistic and holistic interventions are necessary and may be as simple as changing to a healthier diet, removing some obstacle to recovery, or reducing stress, or as complex as classical homeopathy or traditional Chinese medicine. When palliation is used over a long enough time, suppression is the natural consequence.

Palliation is the most common result of almost all health care interventions. This is especially true of conventional medicine but also true for much of alternative medicine as well. Unfortunately, both the practitioner and the patient's expectations are frequently satisfied with palliation. This is the most frustrating aspect of modern health care, whether conventional or alternative. Too few people are striving for a cure.

Suppression: Suppression is when:
(a) a treatment is given for a disease;
(b) the signs and symptoms of the disease go away;
(c) the treatment is removed and the signs and symptoms stay away; but
(d) the whole person is less healthy.

Although the symptoms of concern are better, the whole person is worse, which leads to more and worse disease in the future. In conventional medicine suppression is often a goal. Alternative medicine tries for a higher standard, but because palliation is often what happens, suppression can occur here, too.

Suppression frequently occurs because a treatment is given for a symptom or disease rather than the whole person being treated. Suppression may lead later to another more invasive illness.

Healing: Healing is what a living organism (body–mind) does, or attempts to do, for itself. A treatment can only:
(a) control signs and symptoms (palliate or suppress);
(b) support life in a crisis (palliate or suppress);
(c) attack an invading organism such as bacteria or remove a pathological agent such as a toxin or allergen (palliate);
(d) mechanically repair tissues that have been damaged or are malformed (palliate); or
(e) support and/or stimulate the organism's innate healing processes while the body–mind does the work of healing itself (cure).

Curative treatment involves stimulating the whole organism to heal itself. The palliation and suppression of symptoms does not help stimulate self-healing. Palliation tends to create the opposite effect and suppression actually gets in the way of the whole body–mind's efforts to self-heal.

Meaning of Disease

Vitalism maintains that the pathogenic agent does not directly cause most symptoms accompanying disease; rather, they are the result of the organism's intrinsic response or reaction to the agent and the organism's attempt to defend and heal itself. Symptoms, then, are part of a constructive phenomenon that is the best "choice" the organism can make, given the circumstances at any particular time.

Symptoms can be further described as arising from two situations. The first and most common situation is when the symptoms are from what would traditionally be called a "healing reaction"—the organism's concerted and organized attempt to defend and heal itself (i.e., the organism's homeostatic process). These healing reactions produce what can be called "homeostatic symptoms." Examples are fever and inflammation in infections, almost any reaction of the immune system, and many of the symptoms of chronic disease.

This interpretation of symptoms is generally ignored by mechanism. Instead, it views a symptom as the result of a destructive process and focuses on intervening by relieving the symptom or manipulating the pathological mechanism. Mechanistic medicine is therefore most often working contrary to homeostasis and the organism's attempt at healing (this is usually its intent). When this therapeutic approach is effective, vitalists call the result a "suppression" (Box 5.3). This approach to health care is so pervasive that most people, lay and professional alike, still think nothing of suppressing mild fevers with antipyretics. In contrast, vitalism considers these homeostatic symptoms to be the product of a constructive phenomenon and therapeutically stimulates and encourages this directed healing process.

In contrast, vitalism considers these symptoms to be the product of a constructive phenomenon and therapeutically stimulates and encourages this directed healing process. Rather than simply trying to eliminate a pathogenic agent, as mechanistic therapy might, vitalism focuses more on augmenting the organism's resistance to that agent. That is not to say that vitalists object to removing the agent, only that it should be done in the context of simultaneously increasing resistance (in other words, decreasing susceptibility). The importance of this approach becomes evident when one recognizes that disease is only possible when both a pathogenic agent and a susceptibility to that agent are present.

Healing reactions can take several forms. In the first type, an organism's response to a pathogenic agent does not produce symptoms. When the organism is capable of easily defending itself from the agent, no symptoms are perceivable. This is a common homeostatic process and is demonstrated when a potential pathogen, such as β-hemolytic streptococcus, is cultured from a healthy person's throat. However, when the organism is more susceptible or the relative strength of the pathogenic agent is greater, a threshold is reached and symptoms become perceivable. Successful healing reactions of this type include vigorous acute diseases that quickly resolve. The early naturopaths would have called these acute reactions "healing crises." As the susceptibility of the organism increases relative to the strength of the pathogenic agent, there is a greater likelihood that the healing attempt will not be successful. When such a reaction is unsuccessful but vigorous, death may result, unless there is timely application of vitalistic or mechanistic therapy. Examples of this situation are acute bacterial meningitis and cholera.

When the healing attempt is feeble and therefore ineffective, the reaction usually goes into the "chronic disease" stage. Vitalists observe that suppression seems to increase the likelihood that the reaction will be forced to go into such a chronic stage. In this situation the reaction is "smoldering," and most often the organism cannot overcome the

pathogenic agent unassisted. It just "holds its own," and as the organism's general health decreases over the years, the reaction gradually degenerates, producing symptoms that become less homeostatic as it moves to an end-stage pathology. Palliating the symptoms during this phase of the disease contributes to the declining health over time because palliation means that the underlying susceptibility or problem is not being addressed in a curative manner. If the organism can be therapeutically stimulated to produce a more vigorous healing reaction, it can often successfully complete the original healing attempt. This augmented reaction is another example of a naturopathic healing crisis and would also be called an "aggravation" by the vitalists who practice homeopathic medicine.

Intervening mechanistically by relieving symptoms does little to stimulate or encourage the healing response; it usually actually inhibits the healing response. In contrast, vitalistic therapies can be very effective in helping these healing reactions, because the goals of such therapies are precisely the same as those of the organism. Thus it is thought that vitalistic medicine works because, by honoring this process and thereby strengthening the whole organism, it encourages a more effective healing effort. Ideally, the organism is then able to accelerate and complete its reaction against the pathogenic agent, leading to the permanent disappearance of the symptoms as it returns to a state of health.

It would be naive to say that every stage of the healing reaction is positive and in the best interest of the organism or that no symptoms should be palliated. The modern vitalist acknowledges that palliative intervention is sometimes necessary. In contrast, it is important to note that routine mechanistic intervention can encourage its own worst-case scenarios. When mechanistic therapies successfully suppress an organism's chosen healing reaction, a less effective and less desirable response is often produced. Therefore when suppression occurs, it can lead to a more complicated medical situation. Consequently, the very practice of mechanistic medicine tends to reinforce its practitioner's conviction that such intervention is usually necessary. It should be noted, however, that not all mechanistic intervention leads to suppression. It happens less often when the pathogenic agent can be readily eliminated, such as the use of an antibiotic in nonrecurring acute bacterial infections, or when relatively noninvasive therapies are used, such as natural medicines.

The second type of symptom-producing situation occurs when the organism produces symptoms in response to an organic lesion that arises from the direct pathological influence of a pathogenic agent. These could be called "morbid symptoms," examples of which are symptoms from the mass of an invasive tumor, shortness of breath from emphysema, and pain of an injury or myocardial infarction. It should be mentioned that even these symptoms are the result of the organism's overall effort to maintain homeostasis, and homeostatic symptoms are also often present. In addition, a morbid symptom is not necessarily without utility. For instance, pain is valuable as an indication of tissue damage. As can be seen, many, if not most, of these situations involve end-stage disease. Here mechanistic therapies can be very positive when the goals of the therapy do not conflict with those of the organism.

There are instances when invasive mechanistic intervention will probably be required to save "life and limb." These include such conditions as birth and genetic defects, serious traumatic injuries, crisis situations, overwhelming infections, and many malignancies. Unfortunately, mechanistic intervention does not guarantee a successful outcome either. Even in these situations, however, the effectiveness of vitalistic and natural therapy should not be underestimated, and their concurrent use will certainly augment any mechanistic intervention.

The concept of homeostatic and morbid symptoms can be a useful tool to help the understanding of the healing and disease processes, but in many situations it may not be possible to categorize the type of symptoms produced. A rough rule of thumb, however, would be that virtually all symptoms accompanying reversible or functional diseases are homeostatic. In contrast, many of the symptoms associated with traumatic injury and end-stage pathology would be morbid symptoms.

Scientific Medicine

Although mechanism and vitalism represent opposing perspectives, the systems of medicine that represent these philosophies can be successfully tested and examined with the scientific method.[1] That is not to say that the philosophy of vitalism has been unquestionably proven—only that the validity of vitalistic interventions can be scientifically demonstrated. If a therapy can be proven effective, the effectiveness implies the accuracy of the philosophy on which it is based. Unfortunately, very few of the vast resources of the biomedical community have been directed toward investigating vitalistic medicine.

Conventional medicine, as the dominant health care system and a representative of mechanism, has claimed for itself the title "scientific medicine." However, it is inherently no more or less scientific than vitalistic medicine. A system is scientific only when it has met the criteria of the scientific method. This method requires the collection of data through observation and experimentation and the formulation and testing of hypotheses. Nonprejudicial science can effectively study any system, but the researcher must understand the system's particular paradigm. Experiments on a vitalistic therapy based on a reductionistic and mechanistic model are not going to be constructed to show success, or if they do show success, it will be entirely fortuitous.

The criteria of the scientific method can be met by vitalistic medicine, but only when the researchers recognize that it cannot be studied as though it is reductionistic or based on a simplistic model of linear causality. When the experimental model acknowledges the complexity of a living system in a social context (i.e., holism and circular causality/feedback loops), vitalistic medicine proves to be both verifiable and reproducible and, thus, scientific. Unfortunately, because of its current political and economic dominance, conventional medicine is in the position to dictate (through economic and publication control) that research, and therefore the scientific method will be applied primarily to itself. The result is that most conventional practitioners dismiss vitalistic medicine, along with all alternatives, as unscientific. Ironically, most vitalistic physicians also have extensive training in mechanistic and/or conventional medicine. Generally, they are capable of practicing mechanistically and do so to greater or lesser degrees.

NATUROPATHIC PHILOSOPHY

Vis Medicatrix Naturae

Naturopathic physicians assert that all true healing is a result of *vis medicatrix naturae* (the healing power of nature). Unfortunately, some people in the field of alternative medicine (including some naturopathic physicians and students) have mistakenly translocated this concept to the therapy. These practitioners tend to operate as though this "healing power" is an intrinsic property of the natural therapy or medicinal substance itself. In contrast, proponents of vitalism and naturopathic medicine have always understood that the "healing power of nature" is an inherent property of the living organism. *Vis medicatrix naturae* is the living organism's "desire" and ability to heal itself. As mentioned, the homeostatic process best exemplifies this.

Historically, naturopathy is a vitalistic system of medicine. However, over the past 130 years its eclecticism has allowed it to incorporate a

number of therapies that can function mechanistically. What makes these mechanistic therapies acceptable, given naturopathic medicine's vitalistic foundation, is the emphasis on meeting each patient's pragmatic health care needs. So the application of *vis medicatrix naturae* in practice is constantly adjusted depending on the situation at hand.

Ideally, naturopathic practice involves only the use of therapies that support the organism and encourage its intrinsic healing process to work more effectively while avoiding the use of medicines and procedures that interfere with natural functions or have harmful side effects. Natural medicines and therapies are therefore preferred, because when they are used properly and in appropriate circumstances, they are the least harmful, least invasive, and best able to work in harmony with the intrinsic natural healing process. In addition, their constituents have been encountered in nature for millions of years. This long period of exposure has enabled the body to develop metabolic pathways capable of effectively using, processing, and detoxifying these medicines.

The total organism is involved in the healing attempt, so the most effective approach to diagnosis and treatment is to consider the whole person. In addition to physical and laboratory findings, important consideration is given to the patient's attitude, psychological and spiritual state, social circumstances, lifestyle, diet, heredity, and environment. Careful attention to each person's unique individuality and susceptibility to disease is critical to the proper evaluation and treatment of any health problem.

Naturopathic physicians contend that most disease is the direct result of the ignorance and violation of what would be traditionally called "natural living laws." These general lifestyle rules (including diet) are based on the concept that there is an environment (both internal and external) that optimizes the health of an organism. Analysis of the lifestyles of Paleolithic and healthy primitive and modern cultures gives naturopathic physicians and their progenitors many clues as to what a healthy lifestyle should involve.

Throughout most of modern history, biomedical science has focused primarily on researching the sick. Recently it has finally begun to evaluate what constitutes a healthy lifestyle. To no one's surprise, this lifestyle looks like the same one advocated by naturopaths for the past 130 years. A healthy lifestyle could be generalized to include the following:

- Consuming natural unrefined foods
- Getting adequate amounts of exercise and rest
- Living a moderately paced lifestyle
- Having constructive and creative attitudes
- Connecting to other people socially
- Being present to the spiritual aspects of life
- Avoiding toxins and polluted environments
- Maintaining proper elimination

It is also important to control these areas during illness to remove as many unnecessary stresses as possible and to optimize the chances that the organism's healing attempt will be successful. Therefore patient education and responsibility, lifestyle modification, and preventive medicine are fundamental to naturopathic practice.

Although the practice of naturopathic medicine is grounded in *vis medicatrix naturae,* it also recognizes that mechanistic intervention in the disease process is sometimes efficacious and, at times, absolutely necessary. Therefore naturopathic physicians treat patients with a wide variety of vitalistic and mechanistic therapeutic modalities. It is the circumstances and the goal of the therapy that ultimately determines which approaches are used. Naturopathic physicians have a long-standing tradition of integrating the best aspects of traditional, alternative, and conventional medicine in the interest of the patient. As appropriate, patients are referred to other health care practitioners. Whenever possible, every effort is made to use all treatment techniques in a manner that is harmonious with the naturopathic philosophy.

Natural Medicines and Therapies

Traditionally, medicines administered and prescribed by naturopathic physicians have been primarily natural and relatively unprocessed. Four categories of natural medicines can be defined.

The first consists of substances found in nature that have been only minimally processed. Examples include, but are not limited to, foods, clean air and water, and whole herbs. The early "nature cure" practitioners used this category primarily. The second category involves agents extracted or made from naturally occurring products. Although these medicines have undergone processing, their constituents are still in the form found in the original natural substance. These first two types of natural medicinal substances have synergistic constituents that allow their use at lower doses with a resultant broader and safer therapeutic index. Examples of this category are tinctures and other botanical extracts (some of which are standardized on one or more constituents known to be clinically effective), homeopathic medicines, glandular extracts, and other substances of animal origin.

The third category of natural medicines comprises those highly processed medicinal substances that are derived from a natural source. Often everything has been removed from such substances but the identified active ingredient, and they no longer have any synergistic constituents. Examples of these are the many new nutraceuticals made from plant substances, constituents of biochemical pathways, enzymes, amino acids, minerals, vitamins, and other food extracts.

The fourth category that may be considered natural are those manufactured medicines that are presumed to be identical to naturally occurring substances. They have the advantage of being less expensive and are typically available in higher concentrations. Examples of these manufactured natural medicines include bioidentical hormones, synthetic vitamins, and analogues of plant and animal constituents. However, their use is a compromise because:

- It is difficult to determine whether they are the equivalent of the natural product.
- They lack natural synergistic components.
- They may include contaminants from the manufacturing process; these contaminants are often chemically and structurally similar to the desired medicine but generally interfere with the normal pathways rather than enhance them.

Naturopathic physicians also use many natural physical therapies. What makes a therapy natural is that it is derived from a phenomenon of nature and is used to stimulate the body to heal itself. Examples of these phenomena are air, light, heat, electricity, sound, and mechanical force. Some of these natural therapies are mechanical and manual manipulation of the bony and soft tissues (naturopathic manipulative therapy), physiotherapy modalities (e.g., electrotherapy and ultrasound), hydrotherapy, and exercise therapy. Naturopathic physicians also use lifestyle modification, counseling, and suggestive therapeutics. These therapies are all discussed in more detail in other chapters.

Family and Specialty Practice

Naturopathic physicians, like other types of primary care providers, develop practices that meet their personal interests and skills. Although most are engaged in general and family practice, some also specialized in particular therapeutic modalities and/or types of health problems. In all situations, however, the emphasis is still on treating the whole person. The practice of family medicine requires the use of some medicines, techniques, and devices that are not natural but belong among the comprehensive family practice services offered by the naturopathic profession.

In the modern era of naturopathic medicine many states have expanded the scope of practice so that naturopathic physicians now practice much like other primary care practitioners with pharmaceutical prescribing rights. However, naturopathic physicians generally approach the use of pharmaceuticals differently than conventional physicians. They are seen as temporary interventions to be used to support the patient while other, more vitalistic natural therapies are used to help the patient recover his or her health with the ultimate goal of no longer needing the pharmaceutical.

Many naturopaths have also developed advanced expertise in specific natural therapeutic modalities. These practitioners have usually invested in postgraduate training, such as that available through residencies. Three therapeutic specialties that merit mention are natural childbirth, acupuncture, and homeopathy. There is also a growing trend of specializing in organ systems (e.g., gastroenterology) or diseases (e.g., cardiology).

THE PHILOSOPHICAL CONTINUUM

When the various healing systems are examined and placed on a philosophical continuum, mechanism and vitalism are on different ends of the same health care spectrum. Both ends of this health care continuum have their strengths and weaknesses. Mechanistic medicine is effective for trauma, crisis care, end-stage disease, and many acute disorders. However, it is clearly a failure for most chronic disease. Conventional medicine considers most chronic diseases incurable. Vitalistic medicine, in contrast, has its most dramatic successes with chronic disease and is effective with many kinds of acute disease. It is not very effective with trauma and crisis care or with end-stage disease, although it can be a very useful complement to conventional medicine. As can be seen, both ends of the health care spectrum are necessary if every patient's health care needs are to be met.

Although aspects of naturopathic medicine (e.g., constitutional hydrotherapy) and conventional medicine (e.g., chemotherapy) represent the archetypes of vitalism and mechanism, the space between the ends of this spectrum is a gray area within which both naturopathic and conventional physicians operate on a continual basis. Naturopathic physicians integrate vitalistic therapies with mechanistic therapies, but it is not possible for everyone to be experts in everything. The vast majority of naturopathic or conventional physicians cannot learn and competently practice all types of health care. Consequently, to effectively meet society's health care needs, it is necessary to create an integrated/collaborative health care system. Such a system would have both vitalistic and mechanistic practitioners working together in the same clinical settings.

The trends of popular culture and biomedical science that are finally beginning to study alternative medicine suggest that the creation of an integrated health care system is now well under way. However, it takes no great skill for a mechanistic medical doctor to switch from giving a synthetic drug for a disease to giving a natural medicinal substance (both mechanistically oriented interventions) without understanding vitalistic thinking. If naturopathic medicine becomes just another mechanistic system using natural medical substances to treat disease (instead of a system identified with treating the whole person vitalistically), it will lose its unique niche in an integrated health care system. To survive and thrive in this new environment, naturopathic medicine must keep its vitalistic roots. With a thorough grounding in *vis medicatrix naturae,* modern naturopathic medicine will flourish and achieve a leadership position as the dominant health care paradigm shifts to the integrated medicine of the future.

CONCLUSION

The practice of naturopathic medicine can be summarized most simply as helping the body–mind heal itself in the least invasive, most fundamentally curative manner possible. This approach is not tied to any particular therapy or modality, but rather is oriented to a rational blend of vitalistic and mechanistic principles working with the whole person and educating the patient in the ways of health.

As naturopathic knowledge of health and disease grows, new therapies and approaches to health care will be added as they satisfy the principle of *vis medicatrix naturae.* With integration of the larger health care system, naturopathic medicine's place is assured as the profession that truly understands each unique human being's power to heal.

REFERENCES

1. A thorough review of all health care modalities in use today reveals some that could be considered metaphysical. These include such things as prayer, faith healing, psychic healing, healing touch, touch for health, and medical dowsing. Generally speaking, the actual operator of the therapy must call on God or have some special endogenous skill or "power" that goes beyond intellectual knowledge. This makes these modalities "operator-dependent" and, thus, cannot be validated separately from the practitioner—greatly increasing the difficulty of their scientific verification. Consequently, these modalities are not historically relevant to this discussion of medical philosophy.

Placebo and the Power to Heal

Peter W. Bennett, ND

OUTLINE

INTRODUCTION

As living organisms, we have evolved with an innate capacity for self-healing. In the clinical setting, naturopathic physicians have always relied on this self-healing capability of the individual. The healing power of the mind and body, the "life force," is a cornerstone of naturopathic philosophy and treatment. Naturopathic physicians describe this with a phrase attributed to Hippocrates: *vis medicatrix naturae*. The "inner" power to heal is one of the great mysteries of medicine, and it behooves us as physicians, regardless of our licensing body, to understand the biology and physiology that surround the processes that guide and control this phenomenon. Following this logic, a central problem to be explored and considered is that placebo response has shown medical science that the mind of a patient has a powerful role in therapy. Although the dictionary definition of mind is described as a person's thoughts and consciousness, centuries of writings from many societies and cultures on philosophy, religion, psychology, cognitive science, neuroscience, and artificial intelligence have struggled to clearly define the complex interaction of personality, emotion, perception, memory, thinking, judgment, and spiritual insight. Adding to the difficulty of the semantics of exploring the healing power of the mind is the difficulty to definitively define the scope of physiology and function of the *mind*.[1] Because the definition and understanding of the human mind challenge a consensus of our collective insight and understanding, it is natural that the function and uses of placebos are an area of myth and misunderstanding rather than an area of wisdom and insight.

As time marches on, medicine is beginning to acknowledge, stimulate, and utilize the subliminal healing capacity of the mind. A review of the placebo literature in *Lancet*[2] concluded that the placebo effect has a complex physiological multisystem dimension and should be encouraged in the clinical situation to optimize health and healing—a perspective reached by this author 30 years ago and published in the first edition of this textbook. In November 2000, 17 health centers and agencies gathered together for 3 days to explore the science of self-healing hidden in the power of placebo. This conference focused on the powerful mind–brain physiology of the placebo effect and its potential for affecting the course of human disease.[3] One of the conclusions of the conference was that the "placebo response" has potential use for medical application and needs further exploration.

Research has shown that the impressions and thoughts in a patient's mind, the attending physician's intention, and the combined effect of their relationship have a measurable effect on the health of the patient. The ability of the patient's mind to affect the process of virtually every disease has been well documented,[4,5] and the internal mechanisms and pathways by which the mind can positively or negatively affect the immune and healing processes has been investigated in the scientific literature of psychoneuroimmunology.[6,7] As the body of knowledge documenting the critical role of the patient's psyche in the therapeutic environment has grown, it has become increasingly important for all schools of medicine to teach the healing potential of the human mind.

Conventional medical thinking has turned its opinion of the placebo effect from that of a 19th-century pejorative to a concept that sums up the complex mind–body interactions affecting the power of

people to heal.[3] Unfortunately, the most modern abuse of the concept of the placebo comes from biased critics of alternative medicine who have chosen to label the beneficial effects of these therapies as merely from the placebo. These critics dismiss the science of natural healing as an imaginary phenomenon and the last resort for quack doctors who have no real medical treatments to offer their patients.[8]

The most interesting aspect of the placebo literature is the exploration of the extent of the potential of the mind to influence human health. The "power of placebo" draws on the innate ability of the body to spontaneously heal itself, a fundamental principle of naturopathic medicine. This point separates the care delivered by naturopathic physicians from the pharmaceutical and surgical approaches of current medical "standard-of-care" procedures. If common medical texts on internal medicine or ambulatory care are examined, the word *healing* is not found in the index. Except for the diagnostic evaluation of "self-limiting diseases" and "spontaneous regression," the ability of the human organism to self-right and repair from a state of acute or chronic disease is not explored in modern medicine except under the designation "placebo response." The placebo response therefore represents all the "unknown" variables that conspire to heal a patient despite pharmaceutical and surgical intervention. Although it seems to be a natural area to develop in clinical and hospital settings, the fundamental separation of mind and body in conventional medical thinking may be slowing down a standardization of care that actively engages the hopes and beliefs of all patients undergoing treatment.

PLACEBO RESPONSE

The placebo response represents the power of the mind, through intention, to effect (1) a change in oneself, (2) a change in those around one, and (3) a change in the environment in which one lives. Intention has been observed to affect machines[9] and remote biological systems.[10] Distantly influenced systems include another person's electrodermal activity, blood pressure, and muscular activity; the spatial orientation of fish; the locomotor activity of small mammals; and the rate of hemolysis of human red blood cells. Prayer, an example of intention, has been extensively studied as a therapeutic healing modality.[11] One study showed a dramatic result in cardiac intensive unit recovery when patients were prayed for by someone at a distant location.[12] Patients in this study were 5 times less likely to require antibiotics, 3 times less likely to experience pulmonary edema, 12 times less likely to require endotracheal intubation, and significantly less likely to experience cardiac mortality.

Our biological systems must conform to the laws of physics. Modern physics has investigated the effect of an observer on the system observed. It has been shown that an electron will acquire a definite axis of measurement in the process of measurement. Bell's theorem supports the idea that our universe consists of particles unified instantly as an indivisible whole; our biological homeostatic systems cannot be analyzed in terms of independent parts. The interconnected nature of our biological systems has been known for thousands of years; the ancient Buddhist concept of "interdependent phenomena" or Pratītyasamutpāda accurately describes this paradigm. The Buddhist concept of interconnectedness and interdependency does not imply a Newtonian billiard-ball effect of a cause or causation, but rather an interdependent "held" state of a plurality of conditions and causes. The idea that a healing response can be generated without genuine causation, such as drug treatment, seems to violate the laws of biological systems. Comparing the healing response generated by a thought or intention might not violate the laws of physics, but it has a difficult place in a medical philosophy of cause and effect driven by pharmacodynamics. Interestingly, humans are not the only organisms to be affected by the placebo response; it has been observed in *Caenorhabditis elegans* and the fruit fly *Drosophila melanogaster* through cell signaling indicating a phenotypic response to sensory input, which shows that the placebo phenomenon is not ignoring cause and effect—it merely indicates the potential for more subtle self-regulation than that referenced in modern medical standards of care.[13]

Our current medical system is gradually shifting with the developments in modern physics. These modern ideas of biological systems are diametrically opposed to Cartesian paradigms that our internal and external environment consists of separate parts joined by local connections. Medicine must take a "quantum leap" to catch up with the knowledge we possess about our environment through quantum physics. We can see clearly that it is impossible for a doctor to observe a patient without that observation having an effect on the health of the patient.

Pierre Teilhard de Chardin postulated, and Rupert Sheldrake proved, the possibility of a "morphogenetic field" for the subliminal communication to all members of our species.[14] The effect of human thought on other members of society has been described in human society since the beginning of our earliest cultures.

Naturopathic physicians believe that the body has a powerful ability to maintain health and repair to a healthy state after disease by virtue of its inherent power of vitality. This homeostatic healing mechanism has been selected by nature in the same way that the organs that we consider to be vital to our survival have been selected. Healing happens unaided by simply maintaining an environment that does not obstruct the path of cure.

Because the placebo literature documents the philosophical foundations of the naturopathic healthcare model, it is important to review the full scope of this subject. Integrating known placebo initiators in clinical practice is essential for good patient care.

WHY STUDY THE PLACEBO EFFECT?

For hundreds of years, physicians have watched their patients respond to therapies with a wide range of results. Some patients recover fully, whereas others, with apparently identical diseases and therapies, wither and die. Today, a skilled physician can correctly diagnose the condition of a patient by applying the sophisticated techniques of modern medicine. Then, an appropriate therapy, the efficacy of which has been thoroughly proven in research and clinical trials, can be prescribed. Through this process the patient will have received the best care available through current medical technology. However, if the diagnosis, therapy, and therapeutic interaction do not stimulate the hope, faith, and belief of the patient, the chances of success are measurably diminished. In the literature on the placebo effect[15]; psychoneuroimmunology[6]; and psychosomatic,[16] behavioral,[17,18] and psychiatric[19] medicine, it has been repeatedly demonstrated that the beliefs of both the patient and the doctor, and their trust in each other and the process, generate a significant portion of the therapeutic results.[20]

The placebo and its effect are not separate from any aspect of the therapeutic interaction, nor are they "nuisance variables" muddying a clear clinical picture. Rather, they send the physician a strong message: it is a patient's own belief system that mobilizes the inherent healing powers of the mind. By studying the placebo effect, a physician is better able to fully harness this power to trigger internal healing mechanisms. Yet despite the quantity of documentation, the placebo effect remains one of the most misunderstood areas in modern medicine.

The physician should always strive to stimulate self-healing, or the placebo effect, as fully as possible to maximize its potential for healing. Someday physicians will be able to explore the deepest recesses of the unconscious to directly access therapies that assist the body in the

restoration of internal homeostasis. The optimal model for health care is the marriage of appropriate medical technology with the factors that have been shown to generate the placebo effect. This exciting scenario shines on the horizon as the health care of the future.

Because the doctor–patient relationship is such fertile ground for stimulating the healing response,[21–23] it serves a physician well to comprehend the nature of the placebo phenomenon to fully realize this potential for healing.

HISTORY OF PLACEBO

Both the modern physician and primitive medicine men and shamans of the past used ineffective therapies to stimulate healing in their patients. As Shapiro observed, "the true importance of placebo emerges with a review of the history of medical treatment."[24] It was noted that the historical therapies of the medical profession and traditional healers, "purging, puking, poisoning, puncturing, cutting, cupping, blistering, bleeding, leeching, heating, freezing, sweating, and shocking,"[25] worked because of the placebo effect. Although these practices might seem ludicrous in retrospect, all of these therapies were once considered effective. As an embarrassing epilogue, the placebo literature shows that ineffective procedures are just as pervasive in modern medicine as in the jungle hut of the shaman. We must therefore ask ourselves how unfounded medical therapies can survive peer-reviewed literature and centuries of cultural acceptance.

The power of the patient's belief in the potential for a cure has been consistently observed throughout history. Both Galen and Hippocrates recognized the strong effect of the mind on disease and recommended that faith, treatment ritual, and a sound doctor–patient relationship could provide important therapeutic results.[26] Recognition of the power of positive expectation was recorded frequently in the medical literature of the 17th and 18th centuries. It was in the 18th century that the use of placebos was first defined as a "commonplace method of medicine."[27] As the importance of drug therapy grew in the 19th century, the term *placebo* became identified with medicines involving substances that resembled drugs. However, in the 1940s, because of the increase in double-blind research, it became associated with inert substances that were used to replace active medication.

ORIGIN OF THE TERM *PLACEBO*

The original Latin meaning of *placebo* is "I shall please."[28] Although the term had a purely medical application in the first half of the 20th century, its meaning has been subject to various interpretations throughout the past several hundred years.

Before the 1940s, placebos were pharmacologically inactive substances, such as saline and lactose pills, used to satisfy patients that something was being done for them—in other words, the doctor was "pleasing" the patient. The 1940s and 1950s saw an explosion of the use of double-blind experimental procedures to evaluate the growing number of new drugs and medical procedures. Suspicion arose that all medical therapies contained an element of the placebo phenomenon.[29] This new understanding pressed the scientific community to offer new, far broader definitions.

Shapiro[25] offered the classic definition of a placebo:

> *Any therapeutic procedure (or that component of any therapeutic procedure) which is given deliberately to have an effect, or unknowingly has an effect on a patient, symptom, syndrome, or disease, but which is objectively without specific activity for the condition being treated. The therapeutic procedure may be given with or without the conscious knowledge that the procedure is a placebo, may be an active (non-inert) or inactive (inert) procedure, and includes, therefore, all medical procedures no matter how specific—oral and parenteral medications, topical preparations, inhalants, and mechanical, surgical, and psychotherapeutic procedures. The placebo must be differentiated from the placebo effect which may or may not occur and which may be favorable or unfavorable. The placebo effect is defined as the changes produced by placebos. The placebo is also used to describe an adequate control in research.*

A more accurate definition would be the following: The placebo effect is the process of a physician working with the self-healing processes of a patient. The placebo response is healing that results from the patient's own natural survival and homeostatic defense mechanisms.

Modern placebo definitions extend to its nature, properties, and effects. A placebo can be known or unknown, active or inactive, positive or negative in results (placebo effect vs. nocebo effect), and can extend to all forms of diagnostic or therapeutic modalities,[30] as further defined in Box 6.1.

BOX 6.1 Types of Placebos

1. Known placebo: Placebo used in a single-blind experiment. The doctor knows it is a placebo, but the patient does not.
2. Unknown placebo: Double-blind use of placebo. Neither the doctor nor the patient knows that the medication is a placebo.
3. Active placebo: Any substance that has an intrinsic physiological effect that is irrelevant to the ensuing placebo effect. The vasodilating effect of niacin would make it a good active placebo.
4. Inactive placebo: Any substance that is used with medicinal intent but that has no inherent physiological effect. Aside from the glucose effect in a sugar pill (or, to complicate things, an allergic reaction to some component of the supposedly inert substance), it has no physiological effect.
5. Placebo effect: Any changes that occur in a patient as the result of placebo therapy.
6. Nocebo effect: Any changes that occur as a result of placebo therapy that are perceived as negative or counterproductive to the path of cure.

CLINICAL OBSERVATIONS OF "KNOWN" PLACEBO THERAPY

One of the more dramatic examples of the placebo effect reported in the medical literature involved a patient with advanced lymphosarcoma, which Klopfer[31] reported was highly susceptible to the patient's faith in an experimental drug called Krebiozen. When the patient was started on the drug injections, his enthusiasm was so intense that "The tumor masses had melted like snowballs on a hot stove, and in only a few days, they were half their original size!"[31] The injections were continued until the patient was discharged from the hospital and had regained a full and normal life, a complete reversal of his disease and its grim prognosis.

Within 2 months of this recovery, reports that the drug Krebiozen was ineffectual were leaked to the press. Learning of this report, the patient quickly began to revert to his former condition. Suspicious of the patient's relapse, his doctors decided to take advantage of the opportunity to test the dramatic regenerative capabilities of the mind; a single-blind study was performed on the patient using pure placebo. He was told that a new version of Krebiozen had been developed that overcame the difficulties described in the press, and some of the drug was promised to him as soon as it could be procured.

BOX 6.2 Symptoms and Side Effects of Placebo Response

- Anger[206]
- Anorexia[51]
- Behavioral changes[207]
- Depression[62]
- Dermatitis medicamentosa[51]
- Diarrhea[51]
- Drowsiness[62]
- Epigastric pain[51]
- Hallucinations[56]
- Headache[208]
- Lightheadedness[51]
- Palpitation[51]
- Pupillary dilation[36]
- Rash[51]
- Weakness[51]

With much pomp and ceremony, a saline water placebo was injected, increasing the patient's expectations to a fevered pitch. The recovery from his second near-terminal state was even more dramatic than the first. Tumor masses melted, chest fluid vanished, he became ambulatory, and he even went back to flying again. At this time he was certainly the picture of health. The water injections were continued because they worked such wonders. He then remained symptom-free for more than 2 months. At this time, the final American Medical Association announcement appeared in the press—"nationwide tests show Krebiozen to be a worthless drug in the treatment of cancer." Within a few days of this report, the patient was readmitted to the hospital in extremis. His faith was now gone, his last hope had vanished, and he succumbed in less than 2 days.[31]

Other famous placebo case studies are one reported by Cannon[32] on "voodoo death" caused by belief and one reported by Kirkpatrick,[33] who documented the spontaneous regression of lupus erythematosus resulting, in part, from the patient's belief in the removal of a curse.

Other Clinical Observations

Belief sickens, belief kills, belief heals.[34]

Evans[35] and Beecher[36] reviewed, between them, 26 double-blind studies on the efficacy of active analgesic drugs in the treatment of pain. Independently, they concluded that 35% of patients with pain experienced a 50% reduction in their symptoms after placebo medication. These were particularly remarkable results when viewed in the context of Evans's observation that with a standard dose of morphine, only 75% of the patients experienced a 50% reduction in pain. In calculating the efficiency index of placebo analgesia, a method often used to determine the relative efficiency of drugs, placebo was 0.56 as effective as a standard dose of morphine. This prompted Evans to remark, "Thus, on average, placebo is not a third as effective as a standard injection of morphine in reducing severe clinical pain of various kinds but is in fact 56% as effective."[35]

As discussed previously, the placebo phenomenon has been evaluated in a wide variety of clinical settings in addition to pain management (Box 6.2). When a phenomenon such as the placebo effect has been observed to be active in diverse clinical situations, such as surgery, drug therapy, psychotherapy, and biofeedback, and over a range of physical and mental symptoms, the conclusion that it must be a factor in all aspects of medicine is inescapable.

In addition to the variety of positive effects that placebos produce are the *nocebo effects*, perceived as counterproductive to the therapeutic goals. Widely ranging negative side effects to placebos have been reported in the medical literature.[37] These side effects are frequently consistent with those of the medication that patients believe they are getting. For example, the studies that measure the effects of a supposed aspirin usually show nocebo effects of ulcerlike pain.[38] One study showed that suggestion seems to be a primary cause of nocebo reactions, in contrast to the strong conditioning component found in the placebo response.[39]

In homeopathy, aggravations and ameliorations are commonly seen when a placebo is given to fend off a patient's need to take a medication while the homeopathic physician is waiting to see whether a high-potency remedy will effect a cure. Homeopathic doctors report that placebos can cause anxiety and loneliness as well as calmness and immediate relief from insomnia.[40]

PLACEBO MYTHS

An investigation of the understanding of placebos found in the current medical literature revealed the misconceptions that prevail about the nature of placebo therapy and its effectiveness.[40] A study undertaken to examine doctors' and nurses' attitudes about the efficacy and use of placebos showed that both groups underestimated the number of patients who could be helped by placebo.[41] Physicians showed a consistent pattern of placebo use, as follows:

- Placebos were used to prove the patient wrong through the diagnosis of psychogenic symptoms in patients who were thought to be exaggerating, imagining, or faking their symptoms.
- Placebos were used in the treatment of alcoholic, psychotic, and demanding patients who were disliked by the staff of the hospital.
- Placebos were used as a treatment in situations in which standard treatments failed or the patient was getting worse.

These misconceptions regarding the nature of the placebo accounted for its widespread misuse in patients who were perceived as uncooperative or who were suspected of malingering.

Myths about placebos continue to hinder a full understanding of the power inherent in this aspect of health care. The most common myths are discussed here.[42]

Myth 1

"Because placebos tend to be physiologically inert, it is not possible for them to have an effect on physiological homeostasis."

Fact: Research shows that placebos have a wide range of effects (Table 6.1) that are found throughout all aspects of human physiology.

Myth 2

"Placebos are useful only with symptoms that are associated with psychological or psychosomatic complaints. Patients who need a placebo are hypochondriacs with vivid imaginations and need to be palliated with something to please them."

Fact: Placebos have been shown to be effective in the care of all types of patients, with a consistent level of positive results for a wide variety of accurately diagnosed diseases.

Beecher[20] was one of the first to compile a listing of the therapeutic effectiveness of placebo, thereby uncovering the wide range of therapeutic applications that were previously thought to be limited only to pain control. He concluded, "there is too little scientific as well as clinical appreciation of how important unawareness of these placebo effects can be and how devastating to experimental studies as well as to sound clinical judgement lack of attention to them can be."[20]

TABLE 6.1 Physiological Changes Induced by Placebo

Physiological Function	Physiological Changes
Heart	Improved exercise tolerance[190,191]
	Decreased serum lipoproteins[192]
	Improved T waves[57]
	Decreased pulse rate and arterial pressure[59]
Sympathetic stimulation	Decreased tremulousness, sweating, and tachycardia[51]
Claudication	Increased walking distance[193]
Opioid dependence	Addictive drug withdrawal[194]
Postsurgical trauma	Decreased facial swelling[195]
Diabetic blood sugar dyscrasias (NIDDM)	Lowered fasting blood sugar[196,197]
Gastrointestinal secretion and motility	Decreased gastric acid secretion[198]
	Changes in gastric motility[165,199]
	Healing of duodenal ulcers[200]
Hypertension	Lowered blood pressure[201–203]
	Reduced urinary catecholamines[204]
Motor dysfunction	Improved tremor magnitude[205]

NIDDM, non–insulin-dependent diabetes mellitus.

BOX 6.3 Conditions That Have Been Shown to Respond to Placebo

- Angina[54,190,191,209,210]
- Anxiety[51,211,212]
- Arthritis[38,168,213]
- Asthma[214–217]
- Behavioral problems[218]
- Claudication, intermittent[193]
- Common cold[219–222]
- Cough[223]
- Depression[224,225]
- Diabetes (non–insulin-dependent diabetes mellitus)[196,197]
- Drug dependence[51]
- Dysmenorrhea[226]
- Dyspepsia[227]
- Gastric ulcers[228]
- Hayfever[229,230]
- Headaches, temporal and vascular [231–233]
- Hypertension[234,235]
- Labor and postpartum pain[236]
- Premenstrual syndrome[237]
- Ménière's disease[238]
- Nausea of pregnancy[51]
- Pain[106,239]
- Psychoneuroses[52,240]
- Rhinitis[241]
- Sleep disturbances[242]
- Tremor[54]

The large and ever-growing number of studies on placebos and double-blind research (Box 6.3) supports the following assertion made by Beecher[20] 30 years ago:

> *Many "effective" drugs have power only a little greater than that of placebo. To separate out even fairly great true effects above those of placebo is manifestly difficult to impossible on the basis of clinical impression. Many a drug has been extolled on the basis of clinical impression when the only power it had was that of a placebo.*

Myth 3

"The placebo effect is found only with substances that are inert."

Fact: The placebo phenomenon has been observed across a wide spectrum of medical disciplines including surgery,[43] drug therapy,[44] and biofeedback.[45]

Myth 4

"The patient who responds to placebo therapy can be characterized as someone who is of a typical neurotic disposition."[41]

Fact: Although many studies have tried to impute a personality type, disposition,[45,46] or certain epidemiological class[47] to the patient who responds to placebo, this has yet to be well demonstrated because, in the right circumstances, any person can become a placebo reactor.[48,49]

After reviewing the bulk of the research on this subject, Bush[50] and Wolf and Pinsky[51] concluded that the attempts to pigeonhole personalities into a clinical profile ignored the complexity of the human mind. Gliedman et al.[52] similarly reported that age, sex, marital status, social class, and intelligence were unimportant factors in determining a patient's response to placebo. Wolf summarized that attempts to identify placebo reactors need to

> *identify the nature of the symptom being treated, the motivation of the patient and physician, the nature of the test agent, its mode of administration and the life situation of the subject at the time he is tested. The significant point here is not the apparently conflicting findings of investigators with respect to placebo reactors, but rather that in any given situation, responses to a placebo may vary as compared to any other situation and the significance of situations to human subjects cannot be precisely duplicated.*[51]

PHARMACODYNAMICS

The physiological response of the "inert and inactive" placebo extends into the realm of drug pharmacodynamics. Dose–response time curves, cumulative effects (increasing therapeutic efficacy with repeated doses),[53] variable strengths of analgesia based on a patient's drug expectation,[54] drug interactions,[51,55] and carryover effects[46,56] have all been demonstrated. The effects of placebos are so pronounced that some observers have suggested that they can exceed the effects attributable to potent pharmacological agents.[51]

Packaging and Delivery

Several studies found that the effectiveness of placebo therapy depends on the mode of delivery.[57] For example, one study found that green tablets improved anxiety and yellow tablets improved depression,[58] whereas another study found that blue capsules were more sedative and pink capsules were more stimulating.[59] Placebo injections appeared to be more effective than oral administration after oral placebo has failed to relieve the patient's symptoms.[38]

Placebo Interactions

Benson[60] wrote that the patient's belief was also a powerful force in determining the level of relief afforded by the placebo. An increase in patient expectation enhances the physician's ability to elicit a placebo response. Even if patients know that they are receiving placebos, the expectation and relief brought about by the therapeutic interaction

provide positive results.[61] The importance of expectation was further demonstrated by the observation that the greater the stress level of the patient and the greater his or her need for assistance, the greater the effectiveness of placebo.[62] This was seen even in patient responses to psychotropic drugs: D-lysergic acid diethylamide tartrate 25 (LSD-25) could have no effect if the patient was told that the drug was a placebo.[45,63]

Patients, such as war heroes, who had severe injuries but did not have great mental suffering attached to their pain needed less pain medication than persons with similar injuries who had pain that engendered anxiety and connoted disaster.[64]

PLACEBO HEALING MECHANISMS

When animals or humans can react to their own deviations from homeostasis and when these deviations set off restorative processes, therapeutic intervention, including placebo, has an already existing substrate of recovery for exploitation.[17]

A human being has an intrinsic ability to "self-right"—*vis medicatrix naturae* (the healing power of nature). This is the keystone of a philosophy that has been held for thousands of years by naturally oriented physicians (see Chapter 5). The concept of a homeostatic, self-regulating mechanism is central to the understanding of basic concepts of physiology: negative feedback loops control virtually all systems of the body. According to Guyton,[65] "the body is actually a social order of about 75 trillion cells organized into different functional structures.… [E]ach cell benefits from homeostasis and in turn each cell contributes its share toward the maintenance of homeostasis."

The body can maintain health and reestablish a healthy state after disease by virtue of its inherent vitality. This is part of the definition of a homeostatic mechanism; it has been selected by nature in the same way that organs vital to our survival have been selected. The surviving species are those most fitted and best able to cope with dysfunction. Those organisms that can tolerate the greatest stresses and still maintain normal physiology are the hardiest survivors and ensure the species' ability to increase the limits of its adaptation. Therefore, given that an organism is self-maintaining when in an environment that it has been selected for, healing happens unaided through simply maintaining an environment that does not obstruct the path of cure. As Norman Cousins[66] observed, "without any help, the human body is able to prescribe for itself. It does so because of a healing system that is no less real than the circulatory system, the digestive system, the nervous system, or any of the other systems that define human beings and enable them to function."

The Role of Emotions

Starting in the 1970s and early 1980s, review articles began to examine the effect of the mind on the immune system, emphasizing mechanisms and pathways that gave rise to a new field called psychneuroimmunology.[5] Reviews of studies that explored how specific emotions can increase cancer susceptibility,[67,68] examined the effect of emotions and recovery from cancer,[69] investigated the increased incidence of sudden and rapid death during psychological stress,[70] and monitored the changes in immune function during emotional stress[71,72] all confirmed that emotions play a powerful role in the prognosis of a patient. Cannon[32] and Tregear[73] documented dramatic case histories of pioneering anthropologists who witnessed the power of taboos and curses to kill strong, healthy men and women in third-world cultures throughout Africa, South America, and the South Pacific. Tregear[73] wrote, "I have seen a strong young man die the same day he was tauped [tabooed]; the victims die under it as though their strength ran out as water."

The *Vis Medicatrix Naturae*

The healing process described as *vis medicatrix naturae* demonstrates the significant power and potential of the self-generated healing capacity. For a physician, there is no more powerful stimulator of this healing mechanism, the placebo effect, than a strong doctor–patient interaction. Just walking through the door of the physician's office nudges a patient's internal homeostatic mechanisms into seeking higher levels of health, healing, and adaptation. The placebo effect is a result or effect of the patient's seeking the assistance of the doctor's ability to heal and cure. As Benson[60] noted,

> *When we dissected the placebo effect a number of years ago, we found three basic components: One, the belief and expectation of the patient; two, the belief and expectation of the physician; and three, the interaction between the physician and the patient. When these are in concert, the placebo effect is operative.… Perhaps nothing is being transmitted from the healer to the patient, but rather it's the belief the patient has in the healer that's helpful.*

Conscious Control Over Homeostasis

The body has two internal forces to maintain homeostasis: a lower drive and a higher drive. The lower drive is the inherent internal healing mechanism, the vital force, or the primitive life support and repair mechanism that can operate even in a person who is asleep, unconscious, or comatose. The higher drive is the power of the mind and emotions to intervene and affect the course of health and disease by depressing or stimulating internal healing capacities. The effect of this drive can be seen in the clinical observation of patients who move toward spontaneous remission of a life-threatening disease through positive emotional support[15,69] and in patients who fail to express emotions compatible with the body's attempts to survive.[69]

In any disease process, the consciousness of the patient decides the effectiveness of any therapy. It has been suggested that widely ranging nondrug stimuli have the capacity to modulate human functioning.[74] It is emerging in the medical literature that any sensory stimuli or mental activity is able to alter disease progression. This extends to the thoughts and intentions of those connected to the patient. Experiments in remote intention–generated healing and prayer showed that the intention of others was a factor in the homeostatic capabilities of the mind and body. The fact that the homeostatic mechanism can sense and respond to these remote intentions is a reflection of the power of the human mind. Some authors believe that there is a physiological basis for the unlimited possibility of human voluntary control.[75] The conclusion that awareness or "mind," anyone's mind—the patient, the doctor, or someone who is aware of the patient—can alter the patient's physiology is a testament to the "holos" concept in different schools of alternative and complementary medicine. This idea flies so deeply in the face of our mechanistic model of medicine, it forces a complete paradigm shift in the conventional social ethos of medical care.

The ultimate control of psyche over soma demonstrates the priority of the conscious mind over physiological processes such as immunity and pain control.[76] This puts an enormous responsibility on the physician. He or she must take full account of a patient's mental and emotional states when treating chronic or life-threatening disease.

Physiological Mechanisms

Identification of a biochemical mechanism for placebo analgesia has done more to change the image of placebo therapy than any amount of arguing about the importance of beliefs and the mind.[77]

The mechanisms of the placebo response have been suggested to be a mixture of psychological interactions[78] and cognitive states[79] mediating physiological responses.[19] The psychological components

of the patient's placebo effect have been shown to include decreased anxiety and increased relaxation,[54] conditioning,[18] expectation,[23] and well-being generated by the establishment of a sound doctor–patient relationship.[80,81]

Review articles summarized a wide range of receptor-agonist mechanisms driving the neural pathways in different parts of the brain.[82] To date, endorphin, dopamine, cholecystokinin, interleukins, growth hormone, and cortisol have been implicated. The physiological mechanisms of the placebo effect were suggested to include chemicals, catalysts, and enzymes. It is believed that steroids, catecholamines,[15] the autonomic nervous system,[19,83] neuropeptides, and endorphins[84] are also involved. These physiological mechanisms interrelate synergistically and are currently being researched within the rapidly developing field of psychoneuroimmunology,[7] through which the links between depression, affective disorders, emotions, and the immune system and central nervous system (CNS) are being explored. Susceptibility to depression and sensitivity to pain have now been found to be mediated through neurotransmitters such as catecholamines, serotonin, and dopamine.

The current model for explaining the mechanism by which emotions, mood, and psychological stress suppress immune function involves cerebral–hypothalamic and pituitary interaction, which translates stress and anxiety into an autonomic–endocrine response. This response adversely affects the immune function, particularly after chronic stimulation. Stressful stimulation is received in the sensory cortex of the brain and is then referred to the limbic system and the hypothalamus. This interface of higher-brain functions and homeostatic regulating centers provides the communication link between the psyche and soma. According to Rossi,[19] "The hypothalamus is thus the major output pathway of the limbic system. It integrates the sensory-perceptual, emotional, and cognitive function of the mind with the biology of the body."

The nerve centers that control both branches of the autonomic nervous system (both parasympathetic and sympathetic), nerve cells that secrete endocrine-releasing factors, and neural pathways that release hormones directly into the posterior pituitary are in the hypothalamus. The corticosteroids and catecholamines from sympathetic stimulation are key factors in the alteration of disease susceptibility in response to stress. Corticosteroids inhibit the function of both macrophages and lymphocytes, as well as lymphocyte proliferation.[85] Corticosteroids also cause the thymic and lymphoid atrophy noted by Hans Selye in his experiments on stress-induced immune dysfunction.[86]

The autonomic release of catecholamines stimulates receptors on the surface of lymphocytes, thereby increasing their maturation rate. When lymphocytes are in a mature state, their ability to kill bacteria and cancer cells and produce interferon seems to become paralyzed.[87] Thus a population of mature lymphocytes develops, ready to defend the body from infection and inflammation, yet remains paralyzed until the "red alert" signal of sympathetic fight or flight is turned off, signaling the appropriate time to rest and repair.

A number of other peptides, E-type prostaglandins, somatotropin, histamine, insulin, endorphins, antidiuretic hormone, and parathyroid hormone all have receptor sites on lymphocytes and can stimulate the same cyclic adenosine monophosphate–mediated response resulting in lymphocyte maturation and inhibition.[85] A study of the effect of catecholamines on the human immune system showed that when a physiological dose of epinephrine was injected into a healthy volunteer, there was an increase in the number of circulating suppressor T lymphocytes and a decrease in the number of circulating helper T lymphocytes (changes similar to those found in acquired immunodeficiency syndrome [AIDS]).[85]

Neurophysiology of Placebo Response

Medical research has continued to expand the understanding of the placebo healing response, extending the understanding of the complexity of the brain functions that control healing in the body.[88] One review article did an excellent job of summarizing the psychobiological mechanisms involved in the wide array of medical conditions observed in the placebo response literature.[2] Imaging techniques such as positron emission tomography and magnetic resonance imaging (MRI) have literally illuminated the areas of the brain involved in generating the placebo effect.[89] One fascinating development is the indication that the placebo effect may be especially useful in depression, anxiety, substance abuse, and neurodegenerative diseases like Parkinson's disease and Alzheimer's disease. Research has indicated that the conditioning and anticipation of the patient have a potent effect of stimulating specific brain region activity associated with pain modulation and neurohormonal regulation.

Brain Region Activity

Some of the most interesting research on placebos has evolved out of the new MRI technology. This functional MRI (fMRI) can measure blood flow into specific areas of the brain. One study showed that expectation or hope was able to stimulate a certain part of the brain that is activated by pain medications and is associated with pain relief. Placebo analgesia was found to be related to decreased brain activity in pain-sensitive brain regions, including the thalamus, insula, and anterior cingulate cortex. It was also associated with increased activity during anticipation of pain in the prefrontal cortex, providing evidence that placebos alter the experience of pain.[90]

In another study, researchers found that empathy could activate a portion of the brain. They showed that some of the brain regions involved in feeling physical pain became activated when someone empathized with another's pain. Using fMRI, study participants were observed when they experienced a painful stimulus, and the results were compared with those elicited when the participants observed their spouses receiving a similar pain stimulus. The bilateral anterior insula, rostral anterior cingulate cortex, brainstem, and cerebellum were activated when participants received pain and also by a signal that a loved one experienced pain.[91] A group of researchers at the University of California at Los Angeles, using a new technology called quantitative electroencephalography, showed that "effective" placebo treatment induced changes in brain function that were different from those associated with antidepressant medication. Placebo responders (those who showed a response to placebo) showed a significant increase in prefrontal activity starting early in treatment that was not seen in medication responders or in participants who showed no response to medication or placebo. Because a high percentage of antidepressant medication represents the placebo effect, it is important to be able to predict who will be placebo responders.[92]

Placebo and Stress Physiology

The stress "letdown" of a patient in the therapeutic environment is one of the mechanisms that produces the placebo effect. It results from the patient's perception that a transition from a stressful situation to a nonstressful situation has occurred. Mowrer[87] observed that with a decrease in anxiety, there is a concomitant increase in hope, signifying that the period of suffering is over. Certain familiar images and signals, such as white coats, syringes, behavioral procedures, and clinical protocol, create a conditioned response—relief now that help has arrived. Evans and Hoyle[54] similarly observed that "the reduction of fear through the shared expectations that the doctor's medicine will work—even if unknown to the patient it is placebo—mediates powerful therapeutic effects."

The placebo effect in the clinical environment transforms the emotional and mental stress of the patient. These effects, also observed and described by Franz Alexander,[16] Hans Selye,[86] George Solomon,[93] and Walter Cannon,[94] allow the patient to escape the "fight-or-flight" response that can cause and maintain the state of illness.

Physiological and Psychological Stress

Selye[86] demonstrated that physiological stress can have a dramatic effect on the immune and endocrine systems of the body. Laudenslager[95] went on to show that it is not just stress that creates these physiological changes; the perception that stress is "inescapable" is critical to the response. More recently, studies on the effects of psychological stress demonstrated significant changes in immune capability. Maladjustment to "life-change stress" correlated with reduced activity of natural killer cells,[93] decreased T- and B-cell responsivity,[71] and diminished lymphocyte cytotoxicity.[96] For example, Riley[97] observed increased tumor activity in a controlled stress environment and concluded:

> *Emotional, psychosocial, or anxiety-stimulated stress produces increased plasma concentrations of adrenaline, corticosteroids and other hormones through well-known neuroendocrine pathways. A direct consequence of these increased corticoid concentrations is the injury to elements of the immunologic apparatus, which may leave the subject vulnerable to the action of the latent oncogenic viruses, newly transformed cancer cells, or other incipient pathologic processes that are normally held in check by an intact immune system.*

The damage to the immune system by stress, mediated through the hypothalamic–pituitary axis, has been shown to be due to the increase in serum levels of cortisol. In one study, elderly caregivers were shown to have higher cortisol levels and poor antibody response to influenza vaccine.[98] The effect of cortisol on immune and other regulatory functions, such as the regulation of blood sugar, dehydroepiandrosterone (DHEA), insulin, testosterone, and bone resorption, flag it as having highly destructive potential. Anxiety, depression, heart disease, AIDS, and osteoporosis have all been linked with elevated cortisol levels. DHEA, another adrenal hormone, is also modulated by stress physiology, although it seems to have the opposite effect of cortisol. High levels of DHEA seem to protect the body from the damaging effects of elevated cortisol. Ratios of DHEA to cortisol are highly predictive of the individual's ability to tolerate stress.[99]

Current reviews of the literature relating psychological stress and immune dysfunction support the hypothesis that homeostatic immune mechanisms, both humoral and cellular, are significantly impaired by both natural and experimental stress.[5,61,84,100] Hypertension,[101] common colds,[102] coronary artery disease,[103] and myocardial ischemia[104] were linked to adverse stress physiology. Stress even has the ability to increase the permeability of the blood–brain barrier.[105] The implications of stress-related alterations in the blood–brain barrier expose important insights into enigmatic diseases like chronic fatigue syndrome and stress-induced neurological disorders.

Endorphins, Hormones, and Neuropeptides

> *…one rapidly activated psychoneuroendocrine mechanism through which a placebo stimulus may reduce both depression and pain is produced by stimulating the endorphin system.*[18]

Research on endorphins is a relatively new area of study in the field of psychoneuroimmunology. Original research by Levine et al.[106] suggested that the pain relief noted in placebo studies could be explained by the simple mechanism of endorphin-mediated actions. The original emphasis on endorphins and enkephalins was plausible, considering their known modulation of pain and mood functions. This position was further supported by later observations that depression increased chronic clinical pain[107] and that decreased activity in endogenous opioids may be part of the pathophysiology of depression.[108] With the information that placebo can stimulate endorphins, Levine et al.[106] believed that an explanation for the action of placebos had finally been found. Furthermore, research showed that an endorphin-mediated, pain-suppressant placebo effect could be abolished with the use of Naloxone, an opioid antagonist.[109] The same authors went on to further show that endorphin-mediated placebo effects penetrated other physiological systems besides pain management.[110] However, this hypothesis failed to account for the broad spectrum of placebo effects as well as for the fact that the analgesia associated with hypnosis was not affected by an opioid antagonist.[111,112] It is important to note that later literature suggested that Levine et al.[106] were not entirely wrong in implicating the role of endorphins in the placebo mechanism; rather, these researchers were right for the wrong reason.

TABLE 6.2 Effects of Endorphins on the Immune System

Immune System Function	Endorphin Effect(S)
Lymphocyte production	Increased and decreased
Chemotaxis	Increased
T-cell sensitivity to prostaglandin E_2	Increased
Antibody production	Increased and decreased
Complement	Binding of fractions C5B-C9
T-cell proliferation	Modulation of
Natural killer cell function	Modulation of
B-cell differentiation	Modulation of

Endorphins are mainly derived from three precursor proteins (by separate biochemical processes).[113] These opioid peptides are released from central and peripheral areas in response to pain, stress, and emotions and perform many physiological functions, of which analgesia is but one.[114] However, it is becoming evident that the boundaries between the CNS and the immune system are not as clear as once thought. The several known effects of endorphins on immune system function are listed in Table 6.2.[115]

When the functions of neurotransmitters such as endorphins are found to have such an intimate relationship with immune integrity, the paradigm of a body with functions performed independently by its parts—a Newtonian type of thinking—begins to lose credibility. To further blur the already hazy distinction between the CNS and the immune system, research demonstrated that endorphins and peptide hormones, such as adrenocorticotropic hormone, thyroid-stimulating hormone, human chorionic gonadotropin, and luteinizing hormone, are produced by lymphocytes.[115]

It is clear that the demarcation between the CNS and the immune system is impossible to distinguish. The brain and the immune system are the only tissues in the body that have a memory, and the level of communication between the two argues a taxonomy that identifies them as one. Evidence of the innervation of the thymus gland, bone marrow, spleen, and lymph nodes supports the finding that the immune system is subject to efferent CNS information.[115] In addition, studies demonstrating the atrophy of the thymus and lymphatic tissues in the absence of growth hormone,[116] adrenocorticotropic hormone, and increased steroid production by adrenal cells after interferon stimulation indicate that "in the future it will be difficult to distinguish the receptors and signals that are used within and between the neuroendocrine and immune system."[115]

BOX 6.4 Six Principles of Optimizing Placebo Response in Clinical Practice

- *Prima non nocerum:* Prioritize a hierarchy of therapeutic interventions.
- *Tollem causum:* Remove the obstacles.
- Support the therapeutic relationship.
- Enhance positive emotional states.
- Implement therapeutic conditioning or learning.
- Use altered states of consciousness.

CLINICAL APPLICATION

Whether a clinician intends to initiate a placebo effect in a clinical setting or not, the mind of the patient will initiate some subliminal healing effects according to the patient's hope, expectation, conditioning, anxiety reduction, and meaning around the disease and treatment. A recent article in *Lancet*[2] on placebos concluded, "Any ethical assessment of efforts to promote placebo effects in clinical practice first requires knowledge as to the clinical relevance and importance of placebo effects."

A physician with an interest in psychopharmacological treatment, which can be expensive, elaborate, detailed, time consuming, esoteric, and dangerous, usually has considerable knowledge about such treatment. He or she is interested in the symptoms of the patient and the differential response to various drugs and is careful to observe side effects, which may be dangerous. The physician may encourage the patient to call at any time if side effects develop.[26]

The application of the placebo phenomenon in clinical practice should not be a vague attempt to replace the skill of the medically trained physician with obscure "hand waving," incantations, and inert lactose pills. In primary care and specialty clinical practice, the physician's intent should be to optimize patient care by engaging restorative defense mechanisms. To effectively apply current placebo research, the physician must understand several principles (listed in Box 6.4 and discussed here).

Prima Non Nocerum: Prioritize a Treatment Program and Establish a Hierarchy of Care

Prima non nocerum is the Hippocratic injunction dictating that a physician care for the patient so that self-healing mechanisms can engage. This ancient phrase means "Do not disturb the organism's ability to heal itself." The body must be given the full range of possibilities in allowing the power of homeostasis, *vis medicatrix naturae*, to have its optimum capability. "Doing no harm" means that a patient is supplied with the level of medical intervention that is appropriate to his or her ability to maintain life support. The job of the physician is to determine when homeostasis or the defense mechanism has lost the ability to respond to disease.

Acute traumatic swelling and inflammation and shock are examples of the human defense mechanism responding in a way that threatens the health of the organism. It is most interesting that the organism would make choices, as in shock and inflammation, that could kill it. To practice the principle of *prima non nocerum*, a physician must learn when to act and when to let the body heal itself. This is the highest art of medicine; each case and situation is different, and it is up to the physician to interpret the needs of the moment. By implication, the physician who seeks to apply this principle understands the principles of physiology on which human life depends for homeostasis.

Prima non nocerum does not necessarily mean that a physician withholds invasive therapy: it is the physician's responsibility to determine when the body is unable to reestablish homeostasis and therapy is indicated. If an arm must be severed to save the patient's life, there is no violation of *prima non nocerum*.

However, to enhance the principle of *prima non nocerum*, a physician sometimes must withhold therapies and must be content to leave the patient to self-heal. Hippocrates understood the wisdom of letting the body heal on its own, which is implicit in the injunction to "do no harm." The following account of the treatment of Charles II of England is a case in point[117]:

> *A pint of blood was extracted from his right arm and a half pint from his left shoulder, followed by an emetic, two physics, and an enema comprised of fifteen substances; the royal head was shaved and a blister raised; then sneezing powder, more emetics, and bleeding, soothing potions, a plaster of pitch and pigeon dung on his feet, poisons containing ten different substances, chiefly herbs, finally forty drops of extract of human skull and an application of bezoar stone; after which his majesty died.*

When this treatment is compared with modern procedures, such as mammary artery ligation for the relief of angina—a procedure that has no more benefit than sham artery ligation—it appears that physicians continued throughout the centuries to rely on the placebo effect for the care and cure of their patients. Recently, the invasive standard-of-care procedure percutaneous coronary intervention (PCI) of angioplasty and placing coronary stents was shown to be no better than placebo for stable angina. Missing from the medical community discussion on this study was the remarkable fact that some individuals who underwent the sham "placebo" PCI procedure had results that demonstrated that the placebo effect can affect cardiac perfusion.[118] Our medical culture has very little interest in exploring the physiological limits of self-healing.

Because this effect plays such an important role in health care, simple, noninvasive, and effective treatments should be the goal of all therapeutic approaches. Robert Burton[119] wrote in 1628, "an empiric oftentimes, and a silly chirurgeon, doth more strange cures than a rational physician… because the patient puts confidence in him."

The rational physician will also recognize that healing and curing are not necessarily the same. If a patient is helped in any way by the doctor, with or without the use of a placebo, the path of cure has been assisted, although the specific disease may not have responded. Not all patients can be cured, but most patients can be helped.

Tollem Causum: Remove the Cause of Disease

Tollem causum is the principle that seeks to remove the obstacles to cure. The forces "inhibiting the floodgates of health from opening" must be removed for the full force of the patient's beliefs to effect the path of cure. This concept is fundamental to the philosophy of naturopathic medicine, with its strong emphasis on diet, detoxification, and a pattern of living that is consistent and compatible with the context in which humans evolved. Obstacles to cure block the self-healing capacity of the organism. Contamination with heavy metals and xenobiotics (see Chapter 35), focal infections, electromagnetic pollution, scar tissue, genetic metabolic abnormalities, and parenchymal organ damage defeat the best therapeutic intentions and must be addressed.

The patient's habitat is an important aspect of the therapeutic protocol, not only in the diagnosis and care of internal mental and physiological dysfunction but also in determining which environmental factors may be contributing to dysfunction and disease. These factors might include diet, lifestyle, and living environment. It is of the utmost importance to remove a patient from surroundings that are associated with illness or to assist the patient in creating an environment more conducive to health.

Factors that provide conditioning that reinforces the disease process can be associated directly or indirectly with one's environment. For example, if animals are returned to situations where their experimental neuroses were induced, their pathological behavior reactivates.[120] When a patient leaves the offending environment to receive treatment from a physician, the prognosis is correspondingly more favorable.[17] The physician has the added advantage of a patient's heightened expectation during an office visit; a patient's positive associations with the "healing" environment increase his or her receptivity to treatment.[121] If the home or work environment is a source of "disease" and an obstacle to cure, providing an alternative environment may be a most helpful way to remove the obstacles to cure.

Support the Therapeutic Relationship

Confidence should surround all aspects of the therapeutic interaction. The patient must have confidence in the doctor's ability to assist a cure; the doctor must have confidence in the efficacy of his or her therapy[122]; and there must be an understanding or relationship between the doctor and patient that is mutually conducive to respect, trust, and compassion.

The quality of the doctor–patient relationship is paramount. The therapeutic approach to a patient that optimizes the confidence of the patient in the skill of the doctor stimulates the inherent self-regulating healing mechanisms by relaxing the anxiety the patient has about the illness. Anxiety is a well-known immunosuppressant and aggravates the body's defense mechanisms. An optimum therapeutic relationship, when combined with the clinical skill to remove the cause of homeostatic dysfunction, is the height of therapeutic acumen. As Lewith[123] so accurately stated, "The general practitioner may therefore wish to employ all his knowledge, enthusiasm, consultation technique and sympathy, to create the best possible atmosphere in which to elicit a placebo response from the patient."

Current research on factors contributing to the genesis of the placebo effect consistently document the importance of the doctor–patient relationship.[124–126] The healing power of the therapeutic interaction has been demonstrated by the commencement of the placebo effect even before the actual administration of the pill.[127]

The physician facilitates the cultivation of a sound relationship by developing good communication skills. The art of the bedside manner has been recognized throughout history as the primary skill a successful physician needs.[128] The history of medicine is as much a history of the relationship between doctor and patient as the evolution of medical technology and techniques. Through centuries in which doctors were doing more harm than good, little more than the esteem of their clientele sustained the medical profession. But however little real help the doctor had to offer, it was to him that people turned when illness struck.[129]

Bedside manner has been found in clinical studies to entirely alter the course of double-blind studies, and the quality of a therapeutic encounter has been found to facilitate or disrupt the efficacy of a treatment.[130] Listening to the patient,[130] the verbal and nonverbal communication of the physician, the amount of time spent with the patient,[131] patient education,[132] the demeanor of the physician,[133,] and interview skills[131] have been suggested as factors and components of effective physician communication skills. Communication between the doctor and patient is not simply a process of one party talking and the other side listening. Deep communication between both sides is a process of "interbrain" synchronization—literally, the brain waves of two people talking begin to match each other, as described in a research study by researchers at the Basque research center BCBL.[134] This synchronization or lack of it may be an important aspect of interpersonal communication. The examination of placebo dynamics uncovers the complexity, depth, and importance of the doctor–patient relationship. Many factors may be responsible for the varying therapeutic effects of the physician–patient relationship. An open-minded investigation of this relationship brings us, incredibly, to the possibility of brain-to-brain coupling, an interconnected matrix of the mind of the healer and the healed.[135] Learning to "listen" or synchronize with the patient you are communicating with ensures optimum transfer of information, hope, empathy, and a host of essential dynamics between doctor and patient.

Touch is an important form of communication and is sometimes forgotten as a key aspect of the doctor–patient relationship. Highly skilled clinicians with many years of experience, such as the now deceased Dr. John Bastyr (whose remarkable healing abilities inspired the founding of Bastyr University by those privileged to have been his students), frequently impressed upon clinicians the importance of always using diagnostic and therapeutic touch during a patient visit. The doctor's touch can be diagnostic, therapeutic, and, perhaps most important, a means of communicating that he or she is deeply attuned to the problems, needs, and fears of the patient.[133] Touch can heal by increasing tissue mobility and fluid exchange, as in massage, or by relieving pain, as demonstrated by research on healers who use their hands.[136] Touch has also been documented in well-designed double-blind research to extend an unusual healing power that can be transmitted through the hands to plants and animals.[137]

Among other methods of enhancing confidence between the doctor and patient, the setting in which a doctor provides therapy to a patient also determines its effectiveness. The doctor's office setting is very important for optimum and effective treatment: tools and support systems are more accessible, and a heightened patient response results from seeking out the "healing" environment. In a clinical trial with hypertensive patients, placebo alone was not as effective as when it was administered in conjunction with hospitalization. The visit to the physician represents a search for changes that cannot be found through "self-care" or over-the-counter medicines. According to Frank[138]:

> *In short, it appeared that the placebo situation relieved chiefly anxiety and depression, that the degree of relief was unrelated to personality and autonomic measures, and that the patients who responded strongly to a placebo at one time might not at another. In conjunction, these results suggest that the extent of responsiveness to a placebo depends on the interaction of the patient's state at a particular time with certain properties of the situation. The finding that administration of tests and questionnaires seemed to have at least as beneficial an effect as had the pill implies that any interaction between patient and situation that heightens expectations of help may lead to symptom reduction and improvement in mood. The aspects of the situation producing this effect include not only presentation of a symbol of the physician's healing powers (a pill), but any attention and interest shown by professional personnel.*

This phenomenon was also observed in industry and termed the *Hawthorne effect.* As a direct result of the greater attention factory workers received during investigation, the quality of their work improved.[139] In conclusion, the importance of a doctor–patient relationship and the confidence that it engenders shows that all human beings need to share their feelings and experience the therapeutic benefits of touch: the doctor–patient relationship provides an ideal way to meet these fundamental needs.

Enhance Positive Emotional States

> *Love in all its subtleties is nothing more, and nothing less, than … the psychical convergence of the universe upon itself.*
>
> ***—Pierre Teilhard de Chardin, The Phenomenon of Man***

For optimum enhancement of the psychoneuroimmune system, the physician must assist the patient in developing practices that amplify positive emotional states and reduce a negative emotional state. A negative mental state (anxiety, stress, panic, anger, depression, neurotic behavior, self-deprecation, self-destructive feelings and tendencies, and a weak will to live) hinders the ideal functioning of the psychoneuroimmune endocrine axis, disrupting homeostasis. Engle[140] termed this the *giving-up/given-up complex:*

> *Study of the life settings in which patients fall ill reveals that illness is commonly preceded by a period of psychological disturbance, during which the individual feels unable to cope. This has been designated the giving-up/given-up complex and has the following five characteristics: a feeling of giving up, experienced as helplessness or hopelessness; a depreciated image of the self; a sense of loss of gratification from relationships or roles in life; a feeling of disruption of the sense of continuity between past, present, and future; and a reactivation of earlier periods of giving-up. It is proposed that this state reflects the temporary failure of the mental coping mechanisms with a consequent activation of neurally regulated biologic emergency patterns. Changes in body economy so evoked may alter the organism's capability to deal with concurrent pathogenic processes, permitting disease to develop.*

The importance of reducing negative mental states in acute and chronic conditions has been discussed extensively.[70] Acute psychological stress is documented to cause various forms of cardiopulmonary dysfunction and even death.[61]

Chronic mental and emotional strain causes a breakdown of the immune system and can lead to disease. The homeostatic processes become overwhelmed by autoimmune, microbial, or neoplastic invasion. Major writers on the subject of acute and chronic stress emphasize the high priority of managing the physiologically and immunologically destructive effects of the human body's response to stress. Pelletier[141] listed hypertension, arteriosclerosis, migraine headache, cancer, chronic bronchitis, emphysema, asthma, and arthritis as disease processes that are caused or exacerbated by stress physiology. A study researching the relationship between resistance to streptococcal infections in families and stress load in the family found a positive correlation.[142] Another study on the psychosomatic susceptibility to infectious mononucleosis found that two psychosocial factors, high motivation and poor academic performance, significantly increased the risk of "disease" infection.[143] In still another, anticipation of mood and menstrual discomfort were positively correlated and manipulated, thereby supporting the suspicion that expectations act as a determinant of mood.[144]

The conclusion that there is no acute, chronic, or degenerative disease that is not affected by a patient's mental and emotional state must be drawn from the pervasive immunoendocrine effects generated by the mind and emotions. Wolf[145] and Cousins[146] wrote of the power of panic as a factor in myocardial infarction; Marbach et al.[107] described depression as a component in myofascial pain dysfunction; and Shekelle et al.[147] noted, in a 17-year follow-up study, a twofold increase in the incidence of cancer in depressed patients. The clinical scenarios these observers described imply that the placebo effect can control the onset and advance of a disease by shutting down the destructive thoughts, images, and feelings that mediate stress.

Enhancing positive emotions is the corollary of controlling the damaging effects of negative mental and emotional states. Laughter,[23] hope,[148] acceptance,[64] and the reduction of suffering[149] have been shown to speed the course of healing and reduce the level of pain and distress reported by patients. Although pain is sometimes the only language nature can use to adequately communicate to the patient that something is in need of healing, "the relief of suffering and the cure of disease must be seen as twin obligations of a medical profession that is truly dedicated to the sick."[149]

Acceptance has been observed to be a key factor that assists patients in better understanding their pain.[64] Acceptance does not mean complacency in the face of disease but a rational understanding of the situation and the limitations that can sometimes accompany a disease process.

The importance of cultivating hope in a patient also cannot be underestimated.[150] The fact that a patient seeks the help of a physician or "caregiver" already implies a substrate of hope and is a signal that the patient can visualize the potential for recovery. The treatment needs to merely stimulate this willingness to envision a future of health. Hope is an embodiment of the patient's and the doctor's ability to visualize an image of healing and recovery. This process is a recurrent theme in imagery therapy,[151] visualization therapy,[152] therapeutic touch,[153] and psychic healing.[154] Hope is both an active and a passive placebo. The *passive hope placebo* is that which is brought with the patient as the act of seeking help generates a level of unspoken faith in an image or potential for cure. The *active hope placebo* is generated by the physician, who consciously instills a vision or image of cure in the patient as an adjunct to therapy.

Frank[138] performed a double-blind study in which patients were divided into control and induction groups. The induction group was led through a process whereby their hope was strengthened to conform with the expectations of the therapist[138]:

> *It introduces some perceptual clarity into the process of treatment; and to the extent that all our therapists adhered roughly to the insight model of therapy, it helped to bring the patient's expectations in line with what actually occurred in treatment, and also helped him behave in accordance with the therapist's expectations of a good patient.*

The induction group was actually being consciously strengthened to a level of optimal response but was not being led into false expectations.[155]

This type of patient education or active placebo is a necessary and useful tool for framing and directing a positive outlook and prognosis. If a patient can conceive of a state of wellness, then that state of wellness can be achieved. It is the job and domain of the physician to discover those images, emotions, and perceptions that reside in the conscious and subconscious mind of the patient that block the image of a positive state of health. He or she must actively work to control these with the same level of intent as with any presenting gross complaint or physiological dysfunction. Finding these dysfunctional mental substrates and working with the patient to try to change them is fundamental to treating the true cause of disease (see earlier discussion of *tollem causum*).

Research demonstrated the importance of positive and negative thinking in heart disease and cancer, the two areas of disease that cause the highest death rate. Doctors' health care management protocols should reflect this research in the same way that attention to a proper diet is part of a management approach to high serum cholesterol. It is now clearly established, for instance, that even low levels of stress trigger the onset of myocardial ischemia.[156] We also know from the work of Steven Greer[157] and David Spiegel[158] that attitude and emotional exploration are critical to breast cancer survival. Knowing these scientific facts, all doctors must have strategies for helping their patients explore the areas of stress management, group therapy and support groups, and skills in building positive attitudes.

Implement Therapeutic Conditioning or Learning

> *Those who remain at least dimly aware that everything they say or do to a patient conveys a major or minor, positive or negative, and helpful or harmful psychological impact are likely to be more effective physicians.*[159]

Conditioning of the mind has been suggested as a mechanism by which the placebo effect becomes a learned response.[17,19,138] The future of the therapeutic application of placebo will probably hinge primarily on the use of conditioning. A doctor who can understand this will pay close attention to the stimuli of his or her patients and modify these stimuli in a scientific way to help treat immune-related and neurologically related diseases.

Modern psychology acknowledges two models of conditioning or reinforcement of learning behavior, operant and classical. Operant conditioning is a behavior response that theoretically occurs in the presence of some stimulus that is a positive reinforcement; for example, a rat will learn to press a conditioning bar if a food pellet is dispensed as a result. Classical conditioning is a behavior response created by the simultaneous pairing of unconditioned and conditioned stimuli before an evoked response. This is best illustrated by the experiments of Pavlov and his "salivating dog." In Pavlov's experiment with the conditioning of a dog's salivary response to the ringing of a bell, the bell ring is the conditioned stimuli, and the food is the unconditioned stimuli. The salivation is the unconditioned response to the food that becomes the conditioned response. When the dog finally associates the bell ring with the food, the ringing alone causes salivation, the conditioned response.

The principle of classical conditioning has far-reaching implications for the diagnosis and treatment of disease because of the pervasive and permeating implications that conditioning has in all the sensory stimuli of daily existence, in sickness and in health: "Pavlov's teachings, concepts and basic notions afford the real and ultimately scientific basis for the recognition of the potentialities of medical science attacking diseases from both the psychic and somatic sides."[160]

For the purposes of this discussion, one must recognize that classical conditioning happens randomly in our environment and is closely linked to health and healing phenomena. Subconsciously, we note random events and associate them with previous events and observations, independent of an intended learning behavior. Operant conditioning happens in the context of reward, and classical conditioning happens in the context of associated stimuli. There is a much greater predominance and range of associated stimuli for classical conditioning than for operant conditioning for the genesis of the placebo effect. This is because the operant depends on reward, although operant conditioning can happen in the medical model: "Pain-killing drugs that I have taken in the past kill pain; therefore this capsule, which is a painkiller, will kill my pain."

Gliedman et al.[17] noted that drugs that affect the CNS are readily conditioned, whereas drugs that affect the peripheral nervous system and are secretory stimulators (e.g., atropine and pilocarpine) do not result in the establishment of a conditioned response. The primary importance of psychological states to CNS excitation demonstrates that the pivotal loci of command for conditioning reside within the hypothalamus and the limbic system. Therefore a doctor who can induce a state of central excitation in the patient can encourage and condition the patient to make those changes that are deemed necessary for the recovery of health.

The conditioning of a patient to a placebo response is modified by learning stimuli associated with the illness, the stimuli of the doctor and the therapeutic setting, the stimuli of the therapy, previous health, medical therapy, and authority-related experiences.[161] The way that all of these factors interact in the psyche of the patient determines the nature of the placebo response that is achieved.

Satiation obscures the conditioned response, whereas situations of increased stress seem to potentiate the responsiveness of the placebo effect.[64] The placebo effect, conditioning, and learning may therefore be subject to the nature of central excitatory states as well as levels of stress and distress.

The physiological breadth of the placebo response in humans can now be understood in terms of the variety of interactions and effects that drugs, therapeutic procedures, and sensory phenomena of the medical environment have on the psychosomatic matrix of a patient's consciousness. Rossi[19] noted that this complicated web of sensory processing reveals how any facet of therapy "that alters any aspect of the body's sensory, perceptual or physiologic responsiveness on any level can disrupt the more or less fragile state-dependant encoding of symptoms and thereby evoke a 'nonspecific' but real healing effect that we call the placebo response."

The scientific basis of therapeutic applications of psychoneuroimmunology is based on classical conditioning. Ader and Cohen[162] performed research to show that the immune system could be conditioned for therapeutic purposes. They conditioned immunosuppression in rats by injecting them with a conditioned stimulus of cyclophosphamide (a potent immunosuppressing agent) while feeding them a saccharine solution as an unconditioned stimulus.[162] The idea of conditioning for immunomodulation in human patients is therefore a promising therapeutic modality. Applying conditioning techniques for the treatment of systemic lupus erythematosus involving a dosage that normally had minimal results resulted in a delay in the development of the disease.[163]

To fully account for the extent of previous and future conditioning in a patient, the physician must take a complete and exhaustive history to explore the influences of family, work, accidents, emotional predispositions, medical history, and neutral stimuli as contributing factors during the onset of an illness. Lifestyle and emotional, behavioral, or physiological factors might contribute to maintaining the state-dependent learning pattern of disease and dysfunction or give clues to a successful therapeutic intervention. A good example of this is the demonstration by Batterman and Lower[164] of increased analgesic effectiveness based on similar previous therapy. A physician who knows which therapies succeeded and which failed can take advantage of the patient's conditioning and encourage biochemical pathways that the body has learned. Drug or therapeutic interventions are not procedures that can be predicted in the same way that in vivo experimental results can.

The variables involved in human responses to therapy are clearly underestimated in the current rush of research-oriented therapeutic evaluation.[165] Therefore a patient who has been treated by a number of physicians or practitioners for a complaint and has received no results or relief has been conditioned to believe that consultation and treatment by a physician will provide no positive changes. When the patient visits the next practitioner, even if this practitioner can offer a diagnosis and treatment that are correct answers to the long-sought cure, there are very real patient conditioning factors that must still be considered.

Consider the case of a young woman who underwent treatment for breast cancer and the clinical course of the ensuing metastases. Each time she had a positive response to therapy, she experienced a subsequent remanifestation of the cancer. The result of this conditioning was that she came to equate each new course of chemotherapy as a herald of some new manifestation: she "was torn between a desire to live and the fear that allowing hope to emerge again would merely expose her to misery if the treatment failed."[166]

The parameters of conditioning in a clinical setting extend to all aspects of the patient's sensory perceptions. Consciously or unconsciously, the physician provides an environment for patient learning. Lipkin[167] pointed out that every drug, every apparatus, every injection, and every piece of information or advice carries a suggestion of help and hope, regardless of the physiological effects that may accompany it. The physician must realize that patients are taking in all the information about the surroundings, interactions, and therapy and are making associations that can potentially affect the course of their responsiveness to therapy.

Mowrer[86] observed that the "safety signals" of syringes, laboratory coats, and behavioral procedures were all retained in the patient's psyche for future association. A physician can skillfully take advantage of these signals by encouraging and cultivating response generalization or by associating previous therapeutic situations with subsequent treatments by means of unconditioned stimuli, such as office music, odors, and images. Giving patients some sort of unconditioned stimulus that can be taken home allows them to associate with the conditioned response, eliciting the memory of the therapeutic interaction while patients are away from the doctor's office. These unconditioned stimuli or placebos can be given in multiples at one time[81]; changed for more powerful stimuli[168]; and delivered at the end of an induction, suggestion, or imagery procedure. They should not be limited to pills or other apparent medicaments and should extend to sounds, smells, visualizations, and feelings.

It should be remembered that therapeutic conditioning depends on a perceived physiological shift or change in the patient as described in the theory and research of biofeedback.[169] This shift can be experienced as a sense of relaxation, increased warmth or circulation, altered autonomic tone, or a change in some sensory perception. Patients know immediately when there is no change in their disease or dysfunction after they have been given placebo.[170] Therefore some patients need a more active form of therapeutic management that allows for some level of perceived change. Ideally this perception would be a sense of being free from pain or alteration from a state of abnormal physiological function to a state of improved physiological function. Acupuncture, spinal manipulation, drug therapy, physiotherapy, hydrotherapy, and surgery are all therapies that can create an immediate biochemical effect that is perceived by the patient.

The optimum model to apply to the concept of conditioning therapy and the selection of an appropriate therapy or modality was proposed by Greene and Laskin[171] in their evaluation of myofascial pain dysfunction. During an 11-year follow-up study of patients with myofascial pain dysfunction, these researchers concluded that when comparing the effectiveness of a wide variety of reversible and nonreversible (surgical) therapies, conservative and reversible therapies were the most important and appropriate treatment factors for the patient's health and well-being. Focusing on patient communication, educating patients about the reversibility of the condition and the nature of muscle dysfunction as it relates to stress–pain–spasm, developing a therapeutic strategy based on increasing patient awareness and self-management skills, and selecting a flexible treatment strategy were all found to be essential for achieving a good initial response that could lead to long-term wellness. Greene and Laskin[171] believe that the specifics as to which therapy is most indicated are not as important as the need to focus on the nature of presenting musculoskeletal problems and the factors and complexity of the treatment environment.

The routine use of active pharmacological substances reinforces the relationship between conditioned and unconditioned stimuli. However, the routine use of unconditioned stimuli in the absence of a conditioned response weakens the therapeutic efficacy of the practitioner and has been described as "placebo sag."[18] Therefore the learning of a conditioned response from unconditioned stimuli could diminish if the conditioned stimuli fail to produce an adequate or reliable conditioned response. Without the intermittent demonstration of active strength, the placebo effect will get weaker and weaker.

The implications of placebo sag for practitioners of alternative medicine, who try to work with the body's own defense mechanisms without overwhelming medical intervention, are that periodic use of perceptually active therapy is needed to support a patient who is not able to respond or responds too slowly to a gentler therapeutic nudge. In this case the physician must recondition the vital force to open a path to homeostasis.

In a sense, this may be a paradigm of the therapeutic situation, in which changes toward health are induced in the patient by a doctor who is able to cultivate a basic state of arousal, presumably central in nature. This state of arousal causes the patient to become accessible to the doctor's expectations of the patient.[17]

The typical placebo burst, in which a therapy is initially effective after a short period but then wanes, is now understood in terms of the placebo sag from a lack of effective unconditioned stimuli to maintain the conditioned framework.[168] Physicians who lack the ability to extract themselves from a series of unsuccessful therapies risk eventual placebo sag[18]:

> *[T]herapists who primarily use their active strengths (or unconditioned stimuli) paradoxically will get stronger placebo effects than quacks, will enjoy escalating credibility, and will seem as miracle men—when in fact perhaps only half their miracles can be traced to their active ingredients while the other half is a function of the anticipatory (or conditioned) response elicited by their conditioned features.*

Because the visit to a physician is often initiated by the physical pain of the patient, it stands to reason that skillful pain management is a high priority in establishing a therapeutic conditioned response. Pain management by hypnosis, transcutaneous electrical nerve stimulation, therapeutic touch, direct or indirect manipulation, imagery, acupuncture, meditation,[172] and an understanding that aims to elicit the nature of suffering[166] can all be valuable therapeutic adjuncts to establishing a therapeutic environment that conditions the patient for the full potentiation of his or her healing capabilities. (See Chapter 42 for a full discussion of these techniques.)

With the recent development of standardization of, research into, and concentration of the active components of plant medicines, vitamins, and biochemical precursors, naturopathic medicine and other forms of alternative medicine stand on a stronger therapeutic base because of an ever-growing verification of the pharmaceutical and therapeutic armamentarium. These therapeutic modalities are characterized by safe yet physiologically active substances and procedures; therefore they provide some defense against placebo sag.

Use Altered States of Consciousness

Since ancient times, aboriginal humans have recognized the tremendous therapeutic power that lies dormant in the subconscious mind. For thousands of years, shamans and medicine men have used trance states to engage the most subtle aspects of the patient's subconscious to affect factors in disease pathogenesis and prognosis.[173] In modern medicine, it has been documented that shamanistic healing involving altered states can offer dramatic "spontaneous remissions[33];" the mechanisms of this process have been explored in the theory and application of hypnosis.[4,76]

Most currently accepted techniques employed to trigger the subconscious to effect positive changes in somatic or psychic health involve hypnosis. The placebo effect has been linked with hypnosis, or

"low arousal states," which are therefore believed to be critical factors in the evaluation of the mechanisms and perimeters of placebo.[160] A review of the literature documenting the potency of hypnosis and the observed results of placebo clearly demonstrated that these two areas yielded remarkably similar clinical results. The inquiry into hypnosis grew out of the simple intent to validate the effectiveness of the mind in healing processes, whereas most placebo literature grew out of the intent to demonstrate a certain percentage of chance, fluke, spontaneous remission, or psychosomatic illness as a factor to be ruled out in the delivery of intelligent, scientific health care. Using these antiquated definitions of placebo and hypnosis, one is led to believe that hypnosis describes a process of healing based on the skillful guidance of a qualified practitioner and that placebo describes a process based on chance, regardless of the professional circumstances. On closer inspection, the distinction between the two blurs: they appear to be much the same process.

Illness, healing, and health states shift constantly in the homeostatic system, a system that is affected by stimuli received through the different levels of awareness and can be accessed, investigated, and modified by a variety of techniques. These include placebo, hypnosis, and induced altered states of consciousness. Rossi[19] noted that because memory depends on and is limited to the level of awareness in which the memory was acquired, it is "state-bound information":

> *State dependent memory, learning, and behavior phenomena are the missing link in all previous theories of mind body relationships.… The major thrust of these hypotheses is that mind-body information and state-dependent memory, learning and behavior mediated by the limbic-hypothalamic system, are the two fundamental processes of mind-body communication and healing.… The new approach to mind-body healing and therapeutic hypnosis may be conceptualized as processes of accessing and utilizing state-dependent memory, learning and behavior systems that encode symptoms and problems and then reframing them for more integrated levels of adaptation and development.*

Some psychosomatic phenomena are coded into the behavior of an individual through state-induced patterning. Until the patient can access the state in which somatic complaints are induced, possibly through hypnosis or other methods that break the sympathetic dominance of "encoded" shock,[174] the psyche cannot clear them from the soma[19]:

> *A person in a traumatic car accident experiences an intense rush of the alarm reaction hormones. His detailed memories of the accident are intertwined with the complex psychophysiological state associated with these hormones. When he returns to his usual or "normal" psychophysiological states of awareness a few hours or days later, the memories of the accident become fuzzy or, in really severe cases … the victim may be completely amnesic. The memories of the accident have become "state-bound"—that is, they are bound to the precise psychophysiological state evoked by the alarm reaction, together with its associated sensory-perceptual impressions.*

In accessing these psychosomatic state-dependent areas of homeostatic dysfunction, the physician must use techniques that relax the conscious mind and allow access to subconscious content for reframing. The nature of the visit to a physician encourages a patient into more accessible unconscious states, as demonstrated by higher placebo effects when patients present in a hospital setting.[121] These labile states of consciousness are quite natural; humans constantly cycle in and out of different consciousness states.[121] These cycles, or ultradian rhythms, are described as alternating cycles of hemispherical dominance that change every 1½ hours.

When these cycles are interrupted by behavioral stress, psychosomatic behavioral responses such as ulcers, gastritis, asthma attacks, and rashes develop.[175] A change in these rhythms manifests as a period of psychic repose. If an individual is in the midst of performing a task, daydreaming or the perceived need for a rest or coffee break may be the external manifestation of an internally sensed signal of a change in rhythm. This is also a period when one is highly susceptible to hypnotic suggestion. Because these rhythms are very flexible and labile, they can be invoked through hypnosis, or if the physician senses a natural lull indicating a hemispherical switch, a "natural" trance can be induced.

Centuries ago in India, practitioners of hatha yoga observed the effect of mental states on the breathing patterns of an individual. With anger, frustration, and mental instability, the breath reflects a short, arrhythmic pattern that mirrors the disturbed psyche of the person. Conversely, when a person is in a peaceful, relaxed, deep meditative state, the breath is long, rhythmic, and barely perceptible. Their discovery formed the basis for the development of breathing exercises called *pranayama* (literally, regulation or restraint of the vital energy), which aimed to calm the breath so that deep states of meditation and focused concentration could be attained. Current research has affirmed the powerful effect these exercises have on asthma, diabetes, chronic gastrointestinal disorders, and psychosomatic and psychiatric dysfunction.[176] Traditional literature on the ethnomedical effects of training the mind and energy (prana, qi, ki, lung) in India, China, and Tibet consistently remark on the antiaging effects of these training methods. Research suggests that meditation may have a deep antiaging response on human functioning, potentially measurable in the epigenetic aging effect.[177]

Therapeutic exercises that use somatic stimuli to effect changes in the psyche create fertile environments for stimulating the placebo response. A breathing technique used to decrease sympathetic tone or alter nostril predominance for causing shifts in hemispherical activity,[178] an exercise to release fascial muscle tension and thereby effect mood-enhancing blood flow in the brain,[179,180] and a biofeedback treatment that aids in slowing the heart rate and decreasing negative emotional states[169] are all examples of how the psyche can be accessed by the soma. The whole process of eliciting the placebo response involves an attempt to marshal all the reserves and potential for healing through a doctor–patient interaction, engaging both the patient's mind and body to reestablish homeostatic equilibrium. Therapeutic meditation training has shown benefit in modifying pain.[181] Engaging in a formal or traditional method of meditation training may give the patient enhanced insight into the nature of his or her mind and thereby elicit psychological and physical health benefits.[182] Trained meditators exhibit unique abilities of mental functioning.[183] Medical applications of mind-training methods might be better served by relying on methods with deep cultural experience, at the expense of adopting a liberal, nondenominational, nonsectarian method of "relaxation therapy," as it appears not all awareness therapies are created equal. Traditional meditation-training methods offer the possibility of sustained and enhanced awareness of mental states, which may contribute to positive medical outcomes.[184]

Healthcare professionals can use the wisdom of psychosomatic therapies as a central part of their therapeutic protocol. In addition to the specific therapeutic regimen, treatment of the whole patient can be achieved through these harmonious techniques. If physicians could persuade patients to care daily for their emotions, minds, and spirits

the way they care for their hair or teeth, the effectiveness of any prescribed treatment would be greatly enhanced. As a primary therapeutic adjunct and important basis for preventive medicine, this line of treatment is all too often ignored.

ETHICS

There are two forms of "conscious" placebo use by the physician. The use of a placebo as a gentle therapeutic agent by a practitioner is very different from the use of a placebo in a controlled trial in which the possibility of a known therapy is withheld in a treatment group. Some researchers believe that the use of placebos in clinical trials breaches the Declaration of Helsinki, which states that every patient should be assured of the best proven diagnostic and therapeutic method.[185] The ethical problems of delivering health care in a research design in which there is a possibility of a favorable outcome, and half of the group is denied access to this possible favorable outcome, make it a troubling issue.

The ethical use of placebos has also been questioned in an attempt to determine whether a physician should be deceiving patients during the process of healing.[186] Although some writers advocate a restricted use of pure and impure placebos because of their "deceptive" nature,[169] it becomes clear in a brief review of the current literature[6] that any argument for or against the use of placebo assumes the existence of medical procedures that are free of a potential placebo effect. Brody[29] concluded that a placebo can be called the "lie that heals." However, closer examination shows that it is not the lie that does the healing but, rather, the relationship between the patient and doctor that stimulates a natural self-healing mechanism via psychological, symbolic, and biological intervention[29]:

> *For some time, medical science has looked almost exclusively at technical means of diagnosis and treatment; the doctor/patient relationship that forms the setting for their application has been naively viewed as a noncontributory background factor, relegated to the amorphous realm of the "art of medicine," or simply ignored. In this setting, the placebo effect has inevitably been viewed as a nuisance variable, interfering with our ability to elicit "clean data" from clinical trials; and deception in medicine has been seen either as an unimportant side issue or as a tolerated means toward an end. But as the doctor/patient is rediscovered as a worthy focus for medical research and medical education, the placebo effect assumes center stage as one approach to a more sophisticated understanding of this relationship.*

A physician's correct understanding of the nature of placebo therapy has been observed as able to coexist with its inaccurate use and abuse.[41] It has been recommended, however, that (1) a pure placebo should not be prescribed unless the physician has examined the exact indications even more carefully than when prescribing specific therapy, and (2) to avoid missing a disease process that can be easily treated with an empirically proven protocol (e.g., vitamin B_{12}–deficient peripheral neuropathy), the physician should not relax a diagnostic protocol because a patient seems to be responding to a placebo.[186]

The final ethical hurdle of placebo use, or any medical treatment, for that matter, is the abuse of hope in the patient's path of healing. It is one thing to make a harmless recommendation that provides no therapeutic value, but it is another to subject a patient to the known consequences of a dangerous procedure in the pursuit of a dubious outcome. Hope can be abused, leading the patient to experience unreasonable suffering.[187]

CONCLUSION

Health practitioners must be equipped with a better understanding of placebo therapeutics.[10,188] For many years now, the study of placebos has been recommended to doctors and other healthcare professionals. The ideal environment for the dissemination of the therapeutic implications of the doctor–patient relationship is in medical schools as a required part of the curriculum. After finding a pattern of misuse and misunderstanding about the nature and efficacy of placebo, Goodwin et al.[41] recommended that better education might result in more effective placebo use.

In 1938 Houston[128] wrote of the need to reaffirm the art of medicine because he perceived a trend in medicine that invested in a concept of the therapeutic doctor–patient interaction as "undisciplined thought." Houston's remedy for the intellectual bias that viewed medicine as a "tight, fast-set science" was to emphasize the importance of psychobiology in medical schools[129]:

> *One of the most hopeful moves in medical education is teaching to first-year students the elements of psychobiology. A system of belief is implanted best in the young. It would be my suggestion that psychobiology be taught in the premedical years, that the doctor/patient relationship be the beginning of medical studies. A deep insight into this fundamental philosophy is a chief concern of the internist.*

Positive Mental Attitude

John Nowicki, ND, and *Michael T. Murray, ND*

OUTLINE

INTRODUCTION

A positive mental attitude is one of the foundational elements of good health. This axiom has been contemplated by philosophers and physicians since the time of Plato and Hippocrates. Attitude is reflected by *explanatory style,* a term developed by noted psychologist Martin Seligman to describe a cognitive personality variable that reflects how people habitually explain the causes of life events.[1] Explanatory style was used to describe individual differences in response to negative events during the attributional reformulation of the learned helplessness model of depression developed by Seligman (described in Appendix 12). The Attributional Style Questionnaire developed by Seligman or the Revised Optimism-Pessimism (PSM) scale of the Minnesota Multiphasic Personality Inventory (MMPI) can be used to determine an individual's level of optimism.

In addition to simple conventional wisdom, modern research has also verified the important role that attitude—the collection of habitual thoughts and emotions—plays in determining the length and quality of life. Specifically, studies using various scales to assess attitude, including the PSM scale of the MMPI, have shown that individuals with a pessimistic explanatory style have poorer health, are prone to depression, are more frequent users of medical and mental health care delivery systems, exhibit more cognitive decline and impaired immune function with aging, and have a shorter survival rate compared with optimists.[1–8] One study involved a large cohort of 5566 people who completed a survey at two time points, aged 51 to 56 years at time 1 and aged 63 to 67 years at time 2. This survey included a questionnaire to determine positive psychological well-being by measuring self-acceptance, autonomy, purpose in life, positive relationships with others, environmental mastery, and personal growth. The results showed that people with low positive well-being were 7.16 times more likely to be depressed 10 years later.[9] This research highlighted the fact that although life is full of events that are beyond one's control, people can control their responses to such events. Attitude plays a significant role in determining how people view and respond to the stresses and challenges of life.

EFFECT OF ATTITUDE, PERSONALITY, EMOTIONS ON HEALTH

Longevity

In 1981 the Leisure World Cohort Study undertook a prospective cohort study of nearly 14,000 elderly women and men in a California retirement community to study the relationship between mental attitude and longevity and successful aging.[10] Participants completed a postal survey including seven positively worded items from the Zung self-rating depression scale and were followed to death or December 31, 2016 (a 35-year span), whichever came first. In both men and women, a more negative attitude was associated with significantly higher mortality. The risk of death significantly increased by 2% (women) and 4% (men) for each unit decrease in total attitude score. Overall, the multivariable-adjusted hazard ratio (HR) for death for individuals in the lowest versus the highest quarter of total attitude was 1.24 (1.16–1.32) for women and 1.30 (1.19–1.41) for men. Thus strategies to improve mental outlook may help improve the quantity as well as the quality of life.

Immune Function

The importance of attitude to human health has been examined in the links among the brain, emotions, and the immune system. Research in the field of psychoneuroimmunology indicates that every part of the immune system is connected to the brain in some way, either via a direct nervous tissue connection or through the complex language of chemical messengers and hormones. What scientists are discovering is that every thought, emotion, and experience sends a message to the immune system that either enhances or impairs its ability to function. A simplistic view is that positive emotions, such as joy, happiness, and optimism, tend to boost immune system function, whereas negative emotions, such as depression, sadness, and pessimism, tend to suppress it.

Studies examining immune function in optimists versus pessimists have demonstrated significantly better immune function in the optimists. Specifically, studies have shown that, compared with pessimists, optimists have increased secretory immunoglobulin-A function, natural killer cell activity, and cell-mediated immunity, which is demonstrated by better ratios of helper to suppressor T-cells.[6,11–14]

The immune system is so critical to preventing cancer that if emotions and attitude were risk factors for cancer, one would expect to see an increased risk of cancer in people who have long-standing depression or a pessimistic attitude. Research supports this association; for example, smokers who are depressed have a much greater risk of lung cancer than smokers who are not depressed.[15]

Depression and the harboring of other negative emotions contribute to an increased risk of cancer in several ways. Most research has focused on the effect of depression and other negative emotions on natural killer cells. Considerable scientific evidence has documented the link between a higher risk of cancer and negative emotions, stress, and a low level or low activity of natural killer cells.[16] Negative emotions and stress paralyze many aspects of immune function and literally can cause natural killer cells to burst.[16,17] Furthermore, the prototypical cancer personality—an individual who suppresses anger, avoids conflicts, and has a tendency to have feelings of helplessness—has lower natural killer cell activity than other personality types.[13,14] These studies also indicate that individuals with a personality type that is prone to cancer have an exaggerated response to stress, which compounds the detrimental effects stress has on natural killer cells and the entire immune system.

Depression and stress not only affect the immune system but also appear to hinder the cell's ability to repair damage to DNA. Most carcinogens cause cancer by directly damaging DNA in cells, thereby producing abnormal cells. Some of the most important protective mechanisms against cancer in the cell's nucleus are the enzymes responsible for the repair or destruction of damaged DNA. Several studies have shown that depression and stress alter these DNA repair mechanisms. For example, in one study, lymphocytes from depressed patients demonstrated impairment in the ability to repair cellular DNA damaged by exposure to x-rays.[18,19]

Just as research has identified personality, emotional, and attitude traits that are associated with impaired immune function, the field of psychoneuroimmunology has likewise identified a collection of "immune power" traits that include a positive mental attitude; an effective strategy for dealing with stress; and a capacity to confide traumas, challenges, and feelings to oneself and others.[16,20]

Cardiovascular Health

The cardiovascular system is another system intricately tied to emotions and attitude. The relationship of an optimistic or pessimistic explanatory style with the incidence of coronary heart disease was examined as part of the Veterans Affairs Normative Aging Study, an ongoing cohort study of older men.[8] These men were assessed by the MMPI PSM scale. During an average 10-year follow up, 162 cases of incident coronary heart disease occurred: 71 cases of incident nonfatal myocardial infarction, 31 cases of fatal coronary heart disease, and 60 cases of angina pectoris. Men reporting high levels of optimism had a 45% lower risk for angina pectoris, nonfatal myocardial infarction, and coronary heart disease death than men reporting high levels of pessimism. Interestingly, a clear dose–response relationship was found between levels of optimism and each outcome.

To illustrate how closely the cardiovascular system is linked to attitude, one study showed how measures of optimism and pessimism affected ambulatory blood pressure.[21] Pessimistic adults had higher blood pressure levels than optimistic adults, suggesting that pessimism has broad physiological consequences. Affective well-being (happiness and pleasure) and eudaimonia (sense of autonomy and purposeful engagement with life) have been associated with smaller waist circumference, healthier lipid profiles (e.g., greater high-density lipoprotein cholesterol [HDL-C], lower levels of triglycerides), higher levels of serum antioxidants, and lower levels of inflammatory markers (e.g., C-reactive protein [CRP], fibrinogen).[22]

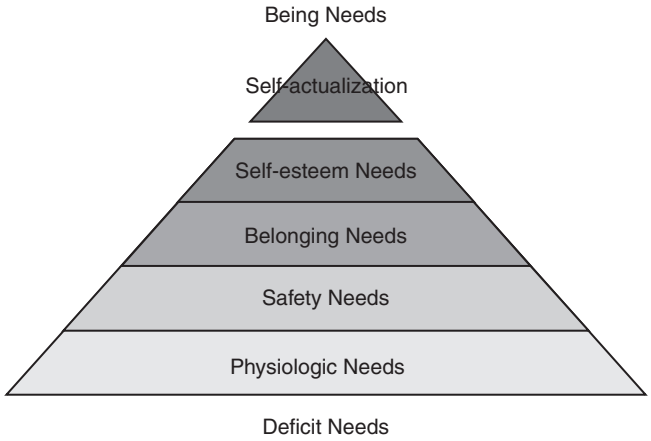

Fig. 7.1 Maslow's hierarchy of needs.

Excessive anger, worrying, and other negative emotions have also been shown to be associated with an increased risk for cardiovascular disease; however, these emotions may simply reflect a pessimistic explanatory style.

SELF-ACTUALIZATION

A physician's role should include facilitating the health of the patient as well as helping the patient achieve *self-actualization,* which is a concept developed by Abraham Maslow, the founding father of humanistic psychology. His work and theories were the result of more than 30 years of intense research on psychologically healthy people. Essentially, Maslow was the first psychologist to study healthy people. He strongly believed that the study of healthy people would create a firm foundation for the theories and values of a new psychotherapy.

Maslow discovered that healthy individuals are motivated toward self-actualization, a process of "ongoing actualization of potentials, capacities, talents, as fulfillment of a mission (or call, fate, destiny, or vocation), as a fuller knowledge of, and acceptance of, the person's own intrinsic nature, as an increasing trend toward unity, integration, or synergy within the person."[23]

Maslow developed a five-step pyramid of human needs in which personality development progresses from one step to the next. The needs of the lower levels must be satisfied before the next level can be achieved. When needs are met, the individual moves toward well-being and health. Fig. 7.1 displays Maslow's hierarchy of needs.

The primary needs that form the base of the pyramid are basic survival or physiological requirements: the satisfaction of hunger, thirst, sexuality, and shelter. The second step consists of safety needs, which are essential for dealing with the world: security, order, and stability. The individual then progresses to the third step, which involves the ability to love and be loved: belonging. The fourth step involves self-esteem and self-respect: approval, recognition, and acceptance. The final step is self-actualization: the use of one's creative potential for self-fulfillment.

In modern life, a person's occupation often correlates with the ability to achieve these needs. Table 7.1 provides an application of Maslow's hierarchy of needs in an occupational environment.

Maslow studied self-actualized people and noted that they had strikingly similar characteristics. Some of Maslow's key findings, in an abbreviated form, include the following:

- Self-actualized people perceive reality more effectively than others and are more comfortable with it. They have an unusual ability to

TABLE 7.1 Practical Application of Maslow's Hierarchy of Needs

Level of Need	General Rewards	Occupational Factors
Self-actualization	Growth	Challenging job
	Achievement	Opportunities for creativity
	Advancement	Achievement in work
	Creativity	Promotion
Self-esteem	Self-respect	Social recognition
	Status	Job title
	Prestige	High status of job
		Feedback from the job itself
Belonging	Love	Work groups or teams
	Friendship	Supervision
	Belongingness	Professional associations
Safety	Security	Health and safety
	Stability	Job security
	Protection	Contract of employment
Physiological	Food	Pay
	Water	Working conditions
	Sleep	
	Sex	

detect the spurious, the fake, and the dishonest in personality. They judge experiences, people, and things correctly and efficiently. They possess an ability to be objective about their own strengths, possibilities, and limitations. This self-awareness enables them to clearly define values, goals, desires, and feelings. They are not frightened by uncertainty.

- Self-actualized people have an acceptance of self, others, and nature. They can accept their own human shortcomings without condemnation. They do not have an absolute lack of guilt, shame, sadness, anxiety, and defensiveness, but they do not experience these feelings to unnecessary or unrealistic degrees. When they do feel guilty or regretful, they do something about it. Generally, they do not feel bad about discrepancies between what is and what ought to be.
- Self-actualized people are relatively spontaneous in their behavior and even more spontaneous in their inner lives, thoughts, and impulses. They are unconventional in their impulses, thoughts, and consciousness. They are rarely nonconformists, but they seldom allow convention to keep them from doing anything they consider important or basic.
- Self-actualized people have a problem-solving orientation toward life instead of a self-orientation. They commonly have a mission in life, some problem outside themselves that enlists much of their energies. In general, this mission is unselfish and is involved with the philosophical and ethical.
- Self-actualized people have a quality of detachment and a need for privacy. Often, it is possible for them to remain above the battle, to be undisturbed by what upsets others. They are self-governing people who find meaning in being active, responsible, self-disciplined, and decisive rather than being pawns or helplessly ruled by others.
- Self-actualized people have a wonderful capacity to appreciate the basic pleasures of life, such as nature, children, music, and sex, again and again. They approach these basic experiences with awe, pleasure, wonder, and even ecstasy.
- Self-actualized people commonly have mystical or "peak" experiences, times of intense emotions in which they transcend the self. During a peak experience, they have feelings of limitless horizons and unlimited power while simultaneously feeling more helpless than ever before. There is a loss of place and time and feelings of great ecstasy, wonder, and awe. The peak experience ends with the conviction that something extremely important and valuable has happened, and thus the person is transformed and strengthened by the experience to some extent.
- Self-actualized people have deep feelings of identification with, sympathy for, and affection for other people despite occasional anger, impatience, or disgust.
- Self-actualized people have deeper and more profound interpersonal relationships than most other adults, but not necessarily deeper than children's. They are capable of more closeness, greater love, more perfect identification, and more erasing of ego boundaries than other people would consider possible. One consequence is that self-actualized people have especially deep ties with relatively few individuals, and their circle of friends is small. They tend to be kind or at least patient with almost everyone, yet they speak realistically and harshly of those who they feel deserve it, especially hypocritical, pretentious, pompous, or self-inflated individuals.
- Self-actualized people are democratic in the deepest possible sense. They are friendly toward everyone, regardless of class, education, political beliefs, race, and color. They believe it is possible to learn something from everyone. They are humble, in the sense of being aware of how little they know in comparison with what could be known and what is known by others.
- Self-actualized people are strongly ethical and moral. However, their notions of right and wrong and good and evil are often unconventional. For example, a self-actualized person would never consider segregation, apartheid, or racism to be morally right, although it may be legal.
- Self-actualized people have a keen, unhostile sense of humor. They do not laugh at jokes that hurt other people or are aimed at others' inferiority. They can make fun of others in general or of themselves when they are foolish or try to be big when they are small. They are inclined toward thoughtful humor that elicits a smile, is intrinsic to the situation, and is spontaneous.
- Self-actualized people are highly imaginative and creative. The creativeness of a self-actualized individual is not of the special talent type, such as Mozart's, but rather is like the naive and universal creativeness of unspoiled children.

CLINICAL APPLICATION OF LEARNED OPTIMISM

The new psychology that Maslow's work referred to may turn out to be "positive clinical psychology."[24] This field of practice was born in 1998 when Martin Seligman chose it as the theme for his term as president of the American Psychological Association.[25] Positive clinical psychology aims to change clinical psychology to have an equally weighted focus on both positive and negative functioning.[26] The approach is based on five key bodies of empirical findings: (1) the absence of positive well-being leads to the development of disorder over time[9]; (2) the absence of positive characteristics predicts disorder above and beyond the presence of negative characteristics[9]; (3) positive characteristics interact with negative life events to predict disorder (so studying only negative life events would produce misleading results)[27]; (4) many aspects of well-being range from extremely negative functioning, through a neutral midpoint, to positive well-being (possibly including happiness to depression and anxiety to relaxation continuums),[28] making it impossible to study exclusively negative or positive well-being; and (5) positive interventions can be as effective as other more commonly used approaches, such as cognitive therapy.[29]

Positive clinical psychology ultimately involves helping patients become optimistic, which, according to Martin Seligman, is our natural tendency.[30] Optimism not only is a necessary step toward achieving optimal health but is also critical to happiness and a higher quality of life.

In many instances, it is not what happens in one's life that determines one's direction; to a large degree, it is the response to those challenges that shapes the quality of life and determines one's level of health. Surprisingly, it is often true that hardship, heartbreak, disappointment, and failure serve as the sparks for joy, ecstasy, compassion, and success. The determining factor is whether these challenges are viewed as stepping-stones or stumbling blocks.

A person's attitude is like his or her physical body: it must be conditioned to be strong and positive. Conditioning an attitude to be positive and optimistic requires adopting specific healthy habits. Four key areas of focus for helping patients develop a positive mental attitude are as follows:

1. Help them become aware of self-talk. Tell them that all people conduct a constant running dialogue in their heads. In time, the things people say to themselves and others percolate down into their subconscious minds. Those inner thoughts, in turn, affect the way people think and feel. Naturally, a steady stream of negative thoughts will have a negative effect on a person's mood, immune system, and quality of life. The cure is to become aware of self-talk and then to consciously work to feed positive self-talk messages to the subconscious mind.
2. Help them ask better questions. The quality of a person's life is equal to the quality of the questions habitually asked. For example, if a person experiences a setback, does he or she think, "Why am I so stupid? Why do bad things always happen to me?" or "Okay, what can be learned from this situation so that it never happens again? What can I do to make the situation better?" Clearly, the latter response is healthier. Regardless of the situation, asking better questions is bound to improve one's attitude. Some examples of questions that can improve attitude and self-esteem when asked regularly include the following:
   "What am I most happy about in my life right now?"
   "What am I most excited about in my life right now?"
   "What am I most grateful about in my life right now?"
   "What am I enjoying most in my life right now?"
   "What am I committed to in my life right now?"
   "Whom do I love? Who loves me?"
   "What must I do today to achieve my long-term goal?"
3. Help them experience gratitude. A large body of recent work has suggested that people who are more grateful have higher levels of well-being and are happier, less depressed, less stressed, and more satisfied with their lives and social relationships.[31,32] Gratitude appears to have one of the strongest links with mental health of any character trait. Helping instill a sense of gratitude has been shown to be a very successful intervention. In one study, participants were randomly assigned to one of six therapeutic interventions designed to improve the participants' overall quality of life.[33] Of these six interventions, it was found that the biggest short-term effects came from a "gratitude visit," where participants wrote and delivered a letter of gratitude to someone in their lives. This simple gesture showed a rise in happiness scores by 10% and a significant fall in depression scores, the results of which lasted up to 1 month after the visit. The act of writing "gratitude journals," in which participants wrote down three things they were grateful for every day, had longer-lasting effects on happiness scores. The greatest benefits with this practice were usually found to occur around 6 months after it began. Similar practices have shown comparable benefits.
4. Help them set positive goals. Learning to set achievable goals is a powerful method for building a positive attitude and raising self-esteem. Achieving goals creates a success cycle: a person feels better about him- or herself, and the better he or she feels, the more likely he or she is to succeed. Some guidelines for helping patients set healthy goals include the following:
   - Be specific. The more clearly the goal is defined, the more likely it will be achieved. For example, if a person wants to lose weight, he or she should define the desired weight and the body fat percentage or measurements to be achieved.
   - State the goal in positive terms and in the present tense; avoid negative words. It's better to say, "I enjoy eating healthy, low-calorie, nutritious foods" than to say, "I will not eat sugar, candy, ice cream, and other fattening foods."
   - Make the goal attainable and realistic. Start out with goals that are easily attainable, like drinking six glasses of water a day or switching from white to whole-grain bread. Initially choosing easily attainable goals creates a success cycle that helps build a positive self-image. Little things add up to make a major difference in the way a person feels about him- or herself.

Counseling is necessary for the severely pessimistic individual. Forms of cognitive therapy appear to be the most useful therapy. Cognitions comprise the whole system of thoughts, beliefs, mental images, and feelings. Cognitive therapy can be as effective as the use of antidepressant drugs in the treatment of moderate depression; in addition, there tends to be a lower risk of relapse—the return of depression—with cognitive therapy.[34] One reason for this is that cognitive therapy teaches people practical skills they can use to combat depression anytime, anywhere, and every day for the rest of their lives. Cognitive therapy avoids the long, drawn-out (and expensive) process of psychoanalysis. It is a practical, solution-oriented psychotherapy that teaches skills a person can apply to improve quality of life.

Mental health specialists trained in cognitive therapy seek to change the way the depressed person consciously thinks about failure, defeat, loss, and helplessness. To do so, they employ five basic tactics that help patients do the following:

- Recognize the automatic negative thoughts that flit through consciousness at the times when they feel the worst.
- Dispute the negative thoughts by focusing on contrary evidence.
- Learn a different explanation to dispute the automatic negative thoughts.
- Avoid rumination (the constant churning of a thought in one's mind) by helping the patient better control his or her thoughts.
- Question depression-causing negative thoughts and beliefs and replace them with empowering, positive thoughts and beliefs.

SECTION 2

Primary and Adjunctive Diagnostic Procedures

During the 20th century, tremendous progress was made in the development of laboratory procedures for the diagnosis of disease. However, this work focused primarily on pathological processes—typically advanced disease; little was done to help the physician recognize physiological abnormalities before they progress to the pathological stage. The problem is further aggravated for doctors of preventive/integrative/functional/natural medicine, who need to evaluate in an objective manner the nutritional status, lifestyle, physiological competency, toxic load, and vitality of their patients. The few available tests that exist tend to be oriented to measuring absolute values rather than functional indices and generally indicate abnormal values only after serious dysfunction develops.

In this section, we have compiled useful assessment methodologies we believe will greatly aid healthcare professionals who want more objective tests in their evaluation of the pathophysiological status of their patients and the causes of dysfunction. These are not meant to replace the standard, pathologically oriented, diagnostic procedures. Rather, we are encouraging the use of methodologies that aid in the early diagnosis of disease susceptibility, quantification of the processes that usually precede clinical disease, and ways to objectively assess foundational causes like functional nutritional deficiencies and toxic load. Where possible, preference is given to tests that measure the uniqueness of the patient's biochemistry rather than abstract absolute values. In keeping with the metabolic and scientific orientation of this textbook, the emphasis has been placed on those procedures that have strong support in the research literature.

Most of these laboratory procedures are on the cutting edge of our understanding of the assessment of the physiological function of metabolically unique individuals. Because it is an emerging field, few experts exist, and many are employed by or associated with the commercial laboratories performing the procedures.

Apoptosis in Health and Diseases

Lise Alschuler, ND, and *Aristo Vojdani*, PhD, MSc, CLS*

OUTLINE

INTRODUCTION

Apoptosis is a distinct form of cell death controlled by an internally encoded suicide program. It is believed to occur in the majority of animal cells. It is a distinct event that triggers characteristic morphological and biological changes in the cellular life cycle. It is common during embryogenesis, normal tissue and organ involution, and cytotoxic immunological reactions, and it occurs naturally at the end of the life span of differentiated cells. Apoptosis can also be induced in cells by the application of a number of different agents, including physiological activators, heat shock, bacterial toxins, oncogenes, chemotherapeutic drugs, various toxic chemicals, ultraviolet and γ-radiation, and hypoxia. When apoptosis occurs, the nucleus and cytoplasm of the cell often fragment into membrane-bound apoptotic bodies, which are then phagocytized by neighboring cells. Alternatively, during necrosis, cell death occurs by direct injury to cells, resulting in cellular lysing and the release of cytoplasmic components into the surrounding environment, often inducing an inflammatory response in the tissue. Apoptosis may occur in one cell, leaving surrounding cells unaffected, as opposed to necrosis, which affects multiple cells simultaneously.

A landmark of cellular self-destruction by apoptosis is the activation of nucleases and proteases that degrade the higher-order chromatin structure of the DNA into fragments of 50 to 300 kilobases and subsequently into smaller DNA pieces of about 200 base pairs in length. Activation of proteases, notably aspartate-specific cysteinyl proteases, referred to as caspases, is of primary relevance to apoptosis. Caspase-3 is considered to be the key mediator of apoptosis of mammalian cells, with apoptotic cells characterized by significant caspase 3 activation.[1] Caspase-3 expression may be measured with immunohistochemical staining with caspase 3 antibodies at 1:50 dilution (DAKO, Carpinteria, CA).[2] Using fluorescent-labeled reagents, it is also possible to tag the DNA break and identify the percentage of apoptotic cells with a high degree of accuracy.[3–8] Unfortunately, there is no test for apoptosis that is clinically relevant. Although there are methodological limitations, essentially the interpretation of an apoptotic assay is fraught with unknowns—the significance of any result being dependent on a lack of a reference standard, itself determinant upon the type and number of cells assayed, the duration of apoptosis, and the timing and duration of the test.[9]

Measurable Features of Apoptosis for Research Purposes

One of the most easily measured features of apoptotic cells is the breakup of the genomic DNA by cellular nucleases. These DNA fragments can be extracted from apoptotic cells and result in the appearance of DNA laddering when the DNA is analyzed by agarose gel electrophoresis. The DNA of nonapoptotic cells, which remains largely intact, does not display this laddering on agarose gels during electrophoresis. The large number of DNA fragments appearing in apoptotic cells results in a multitude of 3′-hydroxyl termini of DNA ends. This property can also be used to identify apoptotic cells by labeling the DNA breaks with fluorescent-tagged deoxyuridine triphosphate nucleotides. The enzyme terminal deoxynucleotidyl transferase catalyzes a template-independent addition of deoxyribonucleotide triphosphates to the 3′-hydroxyl ends of double- or single-stranded DNA. A substantial number of these sites are available in apoptotic cells, providing the basis for the single-step fluorescent labeling and flow cytometric method. Nonapoptotic cells do not incorporate significant amounts of the fluorescent-tagged deoxyuridine triphosphate nucleotides due to the lack of exposed 3′-hydroxyl DNA ends.

Apoptosis can also be characterized by changes in cell membrane structure. During apoptosis, the cell membrane's phospholipid asymmetry changes—phosphatidylserine is exposed on the outer membrane, whereas membrane integrity is maintained. Annexin V specifically binds phosphatidylserine, whereas propidium iodide is a DNA-binding fluorochrome. When a cell population is exposed to both reagents, apoptotic cells stain positive for annexin V and negative for propidium iodide; necrotic cells stain positive for both, and live cells stain negative for both.[5]

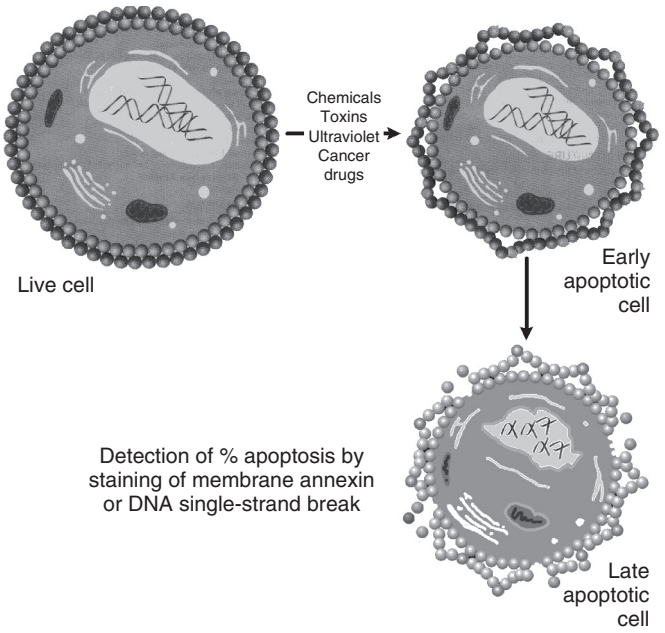

Fig. 8.1 Detection of apoptosis using damaged membrane or DNA single-strand break and flow cytometry.

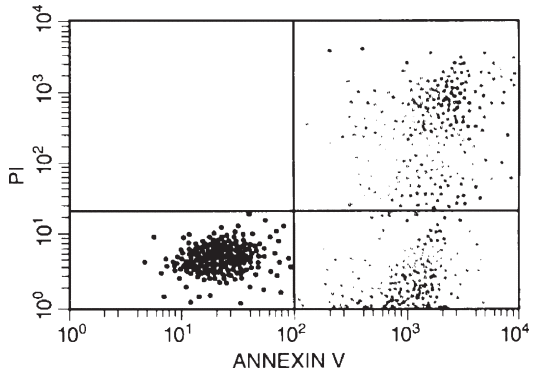

Fig. 8.2 Separation of cells by flow cytometry and detection of apoptotic population.

This process of apoptosis and its analysis by flow cytometry are shown in Figs. 8.1 and 8.2.

Another assessment of apoptosis involves ex vivo cell analysis. Specifically, the expression of active caspase-3 along with the Bcl-2:Bax ratio as markers of apoptosis can be measured. Immunohistochemical staining will reveal the expression of these apoptotic-related proteins, caspase-3 and cleaved caspase-3; the latter is indicative of apoptosis.[10] Bcl-2 is antiapoptotic gene product that exists in ratio to Bax and Bak, which are proapoptotic gene products. This ratio is indicative of the degree of apoptosis, with a decreased Bcl-2:Bax ratio indicative of apoptosis. Cells from Bax(−/−) and Bak(−/−) knockout animals do not respond to apoptosis inducers. In these cells, cytochrome C is not released from the mitochondrial membrane to initiate the caspase cascade.[11] Thus Bax and Bak are critical to apoptosis, and their expression in relation to Bcl-2 is highly correlative to apoptosis.

Different Stages of Apoptosis

The process of apoptosis is divided into three stages:

- Induction
- Sensing or triggering
- Execution

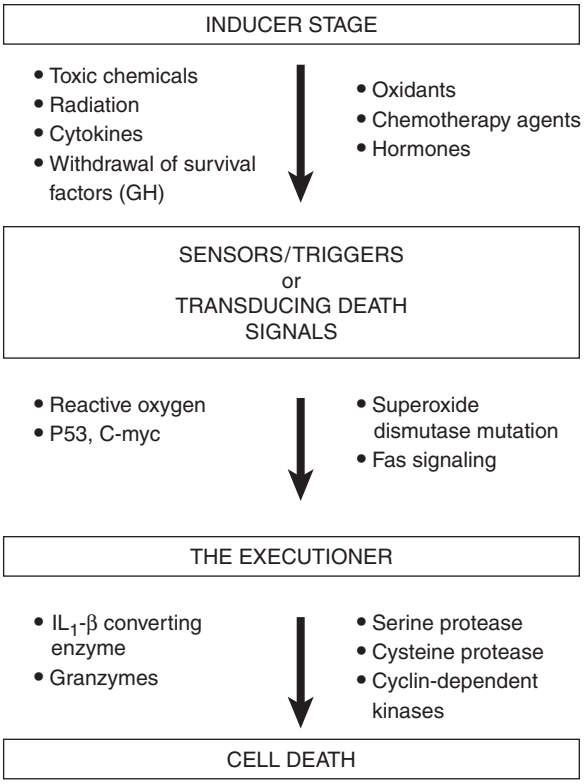

Fig. 8.3 Various stages of "inside-out" cell death or apoptosis.

These stages of apoptosis are depicted in Fig. 8.3. Induction represents the initial events that signal a cell so that apoptosis may begin. This induction phase may be induced by various physical agents, such as toxic chemicals, hypoxia, radiation, chemotherapy agents, hormones, and CD95 or Fas ligation. It has been proposed that the induction stage of apoptosis is prevented by many antioxidants (vitamin C, β-carotene, and vitamin E) and also by various biological response modifiers, including lentinan, thymic hormones, viral antigens, and cytokines.

It is important to note that both extrinsic and intrinsic pathways of apoptosis induction converge in the mitochondria and that the prevention or initiation of apoptosis from this point is the result of cellular redox status.[12] Persistent low to moderate oxidation is consistent with the prevention of apoptosis. Low to moderate oxidative stress within the mitochondrial membrane activates Bcl-2. Bcl-2 maintains the intracellular redox status at a level that is optimal for the cell. Bcl-2 does this by increasing the mitochondrial burn rate of oxygen, thereby increasing electron leakage and oxygen concentration, relative to hydrogen peroxide, in the mitochondrial membrane. This reduces the permeability of the inner mitochondrial membrane and the opening of apoptotic pores. Further, Bcl-2 physically sequesters proapoptotic proteins, Bax and Bak.[13] Bax and Bak normally facilitate the release of cytochrome C from the inner mitochondrial membrane and out into the cytosol, where it initiates the caspase cascade. However, when oxidative stress is acute or high, the inhibitory role of Bcl-2 is altered, and apoptosis can occur. Also, higher levels of reactive oxidative stress generate more hydrogen peroxide within the mitochondria, which, in turn, oxidizes other mitochondrial components, such as cardiolipin, and inner membrane phospholipid. Oxidized cardiolipin moves to the outer mitochondrial membrane and recruits Bax and Bak, thus enabling the release of cytochrome C through Bax- and Bak-controlled pores, finally activating caspases and apoptosis.[14] Also in response to higher oxidative stress, p53 translocates from the cell's nucleus to the mitochondria, where it is de-ubiquitinated and subsequently activates Bax- and Bak-induced apoptosis.[15]

There is, however, a limit to the proapoptotic response to oxidative stress. When oxidative stress is overwhelmingly high and/or prolonged, oxidative damage occurs to cytochrome C and to downstream caspases preventing apoptosis. There are other apoptotic escape mechanisms present in cells as well. Mitochondrial paraoxonase enzymes PON2 and PON3 interact with ubiquinone to reduce oxygen release. This mitigates oxidation of cardiolipin, creating a resistance to apoptosis. In fact, PON2 and PON3 have been established as key factors in the prevention of atherosclerosis because endothelial and macrophage death are the basis of atherogenic plaques.[16]

The induction of apoptosis is entirely dependent on the redox state of the cell and the mitochondrial response to oxidation. Mitochondria can respond to moderate or acute oxidative stress by initiating apoptosis; however, excessive and/or prolonged oxidative stress prevents apoptosis. Glutathione plays a major role in controlling mitochondrial oxidative stress. Reduced glutathione (GSH) donates electrons to reactive oxygen species (ROS), thereby preventing the generation of hydrogen peroxide. In the course of donating the electron, glutathione itself becomes oxidized (GSSG). Oxidized glutathione is then regenerated back to its reduced state through the action of glutathione reductase. On the one hand, the presence of GSH facilitates the destruction of hydrogen peroxide, thereby preventing the release of cytochrome C and delaying apoptosis. This allows the cell to undergo repair, instead of apoptosis, when the oxidative stress is temporary and/or low. On the other hand, by regulating the amount of oxidation, GSH preserves mitochondrial membrane integrity and cytochrome C, ensuring that the capacity for apoptosis in the face of high and/or prolonged oxidative stress is present. If there is a deficiency of reduced glutathione or damage to glutathione reductase (for instance by arsenic trioxide or lead) in the context of high oxidative stress, the cell will be unable to initiate apoptosis.[17] Instead, the cell will be forced to undergo unprogrammed cell death, or necrosis. This is an inflammatory event and will ultimately further contribute to the regional oxidative stress. Thus the induction of apoptosis is intimately connected with the cellular redox potential of cells, itself regulated primarily by glutathione.

The induction stage is followed by a decision on whether or not the cell will undergo apoptosis. The decision to die is under the control of a number of different pathways or cellular sensors that induce the apoptosis signal, which then triggers the central mechanisms. During this stage, enzymes such as interleukin-1β–converting enzymes, serine protease, cysteine protease, granzymes, and cyclin-dependent kinases become activated. Once activated, these enzymes dismantle the cell and trigger the cell-surface changes that cause direct cell recognition and engulfment of the dying cells by phagocytes. These central events are prevented by various antioxidants and biological response modifiers.

Apoptosis Is Induced by Chemicals to Control Malignancy

Many chemicals have the capacity to bind to DNA, form DNA adducts, or cause DNA single-strand breaks, possibly leading to cancer. However, the body is equipped with many factors, enzymes, suppressor genes, and cellular sensors, all with the capacity to prevent the consequences of this DNA damage by activating apoptosis-inducing signals.

The role of apoptosis in regulating tissue growth is readily apparent in the simple equation in which the rate of growth is equal to the difference between the rates of cell proliferation and cell death. Thus tissues expand if the rate of proliferation exceeds the rate of cell death. This is one of the reasons for suggesting that defects in apoptosis may contribute to the transformed state.

An important prediction of the relevance of apoptosis to malignancy is that the rate of apoptosis versus mitosis should influence the behavior of a tumor. Recently, the relationship between the apoptotic and mitotic indexes in a tumor was demonstrated as predictive of outcome: a higher ratio of apoptosis to mitosis within the tumor correlated with a positive prognosis. Further, it was found that this was not simply a function of cell death per se. Tumors with a high incidence of necrosis rather than apoptosis were correlated with a poor prognosis. It therefore follows that treatments or conditions that favor apoptosis should have desirable effects and that defects in the pathways leading to apoptosis are likely to play important roles in the process of oncogenesis.[6,7]

Many reactive chemicals and drugs, such as acetaminophen, diquat, carbon tetrachloride, quinones, cyanide, polyhydroxy polyether, methyl mercury, and organotin, have been implicated in apoptosis (programmed cell death) and necrosis (toxic cell death).[18–25]

Most research on chemical induction of apoptosis is carried out with primary cultures of cell lines (e.g., neurons, thymocytes, carcinoma cells, leukemia cells, neuroblastoma, breast cancer cells, lymphoma); little has been published on the in vivo effects of chemicals on apoptotic cells in animal models and none in humans. Therefore it was of interest to examine the effects of exposure to low levels of benzene, as well as through drinking water concentrations of up to 14 ppb, on the apoptotic cell population, as well as to examine possible changes in the cell cycle progression.[18]

Evidence is sufficient for the carcinogenicity of benzene in humans; therefore there is no safe level of exposure to this chemical or its metabolites. Published case reports, a case series, epidemiological studies, and both cohort and case-control studies have shown statistically significant associations between leukemia and occupational exposure to benzene and benzene-containing solvents.[26,27]

It has been indicated that possibly 800,000 persons are exposed to benzene from coke-oven emissions at levels of less than 0.1 ppm, and 5 million may be exposed to benzene from petroleum refinery emissions at levels of 0.1 to 1 ppm. Since these studies, numerous chemicals have been implicated in apoptosis (or programmed cell death), which arises from damage to DNA. One of the authors, Vojdani, along with collaborators, hypothesized that in individuals with a certain genetic makeup, benzene or its metabolites act as haptens, which may induce programmed cell death. The study involved a group of 60 male and female subjects who were exposed to benzene-contaminated water (at concentrations up to 14 ppm for a period of 3–5 years).[18] For comparison, a control group consisting of 30 healthy males and females with a similar age distribution and without a history of exposure to benzene were recruited. Using flow cytometry, the peripheral blood lymphocytes of both groups were tested for the percentage of apoptotic cell population. When exposed individuals were compared with the control group, statistically significant differences between each mean group were detected (27.5 ± 2.4 and 10 ± 2.6, respectively), indicating an increased rate of apoptosis in 86.6% of exposed individuals ($P < 0.0001$; Mann–Whitney U-test). Flow cytometry analysis of apoptosis in a healthy control and a patient with chronic fatigue syndrome is shown in Fig. 8.4.

It has been demonstrated that benzene induction of apoptosis is caused by a discrete block of the cell-cycle progression. There is a tendency for normal cells to commit "suicide" when deprived of usual growth factors or physical contact with their neighbors due to chemical exposure, which may represent a built-in defense against metastasis. Prompt activation of apoptosis in tumor cells that leave their native tissue presumably eliminates many metastatic cells before they have a chance to proliferate. In cancer, it is tumor cells that neglect to sacrifice themselves or forget to die. Researchers increasingly describe cancer as

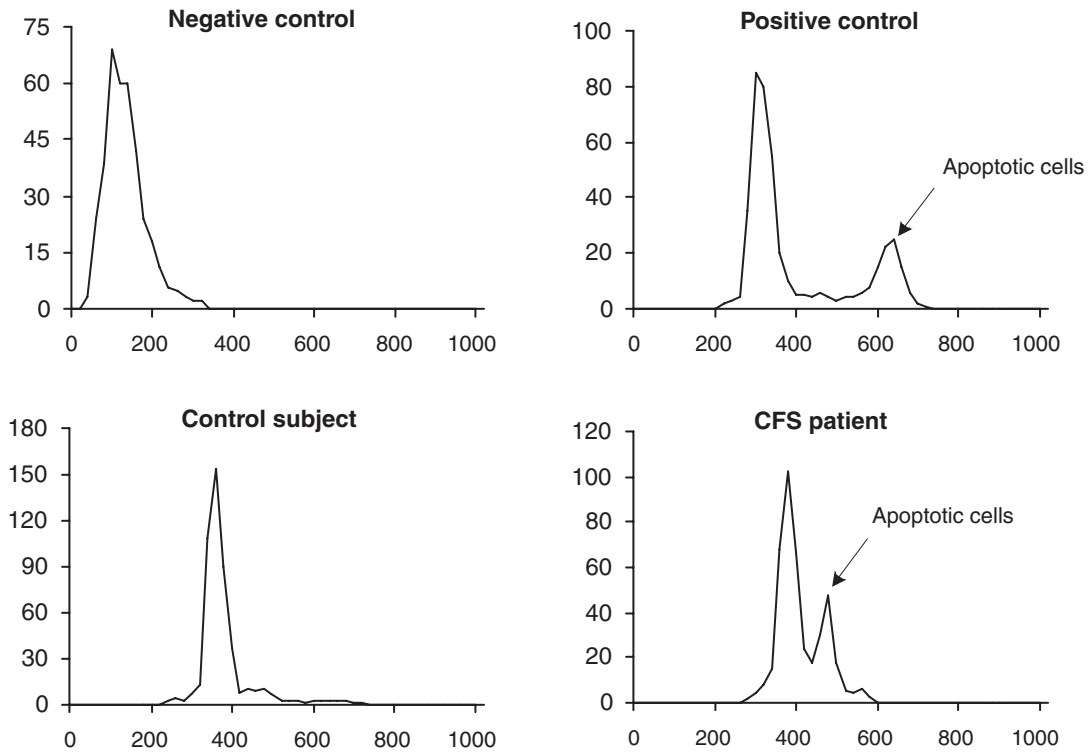

Fig. 8.4 Enhanced apoptotic cell population in benzene-exposed individuals with chronic fatigue syndrome. Flow cytometry analysis of apoptotic cell population in negative control cells (HL-60 leukemic cell line), positive control cells (HL-60 leukemic cells treated with the Apogen camptothecin), control subjects, and benzene-exposed individuals. Peripheral blood leukocytes were isolated, cultured for 12 hours, fixed in paraformaldehyde, labeled with fluorescent-tagged deoxyuridine triphosphate nucleotides, and analyzed for apoptosis by flow cytometry.

a disease involving both excessive proliferation of cells and abandonment of their ability to die. The dysregulation of apoptosis in malignant cells underlies both the initiation and progression of cancer.

Cancer develops after a cell accumulates mutations in several genes that control cell growth and survival. When a mutation seems irreparable, the affected cell usually kills itself rather than risk becoming deranged and potentially dangerous. However, if the cell does not die, it or its progeny may live long enough to accumulate mutations that enable it to divide uncontrollably and metastasize.

In many tumors, genetic damage apparently fails to induce apoptosis because the constituent cells have inactivated the gene that codes for the p53 protein. This protein can lead to activation of the cell's apoptotic machinery when DNA is injured by environmental agents, such as benzene or its metabolites. Therefore it is important to study cell suicide in health and diseases.

CLINICAL APPLICATIONS

Apoptosis in Cancer

The failure of apoptosis in malignant cells in the context of irreparable DNA damage leads to tumor progression. Cancer therapies, namely chemotherapy and radiation, control cancer by inflicting cell damage, which, in turn, triggers apoptosis. Unfortunately, >50% of all human cancers involve a mutation of p53, a central gene in apoptosis. p53 stimulates both the extrinsic death receptor pathway of apoptosis as well as the intrinsic mitochondrial pathway involving a decreased Bcl-2:Bax ratio. Thus it is imperative to find therapies that promote apoptosis independent of p53. Promising therapies in this regard include curcumin[28] derived from *Curcuma longa,* genistein derived from soy,[29] and resveratrol,[30] all of which are under investigative study for this application. Another promising cancer treatment involves the use of recombinant human apoptosis ligands to induce tumor necrosis factor–related apoptosis-inducing ligand (TRAIL). These ligands induce apoptosis via TRAIL, a selective death receptor pathway in a broad range of cancer cell lines, while sparing most normal cell types.[31]

The therapeutic potential for TRAIL-inducing ligands is most promising in combination with cytotoxic chemotherapy agents. Advances in cancer therapy are likely to come in the area of targeted therapies, the majority of which trigger specific receptor-driven pathways that culminate in apoptosis. The centrality of apoptosis induction in cancer cannot be overstated.

Apoptosis in Autoimmune Diseases

In cancer, it is the tumor cells that forget to die; in autoimmunity, immune cells fail to die when they are supposed to. Virtually all tissues harbor apoptotic cells at one time or another. Damaged cells usually commit suicide for the greater good of the body; when this does not occur, disease may develop. Autoimmunity occurs when the antigen receptors on immune cells recognize specific antigens on healthy cells and cause the cells bearing those particular substances to die. Autoimmune disease results from perpetuated immune-mediated tissue destruction and can involve immune cells that are resistant to apoptosis. Under normal conditions, the body allows a certain number of self-reactive lymphocytes to circulate. These cells normally do little harm, but they can become overactive through several processes. For instance, if these reactive lymphocytes recognize some foreign antigen such as microbes on food and haptenic chemicals, then exposure to that antigen causes them to become excited. If, due to molecular

mimicry, these antigens are similar to normal tissues, the activated cells may expand their numbers and attack the healthy tissue, thus causing an autoimmune disease.[3,32,33]

Autoimmune reactions usually are self-limited—they disappear when the antigens that originally set them off are cleared away. In some instances, however, the autoreactive lymphocytes survive longer than they should and continue to induce apoptosis in normal cells. Some evidence in animals and humans has indicated that extended survival of autoreactive cells is implicated in at least two chronic autoimmune syndromes—systemic lupus erythematosus and rheumatoid arthritis. In other words, the lymphocytes undergo too little apoptosis, with the result that normal cells undergo too much.[34,35]

Apoptosis During Viral Infection

Disturbance in the regulation of apoptosis is a component in various diseases. Viral illnesses are among the diseases caused by apoptosis dysregulation. After entering a cell, viruses attempt to shut down the cell's ability to make any proteins except those needed to produce more virus. This act of stalling host protein synthesis is enough to induce many kinds of cells to undergo apoptosis. If the host cell dies, the virus is also eliminated. Therefore certain viruses have evolved ways to inhibit apoptosis in the cells they infect.

Epstein–Barr virus, which causes mononucleosis and has been linked to lymphomas in humans, uses a mechanism that has been seen in other viruses. Epstein–Barr virus produces substances that inhibit apoptosis. Papillomavirus, a major cause of cervical cancer, inactivates p53, a central mediator of apoptosis. Cowpox virus, a relative of which is used as the smallpox vaccine, is another virus that inhibits caspase activation and attendant apoptosis. Investigators interested in antiviral therapy are now exploring ways to block the activity of the antiapoptotic molecules manufactured by viruses.[34]

Apoptosis in Acquired Immunodeficiency Syndrome

Induction of apoptosis by viruses in healthy cells is believed to contribute to the immune deficiency found in patients with acquired immunodeficiency syndrome (AIDS). In these patients, infection with human immunodeficiency virus (HIV) causes T-helper cells to die. As T-helper cells gradually disappear, cytotoxic cells, such as natural killer cells, also perish through apoptosis because they cannot survive without the growth signals produced by T-helper cells. When the number of T cells dwindles, so does the body's ability to fight infections, especially viral and parasitical infections. Researchers have shown that many more helper cells succumb in addition to those that are infected with HIV. It is also highly probable that a large number of the cells die through apoptosis. Apparently, Fas plays a crucial role in this process.

Normally, T cells make functional Fas only after they have been active for a few days and are ready to die. However, helper cells from AIDS patients may display high amounts of functional Fas even before the cells have encountered an antigen. This display of Fas would be expected to cause the cells to undergo apoptosis prematurely whenever they encounter Fas ligand on other cells (such as on T cells already activated against HIV or other microbes). In addition, if the primed cells encounter the antigen recognized by their receptors, they may trigger their own death.

It is also possible that oxygen free radicals trigger the suicide of virus-free T cells. These highly reactive substances are produced by inflammatory cells drawn to infected lymph nodes in patients with HIV. Free radicals can damage DNA and membranes in cells. They will cause necrosis if they do extensive damage, but they can induce apoptosis if the damage is more subtle. In support of the free-radical theory, researchers have found that molecules capable of neutralizing free radicals prevent apoptosis in T cells obtained from patients with AIDS.[34,35]

Therapies with antiapoptotic medication, such as Trolox, a water-soluble analog of vitamin E that prevents oxidative stress, and pyrrolidine dithiocarbamate, a potent inhibitor of nuclear factor-κB, are now the focus of AIDS and autoimmune disease studies.[36,37]

Additionally, protease inhibitors, which are the mainstay of HIV therapy, inhibit apoptosis in immune cells.[38]

The mechanism underlying the apoptosis inhibition is as of yet unknown, but interestingly, supratherapeutic doses of protease inhibitors have an opposite, proapoptotic effect.

Apoptosis in the Heart and Brain

In contrast to cancer, where cells forget to die and insufficient apoptosis occurs, excessive apoptosis accounts for much of the cell death that follows heart attacks and strokes. In the heart, vessel blockage decimates cells that were fully dependent on the vessel. Those cells die by necrosis, partly because they are catastrophically starved of the oxygen and glucose they need to maintain themselves and partly because calcium ions, which are normally pumped out of the cell, rise to toxic levels.

Over the course of a few days, cells surrounding the dead zone, which initially survive because they continue to receive nourishment from other blood vessels, can die as well. Later, however, many cells die by necrosis after being overwhelmed by the destructive free radicals that are released when inflammatory cells swarm into the dead zone to remove necrotic tissue. The less injured cells commit suicide by apoptosis.

If the patient is treated by restoring blood flow, still more cells may die by necrosis or apoptosis because reperfusion leads to a transient increase in the production of free radicals. Similarly, in strokes due to inflammation, the release of such neurotransmitters as glutamate leads to necrosis and apoptosis. Understanding of the factors that lead to the tissue death accompanying heart attack, stroke, and reperfusion has led to new ideas for treatment. Notably, cell death might be limited by drugs and other agents that block free-radical production or inhibit proteases.

Apoptosis also accounts for much of the pathology seen in such diseases as Alzheimer's, Parkinson's, Huntington's, and amyotrophic lateral sclerosis (Lou Gehrig's disease), which are marked by the loss of brain neurons. Elevated apoptosis in these neurological diseases seems to be related to a lack of production of the nerve growth factor and to free-radical damage. It seems likely that a combination of such factors could cause many cells to destroy themselves. Manipulation of this process of cell killing may help in treating these neurological diseases. Studies in animal models imply that long-term delivery of nerve growth factors could protect against programmed cell death in these conditions. Therefore a greater understanding of the mechanisms involved in cell death should greatly enhance those important steps.[32,36,39]

CONCLUSIONS

Apoptosis and cell proliferation play an important role in development, differentiation, homeostasis, and aging.[4–8] The balance established between these two processes depends on various growth and death signals that are influenced by diet, nutrition, lifestyle, and other environmental factors. When the equilibrium between life and death is disrupted by aberrant signals (e.g., low levels of antioxidants in the blood or tissue cells), either tissue growth or atrophy occurs.

Under normal conditions with optimal nutritional factors, tissue homeostasis is sustained by balancing the effects of mitosis and apoptosis. The importance of this balance can clearly be seen when one of these processes becomes predominant (Fig. 8.5). The apoptotic potential within each cell is critical for the health of the host. Apoptosis is

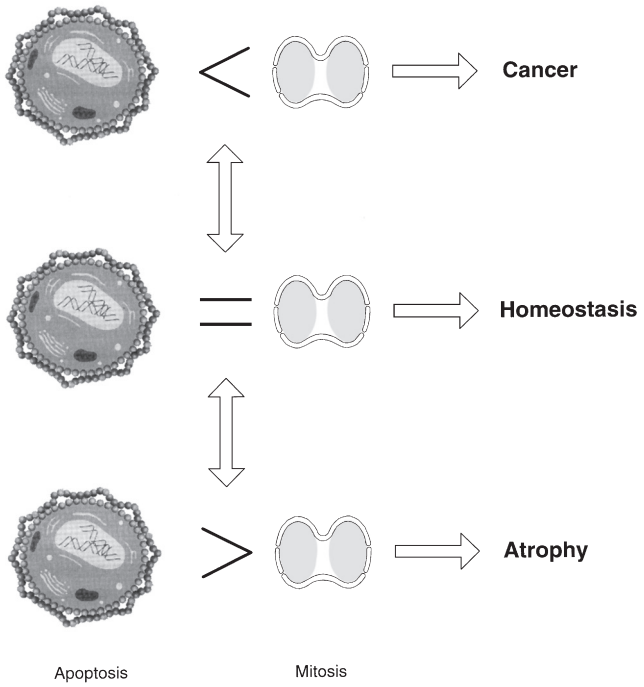

Fig. 8.5 The balance or imbalance between the rate of apoptosis and mitosis determines tissue homeostasis, atrophy, cell proliferation, and the development of cancer.

an elegant response to oxidative stress. This seemingly heroic sacrifice of self for the greater good underpins healthy living. Imbalance of apoptosis regulators, genetic mutations, and viral infections thwarts the healing effect of apoptosis. Finding ways to restore apoptotic and redox balance is critical to health.

Bacterial Overgrowth of the Small Intestine Breath Test

Mary James, ND

OUTLINE

INTRODUCTION

Small intestinal bacterial overgrowth (SIBO) is an abnormal colonization within the small bowel by bacteria normally found in the colon, mouth, or pharynx.[1] SIBO is a major contributor to irritable bowel syndrome (IBS) and uncomfortable symptoms such as bloating, abdominal discomfort, and changes in the stool (e.g., diarrhea).[2] It is also a potentially serious disorder that can lead to problems such as malabsorption and weight loss, anemia, malnutrition,[2] increased intestinal permeability,[3] and bone loss.[4] Breath testing for hydrogen (H_2) and methane (CH_4) provides a simple, noninvasive means of detecting SIBO. Once SIBO has been identified, antimicrobials are typically administered to eradicate the bacteria. Concurrent attention to underlying causes is also essential in preventing recurrences.

Conditions Associated With Small Intestinal Bacterial Overgrowth

SIBO, whose overall prevalence is not yet clear, is an overlooked contributing factor in several common disorders.[5] Several studies, for example, have demonstrated the presence of SIBO in patients with IBS.[6,7] In one study, in which 84% of patients with IBS tested positive for SIBO (vs. 20% of healthy controls), successful eradication of SIBO led to a 75% improvement (compared with a 36.7% improvement in those with incomplete eradication and an 11% improvement in participants receiving a placebo).[8] SIBO has also been observed in patients with acne rosacea,[9] Crohn's disease,[10] restless legs syndrome,[11] nonalcoholic fatty liver disease,[12] interstitial cystitis,[13] chronic prostatitis,[14] chronic fatigue syndrome,[15] and fibromyalgia.[16] SIBO may increase intestinal permeability (a.k.a. "leaky gut"),[17] an abnormality that was shown in a small study to resolve in 75% of patients successfully treated for SIBO.[3] Investigators who found leaky gut in 37.5% of patients with fibromyalgia suggested exposure of immune cells to luminal antigens and consequent immune modulation as a likely mechanism for the pain syndrome.[18]

A variety of anatomical and motor disorders of the small bowel can lead to SIBO, including surgical blind loops, diverticula, strictures, adhesions, tumors, fistulas,[19] sclerodermas,[20] intestinal pseudoobstruction,[21] and diabetic enteropathy.[22] Jejunal diverticulosis[5] and Crohn's disease[23] have both been associated with SIBO, particularly in patients with previous intestinal surgery. Because the symptoms of Crohn's disease and SIBO can be similar, symptoms from SIBO can be mistaken for a Crohn's-related acute flare.[10] Although the concentration of bacteria normally increases exponentially toward the distal end of the small intestine,[19] far fewer bacteria inhabit the small intestine than do the colon.[24] A common feature of most of these disorders is stasis of small bowel contents, which allows bacterial concentrations to increasingly resemble those of the large intestine (Box 9.1).[24,25] Although many of the bacteria found in SIBO are beneficial within the colon, these same microorganisms can have deleterious effects within the delicate environment of the small intestine.

Interestingly, many patients with celiac disease whose symptoms persist despite a gluten-free diet have been shown to have SIBO, with improvement only after bacterial eradication.[26] The incidence of SIBO also increases with age.[27] It has been found that 64% of individuals more than 75 years of age with chronic diarrhea have colonic-type flora in their small bowels,[5] and that SIBO is the most common cause of clinically significant malabsorption in elderly persons.[19]

Pathophysiology

Two major factors that control the numbers and types of bacteria within the small bowel are intestinal motility and gastric acid secretion.[19,24] Accordingly, SIBO has been associated with both intestinal stasis and hypochlorhydria.[25] Other factors influencing SIBO include pancreatic enzyme secretion,[28] disaccharidase production by microvilli,[29] ileocecal valve function,[30,84] bile salts, luminal pH, oxidation-reduction potential,[24] and migrating motor complex function.[31]

The migrating motor complex (MMC) is a system of electrical waves that "migrate" throughout the small intestine, serving to propel

BOX 9.1 Causes of Small Intestinal Bacterial Overgrowth

- Achlorhydria, hypochlorhydria, drug-induced hypoacidity
- Chronic constipation
- Stasis resulting from structural changes (e.g., diverticulosis, blind loops, radiation damage, stricture, fistulas, intestinal pseudo-obstruction, adhesions resulting from prior surgery)
- Dysfunctional migrating motor complex
- Chronic pancreatic insufficiency
- Disaccharidase deficiencies (e.g., lactase)
- Dysfunctional ileocecal valve
- Immunodeficiency (especially of secretory immunoglobulin A)
- Diabetes mellitus
- Scleroderma
- Crohn's disease

luminal contents all the way from the stomach to the terminal ileum over a period of 113 to 230 minutes, depending on the individual.[32] The MMC has been referred to as the "intestinal housekeeper." Its influence on motility is independent of the peristalsis that occurs in the large intestine. For instance, whereas colonic peristalsis is stimulated by eating a meal, the MMC is only active in the fasting state.

The MMC consists of four phases. Phase I, which takes place in the stomach, is devoid of contractions. Phase II is composed of low-amplitude, irregular contractions that progress from the stomach to the small intestine. Phase III, initiating in either the stomach or the small intestine, is the most active phase of the MMC; contractions are of high amplitude and travel the length of the small bowel, serving to cleanse it of food from a recent meal. Phase IV represents a brief transition period back to phase I.[31,32] MMC dysfunction has been demonstrated in many individuals with SIBO, especially in Phase III.[33]

For SIBO to produce clinical consequences, an adequate concentration of organisms with particular metabolic properties within specific locations of the small intestine is required. For example, a heavy concentration of strict anaerobes and coliforms in the proximal small intestine is more likely to be associated with malabsorption than a flora consisting of fewer strict anaerobes or coliforms or when strict anaerobes or coliforms are confined to the distal small intestine.[24] For this reason, SIBO may be asymptomatic in some individuals yet produce signs and symptoms in others. Box 9.2 outlines clinical signs and symptoms that should alert the practitioner to consider testing for SIBO.

Signs and Symptoms

The classic SIBO syndrome is characterized by megaloblastic anemia resulting from vitamin B_{12} deficiency and weight loss and diarrhea secondary to fat malabsorption.[24] However, many patients present with nonspecific symptoms 1 to 2 hours after a meal, including bloating, flatulence, and abdominal pain resulting from bacterial fermentation of intraluminal sugars and associated gas production, and constipation-predominant SIBO is also possible (Box 9.3).[15,26]

Via secretory and osmotic processes, diarrhea may occur even in the absence of significant steatorrhea. Unabsorbed fats and bile salts are modified by bacteria in the colon to hydroxylated fats and free bile acids, respectively, which stimulate colonic secretion of water and electrolytes.[24]

Bile salts, essential to fat emulsification and assimilation, must be conjugated with taurine or glycine to function properly. In SIBO, bacteria in the proximal small intestine can deconjugate bile salts to form free bile acids.[24] This can have two major clinical repercussions:

BOX 9.2 When to Consider Breath Testing for Small Intestinal Bacterial Overgrowth

- Gas, bloating, or diarrhea, usually after eating
- Irritable bowel syndrome, either diarrhea or constipation-dependent
- Unexplained weight loss
- Evidence of malabsorption
- Chronic hypochlorhydria or achlorhydria
- Use of acid-blocking medications (especially proton-pump inhibitors)
- Prior intestinal surgery, chronic constipation, or other causes of intestinal stasis
- Intolerance of disaccharides (e.g., lactose)
- Unexplained vitamin B_{12} deficiency, weight loss, or bone loss
- Unexplained nutrient insufficiencies (e.g., calcium, magnesium, fat-soluble vitamins)
- Unexplained "leaky gut"
- Crohn's disease (especially if history of strictures or small bowel resection)
- Restless legs syndrome
- Nonalcoholic fatty liver disease
- Interstitial cystitis

BOX 9.3 Signs and Symptoms of Bacterial Overgrowth

- Gas, bloating, and flatulence
- Diarrhea or constipation
- Abdominal cramping
- Steatorrhea
- Lactose intolerance
- Megaloblastic anemia

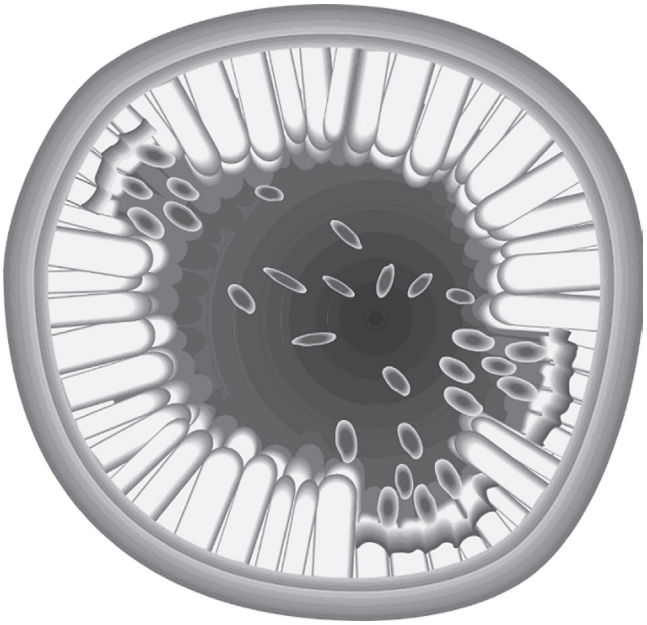

Fig. 9.1 In small intestinal bacterial overgrowth, free bile acids can damage the brush border, resulting in reduced enzyme activity and maldigestion. (Courtesy of Genova Diagnostics, Asheville, NC.)

(1) free bile acids can promote mucosal damage (Fig. 9.1), resulting in reduced brush-border enzyme activities (especially lactase),[34] defects in mucosal uptake of sugars and amino acids, enteric blood loss, and protein-losing enteropathy; or (2) the conjugated bile salt

concentration may fall below the concentration necessary for effective micelle formation, resulting in fat malabsorption, steatorrhea,[24,25] and deficiencies of fat-soluble vitamins.[2]

Fat malabsorption in SIBO can also result from mechanical interference, specifically the formation of a pseudomembrane, thought to represent a maladaptive defense mechanism against the bacterial overgrowth.[35]

Unabsorbed fatty acids can form insoluble soaps with calcium and magnesium, rendering them unavailable.[2] Osteomalacia, night blindness, hypocalcemic tetany,[19] or metabolic bone disease[4] may develop as a consequence of lipid malabsorption in patients with SIBO. Although rare, iron-deficiency anemia may result from blood loss[2] or possibly from an inflammation-induced upregulation of hepcidin, the body's main iron-regulating hormone.[36] SIBO may also lead to vitamin B_{12} deficiency, with megaloblastic anemia and low serum cobalamin levels.[19,24] Although intrinsic factor is not altered by anaerobic bacteria, microbes are capable of detaching vitamin B_{12} from the intrinsic factor, as well as directly using B_{12}.[30] Either mechanism can make the vitamin unavailable. Paradoxically, serum folate values are usually normal or even elevated in SIBO, a result of the bacterial synthesis of the vitamin.[37]

Hypoproteinemia may also occur in SIBO, secondary to protein-losing enteropathy and protein malabsorption.[2,25] In addition, bacteria may metabolize proteins to ammonia and fatty acids, thereby rendering them unavailable to the host.[34]

The composition of bacterial populations contaminating the small bowel is complex and variable.[19] However, the diagnosis of SIBO tends to be oriented less to the identification of specific microorganisms and more to overall bacterial concentrations.[19]

DIAGNOSIS

Endoscopy

Culture of a small bowel aspirate (typically jejunal or duodenal) via endoscopy is a direct method for diagnosing SIBO; abnormally high bacterial counts confirm the diagnosis.[25] Although this technique has been considered the gold standard for diagnosing SIBO, intubation methods are invasive, time-consuming, uncomfortable, and expensive. It also has several shortcomings: (1) because the aspirate is typically taken from only one location, SIBO in the more distal end of the small bowel or concentrated in a large diverticulum or blind loop may be missed[38]; (2) false positives can result from bacterial contamination from the mouth or esophagus[39]; and (3) the traditional threshold of $>10^5$ cfu/mL is not well validated and may only be appropriate for patients with blind loop syndrome as a result of past surgeries (e.g., Billroth II procedure). It is now generally agreed that a lower cutoff of 10^3 cfu/mL is sufficient for a diagnosis of SIBO.[40,41]

Breath Testing

Breath tests were devised as less invasive alternatives to intubation and culture, offering greater patient comfort and convenience. They also offer good sensitivity[42]: a meta-analysis of 12 studies found that lactulose and glucose hydrogen breath testing identified SIBO in 54% and 31% of patients with IBS, respectively, compared with only 4% of the patients via jejunal aspirate and culture.[43]

Breath tests are based on the ability of intestinal microbes to ferment carbohydrates, producing H_2 or CH_4 in the process. A fraction of these gases naturally diffuses from the bowel to the circulation and is excreted with expired air. Because there is no other metabolic source of H_2 and CH_4, pulmonary excretion of these gases is used as a measure of bacterial fermentation during the passage through the bowel.[44]

Breath tests for SIBO commonly employ either lactulose or glucose, a prescribed dose of which is ingested following 1 to 2 days of dietary fiber restriction and a 12-hour fast.[45] In all cases, intestinal bacteria modify the challenge substance, producing an early peak in breath gas values in patients with SIBO. Lactulose is a synthetic, nonabsorbed disaccharide that offers the advantage of traveling the full length of the small intestine. An early H_2 (and/or CH_4) peak is typically followed by a prolonged gas peak representing colonic bacterial activity (approximately 90 minutes into the collection process).[42,46] Glucose, an absorbable monosaccharide, is not suitable for patients with blood sugar disorders such as diabetes, and its rapid absorption reduces the test's sensitivity in the distal ileum.[42] However, its superior diagnostic accuracy in some studies has led to a growing consensus in favor of glucose over lactulose.[47] Differences in methodology between studies may have contributed to the wide range of sensitivities and specificities for lactulose versus glucose (e.g., 31% to 68% and 44% to 100%, respectively, for lactulose; vs. 20% to 93% and 30% to 86%, respectively, for glucose).[41]

During a breath test, breath specimens are collected by exhaling into a special mouthpiece connected to a vacuum-sealed collection tube. A fasting (prechallenge) breath specimen is collected, a specified amount of lactulose or glucose is ingested, and then nine more breath specimens are typically collected at timed intervals every 15 to 20 minutes. Breath levels of H_2 and CH_4 are plotted over time, with earlier rises in breath gas values corresponding to more proximal portions of the small intestine. CO_2 is also measured because insufficient amounts of CO_2 will invalidate results for H_2 and CH_4.

Hydrogen Versus Methane Versus Hydrogen Sulfide

Many studies using carbohydrate challenges have measured only breath H_2. However, 30% to 50% of H_2 producers also produce CH_4,[48] most likely a result of "methanogenic" bacteria, which consume H_2, producing CH_4 in the process.[45] Individuals whose intestines harbor methanogenic bacteria typically produce greater amounts of breath CH_4 during the test, thus being potentially missed on a test measuring only H_2.[49] Because of the lack of consistency and standardization across studies, clinics, and practitioners, a North American group of clinician scientists met for discussion in May 2015.[40] Consensus was reached that CH_4 should be measured along with H_2, especially in cases of constipation or slow transit time.

Some individuals with SIBO also appear to produce hydrogen sulfide (H_2S), a result of intestinal sulfate-reducing bacteria utilizing H_2 equivalents such as acetate and formate. H_2S is not apparent on the standard breath test measuring H_2 and CH_4, and in such a case, the breath gases values may form a flat line. Currently available gas chromatography equipment cannot detect H_2S. However, a preliminary study examining breath H_2S offers promise in diagnosing H_2-negative individuals with SIBO.[50]

Clinical correlations have been noted between various disorders and the production of H_2 versus CH_4. In one study, individuals producing higher amounts of H_2 relative to CH_4 reported significantly increased bloating and cramping after carbohydrate ingestion, whereas individuals producing high CH_4 reported no significant increase in these symptoms.[51] Specific IBS symptoms also vary with breath gas values. For example, CH_4 production has been associated more with constipation-predominant IBS, whereas H_2 production tends to be more associated with diarrhea.[52] SIBO, in general, appears to be more common in diarrhea-predominant IBS than in constipation-predominant IBS.[43]

Interpretation of Breath Testing

Lactulose is normally not fermented until it reaches the bacteria-rich colon. As a result, the typical fasting breath sample contains less than 20 ppm of H_2 or CH_4. An increase in breath gas levels in the later breath specimens (90 and 120 minutes) usually reflects colonic bacterial fermentation and is considered normal. Lack of the expected colonic peak can result from antibiotics or an acidic colonic pH.[53,54] In patients with SIBO, the lactulose is typically fermented in the small intestine, resulting in an early peak in breath gas values.[42]

According to the consensus meeting for SIBO in May 2015, a positive test result (indicating SIBO) is defined by a rise in H_2 of ≥20 ppm above baseline (or a rise in CH_4 of ≥10 ppm above baseline), occurring less than 90 minutes after lactulose or glucose ingestion.[40] A double-peak is not considered necessary for diagnosis. Elevated baseline values occur in up to one-third of patients with SIBO[53] and have been proposed to relate to the fermentation of endogenous brush-border glycoproteins,[55] although future studies are needed to confirm the clinical significance of this finding.[40]

Various factors may interfere with the breath test, resulting in false-negative or false-positive results. Detailed instructions for breath collection help minimize this interference.

False-positive results. The following factors may account for a false-positive result on a breath test:

- Failure to fast for at least 12 hours before the test or to avoid dietary fiber the day before collection can result in excessive "background noise" that contributes to the overall concentration of breath gases.[29]
- Sleeping, smoking, or eating shortly before or during sample collection can increase concentrations of breath gases.[56]
- Fermentation by oropharyngeal flora can lead to early, transient elevations in breath gases after carbohydrate ingestion.[57] As a result, it is recommended that teeth and tongue brushing be performed before specimen collection.

False-negative results. False-positive results on a breath test can be caused by the following factors:

- Diarrhea or the recent administration of antimicrobials can temporarily reduce the concentration of gut bacteria,[58] thus obscuring SIBO. Laxatives and enemas pose a similar risk.[59] Patients are advised to wait at least 1 week after antibiotic therapy before performing the test.
- SIBO confined to the distal ileum may go undetected if the breath gas peak produced in the ileum merges with the breath gases produced by the colonic flora.[42]
- Rapid intestinal transit may cause delayed increases in breath gases, leading to a rise only after the lactulose has already reached the cecum.[60] This is particularly relevant for patients with SIBO who have undergone small bowel resection.

TREATMENT OF SIBO

For a successful clinical outcome, the treatment of SIBO should not only eradicate the bacterial overgrowth but also address symptoms, underlying causes, and complications of SIBO, such as nutrient deficiencies. Although relapses are common, identifying and treating the individual root causes of SIBO can greatly minimize this potential.

Bacterial Eradication

Most patients with clinically significant SIBO host an intestinal flora consisting largely of anaerobes; however, some patients harbor a predominance of gram-negative aerobes, such as *Escherichia coli, Klebsiella,* and *Pseudomonas.*[61] As a result, the most effective antimicrobial agents are those that target both aerobic and anaerobic microorganisms.[19]

Antibiotics

According to a meta-analysis of 10 studies using different antibiotics to treat SIBO, antibiotics were superior to placebo in normalizing H_2 breath tests (51% efficacy for antibiotics compared with 9.8% for placebo).[62] Historically, the first-line antibiotic for SIBO has been tetracycline (250 mg four times daily for 7 days).[19] However, the high prevalence of bacterial resistance to this drug (up to 60% of patients with SIBO)[19] has led to the use of alternative antibiotics. Common alternatives include metronidazole, clindamycin, neomycin, and rifaximin; amoxicillin, ampicillin, chloramphenicol, erythromycin, ciprofloxacin, and trimethoprim/sulfamethoxazole have been used less frequently.[41] The duration of treatment has varied in studies as much as the choice of antibiotic, ranging from 5 days to 1 month.

The minimally absorbed and broad-spectrum antibiotic rifaximin is increasingly recognized for its effectiveness and minimum of side effects.[63] Rifaximin has been widely studied for its use in functional bowel disorders, including SIBO, and was approved by the U.S. Food and Drug Administration (FDA) in 2015 for diarrhea-predominant IBS. In one study, a 7-day course of rifaximin at 400 mg three times daily normalized breath H_2 excretion in 70% of patients with SIBO, whereas tetracycline normalized H_2 excretion in only 27% of patients.[64] In a larger 7-day study, rifaximin at 400 mg three times daily normalized H_2 excretion in 63.4% of patients with SIBO, compared with 43.7% of patients with SIBO taking metronidazole.[65] Longer treatment durations of 10 to 14 days are common.[63]

In cases of excess CH_4 production, the addition of neomycin (e.g., 500 mg twice daily) to rifaximin, ideally for 14 days, has been found to be more effective than rifaximin alone.[66,67] This is because *Methanobrevibacter smithii,* the bacterium considered most responsible for CH_4 production in the gut, is commonly resistant to many antibiotics.

A poor response to antibiotics may indicate mucosal disease, antibiotic resistance, antibiotic-associated diarrhea, or an incorrect diagnosis.[30,68] Recurrence of symptoms after treatment suggests the need for follow-up testing and possible retreatment, as well as a closer examination of underlying causes. Older age, history of surgery such as appendectomy, and chronic use of proton-pump inhibitors increase the likelihood of recurrence.[69] Because prolonged antibiotic therapy significantly raises the risk of diarrhea, *Clostridium difficile* infection, and bacterial resistance,[19] the administration of probiotics is often advised to minimize such side effects.[29] Certain probiotics may also reduce breath H_2 in some patients with SIBO.[70] However, this is an area of ongoing research in SIBO because probiotics have also been observed to exacerbate symptoms in patients.[71]

Herbal Antibiotics

Because conventional antibiotics have shown variable success in eradicating SIBO and can come with side effects (most) or a high price tag (rifaximin), interest has been steadily growing in the use of various botanical agents with antimicrobial activity. Small intestinal fungal overgrowth (SIFO) is also present in some patients with SIBO; thus herbal agents may offer the additional advantage of antifungal activity. Anecdotally, some of the more common antimicrobial and/or antifungal herbs used for SIBO include berberine sulfate or berberine-containing herbs, for example, goldenseal *(Hydrastis canadensis),* barberry *(Berberis vulgaris),* or goldthread *(Coptis chinensis);* oregano *(Origanum vulgare);* allicin (stabilized garlic extract); and neem *(Azadirachta indica).*

In the first formal study examining the efficacy of herbal agents in patients with confirmed SIBO, over a 4-week period, 67 patients received rifaximin and 37 patients received various herbal

combinations (totaling 27 herbs) known to have antibacterial and/or antifungal properties.[72] At follow-up, 46% of the patients in the herbal therapy group had negative lactulose breath tests, compared with 34% of the patients in the rifaximin group.

Antibiotic Alternatives

Peppermint oil, which has been used successfully in patients with IBS, is a volatile oil with antimicrobial properties.[73] Although enteric-coated peppermint oil (dose of 0.2 mL three times a day) dramatically reduced gastrointestinal symptoms and reduced breath H_2 in a patient with SIBO,[74] further research is needed before drawing conclusions about its effectiveness in SIBO.

Addressing the Underlying Causes

Bacterial overgrowth of the small intestine may easily recur if the root causes are not addressed.

Restoration of Gastric Acidity

Because gastric acidity is a critical deterrent to SIBO, restoration of normal stomach pH in patients with hypochlorhydria or achlorhydria is essential. This may include the use of betaine hydrochloride with meals or the discontinuation of antacid medications. A 2017 meta-analysis of 19 studies concluded that the use of proton-pump inhibitors moderately increases the risk of SIBO.[75]

Normalization of Intestinal Motility

As mentioned, intestinal stasis is a major contributing factor to SIBO. When not a result of anatomical or organic causes, reduced motility may be improved with measures such as increased dietary fiber (especially partially hydrolyzed guar gum, which may be safer in SIBO than other forms of fiber[76] and even enhance the effect of rifaximin[77]), water, probiotics, stress management, and exercise.

As stated, impairments in the migrating motor complex (MMC) have been noted in patients with SIBO. The MMC is influenced by both gastrointestinal hormones and the central nervous system. The most active phase of the MMC, Phase III, is induced by serotonin, motilin, and ghrelin. Accordingly, low doses of promotility agents such as serotonin agonists (e.g., tegaserod, prucalopride, or cisapride) and motilin receptor agonists (e.g., azithromycin or erythromycin) are increasingly included in a comprehensive approach to SIBO patients, aimed at preventing relapse[71]; low-dose naltrexone, an opioid antagonist that interacts with the immune system, is also sometimes employed.[78] This is an area of continuing research. In one such study of patients successfully treated for SIBO, tegaserod was shown to dramatically extend symptom-free days posttreatment, and both tegaserod and erythromycin were superior to no prevention at all.[79]

Abdominal/pelvic adhesions (e.g., from prior surgeries) can sometimes restrict motility in the gastrointestinal tract. Anecdotally, such adhesions may be amenable to visceral manipulation.

Dietary Support

An elemental formula supplies daily nutrition in an easy-to-assimilate form and does not contain carbohydrate residues that can feed bacteria. In a study of 124 patients with IBS with SIBO, an elemental diet was found to normalize lactulose breath tests in 80% of patients after 14 days, a statistic not observed with antibiotics; another five patients achieved a negative breath test after following the diet for an additional 6 days, raising the overall success rate to 85%.[80] The precise mechanisms behind the success of an elemental diet are still unclear, although they are postulated to include nutrient deprivation of enteric microbes, stimulation of Phase III of the MMC, and/or stimulation of intestinal immunity.[80]

Diet is increasingly recognized as a critical factor determining success in the treatment of SIBO. Because bacteria thrive on enteric carbohydrates, restricting dietary fermentable oligosaccharides, disaccharides, monosaccharides, and polyols (FODMAPs) can theoretically help reduce symptoms and reduce bacterial counts. A systematic review found that a low-FODMAP diet ameliorated IBS symptoms in all FODMAP studies examined.[81] Adequate spacing of meals (e.g., at least 4–5 hours apart) is another important therapeutic consideration, based on the fact that the MMC is only active in the fasting state.

Patients with SIBO may become lactose intolerant as a result of disaccharidase deficiency. This is often ameliorated with bacterial eradication[82]; however, temporary avoidance of all disaccharides—the premise of the "specific carbohydrate diet"—can also help "starve" the excess bacteria and allow healing of the intestinal lining.[83]

Substituting more easily absorbed medium-chain triglycerides for most dietary fat may be helpful in patients with diarrhea and steatorrhea.[19]

Further research is needed into the role of diet in the treatment and especially the maintenance of remission in SIBO. In the meantime, practitioners continue to experiment and refine various approaches.

Cell-Signaling Analysis

Lise Alschuler, ND, and *Aristo Vojdani*, PhD, MSc, CLS*

OUTLINE

INTRODUCTION

Signaling pathways in normal cells consist of growth and control messages from the outer surface deep into the nucleus. In the nucleus, the cell-cycle clock collects different messages, which are used to determine when the cell should divide. Cancer cells often proliferate excessively because genetic mutations cause induction of stimulatory pathways and issue too many "go-ahead" signals, or the inhibitory pathways can no longer control the stimulatory pathways.[1]

Impressive evidence has now been gathered with regard to the destination of stimulatory and inhibitory pathways in the cell. These pathways converge on a molecular apparatus in the cell nucleus that is often referred to as the *cell-cycle clock.* The clock is the executive decision maker of the cell; apparently, it runs amok in virtually all types of human cancer. In a normal cell, the clock integrates the mixture of growth-regulating signals received by the cell and decides whether the cell should pass through its life cycle. If the answer is positive, the clock leads the process.

THE CELL CYCLE

A schematic of the classic cell cycle is shown in Fig. 10.1. The cell-cycle compartments are drawn such that their horizontal position reflects their respective DNA content. Cells that contain only one complement of DNA from each parent (2C) are referred to as *diploid cells.* Cells that have duplicated their genome, and thus have 4C amounts of DNA, are called *tetraploid cells.*

The cell cycle is classically divided into the following phases:

- G_0
- G_1
- S
- G_2
- M

The cell-cycle phase of G_1 was historically considered to be a time when diploid (2C) cells had little observable activity. Because this time precedes DNA synthesis, the term *Gap 1 (G_1)* was coined. It is known that there is quite a bit of transcription and protein synthesis during this phase. At a certain point in the cell's life, the DNA synthetic machinery turns on. This phase of the cell's life is labeled *S* for synthesis. As the cell proceeds through this phase, its DNA content increases from 2C to 4C. At the end of S, the cell duplicates its genome and now is in the tetraploid state. After the S phase, the cell again enters a phase that was historically thought to be quiescent. Because this phase is the second gap region, it is referred to as G_2. In the G_2 phase, the cell

*Previous edition contributor

produces the necessary proteins that play a major role in cytokinesis. After a highly variable amount of time, the cell enters mitosis *(M)*. DNA content remains constant at 4C until the cell actually divides at the end of telophase.

The enlarged parent cell finally reaches the point where it divides in half to produce its two daughters, each of which is endowed with a complete set of chromosomes. The new daughter cells immediately enter G_1 and may go through the full cycle again. Alternatively, they may stop cycling temporarily or permanently.[2–4] Telomeres, condensed chromatin caps on the ends of chromosomes, dictate the ultimate number of cell divisions that can occur. With each cell division, the telomeres shorten, ultimately to the point that destabilizes the chromosomes sufficiently enough to disallow further mitosis. Thus telomeres are considered to be the "mitotic clock." Telomere shortening is linked to aging, sedentarism, chronic stress, and age-related diseases, including cancer, coronary artery disease, and heart failure. Cell-proliferation capacity, the cellular environment, and epigenetic factors affect telomere length and therefore cells' mitotic capacity.

Telomere length can be assessed, and a clinical test is available. The telomere length is reported as a telomere score, which is a calculation of the telomere length derived from nucleated white blood cells. This result is then compared with the average telomere length of a similarly aged sample population. Although the transferability of this information to other bodily tissues is not well characterized, telomere length measured in this way has been correlated to clinical outcomes such as cancer incidence and mortality from cancer.[5] This information can be used to prioritize interventions that increase telomere length, such as dietary interventions, stress reduction, and antioxidant and vitamin therapies.[6]

Another influence on the cell-cycle clock is circadian rhythms, or the circadian clock. The circadian clock is the result of molecular clocks in each cell, circadian physiology, and, ultimately, the suprachiasmatic nuclei in the hypothalamus. The circadian clock regulates the activity and expression of proteins related to cell-cycle checkpoints, and in turn these checkpoints regulate circadian-clock proteins. Every cell in the body has circadian-clock proteins, so-called peripheral oscillators, which exert rhythmic control of mitochondrial morphology, energy metabolism, and cell division.[7] This has significant clinical implications, particularly in the area of cancer treatment. Both the toxicity and efficacy of cytotoxic agents can vary by more than 50% as a function of when they are dosed in experimental models.[8] Although the clinical implications of this have not yet been discovered, the administration of cytotoxic agents in accordance with the circadian-induced activity of the target cells is gaining ground as a reasonable therapeutic approach.

FLOW CYTOMETRY TO ASSESS CELL-CYCLE STATUS

Flow cytometry identifies cells as they "flow" through a detector while being illuminated with intense light. Tissues are generally disaggregated into single-cell suspensions and stained with one or more fluorescent dyes. The cells are forced to flow within a sheath of fluid, eventually being intersected and interrogated by an intense light source, such as a laser beam. As the cell enters the laser beam, it scatters light in all directions. The measurement of light scattered in the forward direction yields information on the particle's size. Scattered light at right angles to the incident light beam provides information on the internal granularity of the cell. If the cell has been stained with one or more fluorescent dyes, a correlated measurement of more than one cellular parameter can be achieved.

The cell cycle is challenging to study because almost any method can cause perturbations to the activity under study. Newer methods to study the cell cycle allow the ability to assess the cell cycle in living cells. One such method involves labeling the subpopulations of living cells in each phase of the cell cycle with fluorescent proteins. Then, using imaging, one can track and quantify cells in specific phases of the cell cycle using these live cell sensors. This method avoids perturbations to the cell cycle from the test and also allows for the assessment of external influences on the cell cycle.[9]

CLINICAL APPLICATION

Patients Exposed to Carcinogenic Chemicals and Patients With Chronic Fatigue Syndrome

To determine whether peripheral blood lymphocytes (PBLs) isolated from individuals with chronic fatigue syndrome (CFS) and chemically exposed patients represent a discrete block in cell-cycle progression, PBLs isolated from patients with CFS and control individuals were cultured, harvested, fixed, stained with propidium iodide, and analyzed by flow cytometry. The nonapoptotic cell population in PBLs isolated from individuals with CFS consisted of cells arrested in the late S and G_2/M boundaries compared with healthy controls. The arrest was characterized by increased S and G_2/M phases of the cell cycle (from 9%–33% and from 4%–21%, respectively) (Table 10.1 and Fig. 10.2) at the expense of G_0/G_1. Such an abnormality in cell-cycle progression indicates abnormal mitotic cell division in patients who have been exposed to chemicals and who have CFS. From these results,

TABLE 10.1 Percentage of Different Phases of Cell Cycle in Healthy Controls and Patients Exposed to Chemicals

Phase	Healthy Controls	Chemically Exposed
G_0/G_1	88.6 ± 1.4	51.7 ± 2.4
S	8.6 ± 1.2	33.2 ± 4.3
G_2/M	3.6 ± 0.82	21.0 ± 2.6

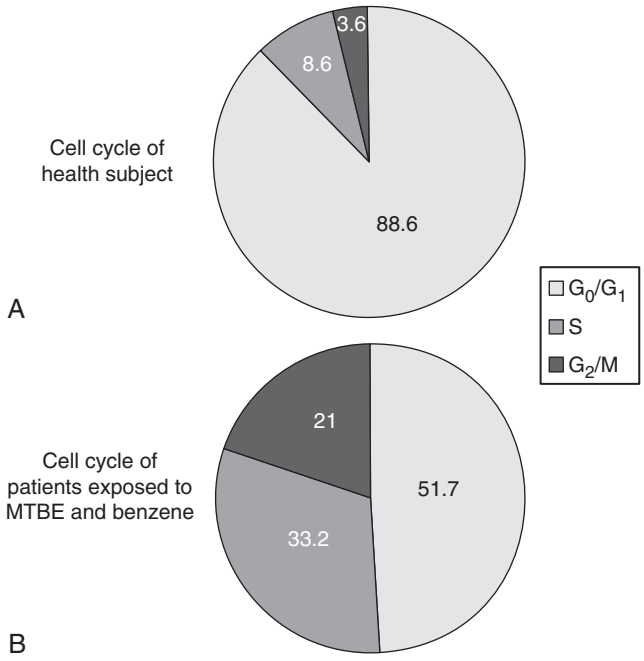

FIG. 10.2 Cell-cycle analysis of peripheral blood lymphocytes from healthy controls (A) and patients exposed to MTBE and benzene (B). Note that in patients' samples, the majority of cells switched from G_0/G_1 to S and G_2/M phases.

it was concluded that the PBLs of patients with chemical exposure and CFS grow inappropriately, not only because the signaling pathways in the cells are perturbed but also because the cell-cycle clock becomes deranged and stimulatory messages become greater than the inhibitory pathways.[10,11] However, to limit cell proliferation and avoid cancer, the human body equips cells with certain backup systems that guard against runaway division. One such backup system present in the lymphocytes of patients with CFS provokes the cell to undergo apoptosis. This programmed cell death occurs if some of the cell's essential components are deregulated or damaged. For example, injury to chromosomal DNA can trigger apoptosis.[1,10,11]

Erythrocyte Sedimentation Rate

Michael T. Murray, ND

OUTLINE

INTRODUCTION

The erythrocyte sedimentation rate (ESR), the rate at which erythrocytes settle out of nonclotted blood in 1 hour, has been one of the most widely performed laboratory tests in the past 75 years. Used primarily to detect occult processes and monitor inflammatory conditions, the ESR test has changed little since 1918 when Fahraeus discovered that the erythrocytes of pregnant women sedimented in plasma more rapidly than they did in nonpregnant women. Since its incorporation into standard laboratory diagnosis, the ESR has been shrouded in medical myths and is often misinterpreted or misused. This chapter provides rational guidelines for its use as a nonspecific measure of inflammatory, infectious, neoplastic, and cardiovascular diseases.[1–4]

ERYTHROCYTE AGGREGATION

Normally, erythrocytes settle quite slowly as the gravitational force of the erythrocyte's mass is counteracted by the buoyant force of the erythrocyte's volume. However, when erythrocytes aggregate, they sediment relatively rapidly because the proportional increase in their total mass exceeds the proportional increase in their volume.

Therefore the major determinant in the sedimentation rate of erythrocytes is erythrocyte aggregation, which usually occurs along a single axis (rouleaux formation). The aggregation of erythrocytes is largely determined by electrostatic forces. Under normal circumstances, erythrocytes have a negative charge and therefore repel each other. However, many plasma proteins are positively charged and neutralize the surface charge of erythrocytes, thereby reducing repulsive forces and promoting aggregation.

The relative contribution of the various "acute-phase" reactant proteins to aggregation is shown in Table 11.1. One protein that has no direct effect on the ESR in physiologic concentrations but is associated with certain inflammatory, degenerative, and neoplastic diseases is C-reactive protein (CRP). Its major function is facilitation of the complement system. Like ESR, the measurement of CRP is used in the monitoring of patients with chronic inflammatory conditions.[1,2] An elevated CRP provides evidence of an inflammatory process despite a normal ESR. Therefore, when used in conjunction with the ESR, it greatly increases the sensitivity in detecting inflammatory and/or infectious processes, especially when variables such as anemia confound the ESR.

The ESR is also elevated in patients with proteinemias (myeloma, macroglobulinemia, cryoglobulinemia, and cold agglutinin disease).[1–4] Disorders of erythrocytes such as various anemias will alter the ESR and may interfere with accurate interpretation.[1–4] Because the ESR is directly proportional to the mass of the erythrocyte and inversely proportional to its surface area, large erythrocytes sediment more rapidly than smaller cells. Therefore in macrocytic anemia, there is an increased ESR, and in microcytic anemia, there is a decreased ESR.

Although the usefulness of ESR determination has decreased as new methods of evaluating disease have been developed, it remains quite helpful in the diagnosis of some diseases, such as temporal arteritis and polymyalgia rheumatica. Perhaps more useful is its ability to monitor these conditions and others, including chronic inflammatory diseases such as rheumatoid arthritis (RA), Hodgkin disease, and other cancers. Although the use of the ESR as a screening test to identify patients who have serious disease is not supported by the literature, it does provide a general gauge of inflammatory processes in the body. It is well accepted that an extreme elevation of the ESR is strongly associated with serious underlying disease, most often infection, collagen vascular disease, or metastatic malignancy. Recently there has been a growing appreciation of the value of the ESR as a marker for atherosclerosis and coronary artery disease.[5,6] In addition, as a sign of chronic low-grade inflammation, it may be helpful as a marker for other conditions as well. For example, in a study of 49,321 Swedish males aged 18 to 20 years, screened for general health and for mental and physical capacity at compulsory conscription examination before military service, there was an inverse correlation between ESR and performance on an IQ test.[7] This result indicated that low-grade inflammation, as indicated by the ESR, was associated with reduced cognitive abilities at ages 18 to 20 years.

PROCEDURES

Various methods for determination of the ESR have been developed. Currently, the Westergren method is recommended by the International Committee for Standardization in Hematology.

TABLE 11.1 Relative Contribution of Acute-Phase Reactant Proteins to Erythrocyte Aggregation

Blood Constituent	Relative Contribution
Fibrinogen	10
β-Globulin	5
α-Globulin	2
Albumin	1

Westergren Method

In the standard Westergren method, the following procedure is used:

1. Dilute venous blood 4:1 with anticoagulant sodium citrate.
2. Put in a 200-mm-long, 2.5-mm-internal-diameter glass tube (Westergren tube).
3. Allow it to stand in a vertical position for 1 hour.
4. At the end of 1 hour, the distance from the meniscus to the top of the column of erythrocytes is recorded as the ESR.

The modified Westergren method uses ethylenediaminetetraacetic acid rather than sodium citrate as an anticoagulant and is more convenient because the same tube of blood can be used for other hematologic studies. The standard and modified methods give identical results.[1–4]

Wintrobe Method

The second most commonly used method is the Wintrobe method. This method is performed with a 100-mm tube (Wintrobe tube) containing oxalate as the anticoagulant. It is more sensitive than the Westergren method in the "normal" to "mildly elevated" range; however, in the more highly elevated ESR, the short tube leads to relatively insensitive readings resulting from packing of cells.[2]

Results

The results of both the Westergren and Wintrobe methods are listed in Box 11.1.

BOX 11.1 Results of Westergren and Wintrobe Methods

- Westergren (normal results)
  - Men: 0 to 10 mm/h
  - Women: 0 to 15 mm/h
  - Children: 0 to 10 mm/h
- Wintrobe (normal results)
  - Men: <6.5 mm/h
  - Women: <16 mm/h

INTERPRETATION

Several factors may result in false-positive or false-negative ESR values; the more significant of these are listed in Box 11.2. In addition, it is important to recognize that in acute disease, the change in sedimentation rate may lag behind the temperature elevation and leukocytosis for 6 to 24 hours, and in unruptured acute appendicitis, the rate may be normal. In convalescence, the increased rate tends to persist longer than the fever or leukocytosis. Box 11.3 lists the most common clinical implications of changes in the ESR. An ESR value exceeding 100 mm/h has a 90% predictive value for serious underlying disease—most often infection, collagen vascular disease, or metastatic tumor.[1]

BOX 11.2 Factors Interfering With the Erythrocyte Sedimentation Rate

False Increase

- Elevated levels of fibrinogen, globulins, and cholesterol
- High room temperature
- Macrocytic anemia
- Menstruation
- Pregnancy
- Running a refrigerated blood sample before it has returned to room temperature
- Tilted erythrocyte sedimentation rate tube
- Certain drugs: dextran, methyldopa, methysergide, oral contraceptive agents, penicillamine, procainamide, theophylline, trifluperidol, vitamin A

False Decrease

- Cachexia
- Clotting of blood sample
- Elevated bile salts
- Elevated phospholipids
- Delay of >2 hours in running the test
- High doses of adrenal steroids
- Hypofibrinogenemia
- Hyperglycemia
- Hyperalbuminemia
- Leukocytosis
- Microcytic anemia
- Newborn
- Certain drugs: adrenocorticotropic hormone, cortisone, ethambutol, quinine, salicylates

Data from references 1 and 4.

Elevated Erythrocyte Sedimentation Rate

Asymptomatic Patients

The presence of an elevated ESR as the only manifestation of a disease process is quite rare. However, when present, it can be highly significant. For example, in one study of 17 patients whose increased ESR was the sole initial clue to disease, two had tuberculosis, one had colon cancer, one had systemic lupus erythematosus, three had ankylosing spondylitis (diagnoses that typically become apparent only after several years of observation), and four men had a persistently elevated ESR several years before a myocardial infarction. The remaining patients developed myeloma, prostate cancer, psoriasis, benign monoclonal gammopathy, and pancreatic cancer.[2]

Although the ESR generally makes a small contribution to disease detection in asymptomatic persons, the presence of an elevated ESR as the only clue to illness in an asymptomatic person indicates the need for a careful diagnostic workup; it may be the first sign of an occult malignancy or a chronic inflammatory disease. The laboratory evaluation for an asymptomatic patient with an elevated ESR should include a complete blood cell count with differentials, blood urea nitrogen and creatinine, alkaline phosphatase measurement, serum protein electrophoresis, urinalysis, guaiac tests of stool, and chest radiograph.[2]

An ESR that exceeds 100 mm/h is definitely associated with infection, malignancy, or connective tissue disease. Rarely does disease remain undiagnosed when the ESR is greatly elevated.[1–4] If an elevated ESR cannot be explained after further clinical evaluation, the ESR should be repeated in 1 month.

BOX 11.3 Clinical Implications of Changes in the Erythrocyte Sedimentation Rate

Increased Rate

- Acute heavy-metal poisoning
- All collagen diseases
- Carcinoma
- Cell or tissue destruction
- Gouty arthritis
- Infections
- Inflammatory diseases
- Leukemia
- Multiple myeloma
- Myocardial infarction
- Nephritis
- Pneumonia
- Rheumatoid arthritis
- Syphilis
- Toxemia

Decreased Rate

- Congestive heart failure
- Polycythemia
- Sickle cell disease

As a Predictor of Coronary Artery Disease

An elevated ESR in white men aged 45 to 64 years was found to be an independent risk factor for coronary heart disease in the National Health and Nutrition Examination Survey-I.[5] The risk was highest when the ESR was greater than 22 mm/h. Subsequent studies and the growing awareness that atherosclerosis is associated with chronic inflammation has given support to the use of the ESR as a prognostic indicator for the risk of coronary artery disease.[6,8] It was hypothesized and later shown that an elevated ESR reflected an elevated blood fibrinogen level (see Chapter 148 for further discussion of fibrinogen). The association of an elevated ESR as a harbinger of coronary artery disease precedes an elevated CRP and can be viewed as an easy-to-use and inexpensive method that indirectly indicates fibrinogen level and aids in the early detection of microinflammation and eventual atherosclerotic burden, even in apparently healthy people.[9,10]

Symptomatic Patients

The ESR is sometimes used to provide confirmation of a disease process when the history and physical findings point toward a specific diagnosis. Although the ESR itself does not diagnose a specific disease, when combined with information gathered in a history and physical, and in conjunction with other laboratory tests, it can be a great help in the formation of a specific diagnosis.

In patients with vague, unsubstantiated illness, the ESR offers limited benefit because of the lack of specificity and the presence of a normal ESR in a wide variety of illnesses. However, the ESR offers great diagnostic benefit when other signs, symptoms, and laboratory findings are present. This is particularly true in malignancies, temporal arteritis and polymyalgia rheumatica, inflammatory arthritis, and suspected infection.

Erythrocyte Sedimentation Rate in Cancer

Malignancy is quite common in symptomatic patients with an elevated ESR. In one study, 70 (8.8%) of 790 clinic patients with an elevated ESR had cancer.[1] However, of the 70 patients with malignancy and an increased ESR, 68 had local signs that led directly to the diagnosis. Thus occult malignancy was present in only 2 of the 790 patients. In addition, the ESR is often normal in patients with cancer, indicating that the ESR should not be relied on as a test to exclude occult malignancy in patients with vague symptoms.

In a prospective follow-up of 300 patients with prostate cancer, an ESR greater than 37 mm/h was associated with a higher incidence of disease progression and death. These findings paralleled other prognostic indicators (e.g., tumor, node, and metastasis staging; grade; performance status; and age) but also indicated that ESR provided additional value in the monitoring of these patients and presumably others with invasive cancer.[3]

Temporal Arteritis and Polymyalgia Rheumatica

Temporal arteritis and polymyalgia rheumatica are related syndromes that can occur together or alone. Both occur in older individuals and are associated with an increased ESR. Symptoms of temporal arteritis include unilateral throbbing headache, scalp sensitivity, visual symptoms, jaw claudication, and localized thickening or loss of pulsation of the temporal artery. Polymyalgia rheumatica is a fast-developing condition characterized by pain and stiffness of the pelvis and/or shoulder girdle, in association with fever, anemia, malaise, and weight loss. It is typically self-limited to 1 to 2 years.

Determination of the ESR is of critical importance in the diagnosis and management of patients with temporal arteritis, a condition that can result in blindness caused by obstruction of the ophthalmic arteries. When the clinical evidence for temporal arteritis is limited, a normal ESR reduces the probability of the disease to less than 1%. When the clinical evidence is strong, it is extremely rare to have a normal ESR. Achievement of a normal ESR by using anti-inflammatory agents, such as cortisone or the natural medicines (e.g., *Curcuma longa,* fish oils, *Ginkgo biloba*), greatly reduces the risk of developing blindness.[1,2]

Inflammatory Arthritis

The ESR is sometimes used to distinguish inflammatory arthritis from other causes of joint symptoms. This is particularly true in the differentiation of RA, which has an elevated ESR, and osteoarthritis, which typically has a normal ESR. Because ESR is not a specific indicator of RA, it is not appropriate to place much value on it as an independent diagnostic predictor of RA. An elevated ESR in patients with joint symptoms simply indicates an active inflammatory process.[1,2]

Suspected Infection

Leukocytosis and fever are better indicators of an acute infectious process than the ESR because the ESR is typically normal during the first stages of infection. However, the ESR is of some value in the differentiation of an intact versus ruptured appendix. Researchers demonstrated that only 2 of 25 patients with nonruptured appendicitis had an ESR of greater than 20 mm/h. In contrast, 67% of patients with ruptured appendixes had an elevated ESR.[1] CRP, however, has emerged as a more accurate measure. The value of CRP for the surgical indication of appendicitis is 4.95 mg/dL.[11] CRP has also been shown to correlate better with joint sepsis than ESR.[11]

Decreased Erythrocyte Sedimentation Rate

The causes of a low ESR (0–1 mm/h) are listed in Boxes 13.2 and 13.3. A low ESR is generally of little significance and may actually indicate a healthy state.[1–4]

Monitoring of Disease Activity

The ESR is well recognized as an aid in monitoring the activity of such inflammatory diseases as temporal arteritis, polymyalgia rheumatica,

and RA.[1–3] In general, improvements in ESR levels generally reflect clinical improvement, and vice versa.

Temporal Arteritis and Polymyalgia Rheumatica

The ESR is the most widely used test for assessing disease activity in patients with temporal arteritis and polymyalgia rheumatica because these conditions have few specific clinical indicators of disease activity. However, both the ESR and clinical status need to be monitored in these patients, and appropriate therapy instituted, if the ESR increases or if there is a worsening in the clinical picture.[1,2,12]

Rheumatoid Arthritis

Although 5% to 10% of patients with RA have a normal ESR, the ESR generally parallels disease activity. Monitoring the patient's ESR therefore provides invaluable feedback on therapeutic effect. An isolated elevated ESR is not useful for prognosis, but sustained extreme elevation of the ESR is associated with a poor prognosis.[1–3] It is important to note that in a meta-analysis of 63 clinical trials or observational studies of RA treatment, the authors concluded that ESR was more sensitive to change than CRP and was the preferred measure of the acute-phase response in RA in clinical practice.[13]

Other Inflammatory Diseases

Other inflammatory diseases, particularly autoimmune diseases such as systemic lupus erythematosus, can be monitored by the ESR in a fashion similar to that for RA.[1-3]

SUMMARY

The ESR is a simple, valuable, and useful laboratory procedure. Although it is a nonspecific indicator of inflammation, an elevated ESR (i.e., greater than 80 mm/h) indicates the presence of significant disease in more than 95% of individuals. The ESR should never be used as the sole diagnostic test. Clinical presentation, comprehensive history, laboratory investigation, and other diagnostic procedures should always be considered when interpreting ESR results. The ESR may be used as a nonspecific gauge of therapeutic efficacy and as a monitoring tool in several inflammatory conditions, including temporal arteritis, polymyalgia rheumatica, RA, certain malignancies, and atherosclerosis.

Fantus Test

Dirk W. Powell, BS, ND

OUTLINE

INTRODUCTION

The Fantus test is a simple in-clinic test for measuring urinary chlorides.[1] It is used to estimate dietary sodium chloride intake.[2] For this purpose, it has been shown to give clinically useful results if two factors are taken into consideration[3]:

- The concentration of urinary chloride is proportional to urinary sodium except with increased ingestion of nonsodium chloride salts (e.g., ammonium chloride or potassium chloride).
- Urinary output of sodium chloride may not be a reliable indicator of sodium intake when an individual has a sodium-wasting disorder (Table 12.1).

CLINICAL APPLICATION

The Fantus test was first described by J. B. Fantus in 1936.[4] It was originally used for the detection of salt and water depletion.[5] However, this test is also useful for monitoring excessive sodium chloride intake. Increased sodium chloride ingestion has been implicated as a causal or aggravating factor in many cardiovascular diseases, hypertension, stroke, osteoporosis, and chronic kidney disease.

Since Ambard and Beaujard implicated salt as a major factor in the pathogenesis of hypertension in 1904,[6] conflicting opinions and contradictory data have confused the understanding of the effect of sodium on blood pressure. In 1944 Kempner published a classic article describing the effective treatment of essential hypertension using a salt-restricted "Rice Diet."[7] Many studies have subsequently confirmed the effect of sodium chloride ingestion on blood pressure and the effectiveness of sodium-restricted diets in treating hypertension.[8–13] Evidence suggests that sodium alone does not raise blood pressure, as had been previously thought, but rather that chloride also plays an important role in the elevation of blood pressure when consumed as sodium chloride, or common table salt.[14,15] Sodium chloride restriction has also demonstrated improvements in chronic kidney disease and cardiovascular disease.[16] Another somewhat surprising finding has been that excessive sodium chloride consumption increases system acidity, theorized to be a result of impairment in the kidney's ability to excrete acid waste products of metabolism.[17]

The Fantus test is an indirect test for sodium and actually measures the chloride ion concentration. Ninety percent of the sodium that Americans consume is in the form of sodium chloride.[18] Considering that sodium chloride intake, rather than sodium ion alone, is a significant factor in blood pressure elevation and blood volume expansion, the Fantus test can be more clinically useful than direct tests for urinary sodium when managing hypertension or other disorders affected by sodium chloride.[13,14]

Research shows a strong dose-dependent relationship between excessive salt ingestion and hypertension.[19] Sodium reduction has been found to reduce and prevent heart attack and stroke.[20,21] Blood pressure is observed to begin falling within weeks of reduced salt ingestion.[22] The health advantages of limiting sodium chloride ingestion are apparent considering the preponderance of evidence that supports the health benefits of salt restriction, particularly with cardiovascular disease, hypertension, osteoporosis, and chronic kidney disease. It is estimated that reducing the average daily sodium intake to 2300 mg could reduce cases of high blood pressure by 11,000,000 annually.[23]

However, attempting to restrict sodium chloride ingestion to recommended or therapeutic levels presents two challenges. First, higher levels of sodium chloride are found in most processed and restaurant foods, which account for more than 70% of the sodium consumed.[24] Second, Americans 2 years old or older are conditioned to accept and prefer highly salted food and consume an average of more than 3400 mg of sodium daily.[25] The 2015–2020 Dietary Guidelines for Americans recommend that Americans consume less than 2300 mg of sodium each day as part of a healthy eating pattern.[26]

Because the Fantus test is an inexpensive, simple in-clinic test, it can effectively monitor sodium chloride intake where frequent sampling is useful in the management of salt-restricted diets. Salt restriction can be beneficial with several disorders, including hypertension, congestive heart failure, premenstrual syndrome, headache, osteoporosis, edema, kidney stones, and chronic kidney disorders.

People who are ingesting excessive amounts of salt may be without overt symptoms or signs of disease. It has been observed in animal studies that a high intake of sodium chloride decreases longevity as a factor separate from blood pressure.[27] In another study, salt-induced

TABLE 12.1 Conditions Where Salt Restriction Can De Deleterious

- Adrenocortical insufficiency
- Addison syndrome
- Renal disease with loss of sodium
- Increased sweat or gastrointestinal loss of electrolytes
- Chronic fatigue syndrome

angiotensin elevation was found to adversely affect the myocardium in humans, even when blood pressure remained within normal limits.[28] It has been observed that the adverse effects of excess salt can persist for an extended time after excess salt ingestion has been discontinued.[29,30]

Identifying people who at risk for the harmful effects of excessive salt consumption is an important aspect of preventive medicine. Included in this group are individuals with chronic renal disease, osteoporosis, hypertension or a family history of hypertension, and individuals over the age of 50.[31]

The Fantus test is also useful in monitoring salt intake in clinical conditions where restricted sodium chloride intake can be an aggravating factor or a trigger for serious symptoms, such as in Addison disease, postural hypotension, chronic fatigue syndrome,[32] and electrolyte imbalance (see Table 12.1).

PROCEDURE

The Fantus reagent is prepared so that the number of drops of silver nitrate ($AgNO_3$) used in the titration step can be recorded as grams of sodium per liter of urine (g Na/L urine).

Method

1. Collect a 24-hour urine sample.
2. Measure and record the 24-hour volume.
3. In a test tube, add one drop of 20% potassium chromate (K_2CrO_4) solution to 10 drops of the sample of the 24-hour urine specimen.
4. Titrate (add one drop at a time) with the 2.9% silver nitrate ($AgNO_3$) solution.
5. Record the number of drops needed for the color to turn from yellow to brown as g sodium/L.

Required Reagents

- AgNO3: 2.9% aqueous solution
- K2CrO4: 20% aqueous solution

Results

Fantus test results are measured as NaCl but can be converted to Na (NaCl × 0.39 = Na).

- Typical Western diet: >3000 mg Na/24 h
- Salt-restricted diet: 2300 mg Na/24 h (or less)

INTERPRETATION

The results of a Fantus test generally reflect the salt content of the diet. The typical Western diet contains 3.4 g of sodium in a 24-hour period. On a salt-restricted diet, the goal is typically to reduce 24-hour urine sodium to 2.3 g Na/24 h or less. The minimum 24-hour sodium intake considered safe is 0.5 g Na/24 h for healthy individuals with intact adrenocortical function. Some conditions require higher sodium chloride intake (see Table 12.1).

A random urine can be tested for urine sodium with the Fantus test and can give an approximation of 24-hour sodium ingestion. A sodium intake of 3.4 g Na/day with an intake of 2750 mL of water from both solids and fluids corresponds to the average water turnover for a 70-kg adult. After evaporation from the lungs and other losses, the amount of water excreted by the kidneys is approximately 1500 mL/24 h.[33] A urinary sodium excretion of 3 g in 24 hours would thus produce a urinary sodium concentration of 2 g/L and a urinary sodium chloride concentration of 5.1 g/L (NaCl). A 24-hour urine sample provides a more accurate estimate of 24-hour sodium intake (i.e., 24-hour urine volume × urinary sodium concentration approximates 24-hour sodium intake).

Fatty Acid Profiling

Patricia M. Devers, DO, and *Warren M. Brown, ND*

OUTLINE

INTRODUCTION

Dietary fat intake and its emerging role in chronic disease highlight the need for proper fatty acid measurement and profiling. Many studies have implicated fatty acid imbalances in various conditions,[1–8] including:

- Cardiovascular disease
- Chronic inflammatory conditions
- Neurological and psychiatric disease
- Cancer
- Diabetes
- Polycystic ovary syndrome
- Chronic obstructive pulmonary disease
- Asthma

Unlike other macronutrients, fat is one of the most difficult dietary intake components to quantify. Patients often misreport their fat intake, and food composition tables are frequently incorrect. There is no single biomarker to assess total dietary fat intake.[9] Although the body digests dietary fat into fatty acids, measuring fatty acids cannot validate fat intake because some fatty acids do not come from the diet and are endogenously made. However, there are some biomarkers that reflect essential fatty acid consumption and others that reflect endogenously produced fatty acids. To interpret these measurements, it is important to first understand the definition, physiology, and metabolism of fatty acids.

Fatty acids are simple in structure: a carbon backbone with a carboxyl group (COO) at one end and a methyl group (CH_3) at the other. They function as energy-storage units, cell membrane structural units, and eicosanoid precursors.

Dietary fats are digested into fatty acids, which are then absorbed into the circulation. Three fatty acids can join with glycerol to form triglyceride molecules. Fatty acids are found in serum, cell membranes, and adipocytes.

Although there are many fatty acid dietary sources, such as olive oil and fish, some food sources are more critical than others. The term *essential fatty acid* means these are essential for life and must come from the diet. There are only two essential fatty acids: alpha-linolenic acid (ALA) and linoleic acid (LA). ALA is found in foods such as flax, chia, walnuts, and unhydrogenated soybean oil.[10,11] LA food sources include sunflower seeds, corn oil, and nuts.[12]

Besides essential dietary fatty acids, there are fatty acids that are made endogenously. The body makes them using three processes: synthesis, elongation, and desaturation.

First, fatty acids can be synthesized from acetyl coenzyme A (acetyl-CoA) units made from dietary carbohydrate digestion and metabolism. Insulin's lipogenic activity allows excess glucose to be converted into triglycerides in the liver. Hence, triglycerides and fatty acids can be made through carbohydrate metabolism.[13]

Next, fatty acids can be formed using elongase and desaturase enzymes. Some endogenous fatty acids are formed by adding carbons to dietary fatty acid backbones: they are elongated by elongase enzymes. In desaturation, some of the single bonds in the carbon backbone are converted to double bonds. Desaturation enzymes create different fatty acids[9,14] (Fig. 13.1).

STRUCTURE AND NOMENCLATURE

As mentioned previously, fatty acids are simple in structure: a carbon backbone with a carboxyl group (COO) at one end and a methyl group (CH_4) at the other. The methyl group is labeled omega (ω).

When profiling fatty acids, nomenclature can be complex. In general, they are designated based on the length of the carbon atom backbone, the number of double bonds, and the first double bond's distance from the carbon chain opposite the carboxyl group.[9,15]

The fatty acid backbone usually ranges between 6 and 22 carbons in length, sometimes longer. Because of the variation in the carbon atom backbone members, fatty acids are categorized as short-chain, medium-chain, long-chain, and very-long-chain fatty acids.

Fatty acids are also classified by a double bond's presence or absence, which determines their saturation degree. Saturated fatty acids have no double bonds. Unsaturated fatty acids have one or more double bonds between carbon atoms. Because fatty acids are necessary for forming cell membranes, saturation can play a role in cell membrane fluidity.

Monounsaturated fatty acids (MUFAs), found in olive oil and avocados, have one carbon-carbon double bond, which can occur at

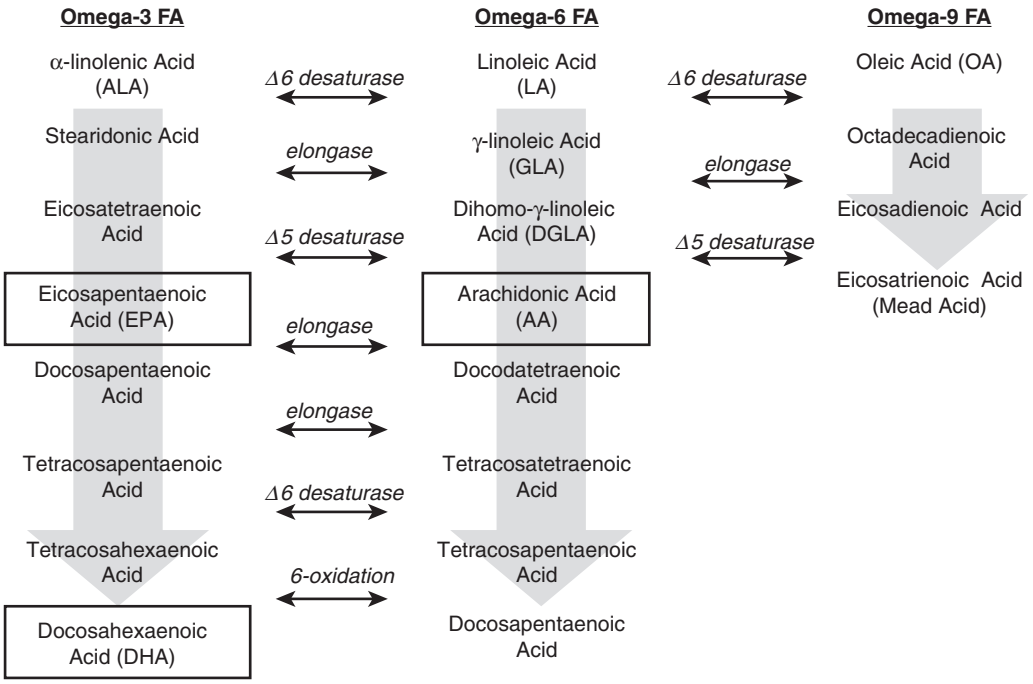

Fig. 13.1 Fatty acid metabolism, elongation and desaturation of essential fatty acids. Chang MI, Puder M, Gura KM. The use of fish oil lipid emulsion in the treatment of intestinal failure associated liver disease (IFALD). *Nutrients*. 2012;4(12):1828 -1850.

different positions within their carbon backbone. The double-bond position designates its name. The most common MUFA is oleic acid, which is found in olive oil. It has a double bond at the ninth carbon and is therefore an omega-9 fatty acid (ω-9).

Polyunsaturated fatty acids (PUFAs), found in foods such as salmon and sunflower seeds, contain more than one double bond. In PUFAs, the first double bond may be found between the third and fourth carbon atom from the ω; these are called omega-3 fatty acids (ω-3). If the first double bond is between the sixth and seventh carbon atoms, then they are called omega-6 fatty acids (ω-6).[15] It is important to note that some laboratories denote *omega* using the letter *n*. For example, omega-3 fatty acids may also be reported as n-3.

If the hydrogen atoms on either side of the double bond are in the same configuration, it is termed a *cis* configuration. Most fatty acids are in the cis configuration. When the hydrogen atoms change configuration, they are considered *trans*. Trans isomers may be induced during industrial processing of unsaturated oil or found in the gastrointestinal (GI) tracts of ruminant animals (cattle, sheep, goats, and deer). Trans fatty acids produced by industrial processing, such as partially hydrogenated vegetable oil, have been shown to cause endothelial dysfunction and may affect cardiovascular risk factors. Ruminant trans fats, as found in dairy products, may be beneficial.[16,17]

In fatty acid profiling, it is important to understand this nomenclature because the abbreviations can vary depending on the laboratory used. For example, stearic acid is a saturated fatty acid with 18 carbons and no double bonds (18:0), whereas oleic acid has 18 carbon bonds and one double bond in the n-9 position (18:1n9). Additionally, eicosapentaenoic acid (EPA) has 20 carbons and multiple double bonds and is represented as 20:5n3. This numerical scheme is the systematic nomenclature commonly used by clinical laboratories. It is also possible to describe fatty acid double bonds in relation to the carbon chain's acidic end, symbolized as delta (Δ). Hence, EPA can also be represented as 20:5 Δ5,8,11,14,17.

MEASUREMENT

Monitoring a patient's fatty acid status offers a way to target dietary therapeutics and alter disease progression. For this reason, usual or long-term dietary intake markers are important. Fatty acids can be measured as free fatty acids in serum, as erythrocyte membrane components, or in adipose tissue.

Adipose tissue fatty acid measurement estimates fatty acid intake ranging from 6 months to 2 years.[18] It is therefore the most ideal reflection of dietary patterns. However, adipose tissue biopsy is not practical. Plasma and erythrocyte assessments are more commonly used because of the ease of specimen collection. Because the life of a red blood cell averages 90 to 120 days, erythrocyte fatty acid assessment is more reflective of long-term status and is therefore preferred to plasma evaluation.[18] For example, omega-3 plasma levels have been shown to be influenced by an acutely high fish oil dose or a short-term dietary increase.[19]

Fatty acid biomarkers are sometimes validated by examining the correlation with measured dietary fat intake. Saturated and monounsaturated fatty acid measurements may not always reflect dietary fat intake because these can be endogenously synthesized from carbohydrates.[20]

Erythrocyte fatty acids are reported as a percentage in the red blood cell (RBC) membrane. When dealing with RBC percentages, one must realize that each fatty acid has an effect on the other percentages. For example, fish oil supplementation (n-3) may increase the overall n-3 percentage, which by default may lower the n-6 percentage.

Plasma measurements are expressed as a percentage or absolute total lipid volume concentration. Again, the percentages are interdependent on the whole. After an omega-3 dose, the peak *concentration* can be observed at 6 hours, whereas the peak *percentage* can be seen at 24 hours. Plasma-based metrics can be sensitive to fasting status and acute intake. In general, RBC-based metrics are more stable over time.[21]

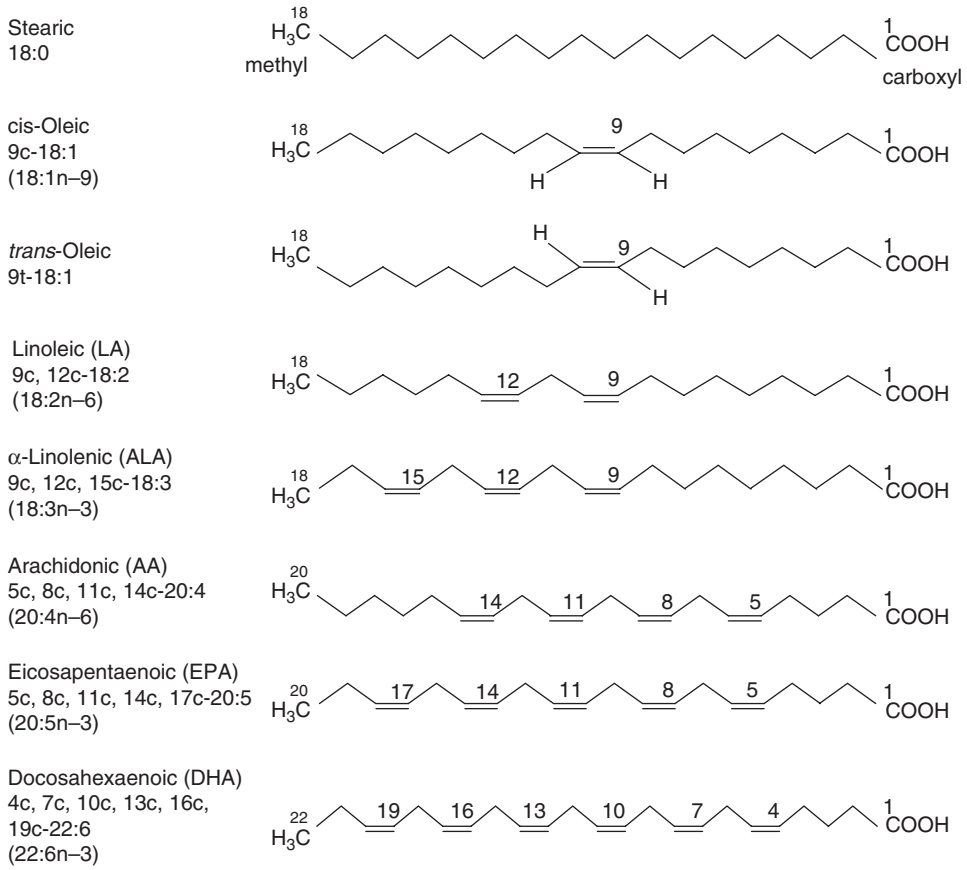

Fig. 13.2 Common dietary fatty acids. Structures of some common dietary fatty acids. Ratnayake W, M, N, Galli C: Fat and Fatty Acid Terminology, Methods of Analysis and Fat Digestion and Metabolism: A Background Review Paper. *Ann Nutr Metab* 2009;55:8–43. https://doi.org/10.1159/000228994

CLINICAL SIGNIFICANCE OF RESULTS

See Fig. 13.2.

Omega-3 (n-3) Polyunsaturated Fatty Acids

Omega-3 fatty acids are positively correlated with healthy aging throughout life and are essential for brain function and cardiovascular health. The average American diet is deficient in n-3 food sources such as oily fish, nuts, flax, and green leafy vegetables. Deficiencies in n-3 fatty acids can result in neurodevelopmental and behavioral disorders, visual changes, skin abnormalities, and heart disease.[22–26]

Many studies show that n-3 fatty acids have significantly positive effects on infant development, cancer, cardiovascular disease, depression, attention deficit hyperactivity disorder, and cognitive decline. These health benefits are mediated through several different mechanisms, including alterations in cell membrane composition and function, anti-inflammatory effects, gene expression, and eicosanoid production.[27]

- **Alpha-linoleic acid (ALA)** is an essential n-3 fatty acid that must be supplied from the diet. From ALA, other important n-3 fatty acids can be endogenously produced by enzymatic elongation and desaturation. ALA is the 18-carbon, 3-double-bond (18:3n3) precursor to make eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), although these are also found in fish oils. ALA dietary sources include green leafy vegetables, walnuts, chia, hemp, and certain plant oils like flaxseed oil and unhydrogenated soybean oil. Several studies on high dietary intake of ALA and higher ALA blood levels show an association with lower fatal coronary artery disease risk.[11] However, there are significant variations in genetics, nutrition, and toxin load that greatly affect an individual's ability to make this multistep conversion.
- **Eicosapentaenoic acid (EPA)** is an omega-3 fatty acid with a 20-carbon chain and five cis-double bonds (20:5n3). It can be enzymatically converted from ALA; however, the efficiency of enzymatic conversion is much lower compared with the absorption from EPA-containing foods. EPA can be obtained by eating oily fish such as cod, mackerel, salmon, and sardines. It is also available in fish oil supplements.

EPA acts as a precursor for prostaglandin-3 (which inhibits platelet aggregation), thromboxane-3, and leukotriene-5 eicosanoids. EPA has beneficial effects on multiple atherosclerotic and inflammatory processes, including endothelial function, oxidative stress, foam cell formation, inflammatory cytokine production and release, plaque formation/progression, platelet aggregation, thrombus formation, and plaque rupture. EPA also reduces atherogenic dyslipidemia and has other beneficial effects arising from its inclusion in membrane phospholipids.[28]

- **Docosapentaenoic acid (DPA)** is made by adding carbons to the backbone of EPA using the enzyme delta-5 elongase. It is an intermediary product between EPA and docosahexaenoic acid (DHA) and can retro-convert back to EPA. It is denoted as 22:5n3. Relatively little is known about the potentially distinct DPA health benefits. Although small amounts are found in seafood, it is more often synthesized from EPA.[29]
- **Docosahexaenoic acid (DHA)** is a DPA metabolite with 22 carbons and six double bonds (22:6n3). DHA's endogenous synthesis from its precursor is extremely low, so measured levels largely reflect

seafood consumption or fish oil supplementation. Fish oil supplementation is commonly a combination of purified EPA and DHA.

Cardiovascular disease researchers have studied seafood consumption and fish oil supplementation for both disease prevention and treatment. Fish oil supplementation has been shown to improve serum lipid levels. It prevents cardiac dysrhythmias by increasing cardiac cell membrane fluidity and prevents inflammatory cytokines from binding to their receptors.[27]

In cardiovascular risk assessment, the Omega-3 Index has emerged as an important biomarker in stratifying patients for targeted therapeutics. The Omega-3 Index is the sum of EPA + DHA percentages in RBCs. A target of >8% is optimal, whereas less than 4% denotes increased cardiovascular risk. Fish oil supplementation and dietary changes using fish, flax, chia, and walnuts are often used as therapeutic interventions.

EPA and DHA are also important in fetal brain development. DHA levels positively correlate with the cognitive and retinal development of the fetus.[27] Additionally, there is a role for n-3 in cancer prevention. Diets rich in n-3 (fish oil, flaxseed) and high n-3 erythrocyte concentrations are inversely related to colorectal and breast cancer development, likely due to n-3's anti-inflammatory properties.[27]

Omega-6 (n-6) Polyunsaturated Fatty Acids

Omega-6 fatty acids play a vital role in many physiological functions. They are particularly important for maintaining bone health, regulating metabolism, and stimulating hair and skin growth. In spite of this, n-6 fatty acids are controversial.

The current standard American diet reflects a higher n-6 intake compared with n-3. Dietary sources include vegetable oils and animal fats. Many human evolutionary diets had a 1:1 dietary ratio of n-3:n-6. The fatty acid intake dietary shift toward n-6 sources associated with the cultivation of food and feeding corn to livestock has been implicated in recent increases in disease.[30] The issues surrounding n-6 fatty acids include potentially proinflammatory effects, their increased susceptibility to oxidation, and their competition with the n-3 fatty acids for the enzymatic elongation and desaturation pathways.

Most of the concern regarding n-6 effects revolves around one of its downstream metabolites: arachidonic acid (AA). AA is the primary precursor in the inflammatory cascade. However, AA is not the only n-6 metabolite, and other n-6 fatty acids can be beneficial. For example, dihomo-gamma linoleic acid (DGLA) is a downstream n-6 fatty acid with many anti-inflammatory benefits. Additionally, linoleic acid has shown significant benefits for cardiovascular risks.

- **Linoleic acid (LA)** is an essential n-6 and denoted as 18:2n6. It is the predominant n-6 in the Western diet, obtained mainly from vegetable oils and nuts. Higher LA intake has been shown to reduce low-density lipoprotein cholesterol, promote insulin sensitivity, and reduce hypertension risk. There is a significant inverse relationship between dietary LA intake and coronary artery disease when using LA to replace dietary carbohydrates and/or saturated fats.[12]
- **Gamma linolenic acid (GLA)** is classified as 18:3n6. It can be produced from the essential LA using the enzyme delta-6 desaturase. This is a very slow enzymatic reaction that is further restricted by systemic inflammation, acute and chronic disease, and vitamin and mineral deficiencies such as zinc and cobalt deficiencies.[31] However, GLA can be supplemented using black currant, borage oil, and evening primrose.

GLA levels are important because GLA is the direct precursor to produce dihomo-gamma linolenic acid (DGLA), which is a highly beneficial and anti-inflammatory n-6. GLA supplementation is rapidly metabolized to form DGLA and therefore is a common therapeutic intervention.[32] However, GLA supplementation can also increase the downstream metabolite AA.[8] Supplementing fish oils (EPA/DHA) along with GLA may mitigate this downstream AA conversion because of enzymatic competition for the delta-5-desaturase enzyme. Delta-5-desaturase is responsible for both AA production and EPA metabolism.

- **Dihomo-gamma-linolenic acid (DGLA)**, 20:3n6, has no significant dietary source (very small amounts can be found in some animal products) and is only metabolized from GLA. Research has confirmed that the inability to convert precursor fatty acids to DGLA is associated with many conditions, including diabetes, cancer, and cardiovascular disease.[33]

DGLA exerts anti-inflammatory effects when it is metabolized into eicosanoids and prostaglandins. These two oxidative DGLA metabolites have shown clinical efficacy by suppressing chronic inflammation, lowering blood pressure via vasodilation, inhibiting smooth muscle proliferation associated with atherosclerotic plaque development, arresting cancer cell growth, and aiding in tumor cell differentiation.[33]

- **Arachidonic acid (AA)**, 20:4n6, is a downstream LA metabolite. There are also preformed AA dietary sources, such as animal fats, eggs, poultry, organ meats, and fish. AA is stored in cell membranes and released in response to injury. After AA release, it can be metabolized into eicosanoids through four different pathways: cyclooxygenase, lipoxygenase, cytochrome P450, and oxygen-species–triggered reactions. These pathways yield prostaglandins, isoprostanes, thromboxane, leukotrienes, lipoxins, and epoxyeicosatrienoic acids. Each can act to promote the inflammatory cascade.[34] AA-derived eicosanoids have important roles in immunopathology and have been implicated in inflammation, autoimmunity, allergic diseases, and cancer.[35]

Monounsaturated Fatty Acids

MUFAs are different from other fatty acids because they have only one double bond in their carbon chain. The carbon atom number making up the backbone and the position of this double bond distinguishes one from another and changes their nomenclature. For example, if the double bond is in the seventh position on the carbon backbone, it is known as an omega-7 fatty acid.

The most common dietary MUFA sources are olive oil and nuts. Diets rich in MUFAs have shown beneficial effects on total cholesterol, low-density lipoprotein (LDL) cholesterol, and high-density lipoprotein (HDL) cholesterol. MUFA diets have been shown to reduce LDL oxidative susceptibility, decrease platelet aggregation, increase fibrinolysis, and increase bleeding time.[36] The mechanism involved in MUFAs' health benefits is still being investigated. However, it has been proposed that changes in the composition of very-low-density lipoprotein (VLDL), VLDL enzymes, and VLDL proteins involved in VLDL catabolism decrease plasma triacylglycerol concentrations. Therefore the rates of VLDL production and triacylglycerol clearance may be altered because of dietary fat type and amount.[36]

- **Oleic acid (OA)** has an 18-carbon backbone with one double bond at the ninth carbon. Therefore it is known as an omega-9 fatty acid, 18:1n9. Olive oil is the main source of OA, which is the most represented MUFA in the diet. OA has attracted much attention because of the wide array of literature extolling the "Mediterranean diet," which is rich in olive oil and nuts. Oleic acid has been shown to reduce saturated fatty acids' inflammatory effects on endothelial cells due to a dampening of cytokine activation.[37,38]
- **Nervonic acid (NA)** is an important omega-9 fatty acid, 24:1n9. NA can be found in small amounts in borage and vegetable oils, but mainly it is an oleic acid elongation product.[39] It is abundant in the brain's white matter and necessary for nerve-cell myelin biosynthesis. NA is essential for brain growth and the maintenance of

peripheral nervous tissue enriched with sphingomyelin.[40] Alterations in NA plasma levels have been implicated in mood disorders and demyelinating disorders. Nervonic acid supplementation may also mitigate diabetic neuropathy.[41]

- **Palmitoleic acid (PA)** is a monounsaturated omega-7 fatty acid, 16:1n7. The main PA dietary sources are dairy products and macadamia nuts. However, PA can also be synthesized from triglyceride breakdown or de novo from surplus carbohydrates.

Dairy products are rich in the trans isomer of PA, whereas macadamia nuts contain the cis isomer. In some studies, the trans isomer from dairy has been associated with less inflammation and lower diabetes risk than other trans fats. PA is involved in insulin sensitivity by exerting distinct effects on insulin signaling and glucose uptake.[42]

Macadamia nuts are associated with improving lipid profiles. However, whether the lipid-lowering effects are due to PA specifically, or other oils or nutrients found in these nuts, remains uncertain.[42]

- **Vaccenic acid (VA)** is a monounsaturated omega-7 fatty acid that is also classified as a trans fatty acid (trans-11-18:1n7). It is a positional and geometric isomer of oleic acid. Unlike trans fatty acids produced industrially, VA is naturally occurring. It is formed when saturated fatty acids are bacterially fermented in the GI tracts of ruminant animals (cattle, sheep, and goats). Dairy products (cheese, milk, butter) and meat from these animals contain VA.[43] Although animal and cell studies suggest that VA may be lipid lowering and antiatherogenic, human studies are limited.

Trans Fatty Acids

Trans fatty acids (TFAs) are unsaturated fatty acids with at least one double bond in the trans configuration. There are two primary dietary trans fat sources: naturally occurring TFAs and industrially produced TFAs.

Naturally occurring TFAs are consumed in meats and dairy products from cows, sheep, goats and other ruminant animals. As noted previously, these ruminant trans fats are produced through bacterial metabolism in the animal's GI tract.[44]

But the more common dietary source in the American diet is industrially formed TFAs, as formed in vegetable oil's hydrogenation or partial hydrogenation. The hydrogenation process converts vegetable oils into semisolid fats for use in margarines, commercial cooking, and manufacturing processes. These hydrogenated oils are increasingly used to improve grocery shelf life, increase vegetable oil stability during deep frying, and enhance taste in baked goods. The major TFA sources in the American diet are deep-fried fast foods, bakery products, packaged snack foods, and margarines.[17]

In recent years, TFAs' dietary implications in public health have received increasing attention. The U.S. Food and Drug Administration (FDA) ruled, effective January 1, 2006, that the nutrition labels for all conventional foods and supplements must indicate trans fatty acid content. This was prompted by the evidence that trans fats promote inflammation and increase coronary heart disease risk. Trans fats also increase triglycerides, increase Lp(a) levels, and reduce LDL particle size.[17]

- **Elaidic acid (EA)** is an oleic acid trans isomer (trans-9-18:1). It is the predominant trans fatty acid in the Western diet. EA is found in margarine, partially hydrogenated vegetable oils, and fried foods. EA, like all TFAs, has been extensively studied for its role in increasing cardiovascular risk and adversely affecting lipid profiles. Additionally, EA has recently been shown to enhance metastatic cancer progression.[45]
- **Vaccenic acid (VA)**, as noted previously, is a monounsaturated omega-7 trans fatty acid. It is formed in ruminant animals' GI tracts and consumed in the diet as butter, cheese, and meats from these animals. Although, as with all TFAs, increased VA intake and elevated levels increase risk, there is evidence that VA shows some health benefit in rodent and animal studies, although human studies are limited.[16] VA's metabolic fate has not been extensively studied. It is well absorbed from the diet, but from there, it is either rapidly oxidized or metabolized to other lipids. Data are evolving as to whether VA is preferentially oxidized for energy.[46]

Saturated Fatty Acids

Saturated fatty acids (SFAs) are made up of a carbon chain with no double bonds. Because fatty acids are cell-membrane structural units, this saturated configuration contributes to decreased cell-membrane fluidity. SFAs are not essential nutrients. They are mainly obtained through dietary intake of animal fats. However, the body is capable of synthesizing SFAs from carbohydrates via de novo lipogenesis. The synthesized SFAs are the same FAs found in dietary animal fats. Therefore reducing disease risk using dietary modification should also include carbohydrate reduction.

Most saturated fatty acid studies focus solely on their tendency to alter lipoprotein metabolism and influence cholesterol levels. Additionally, several studies have demonstrated that SFAs may cause adipose tissue inflammation. This inflammatory process involves the signaling of toll-like receptor 4 (TLR4), a sensor that binds lipopolysaccharides. This receptor activation signals nuclear factor-kappa B (NFk-B) production, which triggers the release of inflammatory cytokines like interleukin 1 and 6 (IL-1, IL-6) and tumor necrosis factor-alpha (TNF-α).[47] This inflammatory process is implicated in overall dietary SFA disease risk.

- **Palmitic acid,** or PA (16:0), is a saturated fat naturally found in animal meat and dairy products, as well as in palm and coconut oils. Recent studies reveal evidence that PA excess causes mitochondrial dysfunction mediated by oxidative stress, an effect known as lipotoxicity. Although investigations are ongoing, PA has been linked to an increase in cardiovascular disease risk, cancer risk, and diabetes.[48]
- **Stearic acid** (18:0) is found mainly in meat and dairy products. Stearic acid (SA) increases Lp(a) levels, although the effects are less harmful than those of trans fatty acids.[49] SA is the only saturated fatty acid with a net neutral effect on serum cholesterol ratios.

Although meat is a primary SFA source, not all meat is created equal. Grass-fed beef contains less total fat and tends to contain more conjugated linoleic acid and antioxidants. Grass-fed beef also tends to have much higher cholesterol-neutral stearic acid (18:0) and less cholesterol-elevating SFAs, such as myristic (C14:0) and palmitic (C16:0) FAs.[50]

Lauric acid (12:0) is a medium-/long-chain fatty acid most often found in coconut oil. Lauric acid's metabolic and physiological properties account for many of coconut oil's properties. Lauric acid can be classified as either a medium-chain or long-chain fatty acid. In terms of digestion, however, it behaves more as a long-chain fatty acid because it gets absorbed with chylomicrons. Detailed studies show that most ingested lauric acid is converted directly to energy rather than stored as fat. Most medium-chain fatty acids are absorbed directly into the portal vein and used for energy.[51]

One of coconut oil's advantages is its resistance to oxidation and polymerization, which makes it a stable cooking oil. Because of its high SFA content (92%), coconut oil has always been classified, along with butter, palm oil, and animal fats, as a saturated fat source that should be consumed in low levels. Although the common perception remains that saturated fatty acids are bad, an increasing number of researchers contend that medium-chain fatty acids are less hazardous than hydrogenated vegetable oils, such as soybean and corn oils.[52] Although lauric

acid is a saturated fatty acid, there is no link between lauric acid and high cholesterol.[53] Infrequent to moderate coconut oil use does not seem to raise cholesterol levels.[51,54]

Fatty Acid Ratios

Despite the knowledge that fatty acids are implicated in many chronic diseases, there is a fundamental gap in fatty acid research. No accepted established reference ranges define optimal levels. This results in difficulty interpreting results in relation to disease progression and risk. Therefore ratios between specific fatty acids, separately and in groups, are often used.[55]

- **Omega-6/Omega-3 Ratio:** As touched on previously, Western diets have changed over the past 100 years. A 1:1 balance (n-6:n-3) existed throughout evolutionary history. The current Western diet averages 15:1 to 16.7:1. The shift to n-6 fatty acids correlates with an increase in many chronic conditions, such as cardiovascular disease, diabetes, cancer, obesity, autoimmune diseases, rheumatoid arthritis, asthma, and depression. The proinflammatory effects of preformed AA, and its formation from n-6 precursors, favors increased thromboxane A2, leukotriene B4, IL-1β, IL-6, TNF-α, and C-reactive protein (CRP). By decreasing n-6 dietary intake and balancing this with increases in flax, walnut, chia, fish, and purified fish oils, these inflammatory effects can be mitigated.[55]
- **Arachidonic Acid/Eicosapentaenoic Acid (AA/EPA) Ratio:** EPA, an n-3 fatty acid, metabolically competes with the inflammatory AA to use the same enzyme, delta-5-desaturase, for metabolism. Omega-6 fatty acid dietary intake, specifically animal fats rich in AA, alters essential fatty acid metabolism in favor of inflammation. Adding fish oils, or increasing overall n-3 intake with oily fish, flax, walnut, and chia, shifts delta-5-desaturase activity toward n-3 metabolism and therefore decreases n-6 precursor conversion to AA. Additionally, a decrease in animal fats is helpful.
- **Linoleic Acid/Dihomo-Gamma-Linoleic Acid (LA:DGLA) Ratio:** The n-6 fatty acid DGLA is anti-inflammatory, and the ability to convert precursor n-6 fatty acids to DGLA is paramount because of its ability to alter disease risk and progression.[33] The enzyme responsible for this conversion is delta-6-elongase, which relies heavily on zinc as a cofactor. Delta-6-elongase is quite sensitive to early-stage zinc deficiency. The ratio of LA:DGLA is often used as a zinc status biomarker in humans, in the absence of confounding factors, such as infection or stress. The richest dietary zinc sources include red meats and liver, nuts, seeds, and grains.[56]

Omega-3 Index

The Omega-3 Index was first proposed in 2004 by William S. Harris, PhD, and Clemons von Schacky, MD, as a way of evaluating the risk of death related to coronary artery disease (CAD). It is defined as the RBC percentage sum of EPA + DHA. Estimations show a cardioprotective target to be >8%, and the level associated with increased cardiovascular risk is <4%. The Omega-3 Index allows clinicians to risk-stratify patients and target therapy with purified fish oils or increased dietary intake of n-3–rich foods. Therapeutic interventions are shown to contribute to a reduced risk of CAD-related death.[57–59]

SUMMARY

Fatty acid profiling aids clinicians in disease risk stratification and can direct dietary modification. Patients often misreport fatty acid intake, and food consumption tables can be unreliable. Fatty acid profiling uncovers deficiencies and imbalances that have clinical implications. Dietary and therapeutic targeting may be warranted. Several dietary and supplementation recommendations can be found in Table 13.1, although this list is not exhaustive. Due diligence is recommended regarding supplementation and dietary intake.

TABLE 13.1 Summary of common fatty acid abnormalities with corresponding clinical associations, and treatment considerations.

Biomarker	Abnormality	Clinical Association	Considerations
OMEGA-3			
ALA	Low	Essential FA	Flax, chia, walnut, unhydrogenated soybean oil[10,11]
EPA	Low	Eicosanoid substrate Anti-inflammatory	Oily fish, purified fish oils[28,29]
DPA	Low	Membrane fluidity	EPA, oily fish, fish oil[29]
DHA	Low	Anti-inflammatory	Oily fish, fish oil supplementaion[29]
OMEGA-6			
LA	Low	Essential FA	Sunflower, corn oil, nuts[12]
GLA	Low	Anti-inflammatory, precursor to DGLA	GLA supplementation, evening primrose, borage, black currant. Recommend adding EPA[32]
DGLA	Low	Anti-inflammatory	Add GLA, as above. Recommend adding EPA[32]
Monounsaturated			
OA	Low	Anti-inflammatory, maintains endothelial function	Olive oil[37,60]
NA	Low	Nerve-cell myelin production, elongation product of OA	Olive oil[61]
PA	Low	Anti-inflammatory, serum lipid alteration	Macadamia nuts[42]
VA	High	May contribute to atherogenesis	Decrease beef, dairy, margarine[17,43]
Saturated			
Palmitic	High	Decreased membrane fluidity	Decrease meat, dairy, carbohydrates[47,48]
Stearic	High	Alteration serum lipids	Decrease meat, dairy[49]

TABLE 13.1 Summary of common fatty acid abnormalities with corresponding clinical associations, and treatment considerations—cont'd

Biomarker	Abnormality	Clinical Association	Considerations
Lauric	High	Decreased membrane fluidity	Decrease coconut oil, dairy[51,53,54]
Trans			
Elaidic	High	Proatherogenic	Decrease processed foods, hydrogenated oils, margarine[17,62]
Ratios			
LA/DGLA	High	Enzyme inhibition	Zinc supplementation, or dietary zinc sources: red meats and liver, nuts, seeds, and grains.[56]
AA/EPA	High	Proinflammatory imbalance of FA	Purified fish oil supplementation or fish, Decrease animal fats[63]
ω-6/ω-3	High	Proinflammatory imbalance of FA	Increase dietary fish, walnut, chia, fish oil supplementation Decrease meat, dairy[64]

AA, Arachidonic acid; *ALA,* alpha-linolenic acid; *DGLA,* dihomo-gamma linoleic acid; *DHA,* docosahexaenoic acid; *DPA,* docosapentaenoic acid; *EPA,* eicosapentaenoic acid; *FA,* fatty acid; *GLA,* gamma linolenic acid; *LA,* linoleic acid; *NA,* nervonic acid; *OA,* oleic acid; *PA,* palmitoleic acid; *VA,* vaccenic acid.

Food Hypersensitivities

Wendy Hodsdon, ND

OUTLINE

INTRODUCTION

The definitions of terms used for adverse food reactions are variable in the literature, among clinicians, and among the general public. The terms *food hypersensitivity* and *food intolerance* are both used to describe any adverse food reactions. More specific terms, such as *allergies, sensitivities, hypersensitivities,* and *intolerances* are often used interchangeably, although they refer to different types of food reactions. Some more specific nomenclature has been proposed, including *toxic food reactions, IgE-mediated food allergy, non-IgE mediated allergy,* and *nonallergic/nonimmunological diseases.*[1] The National Institute of Allergy and Infectious Diseases defines a food allergy as "an adverse health effect arising from a specific immune response that occurs reproducibly on exposure to a given food." This definition includes all immune-mediated reactions without distinguishing the types of immune responses that cause food reactions but does not consider nonimmunological adverse food reactions.[2,3]

The terms used in this chapter are a compilation of the nomenclature described in the literature.[1,2,4] Food hypersensitivity is the all-encompassing description for nontoxic food reactions. Toxic food reactions include food poisoning due to eating contaminated food from an infectious organism (bacteria, virus, or parasite) or a poison in foods and are not addressed in this chapter. Immunological hypersensitivity includes both food allergies (immunoglobulin E [IgE]-mediated allergy) and food sensitivities (non–IgE-mediated allergy). Food intolerances or nonimmunological hypersensitivities describe reactions due to the lack of an enzyme to digest or process food or food additives or transport disorders.[1,5] Table 14.1 defines the terms along with commonly associated clinical conditions.

The percentage of people with food allergies, sensitivities, and intolerances is objectively unknown because many people do not attribute their symptoms to the food they are eating or attribute symptoms to specific foods but with no objective validation. In 2017 a study looking at food allergies in electronic medical records found that 3.6% of adults in America had verified IgE-mediated food allergies.[6] Yet it is estimated that 30% of individuals alter their diet due to a perceived adverse reaction to food.[7] Adverse reactions to foods (food hypersensitivities) are common, and the prevalence of food allergies is rising.[8]

The emphasis in research has been on the classic food allergies, also known as IgE-mediated food allergies. IgE-mediated allergy reactions affect millions of people, cause significant symptoms that can lead to death, and have high healthcare costs.[8]

Recently, more attention is turning to clinical conditions that are related to food but are not immunologically related. Immunological food allergies do not explain the full range of clinical pathology seen with patients in relation to foods. Food sensitivities are also known as non–IgE-mediated reactions and mixed IgE and non–IgE-mediated reactions. Clinical conditions associated with food sensitivities are diseases such as nonceliac gluten sensitivity, irritable bowel syndrome, eosinophilic esophagitis, food protein–induced enterocolitis syndrome (FPIES), fixed food eruptions, and systemic nickel allergy syndrome.[8] The pathophysiology causing these conditions is being debated in the literature. Sicherer and Sampson in their 2017 review article state, "Despite ongoing investigation, there continues to be little basic understanding of the immunopathogenic mechanisms underlying non-IgE-mediated food allergies."[8] Because the mechanisms are unknown, the descriptions and nomenclature are not clear. This author suggests that *food sensitivities* is the best term to describe non–IgE-mediated allergies, including delayed-onset/chronic and cell-mediated food reactions, that occur from an immunological reaction to foods. Food-specific IgG reactions would be included in the definition of food sensitivities, along with other adverse food reactions with an immunological basis.

The term *food intolerance* is reserved for nonimmunologically mediated reactions to foods from a lack of an enzyme, either a digestive enzyme or a processing enzyme, that causes a reaction to foods. Food intolerances, with this definition, could define 15% to 20% of all adverse food reactions.[3] Many food intolerances are associated with enzyme deficiencies or transportation disorders associated with particular genetic polymorphisms. Examples of food constituents that people are intolerant of include lactose, salicylates, sulfites, sodium glutamate, fructose, histamine, sucrose, tyramine, nickel, preservatives, and more.[3] When these conditions are severe, they are identified at birth and classified according to the metabolic system they affect. Some food intolerances are mild or can be acquired or recognized later in life as people have changes in

TABLE 14.1 Food Hypersensitivity Nomenclature

Adverse Food Reactions = Food Hypersensitivities		
Immune-Mediated Adverse Food Reactions = Immunological Hypersensitivity		Nonimmunological Hypersensitivity
Food Allergy = IgE-Mediated Allergy	**Food Sensitivity =** Non–IgE-Mediated Allergy	**Food Intolerance**
Atopic allergy and non-atopic IgE-mediated allergy	Type IIa, type III, and type IV hypersensitivities	Enzyme deficiencies with subdivisions based on causative agent
Examples include: • Anaphylaxis • Urticaria • Angioedema	Examples include: • Celiac disease • Atopic dermatitis • Eosinophilic esophagitis • Eosinophilic gastroenteritis—food protein induced • Allergic proctocolitis—food protein induced • Enterocolitis syndrome • Oral allergy syndrome	Examples include: • Alcohol intolerance • Lactose intolerance • Salicylate intolerance • Sucrose intolerance • Hereditary fructose • Intolerance • Biogenic amine intolerance • Gliadin intolerance

Modified from Dreborg S. Debates in allergy medicine: food intolerance does not exist. *World Allergy Organ J.* 2015;8:1–6. Bolded terms are proposed by author and/or editor.

dietary habits, digestive enzymes, and liver function or increased chemical exposures (affecting DNA transcription of enzymes and/or microbiome).

This chapter focuses on testing for the immune-mediated reactions (including classical food allergies and food sensitivities) and food intolerances. Various testing methods are used as tools to identify a person's reactive foods. The adverse food reaction test depends on the hypothesized type of food reaction (most often determined by the patient's symptoms) along with the patient's medical history and physical examination. This chapter provides a review of the immunology of adverse food reactions and then looks at the different testing methods.

IMMUNOLOGY OF FOOD ALLERGIES AND FOOD SENSITIVITIES

Most individuals do not have food allergies or sensitivities. Instead, they eat a variety of foods, digest them with varying levels of efficiency, and absorb what they need, and their immune systems develop oral tolerance to the food. Oral tolerance describes how the body learns to not react to an antigen (food) when it is delivered through the oral route.[4] The factors that influence tolerance include the person's genetics, microflora, digestive function, vitamin A levels, lipids, and gut epithelial barrier; the route of exposure (skin versus oral route); and the nature and form of the food when it is consumed.[4]

The mucosal immune system is quite complex, consisting of many parts and functions. Key to food reactions are the regulatory T-cells (Treg cells) in Peyer's patches and mesenteric lymph nodes that produce interleukin-4 (IL-4), interleukin-10 (IL-10), and transforming growth factor-β (TGF-β). These cytokines promote B-cell class switching to secretory IgA antibodies (sIgA) and act as a general immunosuppressant for both T and B cell responses.[9] When functioning properly, these allow tolerance to food while still fighting pathogens (bacteria, viruses, parasites, toxins).

Food allergies or IgE-mediated allergy reactions persist in patients with an inappropriate Th2 immune response. Patients with food allergies have food specific CD4+ T cells that express IL-4, IL-5, and IL-13.[9] Research into what causes a breakdown in tolerance and promotes food allergies suggests that adjuvants, alternative routes of sensitization,[9] and loss of intestinal permeability control are all contributing to the increase in food allergies.[10] Adjuvants are substances that stimulate the immune system when given with an antigen. For example, in an illustrative study, mice given cholera toxin (CT) were sensitized to peanut and milk proteins.[11] Allergen-specific IgE antibodies and Th2 cytokines occurred and induced an anaphylaxis response to peanut and milk proteins. The study showed alterations in dendritic cells presenting antigens and in the mesenteric lymph nodes inducing the allergic response.[11] Another hypothesis is that alternative routes of sensitization may be contributing to food allergy reactions. Primary exposure to a food allergen through nonoral routes, such as using creams with peanut oil on the skin, has been implicated in inducing an allergic response.[12] Another paper showed that skin exposure desensitized the allergic response and might help induce a tolerance response in intact skin.[13] Increased intestinal permeability contributes to food allergies through various mechanisms. Efficiency of digestion, transportation of food into the mucosa, mast cell degranulation, and induction of sIgA and cytokines (high levels of IL-4 and IL-9 in the intestines) all contribute to inducing more allergic reactions.[10] The research has focused on understanding food allergy (IgE-mediated allergy) reactions rather than food sensitivity (non-IgE allergy) reactions, although many factors relate to both types of reactions. Genetic background, environmental factors, stress, infection, malnutrition, and microbiota balance all contribute to tolerance and immune-mediated hypersensitivities.[10]

FOOD ALLERGY/HYPERSENSITIVITY/INTOLERANCE TESTING METHODS

A variety of ways to test for adverse food reactions are available, including oral food challenge (OFC), skin-prick testing (SPT), enzyme-linked immunosorbent assay (ELISA) for IgE or IgG antibodies, allergen-specific IgE (sIgE), component-resolved diagnostic tests (CRDs), atopy patch test (APT), breath testing (BT), and controversial energetic testing methods. As immunological methods become more sophisticated, more specific and accurate tests are likely in the future. All methods give different information about adverse food reactions and have specific advantages and disadvantages. Evaluation of adverse food reactions always starts with taking a patient history aimed at identifying the relationship between specific foods and the occurrence of physical symptoms and family predisposition to evaluate possible genetic risk factors. The type of test used depends on the clinical presentation and the results of past tests. Clinical interpretation is required to understand the relevance of the results regardless of the type of testing used.

Oral Food Challenge

The OFC is the most common test used to identify and verify adverse food reactions. The test is extremely versatile and can be used to identify a variety of adverse food reactions, including food allergies, sensitivities, and intolerances. OFCs are indicated to identify the food responsible for acute or chronic symptoms, to expand the diet in patients who have developed tolerance to previously reactive foods, and to identify foods that may have been reactive on other types of testing due to cross-reactivity of antigens.[14]

For patients at risk of severe IgE reaction, OFC for food allergies is performed in an allergist's office or hospital because of the risk of a life-threatening anaphylaxis response.[14,15] A patient with suspected food allergies will eat a gradually increasing amount of food under medical supervision until an age-appropriate dose is reached or symptoms develop. Symptoms often develop in minutes for a food allergy but can appear a couple of hours after the test.[7] This method is recommended for confirming food allergy reactions to reactive foods from SPT and sIgE tests.[14,16]

Food sensitivities and intolerances often have symptoms that are delayed (hours to days after ingesting a food) and are usually not life threatening; therefore OFC can safely be recommended by a variety of clinicians to confirm these types of food reactions.

Method: When testing for food allergies, the OFC can be performed as an open feeding, in which the patient is aware of what he or she is eating; a single-blind OFC, in which the patient is unaware of the food he or she is being fed but the allergist knows what is being tested; or a double-blind, placebo-controlled food challenge (DBPCFC), in which the test food and placebo food are concealed from both the patient and doctor. The DBPCFC is time consuming and difficult to administer and is mostly used in research studies.[15] The challenge food should be eaten in its usual form or the form implicated in the allergic reaction because food processing can significantly affect the allergenic properties of the proteins.[7] OFC is contraindicated when there has been a severe anaphylactic reaction to the test food and when SPT or sIgE exceeds cutoff values, indicating a high probability of severe symptoms with an OFC.

When testing for food sensitivities or intolerances, it is beneficial to eliminate potentially reactive foods from the diet for 8 weeks and then reintroduce foods, watching for symptoms.[2] The precise method will depend on the type of food reaction one is looking for, the clinical presentation of the client, the ability of the person to adhere to a restricted diet, and the preference of the clinician. Methods for testing food sensitivities and intolerances are as follows:

Eliminate potentially reactive foods for 8 weeks:

1. Single suspect food
2. Commonly reactive foods (dairy, eggs, gluten, citrus, nuts/seeds, shellfish, and others)
3. Foods that appear to correlate to physical symptoms
4. Identified reactive foods on food sensitivity test (e.g., food-specific IgG testing)
5. Potentially intolerant foods (e.g., foods containing salicylates or fructose)

Reintroduction in food sensitivities or food intolerances:

1. Encourage the client to keep a journal of symptoms and the timing of reintroduction.
2. Add one food back to the diet by eating 1 serving of the food and waiting 3 days to see if any reactions occur.
3. If no symptoms appear, increase the dose of the food to 2 or 3 servings in a day and observe reactions for the next 3 days.
4. If a reaction occurs, eliminate that food and wait until the symptoms resolve before reintroducing the next food.
5. Continue with the process until all suspected food sensitivities or intolerances have been tested.

Advantages: This method will identify any type of reaction to foods and can be used to confirm a reaction and motivate food elimination compliance, as well as identifying food sensitivities or intolerances. The method is very adaptable and can accommodate a wide variety of people.

Disadvantages: An OFC for a food allergy should only be done with resuscitation equipment available due to possible severe reactions. People can influence the results based on their ideas rather than real reactions when using an open feeding. It is difficult to disguise food for a blinded test. Scoring of symptoms can be useful when evaluating results.[16] When eliminating and reintroducing foods to test for food sensitivities or intolerances, the method can be time consuming and requires the ability to be on a restricted diet for months while keeping good records of symptoms and diet. This method is not appropriate for people with eating disorders or orthorexia.

Clinical Evaluation: Clinicians can consider the severity of the food reaction, the timing and type of symptoms present, and past reactions when developing a specific, individualized protocol. Oral food challenges can be used to confirm associations between foods and symptoms, which can help motivate dietary changes.

Skin-Prick Testing

SPT is the most common test performed by conventional allopathic allergists (MDs) to confirm IgE-mediated allergies, including food allergies and environmental allergies.

Method: SPT is performed by placing a drop of commercially prepared allergen on the skin of the forearm or back and "pricking" or lightly lancing the skin to a depth of 1 mm using a sterile, disposable lancet. After 3 seconds, blot the solution from the skin. A positive and negative control (histamine [10 mg/mL] and physiological glycerine) are used to confirm the reactions. The person is allergic to the allergen when he or she has erythema or swelling greater than that of the positive control in 15 minutes. This method identifies reactions to allergens that produce an IgE-mediated allergy.[17,18] Immunologically, the IgE antibodies that the body has made from past exposure to the allergen are bound to Mast cells that degranulate when the allergen is encountered during the test. A prick + prick (P+P) test is used with fresh foods that have unstable proteins, such as vegetables. This test is done by pricking the fresh food then pricking the patient's skin.[14]

Advantages: SPT is an inexpensive, well-standardized, simple, and low-risk diagnostic test that is more sensitive than ELISA testing for IgE antibodies. There is a high negative predictive value, meaning if there is no reaction on the skin test, there is little possibility of an IgE-mediated allergy assuming the food contains stable proteins in the extracts (such as casein from cow's milk, egg ovomucoid, albumin, and peanut vicilins). When the proteins are not as stable, there is a low predictive value.[14] The test is very accurate for identifying environmental allergies.

Disadvantages: SPT requires that a person be exposed to the allergen before being tested so that the body can produce IgE antibodies. The test can be uncomfortable for patients and is contraindicated in patients with extensive skin disease, those taking antihistamines or other drugs that cannot be discontinued, or those with a recent history of anaphylaxis.[17] The commercial extracts used for SPT contain a mix of major and minor allergenic proteins and can partially degrade during the extraction process. Because these are biological extracts, they may contain cross-reactive allergens.[14] Proteins that degrade with heat have a low predictive value (meaning a negative test does not rule out the possibility of an allergy). With strong clinical indications of food reactions, a P+P test can be used with fresh food.[14] An obvious additional disadvantage is that it primarily detects only IgE-type immunological reactions.

Clinical Evaluation: This test is usually performed by a board-certified allergist. People who report being "tested for food allergies already" have usually had their IgE-mediated food allergies tested through SPT. Intradermal skin testing is a similar, more sensitive test and involves injecting a small amount of the suspected allergen into the skin. This type of testing is more sensitive than SPT but has a higher risk of death, and its value for food allergies is questionable.[17,19]

Radioallergosorbent Testing

Radioallergosorbent testing (RAST) was the first in vitro blood test reported in the literature for identification of IgE antibodies to specific allergens.[20] RAST testing has been replaced by ELISA testing, which is another in vitro test that uses fluorescence instead of radioactivity to perform the test. The basic method of the RAST test has followed different forms as the technology has evolved.

Method: RAST testing is performed using human serum to identify the presence and amount of an antigen-specific IgE antibody present in the serum. In brief, the method involves binding a specific allergen to a solid substrate and adding serum from the person being tested. Antibodies in the serum will bind to the allergen. The sample is rinsed, leaving the bound antibodies behind. A radioactive marker is added to bind to the IgE antibodies bound to the substrate. The radioactive signal can be measured and is proportional to the amount of allergen-specific IgE antibody in the serum. RAST identifies food allergies (IgE-mediated hypersensitivity reactions).[21]

Advantages: This type of testing allows for more convenient identification of allergens in the blood rather than using an SPT. RAST sets the stage for second-generation, allergen-specific antibody tests (ELISA tests) using the same basic method.[22] The newer antibody tests can measure different types of antibodies, use higher-quality allergen extracts, and use different matrix substrates that improve the test accuracy and sensitivity.

Disadvantages: Antibody testing is limiting in that a person needs to be recently exposed to an allergen to have antibodies and a positive result. This type of testing specifically only looks at IgE antibodies and is hampered by cross-reactive proteins and low-quality test agents.[21]

Clinical Evaluation: RAST testing in its original form is not used currently. It has been replaced by quantitative, automated technology, bringing more accuracy and precision to this type of testing.

Enzyme-Linked Immunosorbent Assay

ELISA is a second-generation, allergen-specific antibody test also known as a solid-phase immunoassay. The technology has advanced significantly since RAST was developed in 1961, creating a variety of changes in this type of testing. ELISA test results are reported qualitatively (positive or negative), semiqualitatively (very low, low, moderate, or high reactivity), or qualitatively in the case of some specific tests.

Method: ELISA testing is similar to the RAST test in that an antigen (allergen) is bound to a solid substrate, and serum or whole blood is added to allow for antibodies to bind to the allergen being tested. The sample is rinsed to remove unbound antibodies, and a fluorescent marker is added to bind to the desired antibody. ELISA tests can be used to identify IgE, IgG, IgA, and IgM antibodies depending on the fluorescent marker that is added. sIgE levels are measured routinely to identify food allergies.[8] IgG antibodies could be related to food sensitivities (non-IgE-mediated allergy), although the clinical significance of IgG antibodies to foods is still being debated in the research literature.[23–25] ELISA tests can be performed with whole blood (IgG, IgA), serum (IgE, IgG, IgA, IgM), or saliva (IgA) samples.

Advantages: ELISA testing is versatile, relatively inexpensive, easy to prepare, and readily available, making it a useful screening tool for food reactions.[26] sIgE levels are measured routinely to identify food allergies but should not be used alone to diagnose food allergies.[2] The use of sIgE tests eliminates the risk of systemic reactions that can occur using SPT and OFC,[26] although OFC by a qualified allergist is recommended to confirm food allergies.[16] sIgG testing is generally accepted in the literature for celiac disease, nonceliac gluten sensitivity, and irritable bowel syndrome[24,27] and for patients with unidentified allergic symptoms[25] but is not verified for other symptoms related to food sensitivities.

Disadvantages: A person must have recently eaten the food in question for it to yield a positive result on an sIgG test. More frequent exposure to specific IgG-mediated food sensitivities will induce higher IgG antibody levels in reactive individuals. The amounts of IgG antibodies will decrease as long as the immune system is not reactivated by the food. Cross-reactions between specific food antigens and other agents can cause a positive test reaction even when a person has never eaten the food.

sIgE testing has high false-positive rates, possibly due to cross-reactivity between different similar food proteins.[28] The quality and form of the antigen (food) are difficult to standardize due to natural variability in the extracts and degradation of the testing reagents, which can cause low assay sensitivity.[26] Low assay specificity is found because of the complex mixture of proteins, both allergenic and nonallergenic, in the extracts.[26]

One research study looking at the differences between raw versus processed food allergens showed higher reactivity for processed foods.[29] Most commercially available ELISA tests are made from raw foods, which may mean some processed foods are missed in the testing. Teadorowicz's review article shows how the Maillard reaction increases immunogenicity in food proteins by skewing T-cells to a Th2 response, which most likely affects both allergies and sensitivities.[30] Eggs appear to be a special case, in which cooked eggs (baked) are less reactive than raw or boiled eggs in allergy tests (SPT and IgE ELISAs confirmed with oral food challenge), which highlights the importance of specifying the food antigen in the test being used.[31]

Clinical Evaluation: A positive sIgE test is used with the patient medical history, physical examination, and closely supervised OFC by an allergist to confirm food allergies.[8] Nonconventional medicine practitioners will often use sIgG tests to identify food sensitivities that have not been identified with SPT or sIgE. Confirmation of a food sensitivity also relies on patient history, the physical examination, and the results of sIgG and OFC. The clinical significance of sIgG tests is being debated in the literature, with many articles correctly concluding that sIgG testing does not confirm that a patient has food allergies.[32,33] The research literature is starting to associate positive sIgG tests with specific clinical conditions associated with non–IgE-mediated reactions, such as celiac disease, irritable bowel disease, food protein–induced enterocolitis syndrome, atopic dermatitis, eosinophilic gastrointestinal disorders, and depressive disorders.[24,25,27,34–36] Further research is needed to more fully understand the role of food sensitivities and sIgG testing in clinical pathology.

Specific IgE to Foods

Automated sIgE tests (e.g., ImmunoCAP, Immulite, and HYTEC-288) are automated systems that mimic the ELISA method of IgE antibody detection using traditional extracts containing multiple proteins that are also known as *singleplex extracts.*[22,37,38] Technological advances have allowed quantification of IgE antibodies and specific IgE antibody levels but are not identical between assays and cannot be compared directly.[22,38]

Method: The method is similar to ELISA testing but uses an automated machine and different solid substrates to increase the sensitivity and specificity of the test.

Advantages and Disadvantages: This technology improves on ELISA technology, but it is more expensive and is available only for IgE antibodies. Differences in the composition of the antigens used in the various assays can affect the results of the specificity and comparability of the tests.[22]

Clinical Evaluation: For identifying specific IgE allergens, these methods are less sensitive than skin testing but more sensitive and specific than ELISA testing. This is the most common type of serum testing ordered by a conventional allergist. An OFC is still recommended with automated sIgE tests.[15,18,39]

Component-Resolved Diagnostic Tests or Molecular-Based Diagnosis

CRDs or MBD (ImmunoCAP-ISAC 112) is an IgE antibody technology that uses specific proteins in a food rather than extracts containing a complex combination of food proteins. This allows for identification of which proteins a patient is sensitized to and whether they are dangerous, commonly allergic proteins or relatively harmless proteins.[8,14] This type of testing is sometimes referred to as *multiplex sIgE testing* because it tests for multiple individual allergic proteins.

Method: The microarray biochip is made with purified proteins or recombinant proteins from different common allergens. Common allergens tested include peanut, hazelnut, walnut, soy, rosacea fruits, wheat, and shrimp.[40] Proteins are bound to a microarray biochip, and a small amount of serum or plasma is added. Samples are processed and read with an automated machine to allow protein-specific IgE to be detected.[41]

Advantages and Disadvantages: This technology is being used to identify specific proteins in foods that a person is reacting to. This allows clinicians to correlate clinical reactivity with IgE antibodies to specific proteins in foods or identify if cross-reactivity is occurring with foods carrying homologous proteins.[15,40,42] The utility of CRD has been tested for a variety of commonly allergenic foods and has increased specificity and decreased sensitivity compared with traditional SPT and serum sIgE testing.[37,43,44] The cost of CRD is considered a significant disadvantage for this method.[45]

Clinical Evaluation: Currently, CRD is recommended as an adjunct to SPT and sIgE testing to avoid performing oral food challenges when the risk of severe symptoms is suspected.[15] A more accurate specific immunotherapy (SIT) prescription can be recommended based on the results of CRD for treatment of food allergies.[42,45]

Atopy Patch Test

The APT is most commonly used to identify irritant contact dermatitis and was researched to assess for delayed cell-mediated hypersensitivities to foods (type IV hypersensitivities) but has been shown not to be a useful test for food allergy and is not currently recommended for evaluation of adverse food reactions in the allergy literature.[2,14] APT has also not been shown to be useful in food sensitivities (non–IgE-mediated food allergies) or in children with atopic dermatitis or gastrointestinal reactions to foods, although there may be benefit in more research into these areas.[7] APT may be most useful to identify food intolerance to nickel, incorrectly named systemic nickel allergy syndrome (SNAS). Symptoms include contact dermatitis and gastrointestinal symptoms after eating foods that contain high levels of nickel.[46,47]

Method: APT is performed by using adhesive tape to adhere particular potential allergens to the skin. The patches are left in place for 48 hours, and the skin is examined at 48 and 72 hours for a response. If the skin develops redness or blisters, the person is allergic to the substance.[48]

Advantages: APT is excellent for identifying topical triggers for contact dermatitis. It could be used to identify patients with systemic reactions to nickel from eating nickel-rich foods such as almonds, chickpeas, cocoa, peanuts, and walnuts.[46,47]

Disadvantages: The research examining APT for food sensitivities, atopic eczema, and gastrointestinal diseases has been shown to be unreliable.[2,7] There are not any standardized food reagents for APT, and there is significant variability in interpretation, making it not a useful test for food allergies or sensitivities.[49]

Clinical Evaluation: APT for nickel reactivity may help identify a nickel intolerance.[46,50,51] A controlled, oral food challenge is still necessary to verify SNAS, including a low-nickel diet, which can be challenging to implement.[52]

Breath Testing

BT can be used to determine enzyme deficiencies in some food intolerances and small-intestinal bacterial overgrowth. Many common gastrointestinal disorders with irritable bowel–like symptoms or carbohydrate maldigestion can be identified with BT.

Method: Patients need to prepare for BT by avoiding antibiotics or probiotics for 2 weeks before the test, avoiding prokinetics or laxatives 7 days before the test, and eating only low-fiber meals 24 hours before the test. The patient needs to fast from solids or liquids for 12 hours before the test. A baseline breath sample is taken of hydrogen (or sometimes methane because 20% of patients are not hydrogen producers). The patient is then asked to drink a carbohydrate solution (lactose, fructose, or sorbitol), and breath samples are collected every 20 minutes for the next 2 to 5 hours. Patient symptoms are also recorded. Positive breath tests have increased hydrogen or methane levels.[5,53,54]

Advantages: This diagnostic test is relatively inexpensive, safe, and simple to perform.[54]

Disadvantages: The test can be difficult to prepare for and time consuming to perform. It can take 2 to 5 hours to assess carbohydrate malabsorption. There is variability in how the test is interpreted, and it can be positive for people without clinical symptoms.[54] More research is needed to determine doses for pediatric populations, assess the effect of pre-/probiotics on the test, determine the effect of diet on the test, establish the significance of baseline elevations of hydrogen despite appropriate preparation, and determine optimal time intervals for BT of different substances.[54]

Clinical Evaluation: BT may become a useful diagnostic tool for establishing food intolerances caused by enzyme deficiencies or carbohydrate malabsorption. Although BT is routinely done to diagnose small-intestinal bacterial overgrowth (SIBO), more research will need to be done to establish its use in food intolerances.

Basophil Activation Test

The basophil activation test (BAT) is considered a promising test to identify allergenic foods, but there are challenges in its use outside the research setting. These tests are expensive and require fresh blood and a flow cytometer, which limits their effective use.[8,55,56] OFC can be dangerous in some patients with clinical food allergies. BAT is an in vitro test that is being researched to identify allergies without the need for an OFC after an equivocal SPT or sIgE.[55,57] BAT has the potential to distinguish food allergies from cross-reactivity and to monitor allergic patients on therapy.[56,58] Although this type of testing is not used routinely at this time for allergies, it holds promise for the future.[57,58]

Energetic Methods of Food Sensitivity Testing

Energetic methods of food sensitivity testing, such as Electroacupuncture According to Voll [EAV], Vega testing, Carroll testing, applied kinesiology, electrodermal screening (EDS), and bio-resonance therapy (BRT), are some of the ways alternative medicine practitioners test for adverse food reactions, describing the reaction as energetic and

often not specifying whether the reaction is an allergy, sensitivity, or intolerance. These tests are not validated and most often do not give consistent results.[32,49,59] One study showed that "kinesiology as a diagnostic tool is not more useful than random guessing" after the test was not able to reliably identify wasp venom allergy.[60]

Methods: The methods of these types of tests vary and are generally not elucidated. Most appear to be measuring galvanic skin resistance through an electrical circuit.

Advantages and Disadvantages: Some practitioners have reported good success with these types of devices in identifying food sensitivities and intolerances. Clinical trials using Vega testing and EDS have not shown them to be reliable compared with traditional allergy testing,[59,61] and these tests are not recommended for the identification of food allergies. A review of applied kinesiology literature showed the studies to be unreliable, although many of the studies quoted in the review showed favorable clinical results.[62,63]

Clinical Evaluation: Scientifically, energetic testing methods are unsupported in the literature and should not be used to identify adverse food reactions.

Other Testing Methods

Other testing methods include lymphocyte response testing (ELISA/ACT), cell-size variability testing (ALCAT), provocation-neutralization testing, cytotoxic food allergy testing, and Nambudripad's Allergy Elimination Techniques (NAET), all of which have been used clinically for adverse food reaction testing and treatment. Anecdotal evidence in the form of case studies is positive for NAET[64,65] but could not be found for other testing methods. Systematic, scientific studies either have not been done to verify the clinical relevance of these methods or have shown the tests to be unreliable and clinically questionable.[49,66–68] Review articles suggest that these methods lack scientific rationale, standardization, and reproducibility.[2,14,32,49] Cell-size variability testing had random results with the same sample in a study examining the reproducibility and reliability of this testing method.[69]

CONCLUSIONS

Testing for reactions to foods is being used in clinical practice to confirm or exclude a suspected diagnosis of food allergies, sensitivities, or intolerances and is used as a tool to motivate dietary changes. Selection of the type of diagnostic test and interpretation of the results must be directed by the patient's clinical history, presentation, and the type of suspected adverse food reaction. Clarity around the terms used to describe adverse food reactions will help with the selection and interpretation of testing.

OUTLINE

INTRODUCTION

About 3 billion years ago, the experiment known as "life" began on Earth. All living creatures from the five kingdoms are descended from a single common ancestor. We know that all creatures on this planet are related to one another because we all share the same digital "language of life," known as DNA and RNA, made from five simple nucleic acids, connected along a sugar-phosphate chain. If we could meet our primordial progenitor, we might not recognize it as living at all. We suspect it was nothing more than an RNA receptor-catalyst that somehow replicated itself by consuming chemicals in its immediate environment. These simple "ribo-organisms" were inherently unstable, forming and falling apart quite easily. Only over hundreds of millions of years did these organisms gain more stability when single-stranded RNA evolved into double-stranded DNA, and even more stability when the DNA began coding for proteins that would eventually evolve into cellular structure.[1]

Inherent in this narrative is a central fact that is easy to overlook: life began and continues to evolve within specific environments. We all know the classic riddle, "Which came first, the chicken or the egg?" From the perspective of evolutionary biology, this is not much of a riddle because the chicken's ancestors and their eggs preceded the arrival of the chicken by at least 100 million years. However, on closer reflection, the riddle asks a far deeper and more perplexing question, "What is the relationship between the individual and its environment, between the chicken and its egg?" A hospitable environment had to precede the development of life, and no new life can evolve unless there is an environment to support it, but environments change over time, and a species must change to accommodate the new changes in its environment or invariably become extinct, as the vast majority of species that have lived on this planet have done. The central premise of Charles Darwin's grand theory of the origin of species speaks of survival of the fittest, but over time the fittest species is the one that can adapt best to a changing environment. Adaptation is not exclusive to the development of new species; it also plays a critical role in the survival of any individual within a species as well.

The 21st century may well be remembered as the century in which science first truly began to understand the complex interaction between the genetic information inherent in every individual and the environment to which that individual is exposed.

GENES AND ENVIRONMENT—NATURE AND NURTURE

"Environment" is broadly understood in genetics to include everything that is not the genetic information, or genome, itself. Environment includes climate, physical surroundings, exogenous chemicals or toxins, and infectious agents, but it also includes diet, lifestyle, and behavioral factors. Scientists once believed that genes were immutable archives of digital information that simply coded for proteins, which in turn determined the structure and function of an individual's (analog) body. However, it is now irrefutable that gene expression is substantially affected by and sensitive to environmental change. Genes quite literally respond to the environment to which they are exposed.[2] Because genes respond to the environment we subject them to, the environment itself can be proactively manipulated to alter gene expression and, therefore, to change the health state of the individual. This is the central premise of preventive or functional genomics.

In the interactive symphony between genes and environment, the balance between the two may be altered whenever either changes. Because the environment is inherently unpredictable, one effective strategy to increase the chances of survival has been promoting genetic variation within a species because slightly altered individuals may survive environmental change, whereas others may not. It is rather like a strategy for winning a lottery: odds of winning increase linearly with the greater variety of numbers that one can choose. Variety may truly be the spice of life. If populations from a single species diverge into different environments, the selective pressure over time may eventually lead to the creation of separate species.

The human genome is composed of approximately 3 billion nucleotides of genetic code. If you compare your DNA with the next person you happen to meet, you would find that about 1 in every 1000

*Previous edition contributor

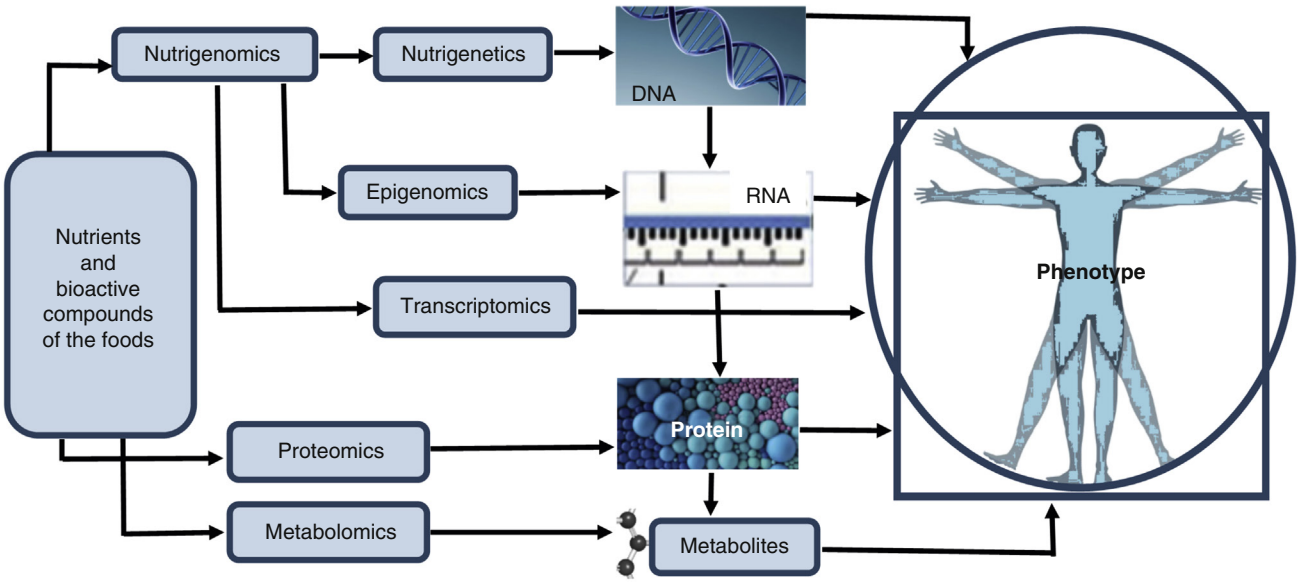

Fig. 15.1 The effects of the nutrients over the genome, proteome, and metabolome. (From Sales NM, Pelegrinin PB, Goersch, MC. Nutrigenomics: definitions and advances of this new science. *J Nutr Metab.* 2014; 202759. PubMed PMID: 24795820.)

nucleotides are different. That means that there are 3 million reasons why the two of you are not the same. These subtle variations of the genetic code are known as polymorphisms (literally, "many shapes," because if the change in the genetic code results in an amino acid substitution, the resulting proteins will have different shapes and slightly altered functions as well). These polymorphisms are largely responsible for our biochemical individuality. Our polymorphisms help make us unique individuals. There are many types of polymorphisms, but by far the most common is the single-nucleotide polymorphism (abbreviated SNP and pronounced "snip"), in which a single nucleotide of the DNA is altered. The sum of all of an individual's polymorphisms significantly affects protein synthesis and physiological function, rendering each individual biologically and biochemically unique.

WHY DO POLYMORPHISMS EXIST?

The theory of natural selection has two central tenets: (1) all organisms compete for limited resources, and (2) organisms with some advantage in acquiring those resources are more likely to survive, to thrive, and to pass on that advantage to their offspring. Polymorphic variations are the ultimate source of these advantages. All polymorphisms that are found to be common in a species must afford some adaptive advantage to survival in some specific environment. Genetic polymorphisms are preserved and become more prevalent in a species when they endow a better chance of survival or of reproduction. The cumulative weight of slight genetic variations over time is the means by which variability within a species arises and by which new species also emerge. However, what may be good for a species and its evolution may not be good for a specific individual because the environmental pressures exerted on a species over millions of years may be very different from the environment encountered in the present.

In individuals, altered polymorphic genes (the legacy of evolution) produce altered proteins, and altered proteins exhibit altered functions. For any given individual, altered protein function may be beneficial, neutral, or harmful, depending on the environment to which he or she is exposed. Prevalent polymorphisms are likely to be beneficial in certain environments but harmful in others. Because we cannot change our genes, the goal of preventive genomics is to alter an individual's environment based on his or her specific genetic variations to optimize his or her genetic potential. Genes themselves cannot be modified, but gene expression can be. One of the common misconceptions of polymorphisms is that they reveal only limitations, but in reality they reveal an individual's potential.

NUTRIGENETICS AND NUTRIGENOMICS

From a clinical perspective, changes in diet are one major way of altering the gene–environment balance and improving an individual's health. Two distinct but interrelated fields of inquiry and knowledge are emerging. Nutrigenetics, also referred to as personalized nutrition, is based on the understanding that our genetic polymorphisms change the way we respond physiologically to specific nutrients. By studying specific polymorphisms and their physiological response to specific nutrients, we can determine a more optimal nutritional regimen for a specific individual based on his or her specific polymorphisms. Nutrigenomics, by contrast, focuses on the effects of specific nutrients (both macro and micro) on the genome and, subsequently, on the body's resulting total pool of proteins (the proteome) and on all its subsequent metabolic activity (the metabolome) as well (Fig. 15.1).[2,3]

Food is, by definition, derived from other living organisms. Inherent in any food is an information code that we read and interpret by eating that food. There is a literal exchange of information that passes between the eaten and the eater. Not surprisingly, central to life is our ability to coordinate our metabolic activities with nutrient availability. Signals from the exterior world (food, toxins, weather, stress, etc.) turn on and turn off specific metabolic processes to improve our chances of survival in an ever-changing world.[4]

The most extreme example of the interaction of food availability and metabolic change is the situation, common in nature, when no food at all is available (i.e., famine). Clive McCay at Cornell University in the 1930s found that by restricting calorie intake in rats by at least 25% from the free-feeding level, he could substantially

increase their average and extreme life expectancies, delay the age of tumor onset, delay cessation of reproductive function, and preserve functional homeostasis or stress response capacity.[5] Since that time, no major investigation has failed to demonstrate significant benefits to health and longevity from calorie restriction. Calorie restriction lowers the level of insulin exposure, which in turn lowers the overall growth-factor exposure, improves age-declining maintenance of mitochondrial function, and helps maintain a long-term favorable balance of the antagonism of insulin to growth hormone.[6] From an evolutionary perspective, this makes intuitive sense. Only when calories are abundant does an individual have the metabolic resources for growth and reproduction. Survival during times of famine necessitates metabolic shifts that conserve resources and promote repair because growth is not an option.[7]

Reducing calorie intake not only lowers overall insulin exposure but is now known to activate the transcription of a family of genes known as sirtuins (SIRTs). The SIRT enzymes appear to have first arisen in primordial eukaryotes, possibly to help them cope with adverse conditions, like famine, and today are found in all plants, yeast, and animals. In response to calorie restriction, SIRT-1 stimulates the production of new mitochondria in skeletal muscle and liver cells, thereby increasing the capacity for metabolic repair and energy production. New mitochondria produce fewer free radicals than the old mitochondria, which leads to less free-radical damage and to delayed onset of metabolic aging. SIRT-1 also has a cascading effect on multiple genes, leading to increased catalase activity, increased free fatty acid oxidation for energy, and reduced inflammation via suppression of the enzyme nuclear factor-κB (NF-κB).[8]

The obvious problem with calorie restriction, however, is that humans like food. Recent studies on the effects of the polyphenol compound resveratrol (initially isolated from grape skins) on obese, sedentary mice suggested that it could mimic the beneficial health effects of calorie restriction even while the mice continued to eat a high-calorie, high-fat diet and did not exercise. Dietary supplementation with resveratrol was found to oppose the effects of the high-calorie diet in 144 of 153 altered biochemical pathways, most of which could be attributed to its activation of the transcription of the enzyme SIRT-1. Resveratrol increased insulin sensitivity, reduced insulin-like growth factor-1 production, increased adenosine monophosphate–activated protein kinase, increased peroxisome proliferator-activated receptor-coactivator-1 (PPAR-1) activity, increased the number of mitochondria, and improved overall motor function.[9] Such research suggests that at some future time we just may be able to have our cake, eat it too, and suffer few of the metabolic consequences of overeating. Nevertheless, the best current nutritional advice for longevity and health remains simply, "eat less." Not only does eating fewer calories lower the insulin load, but it activates the transcription of numerous enzymes that promote mitochondrial regeneration, health, and longevity.

Nutrigenomics helps elucidate the myriad effects of specific nutrients on our genome, as well as helps us rethink and understand the mechanisms by which other nutrients act on our physiology. *Ginkgo biloba* is a commonly prescribed medicinal herb that is known to increase peripheral microcirculation and to contain rather potent antioxidants. The vasodilation allows delivery of these antioxidant compounds to poorly vascularized areas, like the brain. Not surprisingly, ginkgo is commonly used for impaired memory and mental function as we age. Using gene chip assays, researchers examined cellular extracts to look for altered levels of messenger RNA, an accurate measure of gene activity. In vitro studies with human bladder cancer cells that were incubated with ginkgo resulted in suppression of gene transcription by more than 50% in 16 genes and induction of 139 genes by more than 100%. The overall effect of adding ginkgo was to activate genes that code for improved mitochondrial function and antioxidant protection. Subsequent in vitro mouse studies showed activity of more than 12,000 genes and a preferential activation of genes within the brain, with induction of more than 200% of 43 genes in the cortex and 13 genes in the hippocampus, including those genes that promote nerve cell growth, differentiation, regulation, and function, as well as increased mitochondrial activity and antioxidant protection.[10]

This elegant research points to a new understanding of why and how herbal medicines or other specific nutrients can act to change our physiology, but it also helps explain why specific herbs or nutrients act preferentially on specific tissues or organ systems. It is not just *G. biloba* that acts to alter gene transcription. Every medicinal herb, every nutrient, every food, and every pharmaceutical medicine is likely to act in a similar fashion. These compounds do not just have a gross chemical effect on our physiology; they also alter gene expression. Nutrigenomics is forcing us to rethink the ways in which our bodies respond to environmental stimuli in the form of food, herbs, or medicine.

In some areas, nutrigenomics and nutrigenetics can overlap. We propose the use of the term "preventive genomics" to include both nutrigenomics and nutrigenetics because they cannot always be easily separated. To illustrate, PPAR-γ is a nuclear hormone receptor that regulates many cellular functions, such as nutrient metabolism, cell proliferation, and cell differentiation, in response to dietary macronutrients, specifically to carbohydrate and fat intake. PPAR-γ integrates the cellular control of energy, lipid, and glucose homeostasis. Its activation by increased dietary fat or sugar intake is clearly an example of nutrigenomic interaction. However, there is a common polymorphism in the gene that codes for PPAR-γ in which an alanine is substituted for a proline at the 12th amino acid in the protein (the polymorphism is referred to as PPAR-γ P12A). Individuals with the 12A variant display a greater metabolic tolerance to a high-fat diet, leading to a significantly reduced risk of developing insulin resistance, type 2 diabetes, coronary artery disease, and central obesity when consuming a typical Western diet.[11] Individuals with the 12P variant are more sensitive to the ill effects of excessive dietary saturated fat intake, suggesting a clear therapeutic dietary strategy in P-allele carriers to prevent obesity, diabetes, and heart disease.[12]

There are many polymorphisms, like the PPAR-γ proline variation, that exist in a large percentage of the population and appear to increase the risk for certain serious diseases. They beg the question, why do these seemingly harmful polymorphisms exist? It is important to remember that the PPAR-γ proline variation is harmful only in individuals who eat a typical Western diet that is high in calories and saturated fat. It behooves us to remember that in most of nature and for most of human history, too much food to eat was rarely a major risk factor. Quite the opposite was true when food scarcity in winter and famine were common occurrences. In these environments, the ability to extract more nutrition from the same caloric intake would be a distinct advantage for survival. It is only in the past 50 to 100 years in our culture of affluence that these variations have begun to pose significant risks to our health. We call these genes "thrifty genes," a term first coined by D. L. Coleman to explain why the Pima Indians from the desert of the American Southwest were prone to developing obesity and diabetes. Thousands of years of survival in that harsh environment selected for genes that made this group incredibly efficient at retaining calories from food—a distinct adaptive advantage when the food supply was scarce. However, with the 24-hour grocery only a car ride away, their genes are significantly less well adapted to survive.[13] We see similar gene variations that increase inflammation throughout the body. This seems counterproductive until we realize that infectious disease has been a major environmental risk throughout evolution,

and inflammation and immune activation are essentially the same biological process. It is imperative to remember that every polymorphism that exists in humans with significant prevalence confers protection and advantages to survival in some environment. Our task as clinicians is to identify that environment and to recommend it to those patients with that genetic variation.

NATURE VERSUS NURTURE

The reality is that the prevention and cure of complex diseases and syndromes are not to be found exclusively in our genes or our environment but in the interactive symphony between the two. Nature (our genes) provides a plastic template that is largely adaptable to a wide range of environments ("survival of the most adaptable"), and slight variations in those genes can cause altered responses to specific environments (nutrigenetics). In contrast, nurture (our environment) switches genes on and off, largely controlling gene expression (nutrigenomics).

To illustrate this idea of gene–environment interaction, consider the research of Caspi et al.[14] They studied variations in the promoter sequence for the gene coding for monoamine oxidase-A (MAO-A) and found that a promoter polymorphism caused some people to have high-activity MAO-A genes and others to have low-activity genes. Those with high activity MAO-A would deactivate catecholamine neurotransmitters, like dopamine and noradrenaline, more rapidly. They then examined whether these genes played a role in antisocial and violent behavior in men who had been abused as children. Remarkably, they found that men with the high-activity MAO-A gene were virtually immune to the effects of maltreatment as children, seldom if ever becoming violent offenders, whereas men with the low-activity MAO-A gene were much more antisocial and violent, but only if they themselves were abused as children. In other words, for violent behavior to manifest in adulthood, both the low-activity gene (nature) and childhood maltreatment (nurture) needed to be present. If either was missing from the equation, the adult was very likely to be well socialized and nonviolent.

The Centers for Disease Control and Prevention (CDC) published a *Gene-Environment Interaction Fact Sheet* in August 2000[15] that outlines the basic principles of a broad understanding of the causal interaction of genes and environment in human disease. In it, the CDC makes four main points:

1. Virtually all human diseases result from the interaction of genetic susceptibility and modifiable environmental factors.
2. Variations in genetic makeup are associated with almost all disease.
3. Genetic variations do not cause disease but, rather, influence a person's susceptibility to environmental factors.
4. Genetic information can be used to target interventions.

In this brief paper, the CDC essentially outlined the chief tenets of nutrigenetics and of preventive genomics.

Ironically, these ideas are hardly new. In 1909 Archibald Garrod[16] published *Inborn Errors of Metabolism,* in which, after identifying the first human disease that behaved as a true mendelian recessive trait (alkaptonuria), he went further to construct a sweeping hypothesis that altered heredity was "the seat of chemical individuality." "Inborn errors of metabolism," he wrote, "are due to a failure of a step in the metabolic sequence due to loss or malfunction of an enzyme." By examining the subtle end products of metabolism, he continued, we should be able to identify the differences that altered heredity produces in each individual. This is a remarkable insight, given that the words *gene* and *genetic* did not exist in 1909, and it would be roughly 50 years before the structure and true function of DNA were confirmed. Moreover, Garrod's book was published 3 years before the first vitamin was discovered, so he would have had no notion of vitamins as cofactors in enzymatic reactions. He concluded his prophetic work by envisioning the complex interaction between our unique genetic constitution and environmental factors in the exquisitely simple statement "These idiosyncrasies may be summed up in the proverbial saying that one man's meat is another man's poison."

THE CLINICAL UTILITY OF NUTRIGENOMICS AND NUTRIGENETICS

The point of using genetic and genomic information in a clinical setting is to personalize the therapeutic regimen and develop an effective strategy toward true disease prevention. It is a common mistake, however, to think that somehow the new preventive genomic information we can access will make all previous therapies obsolete. This is evident in the mind-set that thinks we can attribute disease risk to polymorphisms without reference to environment (read any genetic newspaper headline). Simply put, genetic information is no more and no less valuable than environmental information. We need them both to make an optimal difference. Furthermore, at this stage in preventive genomic research, there are, at best, only 100 or so polymorphisms about which we have sufficient clinical information to make personalized nutritional recommendations.[17] Although it is useful information, it is insufficient for comprehensive nutritional and therapeutic recommendations.

Carl Sagan once said, "If you want to make an apple pie from scratch, you must first create the universe."[98] Fortunately for making an apple pie, the universe has already been created, and fortunately for making comprehensive nutritional recommendations, natural selection has been active since the beginning of life on this planet. As humans, we and our ancestors have been adapting to environments for the past 3 billion years, if you want to think of all life, or for a mere 600 million years, if you want to think of eukaryotic cells with aerobic respiration. Either way, it is a lot of experimental trial and error that brought us to the present. The proper starting point of nutrigenomics and nutrigenetics is not necessarily genetics but good epidemiology. Good epidemiology can provide the information necessary to determine the best nutrition and lifestyle for the average person. Specific genetic polymorphisms can help health professionals modify these recommendations to meet the specific genetic needs of an individual patient.

Discovering the optimal nutrition and lifestyle for a specific individual will depend on developing a functional matrix that is minimally composed of the following:

1. Good epidemiological dietary and lifestyle data
2. Specific genomic polymorphisms that alter specific macronutrient and micronutrient requirements
3. Functional laboratory assessment of individual function, physiology, and micronutrient status

In terms of Western diets, the Mediterranean diet is one of the best studied, and from an epidemiological perspective, it is arguably the best for disease prevention and optimal health. It has been demonstrated to reduce cholesterol and triglycerides; to prevent atherosclerosis and high blood pressure; and to reduce the risk of senility, stroke, heart disease, insulin resistance, type 2 diabetes, and numerous cancers, including those of the breast, prostate, and colon.[18] Among elderly Europeans, a Mediterranean diet combined with moderate daily activity and no smoking reduces all-cause mortality by 67%, and switching to this healthier diet and lifestyle at age 70 reduced mortality rates by 50%.[19]

Clearly, these results are impressive, but the central tenet of preventive genomics is that these risks can be reduced further with the judicious application of nutrigenetic information gathered from the analysis of individual

polymorphisms. Not all polymorphisms are clinically relevant. Most of our interindividual genetic variation occurs in sections of the DNA that do not actually code for proteins. About 97% of our DNA is either of viral origin, repeats, or simply junk DNA that codes for nothing. To make genomic information clinically useful, polymorphisms must meet four essential criteria; they must be relevant, prevalent, modifiable, and measurable.

1. First, the only polymorphisms of clinical interest in the genome are those that exert an effect on some specific aspect of our biochemistry and physiology (relevant).
2. Second, given our current knowledge of the human genome, only polymorphisms that exist in a substantial portion of a population are likely to be able to be demonstrated in epidemiological and case-controlled studies to be clinically relevant—in essence, we compare polymorphisms that occur in substantial numbers in both groups (prevalent).
3. Third, only polymorphisms whose genetic expression is modifiable via reasonable clinical intervention are clinically useful. Such an intervention may be any modification of environment, including diet, lifestyle, and targeted nutraceuticals or pharmaceuticals. Although genes themselves are not modifiable, the phenotype they generate is modifiable via environmental changes because environment turns genes on and off.
4. Finally, because our genes do not themselves change, we must be able to measure changes in our functional physiology to determine that the environmental changes implemented have been effective in modifying the phenotypic or physiological expression of our unique genes. For this purpose, functional testing must be available and used in conjunction with genomic testing for polymorphisms (measurable).

To illustrate this model of clinical utility, let us consider the example of the detoxification and antioxidant protection afforded by the enzyme glutathione-S-transferase (GST). High levels of toxins and oxidative stress are associated with numerous degenerative diseases and with the aging process itself. Thus an enzyme like GST that protects against such oxidative damage is highly relevant to our health. The GST polymorphisms have been associated with numerous cancers in epidemiological and case-control studies.[20,21] Although there are several isoforms of GST in the body, the μ isoform, *GSTM1,* is the most common in the liver. More than 75% of Caucasians and about 25% of Africans exhibit mutations resulting in complete *GSTM1* deletion.[22] Because other isoforms of GST and other antioxidant pathways exist, it is possible to improve antioxidant protection by maintaining a high reduction potential through exogenous avenues, including dietary antioxidants. Furthermore, men and women who lack the *GSTM1* gene altogether can increase their serum glutathione levels by 16% and 38%, respectively, and their other GST activity by 6% and 8%, respectively, simply by eating four or more servings of brassica vegetables weekly. Interestingly, individuals possessing a *GSTM1* gene showed significantly less benefit.[23] Similar benefits were seen from regular brassica vegetable consumption in reducing colorectal cancer by 53%[24] and lung cancer in smokers by 70%,[25] but again only in individuals lacking the *GSTM1* gene. Thus the increased oxidative stress is attenuated by regular brassica vegetable consumption. Finally, we can validate the clinical efficacy of our intervention strategy by measuring functional levels of oxidative stress through any number of simple laboratory tests, such as urine lipid peroxides, 8-hydroxy-deoxyguanosine, serum glutathione, urine, or plasma cysteine/cysteine ratio, for example. The biological effects of our interventions are measurable.

Personalized Nutrition and Nutrigenetics

Most of the clinically relevant nutrigenomic information available relates to the relationship between polymorphisms with increased chronic disease risk and the dietary therapies and supplements that have been demonstrated to treat the physiological imbalance effectively. This is particularly true of SNPs. In as many as one third of genetic polymorphisms, the corresponding enzyme has a decreased binding affinity for a vitamin or mineral coenzyme, resulting in a lower rate of reaction and altered enzyme function (Fig. 15.2). In a series of review articles, Ames[26] and Ames et al.[27] provided evidence of more than 50 human diseases involving defective enzymes that could be remedied or ameliorated by the administration of higher doses of vitamins or minerals, which at least partially restore enzyme activity. Thus the clinical validity of high-dose nutrient therapy is established but only in genetically susceptible individuals.

CLINICAL APPLICATION

Cardiovascular Disease

Cardiovascular disease accounts for approximately 40% of all deaths in most industrialized countries and is also responsible for significant morbidity and diminished quality of life. Furthermore, using data

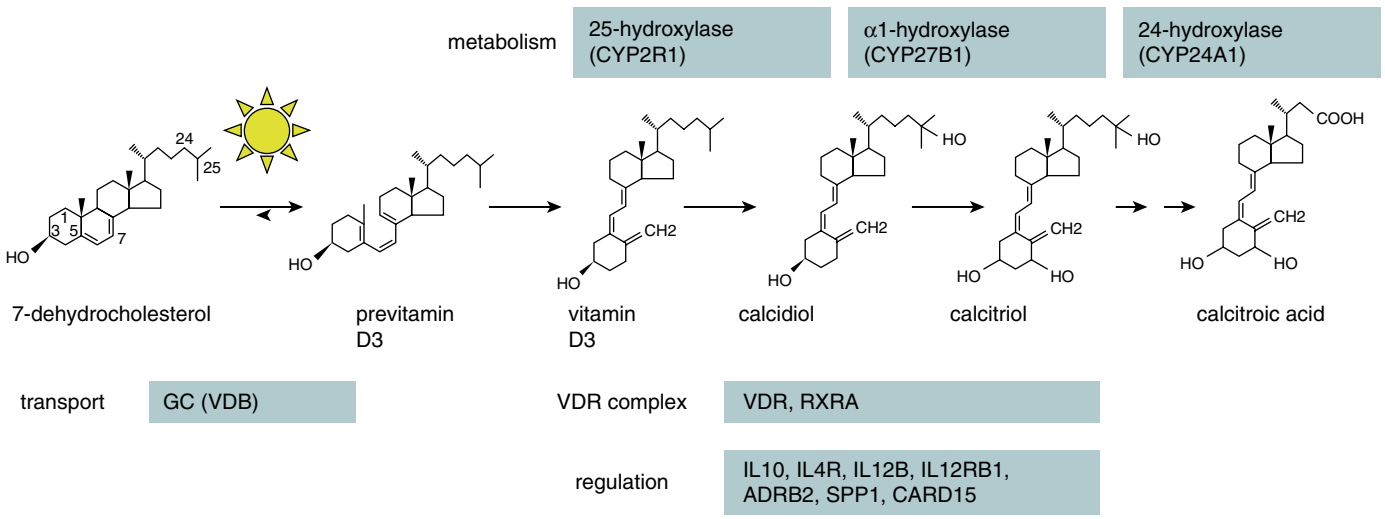

Fig. 15.2 Pathway diagram of genes involved in vitamin D metabolism. (From Wjst M, Altmuller J, Faus-Kessler T, et al. Asthma families show transmission disequilibrium of gene variants in the vitamin D metabolism and signaling pathway. *Resp. Res.* 2006;7:60. PubMed PMID: 16600026.)

from more than 84,000 women who were monitored for 14 years, epidemiology researchers at Harvard University estimated that about 83% of cardiovascular disease could be decreased if everyone ate a reasonably healthy diet, exercised daily, did not smoke, maintained a normal weight, and drank 1 to 2 alcoholic beverages per day.[28] Although these five diet and lifestyle changes seem fairly simple, only 3.1% of the women in the study actually adopted them. Not only is compliance an issue, but epidemiological studies raise deeper philosophical questions because such studies assume that all participants are essentially similar to one another. Are the same therapies equally effective for all individuals? Do all individuals need the same quantities of these diet and lifestyle modifications? Can preventive genomic testing help us individualize our therapeutic protocols?

Let us begin by asking what proportions of carbohydrate, protein, and fat in the diet are the most effective in maintaining normal serum cholesterol levels. Is it a low-fat, low-cholesterol diet as touted by Nathan Pritikin and Dean Ornish? Or perhaps a 40-30-30 (40% carbohydrate, 30% protein, 30% fat), low-calorie "Zone" diet as proposed by Barry Sears? Or a low-carbohydrate, high-protein, high-fat diet such as that made popular by Robert Atkins? Logically they cannot all be the best diet for everyone, yet some people swear by each of them as the answer for an optimal diet.

There is mounting evidence that optimal macronutrient proportions in the diet may be a function of specific polymorphisms. Apolipoprotein-E (Apo-E) is a molecule that mediates the interaction of chylomicron remnants and intermediate-density lipoprotein particles with lipoprotein receptors, including the low-density lipoprotein (LDL) receptor and the chylomicron remnant or Apo-E receptor. It has been suggested that Apo-E allelic variation may account for ≤7% of the variation in total and LDL-cholesterol concentrations in the general population.[29] There are three variations of the Apo-E gene, known as Apo-E2, Apo-E3, and Apo-E4, and these polymorphic variants are important genetic modifiers of serum lipid responses, which consequently may significantly affect an individual's risk for development of coronary artery disease. (Technically, each of these polymorphisms is a haplotype: two individual SNPs at different points in the Apo-E gene that are linked.) Population studies have shown that plasma LDL-cholesterol levels are highest in subjects carrying the Apo-E4 allele, intermediate in those with the Apo-E3 allele, and lowest in those with the Apo-E2 allele.[30] The E3/E3 genotype is the most common in all populations and serves as the benchmark genotype for comparison with any other possible genotype. The Apo-E4 allele is associated with a moderately increased risk of atherosclerosis and coronary artery disease (odds ratio [OR] = 1.53 for men and 1.99 for women in one study).[31] The increase in the risk of all cardiovascular disease in men carrying the Apo-E4 allele is 63% and is 56% for women.[32] Conversely, LDL-cholesterol levels declined with each Apo-E2 allele by 8.8 mg/dL in Hispanics, by 25.6 mg/dL in non-Hispanic white persons, and by 18.1 mg/dL in African Americans.[33]

The association of the Apo-E4 allele with elevated serum cholesterol levels is greatest in populations that consume diets rich in saturated fat and cholesterol compared with other populations. Thus the higher LDL-cholesterol levels observed in people carrying the Apo-E4 allele are manifested primarily in the presence of an atherogenic diet characteristic of Western societies and that the response to dietary saturated fat and cholesterol may differ among individuals with different Apo-E genotypes. Many studies have been conducted to prove this hypothesis.[34] Given that each person inherits two alleles, there are six possible genotypes: E2/E2, E2/E3, E3/E3, E2/E4, E3/E4, and E4/E4. In patients with elevated serum total and LDL-cholesterol, the cholesterol-lowering response to a low-fat, low-cholesterol diet increased as the sum of the allele numbers increased (in other words, response improved in the order of the previously listed six genotypes).[35,36] Conversely, individuals carrying an E4 allele who ate a high-fat diet were much more likely to have elevated serum cholesterol.[37] In contrast, serum triglyceride levels were found to be significantly higher in men, and to a lesser extent in women, who carried an E2 allele. Moreover, the triglyceride levels of individuals with an E2 allele showed a dose-dependent relationship to table sugar consumption, an association not shared with the other genetic variations.[38] Dietary sucrose consumption also increased very low-density lipoprotein (VLDL) cholesterol and triglycerides in Apo-E2 carriers. In contrast, E3/E3 individuals were found to have the lowest triglyceride levels, and E4 carriers were found to have intermediate levels.[39] In another multiethnic study, plasma triglyceride levels were inversely correlated with the number of Apo-E4 alleles (175, 159, and 143 mg/dL with 0, 1, and 2 alleles, respectively).[40] Another study found E4 carriers to have elevations in triglycerides, but only those who consumed alcohol regularly.[41] A study of Turkish men who did not consume alcohol found no elevated triglyceride values in E4 carriers.[42] The most effective dietary therapy to lower triglycerides is restricting carbohydrate, especially sugar, consumption. Because Apo-E2 men are prone to significant triglyceride elevations and their levels are less sensitive to dietary fat intake, a lower-carbohydrate, higher-protein, higher-fat diet may be therapeutically desirable for them.

Individuals with the E3/E3 genotype are moderately affected by dietary fat intake but tend to have lower triglyceride levels than the other genotypes. In one study, individuals with high cholesterol and triglyceride values were treated with a short-term (7-day) very low-calorie juice fast (208 calories/day), and their responses were stratified by Apo-E genotype.[43] Only E3/E3 individuals experienced significant improvement in all parameters, experiencing reductions in LDL cholesterol by 10% and in triglyceride values by 18%. In these individuals, it is tempting to speculate that the low-calorie, moderate 40-30-30 carbohydrate-protein-fat ratio "Zone" diet might be more effective in treating both hypercholesterolemia and hypertriglyceridemia, although no clinical trials to validate this hypothesis have yet been published. Also, in this trial, E2 carriers experienced a 31% drop in LDL levels but a 15% increase in triglyceride levels, lending some additional support for the carbohydrate-sensitive triglyceride hypothesis. E4 carriers had an opposite response to E2 carriers: a dramatic reduction of triglyceride levels by 49% but a rise in LDL levels by 13% while eating only 200 calories/day.

Other dietary interventions that affected cholesterol levels were fiber and alcohol. High intake of soluble fiber (5.7 g/day) reduced LDL cholesterol by 6.6% and 5.6%, respectively, in E3 and E4 allele carriers but had little effect on E2 carriers.[44] Similarly, a study of Korean patients with coronary artery disease found that replacing white rice with whole grains produced the greatest benefit in E3/E3 individuals (12% reduction in triglyceride, 8% reduction in LDL cholesterol, and 8% increase in high-density lipoprotein [HDL] cholesterol levels), as well as moderate benefit in E4 carriers (including a 15% increase in HDL cholesterol values), but there was absolutely no effect on cholesterol levels in E2 carriers.[45] Thus a high-fiber diet may be clinically most useful for E3/E3 individuals, modestly useful for E4 carriers, but not useful for E2 carriers.

The modest consumption (1–2 drinks) of alcohol daily has been shown epidemiologically to be extremely protective against coronary artery disease in the general population. However, Apo-E genotyping reveals that the benefits are not the same for everyone. In a comparison of nondrinkers with drinkers of alcohol, women who were drinkers had lower cholesterol (total and LDL) than women who did not drink, regardless of Apo-E genotype. In men, however, Apo-E2 carriers who were drinkers had lower cholesterol, but Apo-E4 carriers had higher

TABLE 15.1 Lipid-Lowering Therapies Stratified According to Apolipoprotein-E (Apo-E) Genotype

	GENOTYPE[a]		
Therapy	**E2/2 or E2/E3**	**E3/E3**	**E4/E3 or E4/E4**
Diet	Lower carbohydrate	Low calorie, moderate fat	Low fat, no cholesterol Soluble fiber
Alcohol intake	Daily (women and men) (little effect for men)	Daily (women) None (men)	Daily (women)
Exercise	Moderate	Moderate	High-intensity
Pharmaceutical/nutraceutical	Bile sequestrants Statins	Statins	Probucol Statins

[a]The E2/E4 genotype is extremely rare and therefore lacks statistical power in both association studies and prospective trials.

cholesterol, and alcohol consumption had no significant effect for Apo-E3/E3 individuals.[46]

It is worth observing that moderate exercise, although not dietary therapy, was found to be effective in improving serum lipids in E2 and E3 genotypes but not in E4 carriers.[47] In another study, high-intensity physical exercise was most effective in E4 carriers.[48] Thus E2 and E3 carriers may benefit from modest daily exercise, but for an individual with an E4 allele to benefit from exercise, that exercise must be high intensity.

Similarly, knowledge of Apo-E genotype may allow for a more discriminating and more effective use of targeted pharmaceuticals for patients with lipid abnormalities. Statin drugs exhibited a greater cholesterol-lowering effect in Apo-E2 carriers, followed by Apo-E3/E3, with less effectiveness for Apo-E4 carriers. Apo-E2 carriers also showed a better response to gemfibrozil and cholestyramine than the other genotypes. The greatest cholesterol-lowering effects for Apo-E4 carriers came from probucol, a potent antioxidant.[31] However, although statins had a weaker cholesterol-lowering effect in Apo-E4 carriers, statins were most protective in preventing a second heart attack in men with an E4 allele. Statin use reduced the risk of a second heart attack in E4 carriers by 64% compared with only 33% for other genotypes, even though statins reduced LDL cholesterol levels least in Apo-E4 genotypes.[49]

More prospective clinical trials are needed to fully elucidate the optimal therapeutic dietary interventions to protect against coronary artery disease in individuals based on their Apo-E genotype status. However, distinct patterns are beginning to emerge in terms of dietary and lifestyle management for the treatment of coronary artery disease; these are summarized in Table 15.1.

Other variants within the Apo-E gene locus have also been investigated in relation to the association with lipid phenotypes and response to dietary intervention. Evidence suggests that variability in the Apo-E promoter region is associated, independently of the traditional E2, E3, and E4 alleles, with plasma lipid levels,[50] dietary response,[51–53] and cardiovascular disease risk.[54]

Apo-E polymorphisms are the best studied in terms of their association with atherosclerosis and coronary artery disease, but other polymorphisms exert similar effects. Cholesteryl ester transfer protein (CETP) is responsible for the transfer of insoluble cholesteryl esters from HDL to other lipoproteins.[55] The Taq1B polymorphisms of the *CETP* gene result in increased CETP levels, with impaired ability to remove cholesterol from the cells and the bloodstream. The Taq1B polymorphism occurs with lower HDL cholesterol levels and an increased risk of development of atherosclerosis and coronary artery disease.[56,57] In one study, individuals who were homozygous for the Taq1B polymorphism had larger reductions in LDL and VLDL levels through eating a low-fat diet with a high ratio of polyunsaturated to saturated dietary fat.[58] Furthermore, daily moderate alcohol consumption raised HDL levels substantially but only in individuals with the CETP polymorphism.[59,60]

E-selectin (SELE) is a glycoprotein molecule that adheres circulating neutrophils to the endothelial lining of blood vessels. E-selectin is expressed on the surface of endothelial cells after stimulation by inflammatory mediators (mediated by NF-κB). Several polymorphisms in the SELE gene increase adhesion activity of E-selectin, dramatically increasing the risk of atherosclerosis and premature coronary artery disease.[61,62]

The primary therapeutic aim for carriers of a SELE polymorphism is to decrease NF-κB stimulation, in turn reducing SELE expression. Maintaining high antioxidant potential has been shown to decrease NF-κB activation.[63,64] Thus higher levels of dietary antioxidants and possibly supplemental antioxidants may be beneficial. The proinflammatory cytokines tumor necrosis factor-α and interleukin-1 also increase NF-κB activation. Antioxidants, fish oil,[65] and milk thistle (silymarin) supplementation have each been shown to suppress interleukin-1 and tumor necrosis factor-α production directly and would therefore lower NF-κB activation.

The *MLXIPL* gene codes for carbohydrate-responsive element-binding protein (ChREBP). This protein is a transcription factor that binds and activates carbohydrate response element (ChoRE) motifs in the promoter regions of genes responsible for triglyceride synthesis and glycolysis in the liver. Thus ChREBP appears to play a major role in determining fasting triglyceride levels in the blood. Additionally, the *MLXIPL* gene is one of about 26 genes that is deleted in Williams–Beuren syndrome, a neurodevelopmental disorder with several cardiovascular defects.

A SNP in the MLXIPL gene (specifically, the C allele of the G771C polymorphism) shows a strong association with elevated triglyceride levels (OR = 1.29 per copy of the C allele for triglyceride levels >1.7 mmol/L). Median triglyceride levels are 2.07, 1.96 and 1.75 mmol/L for the C/C genotype, C/G genotype, and G/G genotype, respectively.[66]

Conversely, the G allele of the G771C polymorphism is protective against several cardiovascular risk factors.[67] The G allele is associated with lower triglyceride levels (−9.86 mg/dL per G allele; OR for hyperlipidemia = 0.73). Furthermore, stronger adherence to a Mediterranean diet enhances the triglyceride-lowering effect of the G allele (OR = 0.63), and this protection is attenuated when the adherence is low (OR = 0.88). The Mediterranean diet also significantly lowered the risk of cardiovascular pathology in carriers of the G allele more so than in C/C homozygotes on the same diet (hazard ratio = 0.34) and compared with carriers of the G allele who were not on the Mediterranean diet (whose hazard ratio = 0.90).[68]

The *SERPINE1* gene (formerly known as PAI-1) codes for plasminogen activator inhibitor-1. This protein is a member of the serpin family and inhibits both the tissue-type and urokinase-type plasminogen activators. Plasminogen activators are responsible for the conversion of plasminogen to plasmin, which, in turn, degrades fibrin. Thus plasminogen activator inhibitor-1 appears to play a major role in determining the proliferative response to vascular injury by inhibiting the degradation of fibrin and several extracellular matrix proteins by plasmin.

A SNP in the *SERPINE1* gene called the rs6950982 polymorphism is associated with higher levels of several lipids in the blood. People who carry the G allele have higher total cholesterol (A/A: 208, A/G: 210, G/G: 218 mg/dL), higher LDL cholesterol (A/A: 127, A/G: 131, G/G: 136 mg/dL), and higher triglycerides (A/A: 131, A/G: 128, G/G: 154 mg/dL) in the blood. Additionally, men who carry the G allele have higher systolic blood pressure (A/A + A/G: 141.4 mm Hg vs. G/G: 149.8 mm Hg) and diastolic blood pressure (A/A: 81.5, A/G: 82.1, G/G: 85.7 mm Hg). Both men and women with the G/G genotype respond well to the Mediterranean diet for controlling triglyceride levels (~175 mg/dL in the lower-adherence group vs. ~125 mg/dL in the higher-adherence group).[69]

Electrolytes and Hypertension

Hypertension is an independent risk factor for coronary artery disease and for stroke. The therapeutic response to sodium restriction in hypertensive individuals is highly variable. A SNP in the angiotensinogen gene *(AGT)* allows an amino acid substitution in which threonine (T) replaces methionine (M) at amino acid 235. The T allele is associated with increased production of angiotensin, with a tendency for higher blood pressure. There is a stepwise increase of serum AGT from MM to MT to TT genotypes among persons with hypertension[70] and those with normal blood pressure.[71] Although there have been some discrepancies between studies, a meta-analysis of all studies published between 1992 and 1996 showed the 235T allele had a consistent, mild association with hypertension (OR = 1.20), a positive family history of hypertension (OR = 1.42), and more severe hypertension (OR = 1.34).[72] A more recent study (2016) puts the risk of hypertension in carriers of two copies of the 235T allele at an OR of 1.8.[73]

The 235T allele of the *AGT* gene is associated with greater blood pressure decreases than the 235M allele after an intervention to reduce sodium intake (>5 mg/day).[74] Persons with the TT and MT genotypes showed significant systolic blood pressure reductions when consuming mineral salt compared with control subjects ($P < 0.02$ and $P < 0.001$, respectively), but persons with the MM genotype did not ($P < 0.10$). The net adjusted systolic and diastolic blood pressure reduction was –8.6 mm Hg systolic/–3.9 mm Hg diastolic for persons with the TT genotype, –9.0/–5.2 mm Hg for those with the MT genotype, and –5.3/–1.0 mm Hg for the MM genotype.

Aerobic exercise was effective in reducing blood pressure but only in the MM (–3.7 mm Hg) and MT (–3.4 mm Hg) genotypes, and not in the TT (–0.4 mm Hg) individuals, among 477 previously sedentary white Americans.[75] Finally, the use of angiotensin-converting enzyme inhibitors produced more dramatic reductions in blood pressure in 235T allele carriers (TT and MT) than in the MM genotype,[76,77] illustrating the notion that diverse modifications in "environment" (diet, exercise, targeted pharmaceuticals) may produce similar alterations in phenotype (in this case, blood pressure) among genetically susceptible individuals.

Homocysteine and Micronutrients

As mentioned previously, one common physiological effect of SNPs is a decreased binding affinity of a vitamin or mineral coenzyme for the structurally altered enzyme. There is mounting evidence that in most cases, the diminished rate of reaction of that polymorphic enzyme can increase with high-dose cofactor micronutrient supplementation.[78] Perhaps the best-studied example of this model is the enzyme 5,10-methylenetetrahydrofolate reductase (MTHFR), which is responsible for remethylating homocysteine into methionine, allowing methylation reactions to occur efficiently in the body. When methylation reactions are impaired, plasma homocysteine levels rise (Fig. 15.3). Elevated homocysteine values have been associated with an increased risk of atherosclerosis,[79] risk of early coronary artery disease,[80,81] increased risk of hemostasis and venous thrombosis,[82,83] decreased bone density,[84] neural tube defects, spina bifida,[85,86] Alzheimer's disease, macular degeneration, hearing loss,[87] and acute leukemia in adults.[88] The risk of heart disease increases for heterozygotes as well as for 677T/T homozygotes.[89] Folic acid and vitamins B_2 (as flavin adenine dinucleotide [FAD]), B_6, and B_{12} are all cofactors in the methylation cycle, and a dietary deficiency of any of these vitamins can result in elevated homocysteine levels. However, elevated homocysteine levels can also result from two common polymorphisms in MTHFR: a 677C-T nucleotide substitution and a 1298A-C nucleotide substitution. Someone with a 677T/T genotype has a 50% reduction in MTHFR enzyme activity, whereas a 1298C/C genotype has a 32% reduction. In one study, approximately 28% of patients with elevated homocysteine did not respond to supplementation with folic acid, vitamin B_{12}, and vitamin B_6 because they had the 677T/T genotype

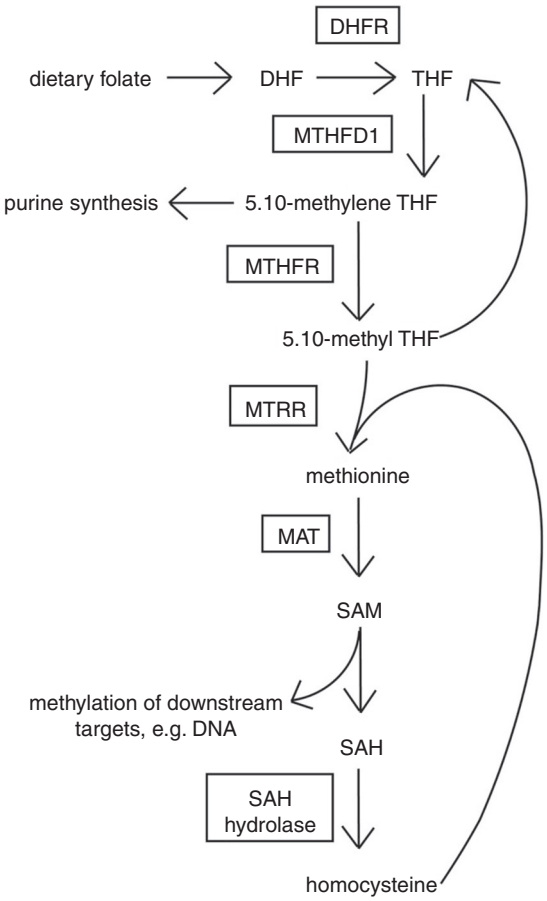

Fig. 15.3 Schematic of the folic acid metabolic cycle. (From Spellicy CJ, Kosten TR, Hamon SC, et al. The MTHFR C677T variant is associated with responsiveness to disulfiram treatment for cocaine dependency. *Front. Psychiatr.* 2013;3:109. PubMed PMID: 233335901.)

and severely impaired MTHFR activity.[90] It is worth noting that the 677C-T polymorphism occurs in the FAD site of MTHFR, suggesting that vitamin B_2 supplementation may be a critical component.[91]

Three rational therapeutic strategies may help resolve elevated homocysteine levels. First is high-dose supplementation of the vitamin cofactors of MTHFR, which relies on the simple logic of the law of mass action in a chemical reaction: higher concentrations of substrates drive the chemical reaction forward. Second, the metabolic products of the MTHFR enzyme, namely, 5-methyltetrahydrofolate, may be supplemented. Third, alternate remethylation pathways may be stimulated by supplementing trimethylglycine or betaine as alternate methyl-group donors. Considering the low cost and high degree of safety associated with each of these options, all three strategies may be employed simultaneously. Regardless, serial plasma homocysteine measurements allow the practitioner to determine whether the therapy employed has been successful.

Although the science of nutrigenomics is still in its infancy, several principles have become clear, with an enormous potential impact for clinical medicine. Nutrients act as dietary signals that alter gene expression (nutrigenomics). In individuals with specific polymorphisms, their specific genetic variation may render that individual more or less sensitive to specific nutrients or environmental stimuli and, therefore, may help determine optimal diet and lifestyle (nutrigenetics). Knowing the effects of these environmental stimuli on gene expression allows us to use this information proactively to alter gene expression and to mitigate risk for developing various forms of chronic disease, like cardiovascular disease. These principles of nutrigenomics and nutrigenetics hold true for macronutrient balance in the diet and for micronutrients, such as vitamins, minerals, and electrolytes. Although our primary focus here has been on nutrient–gene interactions, the same principles hold true for lifestyle changes and targeted pharmaceuticals. Nutritional intervention is merely a more specific application of environmental modification to alter gene expression. What should be clear is that as our knowledge of gene–gene and gene–environment interactions increases, so too will our capacity for delivery of increasingly personalized and primary prevention.

GENOMIC TESTING

From Early Detection to Prevention

We use the term *susceptibility gene* to refer to a polymorphism that may render an individual more susceptible to the development of a chronic disease when exposed to an adverse environment. Most susceptibility genes have a low positive predictive value (the probability that a disease will develop in a person with a positive test result) and a low attributable risk (the proportion of cases of a disease that can be attributed to a susceptibility gene).[92] Therefore some researchers have questioned the clinical utility of susceptibility genetic testing,[93] but such arguments, by applying a single-gene/single-disease model to susceptibility genes, miss the clinical relevance. Susceptibility genes, much like taking a family history, must be seen as important but incomplete contributors in what is invariably a multifactorial risk assessment. In terms of health outcomes, preventive genomic polymorphisms raise risk modestly and are additive in their effects (gene–gene interactions), and their actual phenotype expression is strongly affected by diet, lifestyle, and environment (gene–environment interactions). Rather than negate their clinical utility because of a low positive predictive value and a low attributable risk, these polymorphisms begin to offer a molecular basis for understanding the pathophysiology of complex multifactorial diseases, and an understanding of the environmental factors that affect gene expression begins to evoke effective therapeutic strategies.

Because environment is broadly understood to refer to anything outside the genome itself, therapeutic regimens may be constructed to include any portion of the environment that has been shown to affect gene expression and phenotype. This is truly a holistic approach because effective therapeutic strategies may involve diet, nutritional, and targeted pharmaceutical supplementation; lifestyle and behavioral modification; and the avoidance or elimination of toxins, xenobiotics, and microbes. Intervention at any level of our "environment" may prove clinically beneficial.

Functional medicine is the clinical discipline designed to promote health, to anticipate and prevent disease, or to correct an existing disease by improving physiological function. The underlying assumption is that health and disease lie on the same continuum, and the connecting thread of the continuum is physiological function. Before the manifestation of any frank disease, a progressive loss of homeostasis and increasing dysfunction occur. Clinical intervention in this strategy may begin at the earliest signs of imbalance.[94] The promise of preventive genomics is that the point of effective intervention may begin even earlier, before the beginnings of physiological dysfunction.

Clinical Challenges

Preventive and nutritional genomic testing in clinical practice has its critics, who predominantly argue that there are insufficient numbers of clinical trials to demonstrate the diagnostic and therapeutic efficacy of genomic profiles.[95] However, rather than demonstrating that all pregenomic testing is "premature and scientifically unsound," as suggested by Dr. Muin Khoury of the CDC,[96] such objections merely underscore the perspective shared here. Namely, it is precisely because chronic disease is multifactorial with complex gene–gene and gene–environment interactions that the diagnostic and therapeutic utility of preventive genomic testing must meet the four criteria of being relevant, prevalent, modifiable, and measurable. The last criterion, measurable, is critical at this early stage of preventive genomic testing. We must be able to measure beneficial phenotypic, physiological changes in individuals that result from the therapeutic strategy employed. There will always remain a possibility that other genetic polymorphisms or other environmental influences that we have not yet identified may also affect an individual's disease risk.

A similar cautionary argument should be made in cases in which current genomic knowledge offers conflicting therapeutic advice. A man with an Apo-E4 allele presumably should not drink alcohol, but what if he also has a CETP Taq1B polymorphism for which alcohol has been shown to boost HDL cholesterol levels dramatically? At present, the answer is unknown. Fortunately, because fractionated lipid levels are easily measurable, the effects of moderate, daily alcohol intake on such a specific individual's lipid profile may be easily ascertained. Thus medicine must ultimately be empirical, relying on trial and error until the desired result (e.g., lower serum cholesterol) is achieved.

Bioethical Considerations: Opportunities and Potential for Discrimination

Genetic information, because it represents an unchangeable state, has the potential, at least in theory, to be used in a manner by insurers, employers, and society at large. However, it should be noted that the paradigm for such discrimination views genetic information as representing an individual's immutable limitations, as typified by single-gene diseases (e.g., Tay-Sachs disease, Huntington's disease, sickle cell anemia).

A fundamental cornerstone of preventive genomics is the idea that the phenotypic outcome of any unique genotype is modifiable through environmental change. Preventive genomic testing, rather than revealing an individual's genetic limitations, more accurately reflects an

individual's genetic potential, given the right environment. Genetic polymorphisms have the potential to guide an individual to adopt the appropriate dietary, lifestyle, and environmental changes that can optimize health and longevity.

Now that we know there are irrefutable connections between genes and environment, and we are learning their myriad effects on health and disease, ignorance is no longer ethically neutral. Choosing not to use genomic information in treating patients, now that its health implications are being effectively documented, is ethically untenable. For the first time in the history of medicine, preventive genomic testing allows us to assess individual risk for the development of chronic diseases, to develop comprehensive risk-reduction strategies before imbalances in homeostasis occur, and to institute optimal therapy interventions for patients who are already sick. This new personalized medicine, made possible by the advent of preventive genomics and nutrigenomics, offers practitioners and patients new opportunities for the prevention and treatment of disease and for the promotion of optimal health.

SUMMARY

Preventive genomic testing exploring both nutrigenomics and nutrigenetics is both new and exciting. It affords practitioners both novel and effective avenues to develop personalized therapeutic regimens and to promote optimal disease-prevention strategies. Although what we know is dwarfed by what we do not know, this imbalance does not negate the current therapeutic power that the past 20 years of genomic research has revealed. We agree with the following assertions made by Loktionov[97]:

- There are many examples of effective research on gene–environment interactions.
- There is sufficient evidence to make clinical recommendations on the basis of individualized genomic predisposition.
- There is a need for research on traits that protect from, as well as predispose to, disease.
- Environment modification, especially dietary changes, may be the easiest and most efficient way to influence the risks of many diseases common today.

It is little wonder that Paul Berg, the pioneering researcher in recombinant DNA and genetic engineering and the winner of the Nobel Prize for Chemistry in 1980, once quipped, "At the time, our goal was to focus on the molecular and genetic basis of disease as the starting point for new forms of medicine."[99] However, it is equally true to say that all disease is environmental even when it is also genetic. The symphony between nature and nurture is the very essence of life and health for all creatures who call this Earth their home.

Hair Mineral Analysis

Nick Soloway, LMT, DC, LAc, and *Steve Austin*, ND*

OUTLINE

INTRODUCTION

Despite many research studies since the original publication of this chapter in 1985, there has been little change in the *diagnostic* value of hair analysis (HA). Outside its accepted use for monitoring of heavy-metal toxicity, at this time HA still has only limited clinical application.

In recent years, several attempts have been made to standardize HA testing techniques,[1,2] but laboratories still do not have an agreement on procedures for handling a hair sample.[3–5,6–8,2,9,10]

Many conditions and diseases have been tested for abnormal HA patterns, and a number have been shown to have patterns differing significantly from the norm, including the following:

- Learning disabilities[11–13]
- Birth defects[14,15]
- Hyperactivity[16–18]
- Down syndrome[19,20]
- Neurosis and psychosis[21]
- Senile dementia[22]
- Autism[23,24,25,26,27]
- Alopecia areata[28]
- Insulin-dependent diabetes mellitus[29,30]
- Cystic fibrosis[31]
- Beta-thalassemia[32]
- Spasticity in children[33]
- Repeated exposure to radiographs[34–36]
- Nasopharyngeal cancer[37,38]
- Aplastic anemia[39]
- Breast cancer[40,41,42]
- Bone mineral density[43,44]
- Type 2 diabetes[45]
- Alzheimer's disease[46,47]
- Hypertension[48,49,50,51]
- Hay fever[52]
- Atopic dermatitis[53]
- Insulin resistance/metabolic syndrome[54,55,56,57,58]
- Fibromyalgia[59]
- Hemodialysis[60]
- Amblyopia[61]
- Multiple sclerosis[62]
- Cancer[63,64,65–68,69,70]
- Bipolar disease[71]
- Schizophrenia[72]
- Parkinson's disease[73]
- In vitro fertilization (IVF) pregnancy[74]
- Preeclampsia[75]

HA has been used successfully to test for drug abuse,[76–82,83] and studies have been performed in several locations examining the validity of using HA to test for drug use before the reinstatement of driving licenses.[84,85] That said, however, drug metabolites are not found in most commercial hair analyses.

HA appears to offer potential as a correlating diagnostic tool in a few of the listed conditions, although the hair mineral patterns should not be used exclusively for diagnosis. For example, the high hair sodium values in infants with cystic fibrosis shows very little overlap with those in controls, and one study demonstrated that children with learning disabilities can be diagnosed with 98% accuracy because of a consistent pattern of high hair values of cadmium, manganese, and chromium in conjunction with low values of lithium and cobalt.[11] The usefulness of HA as a research tool hardly can be questioned. However, significant controversy exists about the use of the method for the clinical diagnosis of diseases other than heavy-metal toxicity and as an indicator of nutritional status. Moreover, multiple studies question the interlaboratory and intralaboratory accuracy of HA.[86,87,88–90,6-8,2,91] The difference between research and clinical use is significant. Whereas it may be of interest in a research setting that patients with various skin conditions have lower mean levels of hair magnesium than controls, the two groups overlap so much that the procedure is diagnostically

* Previous edition contributor

useless.[28] Moreover, even when an altered HA pattern has been associated with a disease, generally there are few investigations as to whether mineral supplementation would affect the clinical condition or even revert the hair mineral pattern to normal. Several studies have looked at the relationship between diet and hair mineral status.[49,92–96,51] with varying conclusions. Some showed some dietary influences on hair mineral status,[93–95,96,97] one showed no correlation,[95] and another showed variable correlation.[97] Not all hair minerals showed a relationship to intake, and many of the studies had limitations because of a limited time of reporting nutrient intake. Hair grows approximately 1.5 cm per month, so the hair sample usually contains mineral content outside of the nutrient reporting time. Growth rate also varies with ethnicity.[98] One study tested hair grown in a 2-year period and found a correlation between low hair Ca, Mg, Sr, and BA and an increased presence of hypertension.[51] Gender has been found to result in significant differences in hair minerals,[99,100] which can complicate the interpretation of test results. "Levels of elements in the hair are not strictly comparable between different areas of the world."[101]

Wide overlap of values in disease and control groups is frequently the case with HA, resulting in excessive false-positive and false-negative results. For example, mentally retarded patients have been found to have hair lead, sodium, and potassium hair values approximately twice those of controls,[19] but the standard deviations are extremely large for some minerals (for sodium, 1644.71 ± 1814.93 versus 744.43 ± 1987[28]; and for potassium, 870.15 ± 1009.19 versus 408.35 ± 689.99), and the large overlap greatly reduces the clinical use of HA. In addition, many of the altered HA patterns associated with the diseases previously listed are as yet unconfirmed.

MINERALS

Calcium and Magnesium

Hair calcium and magnesium values were found to be elevated in patients with fibromyalgia,[102] and another study found decreased levels along with iron and manganese.[59] Higher levels of calcium and magnesium were seen in amblyopic children.[61] Chronic stress in children had an association with elevated Ca/Mg ratios.[103] High hair calcium content has been associated with a reduced risk of coronary heart disease,[104] although higher levels were found in hypertensive, obese patients with insulin resistance.[49] Higher hair calcium was associated with an enhanced augmentation index, a measure of arterial stiffness.[105] Low hair calcium content has been found in the last trimester of pregnancy,[106] and hair calcium content increased in response to supplementation during pregnancy.[107] Low hair magnesium levels have been reported in autistic children, children with attention deficit hyperactivity disorder, patients with various skin disorders, and patients with several types of leukemia, whereas high levels have been reported in conjunction with dyslexia and Prader–Willi syndrome.[18,23,28,108–110] An increase in the Ca/Mg ratio seemed to correlate to increased insulin resistance.[55] In contrast, another study saw a decrease in hair calcium and magnesium in metabolic syndrome.[56] A decrease in the Ca/Mg ratio was seen in Parkinson's disease.[73] The meaning of these associations remains unknown for the most part, and contrasting findings make interpretation and usefulness questionable.

A 2001 study concluded that analysis of hair calcium and phosphorus content was of value as a complementary detection tool in abnormalities of bone metabolism.[111] Elevations in both calcium and magnesium were correlated with a low dietary calcium/magnesium ratio in one study, suggesting that this finding may be indicative of an induced hyperparathyroidism,[112] but that hypothesis remains unproven. Hair calcium and magnesium also vary in response to the hardness and pH of the water in which the hair is usually washed.[104] Water consumption from different sources was reported to change hair calcium and magnesium levels; higher hair levels correlated to an increased risk of kidney stone formation.[113] Supplementation of dietary magnesium has been reported to increase hair magnesium levels in deficient children.[114] Nonetheless, in one study of congenital hypomagnesemia, researchers concluded that hair magnesium level was not a useful tool in monitoring mineral status because the values were higher in affected subjects than in subjects who were not deficient.[115] A 2013 study showed that a high hair calcium level was associated with low calcium intake and low bone mineral density.[44]

There is limited evidence to support the use of hair calcium and magnesium measurements in clinical diagnosis at this time.

Chromium

Hair chromium content is low in insulin-dependent diabetics,[30] although there is much overlap with normal persons. Increased insulin resistance was associated with lower hair chromium,[55,58] Chromium levels decrease with age,[32] but the meaning of this change remains unknown. Hair and tissue chromium levels vary greatly during pregnancy, being very high during the first few months of normal pregnancy and subsequently decreasing.[116,117] Late in pregnancy, hair chromium content typically becomes low,[118] suggesting deficiency.[76] However, high hair chromium value in pregnancy is associated with low-birth-weight infants.[119] In patients with gestational diabetes, hair chromium content is high early in pregnancy but decreases in late pregnancy.[117] Increasing dietary intake of chromium has been linked to increasing hair chromium values,[120] but supplemental chromium does not seem to alter hair levels.[116,121] Chromium was found to be higher in patients with a fixed orthodontic appliance. The range of amounts was 8.94 ± 13.1 μg, although the mean was stated to be above the 90th percentile.[122]

Although normal and deficiency ranges should be more clearly defined, hair chromium content appears to have potential future use in clinical settings. However, current knowledge remains inadequate to help clinicians treat patients on the basis of abnormal hair chromium levels alone.

Copper

Oral contraceptive use is associated with decreased hair copper and increased serum copper.[123] High hair copper levels are associated with being female, lactation, idiopathic scoliosis, and pregnancy in some but not all studies.[124–127] Surprisingly, conditions that affect systemic copper status have been shown not to affect hair levels. Copper deficiency,[128] Wilson disease,[129,130] and cirrhosis[131] do not significantly alter hair copper content. Hair copper levels also vary with geographical location.[132] However, fur and liver copper values have been found to correlate in rats,[131] and one study reported that supplemental copper raises hair copper levels.[133] Hair color also has been found to influence the levels of copper in the hair.[127,134]

At this time, hair copper measurement appears unreliable for clinical application.[124]

Manganese

Levels of hair manganese in mothers of infants with congenital malformations and their offspring were significantly lower in one study,[14] which suggest that maternal hair manganese levels may be used as an indicator of the risk for malformations. Hair manganese was inversely associated with working memory in children[135] but found not to correlate with developmental scores.[136] Both nonsignificantly altered[137] and normal levels of manganese[138] have been

reported in patients with epilepsy.[137] Hair manganese values have been reported to be elevated in people with violent behavior, with varying levels of significance.[138,139] Manganese was lower in fibromyalgia,[59] in children with amblyopia,[61] and in rheumatoid arthritis.[140] Evidence that manganese supplementation affects behavior does not appear to exist at present.

Hair manganese may serve as a useful research tool in the study of altered behavior, but the most promising value of hair manganese may lie in the prediction of congenital malformations.

Selenium

Levels of selenium in well water and hair show good correlation.[141] High hair selenium levels are seen in toxicity[142,143] and hyperlipidemia,[144] and low levels are seen in deficiency.[145] Low hair selenium values have been reported in babies with neural tube defects and their mothers.[15] Selenium appears to be transferred transplacentally as measured by hair analysis.[146] Lower selenium was seen in patients with phenylketonuria,[147] cancer,[63,67,68] bipolar disease,[71] and steatohepatitis.[148] Tissue selenium values reflect short-term variations in intake,[82] and hair levels of the element rise significantly after supplementation.[149,150]

As with chromium, insufficient data are currently available to establish reliable norms for measurement of hair selenium values, and the incidence of false-positive and false-negative results remains unknown. Hair selenium measurement shows promise for clinical use when these problems are resolved, although they haven't been as of this writing.

Sodium and Potassium

It is generally accepted, even by proponents of HA, that hair sodium and potassium do not reflect dietary status. High elevations of hair sodium may be diagnostic in cystic fibrosis[31] but require confirmation. A relatively low Na/K ratio has been reported in celiac disease.[151] Although many HA advocates cite low hair sodium and potassium as indicative of "adrenal exhaustion," the only (preliminary) study exploring this subject reported that hair sodium and potassium do not correlate with adrenal function.[152] There have not been any subsequent studies. Except for cystic fibrosis, hair sodium and potassium appear to hold little promise for clinical use.

Zinc

Hair zinc levels have received more research attention than any other mineral. Low hair zinc has been associated with zinc deficiency, anorexia nervosa, hyperactivity, gender, age, atherosclerosis, beta-thalassemia, vegetarianism, lung cancer, leukemia, celiac disease, epilepsy in males, epilepsy in general, short stature in childhood, poverty, insulin-dependent diabetes mellitus, neural tube defects, Alzheimer's disease,[46] hypertension,[48] atopic dermatitis,[153] breast cancer,[153] schizophrenia,[72] hypertension,[154] prostate cancer,[67] liver cancer,[150] poor growth in children,[155] and during pregnancy.[17,29,32,108,156–174] It also has been reported in neonates if the time between pregnancies is short.[175] High hair zinc was associated with low serum zinc in Kashin–Beck disease.[175]

Because a few of these conditions have been associated with potential zinc deficiencies and supplemental zinc has been shown to increase hair zinc levels,[154] practitioners who use HA often rely on hair zinc as an indicator of zinc status. However, one trial reported that hair zinc levels declined after supplementation.[107,156,157,168,176,177]

Other factors that affect hair zinc levels also interfere with the clinical use of this tool. Shampooing and dyeing affect hair zinc levels,[178] as do the sex of the subject,[178–182] age,[127] and hair growth rate. Malnourished children have shown both low[171,183,184] and high[185] hair zinc.

Poor correlations between hair zinc and height,[187] weight, and zinc consumption also have been reported,[133,179] although one study reported a correlation among hair zinc, weight, and zinc consumption.[186] Another study found that obese people of both sexes had higher hair zinc than those of normal weight and that there was a correlation between the degree of obesity and higher hair zinc levels.[187]

Although low hair zinc levels have been reported in patients with insulin-dependent diabetes mellitus,[176] there is generally considerable overlap between cases and controls. To further complicate the picture, in a study of female descendants of noninsulin-dependent (NIDDM) parents, hair zinc was found to be significantly higher compared with women with no family history of NIDDM.[188]

At this time there is no definitive understanding of the meaning of abnormal hair zinc levels. The hypothesis that high hair zinc levels reflect acute deficiency, whereas low levels indicate chronic deficiency, remains unproven.

Other Minerals

Hair iron was found to correlate positively with serum ferritin[189] and other laboratory markers of iron status,[190] although the clinical relevance of this finding is unclear.[191] Hair lithium has been reported to show a linear response to extradietary sources.[13] Low hair levels of lithium also have been reported in conjunction with heart disease, learning disability, and violent behavior.[13] However, research findings are far from the point at which hair lithium could be used to help clinicians diagnose or treat these conditions.[13] It is suggested that whole-body iodine status can be assessed with HA.[192]

DRUG ABUSE

HA has been used to detect drugs of abuse and their metabolites when urine tests were negative.[76,78] Hair analysis has been used as evidence in a court of law concerning past drug abuse.[77] Although there are concerns about the role of HA in testing for drug abuse,[193] HA does seem to be a valuable tool in drug screening.[79–82,194] As mentioned, drug metabolites and not mineral levels are measured in these trials, and drug metabolites typically are not reported on most commercially available hair analyses.

RATIOS

The experimental documentation for most of the "ideal" ratios that have been published by several HA companies has not been substantiated in the research literature. The Zn/Cu ratio has been reported to be altered in violent patients.[139] This ratio was also elevated in survivors of myocardial infarcts.[195] Ca/Mg ratios were elevated in insulin resistance[55] and stress[102] coronary artery calcification.[196] Strong correlations between several mineral ratios and atherosclerosis also have been reported[197]; however, the clinical significance of these ratios is not known. The Mg/Zn ratios helped separate healthy (<1/1) from epileptic (>1/1) subjects in one study.[165]

DISCUSSION

Hair mineral analysis is conceptually enticing and potentially a valuable clinical tool. However, problems abound with standardization of sampling, handling, and analysis of hair samples.[86,87] Additionally, reference values can differ widely,[198,199,10,200] and many variables affect the results.[201]

BOX 16.1 Factors That Affect Hair Mineral Composition

- Gender[134,99,100,211]
- Age[134,212,213]
- Ethnicity[98]
- Environment[214–216,101,211]
- Hair color[127,134]
- Cold waving
- Bleaching
- Exogenous contamination[104]
- Variations in mineral content within a given sample

This is further aggravated by the reporting of different results on the same sample from different laboratories.[87,202,90,7] The distribution of elements within the lipid and nonlipid portions of hair and the treatment of the sample before testing may explain these variances.[5,203,8] As noted, dietary intakes do not consistently correlate with hair levels, and hair color, sex, age, and other variables appear to significantly affect levels of some minerals. Separate norms for age, gender, and hair color are now being established.[127,204,205,99] However, reviews of the literature attempting to establish reference values continue to show a large variance in mean values, standard deviations, and ranges.[132,206,57,91] Although many laboratories make nutritional recommendations, there is no basis for the nutritional advice suggested by some laboratories. See Box 16-1.

Several studies have concluded a diagnostic value of HA[53,64,105,69,192,70] in specific circumstances. However, to date, there haven't been additional studies validating the results of these studies, which reduces the power of their conclusions.

As a result of the gulf between available information on the one hand and the clinical interest of some practitioners on the other, several articles have appeared decrying the misuses of HA.[86,87,207–209] Hambidge[208] has said, "There is a wide gulf between the limited and mainly tentative justification for their use on an individual basis and the current exploitation of multielement chemical analysis of human hair."

Klevay and associates[210] acknowledge the experimental usefulness of HA but go on to say that "its use in clinical medicine for diagnosis, prognosis, and therapy will remain limited until validation by the standard methods of clinical investigation is achieved." Steindel and Howanitz[209] conclude the following:

> *Physicians and other health care professionals who are considering ordering hair analysis to assess nutritional status or who are basing nutritional counseling or therapy on hair analysis should reconsider this approach unless and until the reliability of hair analysis value is established and evidence becomes available that clinical recommendations based on hair analysis improve patient outcomes.*

Even though these comments are over a decade old, the conclusions are still pertinent. The accumulated results of several hundreds of studies do not warrant the use of HA as an independent diagnostic tool. The widespread use of speculative diagnostic procedures invites condemnation, especially when the burden of these speculations falls on the pocketbook and psyche of the patient. HA is a valid and useful screening tool for toxic metal exposure (lead, mercury, cadmium, arsenic, and selenium) and drugs of abuse. It has the potential of becoming a clinical tool of considerable use in other areas. The current nonstandardization of laboratory procedures is more likely to hinder this development than to help it.

Heidelberg pH Capsule Gastric Analysis

Stephen Barrie, ND, PhD, and *Michael T. Murray, ND*

OUTLINE

INTRODUCTION

Proper digestion is a prerequisite for optimum health, and incomplete or disordered digestion can be a major contributor to the development of many diseases. The problem is not only that ingestion of the best nutritional substances may be of little benefit when breakdown and assimilation are inadequate but also that incompletely digested macromolecules can be inappropriately absorbed into the systemic circulation. This process can lead to various immune complex deposition diseases and is now theorized to be an integral part of the etiology of food allergies.

Adequate gastric hydrogen chloride (HCl) is also necessary for the protection of the gastrointestinal tract from ingested pathogens and for the maintenance of the intestinal microbiome. Healthy gut flora is known to be important for proper immune function, vitamin absorption, and the prevention of opportunistic infections such as *Candida albicans* in the gut.

The Heidelberg gastric analysis technique was developed to measure the hydrogen ion concentration (pH) of the digestive tract and determine the acid secretory ability of the parietal cells. Its use of radiotelemetry allows the gathering of this important information in a convenient and accurate manner.

The Heidelberg pH capsule system had its origin about 50 years ago at Heidelberg University in Germany. In research sponsored by Telefunken, a West German electronics firm, the inventor H. G. Noeller studied gastric acidity in 10,000 people. Since then, about 140 studies, according to a PubMed inquiry, have used the Heidelberg system to investigate various aspects of digestion.[1–7] Physicians and researchers now use this technique for measuring the pH of the digestive system.

PHYSIOLOGY OF DIGESTION IN THE STOMACH

The epithelium of the stomach contains many gastric glands. These tubular glands consist of parietal, chief, and mucous cells. The antral portion of the stomach produces the digestive hormone gastrin, the release of which is stimulated by the following:

- Vagal nerve stimulation
- The physical bulk of the ingested food distending the stomach
- Partially digested proteins

After gastrin is absorbed into the bloodstream, it is carried to the gastric glands, where it stimulates the parietal cells to produce HCl acid and, to a lesser extent, the chief cells to produce digestive enzymes (such as pepsin and intrinsic factor). With adequate stimulation, the parietal cells increase their production of HCl by as much as eightfold.

When the pH of the stomach reaches about 2, the gastrin mechanism becomes blocked, and feedback causes the parietal cells to decrease the production of HCl. This concentration of hydrogen ions (by a factor of 100,000) is an energy-dependent process.

Dietary protein is composed of amino acids held together by peptide linkages. Pepsin A, the major gastric protease, cleaves these in the stomach and is most active at pH values of between 2 and 3. It is inactive at a pH of 5 and above. Consequently, to have any significant digestive effect in the stomach, the gastric juices must be acidic.

Trypsin (a protein-splitting enzyme secreted by the pancreas) completes the process, yielding amino acids and dipeptides. The biochemical messenger that stimulates this pancreatic secretion is the acidic bolus of food moving from the stomach into the duodenum.

PROCEDURE

Equipment

The Heidelberg system consists of the following equipment:

- Radiotelemetry capsule—a hard plastic capsule (about 2 cm long × 0.8 cm in diameter) that contains a miniature radio transmitter, a pH sensing device, and a saline-activated battery
- Waistband antenna—receives the signal from the capsule and relays it to the receiver
- Receiver/recorder—receives and translates the signal. The pH reading is displayed on a meter and recorded by a continuous printer for a permanent record. The receiver also contains a calibration probe used to calibrate each capsule with known pH 1 and 7 solutions.
- Heater block—maintains the calibrating solutions at 37°C

Methods

The test can be conducted in two ways: the tethered capsule repeat challenge and the flow-through method. Each gives different information and has its advantages and disadvantages. For both procedures, the test begins after the patient has fasted (food and liquid) for 8 hours.

The Tethered Capsule Repeat Challenge

In the tethered capsule repeat challenge, the capsule is tethered so that it remains in the stomach while the stomach is challenged by the ingestion of a saturated sodium bicarbonate solution (i.e., baking soda).[8] The challenge solution triggers a rise in stomach pH and a subsequent attempt by the parietal cells to reestablish appropriate acidity. The majority of people have a normal initial pH of between 1 and 2.3. Abnormalities of stomach secretions are usually found only after the stomach is challenged. (A more involved protocol can be found in Wright.[8])

The procedure is as follows:

1. The waistband antenna is fastened around the patient's waist, and the receiver/recorder is turned on and calibrated.
2. The patient swallows the capsule, which is attached to a 1-m-long, thin cotton thread (a small amount of distilled water is allowed). The pH reading typically starts at 7 and falls toward 1. After about 5 minutes, the capsule reaches the bottom of the stomach (which normally displays a pH of between 1 and 2), and the remaining thread is taped to the cheek to prevent movement of the capsule out of the stomach and into the intestine.
3. If the fasting pH is normal, the patient swallows the first challenge of 5 mL of the alkaline solution. Within 30 seconds, the pH normally rises to 7, and the patient is asked to lie down on his or her left side (to keep the stomach contents in as long as possible).
4. If stomach function is normal and acid is secreted sufficiently in response to the alkali challenge, the pH returns to normal (between 1 and 2) within 20 minutes.
5. The challenge is repeated up to four times, as long as the response time is within 20 minutes.

Flow-Through Capsule

In the procedure for the flow-through capsule, the capsule is not tethered to a thread and is allowed to move freely from the stomach into the duodenum and the rest of the small intestine. The proponents of this method claim that this allows measurement of the gastric emptying time and intestinal pH, both of which are important parameters.

INTERPRETATION

Results may be classified as normal, hypochlorhydria, achlorhydria, and hyperchlorhydria.

Normal. The patient successfully reacidifies after four challenges (Fig. 17.1). Curve number 1 shows the capsule entering the digestive tract, number 2 shows the capsule reaching the bottom of the stomach and alkaline challenge occurring, and number 3 shows a pH rise after swallow and subsequent reacidification within 20 minutes.

Hypochlorhydria. The patient requires more than 20 minutes to reacidify (Fig. 17.2). Curve number 1 shows a pH of 1 being reached after 30 minutes. Note that on the third challenge, the pH comes back only to about 4.

Achlorhydria. The patient's stomach shows little acid secretion and is not able to secrete enough acid to bring the pH below 4, even on the first challenge (Fig. 17.3). The pH remains at about 4.2 for almost 2 hours.

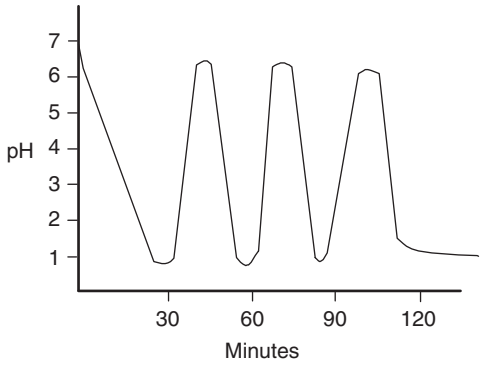

Fig. 17.1 Normal Heidelberg gastrogram.

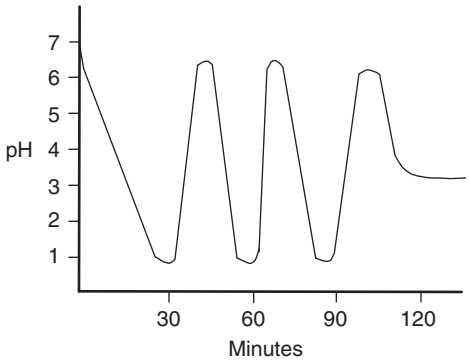

Fig. 17.2 Hypochlorhydric gastrogram.

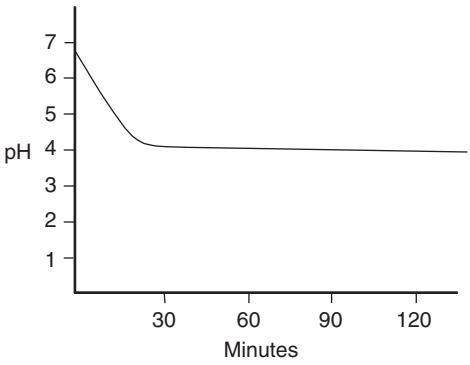

Fig. 17.3 Achlorhydric gastrogram.

Hyperchlorhydria. The gastrogram shows extremely rapid reacidification (within 5 minutes) after each challenge.

Depending on specific curve components, some investigators believe that mucous quantity, fresh or chronic ulcers, and acute gastritis conditions can sometimes be identified.

CLINICAL APPLICATION

Gastritis, indigestion, heartburn, and symptoms of gastroesophageal reflux can be associated with either HCl deficiency or excess. Proper distinction is important for several obvious reasons. Patients with hypo- or achlorhydria incorrectly treated for hyperacidity via acid-blocking drugs may experience symptom relief but also further deterioration of the intestinal structure, function, and intestinal microbiome. Direct measurement of gastric acid secretion through endoscopy, intubation, and aspiration is uncomfortable and unacceptable to many patients. The Heidelberg pH

BOX 17.1 Common Symptoms of Low Gastric Acidity

- Bloating, belching, burning, and flatulence immediately after meals
- A sense of "fullness" after eating
- Indigestion, diarrhea, or constipation
- Multiple food allergies
- Nausea after taking supplements
- Itching around the rectum

Modified from Wright JV. *Healing with nutrition.* Emmaus, PA: Rodale Press; 1985.

BOX 17.2 Common Signs of Low Gastric Acidity

- Weak, peeling, and cracked fingernails
- Dilated capillaries in the cheeks and nose (in nonalcoholics)
- Postadolescent acne
- Iron deficiency
- Chronic intestinal parasites or abnormal flora
- Undigested food in stool
- Chronic candidal infections
- Upper digestive tract gassiness

Modified from Wright JV. *Healing with nutrition.* Emmaus, PA: Rodale Press; 1985.

capsule system offers a convenient and accurate outpatient testing system to clinicians interested in evaluating *functional* gastric acid output.

HCl, pepsin, and intrinsic factor are directly involved in digestion and contribute to the chemical changes in the intestines that assist in the absorption of many nutritional factors. For example, vitamin B_{12} absorption requires intrinsic factor, whereas zinc, calcium, and iron are less efficiently assimilated when gastric acidity is low.[9–11]

INDICATIONS

Many symptoms and signs suggest impaired acid secretory ability, and a number of specific diseases have been found to be associated with achlorhydria and hypochlorhydria (particularly gastric carcinoma and human leukocyte antigen-B_8–related autoimmune diseases). These are listed in Boxes 17.1, 17.2, and 17.3.[12–23] The presence of *Helicobacter pylori* is a major factor in both achlorhydria and hypochlorhydria.[24,25] *H. pylori* induce strong inflammatory responses and a transitory hypochlorhydria, which can progress in ~2% of patients to atrophic gastritis, dysplasia, or gastric adenocarcinoma.

Aging

Numerous studies have shown that acid secretory ability decreases with age. Low stomach acidity has been found in more than half of those older than age 60.[26,27] One study of the elderly found that their tissue

BOX 17.3 Diseases Associated With Low Gastric Acidity

1. Addison's disease
2. Asthma
3. Celiac disease
4. *Dermatitis herpetiformis*
5. Diabetes mellitus
6. Eczema
7. Gallbladder disease
8. Gastric carcinoma
9. Grave's disease
10. Chronic autoimmune disorders
11. Hepatitis
12. Human immunodeficiency virus/acquired immunodeficiency syndrome
13. Chronic hives

23. Thyrotoxicosis
24. Hyperthyroidism and hypothyroidism
25. Vitiligo

Data from references 12 through 24.

nutrient levels could be saturated only through the use of intramuscular supplementation; oral supplementation was ineffective. The authors speculated that this was caused by atrophy of various digestive organs.[28]

CONCLUSION

The Heidelberg pH capsule system is an effective and convenient method to determine gastric acid secretory ability under conditions simulating ingestion of food. The results are extremely valuable in identifying the large number of people who have impaired secretion function. The ramifications of impaired acid secretion are widespread. This technology has become an accepted method of assessing gastric pH in several research settings.

Immune Function Assessment

Heather Zwickey, PhD, and *Brice Thompson, ND, MS*

OUTLINE

INTRODUCTION

Immune physiology involves complex interactions between cells and proteins to mediate an effective response to infectious disease. A healthy immune system eliminates pathogenic microbes while simultaneously creating a biodynamic relationship with normal microflora. Because the immune system must also effectively distinguish between dangerous foreign invaders and self-antigens, immune dysfunction can result in infection, autoimmunity, cancer, allergies, and asthma. Healthy immune function is affected by age, gender, sleep, nutrition, environmental toxins, and exercise. Natural therapies such as herbs, meditation, hydrotherapy, and supplements can also enhance and manipulate immune reactions.

A variety of tests can be used to evaluate the immune system. To determine what type of immune assessment to use for each clinical diagnosis, it is important to understand how underlying immune physiology contributes to a clinical picture. Clinicians can assess the qualitative or functional activity of immune cells. Qualitative data may include things like types, number, and activation states of cells. Cells of the immune system express different proteins on their surface. These proteins, called biomarkers, allow identification of different cells as well as their activation state. To assess immunodeficiency and lymphoproliferative diseases, the number of T cells and B cells must be quantified. Analysis of the functional activity of immune cells involves putting the cells into an in vitro assay system; adding antigen or mitogen; and measuring a function such as cytotoxicity, cytokine production, or antibody secretion. The levels of proteins that are produced by lymphocytes and monocytes, such as cytokines and antibodies, can be analyzed as well. Tests of genetic predisposition to disease can be evaluated with genetic tests. An overview of the assays used to measure cells is given in Table 18.1. A description of these tests is provided in Box 18.1.

ANTIBODIES

Blood

Antibody (also called immunoglobulin) is a protein made by B cells in response to an antigen. Each B cell has specificity for one antigen. This specificity is determined by gene rearrangement long before a B cell ever encounters an antigen. The antibody is found both on the surface of B cells and is secreted. B cells are primarily found in the lymph nodes, Peyer's patches of the gut, and the spleen (80%); however, antibody is readily detectable in the blood and other bodily fluids.

Antibodies look like the letter "Y" (Fig. 18.1). Each part of the antibody has a different function: the arms bind specifically to antigen, whereas the base (the Fc region) allows the antibody to bind to receptors. This base region is called the "isotype." Antibodies come in multiple isotypes based on the constant region of their heavy chain. These different isotypes have functional importance. Some isotypes are better than others at triggering the complement cascade. The Fc receptors of other isotypes allow them to activate specific cells, such as mast cells and eosinophils.

Antibodies are essential to measuring immune function because they can act as both an indicator of disease and as a tool to measure the levels of other proteins and cells. Monoclonal antibodies are a powerful tool (see Box 18.2).

Measuring serum antibody is essential in patients who have repeated or severe infections. Low antibody levels in these patients may indicate

TABLE 18.1 Overview of Assays to Measure Specific Immunity

Type of Immunity	Assays
Humoral immunity	Antibody production: ELISA, cytometric bead array
Cellular immunity	Cytokines: ELISA, ELISPOT, cytometric bead array, RIA, intracellular cytokine staining
	Cytotoxicity: 51 chromium release assay
	Proliferation: CFSE, lymphocyte proliferation assay
Genetics	SNPs genetic microarray

CFSE, Carboxyfluorescein succinimidyl ester; *ELISA,* enzyme-linked immunosorbent assay; *ELISPOT,* enzyme-linked immunosorbent spot; *RIA,* radioimmunoassay; *SNP,* single-nucleotide polymorphisms.

BOX 18.1 Testing Methods

ELISA

The enzyme-linked immunosorbent assay (ELISA) is an assay used to measure proteins of the immune system. In ELISA, an antigen is fixed to the surface of a 96-well plate, and then a specific antibody is incubated with the antigen so that it forms an immunocomplex. This antibody is linked to an enzyme that allows the antigen to be converted into a detectable signal, most often a change in color. The more antigen that is present, the darker the color.

ELISPOT

A variation of the ELISA is the enzyme-linked immunosorbent assay (ELISPOT). Peripheral blood mononuclear cells (PBMCs) are plated on a filter-bottom 96-well plate coated with anticytokine antibody. The plate is cultured for 24 to 48 hours to allow cytokine secretion and capture on the plate. Cells are washed off and detector antibody is added, followed by an enzyme substrate. Cytokine-secreting cells are identified as spots of secreted cytokine.

Cytometric Bead Array

A cytometric bead array uses multiplexed beads labeled with capture antibodies for specific analytes, such as cytokines or other serum proteins. Serum is added together with Phycoerythrin (PE)-labeled detector antibody. The antibody-antigen complex is run through the flow cytometer, and software calculates the level of each analyte based on PE fluorescence of each bead population relative to a standard curve.

Intracelluar Cytokine Staining

The intracellular cytokine-staining technique uses the flow cytometer to ensure production of cytokines in short-term stimulated whole blood or PBMCs before the cytokines are secreted from the cells. One advantage of this assay is that multiple cell-surface and intracellular markers can be analyzed in combination using multiparameter flow cytometry.

Chromium-51 Release Assay

To test the ability of CD8 T cells or natural killers (NKs) to kill, target cells are incubated with a radioactive isotope of chromium-51, which can be released when the cell dies. The CD8 T cells or NKs are then placed in serial dilution with the antigen-presenting cells. Antigen is added in the case of the CD8 T cells. When the target cells are killed by the CD8s, the amount of radioactivity or enzyme can be analyzed.

Lymphocyte Proliferation Assay

The proliferation capability of T cells can be measured by isolating PBMCs, separating the T cells, and incubating with tritiated thymidine (^{3}H). A mitogen such as lipopolysaccharide is added to the cell culture. This mitogen may induce cell proliferation. As the cells divide, they incorporate the ^{3}H into the DNA, and analysis of radioactivity can determine how many cell divisions occurred. An ELISA may also be performed to measure cytokine production by the CD4 T cell.

Carboxyfluorescein Succinimidyl Ester

Carboxyfluorescein succinimidyl ester (CFSE) can be used to measure cell division. In this assay, the parent cell is incubated with CFSE, which is incorporated into DNA during cell division. As the cell divides, each of the daughter cells contains half of the CFSE stain. Every subsequent cell division halves the amount of CFSE in the daughter cells. When these cells are run through a flow cytometer, a characteristic pattern is seen (see Fig. 18.2).

an immunodeficiency. Patients with myelomas and lymphoproliferative disorders may have high antibody levels. For example, patients with alcoholic liver disease often have a polyclonal expansion of immunoglobulin-A (IgA), whereas patients with systemic lupus erythematosus (SLE) and Sjögren's syndrome have polyclonal IgG expansion.[1]

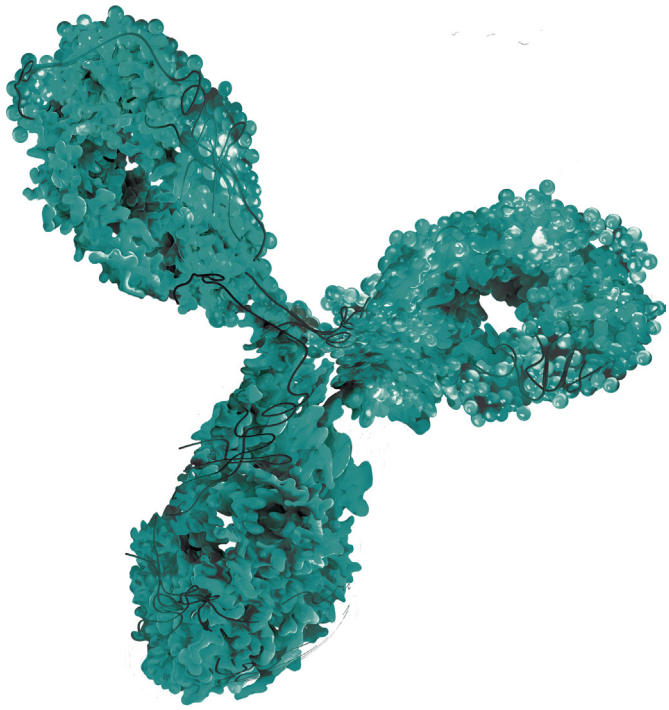

Fig. 18.1 Molecular structure of a human antibody. (mirror-images/iStock.com)

BOX 18.2 Monoclonal Antibodies

One of the primary tools used in many of the assays for immune function is the monoclonal antibody. Monoclonal antibodies are the product of a single B cell. To generate a monoclonal antibody, an antigen is injected into an animal, and the resultant B cells are isolated. These B cells are diluted, and a single B cell is fused with a nonsecreting myeloma cell line to form hybrids. These hybrids then produce the monoclonal antibodies highly specific for the injected antigen. In contrast, when an animal is injected with an antigen, polyclonal antibodies are generated. Many different B cells specific for that antigen release antibody, which is harvested and purified. This collection of antibodies is called polyclonal because, unlike monoclonal antibodies, it has many specificities to the same antigen. Polyclonal and monoclonal antibodies can be tagged with enzymes for fluorescence to detect the original protein antigens for which they are specific.[1]

Many proteins have monoclonal antibodies specific for them, including cell-surface markers, cytokines, and even other antibodies. The quality of the monoclonal antibody can determine the sensitivity and specificity of the test used.

The type of isotype made by B cells can provide clues as to the immunological status of the patient (Table 18.2).

The route and duration of exposure, type of antigen, and genetic background may all affect the isotype of antibody that is produced, as well as the subclass of antibody produced. Upon immediate exposure to a novel infectious organism, the body produces immunoglobulin-M (IgM). After the B cell makes IgM, it class switches to another isotype, as determined by a combination of activation proteins and cytokines. If the patient has been exposed to an infectious agent, the antibody usually will class switch to IgG.

Immunoglobulin-G

IgG is the major antibody found in blood, and it consists of four subclasses, originally described in the 1980s according to their abundance

TABLE 18.2 Antibody Function

Isotype	Serum Levels[a]	Subclasses	Function/Description
IgM	0.5–2.0		Secreted during initial infection; makes large antibody–antigen complexes
IgD	Trace		Function unknown
IgG			Coats microorganisms, making them more likely to be phagocytosed by macrophages, dendritic cells, and neutrophils; neutralizes toxins
	5.0–12	IgG1	Responds to protein antigens
	2.0–6.0	IgG2	Primarily responds to polysaccharide antigens; binds poorly to Fc receptors
	0.5–1.0	IgG3	Responds to protein antigens
	0.1–1.0	IgG4	Response to repeated antigenic exposure; binds poorly to Fc receptors
IgE	Trace		Binds to Fc receptors on mast cells/eosinophils and basophils to elicit allergic response; also involved in response to parasites and worms
IgA			Provides protection at mucosal surfaces
	0.5–3.0	IgA1	Monomeric form found in blood; can trigger inflammation through FcαR1
	0–0.2	IgA2	Dimeric form found in secretions like tears, saliva, and breast milk

Ig, Immunoglobulin.
[a]Serum levels presented in grams per liter.

in serum. IgG1 and IgG2 are present in much higher concentrations than IgG3 and IgG4. All subclasses of IgG are low in pediatric populations. Deficiency in some IgG subclasses results in increased susceptibility to bacterial infections.[2] IgG subtypes vary in their ability to activate complement and Fc-receptor binding. IgG3 has a strong affinity for Fc receptors and has the greatest ability to activate complement. The type of antigen can influence the subclass of antibody response. For example, IgG2 antibodies appear to influence polysaccharide antigens, whereas protein antigens and whole bacteria preferentially elicit IgG1.[3–5]

IgG4 antibodies, found at the lowest concentration in the serum, are generated to repeatedly presented antigens. IgG4-deficient individuals may be more susceptible to pyogenic infections of the respiratory tract. Antibodies against dietary antigens are frequently IgG4. In a community survey of 40 individuals, antifood antibodies to milk, egg, and fish of the IgG4 subclass were found in a significant proportion of a healthy population, indicating that IgG4 antibodies against food antigens cannot serve as markers of atopic disease. Because IgG4 cannot activate complement, it has been hypothesized that it may serve for protective clearance mechanisms and may be a desirable response to dietary antigens.[6] IgG1 and IgG2 have also been found for dietary antigens, but the immunological outcome of these subclasses may be food intolerance that is not caused by immunoglobulin-E (IgE)-mediated hypersensitivity.[7] A larger discussion of the immune response to food can be found in Chapter 14.

Antibodies of each of the IgG subclasses can be detected by a variety of techniques, including radioactive iodine labeling; antigen-coated red cells; immunofluorescence with antigen-coated Sepharose; radioimmunoassay (RIA); and, most commonly, enzyme-linked immunosorbent assay (ELISA) with monoclonal antibodies (Fig. 18.2).[8]

Immunoglobulin-A

IgA can also be made to infectious agents and occurs in two forms, IgA1 and IgA2. IgA in serum predominantly exists in the monomeric form, IgA1. The ratio of IgA1:IgA2 in serum is about 9:1. IgA found in secretions, termed secretory IgA, occurs as dimers. The ratio of IgA1:IgA2 in secretions varies, but it is approximately 6:4 in saliva.[9] Because IgA is found at mucosal surfaces and lines the mucosal surface of the gut, it is not uncommon to find IgA antibody specific for food antigens. Because IgA is at high levels in secretions, it can be found in saliva in addition to serum, and salivary IgA tests are readily available.[10,11]

Immunoglobulin-E

An immune response to parasites, specifically worms, triggers an IgE response.[12] IgE elicits an immune response by binding to Fc receptors on mast cells, eosinophils, and basophils, causing degranulation and cytokine release. In atopic individuals, IgE is also made to allergens. IgE is at low levels in the blood. Measurement of total serum IgE is useful in patients in whom parasitical infection is suspected, but it is not valuable for measuring allergies. Thus the most common method for allergy testing is the skin-prick test.[13] In this test, a small amount of the suspected allergen is placed on the skin. Then the skin is pricked so that the allergen goes under the skin's surface. If the patient is allergic to the allergen, swelling and redness will appear within 15 to 20 minutes.

Total Antibodies

Measuring total antibody in blood involves protein electrophoresis or ELISA and is valuable. However, quantifying the total amount of antibody specific for an antigen is even more desirable. Antibody titers for common antigens, such as those found in vaccines, can be ordered. Each laboratory has its own reference levels for titers because the sensitivity of the test is related to the specificity and affinity of the reagents used.

Autoantibodies

Specific antibodies, rather than total levels, are also measured for circulating autoantibodies. These antibodies can be detected with immunofluorescence, RIA, and ELISA.[14] Indirect immunofluorescence is a method often used to investigate autoantibody presence, specifically Antinuclear antibody (ANA). This method involves growing liver cells in a petri dish, exposing the cells to patient serum, then washing any excess antibody away. If the serum contains ANA, these antibodies will stay attached to the nuclear region of the liver cells. The plate is then incubated with an antibody that has a fluorescent tag and is specific to human IgG. When examined under a microscope, a nuclear staining pattern can be observed if the patient has ANA (Fig. 18.3). If the patient does not have ANA, a more diffuse staining pattern occurs. This method is the least sensitive of all the antibody tests, yet it is the gold standard in diagnosing several autoimmune conditions, such as systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA).[15] Another method of immunofluorescence antibody visualization uses the patient's tissue as opposed to human cells in a petri dish. This method takes patient tissue that is frozen, and sections are cut on a

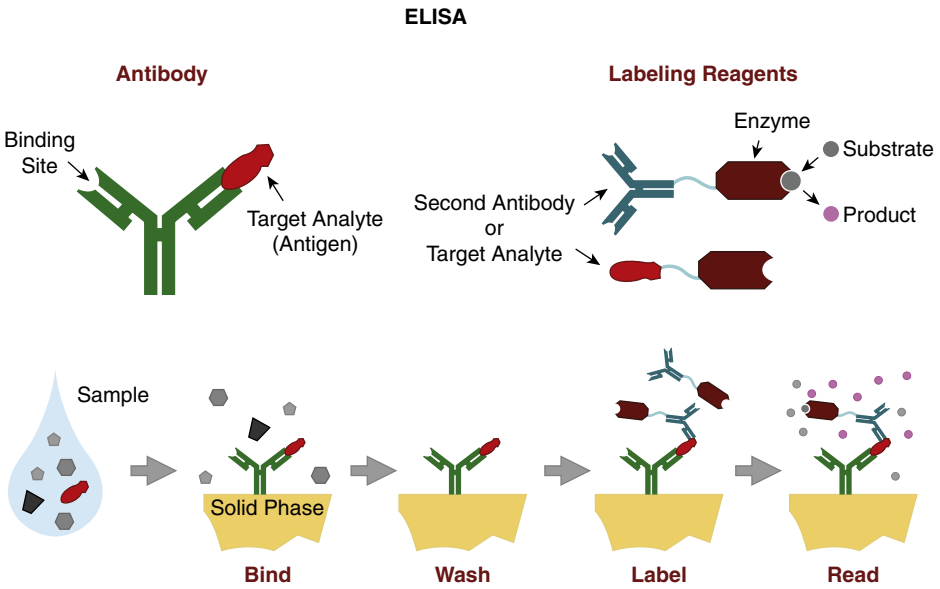

Fig. 18.2 Enzyme-linked immunosorbent assay (ELISA). A capture antibody specific for an antigen in a sample is attached to the bottom of a plate. The sample (blood, saliva, etc.) is added, and excess sample is washed from the plate. A secondary antibody also specific for the antigen is added to the plate. This secondary antibody is labeled with an enzyme. When the substrate for the enzyme is added to the plate, it elicits a color change. The intensity of the color, as measured by spectrophotometry, indicates the amount of antigen that is present.

Pattern	Associated Antigens	Clinical Associations
	Double stranded DNA, histones, DNA/histone complexes, others	SLE, drug-induced lupus, and other conditions
	"ENA antigens": Sm, RNP, SS-A/Ro, SS-B/La Nuclear matrix antigens: (hnRNP), others	Autoimmune rheumatic diseases: SLE, MCTD, Sjögren's syndrome, and other conditions
	Centromere proteins A, B, C located at the kinetochore plates	Scleroderma (CREST syndrome) primary biliary cirrhosis
	Fibrillarin, RNA polymerase, NOR-90, Scl-70, Pm/Scl, ribosomal antigens, others	Autoimmune rheumatic diseases: scleroderma, myositis, SLE, and others

Fig. 18.3 Antinuclear antibody (ANA) immunostaining pattern and clinical associations.

cryostat. This tissue is incubated with patient serum, such that autoantibodies in the serum can bind. A fluorescently tagged secondary antibody specific for human immunoglobulin is then used to detect the autoantibodies. Immunofluorescence examination of biopsy specimens of damaged or normal tissue may reveal deposits of immunoglobulins caused by antibodies reacting with an organ or tissue-specific antigens. This approach is especially important in the diagnosis of antiglomerular basement antibody disease and bullous skin disorders but may show false positives when used for SLE. Current recommendations do not support testing for autoantibodies due to their low specificity, particularly ANA testing, unless clinical suspicion for immune involvement is suspected[16] (see Table 18.3 for a listing of common autoantibodies).

TABLE 18.3 Common Autoantibodies

Autoantibody	Clinical Relevance
Antinuclear antibody	Systemic rheumatic diseases
Smooth-muscle antibody	Nonspecific liver damage; chronic hepatitis
Antimitochondrial antibody	Primary biliary cirrhosis
Endomysial antibody	Celiac disease; dermatitis; psoriasis
Antineutrophil cytoplasmic antibody	Vasculitis
Gastric parietal cell antibody	Pernicious anemia
Adrenal antibody	Idiopathic Addison's disease
Pancreatic islet cell antibody	Insulin-dependent diabetes mellitus
Skin antibodies	Pemphigus vulgaris; bullous pemphigoid
Antiacetylcholine receptor	Myasthenia gravis
Antimyelin basic protein	Multiple sclerosis
Double-stranded DNA autoantibody	Systemic lupus erythematosus
Thyroid stimulating hormone antibody	Graves' disease

RIA is a far more sensitive test used for measuring antibodies that are in low concentrations. In RIA, an antibody specific for human antibody is tagged with a radioactive isotope. Because radioactivity is more sensitive than fluorescence, when this antibody is incubated with an autoantibody, the contact detects even low levels of autoantibody.

Organism-Specific Antibodies

Antibody testing can also be used when determining a diagnosis of conditions like infectious mononucleosis due to Epstein–Barr virus (EBV). EBV does not always induce mononucleosis. In fact, only 30% to 40% of those who are infected with EBV will develop mononucleosis.[17] With clinical evidence, serological testing can be performed to confirm the diagnosis. Typically, a monospot is performed. A monospot is a form of heterophilic testing, which means that serum is tested against phylogenetically unrelated species' red blood cells (RBCs), typically horse, ox, or goat. The test is considered positive if the RBCs stick together (agglutination). The antibodies produced early in the infectious process of EBV will cross-react and bind to proteins on the surface of the nonhuman RBCs. If the monospot is positive, a diagnosis can be made. If it is negative, it does not rule out mononucleosis, and further testing can be done at this time.

Testing for IgM and IgG antibodies against the EBV capsid antigen is a more specific test for mononucleosis. The presence of IgM indicates an acute infection. IgG antibodies against EBV nuclear antigen appear 6 to 12 weeks after infection and persist for life. Their presence early in the course of illness effectively rules out EBV infection as a diagnosis. In contrast, IgG antibodies against "EBV early antigen" can signify a recent infection. Early antigen antibodies can be further broken down to anti-D and anti-R antibodies. Anti-D antibodies are consistent with early infection and disappear after resolution.[18]

Measuring antibody titers is a way of assessing vaccination status in individuals who are unsure of their vaccination history or to confirm vaccine protection. Some people are "nonresponders" to vaccines, particularly the hepatitis B vaccine. These individuals do not generate a robust response to a vaccine. Their antibody titers may be below 10 mIU/mL, whereas >10 mIU/mL signifies that an individual is immune. Nonresponders may require further follow-up to determine the etiological mechanism as to why they are nonresponsive to the vaccine.[19] Additionally, vaccine titer testing may be used in patients who wish to demonstrate that they have active immunity to an infectious agent and do not desire to have additional vaccinations. In cases of pregnancy, vaccine titers may be measured on parents and siblings of the newborn to ensure they are immune to the most common childhood diseases. This strategy capitalizes on the concept of "herd immunity" to ensure newborns' protection against preventable diseases.

Urine

When an antibody is made, the antibody light chains, κ and λ, are made in excess. These are present as free forms in serum and urine. Although small amounts of light chains are found in everyone, people with renal damage excrete higher levels of light chains in their urine. Free light chains are associated with malignant plasma dyscrasia and other lymphocyte-related immunoproliferative disorders. Intact immunoglobulin can also be found in urine.[20]

Cerebrospinal Fluid

IgG can be measured in the cerebrospinal fluid (CSF), which is important in the diagnosis of several CNS disease processes, such as multiple sclerosis, neurosyphilis, and subacute sclerosing panencephalitis.[21] A sample of CSF and serum is obtained, and the amount of IgG and albumin is recorded in a ratio of IgG:albumin for both samples. Albumin is not synthesized in the brain, so comparing this IgG:albumin ratio of the CSF to the serum sample provides an indirect indication of how much IgG has been synthesized within the brain.[1]

MEASUREMENT OF COMPLEMENT AND HIGH-SENSITIVITY C-REACTIVE PROTEIN

Complement

Complement is a series of proteins that result in the destruction of microbes. Assays for complement can either be those that recognize individual complement components (e.g., ELISA for C3 or C4) or functional activity of complement, such as lysis. Measurement of C3 and C4 levels is sufficient, except for rare patients with genetic deficiencies, such as hereditary angioedema. Low levels of complement are more significant than high levels. For example, complement levels may be low in patients with glomerulonephritis or SLE.[22,23] However, the complement levels return to normal when patients are in remission.

High-Sensitivity C-Reactive Protein

C-reactive protein (CRP) is involved in the complement pathway (Fig. 18.4). CRP functions by opsonizing bacteria, marking them for destruction by the complement cascade. Because it is readily detectable in the blood, CRP has become an important marker of inflammation. CRP is released early in infection (the first 4–24 hours) during the same window that many other components of inflammation are being activated, such as inflammatory cytokines. CRP levels are an indirect measure of the cytokine interleukin (IL)-6. IL-6 induces production of CRP as part of the initial immune response against an invading pathogen that triggers the rest of the immune response.[24] However, because it is far easier to measure than cytokines or other proteins, high levels of CRP are a more consistent marker of a recent infection or heavy immunological involvement, as is the case in several autoimmune diseases.[25] Laboratories consistently offer a high-sensitivity test for CRP, called hs-CRP. This test is more sensitive than the original test for CRP, allowing the detection of lower levels of CRP. Consistently high levels of hs-CRP may be diagnostic of chronic inflammation and are values commonly used to determine immune involvement or even cardiovascular disease risk.[26]

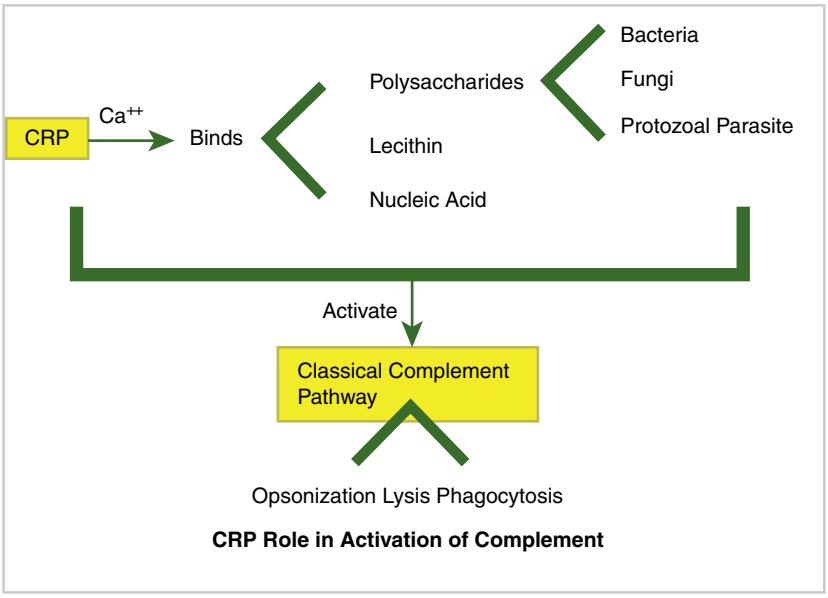

Fig. 18.4 C-reactive protein (CRP) activates the complement pathway.

TABLE 18.4 Regulatory T Cells

Type of Regulatory Cell	Cytokines Made	Action	Development of
Treg cells (CD4+ CD25+ CD152+)[a]	TGF-β, IL-35	Control overall autoimmune state?	Thymus
Type I NKT (cells)	Immunoregulatory		Thymus
(NK cells that express a semi-invariant TCR)	Proinflammatory		
Tr1 cells (CD4+ CD152+)	High IL-10 Moderate TGF-β and IFN-γ No IL-2 or IL-4	Suppress MS; suppress intestinal inflammation; cytolysis	Periphery systemic differentiate from Th0
Th3 cells (CD4+)	High TGF-β Low IL-4 and IL-10 No IFN-γ and IL-2	Oral tolerance	Periphery differentiate in intestinal mucosa
T suppressor cells (CD8+ CD28–)	High IL-10	Suppress DC maturation and function	Periphery

Adapted from Venken et al. 2010[29] and Vignali et al. 2008.[30]
DC, Dendritic cell; *IFN,* interferon; *IL,* interleukin; *MS,* multiple sclerosis; *NK,* natural killer; *NKT,* natural killer T cells; *TCR,* T-cell receptor; *TGF,* tumor growth factor; *Treg,* regulatory T cells.
[a]nTreg (natural Treg) and iTreg (inducible Treg).

MEASUREMENT OF CELLS

Lymphocyte Subpopulations

T Cells

CD4 T cells make cytokines that direct various arms of the immune system. CD8 T cells kill infected cells. The proteins on the surface of T cells that allow them to be identified are listed in Table 18.4. To qualitatively identify T cells and separate them from other cell types, two proteins are used: CD3 and CD4 or CD8. CD3 is a signaling molecule associated with the T cell receptor and is on all T cells. CD4 and CD8 function to increase the interaction between the T cell and the antigen presenting cell. A sample of how T cells appear on a flow cytometry dot plot is in Box 18.3. In healthy individuals, the CD4/CD8 ratio should be approximately 2:1. This ratio may differ in some ethnic groups.[27] CD4/CD8 ratios can be used to evaluate disease progression in patients with human immunodeficiency virus infection.

When a clinician approaches a patient with suspected immunodeficiency, he or she may decide to recommend a functional test. Immunodeficiency could be caused by a cell's inability to proliferate. In this case a lymphocyte proliferation assay or a carboxyfluorescein succinimidyl ester (CFSE) assay would be completed.

BOX 18.3 Sample Flow Cytometry Dot Plot

Flow Cytometry

Flow cytometry is a technique for counting cells and other microscopical particles such as cytokines and proteins. Similar to microscopy, flow cytometry allows the identification of cells based on their morphology and cell-surface proteins; however, flow cytometry evaluates cell populations rather than individual cells. Cells are incubated with monoclonal antibodies specific for certain proteins on their surface. Each antibody is tagged with a different color fluorochrome. The cells are then suspended in fluid and passed through the flow cytometer. Light from lasers in the flow cytometer passes through the cells, allowing detectors on the other side to read the light scatter from the cells based on their granularity and size. The detectors also evaluate the colors of the fluorescence associated with each individual cell. The resulting data are plotted using specialized software.

CD4 T Helper Subsets

CD4 T cells secrete discrete patterns of cytokines. Each pattern is beneficial for different types of immune responses. A single CD4 T cell specific for a single antigen can secrete any pattern of cytokines but will be skewed toward secreting one pattern or another depending on

the initial trigger. CD4 T helper subsets cannot be identified by surface markers. However, because CD4 T helper subsets secrete different patterns of cytokines, intracellular cytokine staining can discriminate between subsets.

The Th0 pattern is secreted by a naïve T cell, that is, one that has not yet seen antigen. It is the cytokine pattern that is designed to simply keep T cells alive. Th0 cells secrete IL-2.

The Th1 pattern is secreted by T cells exposed to bacterial or viral antigens. Overactivity of Th1 T cells has been linked to many autoimmune diseases. Th1 T cells secrete interferon-γ, as well as some other cytokines.

The Th2 pattern is secreted by T cells exposed to worms and parasites but is also involved in allergy and asthma. Th2 T cells secrete IL-4, IL-5, and IL-13.

The Th3 pattern is secreted in response to food. Because the immune response to food should be relatively inert, Th3 cells are considered a type of regulatory T cell (Treg) and are involved in immunological tolerance. Th3 T cells secrete tumor growth factor-β.

The Th9 pattern in T cells is closely linked to Th2, and until recently, they were considered to be the same. Th9 T cells produce higher quantities of IL-9 and do not produce IL-4, in direct contradiction to the cytokines produced by Th2 T cells. Th9 T cells have been implicated in the pathophysiology of asthma and other pulmonic conditions. On the other hand, they may play an important role in cancer surveillance and anticancer activities.[28]

The Th17 pattern is secreted in response to molds and extracellular bacteria. This population of T cells has recently been linked to many autoimmune diseases. Th17 T cells secrete IL-17.

Regulatory T Cells

Tregs play a key role in maintaining tolerance. The loss of Tregs is associated with disease, especially autoimmune disease. Studies of Tregs have been limited largely because of their considerable diversity and lack of unique surface markers; the current state of the science is given in Table 18.4.[29,30] Much of the knowledge about Tregs is from mouse models. Human Tregs have been phenotypically identified as CD4+ CD25+, CD4+ $CD25^{high}$, or CD4+ CD25+ FoxP3+ cells, based on how they stain and present in flow cytometry. CD39 is another protein on the surface of Tregs that may allow reliable identification.[31] Although most CD4 T cells express CD127, Tregs display lower surface expression of this marker.[32] Tregs behave similarly to other regulatory cells, such as Th3 cells found in the gut and Tr1 cells found in the periphery, but Tregs originate in the thymus and produce different cytokines upon stimulation than these other types of regulatory cells. Activation of Th1, Th2, and Tregs can be measured with the expression of CD69.[33]

B Cells

B cells are identified by the surface markers CD19 and CD20 (Table 18.5). In addition to being markers for B cells, CD20 is a marker of non-Hodgkin lymphoma and is a current drug target.[34] Monoclonal antibodies directed at CD19 are therapeutic targets in rheumatoid arthritis.[35] The products of B cells are antibodies and can be measured as described previously.

Monocytes and Neutrophils

Neutrophils and monocytes act early in disease. Tethered to the blood vessel walls, neutrophils are some of the first cells to reach infectious agents. Monocytes can quickly extravasate into tissues, differentiating into macrophages and joining tissue macrophages already present at the site of infection. If monocytes and neutrophils are not functioning properly, severe infections can result. It is rare to find patients with low-functioning monocytes because the consequences can be extreme.

TABLE 18.5 Cell Markers

Antigen	Identity/Function
CD3	Present on all T cells
CD4	Present on T helper cells and some dendritic cells
CD8	Present on cytotoxic T lymphocytes
CD16/CD56	Combination identifies NK cells
CD19/CD20	B-cell markers
Markers of T cell activation	
CD25	IL-2 receptor; serves as a marker for Treg cells
CD28	Activation marker on CD4 and CD8 T cells
CD38	Expressed on T cells after activation; function unknown
CD39	Acts on the nucleotide base responsible for enzymatic cleavage of ATP to AMP; marker for Tregs
CD45RA	Marker of a naïve/resting T cell
CD45RO	Marker of a recently activated T cell
CD69	Early activation marker for T cells, as well as B, NK, monocytes, and neutrophils[24]
CD71	Early activation marker for T cells
CD127	α-Chain of the IL-7 receptor; absence identifies Tregs

AMP, Adenosine monophosphate; *ATP,* adenosine triphosphate; *IL,* interleukin; *NK,* natural killer; *Treg,* regulatory T cells.

When patients have severe staphylococcal or fungal infections, neutrophil numbers should be evaluated, and function should be tested. Neutropenia is more common in neutrophil dysfunction. CD18 is a consistent and reliable marker for neutrophils and can be used as a marker for flow cytometry.[36] In healthy individuals, the neutrophil count normally exceeds 1.5×10^9/L. Mild neutropenia is usually asymptomatic, whereas moderate to severe reductions in numbers are associated with a progressive increase in the risk and severity of infections. Episodes of infection are likely to be life threatening when the neutrophil count falls below 0.5×10^9/L. Neutropenia is a frequent side effect of chemotherapy.[37]

Neutrophil function consists of adhesion, migration, chemotaxis, phagocytosis, and a respiratory burst. Defects in the respiratory burst can cause chronic granulomatosis disease. One simple method to evaluate neutrophil function involves a nitro blue tetrazolium test. In this test, neutrophils ingest and reduce a soluble yellow dye to an intracellular blue crystal. Neutrophils are separated and then stimulated with endotoxin (lipopolysaccharide), and the cells are viewed microscopically.

Neutrophils and monocytes can kill microbes with a respiratory burst. Another test of neutrophil function takes advantage of this activity. Neutrophils or monocytes are incubated with live microbes, such as *Staphylococcus aureus.* After the cells have phagocytosed the organisms, they are washed to remove extracellular organisms. The cells are then lysed, and the lysate is cultured on nutrient agar. Live bacteria will grow on the agar. The number of viable organisms inversely reflects the degree of intracellular killing.

Natural Killer Cells

When cells are infected with a virus or become cancerous, they often express less major histocompatibility complex on their surface. This makes them a target for natural killer (NK) cells. NKs express surface receptors that allow them to recognize the absence of major histocompatibility complex on a target cell and kill it. In addition to this mechanism, NK cells can be identified with CD56.[38] Like CD8 activity, NK function can be measured with a 51-chromium release assay (Box 18.3).

TABLE 18.6 Cytokine Patterns

Immunological Event	Name of Pattern	Cytokines
Inflammation	Proinflammatory	IL-1
		IL-6
		IL-8[a]
		TNF-α
T activation	Th1	IFN-γ
		IL-2
		TNF-α
		GM-CSF
	Th2	IL-4
		IL-5
		IL-10
		IL-13
	Th17	IL-17
T regulation	Th3	TGF-β
		IL-4
		IL-10
	Treg	TGF-β
	Tr1	IL-10
		TGF-β
		IFN-γ

GM-CSF, Granulocyte-macrophage colony-stimulating factor; *IFN,* interferon; *IL,* interleukin; *TGF,* tumor growth factor; *TNF,* tumor necrosis factor; *Treg,* regulatory T cell.
[a]IL-8 is a chemokine.

CYTOKINES

Cytokines are immunomodulatory molecules that play an essential role in cell–cell communication and immune reactions. They are produced by most immune cell types, and many physical symptoms of immune dysfunction are triggered by cytokines. Cytokine expression has been studied extensively in autoimmune disorders, chronic inflammation, and other diseases. Cytokine expression is most accurate when measured locally at the tissue site; however, systemic cytokine levels can be detected in serum and saliva. Cytokines may contribute to disease progression and are thus potential targets for therapeutic intervention.[39,40]

Cytokine levels can be tested with ELISA or cytometric bead array. Because clinical testing for cytokines is relatively new, clinical cytokine testing is not as validated as other forms of testing. Furthermore, cytokine levels are affected by exercise, diet, sleep, age, and gender. Cytokines tend to be secreted in patterns (Table 18.6). Because many natural therapies can modify cytokine expression, skilled clinicians can switch people from one pattern of cytokines to another.

GENETICS

The genetic control of immunity has long been recognized. Many autoimmune diseases map to specific genetic loci. Polymorphisms in the human leukocyte antigen have been linked to insulin-dependent diabetes mellitus, multiple sclerosis, and rheumatoid arthritis. Single-nucleotide polymorphisms (SNPs) in cytokine and cytokine receptor genes are associated with the variability of immune response between individuals to infectious disease.[41] Some clinical laboratories now offer testing for SNPs. SNPs are detected using polymerase chain reaction (PCR).[42] Gene primer pairs for the candidate gene are used to amplify the DNA sequence of the patient's gene. The patient's gene is then sequenced and compared with a standard sequence.

Genetic microarray provides a second test for genetic variability and may allow clinicians to pinpoint genes that are key players in different diseases (Fig. 18.5). In addition to determining patterns of gene expression that contribute to complex disorders, microarray could elucidate gene interactions that lead to clinical symptoms or tell a physician whether a patient is responding to therapy. Microarray involves isolating RNA from tissue, labeling it with fluorescent probe, and then comparing it with a standardized or control tissue by combining the RNA samples and hybridizing them to a chip. The color patterns are read by a computer. The expression of some genes (housekeeping genes) tends to be more stable and can act as a control. There are still several obstacles to overcome with genetic microarray technology, but clinical utility is likely.[43]

CLINICAL SYMPTOMS

It would be an oversight to exclude clinical symptoms as one of the primary ways that the immune system is evaluated. Clinical symptoms usually occur after an immune response is under way, but they are often the first sign to the patient and physician that something may be amiss. Physicians recognized an immune response long before the first immune cells and proteins were discovered. The classic symptoms of inflammation—calor (heat), dolor (pain), rubor (redness), and tumor (swelling)—were originally described and recorded by Aulus (Aurelius) Cornelius, a Roman physician and medical writer who lived from about 30 BC to 45 AD. These hallmarks of inflammation are caused by many complex interactions between cells and cytokines of the immune and nervous system and allow a clinician to make some assumption about immune processes without even drawing blood. For example, calor (heat) refers to fever. If a patient has a fever, a physician may assume that IL-1β is elevated. Table 18.7 illustrates which immune processes underlie the hallmarks of inflammation.

Sickness Behavior

Proinflammatory cytokines act in the brain to induce nonspecific symptoms of infection. In addition to triggering fever, cytokines elicit profound psychological and behavioral changes. Sick individuals experience several symptoms, including malaise, fatigue, weakness, an inability to concentrate, and listlessness. They become sleepy (hypersomnia) and experience depressed activity and a desire to be isolated. These infection-induced changes are referred to as "sickness behavior."[44] Sickness behaviors have a variety of advantages to both the sick individual and the population at large. Malaise, fatigue, and listlessness cause a person to rest and thus conserve energy. Rest further aids the body by decreasing heat loss, whereas shivering increases heat production. Social isolation may help prevent the spread of the infection to others.[45]

Most sickness behaviors are caused by cytokines, and they may help an observant clinician make a diagnosis. For example, fatigue and malaise are most commonly triggered by IL-1β. Interestingly, in some people, tumor necrosis factor-α and IL-6 may cause anger or hostility, and this emotional response leads to the social isolation.[46]

SUMMARY

Choosing appropriate immunological tests requires physiological, economic, and ethical considerations. To choose the right test for the patient, the reliability of the tests, as well as their specificity and sensitivity, must be considered. Assessing the immune system is further complicated by its sensitivity to the environment. Thus running tests in duplicate or triplicate may be necessary to validate results.

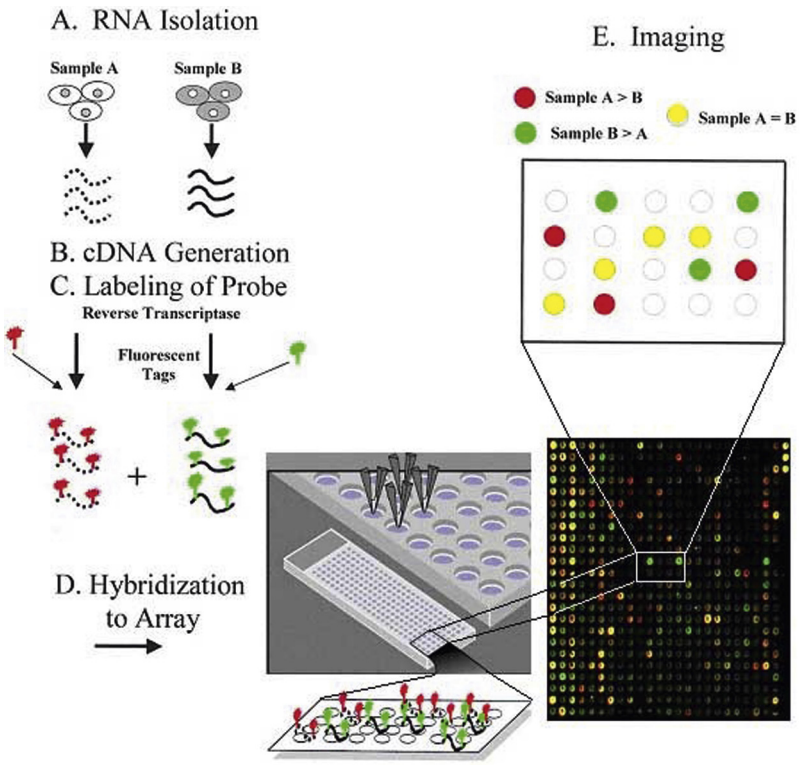

Fig. 18.5 DNA microarray. RNA is prepared from a collection of cells, normal and/or diseased. The RNA is translated into cDNA in vitro. The cDNA from each cell type is labeled with a different color of fluorescent dye. These cDNAs are then added to a chip or bead that has been previously hybridized with DNA probes. A computer analyzes the color of the DNA spots on the chip or bead. Relative difference in color indicates difference in gene expression between the two cell types.

TABLE 18.7 Hallmarks of Inflammation

Latin	English	Cytokines and Cells Involved
Calor	Heat	IL-1β, IL-6 act at the hippocampus, causing the body to increase blood flow, resulting in heat.
Dolor	Pain	TNF-α and IL-1β lead to localized edema that nerve endings sense as pain.
Rubor	Redness	TNF-α and IL-1β cause vasodilation and increased blood flow.
Tumor	Swelling	TNF-α and IL-1β cause increased permeability of the capillaries.

IL, Interleukin; *TNF,* tumor necrosis factor.

Intestinal Permeability

Corene Humphreys, ND, BHSc, Dip Med Herb, Dip Hom, QTA

OUTLINE

INTRODUCTION

The intestinal epithelial barrier (IEB) is a dynamic, multicomponent barrier tasked with the important role of keeping out harmful molecules from the external environment while simultaneously allowing the absorption of nutrients and water vital for host survival. Over the past decade, substantial scientific and clinical research has been undertaken in this field of physiology. Alterations in IEB function have now been implicated in the pathogenesis of a number of chronic inflammatory diseases, including intestinal diseases, cardiometabolic disorders, autoimmune diseases, lung disease, neurological conditions, and systemic infectious diseases. This chapter outlines the core components and pathophysiological roles of the IEB and how they relate to specific disease states. It also outlines key diagnostic tests to identify changes in gut permeability, along with evidence-based therapies to restore intestinal barrier homeostasis.

COMPONENTS OF THE INTESTINAL BARRIER

Spanning approximately 300 to 400 m^2, the gastrointestinal barrier represents the largest surface area in the body that separates the external environment from the internal milieu.[1,2] The primary roles of the IEB are to protect the host from luminal pathogenic bacteria, intraluminal toxins, and antigens while simultaneously allowing for the passage of dietary nutrients, electrolytes, and water.[1,3–5] Structures of the IEB comprise four diverse components: microbiological, physical, chemical, and immunological barriers (Fig. 19.1).[1]

The Microbiological Barrier

The gut microbiota is now recognized as an integral component of the intestinal epithelial barrier for a number of reasons: (1) it promotes resistance to the colonization of pathogenic organisms by competing for attachment sites, (2) it provides nutrients, and (3) it releases antimicrobial substances. The microbiota is also involved in the digestion and absorption of luminal nutrients, which in turn supply energy to intestinal epithelial cells.[6–9]

Over 90% of the human microbiota is derived from seven phyla: *Firmicutes* (gram positive), *Bacteroides* (gram negative), *Proteobacteria* (gram negative), *Fusobacteria* (gram negative), *Verrucomicobia* (gram negative), *Cyanobacteria* (gram negative), and *Actinobacteria* (gram positive), with *Firmicutes* and *Bacteroides* as the dominant species.[10–12]

A dysbiosis can be defined as a reduction in microbial diversity and a combination of the loss of beneficial bacteria such as *Bacteroides* strains and butyrate-producing bacteria such as *Firmicutes*[10] and a rise in pathobionts[12] (symbiotic bacteria that become pathogenic under certain conditions), including *Proteobacteria,* which encompasses gram-negative *Escherichia coli.*[13]

Lipopolysaccharides (LPSs) constitute the major lipidic components of the outer wall of gram-negative bacteria. They are vital for the structure and functional integrity of these bacteria, providing a barrier that protects against penetration of bile salts and other antimicrobial agents while allowing the passage of small hydrophobic compounds. For the host, however, persistent migration of LPSs into the circulatory system can have deleterious consequences.[12] LPSs have also been identified in the scientific literature as "endotoxins."[13] Endotoxins bind to receptors, initiating an adaptive immune response and a signaling cascade, leading to activation of proinflammatory genes.[14] Impaired digestive function along with gut-derived microbial toxins trigger both the onset and maintenance of chronic low-grade inflammation.[15] This, in turn, increases intestinal permeability, allowing the translocation of microbiome-derived LPSs into the bloodstream, resulting in a two- to threefold increase in serum LPS concentration, which can reach a threshold termed *metabolic endotoxemia* (ME). ME may

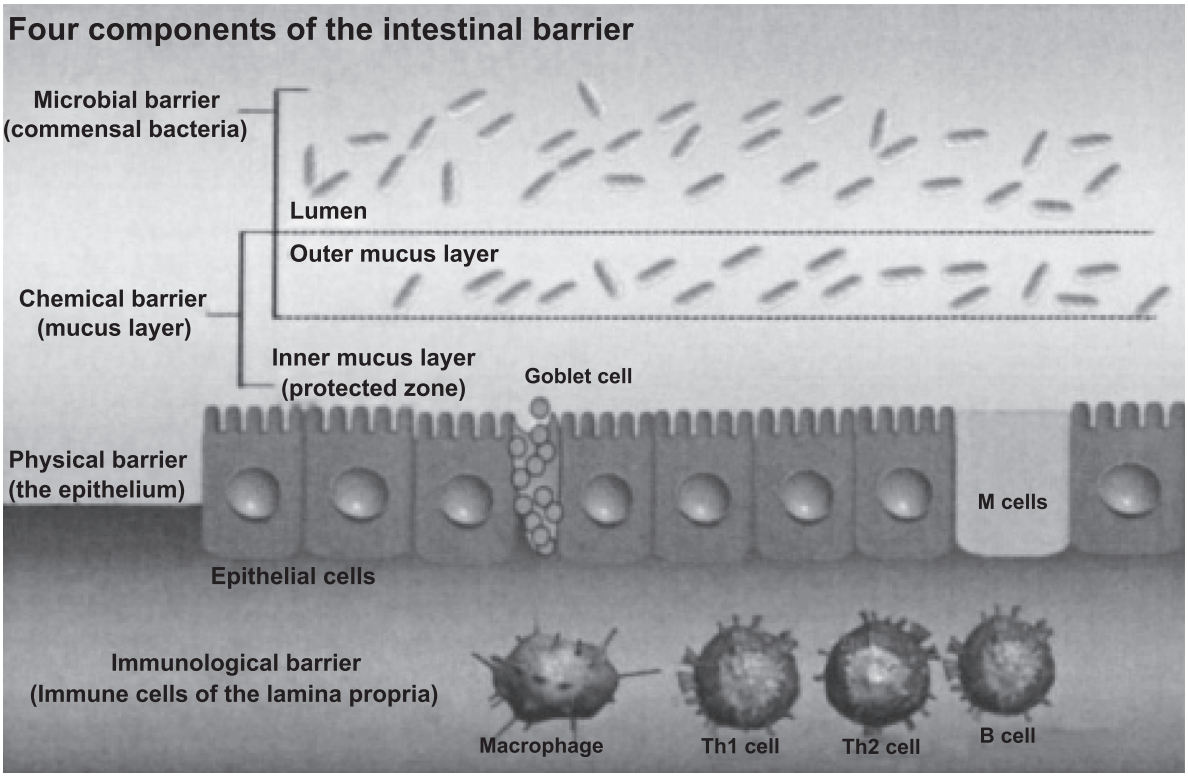

Fig. 19.1 Components of the intestinal barrier. (From Ji J, Qu H, Shu D. Crosstalk between bioactive peptide and intestinal barrier in gut homeostasis. *Curr. Protein Peptide Sci.* 2015;16[7]:604–612.)

trigger toll-like receptor-4 (TLR-4)–mediated inflammatory activation, eliciting chronic low-grade proinflammatory and prooxidative stress. Endotoxemia has been implicated in a number of inflammatory diseases, including sepsis, septic shock, diabetes, and, more recently, obesity-related metabolic disorders. Gut microbiota constitutes the major source of LPSs, and the main portal of entry into the systemic circulation is via direct diffusion through increased intestinal permeability, or from the absorption and incorporation of LPSs into chylomicrons after a lipid-rich meal.[12,16]

Research shows that impaired intestinal barrier function is often associated with alterations in the gut microbiome. When this occurs, instead of maintaining the homeostasis of the immune system, the microbiota can initiate and perpetuate inflammatory responses, thereby triggering or exacerbating intestinal and systemic diseases such as inflammatory bowel disease (IBD) and metabolic syndrome.[11,13,17,18]

The Physical Barrier

The physical barrier comprises the mucus layer, intestinal epithelial cells, and intercellular junctional complexes.[6] The chief role of this component of the IEB is to prevent bacterial adhesion (mucus layer) and regulate transcellular and paracellular diffusion of molecules into the systemic circulation (epithelial cells and tight junctions).[19]

The Mucosal Layer

Immediately below the microbiota and overlying the epithelium is the mucus layer, which functions as both a physical barrier and a biochemical barrier.[5] As the first physical barrier, the mucus layer limits the direct interactions of the intestinal epithelium with microbes, antigens, and toxins while simultaneously allowing nutrient absorption.[17,18,20] The mucosal layer also acts as a lubricant for intestinal motility.[21]

Specialized enterocytes called goblet cells secrete mucus, which is composed of proteins, carbohydrates, lipids, and water.[22] A core component of mucus is large glycoproteins, which belong in the family of secretory-gel–forming mucins. In both the small and large intestine, MUC2 is the primary secretory mucin produced and secreted by goblet cells and forms the main structural unit of the mucus layer.[5,22] As well as acting as the first line of defense against physical and chemical injury from luminal microbial and antigenic contents, secreted mucins serve as a food source for microbes and also provide binding sites for bacteria.[12,19,22,23] At the same time, microbiota and their microbial products are able to modulate mucin synthesis and release through a "crosstalk" feedback mechanism. Thus a symbiotic relationship exists whereby microbiota and mucins work collectively to prevent the invasion of enteric pathogens.[22]

Intestinal Epithelial Cells

Below the mucus layer is the intestinal epithelium, which is organized into a monolayer of invaginations called crypts and villi (finger-like projections) in the small intestine. The bottom of the crypt is composed of stem cells, which differentiate into mature cell lineages as they migrate up toward the villus.[22,24,25]

To date, at least seven different cell lineages have been identified: enterocytes, goblet cells, Paneth cells, microfold cells (M cells), endocrine cells, cup cells, and tuft cells.[6,21] The exact roles of cup and tuft cells have not been fully elucidated.[6] The key physiological roles of the main intestinal epithelial cells are outlined as follows:

Enterocytes comprise approximately 90% of IECs and play an important role in the absorption of nutrients while also serving as a barrier to prevent the translocation of luminal contents into host tissues.[6,19]

Goblet cells secrete mucin and other mucus constituents that form a net-like structure to protect microorganisms from reaching the epithelial surface.[26] They have also been shown to secrete antimicrobial peptides (AMPs) known as trefoil factors, which are involved in intestinal defense and mucosal repair.[1]

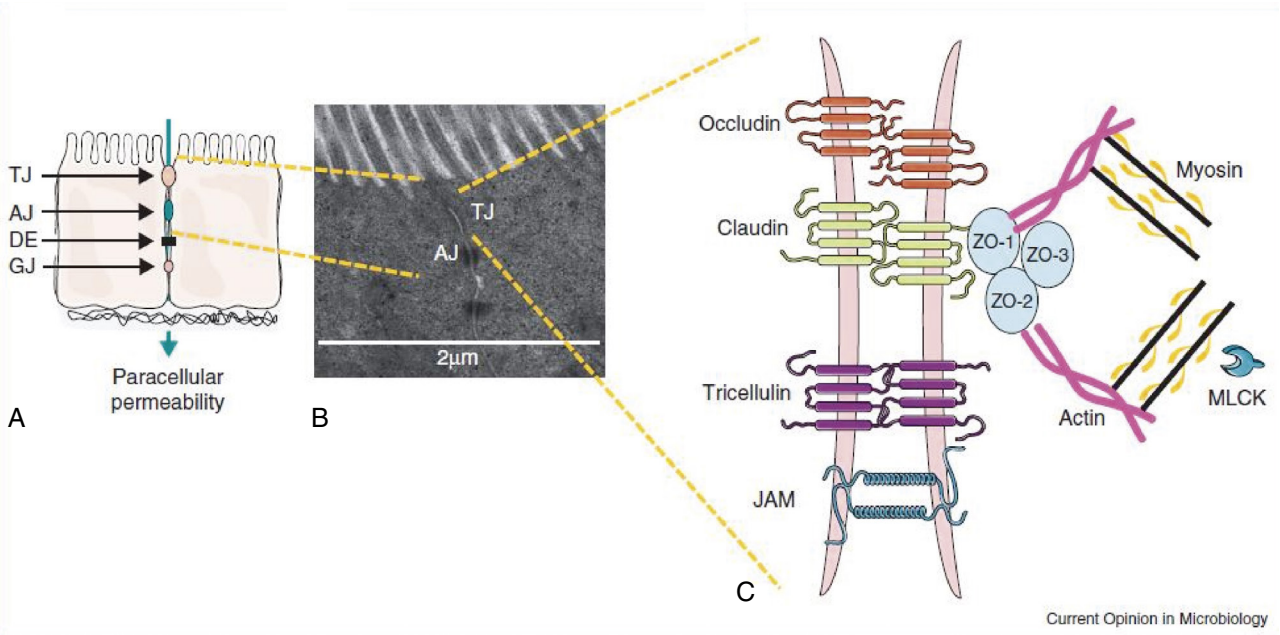

Fig. 19.2 Transmembrane and Intracellular Mechanisms of Paracellular Permeability. (From Barreau F, Hugot JP. Intestinal barrier dysfunction triggered by invasive bacteria. *Curr. Opin. Microbiol.* 2014;17:91-98.)

Paneth cells are composed of large numbers of secretory granules filled with AMPs, and as such, they support and mediate the biochemical barrier function.[5] Antimicrobial substances secreted by Paneth cells include defensins, lysozyme, and regenerating islet-derived protein 3-gamma (RegIIIγ) proteins, all of which help protect against infection from bacteria, fungi, yeasts, and viruses.[1,26,27]

Microfold (M) cells represent the antigenic component of the intestinal epithelial barrier. Located above the Peyer's patches and intestinal lymphoid follicles, M cells are involved in the process of sampling antigenic material, including food antigens, pathogenic bacteria, and their bacterial components, from the lumen and transcytosing to the underlying immune system.[28–31] Commensal bacteria can also be internalized and exported to the gut-associated lymphoid tissue (GALT) via this pathway.[31,32]

Enteroendocrine cells are sensory intestinal epithelial cells that detect and respond to luminal nutrient content by secreting peptide hormones to regulate digestive enzyme secretion, intestinal pH, gastric emptying, satiety, electrolytes, and motility.[33–36] Hormonal mediators secreted by enteroendocrine cells include serotonin, motilin, glucagon-like peptide NPY, and substance P.[34] Enteroendocrine cells comprise less than 1% of the overall intestinal epithelial population, of which serotonin-secreting enterochromaffin cells are the most abundant subtype.[33] Despite their small representation, because they are dispersed throughout the gastrointestinal tract, these cells collectively constitute the largest endocrine system in humans.[35]

Intercellular Junctional Complexes

Intestinal epithelial cells are tightly bound to one another by at least four intercellular junctional complexes, which are vital for the integrity of the epithelial barrier.[37,38] From apical to basal, the intercellular junctions are composed of tight junctions (zonula occludins), adherens junctions (zonula adherens), desmosomes, and gap junctions (Fig. 19.2).[9,19,39,40]

Tight Junctions (Zonula Occludins)

Tight junctions represent the most apical (the side toward the lumen) structure of the intercellular junctional complex and are composed of at least 50 different transmembrane proteins.[9,18,21,37,38] Numerous in vitro and animal studies have identified tight junction disruption as the leading cause of altered intestinal barrier function.[38,39] The primary function of tight junctions is to provide a physical barrier that selectively allows for the passage of water, ions, and small solutes in the space between neighboring cells while limiting access to pathogens, toxins, and xenobiotics.[18,24,41–43]

The four integral transmembrane proteins that make up the tight-junction complex are occludin, the claudin family, tricellulin, and the junctional adhesion molecule (JAM).[39,40] Occludin, tricellulin, and JAM play a regulatory role in tight-junction structure and permeability,[3,20,27,34,44,45] whereas the claudin family is primarily responsible for intestinal barrier function.[26,27,46] Claudins can be differentiated into two main types: barrier enhancing (those that decrease paracellular permeability) and pore forming (claudins that increase paracellular permeability).[20,26,31,46] The specific claudins identified with the sealing function that decreases paracellular permeability include claudin-1, -3, -4, -5, -8, -9, -11, -14, and -19.[18,31,47] Claudins linked to pore formation and enhanced permeability include claudin 2, -7, -10, -12, -15, and -23.[18,48]

Zonula occludins proteins (ZO-1, ZO-2, and ZO-3) are intracellular scaffold proteins that anchor the transmembrane proteins to the cytoskeleton of the cell.[18,27,42,46] Zonulin is recognized as the only physiological regulator of intracellular tight junctions and also plays an important role in the balance between tolerance and immunity.[49,50] Gluten and bacteria (commensals and pathogenic) in the intestinal mucosa have been identified as stimuli that can trigger the release of zonulin.[49,51]

Together, transmembrane and zonulin proteins form a connective network around intestinal epithelial cells via their interaction with the perijunctional actomyosin ring (a dense ring of filamentous actin and myosin that encircles the cell at the region of the adherens junctions and tight junctions).[9,17,18,21,24] Tight-junction functionality is also

regulated in part by myosin light chain (MLC) phosphorylation with the enzyme MLC kinase, which causes actin to contract and open the junctional gap. This results in increased permeability to electrolytes and other small organic molecules.[11,18,20,43]

Historically, the tight-junction complex was thought to be a simple, static paracellular seal. New evidence shows that tight junctions are dynamically and selectively permeable and are able to regulate paracellular flux in both a size- and charge-selective manner.[43,47,51,52] Physiological and pathological factors known to influence tight-junction permeability include dietary peptides, probiotics, enteric pathogens, mucosal immune activation, cytokines, proteases, cellular stress, growth factors, and enteric nervous system signaling.[25,50,52]

Adherens Junctions (Zonula Adherens), Desmosomes, and Gap Junctions

Located immediately below the tight junctions are the adherens junctions, followed by desmosomes and then gap junctions.[24] Adherens junctions and desmosomes form strong adhesive bonds between IECs to hold cells together and protect against mechanical disruption of the epithelial sheet. They are also involved in cell-to-cell communication and are home to proteins that direct epithelial polarization.[12,18,20,24,39,45] Gap junctions are also involved in intracellular communication and help facilitate the exchange of small molecules between intestinal epithelial cells.[9,48,53] Unlike tight junctions, however, these proteins do not regulate paracellular permeability.[12,18,20,24,39,45]

The Biochemical Barrier

Embedded in the mucus layer and far into the gastrointestinal lumen resides the biochemical barrier. The main role of the biochemical barrier is to reduce the load of colonized bacteria and help prevent luminal antigens from having direct contact with host cells.[6] Components that make up the chemical barrier include digestive secretions, AMPs, cytokines, and other inflammatory mediators such as proteases.[26]

Digestive Secretions

The first line of biochemical defense resides within the lumen, where gastric acid, pancreatic juice, and bile participate in the integrity of the intestinal epithelial barrier by altering the pH, thereby creating a bactericidal environment for pathogenic organisms.[19,21] In addition to their antimicrobial role, digestive enzymes degrade dietary proteins, thereby preventing larger immunogenic peptides from reaching the small intestine.[30]

Antimicrobial Peptides

AMPs are secreted by virtually all epithelial cells in the intestine as well as immune cells.[9,18] The chief role of AMPs is to protect the intestinal epithelial barrier against invading pathogens and control the colonization of commensal organisms.[6,12,32,54] AMPs are active against a variety of organisms, including gram-positive and gram-negative bacteria, parasites, protozoa, fungi, and enveloped viruses.[18,54] AMPs destroy bacteria either by enzymatic attack or via nonenzymatic mechanisms that interfere with bacterial membranes via electrostatic interactions.[32] To date, several types of AMPs have been identified, including α-defensins and β-defensins, C-type lectins, cathelicidin, lysozyme, and intestinal alkaline phosphatase.[6] In addition to their role as antimicrobial agents, AMPs also represent a link between the innate and adaptive immune systems.[5,9]

Cytokines

Intestinal epithelial barrier function is also regulated by cytokines, which can have barrier-disrupting or barrier-enhancing effects, depending on the particular cytokine involved (Table 19.1).[3,45] The secretion of proinflammatory cytokines in response to dysbiotic microbiota and other noxious stimuli has been shown to impair gut barrier function and induce the reorganization of a number of tight-junction–associated proteins.[7,34,42]

TABLE 19.1 Effects of Cytokines and Growth Factors on Intestinal Epithelial Barrier Function

Cytokine/Growth Factor	Effects on Intestinal Barrier Function
IFN-γ	↑ paracellular permeability
TNF-α	↑ paracellular and transcellular permeability
IL-1β	↑ paracellular and transcellular permeability
IL-4	↑ paracellular permeability
IL-6	↑ paracellular permeability to cations
IL-10	Restores intestinal barrier defects (neutralizes IFN-γ)
IL-13	↑ paracellular permeability
IL-17	↓ paracellular permeability
TGF-α	Protects against barrier defects (neutralizes free radicals)
TGF-β	↓ paracellular permeability
EGF	Protects against barrier defects (neutralizes free radicals)

EGF, Epidermal growth factor; *IFN-γ,* interferon-gamma; *IL,* interleukin; *TGF-α,* transforming growth factor-alpha; *TGF-β,* transforming growth factor-beta; *TNF-α,* tumor necrosis factor-alpha.

Proteases

Proteases can be present on both the apical and basolateral sides of the intestinal wall. In the gut lumen, they are either produced endogenously (e.g., pancreatic proteases) or from bacteria and food particles. In the lamina propria, proteases are released into the mucosa by macrophages, neutrophils, and mast cells to regulate inflammation.[2] Proteases play a dual role, acting as both degrading enzymes and signaling molecules. In the gastrointestinal mucosa, they are involved in the degradation of the extracellular matrix, mucosal proteins, and bacteria. As signaling molecules, their proteolytic action is capable of altering the structure and function of tight junctions, thereby increasing intestinal permeability.[2,26]

The Immunological Barrier

Residing immediately below the epithelial layer is the lamina propria, which is home to the intestinal immune system.[13] The innate and adaptive immune systems contribute to the immunological barrier, and together, they form the gut-associated lymphoid tissue (GALT), which contains up to 70% of the entire body's immune cells.[19,21] Within the GALT are organized lymphoid follicles, including Peyer's patches, which are primarily located in the distal ileum, and isolated lymph follicles that are mainly found in the colon.[28] The immune cells that make up the innate and adaptive immunity of the gastrointestinal tract include dendritic cells, monocyte/macrophages, neutrophils, mast cells, B cells, and T cells.[28] Collectively, these cells are responsible for antigen sampling and immunological responses to pathogenic microorganisms as well as immune tolerance to commensal flora.[19,21,50]

Secretory immunoglobulin A (sIgA) is the first line of adaptive immune defense and constitutes the major immunoglobulin class in the gastrointestinal tract.[1,18] Immunoglobulin A (IgA) is secreted by

plasma cells (effector B cells) in the lamina propria and is then transcytosed through the intestinal epithelium (with the aid of the polymeric immunoglobulin receptor) and secreted into the lumen as sIgA antibodies.[1,6,13,28] Once in the lumen, sIgA binds to bacteria and viruses, thereby preventing them from attaching to and colonizing epithelial surfaces.[18,26] Another way in which sIgA exerts antimicrobial effects is by entrapment of bacteria in the mucus layer, reducing bacterial virulence factors and phagocytosis of intracellular pathogens as it migrates through the epithelium.[13,55]

LUMINAL TRANSPORT ACROSS THE INTESTINAL EPITHELIUM

Epithelial cells allow for selective permeability by three distinct pathways: the transcellular route, the paracellular route, and the more recently identified unrestricted pathway.[20,39,45]

The **transcellular transport pathway** facilitates the passage of larger molecules (molecular weight [MW]: >600 Da) through the intestinal epithelial cells.[25] Nutrients such as sugars, amino acids, peptides, fatty acids, and vitamins and minerals utilize this pathway.[40,45] Food antigens, bacteria, and bacterial products, including LPSs, primarily use the transcellular route via M cells and other enterocytes such as goblet cells.[12,25,40] These antigens are normally degraded by lysozymes within the intestinal epithelium and enter the lamina propria as small, nonimmunogenic peptides.[17] To date, a number of different transcellular pathways have been described for different luminal compounds based on their size, hydrophobicity, and other chemical traits[12,25,45,56]:

Transcellular uptake—this route is through the plasma membrane of epithelial cells. Small hydrophilic and lipophilic compounds and ions utilize this pathway.

Active transport—nutrients such as sugars, amino acids, and vitamins and minerals migrate through the epithelial barrier using transporters, which requires energy (hence the name "active" transport).

Endocytosis—larger molecules, including proteins, larger peptides, bacteria, and bacterial products, are endocytosed into vesicles and move through the intestinal epithelium via transcytosis and posterior exocytosis.

The paracellular pathway allows for the transport of ions (mostly cations), water, and other inert solutes of low molecular weight (<600 Da) through the spaces between the epithelial cells.[30,34] Unlike the transcellular pathway, the movement of molecules through the paracellular route occurs by diffusion.[57] Currently, three different routes of paracellular flux have been identified, termed the pore, leak, and unrestricted pathways.[39,43] The pore pathway regulates the passage of small-size solutes (approximately 5–10 Å).[20] It is a high-capacity, size-selective, and charge-selective route.[24,52,58] Pore pathway permeability is mainly regulated by subsets of the claudin family of tight-junction proteins.[24,39] Cytokines that enhance the expression of claudin-2 proteins, such as interleukin (IL)-4 and IL-13, upregulate the pore pathway, leading to increased passage of water, sodium, and small cations.[2,20,43,52] The leak pathway allows for the passage of large molecules (up to 125 Å) and is a low-capacity, size-nonselective, and charge-nonselective paracellular route.[20,52,58] Leak pathway permeability appears to be regulated by zonulin, occludin, tricellulin, and MLC kinase.[39,43,58]

The unrestricted pathway this is thought to be a tight-junction–independent pathway that becomes active after direct epithelial damage (i.e., erosions and ulcers). This is a high-capacity, size-nonselective, and charge-nonselective route that allows for the passage of vast quantities of both large (including microbes) and small molecules across the epithelial barrier.[20,39]

Under homeostatic conditions (when the epithelium is intact), luminal flux occurs across both the leak and the pore pathways (Fig. 19.3).[39,52] Pathological insults such as infection, immune-mediated stimuli, and ischemia can compromise the epithelial barrier, leading to an increased flux across the pore pathway, the leak pathway, and the unrestricted pathway.[20] When there is extensive epithelial damage (e.g., necrotizing enterocolitis), the unrestricted pathway becomes the dominant route of transmucosal flux.[20,39]

ASSESSING INTESTINAL BARRIER FUNCTION

The assessment of intestinal barrier function is currently based on two different methods: active and passive measurement. Active tests evaluate trans- and/or paracellular urinary recovery of orally administered probes, whereas passive assessment analyzes the consequences of a disrupted intestinal barrier (i.e., the translocation of luminal compounds and tight-junction proteins into the systemic circulation).[27] Because there is no universal marker to assess all facets of intestinal barrier dysfunction and because each test has varied clinical utility and limitations, the use of more than one test may be necessary for a more comprehensive evaluation of leaky gut.[25,30,59]

Active Assessment of Barrier Function

Active assessment of barrier function loss is predicated on the understanding that orally administered probes of different molecular weights have variable ability to cross the paracellular pathway unless the intestinal barrier has been compromised in some way.[26,27,29] When barrier function loss occurs, the ingested probes are able to cross the intestinal barrier and enter the circulation, and they can be recovered in the urine after renal excretion.[26,27]

Currently, there are a number of different marker probes that can be employed to assess active barrier function. These include the sugar probes lactulose, mannitol, rhamnose, and cellobiose as well as polyethylene glycols (PEG 400, PEG 1500, PEG 4000) and chromium-labeled ethylenediamine tetra-acetic acid (Cr-EDTA).[26,57] For the purposes of this chapter, only the dual-sugar and multisugar tests will be discussed in detail because they are the most commonly used profiles in clinical practice.

Dual-Sugar Test

The lactulose/mannitol dual-sugar test (DST) has been used for more than 50 years and has long been considered the gold standard for the assessment of intestinal permeability.[25,29,30,38,60] The monosaccharide mannitol is a small molecule (MW 182 Da) thought to cross the pore pathway freely, independent of barrier function loss, and thus can be considered a measure of intestinal surface area.[26,27,52,61] The disaccharide lactulose is a larger molecule (MW 342 Da) thought to cross the leak pathway or the unrestricted pathway (after epithelial damage) and is considered a marker of barrier integrity.[4,26,52,61]

DSTs usually evaluate lactulose and mannitol recoveries separately, as well as the lactulose/mannitol (L/M) ratio, for a more complete evaluation of intestinal barrier function.[38]

The ratio of the urinary concentration of lactulose and mannitol represents a measure of the sum of leak pathway permeability and epithelial damage normalized to the surface area.[27,52]

Multisugar Test

A more comprehensive assessment of intestinal permeability can be achieved by the addition of other test probes.[26] This is known as the multisugar test (MST), which involves the simultaneous ingestion of sucrose, lactulose, mannitol, and sucralose to evaluate gastroduodenal, small intestinal, and large intestinal permeability, respectively.[26,27,47]

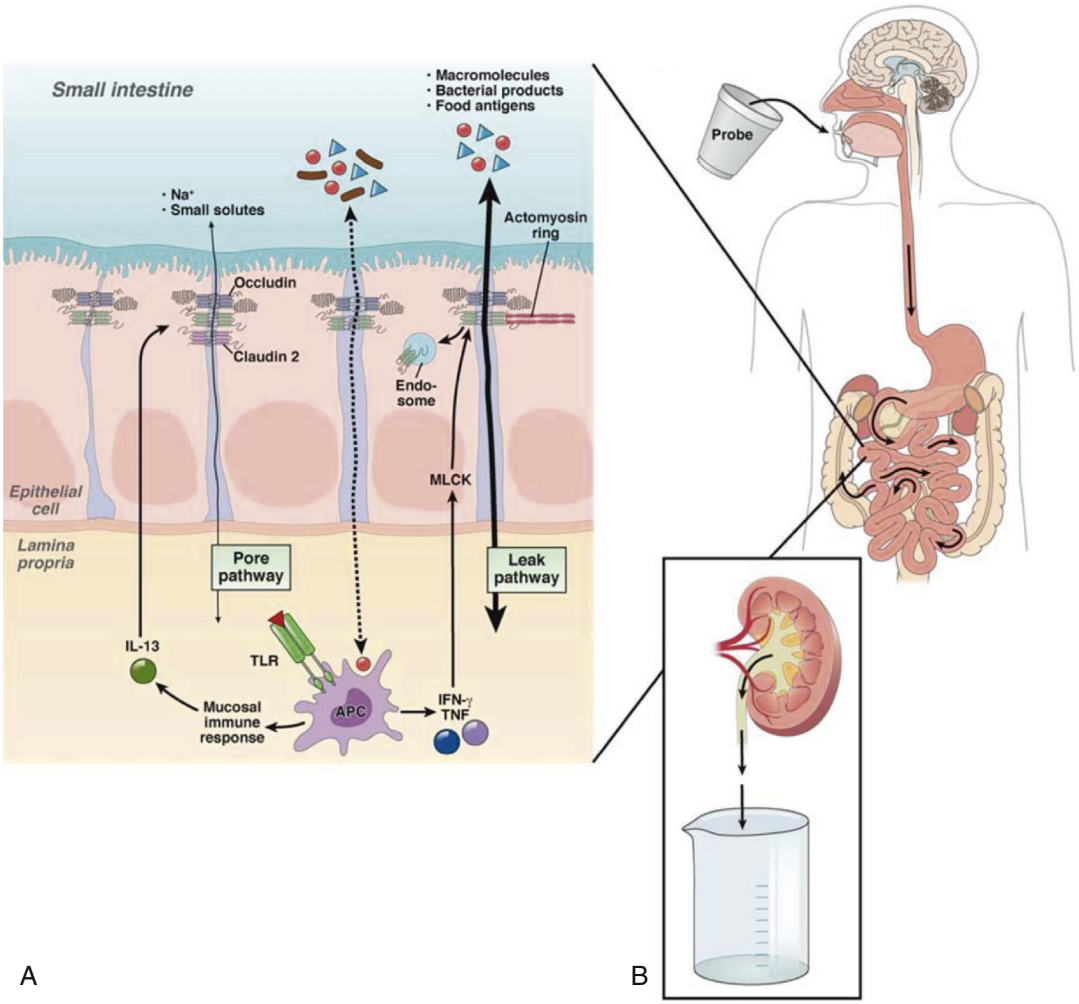

Fig. 19.3 Intestinal permeability pathways and mechanisms of analysis. (From Odenwald MA, Turner JR. Intestinal permeability defects: is it time to treat? *Clin Gastroenterol Hepatol.* 2013;11[9]:1075–1083.)

The disaccharide sucrose is used for gastroduodenal permeability because this sugar is rapidly hydrolyzed by sucrase, an enzyme secreted in large quantities by enterocytes in the duodenum.[38,47,62] As with the DST, lactulose and either mannitol or rhamnose monosaccharides are used for small intestinal permeability because they are degraded in the cecum by colonic bacteria.[25,27,52] Sucralose is an artificial sweetener with a comparable mass to lactulose (MW 397.64 Da). Because this probe is not metabolized and fermented by colonic bacteria, it can serve as a marker for colonic permeability. Sucralose is thought to be absorbed via the leak paracellular pathway.[25,28,27,61–63]

Factors That Affect the Excretion of Sugar Probes

The excretion of orally ingested sugar probes depends on many factors, which can be categorized as follows[25–25,47,62,64]:

- **Premucosal factors:** proper digestion, gastric dilution and emptying, intestinal dilution, transit time, bacterial degradation, alcohol consumption, smoking, and certain medications (e.g., nonsteroidal anti-inflammatory drugs [NSAIDs]).
- **Mucosal factors:** brush-border hydrolysis, permeation pathways, and blood flow.
- **Postmucosal factors:** endogenous sugar production, metabolism, tissue distribution, renal excretion, and proper urine test collection.

Limitations of the Dual-Sugar and Multisugar Tests

Recently, the efficacy of the DST and MST have been called into question by scientists who claim these profiles are not indicative of the transport of macromolecules, such as bacterial toxins and food antigens, that use the transcellular pathway to enter the lamina propria.[29,30] Research shows that only molecules of 5000 Da or greater are capable of challenging the intestinal immune system and initiating a T-cell–mediated response with downstream cytokine and antibody production.[29]

Probes with higher molecular mass, such as proteins and bacteria, have been put forward as alternative markers to determine whether increased intestinal permeability is sufficient to allow bacterial toxins (e.g., LPSs), food antigens and other macromolecules to permeate the gut wall.[30,38,59]

Passive Assessment of Barrier Function

The passive assessment of barrier function loss is based on the understanding that luminal substances such as bacterial endotoxins, bacterial by-products, and tight-junction barrier proteins only migrate into the systemic circulation after barrier function loss. Quantification of plasma or serum levels of these compounds is therefore considered a reflection of the integrity of the intestinal barrier.[26,27]

Examples of passive tests to measure intestinal permeability include zonulin, endotoxin (LPS), intestinal fatty acid–binding protein (FABP), and endotoxin core antibodies (EndoCAbs). Although they hold the advantage of being snapshot tests that don't require a challenge substance or the time-consuming collection of urine, the substances assayed can be difficult to measure due to technical challenges (e.g., endotoxin assays) or endogenous factors such as hepatic metabolism.[26,27] For example, LPS can be readily measured in the portal vein of animals but is challenging to measure in the peripheral blood of humans and requires careful standardization.[4,26] Additionally, certain luminal compounds (e.g., FABP and EndoCAb) are only able to detect acute intestinal damage and thus are more suited to the hospital environment.[25,26] Currently, one of the most common tests offered by functional diagnostic laboratories to assess passive barrier integrity is zonulin.

Zonulin

Zonulin (MW 47,000 Da) is a biomarker of the intestinal barrier integrity of the small intestine.[37,49,65,66] At this time, it is recognized as the only physiological protein known to reversibly regulate intestinal permeability by disassembling intercellular tight junctions.[37,67,68] The secretion of zonulin is mainly derived from the liver but also other tissue, including enterocytes; adipose tissue; the brain, heart, lungs, kidney, and skin; and immune cells.[37,51,69]

In addition to being a marker of intestinal permeability, zonulin may also play a protective role. Zonulin upregulation may be a secondary response to altered metabolism and inflammation, and through its immune-modulating and anti-inflammatory effects, it may help protect tissue from injury.[37]

Zonulin expression has been shown to be upregulated in a number of metabolic,[37,49,67,68,70–74] inflammatory,[75–77] autoimmune,[38,67,78,79] neurodegenerative,[17,29,50,66] and tumoral diseases.[37,49,65,67] Elevated levels of zonulin have also been identified in children with autism spectrum disorders.[80,81]

Test limitations of zonulin

Because zonulin is secreted by many extraintestinal tissues, serum zonulin levels represent a culmination of zonulin from intestinal secretion and other organs, such as adipose tissue, the liver, the brain, the heart, immune cells, the lungs, the kidneys, and the skin.[37,51,69] This may explain why no correlation has been found between serum and fecal zonulin.[82] To date, clinical data on the use of zonulin in patients with IBD is limited.[51] As such, serum zonulin might best be described as a biomarker of metabolic disorders, such as low-grade inflammation, obesity, and metabolic syndrome, and autoimmune conditions, whereas fecal zonulin may be a more representative analyte to evaluate increased intestinal permeability.[37]

Zonulin has demonstrated high intraday variability, which could be due to how it is metabolized within the body and its circulating half-life.[65,77] Because zonulin is a high-molecular-weight protein, it is capable of eliciting an innate immune-mediated response. As such, when zonulin enters the submucosa and, thereafter, the systemic circulation, it can either be engulfed by macrophages or processed by Kupffer cells in the liver. Thus, depending on the host's innate immune response, zonulin levels in the bloodstream may vary.[65] To date, the half-life of zonulin is not known; rather, it is hypothesized to be very short (minutes to hours) based on the half-lives of other proteins of similar size, such as LPSs.[65,76,83] Due to the high day-to-day variability, some researchers have instead proposed testing for IgA and IgG antibodies against zonulin, occludin, and other tight-junction proteins, which are considered more stable markers of tight-junction permeability.[65]

FACTORS AFFECTING INTESTINAL PERMEABILITY

A number of factors have been shown to interfere with the integrity of intestinal barrier function, including enteric infections, a high-fat diet, gluten, food allergens, and drugs such as NSAIDs and proton-pump inhibitors (Fig. 19.4).[4]

Enteric Infections

Virtually all enteric pathogens disrupt the tight-junction barrier (Table 19.2), although the mechanisms by which they do so can vary from organism to organism.[45] Other mechanisms by which enteric pathogens increase paracellular and transcellular permeability include the upregulation of proinflammatory cytokines and immune cell infiltration.[7,40]

Protozoal infections are also associated with damage to the intestinal wall, specifically those caused by *Giardia intestinalis*,[46,84] *Entamoeba histolytica*,[22,46,85] and *Blastocystis hominis*.[86] Protozoa conventionally classified as nonpathogenic (e.g., *Entamoeba coli*) do not appear to alter intestinal permeability.[86]

High-Fat Diet

The Western diet is characterized by a high intake of dietary fats (particularly saturated fatty acids) and sugar (especially fructose) and a low intake of fiber. The long-term effects of an energy-rich, nutrient-poor diet are associated with a number of metabolic disorders that have their origins in altered microbiota and/or increased intestinal permeability with enhanced endotoxin in the portal vein.[26] Consumption of a high-fat diet leads to upregulation of the transcellular pathway (via chylomicron–LPS cotransport), which occurs independent of altered paracellular permeability.[87,88]

Gluten/Gliadin

As previously mentioned, gluten and the gluten component gliadin, along with bacteria, have been identified as the major stimuli that can trigger the release of zonulin.[51,89] It has been postulated that zonulin-driven opening of the tight junctions may be a host defense mechanism to flush out microorganisms and upregulate the innate immune system to protect against colonization of the small intestine.[37,49]

Food Allergies and Intolerance

For food allergies to manifest, intraluminal antigens must first penetrate the intestinal epithelial barrier before gaining access to mast cells in the subepithelial compartment and triggering hypersensitivity reactions.[90] Under normal conditions, most dietary proteins (~90%) are digested by gastric and pancreatic proteases and brush-border enzymes and transformed into peptides and amino acids before being absorbed by enterocytes via the transcellular pathway.[30,90] Once inside the enterocytes, any remaining intact proteins are ordinarily broken down inside lysosomal compartments, thereby preventing undigested proteins from entering the lamina propria.[17,91,92] A small amount (~10%) of intact proteins or partially digested peptides will cross the intestinal wall via the paracellular route. This pathway is regulated by intercellular tight junctions and, once translocated, results in antigen-specific immune responses that support immune tolerance to nonself antigens.[17,89]

Prolonged upregulation of paracellular permeability allows large amounts of nonself antigens to enter the lamina propria, which initiates an allergic reaction characterized by mast-cell recruitment and IgE-mediated antibody production. Inflammatory mediators such as cytokines and proteases also involved in the immune response set up a self-perpetuating situation leading to further gut barrier damage and increased entry of allergens into the circulation.[4,57,93]

Rotavirus

Nonsteroidal Anti-Inflammatory Drugs and Proton-Pump Inhibitors

Altered gut barrier function is estimated to occur in 60% to 80% of patients taking NSAID medication.[4] Even short-term NSAID therapy has been shown to cause changes in intestinal permeability similar to those seen in patients with active IBD.[63,94] Ingestion of NSAIDs initially damages the enterocytes and increases gut permeability. The damaged mucosa is then exposed to endogenous substances such as bile acids, bacterial degradation products, and hydrolytic and proteolytic enzymes, with subsequent immune activation and inflammation.[4,95] Both cyclooxygenase (COX)-1 and COX-2 inhibitors have been implicated in small bowel damage.[95]

Proton-pump inhibitors (PPIs) are another commonly prescribed drug, often coadministered with NSAIDs. Their deleterious effects on intestinal barrier function primarily target the stomach and colon.[4] In addition to decreasing gastric production of HCl, these medications inhibit contractile activity, which interferes with the tight-junction complex via the intracellular actin–myosin cytoskeleton. Research suggests they may also affect paracellular permeability through phosphate-mediated dephosphorylation of tight-junction proteins.[4]

Exposure to Xenobiotic Pollutants

More than 25 tons of food will be processed over the course of an individual's life span, representing the largest load of antigens and xenobiotics confronting the human body. Infection, inflammatory cytokines, nutrient transporter activation, and noxious environmental toxins all alter intestinal permeability. Persistent organic pollutants (POPs) bioaccumulate in human and animal tissue and biomagnify in food chains, thus increasing their concentration and toxicity in the environment. Pollutants that are highly fat soluble are readily reabsorbed via passive diffusion in both the intestines and proximal tubules. These lipophilic compounds can also be actively transported with bile salts back into the bloodstream. POPs damage DNA and mitochondria, stimulate the expression of tumor necrosis factor (TNF)-α, and increase inflammatory cytokines, all of which contribute to increased

intestinal permeability. Alcohol ingestion also increases intestinal permeability to endotoxins and macromolecules, allowing increased toxic and antigenic effects.[96]

Cholinergic signaling is also involved in the regulation of the barrier function. Fluoridated drinking water can cause gastrointestinal distress as fluoride is converted to hydrogen fluoride in the stomach. Chronic gastritis with associated histological changes, including scanty microvilli, surface abrasions, and desquamated epithelium, as well as IBD, have been observed in individuals after consuming fluoride for long periods of time.[97] These have been shown to result from the effect of fluoride on the cholinergic pathway.

Olmesartan, an angiotensin II receptor blocker, has been associated with the development of a sprue-like enteropathy characterized by severe diarrhea and histopathological changes in the intestine.[98,99] A study from the Mayo Clinic first reported the association between olmesartan and enteropathy.[100] Twenty-two patients presented with severe diarrhea and weight loss and biopsies consistent with celiac sprue. However, serological testing for celiac disease was negative, and no patient responded to a gluten-free diet. After cessation of the medication, clinical symptoms resolved quickly, and the histological changes disappeared.

Many studies have shown that disruption of tight junctions leads to a rise in epithelial permeability. For example, methotrexate induces ZO-1 dephosphorylation, which in turn is associated with a change in the protein's localization in epithelial cells in the small intestine; this change may contribute to leakage of the intestinal barrier.[101] Chlorpyrifos, an organophosphate insecticide, has been linked to microbial dysbiosis and modification of the function of the enteric nervous system and its associated cholinergic signaling, which alters the epithelial barrier function and changes tight-junction protein expression.[102]

GASTROINTESTINAL AND SYSTEMIC DISEASES ASSOCIATED WITH ALTERED INTESTINAL BARRIER FUNCTION

Alterations in gut barrier function have been implicated in the pathogenesis of a number of chronic inflammatory diseases, including intestinal diseases, cardiometabolic disorders, autoimmune diseases, lung conditions, neurological disorders, and systemic infectious diseases (Table 19.3).[4,17,39,62] There is much debate among the medical and scientific communities as to whether disrupted intestinal barrier function is an initiating factor or epiphenomenon of inflammatory diseases.[17,45,47,48] To date, the gastrointestinal and systemic diseases with the strongest evidence of altered intestinal barrier function as an initiating and/or developing factor include celiac disease, IBD, irritable bowel syndrome, and type 1 diabetes.[45]

Numerous in vitro, animal, and ex vivo studies indicate that altered intestinal permeability can lead to the development of chronic inflammatory diseases by influencing the mucosal immune system, but only in genetically susceptible hosts with initial exposure to an environmental trigger (i.e., microbial or viral infection, dietary proteins, and toxic chemicals).[6,17,29] Fasano and colleagues have identified a common chain of events triggering the development of autoimmune diseases such as celiac disease and type 1 diabetes. The initiating step is the genetic susceptibility of the host's immune system to identify and misinterpret an environmental antigen from the small intestinal tract. The second step involves the host being exposed to the antigen, and the final step involves the antigen being presented to the mucosal immune system following paracellular passage and entry into the submucosa. Delivery of the antigen to the submucosa triggers a multiorgan process that leads to the development of an autoimmune response.[49]

TABLE 19.3 Gastrointestinal and Extraintestinal Conditions Associated With Intestinal Permeability[4,17,23,45,48]

Gastrointestinal Conditions	Extraintestinal Conditions
Alcoholic liver disease	Acute lung injury
Celiac disease	Asthma
Enteric infections and infestations	Atherosclerosis
Food allergies and intolerance	Atopic allergies
Hepatic encephalopathy	Autism spectrum disorders
Inflammatory bowel disease	Coronary artery disease
Irritable bowel syndrome (IBS)	Environmental enteropathy
Liver cirrhosis	Food allergies
Liver fibrosis	Graft-versus-host disease
Necrotizing enterocolitis	HIV infection
Nonalcoholic steatohepatitis	Hypertension
Nonceliac gluten sensitivity	Insulin resistance
Pancreatitis	Mediterranean fever
Small intestinal bowel overgrowth	Metabolic syndrome
Steatosis	Multiorgan failure syndrome
	Multiple sclerosis
	Neuropsychiatric illnesses
	Obesity
	Osteoporosis
	Parkinson's disease
	Rheumatoid arthritis
	Septicemia
	Type 1 diabetes
	Type 2 diabetes

THERAPEUTIC CONSIDERATIONS

Nutrition has been shown to have a pronounced effect on the microbiota, intestinal barrier function, and the passage of endotoxins into the circulation.[87] Therefore encouraging patients to make positive dietary changes should be part of a holistic treatment plan to restore intestinal barrier function.[26] Consuming a more traditional diet that is rich in fruits and vegetables, whole grains, and foods with prebiotic properties while minimizing processed and refined foods, total fat, and total calories can help reduce circulating endotoxins.[26,87] Such recommendations are supported by research that demonstrated a 71% rise in plasma endotoxins with a Western-style diet and a 31% reduction in circulating endotoxins following the consumption of a more traditional diet.[96]

Nutraceutical Therapies

Given that increased intestinal permeability may well be a consequence of the disease, versus the initiating event, researchers recommend treating the underlying disease(s).[39] For example, IBD is associated with significant increases in proinflammatory cytokines, which are known to increase both paracellular and transcellular permeability.[45] Treating IBD with anti-TNF antibodies or other recognized therapies that address the underlying immune activation has been shown to significantly reduce intestinal permeability.[39]

Natural agents with the greatest evidence for their use in protecting the intestinal epithelium include probiotics and the amino acid glutamine. Other nutraceutical agents with clinical and in vitro evidence to support intestinal barrier function are also described in the following sections.

Probiotics

Probiotics are thought to protect the intestinal mucosa and epithelial barrier through several different mechanisms[6,11,97]:

1. By enhancing the expression and secretion of mucin and β-defensins, thereby preventing the proliferation and migration of commensal and pathogenic organisms across the mucus layer
2. By increasing the production and secretion of sIgA to protect bacteria and their antigens from epithelial colonization
3. By altering gene expression and/or microbiota composition and increasing numbers of commensal bacteria
4. By producing antimicrobial factors (e.g., bacteriocins) that kill or inhibit pathogenic bacteria
5. By enhancing the production of tight-junction transmembrane proteins

Positive peer-reviewed clinical trials evaluating probiotic intervention with intestinal permeability as a primary endpoint are summarized in Table 19.4.

Glutamine

Glutamine is considered a conditionally essential amino acid that serves as a preferential fuel for rapidly dividing mucosal cells such as enterocytes, colonocytes, and immune cells.[45,103,104] It plays a vital role in the maintenance of mucosal growth and in its structure and function, particularly in times of metabolic stress where demand outweighs supply. For example, catabolic states such as burns, sepsis, and recovery from major surgery are associated with low glutamine status and accompanying epithelial atrophy and increased intestinal permeability.[47,103,105] Glutamine also protects against chemotherapy-induced alterations in gut permeability.[106,107] Supplementation with glutamine has been shown to restore intestinal membrane permeability and protect against TNF-α–induced bacterial translocation after intestinal injury.[47,104] In vitro studies suggest glutamine helps restore paracellular permeability by regulating the expression of the tight-junction proteins zonulin and occludin.[56,108]

Given its role in intestinal metabolism and immunity, glutamine was thought to be a promising therapeutic agent for patients with IBD. However, research in this cohort is sparse and conflicting, with studies suggesting it may actually exacerbate symptoms.[103,109,110] Supplementation with glutamine may enhance T-cell function, which can lead to the upregulation of proinflammatory cytokines and aggravate Crohn's disease.[110] Glutamine may also indirectly increase nitric oxide synthesis via its metabolism from citrulline to arginine, with resultant inflammation and tissue injury in patients with ulcerative colitis and Crohn's disease.[111] Some researchers have postulated that discrepant findings may be a result of the timing and duration of glutamine supplementation. It is thought that glutamine intervention should be administered before or at the onset of injury and, failing that, for a longer duration than most studies have allowed.[56] Dosing may also be a critical factor because studies that have yielded positive outcomes for patients with IBS with diarrhea (IBS-D)[112] and hospitalized,[113] postoperative,[114,115] chemotherapy,[106,107] and radiotherapy patients[116] have supplemented with 20 to 30 grams per day (intravenously or orally) for 5 to 30 days.

Miscellaneous Nutraceuticals

Other nutrients with preliminary clinical evidence for supporting intestinal barrier function include bovine colostrum, lactoferrin, and zinc. Bovine colostrum may have potential as a natural agent to protect against NSAID-induced alterations in mucosal integrity by downregulating proinflammatory cytokines.[117–120] Recombinant lactoferrin has also been shown to reduce NSAID-mediated small intestinal permeability following a short-term indomethacin challenge.[121] High-dose zinc (110 mg three times a day for 8 weeks) was reported to reduce intestinal permeability in patients with Crohn's disease in remission.[122]

Natural agents with experimental evidence for supporting intestinal barrier regulation include polyphenols, vitamins A and D, polyunsaturated fatty acids (PUFAs), and butyrate.

To date, a number of polyphenols have been investigated, including quercetin, kaempferol, myricetin, genistein, catechin, and curcumin. The main mechanisms by which polyphenols help restore intestinal permeability are through enhancing tight-junction assembly and neutralizing proinflammatory cytokines (in particular, TNF-α, IL-1β, and IFN-γ).[26,45,46,56]

Vitamin A and D receptors are expressed in a number of organs, including the intestinal epithelium, where they play a role in gene transcription and regulation.[45] Both of these fat-soluble vitamins have been shown to support gut barrier integrity and improve immune function.[56,123] Vitamin A helps regulate the growth and differentiation of intestinal epithelial cells. In animal models and in vitro studies, a deficiency of vitamin A is associated with altered commensal bacteria, reduced villous height, and dysregulated tight-junction protein assembly.[26,124] Vitamin D is thought to protect the intestinal barrier by inducing the expression of tight-junction proteins (specifically ZO-1 and claudin).[6] Low levels of vitamin D are associated with reduced mucosal barrier integrity and increased susceptibility to mucosal damage, which may in turn increase the risk of IBD.[125] In other experimental studies, vitamin D deficiency demonstrated alterations in the microbiome and intestinal epithelial barrier dysfunction.[123]

Animal studies suggest polyunsaturated omega-3 fatty acids can improve villous height and intestinal barrier function and reduce LPS-induced intestinal damage.[46] In vitro research shows that PUFAs support paracellular permeability by modulating occludin and zonulin tight-junction proteins.[126]

Butyrate is a short-chain fatty acid (SCFA) produced by the anaerobic microbial fermentation of oligosaccharides that serves as an important metabolic fuel for colonic bacteria.[28] In vitro studies have demonstrated that butyric acid supports intestinal barrier function by regulating the assembly of the tight-junction proteins zonulin and occludin.[127] Based on animal research, butyrate improves tight-junction integrity by improving transepithelial resistance. It has also been shown to prevent the release of TNF-induced IL-8 secretion, suggesting a therapeutic role for butyrate in inflammatory diseases of the colon.[46,128]

Pharmaceutical Medications for Altered Intestinal Permeability

Larazotide Acetate

The most promising pharmaceutical drug candidate for the treatment of altered intestinal barrier function is larazotide acetate. Also known as AT-1001, larazotide is a zonulin antagonist that protects against gliadin-induced alterations in paracellular permeability in patients with celiac disease.[39] Phase I and Phase II clinical trials have demonstrated an excellent safety and tolerability profile.[126] Although all trials demonstrated a reduction in tissue transglutaminase and intestinal and extraintestinal symptoms after a gluten challenge, improvements in the lactulose/mannitol ratio were reported only in the inpatient setting.[129–132] Phase III clinical trials are currently underway, and its use for other chronic inflammatory diseases associated with zonulin dysregulation is also being explored.[17,49]

Disodium Cromoglycate

The pharmacological agent disodium cromoglycate is a recognized mast-cell stabilizer that has been used for the treatment of IgE-mediated gut permeability.[133,134] More recently, it has demonstrated

TABLE 19.4 Probiotic Intervention Studies Assessing Intestinal Barrier Function

Probiotic(s)	Study Design	Indication(s)	Dose	Outcomes
Lactobacillus rhamnosus GG[144]	Randomized, double-blind, placebo-controlled trial	Atopic dermatitis and food allergies in infants ($n = 27$) Eczema in nursing mothers ($n = 10$)	5×10^8 CFU/g infant formula for one month 2×10^{10} CFU twice daily for one month (mothers)	Alleviated intestinal inflammation and promoted endogenous barrier mechanisms by reducing TNF-α and IL-4
Lactobacillus rhamnosus 19070–2, *Lactobacillus reuteri* DSM 1224[145]	Randomized, double-blind, placebo-controlled crossover trial	Atopic dermatitis (moderate to severe) in children aged 1–13 years ($n = 41$)	2×10^{10} CFU twice daily for 6 weeks	Improved gut barrier (reduced lactulose/mannitol ratio)
Lactobacillus acidophilus-11 *Lactobacillus plantarum* 1258 *Bifidobacterium longum*-88[146]	Randomized, double-blind, placebo-controlled trial	Colorectal carcinoma patients undergoing colectomy aged 25–75 years ($n = 150$)	2.6×10^{14} CFU/day for 6 days preoperatively and 10 days postoperatively	Reduced the rate of postoperative infection and septicemia Reduced serum zonulin concentrations
Lactobacillus acidophilus-11 *Lactobacillus plantarum* 1258 *Bifidobacterium longum*-88[147]	Randomized, double-blind, placebo-controlled trial	Colorectal liver metastases in adults aged 25–75 years ($n = 150$)	2.6×10^{14} CFU/day for 6 days preoperatively and 10 days postoperatively	Reduced the rate of postoperative infection and septicemia Reduced serum zonulin concentrations
Saccharomyces boulardii-17[148]	Randomized, single-blind, placebo-controlled trial	Crohn's disease in adults aged 19–54 ($n = 34$)	200 mg lyophilized *Saccharomyces boulardii* (4×10^8 CFU) every 8 hours for 3 months	Improved intestinal permeability Prevented the activation of NF-κB and downstream proinflammatory cytokines
Lactobacillus rhamnosus GG[149]	Randomized, double-blind, placebo-controlled trial	Gastroenteritis in infants and children aged 9–21 months ($n = 124$)	1×10^{10} CFU/day for 4 weeks	Improved intestinal permeability Increased IgG antibody levels
Streptococcus thermophilus, Lactobacillus acidophilus, Lactobacillus bulgaricus, Bifidobacterium longum[150]	Randomized, single-blind, placebo-controlled trial	Diarrhea-predominant irritable bowel syndrome (IBS-D) in adults aged 32–57 ($n = 30$)	200g Fermented milk containing *Streptococcus thermophilus* 1×10^8 CFU, *Lactobacillus bulgaricus* 1×10^7 CFU, *Lactobacillus acidophilus* 1×10^7 CFU, *Bifidobacterium longum* 1×10^7 CFU twice daily for 4 weeks	Decreased small bowel permeability and improved mean global IBS scores
Lactobacillus rhamnosus GG[151]	Randomized, single-blind, placebo-controlled trial	IBS or functional abdominal pain in children aged 5–14 years ($n = 136$)	3×10^9 CFU twice daily for 8 weeks	Improved intestinal permeability Reduced frequency and severity of abdominal pain
Lactobacillus rhamnosus GG[152]	Randomized, double-blind, placebo-controlled trial	NSAID-induced alterations in gastric permeability in adult males aged 18–38 ($n = 16$)	2.4×10^9 CFU/day for 5 days	Protected the integrity of the gastric mucosal barrier against indomethacin therapy
Bifidobacterium animalis ssp. lactis 420 (B420) and/or Litesse Ultra polydextrose (LU)[153]	Randomized, double-blind, placebo-controlled trial	Overweight and obese adults aged 18–65 ($n = 225$)	1×10^{10} CFU/day for 6 months	B420 and B420 + LU reduced waist circumference and food intake Reduced blood zonulin and hs-CRP correlated with reduced trunk fat mass
Bifidobacterium lactis + Preterm infant formula (Prenan Nestle)[154]	Prospective, randomized case-control study	Preterm infants 27–36 weeks' gestation ($n = 75$)	2×10^7 CFU/g infant formula for 30 days	Decreased intestinal permeability and increased head growth
Lactobacillus acidophilus W22 *Lactobacillus casei* W56 *Lactobacillus paracasei* W20, *Lactobacillus plantarum* W62 *Lactococcus lactis* W19 *Bifidobacterium bifidum* W23 *Bifidobacterium lactis* W51 (Ecologic 825)[155]	Controlled clinical trial	Patients with ulcerative colitis with active pouchitis aged 32–71 years ($n = 16$)	2.5×10^9 CFU twice daily for 8 weeks	Probiotics restored the mucosal barrier to *Escherichia coli* Bacterial diversity correlated with barrier function

CFU, colony-forming unit; *hs-CRP,* high-sensitivity C-reactive protein; *IBS,* irritable bowel syndrome; *IgG,* immunoglobulin G; *IL-4,* interleukin-4; *NF-κB,* nuclear factor-kappa B; *NSAID,* nonsteroidal anti-inflammatory drug; *TNF-α,* tumor necrosis factor-alpha.

promising results in reducing diarrhea-predominate IBS symptoms[135] and functional dyspepsia,[136] although the exact mechanisms by which it improves barrier function have yet to be determined.

A number of pharmaceutical drugs used for the treatment of gastrointestinal diseases are also capable of modifying intestinal permeability. These include steroids, aminosalicylates, anti-TNF agents, and mucosal protectors.[21]

Corticosteroids

Corticosteroids have long been used to induce remission in Crohn's disease. Prednisolone therapy has been shown to reduce intestinal permeability by approximately 50% in patients with Crohn's disease (evidenced by improvements in the lactulose/mannitol ratio).[137] Other clinical research has demonstrated a decrease in permeability in children and adolescents with active Crohn's disease and ulcerative colitis (assessed with the lactulose/rhamnose ratio).[138] The ability of corticosteroids to inhibit the expression of TNF-α and nuclear factor (NF)-κB represent the underlying mechanisms by which these drugs protect against damage to the intestinal barrier.[139]

Aminosalicylates

5-aminosalicylic acid derivatives are often employed for the treatment of uncomplicated, mild to moderate IBD. In vitro studies show that these medications (particularly mesalamine) support the reestablishment of the mucosal barrier by enhancing epithelial restitution and proliferation.[140,141]

Anti-TNF agents

Anti-TNF agents such as infliximab are a more recent class of drugs used to treat IBD. As their name suggests, they work by inhibiting the TNF pathway, thereby reducing inflammation and restoring mucosal integrity.[39,142]

Mucosal Protectors

Mucosal protectors have a long-standing history of use in the treatment of peptic disease. Drugs such as sucralfate and bismuth help protect epithelial cells from gastric acid and pepsin.[143] Gelatin tannate works by forming a protective mucoadhesive layer and reducing the intestinal inflammation and bacterial fermentation associated with infectious diarrhea.[21]

Laboratory Tests for the Determination of Vitamin Status

Joseph E. Pizzorno, ND

OUTLINE

INTRODUCTION

Laboratory assessment of vitamin status is a significant challenge for the clinician. Although measurement of blood and serum levels is easily available, their clinical value is limited to the detection of severe deficiencies. Detection of functional deficiencies requires far more sophistication. A number of diverse methods have been used by researchers and clinicians to try to answer the question, "Does this patient need more of a specific vitamin?" A number of strategies are available to the clinician, three of which will be mentioned here.

The traditional method is to measure levels in specific tissues such as blood, serum, red cells, and white cells. The advantage of this strategy is that establishing population standards is straightforward. However, a key disadvantage of this strategy is that it is absolute (i.e., it is a measure of level, but not function). As can be seen in Fig. 20.1, although a person may have adequate blood levels of a nutrition, indications of inadequacy such as homocysteine will often indicate a functional deficiency even though the blood levels are supposedly adequate.

As our understanding of the genomics of nutrition has evolved, we have now added another more nuanced question: "Does this patient need the activated version of a specific vitamin?" Several chapters on nutrition in this textbook present research showing that a surprisingly large portion of the population does not convert the dietary version of one or more nutrients into one or more of its activated forms. For example, see Chapter 125 Vitamin A for a discussion of the research showing that a surprising 25% to 35% of the general population poorly converts beta-carotene to vitamin A.

A second strategy then is to measure molecules that may increase or decrease when inadequate functional levels of a nutrient is available. For example, inadequate activated folate or vitamin B_6 will result in elevated levels of homocysteine. Chapter 210, Porphyrias provides numerous examples of changes in urinary excretion of multiple molecules that indicate nutritional inadequacy.

A third strategy is to take some of the patient's blood and then use some measure of cellular function and determine the amount of each nutrient needed to optimize function. This is an intriguing idea in need of substantial clinical validation.

ASSESSMENT OF WATER-SOLUBLE VITAMIN STATUS

See Table 20.1 for laboratory tests and optimal ranges for common vitamins.[1–5]

Ascorbic Acid (Vitamin C)

Assessment of vitamin C is particularly difficult because ascorbate readily oxidizes in assay samples. In addition, serum levels reflect recent dietary uptake rather than actual tissue levels. Research in an animal model of vitamin C deficiency (the *Gulo* mouse) clearly demonstrated that a dietary intake that does not lead to serum saturation of vitamin C results in tissue deficits.[6] Serum saturation of vitamin C was required to achieve tissue concentrations similar to wild-type animals, which can synthesize ascorbate. In humans, maximum serum saturation from oral dosing was predicted to be roughly one sixtieth of that achieved with intravenous administration, highlighting the inability of serum levels to predict optimal physiological function.[7,8] Leukocyte levels are not as susceptible to dietary intake but are also readily affected by infection, hypoglycemia, and many common prescription and over-the-counter drugs. Additionally, the uptake of ascorbate into leukocytes significantly underestimates the relative uptake of ascorbate into muscle tissue (which contains roughly two thirds of total body ascorbate), indicating that muscle may be a more labile pool for vitamin C, and more prone to deficiency.[9] The popular lingual ascorbate test does not appear to be reliable because it does not correlate well with leukocyte or serum levels.[10] The loading test, if carefully controlled, is probably most accurate, although good standard ranges have yet to

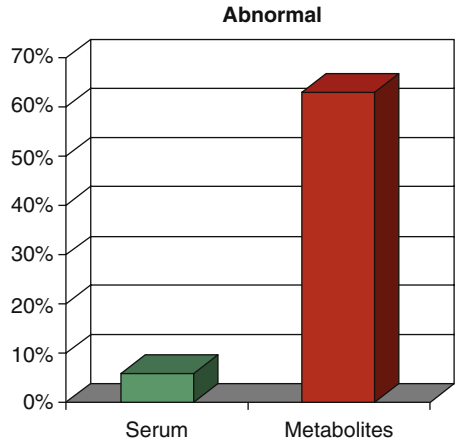

Fig. 20.1 Predicting deficiency by blood level versus metabolite level. (Modified from Joosten E, van den Berg A, Riezler R, et al. Metabolic evidence that deficiencies of vitamin-B12 [cobalamin], folate, and B-6 occur commonly in elderly people. *Am J Clin Nutr.* 1992;58[4]:468–476.)

be determined. Discovery of ascorbate-dependent enzymes involved in cell signaling pathways and epigenetic modulation offer the possibility for more functional analysis in the future, although unfortunately no definitive analysis is currently available.[11] Lastly, polymorphisms in vitamin C transport genes may also be relevant when assessing status; for example, variants in vitamin C transport genes have been associated with serum vitamin C concentrations and modify the strength of the correlation between dietary vitamin C and serum ascorbic acid.[12] Some of these polymorphisms have also been linked to a variety of disease risks, including coronary heart disease, inflammatory bowel disease (IBD), and cancer.[13,14]

Biotin

Biotin is a vitamin B complex especially affected by oral antibiotics. Food is a poor source of this vitamin, making humans more dependent on gut flora sources. Elevation of 3-hydroxyisovalerate (3-HIA) resulting from deficiency of the biotin-dependent enzyme appears a useful measure. Additionally, two studies in which healthy volunteers were intentionally made biotin deficient suggested that elevated urinary levels of 3-HIA-carnitine might be a sensitive indicator, even for a marginal deficiency. This offers greater accuracy and is less prone to laboratory error than the traditional urinary 3-HIA.[15,16] Plasma levels of 3-HIA-carnitine may also prove to be a sensitive marker and reduce the dependency on renal function for an accurate determination, an important consideration during pregnancy.[17]

Folate

Serum folate is too greatly affected by recent consumption to be clinically useful; however, elevated serum folate levels (>45.3 nmol/L) in the presence of a vitamin B_{12} deficiency may reflect a functional folate deficiency known as a "methyl trap" (i.e., a build-up of 5-MTHF that cannot be converted to tetrahydrofolate, because methionine synthesis is impaired).[18] Homocysteine levels may be elevated because of deficiency of vitamins B_6 and/or B_{12} and folate. Erythrocyte folate is more accurate and considered a more reliable indicator of tissue status; it is not influenced by recent dietary intake and represents a 4-month average. Evaluation of other B vitamin status, particularly B_{12}, may be necessary to rule out a folate deficiency. Although the presence of neutrophil hypersegmentation has been used to identify folate deficiency, this also occurs with B_{12} and iron deficiency, making it a very nonspecific marker.[19] Recent advances in mass spectrometry allow for measurement of folate species, including 5-MTHF, THF,

TABLE 20.1 Laboratory Tests and Optimal Ranges for Common Vitamins

Nutrient	Test	Acceptable Level
Water-Soluble		
Ascorbic acid	Serum	>0.3 mg/dL
	Leukocyte	30 mcg/10^8 WBCs
	Load test	0.3–2.0 mg/h in control
		24–49 mg/h after 500 mg
Biotin	3-hydroxyisovalerate	<20 mcg/mg creatinine (overnight urine)
Folate	Erythrocyte folate	>160–650 ng/mL (~350 nmol/L) Note: cut-off recommended for pregnant women is >906 nmol/L
	Serum homocysteine	<10 μmol/L
Niacin	Urinary *N*-methylnicotinamide	>1.6 mg/g creatinine
	2-pyridone 5-carboxamide (2-PYR)	>1.6 mg/g creatinine
	RBC NAD/NADP	>1.3
Pantothenic acid	Urinary pantothenic acid	>1 mg/day
Pyridoxine	Serum level	5.0–50.0 ug/L
	Plasma pyridoxal 5-phosphate	>30 nmol/L
	Urinary 4-PA	>3.0 mol/d
	Serum homocysteine	<9.0 μmol/L
Riboflavin	EGRAC	<1.3
Thiamine	RBC transketolase	<15% increase
	Whole blood thiamine (HPLC)	>16 ng/mL
Vitamin B_{12}	Serum B_{12}	>150 pg/mL
	Urinary methylmalonic acid	<5 mcg/mg creatinine
	Serum methylmalonic acid	<0.45 μmol/L
	Serum homocysteine	<9.0 μmol/L
	Holotranscobalamin	>30 pmol/L
Fat-Soluble		
Vitamin A	Plasma retinol:	15–60 mcg/dL:
	0–5 mo	>20
	6 mo–17 y	>30
	Adult	>20
Vitamin D	25 (OH) vitamin D	40–80 ng/mL
Vitamin E	Plasma α-tocopherol	>16.2 μmol/L
	α-tocopherol:cholestrol	>5.2 μmol/L
Vitamin K	% serum uncarboxylated osteocalcin	<20 ? (optimal not yet determined)

5,10-methyleneTHF, methenylTHF/10-formylTHF, and formylTHF, though this test is not widely available.[20]

Niacin

Although measurement of nicotinic acid in the blood is not very reliable, measurement of its metabolites provides a clinically useful function assessment. Several metabolite tests are now available, including urinary levels of 2-pyridone 5-carboxymide and *n*-methylnicotinamide.[21,22]

Pantothenic Acid

Serum pantothenic acid does not correspond well with dietary intake, although erythrocyte levels are more closely correlated.[23] Measurement of urinary excretion of pantothenic acid appears reliable.

Pyridoxine

Several procedures are available for assessing vitamin B_6 status. Unfortunately, substantial agreement on the best methodology has not been established, because variations in phenotypes significantly alter the results of functional and loading tests. The active form of pyridoxine (pyridoxal 5-phosphate [P5P]) is involved in some 60 enzymes, so deficient activity of these enzymes can be measured as a functional assessment of pyridoxine. Plasma levels of P5P appear to be a better functional indicator than erythrocyte levels, at least in patients with rheumatoid arthritis (RA).[24] Plasma P5P levels show an inverse relationship with C-reactive protein, with low levels observed in a number of inflammatory conditions, including RA, IBD, stroke, and diabetes and, at least in RA and IBD, P5P levels are inversely related to disease severity. It has been suggested that this is caused by a tissue-specific mobilization of P5P to the site of inflammation.[25] Plasma levels below 30 nmol/L (considered borderline deficient) have independently been associated with an increased risk for coronary artery disease, with a particularly high risk when combined with high-sensitivity C-reactive protein.[26,27] High plasma P5P levels have also been associated with a 34% reduced risk for all cancers, according to a recent meta-analysis of nearly 2 million participants.[28] Although suitable for most circumstances, plasma P5P does not appear to be reliable during pregnancy or the acute phase of myocardial infarction, and alternatives should be used. Additionally, it can also be affected by albumin concentration, alkaline phosphatase activity, and alcohol consumption, and decreases after glucose or carbohydrate intake. Urinary 4-pyridoxic acid (PA) is a useful marker of recent intake only, whereas erythrocyte aminotransferase and erythrocyte alanine aminotransferase activation by pyridoxal phosphate may be a better indicator of long-term status.[29] Elevated homocysteine may also be a sign of deficiency, at least in some populations.[30] Plasma 4-PA has also been suggested as a marker, as it is less influenced by inflammation, though it is significantly influenced by renal function. Ratios of various metabolites, such as the PAr index (PA/[P5P+ plasma pyridoxal]) and the ratio of 3-hydroxykynurenine to xanthurenic acid appear to mitigate the effect of some of the many confounders for vitamin B6 status.[31]

Riboflavin

The most common measure of riboflavin is red blood cell glutathione reductase activity. The enzyme is stimulated in vitro by the addition of flavin adenine dinucleotide, and expressed as erythrocyte glutathione reductase activation coefficient (EGRAC). An EGRAC greater than 1.30 is typically used as a cut-off (with higher values indicative of suboptimal status), although one recent study suggested this threshold for deficiency might need to be raised. This same study also demonstrated that riboflavin supplementation caused an increase in hemoglobin status among women with the lowest riboflavin intakes, despite no change in iron intake or absorption.[32] EGRAC is not reliable in individuals with glucose-6-phosphate dehydrogenase deficiency. In this population, pyridoxamine phosphate oxidase may be more appropriate.[33] Blood riboflavin levels are not reliable because of technical difficulties in measurement. Lastly, homocysteine levels may be relevant for those with genetic variation in the methylenetetrahydrofolate reductase gene. Individuals with the TT genotype of the C677 T polymorphism may have increased riboflavin needs.[34]

Thiamine

The most common measure of thiamine is erythrocyte transketolase activity. The enzyme is stimulated in vitro by the addition of thiamine pyrophosphate. Elevation in activity greater than 15% indicates a functional deficiency. The test is not reliable in patients with diabetes mellitus, pernicious anemia, or a significant negative nitrogen balance. For example, growing evidence has indicated that a tissue deficiency of thiamine exists in patients with diabetes, and may increase the risk for vascular and neurological complications. Despite markedly reduced plasma levels of thiamine among individuals with type 1 and type 2 diabetes, erythrocyte transketolase activity remained normal, largely because of an upregulation of red blood cell thiamine transporter levels.[35,36] Advances in high-performance liquid chromatography technology now allow for direct measurement of either whole blood or erythrocyte thiamine, which may be a valuable alternative.[37,38] Both serum and plasma thiamine levels have poor sensitivity and specificity for a thiamine deficiency. Urinary thiamine excretion less than 40 mcg or less than 27 mcg/g creatinine also suggests a deficiency.[39]

Additionally, measurement of amino acids and their ketoacid analogs that are excreted in thiamine deficiency is being used. (See Brally and Lord[4] for a more complete discussion.)

Vitamin B_{12}

Serum levels of vitamin B_{12} are of some value, although they do not track cerebrospinal fluid levels very well, and only a small portion (20%–30%) of total cobalamin levels are bound to transcobalamin and taken up via receptor-mediated cellular uptake. Additionally, at typical cut-off levels, serum B_{12} may miss as many as 45% of B_{12} deficient patients if used in isolation.[40] Erythrocyte cell size is also not reliable, because neurological signs and symptoms can precede macrocytosis by 6 to 12 months.

Serum levels of holotranscobalamin may be the optimal first-line diagnostic procedure, at least among elderly patients. It has been suggested to be one of the earliest markers of negative B_{12} balance, and its diagnostic accuracy is not affected by renal insufficiency, a problem with total cobalamin levels and methylmalonic acid.[41,42] Using a cut-off of 30 and 60 pmol/L holotranscobalamin, a sensitivity of 65% and 90% and a specificity of 90% and 55%, respectively, were shown against a methylmalonic acid standard.[43]

Measurement of either urinary or serum methylmalonic acid is considered fairly sensitive and specific in those with healthy renal function, especially when expressed as a ratio with the urinary creatinine measurement.[44,45] Elevated homocysteine concentrations may indicate deficiency, but it is not specific to B_{12}.

ASSESSMENT OF FAT-SOLUBLE VITAMIN STATUS

Vitamin A

Although liver biopsy is the most accurate method of vitamin A assessment, other less invasive and less expensive methodologies are more appropriate. As with most other nutrients, serum levels of vitamin A fall significantly only after tissue reserves have been depleted, and are subject to numerous laboratory challenges as well as other factors (e.g.,

infection, protein status). Serum retinol binding protein is sometimes used as an alternative to serum retinol because it avoids many of these complications, although it is also susceptible to artificial decreases caused by inflammation or protein malnutrition.[46] Optimal cut-offs have not been clearly established for retinol binding protein, although levels greater than 0.825 μmol/L have been suggested for children and greater than 1.05 μmol/L for adults.[47,48] The dark adaptation test detects early deficiency of this nutrient, and provides a useful alternative (see Chapter 27). The retinol isotope dilution test, using deuterium- or (13) C-labeled retinol, has been cited as the most sensitive indirect marker of vitamin A status, useful for assessment of both deficiency and excess, but is not widely available.[49,50] Lastly, given the variation in the ability to convert β-carotene to retinol, the use of plasma carotene levels is probably not a useful marker of vitamin A status.[51]

Vitamin D

The widespread deficiency of vitamin D has gained a much greater degree of recognition, with most recommendations based on 25(OH) vitamin D levels. Most functional indicators, such as levels of parathyroid hormone, point to a level of 25(OH) vitamin D greater than or equal to 80 nmol/L as being sufficient, although some evidence has suggested higher levels might be optimal, particularly for cancer prevention.[52-54] Prostate cancer may be the outlier among cancers, as a recent meta-analysis of 21 studies found an increase in risk with increasing 25(OH) vitamin D levels.[55] However, a 2018 meta-analysis found that higher 25(OH) levels were associated with reduced mortality among prostate cancer patients, similarly to most other cancers.[56,57] Lastly, the measurement of free 25(OH) vitamin D may have its own clinical utility, such as vitamin D assessment during pregnancy, as it measures the functional activity and is less dependent on changes in vitamin D-binding protein levels. Only recently have reference ranges been suggested.[58,59]

Vitamin E

Despite dietary intake of γ-tocopherol being tenfold greater than α-tocopherol, the preference of the α-tocopherol transfer protein for α-tocopherol results in much higher serum levels, which is why the latter is often used as a biomarker. Emerging evidence suggests that despite the ease in measurement, and the widespread supplementation with α-tocopherol, mixed tocopherols (such as the γ form) are likely of greater physiological importance.[60,61] Unfortunately, optimal levels of other biomarkers have not yet been established, although one review reported a γ-tocopherol levels range between 2 and 5 μmol/L.[62] Somewhat concerning, data from nearly 6000 adults in the NHANES study found signs of more advanced cellular aging (measured by telomere length) in individuals with higher γ-tocopherol levels (α-tocopherol was not associated).[63] It is also important to adjust vitamin E levels to lipid levels, such as triglycerides or cholesterol, with the latter more commonly used.

Adipose and platelet levels have been suggested to be better biomarkers, as have cells with low-density lipoprotein receptors, such as mononuclear leukocytes and buccal mucosal cells.[64]

Vitamin K

In recent years the importance of vitamin K for physiological functions other than blood coagulation has been recognized, including functions related to both bone and vascular disease. For this reason, the traditional methods of assessment, such as prothrombin and clotting assays, may not be sufficient markers of vitamin K status, at least in regard to these other functions.[65] Better functional markers may be serum uncarboxylated osteocalcin (ucOC) levels, or perhaps a serum carboxylated OC to serum total OC ratio. One review suggested that a percent of ucOC greater than 20 is probably optimal, although genetic variations may modify this to some degree.[66-68] Another functional marker is the level of inactive matrix Gla-protein (MGP), referred to as dephospho-uncarboxylated MGP (dp-ucMGP), or sometimes as a ratio indicating the proportion of MGP that is carboxylated. This marker has been associated with arterial stiffness among diabetics and a risk factor for cardiovascular disease.[69,70] However, it is not clear that any of the carboxylated proteins reflect more than short-term vitamin K status. Additionally, although they may accurately assess the activity of menaquinones, it is not clear that they assess the different activity of phylloquinone.[71,72]

CONCLUSION

As described here, many procedures are now available for the assessment of absolute and functional vitamin status. Although research continues in this important area, the reader is advised to carefully study the discussion of urinary organic acids profiling (see Chapter 29). Using metabolic products excreted in the urine now allows the clinician far greater specificity in recognizing dysfunctional enzyme systems, whether they are a result of genetic deviations or nutritional deficiencies.

Lactose Intolerance Testing

Brian Orr, BA, BS, ND, Tina Kaczor, ND, FABNO,* and *Jeff Baker*, ND, DHANP, CCH*

OUTLINE

INTRODUCTION

Lactose malabsorption results from the inability to properly digest lactose, the disaccharide found in mammalian milk. Lactase is an enzyme in the brush border (microvilli) of the small intestine responsible for cleaving lactose into absorbable monosaccharides. Lactase enzyme deficiency leads to lactose malabsorption because the gut is unable to absorb the larger disaccharide. When symptoms such as diarrhea, bloating, flatulence, or abdominal discomfort result from this malabsorption, a diagnosis of lactose intolerance is given. Lactose intolerance affects an estimated 25% to 36% of Americans and 67% to 75% of adults worldwide.[1–3] As shown in Table 21.1, the condition occurs in people of all ethnic backgrounds, with a near 100% prevalence observed in Asians. Within the United States, prevalence parallels country of origin, with the highest rates in African Americans, Hispanic Americans, Asian Americans, and Native Americans.[4]

TABLE 21.1 Prevalence of Lactose Intolerance by Ethnic Group

Group	Prevalence (%)
African blacks	97–100
Asians	90–100
North American blacks	70–75
Hispanics	70–80
Persons of Mediterranean descent	60–90
Persons of Jewish descent	60–80
North American whites	7–15
Northern Europeans	1–5

The generalized nature of abdominal symptoms of lactose intolerance can obscure proper diagnosis,[5] resulting in symptom management through medical intervention. However, when properly diagnosed, lactose intolerance may be treated with patient education, lactase supplementation, and dietary modifications,[6,7] eliminating the need for medical interventions. In patients experiencing symptoms, a nutritional history and objective measures of lactose malabsorption can lead to the diagnosis of lactose intolerance. Objective measures for lactose malabsorption include stool pH testing, lactose tolerance testing, and hydrogen/methane breath testing. In addition, genomic tests are also available to assess the presence or absence of polymorphisms linked to lactase enzyme deficiency.[3]

Controversy surrounds the subject of lactose intolerance stemming from the dramatic decrease in dairy consumption that can result from its diagnosis. Numerous studies showed a correlation between decreased dairy consumption and a rise in calcium-dependent conditions, such as osteoporosis, heart disease, and colon cancer.[8–13] Studies also indicated that food-based calcium was a better source of this nutrient than supplements. Because dairy foods are the richest and best-absorbed dietary sources of calcium, a careful diagnosis should be made before these foods are eliminated from the patient's diet. Dietary limitation of calcium-rich foods should be done only in the context of objectively proven lactose intolerance. There is significant variability in the severity of symptoms,[14] and many patients with lactose malabsorption are able to consume moderate amounts of lactose without symptoms,[15] so both the diagnosis and treatment should be pursued under professional guidance.[16]

PATHOPHYSIOLOGY

Lactose is a disaccharide that can be hydrolyzed by the lactase enzyme lactase-phlorizin hydrolase (LPH) into glucose and galactose, which are actively absorbed in the small intestine (Fig. 21.1). When LPH activity is decreased in the brush border (microvilli) of the distal duodenum and proximal jejunum, then lactose malabsorption results. The presence of lactose malabsorption does not always result in lactose intolerance. Only when the amount of lactose ingested exceeds

*Previous edition contributor

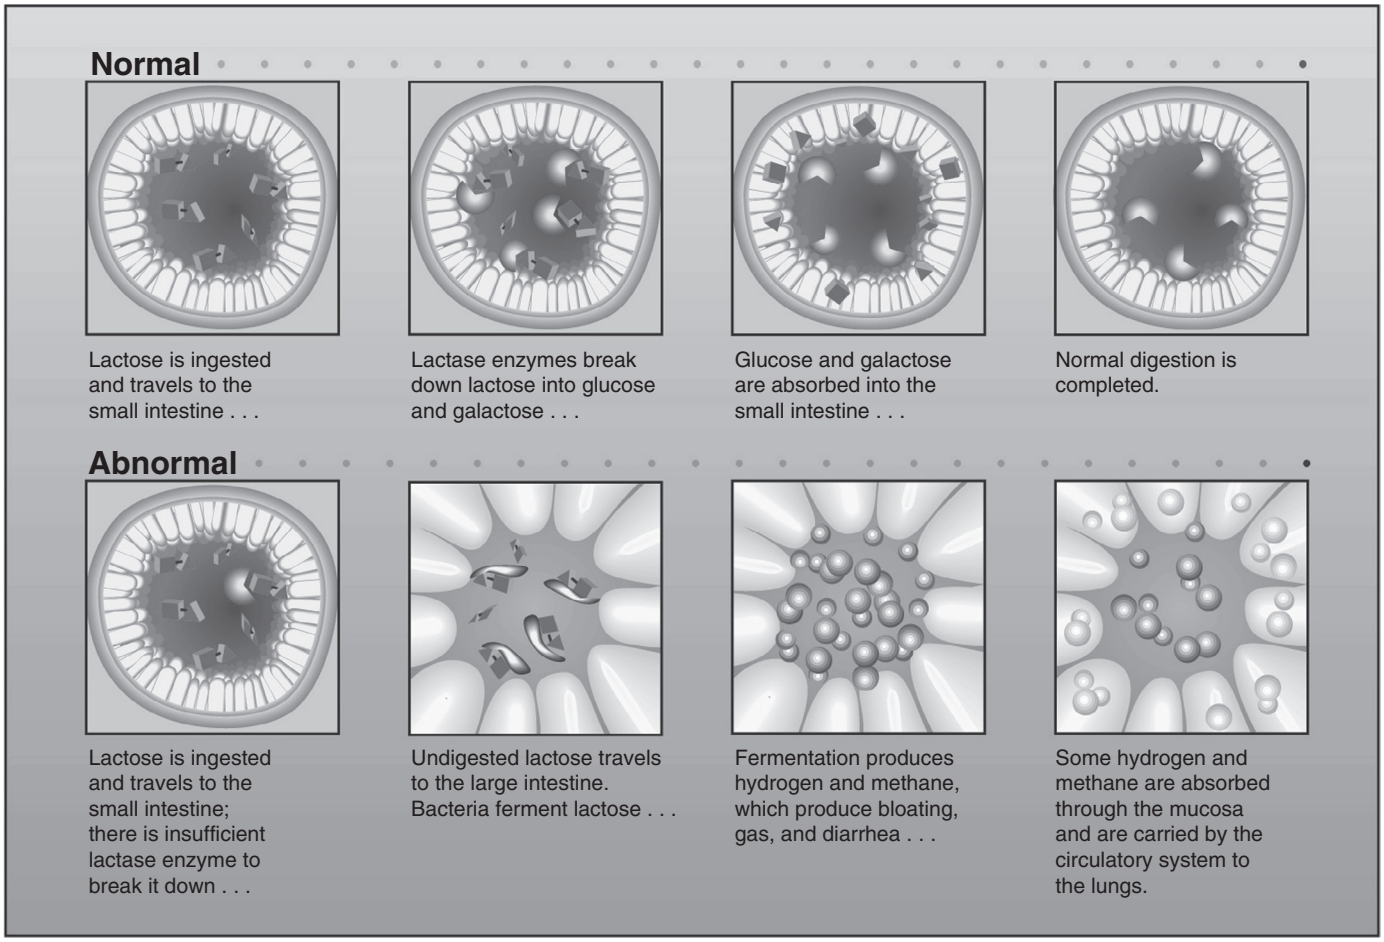

Fig. 21.1 Lactose digestion.

digestive capacity does lactose persist in the lumen, ultimately reaching the colon, where it may lead to osmotic retention of fluid and bacterial fermentation, thus causing the symptoms characteristic of lactose intolerance (see Fig. 21.1).[17] Therefore symptoms of lactose intolerance often require several contributing factors in addition to LPH deficiency, including (1) relatively high lactose load, (2) gastric emptying rate,[18,19] (3) rapid small bowel transit, (4) heightened visceral sensitivity,[20] (5) colonic water absorption capacity,[19] and/or (6) altered bowel flora.[21]

ADULT-TYPE (PRIMARY) LACTOSE DEFICIENCY

The majority of the world's population has a normal decrease in LPH synthesis after weaning. Two genes appear responsible for the control of LPH synthesis. These include the *LCT* gene that encodes the lactase enzyme itself and the *MCM6* gene that encodes two regulatory regions that activate the promoter that transcribes the *LCT* gene.[22] The most common genotype of the *MCM6* gene confers the phenotype of primary lactase deficiency (lactase nonpersistence) by downregulating *LCT* promotion upon weaning.[22,23] Genetically, nucleotides in the *MCM6* gene appear to be primarily responsible for this developmentally programmed loss of transcription of the *LCT* gene.[22,23] However, single-nucleotide polymorphisms (SNPs) in the *MCM6* gene can confer the phenotype of lactase persistence by extending the transcription of the *LCT* gene into adulthood.[22,24,25]

It is theorized that maintaining the ability to digest lactose into adulthood (lactase persistence) is the result of a relatively new evolutionary genetic mutation that occurred after the domestication of farm animals.[2,26] Preservation of lactase synthesis has been associated with several distinct SNPs on the *MCM6* gene that include the following: *–13910C>T, –13915T>G, –14010G>C, –13937G>A, –13907G>C,* and *–13913T>C.* Respective to these SNPs, the variant alleles associated with lactase persistence are *T, T, C, G, G,* and *T.*[3,22,25,27–30] Although the presence of any these SNPs suggests lactase persistence, their absence does not equate to lactase nonpersistence because there appear to be other SNPs that have not yet been determined.[31]

ACQUIRED (SECONDARY) LACTASE DEFICIENCY

Because LPH is located in the brush border (microvilli) of gut mucosal cells, LPH deficiency may be secondary to diseases that damage these cells. Lactose intolerance has been observed as a secondary feature in celiac disease,[32] tropical sprue, acute gastroenteritis, chemotherapy-induced mucositis,[33] cystic fibrosis, alcoholism,[34] pelvic radiation therapy,[35] and Crohn's disease.[36] In secondary lactase deficiency, treating the underlying condition and resultant restoration of mucosal integrity often restores lactase activity.[37]

CONGENITAL LACTASE DEFICIENCY

Congenital lactase deficiency is a rare inborn error of metabolism characterized by very low or absent lactase activity in the intestinal microvilli at birth. Unlike lactase nonpersistence mutations, which affect upstream enhancer regions of *LCT,* mutations in the *LCT* gene itself appear to be responsible for congenital lactase deficiency.[38] Clinical symptoms include severe diarrhea, dehydration, and malnutrition and

BOX 21.1 Symptoms of Lactose Intolerance

Indigestion
Bloating
Flatulence
Nausea
Diarrhea
Failure to thrive
Abdominal cramps

often appear during the first week with the consumption of lactose. Separately, preterm infants may exhibit symptoms of lactase deficiency if born before 34 weeks' gestation, a condition called developmental lactase deficiency.[39] As expected, preterm infants can gain function of the lactase enzyme with time.

LACTOSE INTOLERANCE VERSUS DAIRY ALLERGY

Lactose intolerance and dairy allergy are separate pathologies. Lactose intolerance results from the maldigestion of dairy carbohydrate (lactose), whereas dairy allergy is an immune response to dairy proteins (e.g., casein, lactalbumin, whey). Dairy allergy may involve reactions (e.g., systemic anaphylaxis) that affect the gastrointestinal tract, skin, respiratory tract, or multiple systems. These immediate reactions are often mediated by immunoglobulin-E (IgE) and can cause severe morbidity and even death; however, in such cases, dietary elimination of dairy products is associated with good prognosis.[40] The prevalence of IgE-mediated allergic reaction to dairy protein in the general population is estimated at 1% to 3%, being highest in infants and lowest in adults. However, the prevalence of IgG-mediated allergic reactions may be higher.

DIAGNOSIS OF LACTOSE INTOLERANCE

Clinical suspicion of lactose intolerance should be raised when foods containing milk or milk products produce symptoms of gas, bloating, cramping, or diarrhea (Box 21.1). A short course of dietary manipulation, with careful removal of milk-containing products, can strengthen the case for lactose intolerance as a diagnosis. Stool acidity testing, oral lactose tolerance testing, breath tests for hydrogen and methane, and/or genomic evaluation for *LCT* haplotypes should be used to confirm the diagnosis. Because the presence of lactase deficiency does not always result in lactose intolerance, genomic testing should never be used as a sole determinant in diagnosis. Breath testing provides the most reliable, noninvasive means of determining lactose malabsorption but must be used in the context of symptomology to make the diagnosis of lactose intolerance. In contrast, a positive breath test coupled with the absence of *LCT* haplotyping indicating primary lactase deficiency suggests a secondary causation, the diagnosis of which should be pursued.

There have been conflicting results regarding the presence of lactose intolerance in patients with irritable bowel syndrome (IBS). By definition, the diagnosis of IBS is a functional diagnosis that is made when all organic causes of symptoms have been ruled out. However, studies have shown that patients with IBS have a high rate of lactose intolerance, with the resolution of IBS symptoms upon lactose limitation or removal.[41–43] Rana et al.[44] found that patients with diarrhea-predominant IBS had a higher incidence of lactose intolerance (82%) than patients who had either spastic-type IBS or features of both IBS types. For this reason, lactose intolerance should always be investigated in cases of IBS, a condition that affects up to 20% of Americans.[45]

BOX 21.2 Sources of Lactose

Obvious Sources
Milk (whole, skim, dry powdered, evaporated)
Cheeses
Butter, many margarines
Goat's milk
Half-and-half cream
Ice cream and many sherbets
Yogurt

Hidden Sources
Artificial sweeteners containing lactose
Breads, biscuits and crackers, doughnuts made with milk
Breading on fried foods
Breakfast and baby cereals containing milk solids
Buttered or creamed foods (soups and vegetables)
Cake and pudding mixes, many frostings
Candies with milk chocolate
Cookies made with milk
Hot dogs, luncheon meats, sausage, hash, processed and canned meats
Mayonnaise and salad dressings made with milk
Nondairy creamers (except for Coffee Rich)

A number of studies have suggested that transient lactose intolerance is also associated with infantile colic.[46,47] For susceptible children with lactose maldigestion, only 12 g of lactose (~1 cup of milk) daily has been shown to be associated with increased abdominal pain.[48]

Nutritional History

A detailed history of the patient's average consumption of lactose-containing food should be obtained. Often, patients do not consider yogurt, ice cream, chocolate milk, and milk ingested with cereal as important sources of lactose. They also may not be aware that lactose is added to many nondairy products to provide texture, flavor, and browning and to absorb flavors, aromas, and food colors (Box 21.2). In addition, because of its excellent binding ability, lactose is contained in many drugs and over-the-counter products (Box 21.3). Identifying all sources of lactose is necessary to (1) identify the potential relationship between gastrointestinal symptoms and lactose consumption and (2) develop an effective lactose-free diet, if necessary.

Empirical Testing (Trial Elimination of Milk Products From the Diet)

If the patient experiences symptoms after consuming food products containing lactose, the temporary exclusion of all lactose-containing products from the diet as a preliminary diagnostic procedure may be helpful. However, the diagnosis of lactose intolerance should not be based solely on the elimination of milk products. This subjective test may be misleading if hidden sources of lactose (see Box 21.3) are not removed or if unrelated symptoms coincidently abate during this period.[49]

Stool Testing

The fermentation of undigested disaccharides of any kind within the colon results in the overproduction of fatty acids by colonic bacteria, which lowers the pH of the stool. Normal stool pH is between 6.0 and 7.0 in young children and adults. Although infants may normally have a lower pH due to a high-lactose diet, a pH of less than 5.3 suggests maldigestion. Although pH testing can be used to raise the clinical suspicion of malabsorption, further workup is warranted to make a diagnosis of lactose intolerance.

BOX 21.3 Prescription and Over-the-Counter Drugs Containing Lactose

Prescription Drugs

Ativan
Bumex
Calan
Coumadin tablets
Erythromycin
Glucotrol
Lasix
Lotronex
Mevacor
Premarin
Prilosec
Propecia
Reglan
Synthroid
Vasotec
Xanax

Over-the-Counter Drugs

Actifed tablets
Allbee C-800 Plus iron tablets
Benadryl tablets
Chlor-Trimeton Allergy tablets
Ferro-Sequels
Imodium A-D caplets
Marezine tablets
Pepcid AC chewable
Slow FE iron tablets
Sudafed Plus tablets
Unifed Chewable tablets

Breath Testing

Breath testing is the method of choice for diagnosing lactose maldigestion.[50] It is sensitive and specific,[51] simple to perform, noninvasive, and inexpensive.[49] Breath testing is based on the ability of intestinal microbes to ferment carbohydrates, in this case lactose, producing hydrogen or methane in the process. A fraction of these gases naturally diffuses from the bowel to the circulation and is eliminated via the lungs. Because there is no other metabolic production of hydrogen and methane, pulmonary excretion of these gases may be used as an indirect measure of lactose maldigestion, indicating lactase deficiency.[52]

The benefits of breath testing are as follows:

- Its results correlate strongly with the symptoms of lactose intolerance.[53]
- It can be done at home by the patient or in the physician's office.[54]
- The lower challenge dose of lactose causes significantly fewer side effects than the large doses used in blood and urine galactose tests.[55]
- The breath hydrogen/methane test is the standard in pediatric cases in which other tests would be difficult to perform.[56–58]

Historically, breath testing measured hydrogen only. However, Tormo et al.[59] showed that methane is produced instead of hydrogen in some patients with lactose malabsorption. They concluded that measuring both gases was necessary for accurate diagnosis of lactose maldigestion. Other researchers suggested that although methane was produced predominantly in some cases, hydrogen production correlated more strongly with symptoms; therefore hydrogen testing alone might be sufficient for the diagnosis of lactose intolerance.[60,61] Breath testing using a radiolabeled carbon molecule (^{13}C) in the lactose structure showed poor correlation with lactose intolerance, as evidenced by poor $^{13}CO_2$ output by the lungs.[53]

Procedure

After an overnight fast, a baseline breath sample is collected 30 minutes after rising. The patient then ingests a challenge dose of lactose (up to a maximum of 25 grams), and breath samples are collected 1, 2, and 3 hours after ingestion of the challenge dose.[62,63]

Interpretation

If lactose maldigestion is present, breath levels of hydrogen or methane will rise within 1 to 2 hours after ingesting the lactose challenge. As little as 2 g of carbohydrate reaching the colon produces a detectable increase in breath hydrogen.[64]

Hydrogen and Methane Responses

The normal breath hydrogen level in a healthy, fasting patient is less than 10 ppm. Patients with lactose malabsorption show an increase in breath hydrogen concentration of 20 ppm or more during the test.[65,66]

The normal breath methane level in a fasting patient is 0 to 7 ppm. An increase of at least 12 ppm of methane alone during the test is considered positive for lactose malabsorption, regardless of the hydrogen response.[67–69]

If both breath hydrogen and methane rise after a lactose challenge, the two responses are added to estimate the degree of malabsorption. The increases in breath hydrogen and methane levels together must be 20 ppm or more to suggest lactose malabsorption.[69] The extent of elevation relates to the degree of malabsorption.

False-Positive Results

False-positive results occur rarely and are usually a consequence of the following interfering factors:

- *Fiber intake.* Fiber should be avoided 24 hours before the test. Ingesting fiber in food or in supplements increases fermentation and hydrogen production.[70–72]
- *Exposure to tobacco smoke.* Tobacco smoke increases hydrogen levels and should be avoided immediately before and during testing.[73]
- *Sleeping.* Sleeping between breath sample collections may increase both hydrogen and methane levels.[74]

False-Negative Results

Breath hydrogen/methane testing has a false-negative rate of approximately 5%; the false-negative rate is 10% if only hydrogen is measured. False-negative results can occur because of the following factors:

- Use of lactase supplements.[55]
- Use of antibiotics before the test. Antibiotics decrease the bacteria that ferment lactose.[75]
- Use of laxatives or enemas before the test. These decrease hydrogen and methane responses in patients with lactose malabsorption and reduce fermentation in the colon.[76]
- Severe diarrhea or hyperacidic colon contents. Hyperacidity inhibits the production of hydrogen and promotes the production of methane by colonic bacteria.[77,78]

High Baseline Levels

An elevated baseline level of breath hydrogen indicates that one or more interfering factors are present. Testing must be repeated to obtain reliable results. A baseline breath hydrogen level of greater than 10 ppm can be due to the following:

- Improper fasting
- Consumption of high-fiber foods the day before testing
- Performance of test immediately after awakening[67]

A baseline breath hydrogen level of more than 20 ppm can be due to the following:

- Possible small intestine bacterial overgrowth.[79] Elevated fasting levels of hydrogen occur in up to one third of patients with small intestinal bacterial overgrowth[80] and may be caused by the fermentation of endogenous brush-border glycoproteins.[81]
- Small intestine bacterial overgrowth may elevate baseline methane readings as well.[67,79,81,82]

Genomic Testing

Genomic testing requires a single blood sample and avoids the diet restrictions, lengthy collection regimen, and potential for abdominal symptoms that are associated with using an oral lactose challenge. The *LCT* gene on chromosome 2 encodes for the enzyme LPH, and the wild type is associated with lactase nonpersistence. Lactase persistence is associated with two polymorphisms on the enhancer region upstream from *LCT,* C/T_{13910} and G/A_{22018}. Heterozygotes are considered to have lactase persistence but with intermediate lactase activity. Homozygotes T/T_{13910} and G/G_{22018} have the lactase persistence genotype, whereas C/C and G/G homozygotes carry the wild-type nonpersistence genotype. Genomic testing, although useful, only establishes a lactase enzyme deficiency, the presence of which does not always lead to lactose intolerance symptoms. Heterozygotes, although considered carriers of lactase persistence genotyping, can have bouts of impaired lactase activity due to stress or infection, rendering intermittent bouts of lactose intolerance.[83] Therefore testing for lactose malabsorption through an objective measure of lactose malabsorption, such as hydrogen breath testing, is still warranted.[84]

Tissue Sampling

An endoscopic biopsy of the jejunum can assess the presence of lactase as well as other disaccharidases, although this test is rarely used due to the expense and discomfort involved. Morphologically, enterocytes would not show abnormality in cases of primary lactase deficiency but may show blunting of microvilli or inflammatory changes associated with secondary causes of lactose intolerance.

Blood Testing

Lactose tolerance testing (LTT) was formerly used but has been replaced by more sensitive breath testing, as previously described. LTT required a large dose of glucose challenge, up to 50 g, which often led to abdominal symptoms that are avoided with the lower doses used in breath testing. If the rise in serum glucose after challenge was less than 26 mg/dL during the ensuing 2 hours, then lactose maldigestion was presumed. Another similar test uses radiolabeled lactose,[18] C-lactose. Although it has been shown to have the ability to differentiate between those who can digest lactose and those with maldigestion, this method has not been evaluated for its ability to identify symptoms directly related to lactose intolerance,[79] and it is not available clinically.

OTHER TYPES OF SUGAR INTOLERANCE

The inability to properly digest other types of saccharides can produce symptoms similar to those caused by lactose intolerance. For this reason, it may be necessary to investigate other types of sugar intolerance, especially in patients whose clinical test results do not support a diagnosis of lactose intolerance. Commonly ingested sugars, such as fructose, sucrose, and maltose, should be considered if sugar intolerance is suspected in the presence of normal breath and genetic testing. (See Chapter 9, Bacterial Overgrowth of the Small Intestine Breath Test, for a more in-depth discussion of carbohydrate intolerance testing.)

SUMMARY

The majority of the world's population is lactase deficient. However, lactose intolerance may not develop in all of these individuals. A comprehensive evaluation that incorporates diagnostic testing, the patient's nutritional history, and the relationship between diet and gastrointestinal symptoms is necessary for an accurate diagnosis. Proper diagnosis of lactose intolerance allows for dietary modifications that may allow a limited amount of dairy products in some lactose-intolerant individuals. Exclusion of lactose-containing foods altogether should be done only for those requiring strict avoidance, with careful attention to the replacement of lost nutrients, such as calcium. Breath testing of hydrogen/methane production after a lactose challenge is the diagnostic method of choice.

Metal Toxicity: Assessment of Exposure and Retention

David Quig, PhD

OUTLINE

INTRODUCTION

It is imperative that clinicians understand and apply in practice the distinction between metal toxicity, as clearly defined by standards of care, and the *toxic effects of metals* that may be associated with the net retention of toxic elements; it is not just a matter of semantics. The incidence of high-level exposure to toxic metals and acute poisoning/toxicity is rare and is most commonly associated with occupational sources. Associated symptoms are well defined and accepted. A plethora of published research has clearly defined many of the specific biochemical mechanisms by which even much lower levels of metals elicit a vast array of adverse effects that can culminate in neurotoxicity, nephrotoxicity, cardiovascular and pulmonary disease, cancer, teratogenicity, and dysregulation of immune function. Despite knowledge of the adverse effects of metals on the most basic biochemical processes that may affect human health, the fact that environmental exposure with cumulative retention of "subthreshold" levels of toxic elements may warrant clinical intervention is not generally accepted by the dominant medical community. However, with respect to lead, mercury, and cadmium, a consultant to the National Institute of Environmental Health Sciences stated that the margin between the levels of exposure for people in industrialized nations and the levels of exposure that are currently recognized as producing the lowest adverse effect levels is small.[1,2]

The established laboratory tests accepted for a diagnosis of metal toxicity (e.g., blood lead) do not provide an estimate of the actual levels of metals that have accumulated in the body. The purpose of this chapter is to provide an overview of the various laboratory tests for the (1) objective assessment of exposure to toxic metals and (2) estimation of net retention of toxic metals. It is beyond the scope of this chapter to discuss the sources and symptoms associated with net retention of the most commonly encountered metals. (See Crinnion and Pizzorno, *Clinical Environmental Medicine,* Elsevier, 2018, for a comprehensive discussion of toxic metals.) Thorough reviews of these topics have been published elsewhere.[3–7]

The most commonly encountered toxic metals (mercury, lead, cadmium, and arsenic) are natural constituents of the earth's crust, but their increasing abundance in air, water, and surface soil results primarily from industrialization and energy production (pollution). Consequently, the environment today has become contaminated to the point that everyone, regardless of occupation, is at higher risk for at least long-term, low-level exposure to toxic metals. However, consistent with the basic principles of toxicology, confirmation of exposure is by no means valid documentation of clinically significant retention. In reality, the toxic effects of metals for an *individual* are exhibited when the level of retention exceeds physiological tolerance, and net retention (body burden) is determined by the relative rates of toxic metal assimilation and excretion.

Two important concepts that have been largely overlooked with respect to metal toxicity may explain the discrepancies of opinion expressed by practitioners of conventional medicine and preventive medicine. The first is the potential for the combined effects of multiple toxic metals, which can have additive, but also synergistic, adverse physiological effects (and, of course, toxic chemical exposure aggravates the problem),[8,10] even in children with environmental exposures.[9] This concept should be further extended to include consideration of the potential combined effects of organ toxicants and toxic metals, the total toxic load. The broad heading of "toxic chemical entities" includes not only naturally occurring and synthetic exogenous compounds but also noxious endogenous compounds derived from a severely disrupted dysbiotic or poorly functioning gastrointestinal (GI) metabolome. An additional factor is the remarkable individual variability in susceptibility or tolerance to toxic elements. Established precedence for the phenomena has been provided by such observations as the rapid contact allergic response that is elicited by mercury in a small percentage of a population.[11] Individual variability in susceptibility is determined in part by genetic polymorphisms, nutritional status, and the total toxic load. The factors of multiple toxicants and individual variability impede simple interpretation of any laboratory test result for an individual patient.

No single definitive test can be used to diagnose the toxic effects of excessive retention of toxic elements; any test result must be interpreted in conjunction with a thorough review of a patient's physical findings,

exposure history, and symptoms. However, the symptoms associated with toxic metal retention appear to be diverse and rather nondescript, and they may not be fully expressed until later in life. Clear examples of such latency of symptom expression have been provided for lead and hypertension[12] and cardiovascular mortality.[13] Therefore to address the needs of clinicians who focus on preventive medicine as opposed to crisis management, the following review of laboratory tests emphasizes testing that has greater sensitivity with respect to the detection of the bioaccumulation of toxic elements. Emphasis has been placed on the distinction between testing that is most appropriate for assessment of exposure versus net retention.

ASSESSMENT OF TOXIC METAL EXPOSURE

Hair Elemental Analysis

When performed properly, hair elemental analysis can serve as a qualitative screening test for exposure to toxic metals, but it is not a reliable method for the diagnosis of metal toxicity or net retention. Hair is an excretory tissue that can provide a cumulative record of bioavailable trace elements in the body, and the hair content of mercury, arsenic, lead, and thallium has been used as evidence for the cause of death.[14] Once metals are incorporated into growing hair, there is no back exchange into the body; the concentration of metals in hair is usually far greater than that in blood or urine. The length of the hair specimen analyzed dictates the duration of time during which exposure occurred, and segmental analysis of hair can be used forensically to estimate the temporal course of exposure. A study of the lead and mercury content of hair from a long-deceased president of the United States was performed at the Armed Forces Institute of Pathology in Washington, DC, exemplifying the potential utility of hair analysis for exposure to toxic metals.[15] Detection of toxic metals in hair actually predates that in blood and urine.[16] A growing number of peer-reviewed publications support the value of elemental analysis of hair specimens for the detection of exposure to toxins, and some national laboratories have been performing hair elemental analysis for mercury, lead, and arsenic for years. Arsenic in both hair and urine confirmed arsenic exposure from an arsenical pesticide in an individual with peripheral neuropathy and macrocytosis.[17] Hair levels of lead, manganese, cadmium, and other toxic metals have been correlated with psychological conditions and deviant or violent behaviors.[18] Lead, cadmium, and mercury levels in children's hair have been inversely correlated with childhood intelligence. Hair analysis has been used to identify historical as opposed to current exposure to lead.[20] School children with relatively high levels of lead in their hair had slower reaction times and less flexibility in changing their focus of attention than children with relatively low concentrations of lead in their hair.[21] More recently, hair levels of lead and barium were found to be higher in rural populations in relation to their proximity to oil fields (contaminated water) in the Thar Jath oil fields in South Sudan.[19] The Agency for Toxic Substances and Disease Registry (ATSDRss), the U.S. Environmental Protection Agency, and the National Academy of Sciences recognize the scientific validity of hair mercury levels as an indicator of maternal and fetal exposure to methylmercury. In a cognitive performance study of children in the Faroe Islands, there were detectable effects on brain function in the children whose mothers had elevated levels of hair mercury.[22] A history of fish consumption and mercury in hair samples are considered the best indicators of human exposure to methylmercury.[23] Fish consumption among Scandinavian[25] and Tyrrhenian men,[26] Amazonian children,[27] and people from the Minamata Bay area[15] and the San Francisco Bay area[24] was positively correlated with hair and blood mercury levels. Note that hair elemental analysis definitely provides useful information about exposure to methylmercury (fish consumption); however, it is not nearly as useful for disclosing information about exposure to inorganic mercury as derived from dental amalgams.[15] The concentration of methylmercury in hair is about 300 times higher than that in blood.[28] In sharp contrast, about 75% of total hair arsenic is present in the inorganic form.[29]

Although an increasing number of peer-reviewed published studies support the clinical utility of elemental analysis of hair for the assessment of exposure to specific toxic metal forms, some considerations prevent its acceptance by governmental agencies in the United States. In June 2001, the Agency for Toxic Substances and Disease Registry (ATSDR) convened a panel of scientists with some expertise in hair analysis or risk assessment to explore "the state of the science of hair analysis."[30] Overall, the discussion was objective and focused on the existing scientific data. In a summary statement from the meeting, it was concluded that "in general, hair analysis results can provide limited qualitative insights into environmental exposures and rarely can answer questions about potential health effects."[27]

The primary concerns raised by the group pertained to uncertainties about the quantitative relationship among the actual "internal dose," the rate of incorporation into hair, and the current lack of well-established data to enable one to predict potential health effects for a given concentration of a specific metal in hair. Such criticisms are irrelevant to those who understand the limitations of hair elemental analysis.

Overinterpretation of the results of elemental analysis of hair is a serious concern shared by science-based laboratories and astute clinicians as well as the ATSDR. It should be kept in mind that the ATSDR has been interested in the use of hair analysis as an initial screening tool for inexpensive and noninvasive monitoring of populations in the vicinity of known sites of contamination. The goal of the ATSDR to be able to use hair elemental analysis as confirmation of toxicity is quite different from the use of the test in preventive or environmental medicine to provide an initial indication of exposure.

The consensus report by the ATSDR is consistent with the aforementioned statement that hair analysis can provide some qualitative information about exposure to toxic metals but does not provide a basis for the diagnosis of metal toxicity. As such, hair analysis may be helpful to clinicians as a step toward identifying potential health problems that may be associated with toxic metal exposures before overt symptoms are expressed. Further testing should be performed before treatment options are considered. The clinician should be wary of laboratories that perform hair analysis as a vehicle to sell nutritional supplements and should be aware of interlaboratory variation.[31] Clinicians are encouraged to use only laboratories that can validate their certification or accreditation and incorporate state-of-the-art methodologies for washing, digesting, and analyzing hair specimens.[32] Appropriate quality control characteristics and the validation of the establishment of reference ranges, accuracy, precision, and reliability of state-of-the-art hair analysis have been described.[33-35]

Blood Analysis: Toxic Metal Exposure

For the most commonly encountered toxic metals, the current standard for diagnosis of metal toxicity is abnormally high concentrations in whole blood or urine (e.g., thallium, arsenic). However, blood analysis for toxic metals is a better indicator of exposure than toxicity in most cases. Distribution of metals, such as lead, in the body has been long recognized as initially dependent on the rate of delivery via the blood to various tissues and organs.[36] Subsequent redistribution then depends on the relative affinities of tissues for the metals and toxicokinetics that can vary markedly among individuals. Tissue affinities for metals are determined in large part by the high relative intracellular concentrations of reduced glutathione and metallothionein.[37]

Furthermore, blood levels can fluctuate considerably with intermittent exposure and assimilation. Thus as stated by the ATSDR and the Centers for Disease Control and Prevention, the concentration of lead in the blood reflects mainly the exposure history of the previous few months and does not necessarily reflect the larger burden and much slower elimination kinetics of lead in bone.[10]

Examining kinetic models of metal metabolism shows that the blood compartment has the shortest half-life. Metals leave blood by excretion (urine, bile, and sweat) and transfer to tissues. The retention by tissues, such as bone, kidneys, and brain, accounts for the much longer biological half-lives of most toxic metals in the body. This simple concept has been clearly demonstrated in numerous studies and in the *Physician's Desk Reference.*[29] Adult and pediatric patients who were diagnosed with lead toxicity on the basis of elevated blood lead values exhibited marked reductions in blood lead levels after chelation therapy with Chemet (DMSA).

However, 2 weeks after cessation of chelation, blood lead levels rebounded to between 60% and 85% of pretreatment levels (the rebound effect has been associated with all pharmacological chelators). The relationship between blood lead levels and the quantity of lead excreted in urine after calcium disodium edetate (Ca-EDT) DMSA chelation is nonlinear, in that arithmetic increases in blood lead are associated with exponential increases in urine lead excretion.[1,39]

Under extreme conditions of grossly excessive retention of metals (long-term occupational exposure), the equilibrium between tissue stores and blood can result in blood metal levels that are at or above the established threshold values for the diagnosis of metal toxicity but still do not indicate the extent of total body metal retention. The currently established standard of blood lead levels for the assessment of lead toxicity in children is disturbing because no minimum response levels have been established for lead because a threshold has yet to be defined for the most sensitive effect of lead neurotoxicity.[45]

Interestingly, separation of blood into the plasma versus red blood cell components can provide valuable information to the clinician about the primary sources of exposure to mercury. Approximately 95% of methylmercury, most commonly derived from contaminated fish, partitions into red blood cells,[46,47] whereas about 90% of inorganic mercury (amalgams, occupational exposure) is found in the plasma compartment bound to albumin, cysteine, and nonspecific proteins.[32]

Because the first step in successful detoxification is to remove the source of exposure, documentation of the primary source of exposure to mercury can be instrumental for efficient detoxification. Blood arsenic levels, albeit with a very short half-life (approximately 6 hours), reflect exposure to inorganic arsenic but not dietary organic arsenic (shellfish), which is rapidly excreted in the urine.[48,92] The blood levels of metals derived from orthopedic metal implants have come to the forefront, especially with respect to metal-on-metal (M/M) total hip arthroplasty. All patients with such M/M prostheses will have elevated levels of cobalt and chromium.[40,41] The wear-related release of the metal debris has been causally associated with not only local tissue damage[42] but also remote adverse effects on a wide array of physiological/biochemical processes and functions.[43,44]

Urinalysis of Toxic Elements Exposure: Unprovoked

In general, urinalysis for toxic metals does not provide a scientifically valid basis for the diagnosis of metal toxicity. However, in some cases it provides an indication of very recent or ongoing exposure. Such is not necessarily the case for lead because urinary lead is generally not a useful biomarker to estimate low-level exposure. However, elevated urinary lead-chelate complexes resulting from the EDTA Ca-EDTA or DMSA mobilization test provide a good means to estimate net retention of lead.

A different scenario exists for organic arsenic and inorganic and methylmercury. The most commonly accepted biomarker for exposure to inorganic mercury is the urinary level of inorganic mercury.[49] However, the World Health Organization (WHO) standard for occupational exposure is very high (50 mcg/g creatinine).[50] This high standard has been challenged because neurological impairment has been reported for occupationally exposed subjects[51,52] whose urinary mercury levels were well below the WHO standard. Evidence that urinary mercury levels are indicative of exposure to implanted mercury amalgams has also been published.[53] In a study of more than 1000 Vietnam-era veterans reported by the National Institute of Dental Research, a highly statistically significant correlation was detected between the level of amalgam exposure and urinary mercury levels. Several other studies have reported an association between amalgam exposure and urinary mercury levels.[54,56-58] Elevated levels of urinary arsenic have been detected in workers during periods of occupational exposure, including copper smelting, spraying of insecticides or herbicides, and application of wood treatments.[61]

Arsenic can be markedly and transiently elevated in individuals within 48 hours after consumption of shellfish that contain high levels of relatively nontoxic species of organic arsenic (e.g., arsenobetaine, arsenocholine).[62] Urinary mercury is frequently elevated in consumers who regularly consume fish.[15,63] Therefore analysis of an unprovoked urine specimen is highly recommended to avoid alarmism and misinterpretation of the results of a urinary metals provocation test. Patients should be instructed to abstain from the consumption of fish and shellfish for about a week before a chelation challenge is performed. Elevated urinary values of arsenic and mercury associated with the specific dietary and occupational conditions reflect recent or ongoing high-level exposure but are not necessarily reflective of the body burden of the specific elements. Although blood metal levels reflect transient transport in the body, urinary levels qualitatively reflect excretion of an unknown fraction of the total body pools of assimilated metals.

Urinalysis: Biomarkers of Renal Cadmium Toxicity

Toxic metals such as cadmium, mercury, and lead are known to be nephrotoxic at high levels of assimilation. Cadmium is of particular concern because of its exceedingly long residence time in the kidneys.[64] Therefore in addition to urine levels of cadmium, urinary biomarkers of renal damage should be assessed for documentation of cadmium toxicity. Early markers of cadmium-induced renal damage include proteinuria, glucosuria, aminoaciduria, hypercalciuria, and polyuria.[65] Sensitive urinary biomarkers for more advanced cadmium-induced renal tubular damage include elevated levels of the low-molecular-weight protein β_2-microglobulin, retinal-binding protein, *N*-acetyl-β-D-glucosaminidase (NAG), and Cystatin C (especially in patients where serum creatinine may be misleading (e.g., very obese, elderly, or malnourished patients).[66] Abnormal urinary levels of NAG have also been reported in association with markedly high urinary mercury levels (35 mcg/g creatinine) in chlor-alkali workers with long-term exposure to inorganic mercury.[67] It is noteworthy that the urinary NAG levels were correlated with urinary mercury and integrated dose of exposure but not with concurrently measured blood mercury levels.[53] Thus it appears that assessment of urinary biomarkers of renal damage may be useful in the diagnosis of toxicity in cases of very high exposure to cadmium and perhaps mercury. However, negative findings for the renal biomarkers do not exclude the possibility of related nephrotoxicity retention that is most commonly encountered in general clinical practice.

ASSESSMENT OF RETENTION: URINALYSIS, PROVOCATION TESTS

The best currently available method to estimate the level of retention of toxic metals in the body is urinalysis for toxic metals after the administration of chelating agents.[55] In the 1970s, the value of a standardized calcium-disodium EDTA (Ca-Na_2-EDTA) provocative test was recognized as sensitive to determine the mobile and potentially toxic body lead stores and to assess response to chelation therapy in pediatric patients with high blood lead levels.[68–70] Subsequently, Markowitz and Rosen[61] described the results of a comparable, yet more convenient test that would permit use in a greater number of qualifying patients.

The concept and value of using metal complexing agents to estimate the net retention of readily accessible toxic elements has gained some acceptance, but it is not accepted by the American College of Medical Toxicology.[59]

That position is in direct conflict with a renowned nephrologist who has stated that "the best measure for assessing the total accumulation of lead in the body is the calcium disodium EDTA lead mobilization test."[60] Several other pharmaceutical agents are widely used for this purpose. The most commonly used pharmaceutical agents are Ca-Na_2-EDTA, Dimaval-(RS)-2,3-dimercapto-propropane-1 sulfonate (DMPS), and mes-2,3-dimercaptosuccinic acid (DMSA). Nonpharmaceutical compounds that have also been used as possible provocation agents include N-acetyl-cysteine (N-AC) and potassium-citrate (K-citrate).[72] The latter compounds are not chelators by definition and have not been studied extensively or compared with the efficacy of the well-established Ca-EDTA lead mobilization test.

EDTA

Ca-Na_2-EDTA is the only form of EDTA approved for lead decorporation by the U.S. Food and Drug Administration (FDA). It has been used for decades as the provocation agent and therapeutic agent of choice for patients with high blood lead levels. The true chelator is also well known to be effective for increasing the urinary excretion of antimony, gadolinium, iron, cobalt, trivalent chromium, copper, nickel, cadmium, and manganese.[73] Ca-EDTA also has a high affinity for zinc and, if not used properly, can cause zinc depletion. Clinicians are strongly encouraged to assess glomerular function before use (Ca-EDTA mobilized metals are excreted in the urine). Before attempting to embark on the safe and effective use of Ca-EDTA, clinicians should attend specific training courses. Although the "slow-push" Ca-Na_2-EDTA protocol introduced in the United States appears to be effective for increasing the urinary excretion of lead,[74] it has not been formally evaluated for safety. Ca-EDTA is not an effective chelator of mercury as are the dithiol metal complexing agents discussed next.

DMPS

DMPS appears to be the most productive agent for the mobilization of mercury, as determined in vitro[75] and in a comparative study during the Iraqi mercury crisis, in which people were acutely poisoned after consumption of grains contaminated with a methylmercury-containing fungicide.[76] More relevant to the typically encountered clinical situation, a DMPS provocation study was conducted with volunteer college students.[77] Subjects with and without amalgam fillings were given 300 mg DMPS (orally), and all urine was collected over the subsequent 9 hours. DMPS raised mean urinary mercury for the nonamalgam group from 0.27 to 5.1 mcg and that of the amalgam group from 0.7 to 17.2 mcg over the 9-hour period. A highly significant positive correlation was detected between the amount of mercury excreted after the DMPS challenge and amalgam surface area.

An additional study supports the value of provocation testing for people occupationally exposed to mercury vapors. A comparison of urinary mercury levels was made before and after oral administration of a 300-mg dose of DMPS to dental technicians, dentists, and nonoccupationally exposed controls.[46] Unprovoked urine mercury levels were comparable for dental technicians and dentists and were about five times higher than those in controls. Compared with preprovocation values, DMPS-induced urinary mercury (micrograms per 6 hours) increased by a factor of 87, 49, and 34 for the technicians, dentists, and controls, respectively. Post-DMPS urinary mercury levels were 16 and 6 times higher than in controls for the technicians and dentists, respectively. The group's mean urinary mercury for the technicians after DMPS was 424 ± 85 mcg/6 h. The baseline urinary coproporphyrin level, which is an established biomarker of mercury-induced disruption of heme biosynthesis, was significantly correlated with urinary mercury levels after DMPS but was not correlated with baseline urinary mercury levels. The researchers concluded that post-DMPS urinary mercury levels were better indicators of exposure and retention than unprovoked urinary mercury levels.

The pharmacokinetics of DMPS have been well defined,[78,79] and the efficacy of DMPS for detoxification of mercury,[80] arsenic,[81] and lead (pediatric)[82] has been documented. Although DMPS is not approved by the FDA, it is registered in Germany with the German Drug Regulatory Authorities and is available in the oral form without a prescription.[68] DMPS is no longer available to clinicians in the US. DMPS is associated with a very low incidence of serious side effects,[68] and its safety in general was evident from the observations made during the course of extensive IV administration (250 mg every 4 hours for 12 consecutive days) in a young woman who had severe arsenic toxicity.[71] The most commonly reported side effects associated with DMPS are nausea, weakness, vertigo, chills, fever, cutaneous reactions/itching, erythema multiforme, and elevations of transaminases.[69,71,72] An extensive review of the German literature about the pharmacokinetics, affinities for various metals, and side effects of DMPS is available.[72]

The recommended IV dose of DMPS is 3 to 5 mg/kg (not to exceed 250 mg to avoid hypotension).

A detailed description of an extensively used oral DMPS provocation protocol has been presented,[68] as well as an IV DMPS provocation protocol.[6] To establish the basal urinary rate of metal excretion, the patient is instructed to fast overnight and collect a first-morning urine specimen. In the morning, with an empty stomach and after the bladder is emptied, the patient is given about 300 mg DMPS (5 to 10 mg/kg) orally or 3 to 5 mg/kg intravenously. All urine is collected for the subsequent 6 hours.[68] A light meal (no seafood or fish) may be consumed about 2 hours after oral ingestion, and fluid consumption is encouraged. The specific laboratory instructions should be followed for shipping the specimen. Metals mobilized by DMPS are excreted primarily by the kidney and to a much lesser extent by the liver (biliary/fecal).[68]

Equilibrium and stability constants (in vitro) for various DMPS–metal complexes have been presented.[83] In the clinical setting, DMPS is effective for the mobilization and excretion of bismuth, mercury (organic and inorganic), copper, lead, arsenic, antimony, nickel, tin, tungsten, and gold but does not affect thallium, aluminum, or uranium excretion. In the majority of adult patients, mercury is the predominant metal excreted after DMPS, and elevation of copper is normal (about five times higher than the preprovoked urine level). As mercury levels decline during detoxification therapy, it is common to see increased urinary levels of other metals, such as lead and tin, with subsequent challenges. The shifting pattern of the metal species excreted is based on a

combination of affinities of DMPS for the different metals as well as on mass competition for metal-binding sites. There are no well-established guidelines for the interpretation of the results of the DMPS challenge test. Therefore conclusions about toxicity cannot be made from the DMPS test results alone. Consideration has to be given to the overall medical examination, medical and exposure history, and presenting symptoms. If a decision is made to proceed with some form of detoxification therapy, the initial challenge result can serve as a reference point against which subsequent challenge results can be compared with to evaluate the efficacy of treatment. The levels of other toxic metals excreted should always be considered, and one should note that DMPS does not provide direct information as to the level of mercury present in the central nervous system. It is beyond the scope of this chapter to discuss protocols for metal detoxification, but it is emphasized that if a pharmaceutical metal complexing agent is to be used, the glomerular filtration rate must be assessed before initiation and periodically during the therapy.

Some clinicians use transdermal DMPS for both diagnosis and treatment. However, one study found no measurable presence in blood or urinary DMPS after a standard dose.[84]

DMSA

Another dithiol metal-complexing agent, DMSA, is also widely used for provocation testing, as well as detoxification therapy for lead, mercury species, and other sulfhydryl reactive metals (e.g., arsenic, antimony). Several studies demonstrated the effectiveness of DMSA to increase the urinary excretion of lead[85–87] and mercury and decrease the blood levels of these metals.[30,88–90]

DMSA was approved by the FDA for lead detoxification in children with lead poisoning and is an agent of choice for lead detoxification in children and adults. DMSA appears to be considered by some to be the "new chelator" for lead. Only about 20% of orally administered DMSA is systemically available after a single dose.[29] DMSA, when used in conjunction with Ca-Na_2-EDTA, increases cumulative urinary lead excretion and ameliorates the Ca-EDTA–mediated redistribution of lead to soft tissues.[81,91] DMSA is restricted to the extracellular compartment and does not have direct access to the elements retained in the cells or interstitial fluid, and it does not appear to cross a healthy blood–brain barrier. In rodent models, however, DMSA has been demonstrated to be effective in decreasing the levels of lead and mercury in the brain.[77,82,83,85] Animal studies also indicated greater efficacy of DMSA for lead detoxification when concomitantly administered with antioxidants.[78,79] This is true for all bona fide metal-complexing and metal-chelating agents. N-acetyl cysteine alone appears to enhance lead excretion to a much lesser degree than DMSA, but in contrast, the potential effects of α-lipoic acid alone are equivocal. To date, no reliable studies have been published to indicate that lipoic acid is an effective metal-binding agent that has a net effect on metal excretion in humans, and the potential for lipoic acid–induced mercury redistribution, particularly to the brain, is a significant consideration.[86]

DMSA is generally well tolerated with common but mild side effects, including GI bloating and/or gas, occasional loose stools, and skin rash. Assessment of liver enzyme levels is recommended before and periodically during extended administration. Compared with DMPS and Ca-EDTA, DMSA has minimal effects on essential elements such as copper and zinc. DMSA is excreted almost exclusively as a mixed disulfide with two molecules of cysteine.[87] Thorough reviews of the pharmacokinetics and clinical use of DMSA have been presented.[6,68,69,88] It should be noted that there is a tremendous difference between the DMSA protocol described for acute lead poisoning[76] and that commonly used for chronic lead retention.

Various protocols for DMSA provocation testing have been suggested.[6,89] However, a convenient and productive provocation protocol has been described that entails giving a single dose of DMSA orally (30 mg/kg, not more than 2 g) on an empty stomach and bladder followed by collection of all urine for the subsequent 6 hours.[62] The peak rate of excretion of metals occurs after about 3 hours. The protocol is well tolerated, enhances compliance, and significantly reduces exposure to the compound. Patients should be advised in advance that their urine will transiently have a foul, sulfurous odor and that transient GI inconvenience may occur.

Nonpharmaceutical Agents

Nonpharmaceutical compounds, such as *N*-acetyl-L-cysteine (*N*-AC) and potassium citrate (K-citrate), have been tested for efficacy as provocation agents for mercury in one published study.[62] Urinary mercury levels, expressed as micrograms per liter, were compared before and after a single oral dose of *N*-AC (30 mg/kg), K-citrate (5 g in 200 mL water), DMSA (30 mg/kg), or DMPS (Unithiol, 250 mg in 5 mL water). Basal urinary mercury levels (about 5 ug/L) were comparable for all of the treatment groups, each of which contained 16 to 65 multisymptomatic subjects. All subjects either had dental amalgams or had recently undergone removal of amalgams. Urine was collected for 3 hours after the challenge compounds were given, except that urine was collected for only 2 hours after the DMPS. The different collection time for the DMPS prohibits valid comparisons of the effects of the other agents. The high bolus doses of *N*-AC and K-citrate significantly increased urinary mercury, by 131% and 83%, respectively, compared with basal values. Under these conditions of different collection times, DMSA and DMPS increased mercury excretion by 163% and 135%, respectively. No mention was made of the urine volumes associated with the different test groups, and, clearly, the data would have been easier to interpret had the results been standardized per gram urine creatinine.

Grossly misleading values for urinary metals can be associated with the expression of excreted metals per unit volume because urinary output can vary considerably. No other data are currently available to permit further evaluation of the value of the nonpharmaceutical compounds as provocation agents. These two compounds also should be tested in animal models to determine whether they are associated with significant redistribution of metals among various tissues because neither is a true chelator, and their stability constants are relatively low. Currently, no definitive studies are available to assess the utility of parentally administered reduced glutathione as a direct metal-complexing agent. A final note about other routes of administration of various authentic and potential metal detoxification agents, particularly with respect to provocation testing, is that the author has not been able to find any published research addressing the systemic bioavailability or efficacy of any agent that is given via a transdermal delivery system.

FECAL METALS ANALYSIS

Several toxic metals, including mercury, lead, thallium, and cadmium, are naturally excreted primarily or partially in bile. Therefore under certain conditions, analysis of fecal metals, without provocation, may provide at least qualitative information about the rate of biliary excretion of assimilated metals. However, contaminated foods present a significant source of exposure to metals, and metals that have not been assimilated by the gastrointestinal tract can contribute overwhelmingly to the total amount of metals measured in a fecal specimen. In addition to dietary contamination, fecal mercury is very much influenced by the amount of mercury that is present in the mouth in the form of mercury amalgams.[90] Fecal mercury concentrations, expressed per gram of dry weight, are roughly an order of magnitude higher in people who have an average of six to eight medium-sized amalgams than in individuals who are amalgam-free.[90] Day-to-day variability in fecal mercury levels in amalgam bearers is remarkably small. Fecal mercury levels are highly correlated with the number of

amalgams (Fig. 22.1). Further, it has been demonstrated that fecal mercury levels decline significantly after extraction of amalgams.[91] Therefore levels of fecal metals generally are more a representation of exposure to metals than an indication of total body retention. Current research efforts are focusing on the identification of metal-complexing agents or phytonutrients that increase the biliary/fecal excretion of metals. Fecal metals have been analyzed in autistic children ($n = 54$), and, on average, metal levels were significantly higher compared with those in age-matched, neurotypical controls ($n = 83$).[83] The reason for the higher levels in association with autism is not known, and pica is a possible issue that may contribute to higher levels of exposure in patients with autism.

CONCLUSION

Long-term, low-level exposure to environmental toxins is a growing global problem, and evidence is accumulating to link the bioaccumulation of toxic metals in humans to subtle and overt long-term toxic effects, poor health, and substantially increased disease risk. Increasing numbers of patients dissatisfied with the care provided by clinicians who rely only on methods for the assessment of acute metal poisoning are seeking out clinicians who are aware of the value of tools that are yet to be accepted for the assessment of subacute metal toxicity. Analyses of metals in hair, blood, and urine all have advantages and disadvantages, and no single currently available laboratory test can unequivocally permit a valid diagnosis of "subclinical" metal toxicity. The results of the various tests discussed in this chapter, along with a complete medical examination, exposure history, and other findings, can be used to design a comprehensive therapeutic detoxification program. Table 22.1 provides an overview of the value of the various tests for assessing a patient's potential problem with toxic elements. To close, it is emphasized that there is a need for better chelating agents that have much greater volumes of distribution and the ability to *safely* cross a normal blood–brain barrier and directly remove neurotoxic elements from the central nervous system. Perhaps research toward finding a cure for Parkinson's disease or premature dementia will provide such agents.

TABLE 22.1 Summary of the Potential Clinical Value of Hair Analysis and Urinalysis

		URINE (RETENTION)			
Metal/Metalloid	**Hair (exposure)**	**No Provocation**	**DMSA**	**DMPS**	**Ca-Na_2-EDTA**
Aluminum	Fair	Poor	Poor	Poor	Fair, best with deferoxamine
Antimony	Good	Poor	Good	Good	Good
Arsenic	Inorganic, Good	Poor	Good	Excellent	Poor
Cadmium	Fair	Poor	Fair	Fair	Good with IV GSH
Inorganic mercury	Poor to fair	Poor	Excellent	Excellent	Poor
Iron	Poor	Poor	Poor	Poor	Good, best with deferoxamine
Lead	Good	Poor	Good	Fair	Excellent
Nickel	Poor	Poor	Fair	Fair	Good
Organic mercury	Excellent	Poor	Excellent	Excellent	Poor
Tin	Poor	Poor	Good	Good	Good
Tungsten	Good	Poor	Fair	Fair	Poor
Uranium	Good	Poor	Poor	Poor	Poor

Summary of the potential value of hair analysis (exposure) and the most commonly used provocation agents used in conjunction with urinalysis for the detection of retention of specific metals. The qualitative guidelines are based on the author's perception of affinities (in vivo) derived from the examination of thousands of test results and stability constants as determined under highly defined conditions in vitro. The information provided does not include the potential use of adjunctive agents and/or protocols and does not cover all known metal complexing agents.
Ca-Na_2-EDTA, calcium-disodium ethylenediaminetetraacetic acid; *DMPS,* Dimaval-(RS)-2,3-dimercapto-propane-1 sulfonate; *DMSA,* meso-2,3-dimercaptosuccinic acid; *GSH,* glutathione; *IV,* intravenous.

Mineral Status Evaluation

Andrea Gruszecki, ND

OUTLINE

INTRODUCTION

Minerals are inorganic elements found in the earth's crust; they are found in soil and water in varying proportions. The therapeutic effect of minerals has been recognized for more than 2000 years in Asian medicine[1] and Western civilization. As early as the 2nd century BC, salt was mixed in vinegar with other spices and prescribed for various health conditions.[2] The Native American *Dine*' (Navajo) people traditionally used juniper ash in recipes to maintain their health; juniper ash is now recognized as a source of calcium.[3] In Europe, calcium was first recognized as an essential element (for fowl) in 1790 by Dr. George Fordyce, and iodine was first recognized as a component of thyroxine by chemist Eugen Baumann in 1896.[4] Scientific studies assessing the bioavailability of minerals in humans first appeared in the literature in the 1960s,[5,6,7] and over the ensuing years, it became clear that minerals play an important role in the biochemistry of the human body.[8,9]

The human body may contain over 60 elements; currently, 15 of these elements are considered essential. Although up to 25 elements may be considered functional in human physiology, the question of which elements are essential for human life and health remains unresolved for some of the micromineral ("trace") elements.[10] Either a deficiency or an excess of physiologically active minerals may have deleterious effects on multiple enzyme systems, nerve tissues, and organs, including the brain, heart, thyroid, liver, kidneys, and skin. Reliable assessments of mineral element status are required to evaluate and monitor a patient's mineral status.[11] Analytical considerations for assessment may include specimen selection, collection equipment, preanalytical variables, and methodology.[12]

SPECIMEN SELECTION

The majority of nutritional elements are best evaluated in blood or urine.[13] Hair may be useful in the determination of some mineral element deficiencies.[14] (See Chapter 16, Hair Mineral Analysis, for a critical review of the research.)

Blood

If blood is selected as the specimen type, further consideration should be given to which compartment of blood (serum, cell, or both) is required for accurate evaluation. For example, the cations sodium, potassium, calcium, and chloride are important extracellular components of the blood's serum compartment. Clinically significant electrolyte abnormalities are common with poor oral intake, age over 65, alcoholism, diuretic use, and/or recent history of electrolyte abnormality. These clinically present with symptoms such as vomiting, chronic hypertension, recent seizure, and/or muscle weakness.[15] Urinary electrolytes are more commonly analyzed in hospital settings and may provide insight regarding volume status, hyponatremia, acute kidney injury, metabolic alkalosis, hypokalemia, and urine anion gap (net charge).[16] The use of older diuretic medications may also disrupt electrolyte balance and influence the selection of specimens.[17] Recent dietary intake may rapidly alter serum levels of other minerals or cause wide day-to-day variation in serum or urine levels. Nutrient elements that serve as cofactors in proteins and enzymes, such as magnesium[18] and zinc,[19] may be primarily intracellular and may be best assessed from within blood cells (erythrocytes). Whole blood and intracellular assessments provide a longer window of exposure than serum samples

because the elements within blood cells represent 60 to 120 days of nutrient element exposure. Both compartments may be assessed with a whole-blood specimen, which may be preferred if an excess of a nutrient element, such as manganese, iron, or copper, is suspected.[13]

Urine

Urine may be the preferred specimen for nutrients such as iodine.[11] Urinary assessments require normal renal function for accuracy. Animal studies indicate that excess mineral consumption is excreted in the urine to maintain homeostasis, and excretion may rapidly decrease to reflect an insufficient intake of all minerals.[20]

Hair

Hair may accurately reflect a nutrient element deficiency, and some hair mineral ratios have been associated with medical disorders.[21] However, the research has been inconsistent. Newer studies are confirming relationships between hair and blood for some nutrient elements and disproving others.[22] Other studies are exploring the relationship between hair element concentrations and specific disease states.[23] The interpretation of hair results may be confounded by the ease with which hair can be contaminated by external sources of exposure. With that proviso, hair analysis can accurately reflect exposure to, and absorption of, a limited number of elements (e.g., chromium) or deficiencies of others (e.g., copper). Research is ongoing to define the physiologic mechanisms that incorporate nutrient elements into hair tissues. Currently, for many mineral elements, a quantitative measurement from a hair sample may not represent a quantitative measurement of an ingested dose of mineral from the diet and supplements.[24] In addition, external contamination may mask a deficiency or artificially increase the amount of mineral element found in a hair sample because external contaminants bind to the cysteine residues of the hair.[25] The most appropriate use of hair analysis appears to be in the assessment of toxic metal exposure. The utility of hair analysis remains highly controversial; it remains an "unproven practice" according to the American Medical Association, yet it is approved by the Centers for Disease Control and Prevention for the assessment of methylmercury and other toxic metals.[26]

COLLECTION EQUIPMENT

Clinicians may employ whole-blood or urine analysis in the evaluation of mineral status because these fluids are the simplest and most economical to collect and transport.[12,14] Tests of whole blood require no centrifugation and, like urine, require no special treatment other than collection, refrigeration, and shipping in approved containers. If samples of cellular blood components are collected, they must be centrifuged immediately per the laboratory's instructions. If not centrifuged in a timely manner, cells may disintegrate, falsely increasing the amount of nutrient elements in the serum or plasma of the sample and falsely decreasing the amount of nutrient element available in the surviving cells. Appropriate, mineral-free containers provided by the laboratory must be used with most element collections to prevent possible leaching of elements from collection devices or shipping containers. Hair analysis has the benefit of convenience and low cost. Hair samples are noninvasive, are stable at room temperature, and require no onsite processing to improve sample quality.

PREANALYTICAL VARIABLES

Preanalytical variables in the specimen-collection process occur before the receipt of a specimen by the laboratory.[12,27,28] Careful attention to collection, preparation, and shipping may decrease preanalytical errors that may affect laboratory results. The timing of specimen collections may be important because some results may be affected by a recent intake of meals or medicines. Variables such as age, gender, ethnicity, time of day (diurnal rhythms), season, tobacco use, or the presence of comorbid conditions may alter analyte levels and must be borne in mind by the interpreting physician. Alterations in renal function may be particularly problematic for the collection of urine specimens. Liver disease or inflammation may alter the levels of acute-phase and metallothionein proteins that bind to nutrient elements and metals.[29] Renal wasting disorders may increase urine levels and decrease blood levels of creatinine, minerals, and other analytes. Renal clearance disorders may decrease urine levels of creatinine, minerals, and other analytes.[30] Medications, such as diuretics, may alter renal function and mineral levels; all medications may be reviewed with the patient's pharmacist before interpreting results.

METHODOLOGY

The analytical method used by a laboratory to assess nutrient elements and other metals must be sensitive, specific, accurate, precise, and timely.[12] The detection limit of the methodology is important for the analysis of trace or "ultratrace" microminerals. Spectrometry methodologies, such as inductively coupled plasma-mass spectrometry or inductively coupled plasma-optical emission spectrometry, are considered state of the art. Reputable laboratories are Clinical Laboratory Improvement Amendments (CLIA) certified, use highly trained personnel, and choose to participate in third-party proficiency testing.[31] Proficiency testing ensures the reproducibility and reliability of the laboratory's internal quality control programs (IQCPs) and ensures reliable, reproducible results.[32] Some of the quality controls that may be used in each batch of samples processed include the use of reagent blanks, the replication of analyses to ensure precision, and the use of certified reference samples with known amounts of the metals of interest to ensure accuracy, specificity, and sensitivity. Reference values for some minerals have been standardized in the literature; for other elements, laboratories must establish their own reference values.

MINERALS AND DISEASE

Several minerals are required to maintain the necessary functions of life.[12,11,33] Minerals may be considered essential if a deficiency (lack) of the mineral results in significant disease or death. Nonessential minerals may affect physiologic function and have health benefits, but they have not yet been proven essential. Macrominerals are required in daily amounts of milligrams to grams; microminerals are required in daily amounts of micrograms to milligrams. Some minerals, such as electrolytes, dissociate into charged ions in the body fluids (electrolytes) and may be important in the maintenance of membrane potentials needed for muscle contractions and nerve conduction. Both macro- and microminerals are necessary cofactors in metabolic functions, and either an excess or a deficiency may be detrimental to health.

Homeostatic regulation maintains the balance of nutrient elements in the body. Regulation mechanisms may include intestinal assimilation, protein chaperones for blood transportation, storage in body tissues, and excretion mechanisms (Fig. 23.1).

Homeostatic mechanisms may be disrupted by genetics, poor diet, substances that block assimilation, toxins that displace minerals or compete for receptor sites on enzymes and cells, diseases of malabsorption, liver disease, or renal disorders. Either over- or undernutrition may be problematic for mineral homeostasis.[34] High levels of meat consumption in Western diets may excessively raise iron levels, and consumption of processed foods may result in a dietary deficiency

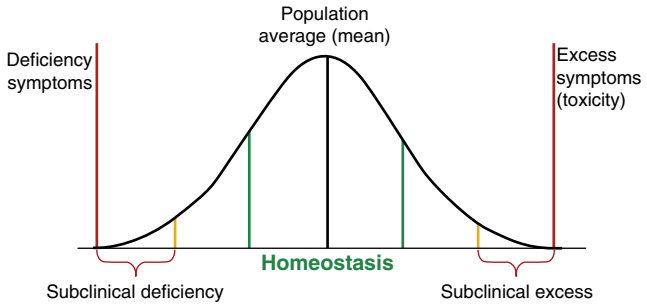

Fig. 23.1 The level of a mineral element in a tissue sample is determined by mineral availability and individual variance in assimilation, transport, and cellular uptake capacity.[12,37]

of multiple minerals.[35,36] Inherited mutations that disrupt mineral homeostasis are rare, but important, disruptors of patient health. The most common disorders include the iron-storage disorder hemochromatosis, the copper disorders Wilson disease and Menkes syndrome, the zinc-deficiency disorder acrodermatitis enteropathica, and sulfite oxidase deficiency (lack of molybdenum cofactor). The effects of inherited variation in the general population on mineral status is an important new area of research.[37]

Levels of various nutrient elements have been associated with disease states and may be considered clinical biomarkers.[8] Cirrhosis may lower levels of serum selenium,[38] calcium,[39] magnesium,[40] and zinc.[41] Emphysema or certain cancers may increase serum copper levels, and both copper and manganese levels may increase during congestive heart failure, infection, or psychoses.[42] Heart tissue levels of selenium, iron, copper, zinc, and phosphorus have been associated with ejection fraction and cardiac index.[43] In men infected with human immunodeficiency virus (HIV), helper T-type 4 cells appear closely correlated with serum magnesium concentration.[44] Although other associations have been observed between trace minerals and breast cancer,[45] gastrointestinal malignancy,[46] and malignant ascites,[47] there have been null studies for these conditions as well. It is important to remember that observed associations between certain disorders may be variable and based on patient status, ethnicity, or the stage of the disease when studied; both may confound the results of such studies.

The ratios between some trace elements have been associated with specific disorders. Levels of magnesium and copper, and their ratios, may be predictive for lower limb ischemia, atherosclerosis obliterans, and risk of aortic aneurysm.[48] The relative concentrations of copper, zinc, and selenium in whole blood and thyroid tissue may present in specific patterns for various thyroid disorders and thyroid cancer. Serum copper and copper/zinc ratios were shown to be increased in breast cancer but not in benign breast diseases.[49] In another study, serum copper-to-zinc ratios were shown to be of diagnostic and prognostic value in head, face, and neck cancer, with alterations in copper, zinc, and the copper-to-zinc ratio related to the stage of the disease.[50] Clinicians specializing in the treatment of certain disorders may wish to review the literature for associations between mineral status and the disorder of interest.

ESSENTIAL MACROMINERALS

Calcium

Calcium is the most common cation in the body and the primary component of tooth and bone.[51] Normal calcium levels are necessary for muscle contraction, enzyme function, protein stabilization, neuron firing, hormone release,[52] and blood coagulation.[53] Calcium may also act as a second messenger for some cell-signaling pathways. Calcium reserves in the body are maintained through multiple mechanisms, which include parathyroid hormone, dietary calcium intake, assimilation of calcium from the digestive tract, and renal calcium excretion. Disruption of these calcium homeostasis mechanisms may result in either hypercalcemia or hypocalcemia.[54,55]

The parathyroid gland monitors the blood calcium level and responds to low calcium concentrations by releasing parathyroid hormone (PTH). PTH increases the level of 1,25-dihydroxyvitamin D (calcitriol) and stimulates bone resorption to increase blood calcium levels. Serum calcium is so closely regulated by the parathyroid gland that its use as an indicator of calcium balance is not reliable when considered in isolation. Calcium is also regulated as it is transported across cell membranes; calcium status affects the function of the endoplasmic reticulum, the mitochondria,[56] and the sarcoplasmic reticulum of muscle cells. Measurement of physiologically active ionized calcium may be more useful in the independent evaluation of calcium status.

Hypercalcemia is defined as a total serum calcium concentration of greater than 10.4 mg/dL or an ionized serum calcium of greater than 5.2 mg/dL.[55,57] Hypercalcemia may occur because of excessive bone resorption (immobilization), hyperparathyroidism, vitamin D toxicity, and the presence of cancer or granulomatous disorders. Hypercalcemia occurs when the kidney's capacity to excrete calcium is exceeded. Mild hypercalcemia may be asymptomatic. More severe hypercalcemia may result in anorexia, nausea, vomiting, constipation, abdominal pain, fatigue, polyuria, arrhythmia, and hypertension.[58] Severe hypercalcemia may progress to symptoms of confusion, delirium, and coma. Hypercalcemia may induce renal insufficiency, nephrogenic diabetes insipidus, kidney stones, or vascular and soft tissue calcifications.

Hypocalcemia is defined as a total serum calcium concentration of less than 8.8 mg/dL or an ionized calcium level of less than 4.7 mg/dL with normal plasma proteins.[55,59] Hypocalcemia may occur because of hypoparathyroidism or pseudohypoparathyroidism, vitamin D deficiency or dependency, magnesium deficiency, acute pancreatitis, hyperphosphatemia, or renal tubular disease. Renal tubular disease may increase calcium excretion into the urine or decrease the conversion of precursors into active 1,25-dihydroxyvitamin D. During pregnancy, serum calcium and albumin levels may decrease. Medications, such as anticonvulsants, rifampin, furosemide, or bisphosphonates, may contribute to hypocalcemia. Steroid medications may decrease the gastrointestinal absorption of calcium. Hypocalcemia is typically asymptomatic but may present with dry and scaly skin, brittle nails, coarse hair, muscle cramps (legs or back), swelling of the optic nerve (papilledema), and cardiac arrhythmia or neuropsychiatric symptoms such as depression, cognitive decline, or psychosis due to diffuse encephalopathy.[58,59] More severe hypocalcemia may progress to neuromuscular irritability (spasms, tetany) and sensory parasthesias. Hypocalcemia may be associated with liver disease, nephrotic syndrome, congestive heart failure, or malnutrition.

Calcium may be evaluated in serum, whole blood, urine, or hair samples.[54,55] Serum calcium is reported as total calcium (approximately 40% protein-bound and 60% ionized calcium ions). High serum protein (albumin) levels may falsely elevate and low serum protein levels may decrease serum calcium levels. A whole-blood analysis of calcium will assess calcium present in serum, the cell membranes, and intracellularly. Urinary calcium levels will reflect gastrointestinal assimilation, bone turnover, and renal filtration. Up to 300 mg/24 hours may be excreted by subjects on unrestricted diets. Hair calcium may reflect nutritional status, and the hair calcium-to-magnesium ratio has been associated with levels of coronary artery calcification in older subjects.[60,61] Hair mineral deposition may also be altered by the presence of comorbid disorders.[62] However, hair contamination may occur because of calcium-rich "hard" water or hair products (perms, dyes, bleaches).[63]

Calcium (Ca) may be considered in relation to phosphorus (P), and a Ca:P ratio of 1.3:1 has been suggested for the maintenance of bone density.[64] Reduced calcium and increased phosphorus intake is common in Western diets and results in a low Ca:P ratio. Food sources of calcium include dairy products, canned fish with bones (e.g., salmon, sardines), green leafy vegetables, nuts, and seeds. Assessment of dietary intake of calcium is confounded by multiple factors that affect absorption, such as the quantity of fiber and other natural chelators in the diet,[65] gastric acidity, the ratio of dietary calcium to phosphorus and magnesium, gut transit time, and other factors.

Chloride

Because chloride is a halogen, most do not consider it a mineral, but technically it is classified as such. Chloride is the most common anion in the body and is primarily found in the extracellular blood compartment (serum or plasma).[66,67] Chloride, with sodium, potassium, and bicarbonate, regulates water distribution, osmotic pressure, pH, and ion balance in the extracellular compartment of the blood. Chloride is necessary for the production of hydrochloric acid in the stomach and is also essential in cellular pump functions. Chloride levels are regulated by renal excretion into urine, and chloride may also be excreted in sweat.

Chloride is typically evaluated as part of an electrolyte (serum elements) panel; levels of chloride (Cl) and sodium (Na) indicate the amount of salt (NaCl) in the blood. Symptoms of an electrolyte imbalance may include chronic vomiting, diarrhea, weakness, or respiratory distress. Chloride and other electrolytes may become imbalanced during episodes of metabolic or respiratory acidosis or alkalosis. Renal disorders may also disrupt electrolyte balances.[68] Dehydration, diuretic medications, and high doses of either antacids or baking soda may lower chloride levels. Glucocorticoid or mineralocorticoid medications may alter electrolyte balance and increase urine output.[69] Chloride ions are obtained through the diet and normally pass easily through the intestinal barrier.

Chloride may be evaluated in serum and urine, and urinary chloride is a necessary component of a full electrolyte assessment or metabolic panel.[66,67] Chloride sweat testing may be used in the diagnosis of cystic fibrosis.[70] Urine chloride analysis, and often the analysis of urine sodium as well, may be important when considering alkalosis or acidosis or when assessing high or low serum chloride levels. Depending on the patient's condition, serum and urine chloride levels may differ. Urinary chloride may help determine whether chloride loss is related to salt loss or due to an excess of adrenal hormones (cortisol or aldosterone), which may alter electrolyte excretion. Increased serum chloride (hyperchloremia) may occur because of dehydration, Cushing disease, or kidney disease (renal clearance disorders). Acid–base dysregulation resulting in metabolic acidosis or respiratory alkalosis may also increase serum chloride.[71] Low serum chloride (hypochloremia) may occur because of congestive heart failure, chronic vomiting, or Addison disease. Lung diseases, such as emphysema, may result in chronic respiratory acidosis and metabolic alkalosis, lowering serum chloride. Decreased urinary chloride may occur because of Cushing disease, primary aldosteronism, congestive heart failure, gastrointestinal malabsorption, or diarrhea. Increased urinary chloride may occur because of dehydration, Addison disease, high salt intake, or insufficient calorie intake. If both urinary chloride and sodium are elevated in a patient on a salt-restricted diet, the patient may not be diet-compliant. See Chapter 12, Fantus Test, for the use of urinary chloride as a measure of salt consumption.

Magnesium

Magnesium is a cation found primarily in the intracellular (35%–45%) compartment of the blood.[55,72,73] Up to 55% of magnesium is found in bone, and this reservoir may be mobilized for the maintenance of serum levels. Serum magnesium levels may affect nerve conduction, muscle contraction, and cardiovascular functions. Transportation of magnesium across the cell membrane is regulated by dedicated transporters. Magnesium is a cofactor for over 300 intracellular enzymes that participate in energy production, oxidative phosphorylation, glycolysis, cell replication, nucleotide (DNA) metabolism, and protein synthesis. Approximately 80% of a cell's magnesium is bound to ATP, which helps make the ATP bioactive.[74]

Hypermagnesemia (serum concentration >2.6 mg/dL) is uncommon without magnesium supplementation (or ingested as laxatives or antacids).[75] Other causes may include renal failure, hyperparathyroidism, dehydration, early diabetic acidosis, Addison disease, rhabdomyolysis (muscle breakdown), or a history of familial hypocalciuric hypercalcemia. Increased serum magnesium and copper levels may be seen with seizure disorders. High magnesium concentrations may decrease serum calcium levels. Medications that may increase magnesium levels include aspirin, thyroid medication, potassium-sparing diuretics, lithium carbonate, and antibiotics (review medications with a pharmacist).[74] Magnesium intoxication may occur if magnesium is supplemented and renal failure is present. Deep tendon reflexes are lost as magnesium levels increase above 5 mg/dL. As levels rise higher, magnesium depresses the nervous system; symptoms of magnesium intoxication may include hyporeflexia, hypotension, lethargy, disorientation, respiratory depression, and cardiac arrhythmia leading to cardiac arrest (>15 mg/dL).

Hypomagnesemia occurs because of inadequate magnesium intake, malabsorption, or increased excretion from the kidney or gastrointestinal tract.[76] Low magnesium concentrations may be associated with poor diet, alcoholism, inflammatory bowel disorders, poorly controlled diabetes, chronic diarrhea, recent hospitalization or surgery, or toxemia of pregnancy.[77] Magnesium blood levels are also lower in the second and third trimesters of a normal pregnancy. Medications such as proton-pump inhibitors, antacids, diuretics, digoxin, insulin, laxatives, phenytoin, glucocorticoids, steroid hormones, hormone antagonists, some antibiotics, antihistamines, and antivirals may decrease magnesium levels (review medications with a pharmacist).[74] High doses of calcium, vitamin D, or caffeine may further exacerbate magnesium losses. Low magnesium concentrations may result in symptoms of neuromuscular excitability (muscle cramps, spasms) or cardiac arrhythmia. Good dietary sources include green leafy vegetables, nuts, soybeans, and cocoa mass. Hard water may contain magnesium salts and contribute to magnesium intake.

Serum magnesium may be the most commonly used but least accurate assessment of magnesium status.[55] The serum magnesium concentration may be influenced by recent dietary intake and other factors; it constitutes only about 1% to 3% of total body magnesium and does not reflect magnesium levels in cells.[77] The binding of magnesium to serum proteins is subject to many uncontrollable variables. Serum magnesium levels as low as 1.2 mEq/L have been measured in patients with normal total body magnesium.[78] Measurement of magnesium status presents some difficulties; currently, the magnesium retention (load or tolerance) test may be the most accurate, although cumbersome, method of assessment in adults.[79] The retention test requires a parenteral infusion of magnesium with subsequent urine collection to evaluate urinary magnesium.[80]

Other methods of assessing magnesium include ionized magnesium concentrations (in blood, plasma, or serum), urinary magnesium, and erythrocyte concentrations.[55] Erythrocyte concentrations of magnesium are not subject to the same transient fluctuations as serum and may be more reliable indicators of status than serum levels.[81] The analysis of white blood cell (WBC) magnesium content has also been

explored. The concentration of magnesium in leukocytes has been inversely associated with the risk of tachyarrhythmias. WBC assessments of magnesium may not be accurate in all patients; inherited variation in the *MAGT1* magnesium transporter gene[82] may reduce the amount of magnesium in WBCs and result in a form of immunodeficiency. The best test to evaluate total body magnesium sufficiency may well be whole-blood analysis because this will assess total magnesium in serum, intracellularly, and in the cell membranes of both red blood cells (RBCs) and WBCs. Ionized magnesium and total magnesium appear to provide similar information.[83] Increased urinary excretion in individuals with type 1 diabetes has been shown to decrease erythrocyte levels, without significant hypomagnesemia.[84] A 24-hour urinary magnesium may be useful to reflect dietary changes in magnesium intake.[85] Healthy kidneys restrict the excretion of magnesium when concentrations or intakes are low and permit excretion when serum levels are restored. The current scientific literature remains divided in regard to hair Mg levels reflecting intracellular levels. External Mg contamination of hair may result from recent hair treatment, hair color, or hard water exposure, confounding hair element evaluations.

Phosphorus

The element phosphorus is a necessary component in cell membranes, DNA, and RNA.[55,86] Phosphorus is primarily used in bone mineralization (85%), adenosine triphosphate (ATP) metabolism, pH homeostasis, and cell signaling. Phosphorus is bound to oxygen in all living systems and is found in the body as phosphate (PO_4^{3-}). Phosphorus, in the form of phosphoryl groups (PO_3), is attached to and removed from molecules during cell signaling. Phosphorus homeostasis is regulated by the parathyroid gland and vitamin D.

Hyperphosphatemia may occur because of renal insufficiency (GFR < 30 mL/min), hypoparathyroidism, pseudohypoparathyroidism (hormone resistance), or granulomatous disease (immunodeficiency).[86,87] Less commonly, hyperphosphatemia may occur because of diabetic ketoacidosis, rhabdomyolysis, tumor lysis syndrome (cancer therapy), and excessive exercise or occasionally because of the excessive use of oral or rectal (enema) phosphate salts. The condition is asymptomatic but may present with symptoms if hypocalcemia is also present (dry and scaly skin, brittle nails, coarse hair, muscle cramps [legs or back], swelling of the optic nerve [papilledema], cardiac arrhythmia, or neuropsychiatric symptoms). Elevated serum phosphate has been associated with an increased risk of cardiovascular disease, heart failure, and kidney disease. Chronic hyperphosphatemia may induce the precipitation of calcium into vascular and soft tissues; the calcifications may appear on imaging studies.

The kidney normally compensates for low phosphorus intake. Hypophosphatemia occurs when serum phosphate is less than 2.5 mg/dL.[86,88] Symptoms of hypophosphatemia may include anorexia, anemia, muscle weakness, bone pain, increased susceptibility to infections, peripheral parasthesias, loss of coordination, or respiratory distress. In children, chronic hypophosphatemia may present as rickets; in adults, it may present as osteomalacia. Causes of hypophosphatemia include alcoholism, respiratory alkalosis, the recovery phase of diabetic ketoacidosis, hyperparathyroidism, Cushing syndrome, hypothyroidism, vitamin D deficiency, malabsorption syndromes, renal wasting, severe anorexia nervosa, or the presence of other electrolyte imbalances (hypomagnesemia or hypokalemia). The excessive use of theophylline (respiratory inhalers) or antacids and the chronic use of diuretic medications may also deplete phosphate levels.

Phosphate is measured in serum, plasma, or urine.[55] Serum or plasma phosphate results may be compromised if specimens are hemolyzed, have a high fat content, or have high bilirubin concentrations. With normal renal function, urinary phosphorus reflects dietary status. Hair phosphorus has not been documented to reflect dietary status or biochemical phosphorus status.

Potassium

Potassium is the primary intracellular cation.[89–91] Intracellular potassium concentrations may be 30 times higher than serum or plasma levels. The high intracellular levels are maintained by adenosine triphosphate (ATP)-dependent cell membrane transporters, which exchange sodium for potassium. The sodium–potassium "pumps" are essential for the maintenance of the ionic gradients (membrane potentials) needed for muscle contractions and nerve conduction. Potassium diffuses out of cells with the concentration gradient if the pump's activity is inhibited. The kidney is slow to adapt to changes in potassium concentrations in the blood.

Hyperkalemia is defined as a serum potassium concentration of greater than 5.5 mEq/L.[89,90,92] Symptoms of hyperkalemia may include peripheral tingling or paresthesias; muscle weakness, which rarely progresses to flaccid paralysis; and cardiac arrhythmia, which may progress to ventricular fibrillation or asystole. Hyperkalemia may be asymptomatic until arrhythmias occur. The causes may include increased potassium intake (supplements), kidney injury or chronic renal disease that decrease excretion, hypoaldosteronism, Addison disease (with sodium depletion), congenital adrenal hyperplasia (salt wasting), metabolic acidosis, and dehydration. The ingestion of large amounts of fruit or fruit juices may increase potassium levels. Medications that may contribute to hyperkalemia include potassium-sparing diuretics, angiotensin-converting enzyme (ACE) inhibitors, nonsteroidal anti-inflammatory agents (NSAIDs), heparin, digitalis, α- and β-blocker antihypertensives, and angiotensin receptor blockers. "Pseudohyperkalemia" may occur if comorbid platelet, erythrocyte, or mixed-type blood disorders are present and may result in preanalytical platelet activation or hemolysis.[93] It can also occur from excessive, long-term consumption of glycyrrhizin from licorice root. Plasma potassium may be more accurate in such patients.

Hypokalemia is defined as a serum potassium concentration of less than 3.5 mEq/L.[89,90,94] Hypokalemia may be most apparent in erythrocytes; potassium is primarily an intracellular electrolyte.[95] Symptoms of potassium loss may begin with fatigue or muscle weakness and cramping and progress to tetany, rhabdomyolysis (muscle breakdown), respiratory distress, muscle and intestinal paralysis (bloating, constipation, pain), and cardiac arrhythmias. Chronic hypokalemia may impair the kidney's ability to concentrate urine and result in polyuria (excessive urination) and polydipsia (excessive thirst). Hypokalemia is usually caused by decreased potassium intake or increased potassium losses from the gastrointestinal tract or the kidney. Gastrointestinal losses may be precipitated by severe or chronic vomiting or diarrhea, laxative abuse, bowel diversion surgery, villous adenoma of the colon (rare), or the ingestion of bentonite clay (binds potassium). Renal losses may occur because of Cushing syndrome, hyperaldosteronism, congenital renal hyperplasia, acquired renal tubular dysfunction, or inherited renal-wasting disorders (Bartter, Gitelman, Liddle, or Fanconi syndrome). Hypomagnesemia may induce increased renal excretion of potassium, as may excessive intake of glycyrrhizin, a component of black licorice candies and licorice root herbal supplements. A potassium shift from the intracellular to the extracellular compartment may occur because of hyperthyroidism or the rare, inherited condition familial periodic paralysis. Medications that may contribute to hypokalemia include β-adrenergic agonists, decongestants, bronchodilators, diuretics, mineralocorticoids, glucocorticoids, antibiotics, caffeine, sodium polystyrene sulfonate, and labor-suppressing medications. Fruits, vegetables, seeds, and nuts are good dietary sources of potassium. Potassium supplements may be required by some individuals, but their use must be carefully monitored.

Potassium concentrations may be evaluated in serum, plasma, erythrocytes, whole blood, or urine.[89] Hair potassium has not currently been associated with either dietary intake or nutrient status. Reference values are different for plasma and serum samples. Platelets rupture during coagulation, and the increased potassium is found in the serum, so the serum reference values are higher. The patient's platelet count may have an effect on the potassium level in serum samples as well; high platelet counts (thrombocythemia, thrombocytosis) may result in pseudohyperkalemia. Blood samples must be processed quickly and correctly to prevent preanalytical errors that may occur. Cooling of a sample before separation may falsely increase serum or plasma potassium levels. Leaving unseparated samples at room temperature for long periods before processing may falsely lower serum or plasma potassium levels. Delayed transport, rough handling, or failure to release the arm tourniquet before blood collection may cause tissue damage and falsely elevate potassium samples as erythrocytes break open. In addition, serum or plasma concentrations may not reflect intracellular losses during early potassium deficiency. The renal tubular response is slow to adapt to potassium depletion and may take a week or more to adjust ion exchanges and conserve potassium.

Erythrocyte (RBC) potassium concentrations may be a more accurate indicator of the potassium content in other types of cells than serum or plasma.[95] Although RBCs do not have nuclei, the sodium–potassium membrane pump that maintains the proper influx and efflux of these ions is intact and may respond quickly to restore intracellular levels when potassium becomes available. The rapid restoration of intracellular levels is essential for the continued firing of neurons and for cardiac contractility. Reduced intracellular levels have been associated with changes in the cardiac recovery phase (electrocardiograms).[96] Evidence indicates that obesity may decrease the efficiency of the sodium–potassium pumps.[97] The whole-blood potassium concentration may be almost as accurate as the RBC potassium level because 98% of potassium is intracellular.[98]

Urinary potassium may be used to confirm and diagnose abnormal blood potassium levels.[89] Urinary renal excretion of potassium is also used to estimate daily potassium intakes. A 24-hour collection is the preferred reference method, although collections of shorter duration (7 p.m.–7 a.m.) may also be acceptable.[99] Within the reference values, the highest tertile (third) of potassium excretion has been associated with a decreased risk of hypertension,[100] cardiovascular events, and mortality.[101] Urinary potassium concentrations may decrease because of low aldosterone levels or the use of medications such as NSAIDs, beta blockers, or pharmaceutical lithium. Urinary potassium levels may increase because of renal disease or rhabdomyolysis (muscle breakdown).

Sodium

Sodium is the primary cation in the extracellular fluid.[89,102] The sodium–potassium ATPase pumps maintain the intracellular potassium and extracellular sodium concentration gradients and establish the membrane potentials necessary for neuron firing, cardiac function, and muscle contraction. Sodium is evaluated as part of an electrolyte (serum elements) panel; levels of sodium (Na) and chloride (Cl) indicate the amount of salt (NaCl) in the blood.[103] Symptoms of an electrolyte imbalance may include chronic vomiting, diarrhea, weakness, or respiratory distress. Electrolytes are commonly monitored in patients with hypertension, heart failure, and liver or kidney disease.

Sodium is absorbed by the gastrointestinal system, and the kidneys excrete all but 1 to 2 meEq/L of the approximately 200 meEq/L of sodium chloride ingested daily. Sodium, with chloride, potassium, and bicarbonate, regulates water distribution, osmotic pressure, pH, and ion balance in the extracellular compartment of the blood. Disruption of the body's fluid volume or fluid-compartment equilibrium may occur if there is a loss, gain, or inappropriate retention of either sodium or water. The regulation of extracellular water and sodium status occurs in the renal tubules of the kidneys. The extracellular fluid volume includes the blood volume, and signaling systems that regulate blood pressure, including the renin–angiotensin–aldosterone system, antidiuretic hormone, and renal dopamine, may alter sodium and water regulation in the kidney.

Hypernatremia is a hyperosmolar condition, defined as serum sodium of greater than 145 mEq/L, and occurs when water loss is greater than water intake.[102,104] Hypernatremia is uncommon with normal kidney function but may occur because of dehydration, Cushing syndrome, diabetes insipidus, adrenal tumors (secrete deoxycorticosterone), congenital adrenal hyperplasia, osmotic diarrhea, hypothalamic disorders, or an impaired thirst mechanism.[105] Hypernatremia may be more common in the aged, those with impaired mental status, and infants because these individuals may have difficulty rehydrating unassisted. Hypernatremia commonly presents with thirst and proceeds to neurologic symptoms (confusion, agitation, dry mucous membranes, decreased urination, muscle spasms, parasthesias, tremors, ataxia, seizures, coma) as water shifts from cells into the extracellular compartment. Medications such as anabolic steroids, diuretics, glucocorticoids, laxatives, cough medications, and oral contraceptives may increase sodium levels (review medications with a pharmacist). Hypernatremia resulting from salt ingestion rarely occurs with normal renal function. The treatment of hypernatremia depends on the water (fluid) status of the patient. Hypernatremia may be hypovolemic (extracellular water loss greater than sodium loss), euvolemic (increased sodium but normal extracellular water levels), or hypervolemic (sodium levels increase and extracellular water increases). Urine sodium and osmolality may be used with serum assessments to determine whether the kidney is the cause.

Hyponatremia is defined as a serum sodium level of less than 136 mEq/L and indicates an excess of extracellular water volume compared with sodium concentration.[89,102,106] Low serum sodium levels may be caused by a water–sodium imbalance or by the presence of excess glucose or lipids in the blood ("pseudohyponatremia"). Causes of sodium loss may include diarrhea or vomiting, renal disease or injury, mineralocorticoid deficiency, Addison disease, hypothyroidism, syndrome of inappropriate antidiuretic hormone secretion (SIADH), cirrhosis, heart failure, pancreatitis, rhabdomyolysis, physical or emotional distress (increased vasopressin), small bowel obstruction, or increased fluid intake. Endurance or extreme sports athletes may ingest large quantities of water during events and experience acute hyponatremia if they do not replace salt as well. Symptoms of hyponatremia include nausea, weakness, confusion, and lethargy and may progress to ocular palsy, confusion, and coma if the sodium loss becomes severe. Medications that may contribute to hyponatremia include thiazide diuretics, barbiturates, carbamazepine, chlorpropamide, clofibrate, opioids, tolbutamide, ACE inhibitors, tricyclic antidepressants, NSAIDs, and vincristine. Dietary sources primarily include table salt, sea vegetables (e.g., kelp, seaweed), dairy products, and spinach.

Hyponatremia may occur during isosmotic, hyperosmotic, or hypoosmotic conditions.[89,106,107] Isosmotic hyponatremia is actually pseudohyponatreima; plasma sodium is decreased, but osmolality, glucose, and urea levels are normal. The phenomenon is exclusive to samples assessed using flame emission spectrophotometry or ion-selective electrodes and only occurs in samples from patients with hyperproteinemia or severe hyperlipidemia. Hyperosmotic hyponatremia occurs most commonly because of severe hyperglycemia as the water and sodium shift compartments to compensate for the excess glucose. Sodium levels will decrease about 1.6 mEq/L for every 100 mg/dL increase in glucose.

Hypoosmotic hyponatremia occurs because of a greater loss of sodium (depletional) compared with water or because of an increase in the extracellular water volume (dilutional).

Depletional hyponatremia presents clinically with orthostatic hypotension, tachycardia, and decreased skin turgor ("tenting"). Low urine sodium during depletional hyponatremia indicates an appropriate renal response; the loss is likely from the gastrointestinal tract or the skin (excessive sweating). High urine sodium indicates renal wasting of sodium, metabolic alkalosis, or the use of thiazide diuretics. Dilutional hyponatremia occurs because of water retention and presents clinically as weight gain or edema. This may occur because of renal disease or nephrotic syndrome, congestive heart failure, or hepatic cirrhosis. If hypoosmotic hyponatremia presents with normal extracellular water volume, likely causes include SIADH and deliberate excess water intake.

Sodium is most commonly measured in blood or urine, although it may also be measured in sweat, feces, and gastrointestinal fluids.[89] Whole blood, serum, or heparinized plasma may all be used to assess sodium concentrations, although no information on the status of the extracellular compartment will be available from whole-blood analysis. Urinary sodium is always evaluated as a component of sodium blood level evaluations. Urinary sodium may be increased because of an increased blood sodium level, Addison's disease, diuretic use, or renal wasting of sodium. Higher urinary sodium levels have been associated with an increased risk of cardiovascular events and mortality.[108] Urinary sodium levels may be low because blood levels are low; because urinary excretion of sodium is compromised (nephrotic syndrome); or because of dehydration, congestive heart failure, or liver disease.

ESSENTIAL MICROMINERALS

Copper

Copper is an essential component of copper-incorporating oxidase enzymes and other metalloproteins.[12,109,110] Copper-dependent enzymes are necessary for energy production (cytochrome c oxidase), collagen cross-linking, hemoglobin synthesis, norepinephrine synthesis, histamine catabolism (diamine oxidase), melanin synthesis, and antioxidant status (superoxide dismutase). Two thirds (about 60 mg) of total body copper is sequestered in bone or muscle tissues. Free copper ions may interact with cellular components to generate free radicals. Special "chaperone" proteins keep intracellular copper bound to prevent this cellular damage by free copper ions; however, inherited variations in chaperone proteins may compromise their ability to bind copper.[111] Copper absorbed from the gastrointestinal tract is bound to albumin and transported to the liver. Ninety percent of the copper exported from the liver is bound to ceruloplasmin; urinary excretion is limited to ionic, not bound, copper. Both copper excesses and deficiencies may be inherited or acquired. Inherited conditions are the result of genetic mutations and are usually X-linked (maternal inheritance). Acquired conditions may be the result of environmental exposures or supplementation choices.

Excess copper in the body may have toxic effects.[12,109,110,112] High levels of intracellular copper may inhibit protein synthesis or gene expression. Copper excess may be acquired or the result of inheritance. True acquired toxicity (poisoning) is rare but may occur because of contamination (storage of acidic foods or beverages in copper containers, contaminated water, or cooking in corroded copper or with brass utensils). Symptoms after ingestion may include nausea, vomiting, and diarrhea. Excess copper is primarily excreted in the bile, and liver disorders that decrease bile excretion may increase copper levels. Subclinical acquired copper excess may require a liver biopsy with visualization of Mallory hyaline bodies for confirmation. Rarely, large amounts of copper may be accidentally absorbed through the skin or ingested (gram quantities). Symptoms may then progress to hepatotoxicity, hemolytic anemia, and anuria (renal failure) and may result in death if not promptly treated. High copper levels may be seen with rheumatoid arthritis and some types of cancers. Serum copper and magnesium may be increased with seizure disorders.[113] The use of carbamazepine or phenobarbital may increase copper blood levels (review medications with a pharmacist). Individuals with Wilson disease, a genetic disorder of impaired copper transportation, may be at risk for toxic effects at copper intake levels considered normal for the average population and may present with low ceruloplasmin; Kayser–Fleischer rings in the cornea; and hepatic, neurologic, psychiatric, or reproductive disorders.[114]

Clinical hypocupremia is rarely noted because of dietary deficiency.[12,109,110,112] Acquired copper deficiencies may occur because of childhood protein deficiency (kwashiorkor), persistent infant diarrhea (cow's milk–based diet), malabsorption syndromes, gastric surgery, or excessive zinc supplementation (>50 mg daily). Copper deficiency may delay normal development or result in symptoms of neutropenia, osteopenia, myelopathy, neuropathy, optic neuritis, and iron-resistant hypochromic anemia. Levels of serum copper and ceruloplasmin may, or may not, be low. Copper deficiency may be found in association with premature birth, cystic fibrosis, or aceruloplasminemia (iron deposition). Menkes syndrome is an X-linked mutation in males that results in low ceruloplasmin and low copper levels in serum, the liver, and copper-dependent proteins. Severe symptoms (intellectual disability, gastrointestinal symptoms, hypopigmentation, skeletal changes, hair texture changes, arterial ruptures) occur in affected individuals, and the diagnosis is usually made in early childhood. Individuals with less severe disease may have partial enzyme activity and a milder form of the disease (occipital horn syndrome). Subcutaneous injections may restore peripheral copper levels, but passage through the blood–brain barrier remains limited. Dietary copper sources include beans, eggs, fish, fresh fruits, liver, milk, mushrooms, nuts, oysters, peas, poultry, and whole grains.

Copper may be evaluated in serum, plasma, whole blood, erythrocytes, urine, stool, and hair.[11,12] Hair may provide an estimate of nutritional copper status, and hair copper levels may increase or decrease in certain disease states.[115–117] However, hair cannot discern the presence or absence of inherited copper metabolic disorders, and hair may be easily contaminated by copper-based products used in pools, hot tubs, or plumbing. Fecal copper levels reflect excess dietary copper from bile excretion and unassimilated dietary copper in the stool. Urinary copper reflects the excretion of ionic copper and may be used in conjunction with blood levels to assess the presence of inherited copper metabolic disorders. Accurate urinary copper assessments require normal renal function. Urinary copper may be very high if patients with Wilson disease are treated with chelators during urine collection. Wilson disease is diagnosed when serum ceruloplasmin is low but urinary copper excretion is high.[114] Menkes disease is likely if blood, urine, and hepatic copper levels are low. The most frequently used assessments of copper status are serum or plasma copper and ceruloplasmin.[11] If excess copper intake or exposure is suspected, then whole blood (total copper) and ceruloplasmin may be the best choice because the sample includes both intracellular and extracellular copper. Erythrocyte copper may have some utility in certain patient populations, such as patients with Alzheimer's disease, where elevated RBC copper has been found in Alzheimer's subjects but not in controls.[118]

Iodine

The element iodine, ingested as the compound iodide, is essential for the synthesis of the thyroid hormones thyroxine (T4) and triiodothyronine (T3).[19,119] Metabolic activity (ATP production, protein

synthesis, enzyme activity, development of skeleton and nervous system, etc.) is regulated by thyroid activity. Thyroid function is regulated by thyroid-stimulating hormone (TSH) from the pituitary gland, which increases the uptake of iodine by the gland. Approximately 80 μg of iodine is used to synthesize thyroid hormones daily. A healthy thyroid gland concentrates about 75% of total body iodine (15–20 mg). Iodide intake varies based on location and the amount of iodide available in the soil. Landlocked populations and those at higher altitudes, far from the ocean, may be more at risk of iodine deficiency. The accumulation of radioactive iodine (^{131}I) in the body may occur after accidental emissions from nuclear power plants and increase the risk of developing thyroid cancer; the uptake of ^{131}I is less likely with adequate iodine status.

Iodine excess may occur if doses of greater than 1.1 mg daily are chronically ingested by iodine-sufficient adults.[120,121] Exceeding this dose may increase the risk of iodine-induced dysfunction in susceptible populations, such as individuals with iodine deficiency, preexisting thyroid disease, the elderly, neonates, or during pregnancy (prenatal exposure). Although there are biological mechanisms in place to control thyroid hormone synthesis during iodine excess,[122] the iodine exposure may also increase TSH and the risk of goiter and hypothyroidism in some susceptible individuals and in neonates.[123] Excess iodine may also increase the risk of thyroiditis and thyroid papillary cancer. The accidental ingestion of more than 50 mg of iodine daily for 2 months by 43 older adults occurred during a study, and the effects were reviewed in a separate study.[124] Of the 43 subjects taking the high iodide dose, 10 subjects developed hypothyroidism (elevated TSH) while taking the iodide; all but two had returned to normal TSH levels 1 month after discontinuing the iodide supplement. Three subjects developed hyperthyroidism (low TSH) while taking the iodide dose, which persisted 1 month after discontinuation. High levels of iodine exposure may occur if iodinated radiographic contrasts or medications such as amiodarone are used (review medications with pharmacist). Iodine excess may result in symptoms of increased salivation, gastrointestinal irritation, acne-like skin lesions, and a brassy taste in the mouth. Acute iodine poisoning may include symptoms of a burning feeling in the mouth, throat, and stomach; fever; nausea, vomiting, and diarrhea; weak pulse; and cyanosis. Symptoms may progress to coma. High doses of iodine may be contraindicated with antithyroid medications, ACE inhibitors, and potassium-sparing diuretics and during pregnancy. Large doses of potassium iodide may decrease the efficacy of the anticoagulant coumarin.

Iodine deficiency may result in various disorders.[119–121] If iodine intake is less than 100 μg per day, TSH levels will rise. During deficiency, the thyroid gland is stimulated by increasing levels of TSH and increases in size because of overstimulation by TSH (colloid goiter). Most individuals remain euthyroid, but if iodine deficiency is severe, hypothyroidism may result. Iodine deficiency in adults may impair cognitive function and is the most common cause of goitrous hypothyroidism. Perinatal iodine restriction may have permanent developmental effects on cognition and may result in lower IQ levels. During pregnancy, iodine requirements roughly double. Maternal deficiency may increase the risk of attention deficit and hyperactivity. Severe maternal deficiency (development of goiter) causes cretinism (cognitive impairment, deafness, motor impairments, poor growth, developmental delay), miscarriage, or stillbirth. Food sources of iodine include sea vegetables, seafood, dairy, eggs, and grains; all food sources are highly variable in iodine content due to local conditions and production practices. Dietary iodide is easily assimilated by the gastrointestinal tract, but consumption of goitrogenic (soy, cassava, cruciferous vegetables, some beans, millet, and sweet potato varieties) foods may prevent uptake. Iodized table salt may be an acceptable source of iodide; however, restaurants and processed food manufacturers rarely use iodized salt in food production. Adequate selenium, iron, and vitamin A are required to support iodine use by the thyroid gland. Tobacco use may impair iodine uptake by the thyroid gland. The presence of intestinal parasites, such as *Ascaris lumbricoides,* hookworm, or *Entamoeba histolytica,* may prevent iodide absorption by the gastrointestinal tract.[125] Many environmental toxins, especially metals, impair iodine absorption and utilization (see Chapter 183, Hypothyroidism).

Urinary iodine is the international standard for the evaluation of iodine status because more than 90% of dietary iodine is excreted in the urine within 24 to 48 hours of ingestion.[11] Although often used as a surrogate,[126] the assessment of serum thyroid biomarkers has limited utility in the evaluation of iodine status.[127,128] Whereas some studies show no association between TSH, T4, and urine iodine levels, other studies indicate that serum T4 may be a conditionally useful biomarker in children and adults. Interventional studies indicate that serum TSH levels may be reflective of iodine status in newborns but are not a sensitive indicator of iodine status in developing children or adults, although serum thyroglobulin may be used in school-aged children. Similar studies indicate that serum TSH may be a useful indicator of iodine status in pregnant or nursing women. Serum T4 is not considered accurate for pregnant or nursing women. For serum T4 to be an accurate surrogate for iodine, there must be a moderate baseline T4 status.

Iodine intake over the past few days is best reflected in urinary iodine assessments. The World Health Organization defines iodine deficiency as median urinary iodine concentrations of less than 100 μg/L (< 150 μg/L during pregnancy).[126] Urinary iodine excretion of greater than 300 μg (> 500 μg during pregnancy) is considered excessive. Urinary iodine of less than 20 μg/L is considered severe deficiency. Multiple 24-hour urine collections are recommended to estimate iodine intake in individual subjects. It has been suggested, in a non–peer-reviewed trade magazine, that whole-body sufficiency of iodine may be assessed in urine using an "iodine loading test." The interpretation of the results of this test presupposes specific receptor/storage sites that take up and store iodine/iodide.[129] When body storage of iodine/iodide is optimal, the percentage excretion of an oral loading dose of iodine/iodide excreted in urine is maximal; some authors purport that body stores are optimal when excretion is 90% or more.

Iron

Iron is distributed into virtually all compartments in the body.[130] Iron is used by peroxidase, cytochrome, and other enzymes, such as cystathionine-β-synthase (CBS) and enzymes of the tricarboxylic acid cycle. Iron is found in nonenyzme proteins such as hemoglobin, myoglobin, and mitochondrial iron–sulfur clusters[131]; storage proteins such as ferritin or hemosiderin; and in the transport protein apo-transferrin. Strict conservation of iron stores in the body, even when iron is in excess, results in the loss of approximately only 1% of total body iron daily. Regulation of iron intake occurs in the gastrointestinal tract, where iron assimilation may be modulated by hepcidin so that about 1 milligram of iron is absorbed daily.[132] Both iron excess (overload) and iron deficiency may impair homeostasis[133]; the abnormal distribution of iron during various disease processes may contribute to their symptomology and presentation.

Iron overload may be acquired or hereditary.[132,134] Acquired iron overload (hemosiderosis) may occur because of excessive iron therapy, hemodialysis, multiple blood transfusions (for sideroblastic anemia, hemolytic anemia, pyruvate kinase deficiency, and thalassemia major), acute overdose, chronic liver disease, or alcoholism. Individuals with β-thalassemia intermedia may develop iron overload because of increased intestinal absorption. An acute iron overdose damages organs and intestines, resulting in vomiting and diarrhea.

TABLE 23.1 Anemia of Inflammatory Response[a,130,141,143]

Disorder	Serum Iron	TIBC	UIBC	Transferrin	Transferrin % saturation	Ferritin	Hemoglobin
Iron deficiency	Low	High	Low	High	Low	Low	Low
B_{12} deficiency	High	Low	High	Low	High	High	Low
Anemia of chronic disease	Normal or Low	Normal or Low	Normal or High	Normal or Low	Normal or Low	Normal or High	Low
Hemochromatosis	High	Low	High	Low	High	High	Normal
Thalassemia	High	Low	High	Low	High	High	Low
Porphyria cutanea tarda	High	Low	High	Low	High	High	Normal

TIBC, Total iron-binding capacity; *UIBC,* unsaturated iron-binding capacity
[a]Adapted from the Iron Disorders Institute. http://www.irondisorders.org. Accessed November 1, 2017.

Hereditary hemochromatosis occurs primarily in Caucasians of Northern European descent and is the result of mutations in the *HFE* gene. The disease is characterized by iron accumulation in the liver and other organs (C282Y homozygous or C282Y heterozygous together with a heterozygous H63D or S55C).[135] Early symptoms include fatigue and lethargy; characteristic late symptoms include bronzing of the skin (palms), cirrhosis, diabetes, and increased risk of hepatocellular carcinoma and neurodegenerative diseases.[132,133,136] Juvenile hereditary hemochromatosis, from mutations in the *HEF2* or *HAMP* genes, results in symptoms that present before 30 years of age and that include hypogonadotropic hypogonadism, cardiomyopathy, arthropathy, and liver fibrosis or cirrhosis.[137] Other mutations result in African iron overload (also known as Bantu siderosis) and ferroprotein deficiency, iron-storage diseases that deposit iron primarily into macrophages. Inherited disorders such as aceruloplasminemia, hypotransferrinemia, Friedreich ataxia, and porphyria cutanea tarda may also result in iron overload.

Iron deficiency is one of the most common mineral deficiencies worldwide,[130,132,134] although isolated iron deficiency is uncommon in the United States.[133] Iron deficiency is most common in children, reproductive-aged women, and the elderly. Deficiency may be secondary to poor diet, obesity, chronic kidney disease, gastrointestinal malabsorption, gastrointestinal tumors,[138] gastrointestinal parasites, gastric bypass surgery, or blood loss. Blood losses may result from comorbid disease, blood donations, or extreme endurance training. Iron depletion occurs in gradual stages, and different biomarkers are useful at different stages. Iron-deficiency anemia may result in symptoms such as fatigue, pallor, headaches, dizziness, impaired cognitive function, behavior or motor difficulties (developing children), poor immune responses, decline in exercise performance, tachycardia, dyspnea, and difficulty regulating temperature (iodine deficiency or comorbid hypothyroidism). Symptoms may progress to nail spooning, brittle nails, loss of taste, angular cheilosis (skin lesions at the corners of the mouth), atrophic glossitis ("bald," sore, tongue),[139] or pica. Co-occurring deficiencies in vitamin A, copper, or zinc may further impair iron metabolism. Dietary sources include beans, dark green leafy vegetables, dates and figs, dried fruits, egg yolk, fish, molasses, nuts, organ meats, red meat, shellfish, and whole and enriched grains. Iron deficiency may increase manganese absorption by the gastrointestinal tract.

A variety of tests and methods may be used to assess iron status,[130,132,134] and a variety of physiologic conditions must be considered when interpreting iron results (see Table 23.1).[130,140] Serum iron, total iron-binding capacity (TIBC), serum transferrin, serum ferritin, hematocrit, hemoglobin, soluble transferrin receptor, and zinc protoporphyrin may all play a role in diagnosing iron disorders. The use of various commercial methodologies to measure some of these analytes requires each laboratory to establish its own reference values for those tests. Although the majority of iron is sequestered inside the erythrocytes as heme iron, and iron supplementation improves RBC hemoglobin content (during pregnancy), erythrocyte iron is not commonly measured in conventional laboratories.[142] Iron test results may be affected by diurnal variation (test in morning), stage of menstrual cycle, use of iron supplements or intake of a high-iron diet, oral contraceptives (raise iron values), hepatitis, and the presence of acute or chronic inflammation. Methotrexate may increase iron test results. Testosterone, high-dose aspirin, metformin, and adrenocorticotropic hormone may decrease iron test results.

Serum iron evaluates the level of iron in circulation.[140] A low serum iron with a high transferrin or TIBC may be an indication of iron deficiency.[130,143] During chronic diseases, serum iron, transferrin, and TIBC are all decreased. Serum iron increases, and unsaturated iron-binding capacity decreases during iron overload. High levels of stress or sleep deprivation may transiently decrease serum iron levels.

TIBC is assessed by saturating a blood sample with iron and comparing the saturated sample (transferrin saturation) with the serum iron results to obtain the TIBC and the transferrin percent saturation:

$$\text{Transferrin \% saturation} = \frac{\text{serum} \times 100}{\text{TIBC}}$$

Normally, about 30% of transferrin is bound to iron. Transferrin levels will decrease because of liver disease, nephrotic syndrome, low protein intake, or iron overload, and the transferrin saturation will increase. TIBC levels will increase during iron deficiency, and the transferrin saturation will decrease. Plasma iron levels decline in stage 2 iron deficiency, and TIBC rises.

Serum transferrin represents the unsaturated iron-binding capacity (UIBC) and may be used instead of the more expensive transferrin saturation test:

$$\text{TIBC} = \text{UIBC} + \text{serum iron}$$

Transferrin levels may decrease because of nephrotic syndrome or other renal-wasting disorders.[144] Hemoglobin levels usually remain in range during stage 2 iron deficiency, whereas serum transferrin receptor concentrations increase.

Ferritin is the primary intracellular iron-storage protein, and serum ferritin estimates the amount of iron stored in the body.[130] Serum ferritin decreases during the first stage of iron deficiency as iron stores are depleted and bone marrow iron decreases. Low levels of ferritin indicate iron deficiency; however, high levels may occur not only with iron-storage disorders but with a variety of acute and chronic diseases or with the presence of malignancy.

Hemoglobin is found within erythrocytes, and the hematocrit value roughly estimates the number of RBCs.[144] Hemoglobin and

hematocrit values are assessed during a complete blood count. In the third stage, iron-deficiency anemia (IDA), hemoglobin and hematocrit levels decrease, and microcytic hypochromic anemia occurs. An elevated hematocrit may indicate polycythemia, dehydration, pulmonary disease, congenital heart disease, renal tumor, tobacco use, or high-altitude living. Hematocrit results may also be altered by recent blood transfusion or donation.

The soluble transferrin receptor (sTfR) is used when ferritin results may be compromised by a preexisting or concurrent inflammatory disorder (ferritin is an acute-phase reactant during inflammation).[145,146] The sTfR assessment is not affected by the level of inflammation and may be used to discern whether anemia is caused by iron deficiency or chronic disease. sTfR rises with the onset of iron-deficient erythropoiesis and continues to rise as iron deficiency progresses to anemia. sTfR will also elevate because of hemolytic anemias, myelodysplastic syndromes, and the use of erythropoietic stimulation medications. Importantly, sTfR does not rise during anemia of chronic disease.

Zinc protoporphyrin (ZPP) is a heme-precursor protein.[147] When there is insufficient iron to synthesize heme, or if an exposure to the toxic element lead occurs, ZPP levels rise. ZPP is measured in the free erythrocyte protoporphyrin test, and a ZPP:heme ratio may be included in the results. A change in the ZPP:heme ratio may be the first indication of insufficient iron reserves in pediatric populations, and the ratio will shift before symptoms of iron deficiency appear. ZPP may also be elevated due to comorbid infection, inflammatory disorders, anemia of chronic disease, or inherited porphyria. The results must be interpreted with the patient's symptoms and history in mind.

Iron levels may occasionally be evaluated in urine or hair. Urinary iron excretion is variable and is not considered to reflect tissue iron stores; however, increased urinary iron excretion may be an indicator of exposure to the toxic element lead.[148] Increased iron excretion may be a causative factor in intractable IDA and may be evaluated in such cases.[149] The iron levels in hair have not been correlated with more conventional blood estimates of iron status; however, research continues in this area. Recent studies have correlated low hair iron (and other elements) with growth retardation[62] and demonstrated a positive association between hair iron levels and levels of behavioral traits (novelty seeking, extraversion) and physical activity.[150]

Manganese

Manganese is an essential cofactor for enzymes in multiple biochemical pathways, including antioxidant protection (mitochondrial superoxide dismutase), glucose synthesis (pyruvate carboxylase), the urea cycle (arginase), and connective tissue and cartilage synthesis (glycosyltransferases).[12,151] Although essential, manganese at high levels may have toxic effects in the nervous system. Manganese and iron may compete for uptake in the gastrointestinal system. Manganese uptake increases during iron deficiency and decreases during a high-iron meal. Manganese is transported in the body bound to albumin or transferrin and excreted from the body primarily through the bile.

Manganese levels of greater than 5.4 µg/L serum or greater than 20 µg/L whole blood indicate manganese exposure or retention.[12,152] High levels of manganese exposure may occur because of occupational inhalation of manganese dust; inhalation of methylcyclopentadienyl manganese tricarbonyl (MMT) gasoline additive; or ingestion of manganese in supplements, food, or water.[151] Exposed infants and children may not excrete manganese efficiently until their hepatic systems are fully developed, and adults with liver disease may have cholestasis and increased manganese retention. Symptoms of hypermanganesemia may contribute to hepatic encephalitis and resemble the neurologic symptoms of Wilson disease or Parkinson's disease; however, manganism is unresponsive to L-dopa therapy.[152–154] In rare individuals, a mutation in the SLC30A10 zinc/manganese cellular transporter may result in a syndrome of hepatic cirrhosis, dystonia, polycythemia, and hypermanganesemia,[155] which may run in families.

Human manganese deficiency has been demonstrated in small experiments or during chronic parenteral nutrition.[12,151,152] Symptoms in children may include growth delays and skeletal abnormalities. Symptoms in adults may include low cholesterol; skin rash or lesions; abnormal glucose tolerance; and increased blood calcium, phosphorus, and alkaline phosphatase. Human studies indicate that low manganese levels may increase the risk of seizures[156] and may be associated with Alzheimer's disease and risk of cognitive impairment.[157] Dietary sources include dark green leafy vegetables, dried fruits, dried legumes, nuts, and whole grains.

Manganese levels may be assessed in serum, whole blood, erythrocytes, urine, and hair.[12,13,158,159] For serum collections, a plastic cannula should be used to prevent contamination from steel needles, and specimens should be discarded and redrawn if hemolysis occurs during sample collection or processing. Serum manganese levels represent approximately 30% of total body manganese and may vary based on recent dietary intake. Serum manganese may also require an evaluation of lymphocyte manganese superoxide dismutase activity to accurately assess nutritional deficiency. Whole-blood levels may be used to monitor manganese excess and may provide a more accurate assessment of recent dietary intake over the life span of the RBC (60–120 days).[160] Erythrocyte manganese represents about 60% of total manganese and may provide further diagnostic insight for specific conditions such as prolidase deficiency (imidodipeptiduria),[161] which presents with increased erythrocyte manganese and normal serum levels. Urinary manganese is considered to have a short half-life postexposure and may better reflect recent dietary and environmental exposures rather than body nutritional status. Hair manganese has been evaluated in multiple studies,[162–164] but the possibility of external contamination must be eliminated before the interpretation of results.[165]

Molybdenum

Molybdenum is an essential cofactor for enzymes involved in sulfur metabolism (e.g., sulfite oxidase), uric acid synthesis (xanthine oxidase), and detoxification (aldehyde oxidase, mitochondrial amidoxime reducing component).[12,166,167] The element must be complexed into a pterin protein to act as a cofactor in biochemical reactions,[168] and inherited deficiency of the cofactor results in microcephaly, developmental delay, and neurologic symptoms within a week of birth. Affected individuals have increased levels of urinary sulfite, S-sulfocysteine, xanthine, and hypoxanthine and decreased uric acid in their blood.[169] Molybdenum is assimilated in the gastrointestinal tract as molybdate (MoO^{2-}_4); once assimilated, more than 80% of the molybdate binds to erythrocyte proteins. Excess dietary molybdenum is excreted by the kidneys, and experimental ingestion of up to 1.5 mg daily for 24 days produced no adverse effects in young men.[170]

Dietary molybdenum excess in humans is not well documented. Ingestion of 10 to 15 mg of molybdenum in the daily diet occurs in some isolated Armenian populations and has been correlated with increased blood levels of uric acid. Increased uric acid, arthralgias, and ceruloplasmin levels have been reported with occupational molybdenum exposures.[12]

Reported dietary deficiency is rare but has been documented when molybdenum-deficient parental nutrition has been administered to patients. Chronic molybdenum deficiency causes sulfite toxicity.[171] Deficiency symptoms included tachycardia, tachypnea, headache, nausea, vomiting, and progression to coma. Animal studies indicate that tungsten exposures may increase the excretion of molybdenum, even when molybdenum is deficient in the diet.[172] Dietary sources of molybdenum include beans, peas, red meats, and whole grains.

Molybdenum was once considered difficult to measure, but inductively coupled plasma mass spectrometry has sufficient sensitivity to measure molybdenum in biological samples, such as whole blood, erythrocytes, serum, plasma, or urine.[12] The average value for whole blood is 1 μg/L; for plasma or serum, the average is 0.5 μg/L. Urinary molybdenum ranges, on average, from 40 to 60 μg/L daily and varies with dietary intakes. Urinary molybdenum has been compared with femoral neck and lumbar bone mineral densities, and an inverse relationship has been found: the higher the urinary molybdenum, the lower the bone mineral density.[173]

Selenium

Selenium is an essential component of selenoproteins vital for various metabolic and antioxidant functions.[12,174,175] Selenoproteins all contain selenocysteine, which is now considered the 21st amino acid. Glutathione peroxidase (antioxidant), iodothyronine deiodinase (thyroid hormone), thioredoxin reductase (intracellular redox status), and selenophosphate synthase (selenoprotein synthesis) all require selenocysteine in their structures, as do the antioxidants selenoprotein P and selenoprotein W. The human synthesis pathway has only recently been defined and may be affected by inherited variations in the pathway enzymes,[176] with clinically significant results. Animal studies indicate that selenium may have synergistic antioxidant effects with vitamin E.[177]

Dietary selenium is primarily selenomethionine. Both organic and inorganic selenium may be absorbed by the gastrointestinal system, although the absorption of some inorganic selenium may require the presence of glutathione.[178] Intakes in the United States and Canada are generally considered sufficient. Selenium sufficiency may reflect dependence on local food production; in some areas of the world, selenium-deficient soils and dependence on locally grown foods may predispose human populations to selenium deficiency; in other areas, high selenium levels may be found. Excess selenium is normally excreted by the kidneys.

Toxic levels of selenium exposure may occur because of supplementation, industrial exposure, or high levels in local soil or water, which may bioaccumulate into food plants and animals.[12,174,175] Chronic exposure to high amounts of selenium in food, water, or soil may increase the risk of amyotrophic lateral sclerosis.[179] Inorganic selenates may be more toxic than organic selenium compounds and may cause symptoms at lower levels of exposure.[180] Early signs and symptoms of selenosis (chronic exposure) include a "garlic" odor on the breath, brittle nails, and hair loss and progress to fatigue, irritability, gastrointestinal symptoms, mottled teeth, skin rashes, and neurologic disorders. Toxic effects have been associated with selenium intakes of 850 μg daily. The tolerable upper intake level for adults is 400 μg daily from all sources, but newer evidence indicates that daily intake in excess of 250 to 300 μg daily may increase the risk for type 2 diabetes, dermatitis, and hair loss.

Selenium deficiency may occur because of low levels in local soil and water, because of malabsorption syndromes, or because of inherited variations in selenocysteine insertion protein (SECISBP2 tRNA), which impairs thyroid hormone synthesis and antioxidant status and decreases plasma selenium levels.[176] Systemic selenoprotein deficiency results in photosensitivity and hearing loss; the effects of partially active pathways are unknown at present.

Symptoms of severe deficiency may include muscle weakness, muscle wasting, and cardiomyopathy. Severe deficiency may also decrease male fertility.[12,174,175] Severe dietary selenium deficiency during child development may result in multifactorial Keshan (cardiomyopathy) or Kashin–Beck (joint deformities, dwarfism) disease; these conditions are seen primarily in areas of China with selenium-deficient soil. The risk of deficiency may be increased because of bariatric surgery, malabsorption syndromes, renal dialysis, and specialized medical diets (phenylketonuria, homocystinuria, maple syrup urine disease). Selenium levels may be lower in HIV+ individuals in developing countries or due to local selenium-deficient soils. Marginal selenium deficiency may impair cognitive function,[181] thyroid function, and immune or inflammatory responses. Deficiency may increase the risk of cardiovascular disease, reproductive disorders, or mood disorders. Poor immune responses in selenium-deficient individuals may increase viral virulence and the severity of viral diseases. The use of cisplatin or other medications may decrease selenium levels (review all medications with a pharmacist). Dietary sources of selenium include Brazil nuts,[182] fish, seafood, meat, brown rice, and sunflower seeds.

Selenium status may be evaluated by whole blood, serum, plasma, urine, and hair.[12] The types of selenium ingested may sequester in different compartments in the blood; organic selenium increases plasma and urine levels, whereas inorganic selenite does not.[183] Whole-blood analysis measures selenium in both the intracellular and extracellular compartments and may be the best assessment if selenium excess is suspected. Serum and plasma are the most commonly assessed, despite the fact that serum levels may decrease during acute-phase activation or chronic inflammation.[184] Lower levels of serum selenium have been associated with an increased risk of anemia in adults over 65 years old.[185] Erythrocyte levels remain stable, even as serum or plasma levels decrease, and may provide a better assessment of recent dietary intakes over the life span of the RBC (60–120 days).[186] Urinary selenium levels reflect recent dietary and environmental exposures.[187] After the injection of 2,3 dimercaptopropane-1-sulfonate (DMPS), less urinary selenium is excreted by subjects with amalgams, which indicates that selenium may bind to mercury.[188] Hair selenium has been correlated with plasma levels in Polish subjects.[189] Altered hair selenium levels have been demonstrated in subjects with nonalcoholic fatty liver disease[190] and hyperlipidemia,[191] compared with controls. Hair is easily contaminated from external sources, and selenium from antidandruff shampoos may greatly increase hair selenium levels.[192]

Zinc

Zinc is an essential cofactor and catalyst in approximately 300 enzymes.[12,193,194] Zinc, cysteine, and histidine combine to form folded "zinc finger" compounds used in cellular metabolism as a structural stabilizer in proteins and membranes or as a regulator of gene expression. Adequate zinc is required for normal growth and development. Zinc is also used during the conversion of vitamin A precursors, cell signaling, hormone synthesis, and nerve transmission. Blood plasma contains less than 1% of total body zinc, and 80% of plasma zinc is bound to albumin. Zinc in erythrocytes is present as the enzyme carbonic anhydrase; RBC levels are about 10 times greater than plasma levels. Zinc assimilation in the gastrointestinal tract is variable based on the availability of zinc in the diet; zinc absorption may range from 20% to 50% of the zinc in a sufficient diet and may increase to 100% absorption of the zinc in a deficient diet. Zinc uptake may be inhibited if large amounts of supplemental iron are taken simultaneously or due to inherited variations in the *ZIP4* (SLC39A4) gene.[195] Excess zinc is excreted into the gut and incorporated into stool or excreted by the kidneys.

Zinc, in excess, has toxic effects.[12,194,196] Excessive supplementation, accidental exposure from galvanized food or beverage containers, or industrial exposure to zinc-oxide fumes may all result in toxic levels of zinc. Symptoms of toxic levels of zinc ingestion may include headaches, abdominal pain, vomiting, diarrhea, and loss of appetite. Symptoms of inhalation (metal fume fever) may include fever, sweating, shortness of breath, nausea, fatigue, and myalgias 4 to 12 hours

postexposure; symptoms then resolve after 12 to 24 hours in a zinc-free environment. Chronically high levels of zinc exposure may decrease copper levels and result in nerve damage. Chronic high doses of zinc (100–150 mg daily) block gastrointestinal copper assimilation and result in low blood copper levels. Signs and symptoms include erythrocyte microcytosis (small RBCs), neutropenia (low WBCs), poor immune responses, and an increased risk of urinary lithiasis (kidney stones).[197] Higher zinc doses of 140 to 450 mg daily may alter iron metabolism and reduce levels of high-density lipoproteins. Local applications of zinc in the nasal passages may damage olfactory nerves; intranasal zinc sprays and gels are no longer recommended because the loss of smell may be permanent.

Marginal zinc deficiency may be prevalent in developing countries or areas dependent on cereal grain-based diets high in phytate and fiber.[193] In the United States and Canada, zinc deficiency may occur because of inadequate intake, increased excretion, or increased requirement.[12,194] Zinc deficiency may occur because of poor diet, gastrointestinal malabsorption, chronic diarrhea, cystic fibrosis, liver disorders, alcoholism, diabetes mellitus, chronic kidney disease, sickle cell disease, HIV+ status, physical trauma, pregnancy, and lactation. Severe zinc deficiency may cause symptoms of intrauterine growth restriction, impaired development, short stature,[198] loss of appetite, immune dysfunction, weight loss, delayed wound healing, taste abnormalities, poor concentration, and fatigue. Symptoms may progress to night blindness, hair loss, diarrhea, delayed sexual development, male hypogonadism, impotence, and eye lesions or skin lesions.

The very young and very old may have an increased risk of zinc deficiency.[12,194,199,200] Inherited variations in the metal-binding protein metallothionein 2A (MT2A-5 A/G) may result in GG phenotypes having lower zinc and, perhaps, higher copper and lead levels than the wild-type AA phenotype.[201] Inherited variations in the *ZIP4* zinc transporter (SLC39A4) may result in severe zinc deficiency (acrodermatitis enteropathica) with classic indications of low (<30 µg/dL) serum zinc, periacral and periorificial dermatitis, alopecia, and diarrhea.[199] Inherited variations may be suspected if zinc is persistently low (< 50 µg/dL), with symptoms of poor growth, anorexia, and mild nonspecific dermatitis that improve with zinc supplementation. Severe zinc deficiency in infants may occasionally occur because of inherited variations in zinc transporter 2 (SLC30A2) specific to the mammary gland, which results in low levels of zinc in breast milk but normal maternal zinc levels. The zinc content of breast milk decreases after the first 6 months; dietary zinc is required to meet infant needs at approximately 6 months postpartum.

Approximately 40% of individuals over 60 years old may be zinc deficient if no supplemental zinc is used; even with supplementation over 20% may still be zinc deficient due to comorbid conditions or gastrointestinal dysfunctions.[12,200] Strict vegetarians or vegans on primarily grain-based diets may require 50% more dietary zinc because of the decreased availability of zinc in the diet.[193] High intakes of supplemental iron or calcium may impair zinc uptake; patients may be monitored for zinc status during supplementation. Zinc excretion may increase because of muscle breakdown and excretion of ketone bodies during extended fasting or the use of extremely low-calorie or ketogenic diets. Medication use may alter zinc uptake. Tetracycline, quinolone antibiotics, or bisphosphonates lose efficacy and reduce zinc assimilation if taken together (consult with a pharmacist for dosing regimens). Anticonvulsants (sodium valproate, etc.), thiazide diuretics, and ethambutol may all increase zinc excretion. Medications such as penicillamine, used to treat Wilson disease, or diethylenetriamine penta-acetate (DTPA), used for iron overload, may severely deplete zinc. Review all medications with a pharmacist if zinc–medication interactions are suspected. Dietary sources of zinc include oysters, crab, meats, beans, chickpeas, and cashews. Soaking beans, grains, and seeds before cooking and the use of leavened grain products increase bioavailable zinc from plant-based foods.[193]

Although zinc may be measured in whole blood, serum, plasma, erythrocytes, urine, and hair, nutritional zinc status is difficult to discern because homeostatic mechanisms maintain plasma zinc until the deficiency is severe.[12,202] Plasma zinc is the most commonly used assessment; however, plasma zinc is considered insensitive to dietary intakes, has a diurnal shift (higher in the morning), and must be interpreted in conjunction with serum albumin levels, urinary zinc, and an assessment of acute-phase reactants (zinc levels decrease; copper levels increase).[203] Plasma is preferred over serum because zinc levels may be 5% to 15% higher in serum samples. A repeated fasting plasma zinc of less than 70 µg/dL is suspicious for marginal deficiency, and a level of less than 30 µg/dL indicates deficiency. Whole blood and erythrocytes may also be used and may have different associations with health and disease.[204–206] Because the majority of zinc is intracellular and bound to enzymes, whole-blood levels may provide the best overall blood assessment of zinc status. Urinary zinc may be used in conjunction with serum zinc levels to determine whether kidney function is a contributing cause for abnormal serum/plasma results. Increased urinary zinc excretion may deplete serum zinc levels. Renal failure may decrease urinary zinc and increase serum/plasma levels. Urinary zinc levels may also reflect dietary intake, but they are not sensitive enough to be used as a screening test for mild or moderate deficiency.[202] Hair samples may indicate zinc deficiency but may be easily contaminated by external sources such as hair products, which may artificially elevate hair zinc levels.

POTENTIALLY ESSENTIAL MINERALS

Bromine

Bromine is an unstable element found in nature as bromide. Although in high amounts bromine or bromide exposures may have toxic effects, increasing evidence indicates that lower levels of bromide in the human body may be beneficial, and perhaps essential, for human health.[10,207–209] Brominated proteins may play a role in neurologic signaling, immunity, collagen synthesis, and rapid eye movement (REM) sleep.[210]

High levels of bromine or bromide exposure may be associated with negative effects. Bromide is found in food, water, and seawater. Industrial exposure to bromine gas may occur; bromine may be used in pool or hot tub cleaners, pesticides, and fire retardants.[211] Brominated vegetable oils may be used in food preparation or added to soft drinks.[212] Bromide may be found in veterinary medications and occasionally in human pharmaceuticals (Germany, Japan).[213] Pyridostigmine bromide was distributed and may have been taken by some U.S. troops during the first Persian Gulf war as a nerve agent antidote.[214] Bromide levels may be higher in areas of radioactive fallout.[215] Signs of acute inhalation exposure may include dyspnea, cough, headache, dizziness, and irritation of mucous membranes. Acute ingestion of a large amount of bromine may result in gastrointestinal symptoms (nausea, vomiting, etc.). Chronic, excessive ingestion of brominated vegetable oils may result in dermatologic or neurologic symptoms. Higher plasma bromine levels have been associated with increased levels of TSH.[216]

Low levels of bromide intake may alter acetylcholinesterase signaling,[207] sleep quality,[209] collagen cross-linking,[208] and the function of G protein-coupled receptor 7 (GPR7) in the nervous system.[217] The antimicrobial function of eosinophil peroxidase in WBCs is inhibited by low bromine levels.[10] Bromine levels in serum and erythrocytes are decreased by peritoneal dialysis.[218] Dietary sources of bromide include fish, grains, and nuts.

Bromine has been measured in blood,[219] serum,[220] and urine.[221] In whole blood, typical bromide levels may range from 0.3 to 1.2 mg/dL. Whole blood levels of greater than 1.2 mg/dL have been associated with altered electroencephalogram readings. Serum levels of greater than 1250 µg/mL are considered toxic. Urinary bromide may be used to monitor industrial exposures to 1-bromopropane or other bromine/bromide compounds.

Chromium

Chromium (as a component of "glucose tolerance factor" or chromodulin) was proposed as an essential element more than 50 years ago after patients on long-term parenteral nutrition developed glucose intolerance, ataxia, peripheral neuropathy, and weight loss, which improved with the addition of trivalent chromium.[12,222–224] Chromium may be biologically active, yet multiple studies have failed to confirm the presence of biological chromium-binding compounds in humans. Studies have also failed to confirm the claims that chromium improves body composition or muscle mass.[225,226] Although recent studies in Asian populations have correlated lower plasma chromium levels with metabolic syndrome and type 2 diabetes,[227] the majority of randomized controlled trials do not demonstrate evidence of prevention or treatment of glucose intolerance or type 2 diabetes at the usual supplement dose of 200 µg daily. For most glucose-intolerant subjects, higher doses may be required to achieve benefit, but safety studies to support the use of higher doses are lacking. There is some evidence that increasing chromium intake for mildly glucose-intolerant subjects on low-chromium diets may be beneficial,[228] and one study using a biotin-chromium supplement with obese subjects with type 2 diabetes reported improvements in glucose response and biomarkers for cardiovascular disease and atherogenesis.[229] Less than 3% of dietary chromium is absorbed in the gut, although vitamin C, niacin, NSAIDs, aspirin, beta blockers, corticosteroids, or insulin may increase absorption (animal studies). The supplement chromium picolinate may have greater bioavailability, passing directly through the jejunum and being incorporated into cells. Dietary trivalent chromium is bound to transferrin or albumin in the plasma, and excess is excreted in the urine.

The toxic effects of chromium vary based on whether the exposure is trivalent or hexavalent chromium. Trivalent chromium (Cr^{III}) is considered nontoxic at normal dietary intake and supplementation levels; however, hexavalent chromium (Cr^{VI}) is considered toxic in any amount. Chromium may be ingested, inhaled (industrial exposures), or absorbed through the skin.[230,231] Ingestion of hexavalent chromium may result in inflammatory changes in small intestine, pancreas, and liver tissues (animals) and may increase the risk of gastrointestinal and lung cancers. Respiratory exposure may result in bronchial asthma, respiratory tract polyps, nasal and septal ulcerations, or nasopharyngeal irritation and inflammation and may increase the risk of lung cancer. Topical exposure to very high levels of hexavalent chromium may result in allergic dermatitis. Hexavalent chromium is a component of joint-replacement prosthetics and may be found in drinking water supplies as a contaminant.[232] Trivalent chromium is found in supplements and dietary chromium. Although few symptoms are associated with trivalent chromium exposure, human studies indicate that long-term chromium picolinate supplementation ranging from 600 to 2400 µg/day may result in kidney or liver damage in some individuals. Patients with comorbid renal or liver disorders may be at particular risk.

True dietary deficiency has not been documented for chromium. The most likely cause of low chromium levels is increased urinary excretion from poor diet, renal disorders, or intense athletic training.[233] Diets high in simple carbohydrates may increase chromium excretion. Trivalent chromium may be obtained from whole grains, brans, green beans, broccoli, nuts, and egg yolks.

Chromium may be measured in serum, plasma,[227] erythrocytes, whole blood, and urine by laboratories using element-free collection devices and inductively coupled plasma mass spectrometry (ICP-MS) technology.[12] Serum values are considered normal at 0.1 to 0.2 µg/L. Recent evidence indicates that RBC chromium levels primarily reflect exposure to toxic hexavalent chromium (Cr VI) because trivalent chromium does not enter erythrocytes.[234] Whole blood provides an assessment of both compartments and, therefore, total chromium exposure. Urinary chromium levels may not reflect dietary intake because renal excretion may be altered by exercise and high-carbohydrate diets.[233]

Fluorine

Fluorine, as the metal compound fluoride, is found naturally in water sources at varying levels.[235] Fluoride is not considered essential because deficiency does not result in overt death or disease; however, lack of fluoride increases the risk of dental caries and gum disease, which may contribute to cardiovascular or chronic inflammatory disease. Fluoride is absorbed by the gastrointestinal system and moves quickly from the circulation into the bones and teeth, where 95% of the body's fluoride is found. Approximately 90% of excess fluoride is excreted in the urine. Fluoride is deliberately added to water supplies in the United States and some areas of Canada.[12,236] Internationally, fluoride-poor areas may supplement salt or milk with fluoride instead. In the body, fluoride is incorporated into hydroxyapatite, which, as fluoroapatite, strengthens bones and tooth enamel.[10] Although fluoride may increase the density of osteoporotic bone, it has not been shown to alter the underlying structural defects in the bone trabecular pattern that increase the risk of fracture.[237]

Excess fluoride exposure may occur industrially, from high levels of fluoride found naturally in springs or groundwater (>4 mg/L), or from the overuse of fluoride-containing products such as powdered infant formula, tea (*Camellia sinensis*), fluoride supplements, or fluoridated dental products.[237] Young children may be at risk if they swallow fluoridated toothpaste.[12] Medications, such as anesthetics, antibiotics, antiinflammatories, and cancer treatments, may contain fluoride. ^{18}F-fluorodeoxyglucose is used as an imaging agent for positron emission tomography (PET) scans.[10] Low-salt diets may decrease the element's excretion in the urine and increase fluoride retention. Symptoms of acute fluoride poisoning may include gastrointestinal symptoms and progress to excessive salivation, excessive lacrimation, sweating, and muscle weakness. Chronic ingestion of higher levels of fluoride may contribute to the risk of hypothyroidism.[238] A recent meta-analysis indicates that in utero exposures may contribute to lower IQ levels at fluoride exposure levels considered safe for adults.[239] The most obvious sign of chronic excess fluoride ingestion is fluorosis, the development of chalky, white patches on erupting teeth, which may stain yellow or brown. Continued exposure (plasma fluoride > 4 micromoles/L) may weaken or pit tooth enamel and progress in adults to osteosclerosis (excessive bone hardening), spinal exostosis (new abnormal bone growth), and genu valgum (knock-knee).[240] Symptoms of skeletal fluorosis may include joint pain and stiffness and may progress to calcification of ligaments, immobility, muscle wasting, and spinal cord compression. The use of the antifungal voriconazole may result in symptoms of fluorosis.[241]

Low levels of fluoride are associated with an increased risk of dental caries.[12,237] Dietary sources include bone-in marine fish (sardines, etc.), tea, grape juice, and crab.

Fluoride may be measured in plasma or urine.[12] Individuals drinking U.S. fluoridated water may have plasma fluoride levels of 0.1 to 0.4 mmol/L and urinary fluoride levels of 0.2 to 3.2 mg/L.[242] Drinking water samples may also be assessed for fluoride concentration with laboratory analysis. For urine and water samples, a special fluoride-specific

electrode is usually used to directly determine concentration. Tissue (blood) samples require special processing to remove the fluoride from the organic material before measurement.

Lithium

The element lithium is found sporadically in natural drinking water sources and is not considered an essential element, although it may have biological effects at low doses.[10] Lithium is absorbed by the gastrointestinal tract and excreted from the kidneys much like sodium.[243]

Lithium has been shown to upregulate the expression of glutathione S-transferase[244] and the antiapoptosis genes *BCL2* and *IRS2* in vitro. Lithium also down-regulates the proapoptosis genes Bcl2-associated agonist of cell death *(BAD)* and Bcl-2 homologous antagonist/killer *(BAK1)*.[10] Lithium has also been shown in vitro to inhibit the expression of glycogen synthase kinase-3β, an enzyme involved in Alzheimer's disease pathogenesis. Lithium exposure may alter thyroid function; urinary lithium levels have been inversely associated with plasma concentrations of T4 and positively associated with TSH in women,[245] and plasma levels of lithium carbonate have been associated with TSH levels in children.[246]

High levels of lithium carbonate are used as a pharmaceutical in the treatment of mania and bipolar disorder; responses to lithium therapy may depend in part on the patient's ethnicity and inheritance of glutamate decarboxylase-like protein 1 *(GADL1)*.[10] *GADL1* variants rs17026688, rs17026651, and IVS8 + 48*del*G may predict lithium response in patients of Han Chinese descent.[247] Because of its chemical similarities to sodium, renal lithium conservation may be increased in dehydrated patients.[243] Toxicity information is based on studies of lithium carbonate. High levels of lithium carbonate may result in lethargy, dizziness, weakness, poor coordination, slurring speech, gastrointestinal symptoms, confusion, or restlessness.[248] Chronic exposure to high levels of lithium carbonate may impair renal and thyroid function. Blood levels greater than 2.5 mmol/L may result in tremors, muscle rigidity, hyperreflexia, seizures, and renal failure. Prenatal exposure to lithium carbonate during the first trimester may result in the development of cardiac malformations.[249] The use of medications such as acetazolamide, ACE inhibitors, angiotensin II receptor antagonists, antacids, caffeine, calcium channel blockers, NSAIDs, theophylline, or psychiatric medications such as haloperidol, methyldopa, and selective serotonin reuptake inhibitors may alter the metabolism of lithium carbonate.[250]

Symptoms of deficiency may affect the central nervous system, and behavioral disorders have been associated with low lithium levels.[10] Population studies have associated lower levels of lithium exposure (2.0–5.0 μg/L) in drinking water with a higher risk of dementia, vascular dementia, and Alzheimer's disease compared with populations with more than 10 μg/L in drinking water.[251] No association has been found in population studies for the incidence of bipolar disorder and lithium levels in drinking water.[252] Low hair lithium levels have been associated with heart disease, learning disabilities, and violent behavior.[253]

Lithium levels may be evaluated in serum,[243] erythrocytes,[254] urine,[255] or hair.[253] Serum is most commonly used to assess levels of lithium carbonate and may correlate with RBC levels.[256] Urinary lithium values were found to range from 11.0 to 50.5 μg/L in a Japanese population. Hair lithium levels averaged 0.063 μg/g in a study of U.S. adults, and hair levels may correlate with lithium supplementation.

Vanadium

Vanadium is not currently considered an essential nutrient cofactor for any human enzyme, although it is essential for some rodents (rats) and other mammals.[257] Because of this, animal studies using this element may not translate directly into human populations. Vanadium may compete with phosphate-binding sites in human enzymes.[258] Increasing evidence suggests vanadium may have effects on cell metabolism and immune responses, particularly humoral B cell responses,[259] and sodium–potassium ATPase.[260] The oxidation state of vanadium may determine whether it is found in the cell or the plasma. Vanadium^{IV} binds to transferrin in the blood and is primarily found in the plasma. Intracellular vanadium is found primarily in the kidneys, spleen, bones, and liver, and is typically found as vanadium^{IV} or vanadium^{V}. Small human studies indicate that vanadium may result in minor improvements in glucose metabolism, glycogen synthesis, and HbA1c levels in subjects with type 2 diabetes; however, vanadium may also increase triglyceride levels, and large, well-controlled studies are needed to confirm findings and establish dosing.[261,262] Assimilation of vanadium by the gastrointestinal tract is poor (3%–20%). Vanadium is primarily excreted through the kidneys.

High levels of vanadium exposure, either ingested or inhaled, have toxic effects.[263–265] Toxic vanadium compounds may be encountered in industrial settings and released into the environment as industrial waste (coal emissions, fly ash, fuel oils, jet exhaust).[266] Several organic vanadium compounds have been tested as treatment agents for diabetes and cancer. Inhalation of vanadium compounds may result in cough, sputum, exertional dyspnea, wheezing, headache, nausea, palpitations, nosebleed, abnormal breath sounds (wheezes, rales, rhonchi), eye irritation, and throat inflammation. Ingestion of vanadium compounds may result in headache, nausea, and diarrhea. Chronic high levels of exposure may progress to distal tremors (hands), diarrhea, blood cell abnormalities, hair and nail changes, green-hued tongue, hypertension, and enlarged liver. Industrial exposures to vanadium compounds have been associated with altered response times, cognition, and mood in Chinese factory workers.[267]

Although vanadium deficiency has not been studied in humans, low levels of vanadium have been associated with several chronic diseases. A study of Chinese industrial workers associated low levels of vanadium with an increased risk of atherosclerosis (higher cholesterol, lower high-density lipoprotein C [HDL-C], poor apoB:apoA1 ratios); the association was strongest in male subjects. Another study found an inverse correlation between new-onset type 2 diabetes in Chinese individuals and plasma vanadium levels.[268] The subjects with the lowest levels of vanadium had the highest risk of diabetes. Food sources of vanadium include mushrooms, shellfish, peppers, parsley, dill weed, grain, and grain products.

Vanadium levels may be evaluated in whole blood, serum, urine, or hair.[265] Serum or whole blood is preferred because very little vanadium is found in RBCs. The average serum concentration due to dietary vanadium exposures is less than or equal to 2 μg/L. The average urinary vanadium level from normal background exposures (based on study controls) was found to be 2.7 μg/L. Women in the highest third of urinary vanadium concentration were shown to have a lower risk of breast cancer (64%–40%) compared with those in the lowest third.[269] Hair levels of vanadium have not been correlated with ingestion in studies of children exposed to elevated vanadium in drinking water.

CONCLUSION

Newer technologies and methodologies continue to improve the detection of mineral elements. Testing for mineral excess or deficiency may be an important step in the diagnosis of patients and may be necessary to confirm the effectiveness of supplementation or dietary changes.[270,271] It is important to remember that a laboratory result is only as good as the laboratory performing the assay. Reputable laboratories will have quality assurance and quality control procedures in place[32,272] and will participate in third-party proficiency testing when available.

Proper collection and analytic procedures must be followed to ensure accurate results. For mineral element analysis, such procedures may include the preanalytical preparation of hair samples.[273] For blood samples, element-free collection equipment is essential to prevent contamination and false high results. Careful preparation of separated blood components is also required to ensure the accuracy of results. Urinary samples may occasionally be contaminated by personal hygiene products, and hair may be easily contaminated by minerals in bathing water or by elements in hair products.[274] The interpretation of results must always include the consideration of the patient's history and physical condition because, in the end, it is the patient who is treated, not the laboratory results.[273]

Mold Exposure Assessment

Ann Shippy, MD

OUTLINE

INTRODUCTION

Chronic exposure to environmental toxins, including mycotoxins and microbial volatile organic compounds (mVOCs) from mold, is an important emerging area of medicine. Despite recent advances in the technology to test for mold and mycotoxins, there is much more that needs to be known to provide the best care. Identifying patients affected by mold is challenging because there are no standards of care for testing or treatment. Many physicians are not even aware of the effects of mycotoxins, and medical organization statements have not incorporated the most recent research and testing capabilities in their position statements and recommendations. How many years of research and legal battles did it take to identify smoking tobacco as a health hazard and then to change public policy? Most people now realize that breathing in smoke and air pollution is detrimental to their health. At this time, most people and healthcare providers do not realize the harmful effect of the inhalation or ingestion of mold toxins from buildings that are commonly water damaged and many food products. It is likely that, one day, we will look back at mold exposures in food and buildings in the same way we look at the danger of tobacco use now—it seems so obvious.

DEFINITIONS

Mycotoxins: Mycotoxins are fungal secondary metabolites that bioaccumulate, leading to carryover and concentration into animal fluids, organs, and tissues. As a consequence, mycotoxin determination in biological samples from humans and animals has been reported worldwide. Because most mycotoxins show toxic effects at low concentrations and considering the extremely low levels present in biological samples, the application of reliable detection methods is required.[1]

mVOCs: mVOCs are chemicals with low molecular weights, high vapor pressure, and low water solubility produced by fungi and bacteria during metabolism. These chemical characteristics allow mVOCs to easily evaporate into the air or "off-gas," and they may have an odor. Volatile organic compounds (VOCs) can be produced through industrial or biological processes. In the industrial setting, VOCs are commonly used or are created as by-products in the manufacture of paints, pharmaceuticals, refrigerants, petroleum fuels, dry cleaners, furniture, household cleaners, and other common products.

CHALLENGES

1. There has been little research on the effects of chronic exposure to low levels of mycotoxins and mVOCs in humans. This means much of the clinical application has to be extrapolated from primarily cell and animal studies and a few human studies.
2. The technology to detect mycotoxins and mVOCs in humans or the environment is in its infancy. Thus there are no defined, well-accepted protocols. There is considerable noise and confusion over the best practices, although there has been moderate progress in the past decade in developing technology to detect mycotoxins in food, the environment, and humans.
3. There is a lack of research on how to treat patients affected by toxic mold most effectively and the best ways to monitor their progress.
4. There is a lack of research to identify the safe levels of mycotoxins and mVOCs accounting for the synergy of other environmental toxins or the genetics and nutritional status of the individual.
5. The U.S. government and other governments and organizations, such as the World Health Organization (WHO), have not yet updated their policies based on progress with the testing technology that has been added in the past decade to improve the detection of mycotoxins and correlate them to human illness. Much more research needs to be funded.
6. Mycotoxin-induced illness is likely a significant health-damaging epidemic based on the high prevalence of water-damaged buildings and the extensive presence of mycotoxins in the food supply.
7. Addressing this epidemic may be an enormous financial burden because many buildings such as residences, schools, businesses, and governments that affect the health of their inhabitants are in need of extensive remediation for acceptable or optimal human health.

8. The governmental regulations of mycotoxins in food vary greatly by country. Global standards are needed that account for the synergy of mycotoxins. This will also have a significant financial impact as even more batches of crops and products are deemed inedible.

Symptoms to Consider in Mycotoxin Illness from Contaminated Food or Inhalation

At the time most government policies and medical organization statements were published, there was no testing available to correlate mycotoxins present in humans and the environment with human disease, and thus such policies are outdated. Most of the research on mycotoxins is done on animals or other organisms. Because controlling mold in animal feed is a challenging, ongoing worldwide issue, there is extensive animal research. Standard medical education teaches clinicians to consider mold only as an allergy or asthma issue or in the differential diagnosis for an infectious disease in immunocompromised patients, not as a toxicity issue. Certainly, mold infection is a recognized cause of morbidity and mortality in transplant patients on immunosuppression, patients on chemotherapy, and those with autoimmunity or immunodeficiency.[2] Few health care providers are aware of the toxic effects of mold on their patients. As more health care providers gain experience in recognizing mold-related illness, emerging research is showing promise for identifying mold toxin exposure as an underlying contributor to many illnesses.

Research estimates that up to 50% of residential and work environments in North America have had water damage[3] and that mold exposure should be considered in all patients with any chronic respiratory condition. Of particular significance is the finding that in adult-onset asthma, two thirds of cases are caused by exposure to water-damaged buildings. The relationship of indoor mold exposure from water-damaged buildings to other health conditions has less research available. Mold exposure has been linked to neurotoxicity, autoimmunity, immunotoxicity, and cytotoxicity. The carcinogenic effects of food-borne mold contamination are well established.

Research supports that environmental toxins drive disease in the general population, not just those who are genetically or nutritionally the most susceptible. Mycotoxins and mVOCs are joining the categories of pesticides, metals, solvents, and persistent organic pollutants in affecting health and longevity.

Positions of National and International Organizations on Mold and Nonrespiratory Conditions

World Health Organization

- "Microbial growth may result in greater numbers of spores, cell fragments, allergens, mycotoxins, endotoxins, β-glucans and volatile organic compounds in indoor air. The causative agents of adverse health effects have not been identified conclusively, but **an excess level of any of these agents in the indoor environment is a potential health hazard."**[3]
- Mycotoxins, or fungal toxins, are low-relative-molecular-mass biomolecules produced by fungi, some of which are toxic to animals and human beings. Mycotoxins are known to interfere with RNA synthesis and may cause DNA damage. Some fungal species may produce various mycotoxins, depending on the substrate. In the case of *Penicillium,* one such compound is penicillin, a strong antibiotic. Several mycotoxins (e.g., aflatoxin from *Aspergillus flavus* and *Aspergillus parasiticus*) are potent carcinogens. Many mycotoxins are immunotoxic, but the trichothecene mycotoxins are immunostimulating at low doses.[4] Numerous mycotoxins have been classified by their distinct chemical structures and reactive functional groups, including primary and secondary amines, hydroxyl or phenolic groups, lactams, carboxylic acids, and amides. The mycotoxins that have perhaps received the most attention are the trichothecenes, produced by *Stachybotrys chartarum.* Bloom[5] showed that several mycotoxins produced by *S. chartarum* and *Aspergillus versicolor* (i.e., macrocyclic trichothecenes, trichodermin, sterigmatocystin, and satratoxin G) could be present in most samples of materials and settled dust from buildings with current or past damage from dampness or water damage. Charpin-Kadouch[6] compared the levels of macrocyclic trichothecenes in samples from 15 flooded dwellings known to be contaminated with *S. chartarum* or *Chaetomium* and a group of nine dwellings without visible mold. The level of macrocyclic trichothecenes was significantly higher in floor dust from the moldy houses than from the reference dwellings; the levels in wall samples from moldy houses were also higher.

Centers for Disease Control and Prevention[7]

- A link between other adverse health effects, such as acute idiopathic pulmonary hemorrhage among infants, memory loss, or lethargy, and molds, including the mold *S. chartarum (Stachybotrys atra),* has not been proven. Further studies are needed to find out what causes acute idiopathic hemorrhage and other adverse health effects.
- Standards for judging what is an acceptable, tolerable, or normal quantity of mold have not been established.
- In summary, *S. chartarum (S. atra)* and other molds may cause health symptoms that are nonspecific. At present, there is no test that proves an association between *S. chartarum (S. atra)* and particular health symptoms. Individuals with persistent symptoms should see their physician. However, if *S. chartarum (S. atra)* or other molds are found in a building, prudent practice recommends that they be removed.

U.S. Environmental Protection Agency

The U.S. Environmental Protection Agency (EPA) website has extensive resources to address identifying, preventing, and remediating water damage and mold, plus guidelines for schools. However, at the time of this writing, the medical content has not been updated since 2004.

Water-Damaged Buildings

Water-damaged buildings expose their occupants to a diverse range of toxins, with many physiologically damaging effects. Chemical, microbial, and physical processes that break down building materials produce toxins. Tables 24.1 and 24.2 list the metabolite toxins released, organisms involved, physiological effects induced, and disease associations. Tables 24.3 and 24.4 shows that bacterial growth also releases toxins in water-damaged buildings.

The strongest correlations to mold exposure and symptoms are neurological and immunological, but such exposure can affect all systems of the body. Food-borne mycotoxins have been shown to cause cancer, impaired child growth, neural tube defects, immunotoxicity, gastroenteritis, and renal disease.[8] Studies comparing mycotoxins with pesticides show that mycotoxins can be more toxic than pesticides.[9] Even more concerning is the research showing that fungal metabolites have synergistic genotoxic and other harmful effects.[10]

mVOCs are low-molecular-weight compounds and include numerous alcohols, esters, ethers, ketones, aldehydes, terpenoids, thiols, and their derivatives. They diffuse into the air and enter the body through the lungs and skin. mVOCs are even more toxic than the chemicals traditionally thought of as being industrial toxins. A study comparing fungal VOCs showed a greater toxic effect than formaldehyde, xylene, benzene, and toluene.[11] I-octen-3-ol studies predict it to be more toxic to human embryonic stems cells than toluene.[12] Increased levels of biomarkers such as myeloperoxidase, lysozyme, and eosinophil cationic protein are related to symptoms of headache, nausea, and mucosal irritation as inflammation increases from exposures.

Neurotoxicity is clearly associated with mold exposure and other toxin exposures. One study evaluated neurobehavioral and pulmonary

TABLE 24.1 Toxic Metabolites Produced by Bacteria Isolated From Water-Damaged Materials and Indoor Air

Metabolite	Organisms	Physiological Effects	Disease
Valinomycin	*Streptomyces griseus*	Mitochondrial poison	Unknown
Leptomycin B	*Streptomyces species*	Inhibition of inducible nitric oxide synthetase	Unknown
Toxic peptide	*Bacillus amyloliquefaciens*	Depolarized transmembrane. Decreased ATP and NADH cell death	Unknown
Mitochondrial toxin	*Bacillus pumilus*	Disruption of mitochondrial membrane	Unknown
Mitochondrial toxin	*Nocardiopsis species*	Disruption of mitochondrial membrane	Unknown
Cytostatic compounds	*Coculture of S. chartarum and S. californicus*	Cytotoxic compounds that are just as toxic as doxorubicin and AMD	Unknown

AMD, actinomycin D; *ATP*, adenosine triphosphate; *NADH*, nicotinamide adenine dinucleotide.
Adapted from Thrasher JD, Crawley S. The biocontaminants and complexity of damp indoor spaces: more than what meets the eyes. *Toxicol Ind Health*. 2009;(9-10):583-615

TABLE 24.2 Mycotoxins Produced by Toxic Molds

Metabolite	Organisms	Physiological Effects	Disease
Gliotoxin	*Aspergillus fumigatus, terres, flavus, niger; Trichoderma virens; Penicillium* spp.; *Candia albicans*	Immune toxicity, immunosuppression, neurotoxicity	Invasive aspergillosis
Aflatoxin B1, kojic acid, aspergillic acid, nitropropionic acid	*Aspergillus flavus*	Liver pathology and cancer; immune toxicity; neurotoxicity	Carcinogenesis
Fumigaclavines, fumitoxins, fumitermorgens, verruculogen, gliotoxin	*A. fumigatus*	Lung disease; neurotoxicity; tremors; immune toxicity	Aspergillosis
Ochratoxin A		Immunosuppression	Balkan endemic nephropathy (BEN)
Urinary tract tumors	*A. niger*		BEN
Aspergillosis	*Penicillium verrucsom*	Lung disease	
Ochratoxin A	*Aspergillus ochraceus*	Nephropathology	Urinary tract damage
Penicillic acid, xanthomegnin, viomellein, vioxanthin			Tumors
Sterigmatocystin, 5-methoxy-sterigmatocystin	*Aspergillus versicolor*	Liver pathology and cancer	Carcinogenesis
Chaetomiums	*Chaetomium globosum*	Cytotoxicity	Unknown
Chaetoglobosum A and C		Cell division	Unknown
Griseofulvin	*Memnoniella echinata*	Carcinogenesis?	Unknown
Dechlorogrseofulvins			Reproductive toxin
Trichodermin			Hypersensitivity?
Trichodermo		Protein synthesis inhibition	
Mycophenolic acid	*Penicillium brevicompactum*	Cytotoxic; mutagen	Unknown
Botryodiploidin	*Penicillium expansum*	Immune toxicity; cytotoxic	Unknown
Patulin, citrinin, chaetoglobosin, roquefortine C			Tremors
Verrucosidins	*Penicillium plonicium*	Cytotoxicity	Tremors
Penicillic acid, nephrotoxic glycopeptides			Nephropathology
Trichothecenes	*Trichoderma* spp.	Trichothecene toxicity	Unknown
Trichodermol, trichodermin, gliotoxin, viridin		Immunotoxicity	Immune impairment
Fumonisins	*Fusarium verticillioides (aka moniliforme)*	Neural tube defects in animals and humans	Central nervous system (CNS) birth defects
Spirocyclic	*Stachybotrys chartarum*	Respiratory bleeding	Pulmonary bleeding
Drimanes, roridin		Protein synthesis inhibition	
Satratoxins (F, G, H)		Neurotoxicity	
Hydroxyroridin E		Cytotoxicity	
Verrucarin J, trichodermin, dolabellanes, altrones B and C, stachybotrylactams		Immune toxicity	

Table 24.2 demonstrates that mycotoxins disrupt mitochondrial function; misbalance nitric oxide synthesis; and create inflammatory mediators, neurotoxicity, cytotoxicity, immune suppression, carcinogenesis, and mutagenesis. This long list can cause patients' symptoms to be diverse and complex.

Adapted from Campbell AW, Thrasher JD, Gray MR, Vojdani A. Mold and mycotoxins: effects on the neurological and immune systems in humans. *Adv Appl Microbiol.* 2004;55:375–406; Pizzorno J, Shippy A. Is mold toxicity really a problem for our patients? part 2-nonrespiratory conditions. *Integr Med (Encinitas).* 2016 Jun;15:8-14.

impairment via comparison among three groups: (1) those exposed to indoor molds, (2) those exposed to chemicals, and (3) "unexposed" community referents.[13] Both the mold- and chemical-exposed groups had similar findings of decreased balance, longer reaction times, increased blink reflex latency, increased color discrimination errors, decreased visual field, and reduced grip strength; measures of cognitive and memory performance were abnormal.

Another study of individuals exposed to mold in their homes found multiple neurological deficits in 70% and abnormalities in T and B cells in more than 80% of the patients.[14] A study of individuals working in a well-documented water-damaged school building compared with "unexposed" controls found statistically significant loss of visual contrast sensitivity (VCS), a sensitive measure of neurodysfunction, as well as increased respiratory problems.[15]

Exposure to mold/damp buildings increases the production of multiple inflammatory molecules and alters immune function mediators. The immune systems of those working in damp buildings react to exposure with a 2- to 1000-fold increased production of a wide variety of these inflammatory/immune mediators.[16] Animal studies clearly show mold-induced immunotoxicity as well.

In some cases, multiple sclerosis could be a mold toxin disease from gliotoxin produced by various species of *Aspergillus* and *Candida.* Gliotoxin suppresses immune function, increases the permeability of the blood–brain barrier, and is highly neurotoxic.[17]

In a study on chronic fatigue syndrome (CFS), a high correlation was found between the presence of mycotoxins in the patient's urine and having a diagnosis of CFS. Of participants, 93% had one mycotoxin present, and 30% had two or more mycotoxins present.[18]

Importantly, as the incidence of autoimmune disorders increases, cases of autoimmune diseases and related symptoms have been reported among the occupants of damp buildings.[19] When seeing patients with autoimmune diagnosis, it is important to consider mold exposure as an underlying trigger that is potentially treatable.

ASSESSMENT OF MOLD EXPOSURE

IgG or IgE Allergy Serum Testing

IgG or IgE allergy serum testing is an older method, but is sometimes helpful in raising the suspicion of current mold exposure. Some practitioners also use it to see if IgE and/or IgG levels are reduced with treatment, to evaluate the effectiveness of remediation/avoidance of exposure, and to consider immunotherapy. It is not conclusive, but levels of antibodies can correlate with the types and levels of mold the patient is being exposed to.

Mycotoxin Urinary Levels

The latest acceptable technology tests urine samples. Results are not conclusive if negative because all mycotoxins cannot yet be tested for. See the advantages and disadvantages of the two available technologies in Table 24.5.

Inflammatory Markers and Hormones

Inflammatory markers and hormones can be indicators for toxic exposures but are not conclusive if positive or negative. They can be helpful in monitoring a patient's progress. These markers are part of the Shoemaker protocol.

Proteomics

Proteomic has promise in the assessment of mold exposure, but currently this approach is used only in research and is expensive.

Genetics

Genetic testing can be helpful to establish individual treatment programs. Consider human leukocyte antigen (HLA) type, methylation, P450, *COMT*, glutathione, *NAT*, *VDR*, and mitochondrial and histamine single-nucleotide polymorphisms (SNPs). Toxins affect individuals in different ways depending on their genetics, synergistic toxins present, and nutritional status. Early genetic testing can help identify those most susceptible to mold toxins and other environmental toxins.

Visual Contrast Sensitivity Testing

Visual contrast sensitivity (VCS) measures the ability to see details at low contrast levels. Although it is useful for early detection of neurodegeneration, it does not differentiate the cause. Biotoxins reduce available oxygen to the optic nerves as a result of reduced blood flow, which can affect the ability to detect the "edge" between light and dark and lead to a reduction in night vision and increased light sensitivity.

This is an easily available and inexpensive test. However, it is a nonspecific test of neurological function (i.e., not diagnostic for mycotoxin illness). A positive test may reveal a 92% chance that a patient has biotoxin illness, but again, it does not determine which toxin—it could be mold toxins or an environmental neurotoxin, such as mercury. Positive tests usually indicate mold exposure but can also be attributed to Lyme disease or other biotoxins.

Testing needs to be conducted at a distance of 18 inches from the screen and should be done in the daytime.

False positives can occur with cataracts or other vision abnormalities

Laboratory Testing Technology

Testing for the mycotoxin load present in humans via sampling tissue and body fluids is still very limited. There are likely hundreds of mycotoxins, possibly even an order of magnitude more, but only a few can be commercially tested for in human samples or the environment, except in research laboratories.

Qualitative polymerase chain reaction (QPCR) can now be used to detect and quantify the presence of 45 molds in human tissue and the environment.

TABLE 24.4 Health Hazard Evaluation Report HETA 2005-0135-3116, Alcee Fortier Senior High School New Orleans, Louisiana, September 2010, Department of Health and Human Services, Centers for Disease Control and Prevention, Workplace Safety and Health, National Institute for Occupational Safety and Health

	AFSHS	WHHS	Prevalence Ratio	*p*-Value

Rash, dermatitis, or eczema (on face, neck, arms, or hands)	12 (14)	4 (4)	3.70 (1.24, 11.06)	0.01

Enzyme-Linked Immunosorbent Assay

An enzyme-linked immunosorbent assay (ELISA) is currently available through Real Time Labs (RTL).

- What it tests for: 16 of the most common mycotoxins, especially for *Macrocyclic trichothecenes* (most toxic trichothecenes), for which the laboratory has a U.S. patent
  - Ochratoxin A
  - Aflatoxins (B1, B2, G1, G2)
  - Trichothecenes (satratoxin G, satratoxin H, isosatratoxin F, rodirin A, rodirin E, rodirin H, rodirin L-2, verrucarin A, verrucarin J)
  - Gliotoxin
  - Chaetoglobosin A
- What these mycotoxins correspond to regarding mold presence:
  - Aflatoxin = *Aspergillus flavus*
  - Ochratoxin A = *Aspergillus ochraceus, Aspergillus niger, Penicillium verrucosum*
  - Gliotoxin = *Aspergillus fumigatus,* possibly
  - Macrocyclic trichothecenes = *S. chartarum*
  - Simple trichothecenes = *Fusarium* species
  - Chaetoglobosin = *Chaetomium*
- What it misses: More than 50,000 different species of mold are not test for; only 200 are currently documented to cause serious health risks to humans or animals.
- Methods: College of American Pathologists (CAP) certified, Clinical Laboratory Improvement Amendments (CLIA) accredited; ELISA (antibodies prepared against mycotoxins); very sensitive test (can detect traces of mycotoxins in the ng/mL [= ppb])
  - Urine-based (blood test not validated in blood components, per RTL): turnaround is 10 days after receiving the sample.
  - Options are available to test for mycotoxins in the sputum, bronchoalveolar lavage (BAL), nasal wash, and tissue sample (requires consulting with medical team at RTL to discuss preparation).
  - Is there a test for food-based mycotoxins? Per RTL, it is "unlikely" that aflatoxin- or ochratoxin-positive urine correlates to food-based mycotoxins.
- Troubleshooting: If the test result is negative but the patient is very sick, it can indicate that the individual has poor detoxification and isn't able to remove/liberate mycotoxins from the body; a positive test does *not* differentiate current exposure from previous exposure.
- Other tests: RTL can test clothing and other things for mycotoxins and also performs Environmental Relative Moldiness index (ERMI) and mycotoxin testing from environmental samples; it can also test sinuses for mold (molecular fungal DNA panel).

Mass Spectrometry

Mass spectrometry testing is currently available through Great Plains Labs.

- What it tests for: Seven different mycotoxins from four species of mold, with more on the way
  - Aflatoxin M—main metabolite of aflatoxin B1 (from *Aspergillus*)

TABLE 24.5 Comparison of ELISA and Mass Spectrometry for Mycotoxin Testing

ELISA		MASS SPECTROSCOPY	
Advantages	**Disadvantages**	**Advantages**	**Disadvantage**
Well characterized, well understood Trusted Straightforward to troubleshoot Good sensitivity and selectivity with broad dynamic-range antibody against specific class of analytes	Must have a specific antibody (mono- or polyclonal in nature) Limited range of analytes to be detected	Well characterized, used in drug testing, wide range of analytes can be tested High sensitivity and precision for identification of analytes	Narrow dynamic range of analytes, must have parent compound for comparison to specimen Selectivity of analyte is not as good and as easy to optimize Heavy training of technologist required High cost of equipment and maintenance
Instruments are flexible and scalable, can be manual process or automated	Assays are multistep; lot-to-lot variation in the antibody product must be carefully controlled	Sample volumes are low	
	Reagent usage and antibody cost can be high	Day-to-day reagent costs are low	
Equipment is low cost	Time to complete assay is 1–3 hours Technologist must be well trained on pipetting and washing techniques	Samples can be run and analyzed in minutes	

  - Ochratoxin A (produced from *Aspergillus* and *Penicillium* families)
  - Sterigmatocystin—closely related to aflatoxin (produced from *Aspergillus, Penicillium,* and *Bipolaris*)
  - Roridin E—a macrocyclic trichothecene (from *Fusarium, Myrothecium,* and *Stachybotrys*)
  - Verrucarin A—a macrocyclic trichothecene mycotoxin (from *Stachybotrys, Fusarium,* and *Myrothecium*)
  - Enniatin B1—categorized as cyclohexadepsipeptides (from *Fusarium*)
  - Zearalenone—produced by *Fusarium*
- Methods: Advanced liquid chromatography mass spectrometry (MS/MS); very sensitive (can identify parts per trillion [ppt; vs. ppb in ELISA testing])
  - Urine-based sample
  - History: Released in 2017

TREATMENT

Unfortunately, there are no widely accepted protocols and very limited data on treatment efficacy. Treating environmental illness, including mold, requires a comprehensive approach.

1. Avoidance

The primary pillar of treatment is to minimize additional toxin exposure. Once an individual is symptomatic, he or she may become sicker, or not improve, if he or she is exposed to any other environmental toxins. Make sure that the patient eliminates all of the toxin exposures that he or she can. Guide the patient to avoid new cars, new paint, flame retardants, plastic, pumping gas, cosmetics, pesticide, and preservatives and other contaminants in food and water. Exposure to all toxins must be minimized as much as possible. The first step is to identify the source of the mold. Consider home, work, school, car, farming (silos, hay, and animal feed), and food. It is also possible that the patient is colonized/infected with mold that is producing the toxins. Even the brain has been shown to harbor mold, contributing to Alzheimer's disease.[20]

2. Enhance Detoxification Pathways

Enhancing detoxification pathways, optimizing the gastrointestinal tract, and supporting mitochondrial function are critical for most patients to fully recover. Although there is limited research directly related to mold, treatment options to consider include the following:

- N-acetylcysteine (NAC): NAC reduces the oxidative damage and inhibits the apoptosis induced by *Fusarium* toxins in porcine kidney cells. It is effective through multiple pathways.[21–23]
- Binders: Clay, charcoal, modified citrus pectin, cholestyramine/Welchol[24,25]
- Glycine
- Sauna—infrared if possible[26]
- Hyperbaric: Hyperbaric oxygen treatment improved attention deficit disorder and slowed reaction time in mold-exposed subjects in 10 sessions.[27]
- Liposomal glutathione[28]
- Hormonal support as indicated, including thyroid, estrogen, dehydroepiandrosterone (DHEA), testosterone, and melatonin[29,30]
- Curcumin[31]
- Vitamin E[29,32]
- Quercetin, selenium, glucomannan, nucleotides, antimicrobial peptides, probiotics, polyunsaturated fatty acids, oligosaccharides, and plant extracts: These products inhibit trichothecene-induced oxidative stress by (1) inhibiting reactive oxygen species (ROS) generation and induced DNA damage and lipid peroxidation, (2) increasing antioxidant enzyme activity, (3) blocking the mitogen-activated protein kinase (MAPK) and nuclear factor (NF)-κB signaling pathways, (4) inhibiting caspase activity and apoptosis, (5) protecting mitochondria, and (6) regulating anti-inflammatory actions.[33]

3. Comprehensive, Integrated Care

Integration of genetic SNPs, proteomics, exposomics, and other markers of the cellular function of the immune, detoxification, mitochondrial, and methylation systems may help identify those most affected, as well as identify potential treatment options. In addition, assessing potential nutritional deficiencies and levels of other environmental toxins may help identify those with increased individual susceptibility. Given the complex nature of the interaction between the human genome and environmental toxins, the science of bioinformatics will be necessary to more fully understand the full severity and magnitude of mold exposure and its effects on human health.

CONCLUSION

Mold metabolites have a harmful impact on human health. It is imperative that more research be done to further understand the effects of mold on human health, identify the best ways to test patients and indoor environments, and develop optimal treatment approaches for patients, especially given the common occurrence of water damage in buildings and the presence of mycotoxins in food.

Nonmetallic Toxic Chemical Assessment

William Shaw, PhD

OUTLINE

INTRODUCTION

Nonmetal toxic chemicals cause diseases of virtually every organ in the human body and in virtually all animals, including fish, amphibians, reptiles, birds, and mammals. In addition, such chemicals may alter the microbiome in the soil and water and in the gastrointestinal tracts of animals. Such toxic chemicals come from multiple sources, including the air, water, food, pharmaceuticals, cosmetics, cleaning agents, and prescription and over-the-counter medications. Roughly 13,000 chemicals are used in cosmetics, of which only 10% have been properly evaluated for safety.

Doris Rapp, a physician and pioneer in the field of environmental medicine, reported that in 1998, more than 80,000 different chemicals with a total weight of 1.2 billion pounds were used in the United States.[1] With a population of about 300 million people at the time, that calculates to 4 pounds of chemicals for every person in the nation. Furthermore, less than 10% of the chemicals used have been even partially evaluated for safety, and in the majority of those evaluated, there was no assessment of safety for women and children. Dr. Rapps books *Is This Your Childs World?*[2] and *Our Toxic World*[1] are excellent, comprehensive works on the clinical effects of both metal and nonmetal toxic chemicals.

Furthermore, the vast majority of people today are not exposed to a single chemical but to a wide variety of chemicals. In such cases, the cumulative effects of multiple chemical exposures over long periods of time are much greater than just the additive effects of such chemicals. The Environmental Working Group's study commissioned five laboratories to examine the umbilical cord blood of 10 babies of African American, Hispanic, and Asian heritage and found more than 200 chemicals in each newborn.[3]

Results from the widest-ranging European survey of human toxic contamination show that 76 persistent, bioaccumulative, and toxic industrial chemicals were present in the blood of those tested.[4] The World Wildlife Fund (WWF) and the Co-operative Bank collected and analyzed the blood of 47 people from all over Europe. These included 39 Members of the European Parliament (MEPs),[4] observers from accession countries, 1 former MEP, and 3 WWF staff, representing 17 countries in Europe.[4] Blood samples were analyzed for an unprecedented 101 chemicals from five groups: organochlorine pesticides such as dichlorodiphenyltrichloroethane (DDT), polychlorinated biphenyls (PCBs), brominated flame retardants, phthalates, and perfluorinated compounds (PFCs). A total of 76 different chemicals from the 101 looked for were found in the blood of those tested.

The highest number of chemicals found in one person was 54, and the median number of chemicals detected was 41. At least 13 of the same chemicals were found in every single person tested, including chemicals banned in Europe over 20 years ago as well as chemicals in widespread use today, such as phthalates and PFCs. This huge toxic burden is more fully covered in Chapter 35, Environmental Medicine, and comprehensively in *Clinical Environmental Medicine* (Crinnion and Pizzorno, Elsevier, 2018).

NONMETALLIC TOXIC CHEMICALS, METALLIC TOXIC CHEMICALS, AND TOXIC METALS

The reason for differentiating metal and nonmetal toxic chemicals is that these two groups are analyzed in blood and urine by different technologies. The toxic metals were primarily tested first by atomic absorption and later by induction-coupled plasma mass spectrometry (ICP-MS). The nonmetal toxic chemicals have been tested effectively with gas chromatography, followed by gas chromatography combined with mass spectrometry (GCMS), and then with liquid chromatography combined with mass spectrometry (LC/MS). The main advantage of ICP-MS for toxic metals is that a large number of metals (50 or more) can be tested simultaneously on a single sample, such as blood, urine, stool, or hair, without the use of chromatography. Testing of nonmetal toxic chemicals typically requires much more complex sample extraction and almost always complex chromatography. These differences in the analytical testing of metal and nonmetal toxic chemicals have made the testing of metal toxic chemicals faster and cheaper than the testing of nonmetal toxic chemicals, resulting in much greater research and knowledge regarding metal toxic chemicals compared with nonmetal toxic chemicals. The ease of analytical testing has also led to much more regulation on contamination with toxic metals compared with nonmetal toxic chemicals.

Until very recently, screening tests for a wide variety of toxic chemicals were only available by the clinician ordering a few tests at a time from large reference laboratories. Because most individuals had no idea what chemicals they were exposed to, it was prohibitively expensive to order a large number of chemical tests. Recently, however, tests for a large variety of toxic chemicals have become available.

COMMON TOXIC CHEMICALS AND DISEASE

Some of the most common diseases associated with toxic chemical exposure include diabetes; impaired fertility; developmental disorders, such as attention deficit disorder and autism; psychiatric disorders; autoimmune diseases; neurotoxicity, including psychiatric disorders; and cancer.[1] Because many toxic chemicals affect the function of mitochondria, fatigue and exercise intolerance may be common in toxic exposures.[5] The marked decline in sperm counts and testosterone in males over the past few decades poses an existential threat to the human race and even to all life on Earth.[1] Excessive toxic chemical exposure should be ruled out as a cause of virtually any chronic disease. Some have discounted this toxic load with remarks such as: Oh well, why should I worry about toxic chemical exposure if everyone has it?

Although many people frequently have no detectable amount of specific toxic chemicals, every single person tested in the Great Plains Laboratory (GPL) had some detectable chemicals in their urine samples. The most important factor for toxic chemical tests is *not* whether there are detectable amounts, but if there are *high* amounts compared with a normal population or if their level exceeds the threshold found to be associated with increased disease risk.

Very high concentrations of toxic chemicals, such as those above the 95th percentiles of the entire population and especially values that are multiples of the 95th percentiles, are usually associated with severe health impairment. Those with multiple exposures are at even greater risk. Some of the highest toxic chemical values found at GPL have been in young children with autism. People who think they have healthy lifestyles and who consume organic food are often shocked at the amounts of chemicals found in their urine samples. For example, one of these individuals found her urine perchlorate value was more than 50 times the 95th percentile value for perchlorate. Organic farms frequently have nonorganic farms or golf courses as neighbors. When the golf course or nonorganic farm is sprayed, the chemicals used can travel many miles on a windy day or even evaporate and become a part of the next rainfall. One of the best sources of reference ranges is those from the US Centers for Disease Control and Prevention (CDC) National Health and Nutrition Examination Survey (NHANES).[6] (Parenthetically, this NHANES group was the author's first employer after earning his PhD degree in biochemistry.)

The NHANES study is one of the best data sources for toxic chemical data because it selects the population to be evaluated using highly sophisticated statistical techniques that evaluate virtually all people of both sexes in the United States of every age, race, and geographical region. The survey is unique in that it combines interviews and physical examinations of the subjects tested. The survey uses top-notch analytical methods, employing mass spectrometry in most cases. The statistical analysis of the data is also top notch, and the number of subjects is quite large, ranging from 1000 to 2000. Fig. 25.1 shows an example of the NHANES data for dimethylphosphate, a major metabolite of many different organophosphate pesticides. The NHANES reports have similar data for hundreds of environmental chemicals. Urine data are always reported with creatinine corrections, allowing for comparisons of data from individuals with differing fluid intakes. The statistical analyses of the data are performed by the National Center for Health Statistics (NCHS). Some of the most important toxic chemicals are those used in agriculture as pesticides, primarily as insecticides and herbicides that kill weeds, which are considered to be any plants that grow where humans do not want them growing.

Toxic chemicals may affect every organ in the body, but some of the toxic chemicals of greatest concern are those that affect the brain and nervous system, those that affect reproduction and fertility by mutagenesis or other mechanisms, and those that affect the development of children. In addition to chemicals that harm the human body directly, some chemicals may cause harm by altering the microbiome of the soil and the intestinal tracts of both humans and animals.

INDICATIONS FOR TOXIC CHEMICAL TESTING

Toxic chemical testing should be used whenever the patient has an occupational exposure to chemicals used in the workplace, such as the following:

- Pesticide applicators or agricultural workers exposed to glyphosate, organophosphate pesticides, 2,4-dichlorophenoxyacetic acid (2,4-D), or pyrethroid pesticides
- Workers in plastics factories using phthalates or vinyl chloride
- Workers in any type of industrial factories in which volatile solvents such as benzene, xylene, butadiene, propylene oxide, ethylene oxide, acrylonitrile, bromopropane, and others are regularly used
- Patients who have been treated with intravenous solutions from plastic bags or administered through plastic intravenous tubing, and may currently be contaminated with phthalates or vinyl chloride
- Workers in furniture, upholstery, and drapery industries using a variety of flame retardants, many of which are highly toxic
- Individuals who commonly employ paints, stains, or varnishes in their employment (including individuals using these chemicals occasionally, such as repainting the inside of the house, who may sometimes have symptoms such as severe fatigue)
- Individuals involved in dry cleaning or cleaning of industrial or military equipment
- Firefighters, police officers, and other rescue workers exposed to a wide variety of chemicals in general disasters such as the 9/11 terrorist attacks or other large fires
- Pilots, flight attendants, and even passengers because they can be exposed to jet engine exhaust and/or chemicals used to disinfect conduits that are circulated through the air system of the plane
- Physicians, nurses, other medical personnel, and restaurant workers who frequently wash their hands using toxic antibacterial hand soaps containing hexachlorophene, para-chloro-metaxylenol (PCMX), triclosan, and triclocarban
- Workers like police officers or car and airplane mechanics who may be exposed to vehicle exhaust fumes

The list of conditions for which toxic chemicals should be tested for people who do not obviously have occupation exposures includes the following:

- Patients with any illness that is life-threatening or severely debilitating, such as cancer, multiple sclerosis, autism, attention deficit disorder, Alzheimer's disease, and many others
- Patients with chronic illnesses that are not severely debilitating or life-threatening but are significantly reducing quality of life, such as arthritis, fatigue, and others
- Patients (both men and women) with impaired fertility
- Children with birth defects or failure to reach developmental milestones
- Women and men who want to reduce their chances of having a baby with a significant disease
- Any individual who wants to optimize his or her health and fitness

A list of toxic chemicals that are commonly found in human urine samples is given in Table 25.1. Note that some of the chemicals tested are common metabolites of more than one parent toxic chemical.

An entire book (such as *Clinical Environmental Medicine*) is needed to cover even most of the chemicals in Table 25.1 and the other chemicals[7-39] that are usually tested in the blood. A few summaries of the use and toxicity of some of the most commonly used major toxic chemicals follow.

Urinary *para*-Nitrophenol (1999-2010)

Metabolite of Ethyl Parathion, Methyl Parathion, and Nitrobenzene

Geometric mean and selected percentiles of urine concentrations (in µg/L) for the U.S. population from the National Health and Nutrition Examination Survey.

	09-10	**.440** (.388-.499)	**.490** (.410-.580)	**1.03** (.930-1.12)	**2.18** (1.89-2.48)	**3.14** (2.67-3.62)	1197

Limit of detection (LOD, see Data Analysis section) for Survey years 99-00, 01-02, 07-08, and 09-10 are 0.8, 0.1, 0.1, and 0.1 respectively.
< LOD means less than the limit of detection, which may vary for some chemicals by year and by individual sample.
* Not calculated: proportion of results below limit of detection was too high to provide a valid result.

Biomonitoring Summary: http://www.cdc.gov/biomonitoring/Nitrobenzene_BiomonitoringSummary.html

Fig. 25.1 Representative table from the Centers for Disease Control and Prevention (CDC) National Health and Examination Survey (NHANES) publication *Fourth National Report on Human Exposure to Environmental Chemicals* (February 2015, p. 128). The survey covers a number of years so that the reader or researcher can determine trends in the exposure of the population. Thus the values for the 75th, 90th, and 99th percentile appear to be steadily increasing over the last 10 years (1999-2008) of the survey, indicating greater toxic exposure to the population. This trend is apparent in all age groups. (From Centers for Disease Control and Prevention. Fourth National Report on Human Exposure to Environmental Chemicals. February 2015. https://www.cdc.gov/biomonitoring/pdf/FourthReport_UpdatedTables_Feb2015.pdf.)

TABLE 25.1 Common Metabolites of Toxic Chemicals Tested in Urine

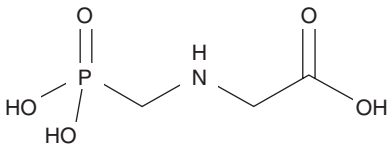
Parent Toxic Chemical	Metabolite Commonly Tested in Urine	Brief Summary of Toxicity
Xylene[32]	2-Methylhippuric acid (2MHA) 3-Methylhippuric acid (3MHA) 4-Methylhippuric acid (4MHA)	These are metabolites of xylenes, solvents found in paints, lacquers, cleaning agents, pesticides, and gasoline. Exposure to xylenes generates methylhippuric acid isomers. Avoid/reduce exposure to these substances.
Benzene[33]	N-Acetyl phenyl cysteine (NAP)	NAP is a metabolite of benzene. Benzene is a solvent that is widespread in the environment. It is found in cigarette smoke and gasoline and is a by-product of all types of combustion, including motor vehicle exhaust. Treatment consists of removing sources of exposure.
Styrene/ethylbenzene[32]	Phenylglyoxylic acid (PGO)	Exposure to environmental or workplace styrene may increase phenylglyoxylic and mandelic acid. Reduce exposure by eliminating the use of plastic and Styrofoam containers for cooking, reheating, eating, or drinking. Elimination of styrene can be accelerated by supplementing with glutathione and N-acetyl cysteine (NAC).
MTBE/ETBE[34]	2-Hydroxyisobutyric acid (2HIB)	2-HIB is formed endogenously as a product of branched-chain amino acid degradation and ketogenesis. This compound is also the major metabolite of gasoline octane enhancers such as MTBE and ETBE. Elevated levels indicate environmental exposure. Use of purified water is useful if local water is contaminated.
Diethylphthalates[35]	Monoethyl phthalate (MEP)	MEP from diethyl phthalate is the most abundant phthalate metabolite found in urine. Diethyl phthalate is used in plastic products. Elevated values indicate exposure from various possible sources. Elimination of phthalates may be accelerated by sauna treatment.
Organophosphates[36]	Dimethylphosphate (DMP) Diethylphosphate (DEP)	DMP and DEP are major metabolites of 147 organophosphate pesticides. Reduce exposure by eating organic foods and avoiding the use of pesticides in your home or garden. Living near agricultural areas or golf courses and areas regularly sprayed with pesticides will increase exposure. Elimination of organophosphates can be accelerated by sauna treatment.
Pyrethroids[37]	3-Phenoxybenzoic acid (3PBA)	3-PBA is a metabolite of six different pyrethroid insecticides. Elimination can be accelerated by sauna treatment.
2,4-Dichlorophenoxyacetic acid (2,4-D)[38]	Parent measured	2,4-D was an ingredient in Agent Orange and is most commonly used in agriculture of genetically modified foods and as a weed killer for lawns. Reduce exposure by eating organic foods and avoiding the use of pesticides in your home or garden.
Mitochondrial dysfunction marker	Tiglylglycine (TG)[39]	TG is a marker for mitochondrial dysfunction. Mutations of mitochondrial DNA may result from exposure to toxic chemicals, infections, inflammation, and nutritional deficiencies.
Acrylamide[79]	N-acetyl-S-(2-carbamoylethyl)-cysteine (NAE)	NAE is a metabolite of acrylamide, which is detoxified through a two-step process. First, acrylamide is metabolized by the cytochrome P450s. Second, it is conjugated to glutathione to make it more water soluble. Acrylamide is used in many industrial processes, such as plastics, food packaging, cosmetics, nail polish, dyes, and treatment of drinking water. High levels of acrylamide can elevate a patient's risk of cancer and cause neurological damage. Supplementation with glutathione can assist in the elimination of this compound.
Diphenyl phosphate[13-16]	Diphenyl phosphate	This is a metabolite of the organophosphate flame retardant triphenyl phosphate (TPHP), which is used in plastics, electronic equipment, nail polish, and resins. TPHP can cause endocrine disruption. Studies have also linked TPHP to reproductive and developmental problems.
Perchlorate[17-19]	Perchlorate	Perchlorate is used in the production of rocket fuel, missiles, fireworks, flares, explosives, fertilizers, and bleach. Studies show that perchlorate is often found to contaminate water supplies and food sources. It can disrupt the thyroid's ability to produce hormones. The US Environmental Protection Agency has also labeled perchlorate a likely human carcinogen. Patients who are high in perchlorate can use a reverse-osmosis water treatment system to remove perchlorate.
1,3 Butadiene[20-23]	N-Acetyl (3,4-dihydroxybutyl) cysteine (NABD)	NABD is a metabolite of 1,3 butadiene, which is evidence of exposure to synthetic rubber, such as tires. 1,3 butadiene is a known carcinogen and has been linked to increased risk of cardiovascular disease. Individuals who come into contact with rubber, such as car tires, could absorb 1,3 butadiene through the skin.
Propylene oxide[24-25]	N-Acetyl (2,hydroxypropl) cysteine (NAHP)	NAHP is a metabolite of propylene oxide, which is used in the production of plastics and as a fumigant. It is also used in the preparation of lubricants, surfactants, and oil demulsifiers and as a food additive, an herbicide, a microbicide, an insecticide, a fungicide, and a miticide. Propylene oxide is a probable human carcinogen.
1-Bromopropane[26-28]	N-Acetyl (propyl) cysteine (NAPR)	NAPR is a metabolite of 1-bromopropane. Chronic exposure can lead to decreased cognitive function and impairment of the central nervous system. Acute exposure can lead to headaches.

TABLE 25.1 Common Metabolites of Toxic Chemicals Tested in Urine—cont'd

Parent Toxic Chemical	Metabolite Commonly Tested in Urine	Brief Summary of Toxicity
Ethylene oxide[29-31] Vinyl chloride Halopropane	2-Hydroxyethyl mercapturic acid (HEMA)	HEMA is a metabolite of ethylene oxide, which is used in the production of agrochemicals, detergents, pharmaceuticals, and personal care products. Chronic exposure to ethylene oxide has been determined to be mutagenic to humans. HEMA is also a metabolite of vinyl chloride and halopropane, which are used in many commercial chemical processes, such as foam gluing, dry cleaning, and in the production of solvents. Supplementation with glutathione should assist in the detoxification process of these chemicals.
Acrylonitrile[10-12]	N-Acetyl (2-cyanoethyl) cysteine (NACE)	NACE is a metabolite of acrylonitrile, which is used in the production of acrylic fibers, resins, and rubber. Acrylonitrile is metabolized by the cytochrome P450s and then conjugated to glutathione. Supplementation with glutathione should assist in the detoxification of acrylonitrile.

THE MOST COMMON TOXIC CHEMICALS

Glyphosate



Glyphosate is one of the most prevalent chemicals used in agriculture. Some countries use glyphosate in greater amounts than all other agricultural chemicals combined. Monsanto brought it to market in 1974 under the trade name **Roundup**, and Monsanto's last commercially relevant US patent expired in 2000.[40] Many companies now produce the herbicide. By 2016 there was a 100-fold increase from the late 1970s in the frequency of application and volume of glyphosate-based herbicides applied, with further increases expected in the future, partly in response to the global emergence and spread of glyphosate-resistant weeds.[40]

The amount of glyphosate used as a weed killer or herbicide proliferated with the development of genetically modified foods that were genetically modified to be resistant to the plant-killing action of glyphosate. The availability of genetically modified food plants that were patented by Monsanto was a major factor in the tremendous increase in glyphosate use. Corn and soy seeds were the first crops to be marketed as Roundup Ready. Current glyphosate-resistant crops include soy, corn, canola, alfalfa, sugar beets, and cotton, with wheat still under development. In 2015, 89% of corn, 94% of soybeans, and 89% of cotton produced in the United States were genetically modified to be glyphosate-tolerant.[40]

In addition to the use of glyphosate on genetically modified crops, glyphosate is also applied to many nongenetically modified crops as a desiccant in the process called preharvest **crop desiccation**, referring to the application of an herbicide to a crop shortly before harvest. As a systemic herbicide, glyphosate is not a true desiccant because it can take weeks rather than days for the crop to die back after application.[41] Nongenetically modified foods with which glyphosate has been used as a desiccant include wheat, barley, oats, sunflowers, potatoes, lentils, garbanzo beans, and many others.[42] In addition, glyphosate is also used as a desiccant for nonfood crops such as cotton and tobacco.[43] The shikimic acid pathway of weeds and common nongenetically modified (non-GMO) food plants produces aromatic amino acids needed for plant growth; glyphosate inhibits a key enzyme in this pathway, leading to the death of the weed or non-GMO plant. The DNA of GMO corn, soy, and other food plants is modified so that it is relatively resistant to glyphosate. The makers of glyphosate claim that the toxicity of glyphosate is negligible because humans and other mammals lack the shikimic acid pathway, but research to disprove the toxic effects of glyphosate on many other biological processes is missing.

The human safety of glyphosate has been seriously questioned by a broad group of 14 health experts who are predominantly professors in institutions of environmental health or medical schools or are other environmental professionals.[44]

Starting in the mid-1990s, a chronic kidney disease of unknown etiology (CKDu) was discovered among the rice paddy farmers in the North Central Province of Sri Lanka.[45] Individuals with this kidney disease have substantially higher amounts of glyphosate in their urine than individuals without kidney disease. The government of Sri Lanka subsequently banned the use of glyphosate in that country.

In the following two decades, the disease spread rapidly to other farming areas. The age-standardized prevalence of the disease is estimated at 15%,[45] affecting a total population of 400,000 patients, with an estimated death toll of approximately 20,000 in the period[45] The unique feature of CKDu is that its etiology does not include commonly known risk factors for CKD, such as diabetes mellitus, hypertension, or glomerular nephritis.[45]

A similar incidence of deaths due to CKDu in sugar cane workers has been reported in Central America.[45] In those cases, it is suspected that toxic chemicals such as arsenic may form chelation complexes with glyphosate that prolong the persistence of glyphosate in the soil and water and that may also lead to contamination of humans who drink water containing such metal chelates. Such chelates of glyphosate prolong the life of glyphosate in the environment to as long as 22 years.

Although glyphosate was designed to kill weeds, it also kills susceptible bacteria that have biochemical pathways similar to plants and weeds. Shehata et al.[46] found that glyphosate exposure in poultry can lead to a marked increase in pathogenic bacteria, such as *Salmonella* and *Clostridia* species, that were resistant to glyphosate in the stool samples of the poultry and to a significant decrease in beneficial flora, such as *Enterococcus faecalis, Enterococcus faecium, Bacillus badius, Bifidobacterium adolescentis,* and *Lactobacillus* species, which are susceptible to glyphosate.

In addition, ingestion of the herbicide could be a significant predisposing factor that has been associated with an increase in diseases mediated by *Clostridium botulinum*[47,48] in cattle, and perhaps even in the farmers exposed to infected cattle.[49] *C. botulinum* is one of three species of *Clostridia* bacteria that produce large quantities of the precursors of 3-[3-hydroxyphenyl]-3- hydroxypropionic acid (HPHPA), a phenolic compound.[50] This compound inhibits the enzyme dopamine–β-hydroxylase that converts dopamine to norepinephrine in neurons in

the brain and in the sympathetic nervous system.[50] Excessive amounts of the dopamine metabolite homovanillic acid have been found to be prevalent in urine samples from children with autism.[45]

Shaw reported[45] on a case study of triplets exposed to high amounts of glyphosate due to excessive ingestion of GMO corn tortillas. Two of the children had autism, and the third had a suspected seizure disorder. All of the children had high biochemical markers indicating mitochondrial damage. All three children had markedly elevated urinary glyphosate, with their mean baseline value—34.4 µg/g creatinine—being 25.5 times the median value of 1.35 µg/g creatinine and 24.1 times the mean value of 1.43 µg/g creatinine of the study's internal reference range. The glyphosate value in the urine of one of the retested triplets decreased dramatically (94% decrease) after switching to an organic food diet, and symptoms of autism declined considerably after organic diet implementation.

The female of the triplets did not have elevated phenolic compounds on either organic acid test but did have a significantly elevated value of the metabolite tiglylglycine, a marker for mitochondria complex 1 dysfunction or mutations in the mitochondrial electron transport chain.[45] In addition, the triplets mother also had significantly elevated tiglylglycine.

All of the triplets had elevated succinic acid in their urine, an indicator of mitochondrial dysfunction (see Chapter 29, Urinary Organic Acids),[45] on at least one of the two organic acids tests performed on these patients. Both males had elevated succinic acid on one of the two samples, whereas the female had elevated values on both organic acid tests.

Succinic acid is metabolized by the enzyme succinic dehydrogenase, which is significant in that it is both a Krebs cycle enzyme and a component—complex 2—of the mitochondrial electron transport chain, making this metabolite a marker of mitochondrial complex 2 dysfunction. Succinic acid has been found to be a sensitive marker for a variety of other toxic chemicals as well, including both metal and nonmetal toxic chemicals.

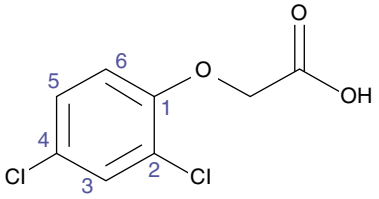
In addition to elevated markers associated with mitochondria damage, the high quantity of phenolic compounds produced by *Clostridia* bacteria in the two male members of the triplets is consistent with the previous reports that glyphosate can alter the intestinal flora of exposed animals and humans. Both males with the elevated *Clostridia* markers had depressed conversion of dopamine to norepinephrine, **leading to overproduction of dopamine, a feature prevalent in autism**.[45] The pH of certain compartments of the neurons is a critical factor in maintaining neurotransmitters in the biochemical form that is most stable and least toxic.

The synaptic vesicles that store dopamine and norepinephrine maintain an acidic pH of around 5.2, a pH that maintains the optimum stability of these neurotransmitters. These vesicles also contain dopamine-beta-hydroxylase that converts dopamine to norepinephrine. If this enzyme is blocked by *Clostridia* metabolites, dopamine accumulates in the synaptic vesicles to the point that excessive dopamine leaks out of the synaptic vesicles and enters the cytoplasm, which has a pH of 7.4, a pH at which dopamine is highly unstable and is converted to a number of highly unstable and toxic metabolites called dopamine quinones and aminochromes.[45] Paradoxically, some of these toxic metabolites become even more toxic when they react with glutathione. Dopamine toxic metabolites covalently bind to the mitochondrial proteins and the neuronal structural proteins actin and a/b-tubulin of the cytoskeleton, inducing autophagy, the formation of clusters of condensed chromatin, mitochondrial DNA damage, oxidative damage, impaired mitochondrial energy production, and finally cell death.[45]

In addition to autism and kidney disease associations, the International Agency for Research on Cancer of the World Health Organization (WHO) published a summary of its monograph on glyphosate and classified it as probably carcinogenic in humans (category 2A) based on epidemiological, animal, and invitro studies.[51] Seralini etal.[52] reported that female rats exposed to glyphosate or to glyphosate in a commercial product called Roundup, in which other chemicals are present, developed mammary or pituitary tumors at a rate higher than controls. Treated male rats developed increased rates of liver necrosis and kidney abnormalities compared with controls. The findings of abnormal kidneys in the exposed rats are consistent with the kidney disease described in Asia that is associated with thousands of deaths related to high glyphosate in the urine. A meta-analysis published in 2014 identified an increased risk of non-Hodgkins lymphoma in workers exposed to glyphosate formulations.[53]

One of the highest values for urine glyphosate recorded at The Great Plains Laboratory (GPL) was in a man who only ate organic food but who used chewing tobacco regularly. Tobacco that is dried appears to be saturated with glyphosate.[43]

2, 4-Dichlorophenoxyacetic Acid (2, 4-D)



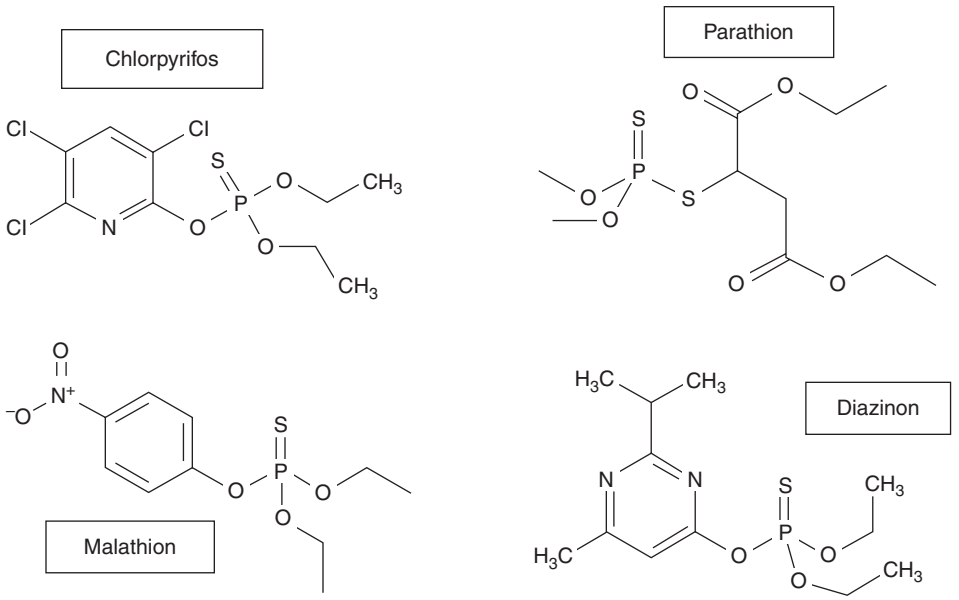
2, 4-D is a major herbicide intended to kill unwanted vegetation such as broadleaf weeds and woody plants. It is used in agriculture and on residential properties. People can be exposed to herbicides by breathing them in the air, by skin contact from residential use or living near application sites, and by eating contaminated food and drinking contaminated water.[54] Neuritis, weakness, nausea, abdominal pain, headache, dizziness, peripheral neuropathy, stupor, seizures, brain damage, and impaired reflexes have been associated with dermal or oral exposure.[55] 2, 4-D is a known endocrine disruptor and can block hormone distribution and cause glandular breakdown. It is linked to immune system damage, birth defects, and reproductive issues, possibly due to its frequent contamination with dioxins.[55] Small amounts of 2, 4-D may be found in many urine samples because of widespread environmental contamination. 2,4-D was a major component of a chemical mixture called Agent Orange used by the US military during the Vietnam War to increase the visibility for warplanes by destroying plant undergrowth and crops.[54]

Some of the toxicity of Agent Orange has been attributed to contaminating molecules called dioxins that arose during manufacturing. 2, 4-D may not be as contaminated with dioxins as in the past.[56] Although the presence of dioxins in 2, 4-D has been banned, they have recently still been detected. A July 2013 Four Corners investigation found elevated levels of dioxins in a generic version of 2, 4-D, one of Australias most widely used herbicides. One scientist said the product tested by Four Corners, which was imported from China, had one of the highest dioxin readings for 2, 4-D in the past 10 to 20 years, and could pose potential health risks.[57]

Recently, genetically modified food plants resistant to both glyphosate and 2, 4-D have been introduced into agriculture, using herbicides containing both glyphosate and 2, 4-D.[58]

The highest value at GPL was that of a child with autism with a urine value 28 times the 95th percentile. The child had a urine succinic acid (a marker for mitochondrial complex 2 abnormality) more than 10 times the upper limit of normal, a value more abnormal than individuals with proven mitochondrial DNA deletions. The tiglylglycine marker was in the normal range, indicating that the effects of the 2, 4-D were primarily on complex 2 versus complex 1 of the mitochondrial respiratory chain. The child was treated by sauna therapy for about an hour almost daily for 3 months, along with an organic food diet, after which a repeat test found no detectable 2, 4-D and a considerable improvement in autistic symptoms. The source of 2, 4-D was unable to be identified.

Organophosphates



Organophosphates are one of the most toxic groups of substances used throughout the world. Four common organophosphate structures are illustrated in the accompanying graphic. There are nearly 3 million poisonings per year, resulting in 200,000 deaths.[59] They are often used as biochemical weapons and terrorist agents but are most commonly used in pesticide formulations.[59] Children exposed to organophosphates have more than twice the risk of developing pervasive developmental disorder (PDD), an autism spectrum disorder, and children born to mothers living within 500 m of fields where organochlorine pesticides were used were more than six times more likely to develop autism than children whose mothers did not live near such fields.[60] Maternal organophosphate exposure has been associated with various adverse outcomes, including having shorter pregnancies and children with impaired reflexes.[60]

Approximately 340 million kilograms of pesticide active ingredient is used agriculturally in the United States annually, and 85% of US households store at least one pesticide for home use.[61] These insecticides kill insects (and mammals such as humans) by the inhibition of the enzyme acetyl-cholinesterase and other enzymes in which serine is part of the enzyme active site, such as dipeptidyl peptidase IV. When acetylcholine breakdown is inhibited, overstimulation can lead to constant nerve transmission or overstimulation of neurons or muscles, resulting in excessive salivation, abnormal behavior, diarrhea, urinary incontinence, vomiting, tremors, muscle paralysis, and even death.[62] High exposure levels have been associated with attention deficit, memory impairment, and pervasive developmental disorders.[60] Exposure has also been linked to violent behavior, depression, and suicide and may have played a role in the onset of Gulf War syndrome.[63-65] If levels are high, toxicity can be measured by decreased cholinesterase or pseudocholinesterase activity in plasma.[62] Acute toxicity is treated with atropine and/or pralidoxime.[66] Organophosphate exposure can be reduced by eating organic foods, avoiding the use of pesticides in the house or garden, avoiding residence near agricultural areas or golf courses, and staying indoors if insecticides are being sprayed. Lice shampoo, pet flea collars, and flea spray are also major sources of organophosphates. Remove sources of exposure if possible. A total of 147 different organophosphate pesticides can be detected by their metabolites DEP and DMP[67] (Table 25.1). Patients with values for organophosphates over the 95th percentile of the reference range with which GPL consulted included those with autism, Aspergers syndrome (a form of mild autism), severe uncontrolled temper tantrums, amyotrophic lateral sclerosis (ALS), vascular dementia, Parkinson's disease, and Huntingtons syndrome. One of the children with autism with high urine organophosphates was from the Miami, Florida, area, in which organophosphates had been widely sprayed to control mosquitoes implicated in the spread of the Zika virus. Initial results from GPL suggest organophosphates are the most common toxic chemical group in which the urine values of patients commonly exceed the 95th percentile.

TREATMENT OF NONMETAL TOXIC CHEMICAL EXPOSURE

The first and most important step in all chemical exposures is to identify the source of the toxic chemical exposure and remove the patient from the exposure. This may be simple if the patient is industrially exposed in a chemical plant or is a pest exterminator who is exposed to pesticides every day. Chemicals in cosmetics, such as phthalates, triphenylphosphates, and solvents, may be absorbed through the skin. Many individuals are exposed to chemicals through their ingestion of food and water, so switching to an organic diet is highly effective in removing pesticides and herbicides from the body. It is important to understand the difference in the terms *organic* and *non-GMO*. Organic foods are foods that have not received treatment with synthetic pesticides, herbicides, or other restricted chemicals. Non-GMO labels on foods mean the foods are not from genetically modified plants, but the food could still be highly contaminated with toxic chemicals used as pesticides and herbicides. In the case of the triplets with autism discussed previously, there was a 94% reduction of glyphosate in less than 2 months by switching to an organic diet.

Use of supplements that combine with various metabolites of toxic chemicals is also useful to accelerate the detoxification of large numbers of toxic chemicals. Glutathione and glutathione precursors such as n-acetylcysteine frequently combine with oxidation products of Phase I detoxification enzymes to form less toxic Phase II detoxification conjugates. Liposomal glutathione, taken orally, appears to be more effective than plain glutathione because of better absorption from the gastrointestinal tract. Although glutathione may be given

intravenously as well, oral administration is often cheaper and more convenient than intravenous infusions for long detoxification protocols. Glycine, an amino acid, may also be used orally to increase the excretion of oxidized metabolites of benzene and xylene as glycine conjugates.

Sauna treatment is another common treatment used for detoxification. Mercola and Crinnion have outlined a comprehensive sauna treatment for detoxification, with some protocols using flush niacin (not niacinamide or time-release niacin).[68,69]

Oral Manifestations of Nutritional Status

Michael T. Murray, ND

OUTLINE

INTRODUCTION

The structures and lining of the oral cavity offer valuable and easily accessible information on the nutritional status of an individual. Lesions may indicate a nutrient deficiency or may be manifestations of gastrointestinal or other disease.[1] Because of the very rapid cell turnover of the oral mucosa, these lesions often may precede other manifestations of nutrient deficiency or systemic disease. Some typical lesions are mucosal ulceration, cheilosis, gingivitis, and glossitis. The majority of people in the United States are deficient in one or more nutrients, so signs of nutritional deficiency are common.

THE HEALTHY MOUTH

The ventral surface of the healthy tongue is covered with a smooth, pink mucous membrane and lymphoid follicles. On the dorsal surface, the filiform, fungiform, and circumvallate papillae (which contain the organs of taste) produce a rough, grayish-red appearance. The thick epithelial tufts of the filiform papillae give the tongue its characteristic grayish-white coating, whereas the globular, pale red fungiform papillae give it a speckled pink appearance. Furrows are not characteristic of the healthy tongue.

The buccal mucosa has a grayish-red color and may be crossed by fine grayish ridges where it touches the closed teeth.

Healthy gums have a light-reddish appearance and cover the roots of the teeth completely.

The assessment of oral health, obviously, must include the health and status of the teeth. Patients should be asked about their dental history and encouraged to have regular dental checkups. Here are some key nutritional considerations for the examination of the teeth[2]:

- Having fewer than 20 teeth as an adult is associated with a significantly reduced capacity to eat nutritious foods, such as salads, raw fruit and vegetables, nuts, and whole-grain products. The same applies even to denture wearers.
- Bulimia may manifest as erosive tooth wear.
- Osteoporosis may manifest initially as changes in jaw structure and/or loose teeth.
- The presence of mercury amalgams may be associated with systemic disease, especially neurological conditions.

ABNORMALITIES OF THE ORAL MEMBRANES

Table 26.1 summarizes the typical oral manifestations associated with a particular nutrient deficiency, and Table 26.2 summarizes common disorders associated with oral manifestations.[1–12]

In general, ulceration should be considered a nonspecific expression of a disease state. A search for the etiology will usually result in a specific therapy. Aphthous stomatitis is a common example of a mucosal ulceration and is discussed in detail in Chapter 147.

Similarly, cheilosis is a common expression of an acquired nutrient deficiency. Gingivitis is associated with the classic signs of scurvy, but other nutrients have now been shown to play a role in gingival health; this subject is discussed in Chapter 208. Glossitis is associated with numerous vitamin deficiency states, each with a characteristic appearance.

Like glossitis, intraoral burning represents a nonspecific expression of a possible nutrient deficiency or systemic disease.[3–5] Possible causes in addition to those listed in Table 26.2 are as follows: xerostomia; dentures; deficiencies of iron, vitamin B_{12}, folic acid, vitamin B_6, and protein; steatorrhea; antibiotic use; changes in mucosal innervation; and anxiety states.

In people who do not wear dentures, nutritional disorders are the most common causative factors.[2]

Leukoplakia is any white lesion of the oral cavity that cannot be removed by rubbing the mucosal surface. Although lesions are usually only a sign of chronic irritation, 2% to 6% represent either dysplasia or early invasive squamous cell carcinoma.[4]

Erythroplakia is similar to leukoplakia, except that it has a definite erythematous component. This is a far more serious sign, with 90% of such lesions representing dysplasia or carcinoma.

TABLE 26.1 Oral Signs of Nutrient Deficiency

Nutrient	Signs of Oral Deficiency
Vitamins	
Biotin	Geographical tongue, atrophy of lingual papillae
Folic acid	Gingivitis, glossitis with atrophy or hypertrophy of filiform papillae, cheilosis
Niacin	Intraoral burning, canker sores, halitosis, glossitis, tongue swollen with red tip and sides, swollen red fungiform papillae, filiform papillae becoming inflamed and losing their epithelial tufts (giving the characteristic slick red appearance)
Pyridoxine	Intraoral burning, glossitis, mucosal ulcerations and erosions, cheilosis
Vitamin B_{12}	Intraoral burning, mucosal ulcerations and erosions, painful glossitis with a beefy red or fiery appearance, eventually resulting in an atrophic (smooth and shiny) tongue
Riboflavin	Soreness and intraoral burning, cheilosis, angular stomatitis, glossitis with a magenta tongue
Vitamin C	Sore and bleeding gums, deep blue-red color to gums, loose teeth, follicular hyperkeratosis
Vitamin D	Intraoral burning
Vitamin E	Glossitis
Minerals	
Calcium	Periodontal disease, tooth decay
Iron	Cheilosis, atrophic glossitis, gingivitis, candidiasis, intraoral burning or pain, mucosal ulcerations and erosions, pallor
Zinc	Cheilosis, atrophic glossitis, gingivitis, candidiasis, intraoral burning or pain, mucosal ulcerations and erosions, pallor

TABLE 26.2 Common Disorders Associated With Oral Manifestations

Oral Manifestation	Disorder(s)
Cheilosis	Crohn's disease, acrodermatitis enteropathica, alcoholism, celiac disease, malabsorption syndrome
Gingivitis	Crohn's disease, anorexia nervosa, celiac disease, scurvy
Erythroplakia	Dysplasia or carcinoma
Glossitis	Crohn's disease, diabetes, alcoholism, celiac disease, malabsorption syndrome, pernicious anemia, iron-deficiency anemia, amyloidosis, carcinoid syndrome, cigarette smoking, anemia
Intraoral burning	Menopause, diabetes mellitus, esophageal reflux, Sjögren's syndrome
Leukoplakia	Chronic irritation, dysplasia, early invasive squamous-cell carcinoma
Ulcerations, erosions	Crohn's disease, ulcerative colitis, celiac erosions disease, corticosteroid use, acrodermatitis enteropathica, anorexia nervosa, pernicious anemia, iron-deficient anemia, mercury poisoning, nicotine withdrawal

Rapid Dark Adaptation Test

Dirk W. Powell, BS, ND

OUTLINE

INTRODUCTION

The earliest sign of functional vitamin A deficiency is a decrease in dark adaptation, or poor night vision. Serum retinol levels are not predictive of subclinical states. However, classic dark adaptation testing is a cumbersome and time-consuming process (usually taking 45 minutes or longer).

A rapid test (6 minutes) was described by Thornton[1] and evaluated by Vinton and Russell.[2] This rapid dark adaptation test (RDAT) has significant clinical utility. The basis for the test is the measurement of the time of the so-called Purkinje shift. This term refers to the shifting of peak retinal wavelength sensitivity from the red toward the blue end of the visual spectrum during the transition from day (cone-mediated) vision to night (rod-mediated) vision. When color vision is nonfunctional, this shift causes the intensity, not the color, of blue to appear brighter than red under dim lighting.

CLINICAL APPLICATION

The RDAT is a clinical screening tool appropriate for use in adults and in children and could complement biochemical determination of vitamin A and/or zinc in clinical settings.[3] Although various dark adaptation tests have the advantage of being an in vivo test, and therefore directly relevant to function, they are somewhat less specific. Table 27.1 lists conditions that may give abnormal dark adaptation results despite normal serum levels of vitamin A.

PROCEDURE

Method

1. The procedure is explained to the subject.
2. The subject's vision is light-adapted by fixation on a standard x-ray viewing box for 1 minute at a distance of 0.5 meters. The x-ray viewing box is then turned off (the darkroom light remains on).
3. The subject is given all 18 disks mixed in random order, and a stopwatch is started.
4. The subject separates the white and then the blue disks as fast as possible. Under these controlled lighting conditions, the subject will not be able to recognize the colors, because the cones cannot distinguish color with the limited light available. The ability to separate the disks by brightness therefore depends on the rods. Any disk mistakenly separated by the subject is returned to the original pile until 100% accuracy of sorting is achieved, at which point the stopwatch is stopped and the time is recorded as the result.
5. The first test performed by a subject should be redone to allow for learning and standardization.

Required Equipment

- Lightproof room
- A standard darkroom light fixture fitted with a 7.5-W bulb and a neutral-density filter (allowing 1% transmittance). The bottom of the fixture is suspended 1.2 m above the work surface so that the target brightness on the work area is approximately 0.0068 candela/m^2.
- Munsell color disks with matte finish: five white disks (N9.5/-), six blue disks (5PB5/10), and seven red disks (5R5/10) (available from Munsell Color and Macbeth Division, Baltimore, MD)
- A nonreflective work surface
- A stopwatch
- A standard x-ray viewing box

TABLE 27.1 Conditions CAUSING Abnormal RDAT Results in Subjects With Normal Levels of Vitamin A

- Zinc deficiency
- Cataract
- Retinitis pigmentosa
- Diabetic retinopathy
- Macular degeneration[4,5]
- Severe errors of refraction
- Miosis caused by pharmaceutical agents
- Tinted corrective lenses

RESULTS

Normals[2]:

- 20 to 39 years old: 3.03 ± 1.00 minutes
- 40 to 60 years old: 4.41 ± 0.83 minutes

Vitamin A deficient:

- 7.63 ± 1.79 minutes

INTERPRETATION

The RDAT resultant time depends largely on the individual setting. However, the difference in the RDAT time between normal and vitamin A–deficient individuals is significant, and therefore standardization is easily achieved. The normal values depend on the age of the subject, with older subjects having an increased RDAT time.

Biomarkers for Stool Analysis

Joseph Katzinger, ND

OUTLINE

INTRODUCTION

Gastrointestinal (GI) dysfunction is a remarkably common experience in the United States.[1] The popular media are saturated with advertisements promising to soothe a wide variety of complaints, including (but by no means limited to) constipation, indigestion, reflux, bloating, and cramping. Those seeking relief beyond that offered on their local pharmacy shelves are substantial in number: GI-related complaints account for a significant percentage of visits made to primary care providers' offices.[2] As a group, many GI diseases carry significant morbidity and mortality—and many are currently poorly treated or in some cases completely untreated.[3] Yet the burden of GI diseases goes beyond individual physical costs: one survey estimated that over $40 billion is dedicated to addressing GI-related issues annually.[4] This is likely to be an underestimate, however, as a 2015 analysis estimated the hospitalization cost alone due to just GI hemorrhages in the United States at $5 billion annually.[5] Given the substantive toll that GI-related illnesses place on patients and the healthcare system—and given that current treatment methods to address them may be less than effective—it must be asked: What options do clinicians have to fully support their patients?[6]

Laboratory diagnostics that assess the stool for insight into the state of health of the gut have existed for decades, yet the evolution of technology is such that more sensitive and specific tools now exist for easy clinical application. Biomarkers for stool analysis measure key physiological aspects of the gut: digestion/absorption (D), immunology/inflammation/infectious processes (I), and gut microflora balance (G)—or DIG. This physiological assessment of DIG mirrors functional status and provides a critical, noninvasive way to evaluate and clinically approach the patient with GI complaints (Fig. 28.1). Assessed together, stool analysis biomarkers provide an effective means of capturing underlying physiological disruption that manifests as disease—eliminating the need for costly diagnostic testing where unnecessary; highlighting those individuals specifically at risk for organic disease who require immediate specialty referral; and identifying the source of gut dysfunction to apply simple, cost-effective treatments.

OVERVIEW OF THE GASTROINTESTINAL TRACT

A popular adage expounds, "You are what you eat." Over the course of a lifetime, it is estimated that a well-nourished adult will consume between 25 and 50 tons of food.[7] Yet given that these macronutrients—fats, carbohydrates, and proteins—must ultimately be broken down, taken up, and assimilated, perhaps the more appropriate maxim is this: "You are what you digest and absorb."

Once taken in, dietary foodstuffs undergo a series of complex digestive processes in this tube within a tube. The human gut has a massive absorptive surface area to capture macronutrients and micronutrients critical to optimal physiological function, yet the impacts of its processes are increasingly understood to go beyond traditionally defined roles of digestion and absorption. The mucosal surface of the GI tract is the primary interface with our external environment, and the interaction of gut commensal microflora with this mucosal surface is critical for differentiating self from nonself—a phenomenon known as "oral tolerance." In addition, more than 70% of the body's immune tissue sits within the gut and is both closely interconnected to—and continuously interacting with—the largest concentration of nervous tissue outside of the central nervous system (CNS). These immunomodulatory and neuroendocrine functions give credence to clinical concern that gut dysfunction may be a root cause not only at the level

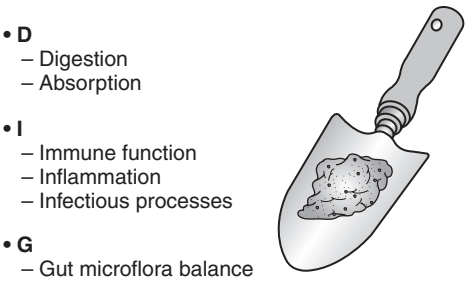

Fig. 28.1 Key physiological and functional processes of the gastrointestinal tract: DIG.

of local digestive issues like constipation, gastroesophageal reflux disease, and irritable bowel syndrome (IBS) but also for many chronic, systemic illnesses like inflammatory bowel disease (IBD), Hashimoto thyroiditis, systemic lupus erythematosus (SLE), rheumatoid arthritis, and migraine.

The following sections provide a broad-based overview of digestive physiology, followed by an in-depth look at key aspects of the gut utilizing the DIG framework—digestion/absorption (D), immunology/inflammation/infectious processes (I), and gut microflora balance (G)—and the biomarkers that provide insight into their function and/or dysfunction.

DIGESTIVE PHYSIOLOGY 101

Brain

As anyone watching a late-night food commercial may attest to, the process of digestion begins long before any food enters the mouth or stomach. The cephalic phase of digestion begins when anticipatory, visual, gustatory, and/or olfactory stimuli activate central nervous system (CNS) centers and result in parasympathetic stimulation of gastric activity.[8]

Mouth

Homogenization of ingested food first occurs in the mouth via the grinding and mixing action of the teeth. Salivary glands provide hydration to form a bolus and protect the pharyngeal and esophageal mucosa, primarily with secretory immunoglobulin-A (IgA) antibodies. The process of starch and fat hydrolysis is initiated with the release of lingual lipase, salivary amylase, and ptyalin.[9,10]

Esophagus

As the food bolus is swallowed, the epiglottis closes, providing a one-way valve that allows the food to pass into the GI tract and not the respiratory tract. Food is then transported down the esophagus in peristaltic waves past the lower esophageal sphincter and into the stomach.

Stomach

The stomach produces churning action and initiates protein and lipid hydrolysis. Peptides, amino acids, and fatty acids released in this process synchronize the release of pancreatic juice and bile into the small intestine.[9] About 2 L of gastric juice is produced each day, containing several important components.[11] Hydrochloric acid (secreted by the parietal cells) activates pepsinogen to convert to pepsin, which renders some minerals (e.g., calcium and iron) more absorbable. It also creates an essentially sterile environment to prevent bacterial overgrowth. Mucus forms an acid- and pepsin-resistant coating for the stomach lining. Gastric lipase secreted by gastric mucosa begins to hydrolyze triglycerols, producing 1,2-diacylglycerols and fatty acids. The optimal pH of gastric lipase is about 4, but the enzyme is active up to pH 6 or 6.5.[12] Several GI hormones, including gastrin, somatostatin, and ghrelin, are also produced by cells within the stomach.[13]

Liver and Biliary System

The liver is the largest gland in the body and performs an extraordinary number of tasks that affect every system of the body. Although the liver has critical vascular and metabolic functions, its secretory and excretory functions—especially as related to the synthesis and secretion of bile acids—are those that most directly affect digestion.

Because the by-products of lipid digestion have limited ability to dissolve in water, they have difficulty reaching the epithelial surface of the small intestine, which is covered by the unstirred water layer. To be more effectively absorbed, they must form aggregates (micelles) with bile acids (which act as biological detergents) that can penetrate the unstirred water layer. Without bile acids, only a small number of lipid molecules permeate through the water layer to be taken up by the brush-border membrane of the enterocytes. Finally, fat-soluble antioxidants (vitamins A, D, E, and K, as well as lutein and lycopene) also require bile acids for optimal absorption and utilization.

Pancreas

The pancreas plays a vital role in supporting the ongoing breakdown of the semifluid mass of partially digested food that flows from the stomach to the small intestine (chyme). Pancreatic duct cells secrete bicarbonate, which is critical for rapidly neutralizing gastric acid to preclude damage to the duodenal mucosa. In addition, pancreatic exocrine function results in the secretion of proteases, amylases, and lipases that further break down macronutrients (proteins, carbohydrates, and lipids) so that their components are readily absorbed across the intestinal mucosa.

Primary pancreatic exocrine insufficiency results from organic diseases of the pancreas (e.g., chronic pancreatitis, cystic fibrosis, severe acute necrotizing pancreatitis, pancreatic cancer). Secondary pancreatic exocrine insufficiency results from extrapancreatic diseases such as celiac disease and Crohn's disease, GI and pancreatic surgical resection, as well as any condition that results in a compromise or blunting of the small intestinal brush border. These include inflammatory processes, infectious agents, food allergies, and dysbiosis and/or small bowel bacterial overgrowth. Pancreatic exocrine insufficiency has now been recognized to result from both type 1 diabetes (26%–57%) and type 2 diabetes (20%–36%).[14] Whether of primary or secondary etiology, any compromise of pancreatic exocrine function can result in significant malnutrition-related morbidity and mortality.[15]

Small Intestine

Most digestion and assimilation occur in the small intestine. Digestion is mediated chiefly by pancreatic enzymes, including proteolytic enzymes, nucleolytic enzymes, lipases, α-amylase, and phospholipase A_2, which hydrolyze macromolecules to oligomers, dimers, or monomers.[9] Pancreatic enzymes are most active in the neutral pH range,[11,16] and bicarbonate begins the process of neutralizing stomach acid. Pancreatic proteases are secreted into the duodenum as inactive precursors, trypsinogen, chymotrypsinogen, and proelastase, and are activated by brush-border enzymes, such as enterokinase, to form trypsin, chymotrypsin, and elastase, respectively.[11]

The digestive and absorption capacities of the small intestine are greatly enhanced by circular folds and fingerlike projections of the intestinal mucosa called microvilli. This region, dubbed the "brush border," increases the luminal surface area of the intestinal wall by about 600 times, creating a total absorptive surface of approximately 200 to 250 m,[2] essentially the size of a tennis court.[11,16,17]

Even after prolonged contact with pancreatic enzymes, a substantial portion of ingested carbohydrates and amino acids depend on hydrolytic enzymes (disaccharidases such as maltase, sucrase, lactase, enterokinase, and peptidases) produced by the brush-border membrane to complete their digestion.[11]

For this reason, damage to the intestinal brush border—resulting from inflammation, trauma, parasitical infection, bacterial overgrowth, long-term nonsteroidal anti-inflammatory drug use, and other factors—may interfere significantly with the proper absorption of nutrients. Such damage also can disrupt the intercellular tight junctions that are vital to the protective-barrier function of the gut mucosal layer, increasing the intestinal permeability of potentially harmful macromolecules, such as bacteria and toxins, into the systemic circulation. This state of increased intestinal permeability, sometimes referred to as "leaky gut," has been cited as a potential contributory or causative factor in gluten enteropathy, Crohn's disease, food allergy, various arthritides and autoimmune diseases, chemotherapy complications, and a variety of other clinical conditions.[18–22]

Recent work has implicated zonulin, the human analog to an endotoxin produced by *Vibrio cholera,* as the master regulator of intercellular tight junctions. The two known triggers of zonulin release, which in turn lead to tight junction disassembly, are bacterial toxins and gliadin.[23]

Large Intestine

A primary role of the large intestine is to absorb water, about 1 L/day. The large intestine also provides an environment for microbial fermentation of soluble fiber, starch, and undigested carbohydrates. Soluble fibers are more readily fermented than insoluble fibers.[24]

Nondigestible carbohydrates (e.g., fiber), polysaccharides, and oligosaccharides contain chemical bonds that make them incapable of complete digestion by pancreatic or brush-border enzymes. As they move through the digestive tract, these undigested compounds play an important role in intestinal transport mechanisms. Once in the colon, they are cleaved and modified by enzymes produced by resident colonic bacteria to form short-chain fatty acids (SCFAs) and various gases, such as methane, hydrogen, and carbon dioxide.[12]

ASSESSING GASTROINTESTINAL HEALTH: DIG

As noted previously, a clinical approach to evaluating the functional state of gut health can be one that is based on the primary physiological roles of the gut. This approach is captured by the mnemonic DIG: digestion/absorption (D), immunology/inflammation/infectious processes (I), and gut microflora balance (G).

DIGESTION/ABSORPTION

Digestive Dysfunction

The first step in optimizing GI health is optimizing digestive function. Because numerous organs are involved in the digestive process, maldigestion can occur with malfunction at any level of digestive physiology, resulting in both local and systemic signs and symptoms. Maldigestion may result from an inadequate cephalic phase, leading to inadequate secretion of salivary amylases and proteases; insufficient mastication; hypochlorhydria; pancreatic insufficiency; bile insufficiency; small intestinal villous atrophy; and brush-border enzyme destruction.

As an example, hypochlorhydria has been hypothesized to be the root cause of a number of clinical conditions, including reduced mineral and amino acid absorption, depression, and other syndromes.[25,26]

In addition, interest has been expressed in the medical literature about the connection between the robust use of pharmaceuticals promoting gastric acid blockade and chronic clinical complaints. Research indicates that small bowel bacterial overgrowth and associated disorders, such as blunting of brush-border enzyme activity and decreased pancreatic exocrine function, may be an iatrogenic consequence of overprescribing of proton-pump inhibitors.[27–29] Given that long-term use of drugs that markedly reduce gastric acid secretion may negatively affect dietary and nutraceutical calcium absorption, concern has also been raised about their potential to increase the risk of fracture in individuals with osteoporosis, although the greatest potential for this may be in patients already at risk for loss of bone mineral density.[30–33]

A 2019 meta-analysis, which included 32 studies and over 2 million individuals, found an increase in risk for any-site, hip, and spine fractures associated with the use of proton-pump inhibitors, which was strengthened by the duration of use, suggesting causality. Importantly, this increase in fracture risk was not associated with a decrease in bone mineral density.[34]

Maldigestion associated with pancreatic exocrine insufficiency results in inadequate delivery of enzymes to the small intestine and can lead to the inadequate breakdown of fats, carbohydrates, or protein. The net effect is poor nutrition and an unhealthy environment for the flora of the large intestine. Significant decreases in exocrine pancreatic secretion have been associated with the aging process[35] and, clinically, are associated with osteoporosis[36,37] and diabetes.[38–40]

Absorptive Dysfunction

Malabsorption can be characterized by abnormal fecal excretion of fat (steatorrhea); abdominal pain; and variable malabsorption of fats, fat-soluble vitamins, other vitamins, proteins, carbohydrates, minerals, and water. Common causes include the following:

- Maldigestion
- Hypochlorhydria
- Small bowel bacterial overgrowth
- Deficient bile production, resulting in inadequate solubility of fatty acids[12]
- Chronic inflammation of the small intestine
- Rapid transit, which does not allow adequate time for absorption

Malabsorption often increases with age[41]: atrophic gastritis is estimated to affect 10% to 30% of individuals more than 50 years old and often leads to inadequate absorption of key nutrients, such as vitamin B_{12}.[42] To date, deficiencies in vitamin B_{12}, vitamin C, vitamin D, magnesium, calcium, and iron have all been associated with hypochlorhydria.[43,44]

General malabsorption syndromes are associated with many disorders of the intestinal tract, including celiac disease, gluten enteropathy, IBD, infectious processes such as giardiasis and cryptosporidiosis, lactose intolerance, and eosinophilic gastroenteritis. Because amino acids, carbohydrates, vitamins, and minerals are absorbed through different processes, individuals with malabsorption are at risk for the development of a wide range of nutrient deficiencies.

Biomarkers for Digestion/Absorption

Pancreatic Elastase 1

Pancreatic elastase 1 (PE1) is a proteolytic enzyme secreted exclusively by the human pancreas, and as such, it reflects overall pancreatic exocrine function.[45] It is an extremely stable, reliable, and specific marker[46] and correlates well with gold-standard, stimulated pancreatic function tests.[47] PE1 is concentrated fivefold to sixfold higher in feces than when it enters the duodenum, reflecting the overall stability of this biomarker in the GI tract.[48] It is not degraded during intestinal transit and is generally not affected by increases or decreases in intestinal transit time,[49] although its sensitivity may be diminished in cases of liquid diarrhea.[50] Unlike other pancreatic markers, such as chymotrypsin,

PE1 results are not affected by pancreatic enzyme replacement therapy,[46,47] a feature that makes it a valuable marker for monitoring and adjusting exogenous enzyme replacement.[46]

PE1 appears to have less sensitivity when diagnosing mild exocrine pancreatic insufficiency and may have limited use in differentiating pancreatic from nonpancreatic steatorrhea or diarrhea.[51] Previous analyses suggest a sensitivity of 54% to 65%, 75%, and 95% to 100% for mild, moderate, and severe insufficiency, respectively, with an overall specificity of 79%. It should be noted that other indirect assessments of pancreatic function, such as the 72-hour fecal fat test, have very poor sensitivity for mild/moderate insufficiency.[52]

Although research typically indicates levels of PE1 less than 200 mcg/g to be consistent with normal pancreatic exocrine function, healthy individuals produce on average 500 mcg/g of PE1. PE1 levels greater than 200 mcg/g and less than 500 mcg/g suggest a deviation from optimal pancreatic function, values between 100 and 200 mcg/g suggest moderate pancreatic insufficiency, and values less than 100 mcg/g are considered to be consistent with severe pancreatic insufficiency.[53,54] Enzymatic support of pancreatic insufficiency is warranted, and the strength of supplementation—typically based on the level of lipase units—should be modulated based on the degree of pancreatic insufficiency indicated by the PE1 level (Table 28.1).

Reduced PE1 has been reported clinically in patients with type 1 and type 2 diabetes,[55,56] chronic pancreatitis,[57,58] osteoporosis,[37] cystic fibrosis,[59] trauma states,[55] and intestinal malabsorption states associated with mucosal atrophy such as celiac disease.[60,61]

Putrefactive Short-Chain Fatty Acids

Valerate, isovalerate, and isobutyrate are produced exclusively by bacterial fermentation of proteinaceous material (polypeptides and amino acids). These SCFAs are putrefactive, and their presence suggests underlying maldigestion and/or malabsorption from dysfunctional states, such as hypochlorhydria or exocrine pancreatic insufficiency,[62] or bacterial overgrowth in the small intestine. Other causes are GI disease (resulting from the fermentation of blood or mucosal cells delivered to the colon)[63] and rapid transit time (resulting from inadequate time for digestion and absorption of peptides and amino acids).[64]

Increased levels of SCFAs, including acetate, propionate, butyrate, and valerate, have all been associated with increased adiposity and obesity, although decreased SCFA levels have been associated with colorectal cancer.[65,66] A 2019 systematic review and meta-analysis found that levels among those with IBS differed from healthy controls, but they were not consistently elevated. Those with constipation-predominant IBS had lower butyrate and propionate levels, whereas those with diarrhea-predominant IBS had elevated levels of butyrate only.[67]

Fecal Fats

Fecal fats include triglycerides, long-chain fatty acids, cholesterol, and phospholipids, and are derived primarily from the dietary ingestion of fat. Elevated levels of fecal fats in the stool suggest fat malabsorption (steatorrhea), which can occur as a result of maldigestion and/or impaired uptake of fatty acids. In addition, any condition that results in impairment of lipase activity and bile acid production and release may result in fat malabsorption. These include pancreatic insufficiency, cholestasis, short bowel syndrome, and celiac disease.[68]

TABLE 28.1 Pancreatic Elastase 1 Levels, Degree of Pancreatic Insufficiency, and Enzyme Supplementation

>500 mcg/g	Optimal
351–500 mcg/g	Normal, but not optimal
201–350 mcg/g	Mild insufficiency
101–200 mcg/g	Moderate insufficiency
<100 mcg/g	Severe insufficiency

IMMUNOLOGY/INFLAMMATION/INFECTIOUS PROCESSES

As noted previously, more than 70% of the body's immune tissue sits within the GI tract.[69] This immune tissue has a complex and dynamic relationship with the commensal microflora that colonizes its surface—the primary interface with an external environment rich in both supportive dietary antigens as well as pathogenic agents. The gut commensal microflora exists in this macronutrient-dense intestinal environment and is a significant contributor to the process of digestion, building of essential nutrients, and holding nonbeneficial bacterial counts in check. How is it, then, that host immune function is modulated to allow for the acceptance of self (as well as supportive commensal organisms and dietary antigens), even as it is vigilantly surveying for and combating against pathogenic microorganisms?

The answer appears to lie with an exquisitely balanced, ongoing inflammatory response by the intestinal immune system: it is capable of mounting strong inflammatory responses against pathogenic agents while concomitantly providing inhibitory signals that preclude responses against commensal bacteria.[70,71] Any alteration of this equilibrium, for example, as a result of gut microflora imbalance, genetic predisposition, or immune dysregulation, will result in an upregulation of the gut inflammatory response. Diagnostically, this may be reflected by the release of the biomarker calprotectin from neutrophils.[72] Clinically, the breakdown of this intestinal immune balance has been implicated in the development of diseases marked by significant inflammation, such as IBD,[73–75] and has been postulated to play a role in the development of extraintestinal allergic and autoimmune disorders.[76] For example, dysbiosis appears to be a hallmark of rheumatoid arthritis, and the effectiveness of recently developed biopharmaceuticals, such as etanercept, may in part be due to a shift in the microbiota composition.[77] Alterations in microbiota populations have also been reported for conditions not recognized as having an autoimmune component, for example, hypertension, and atherosclerotic cardiovascular disease has been associated with microbial shifts.[78,79] Similarly, changes to gut microbiota populations may drive a variety of pathways that contribute to diabetes and obesity (Fig. 28.2). Microflora imbalance has also been reported in patients with IBS.[80]

Biomarkers for Immune Function, Inflammation, and Infectious Processes

Eosinophil Protein X

Eosinophil protein X (EPX), also known as eosinophil-derived neurotoxin (EDN), is a basic cellular protein with potent cytotoxic and neurotoxic properties and is a marker of eosinophil activation and degranulation. Mobilization of eosinophils in the gut appears to occur in response to immune-mediated inflammatory responses.[81,82]

Clinically, fecal elevations of EPX have been described in IBD, IgE-mediated food allergy, parasitical infections, and collagenous colitis.[83–93] For example, in a small study, fecal EPX levels were shown to out-predict both skin-prick tests and atopy patch tests for diagnosing cow's milk allergy in toddlers.[94]

Calprotectin

Calprotectin belongs to a group of calcium-binding neutrophil-derived proteins. Because neutrophils are typically mobilized in response to increased mucosal permeability, cell or tissue damage, and infectious processes, elevations in calprotectin may be seen in the presence of inflammatory, neoplastic, and/or infectious disease processes.[95,96]

Clinical application of this biomarker has been directed toward discerning the best approach for the patient with functional abdominal symptomology. Specifically, calprotectin has been evaluated (in conjunction with Rome criteria) as a diagnostic biomarker to distinguish between IBS and IBD.[97–99] Surveys indicated that up to 12% of primary care visits comprised IBS-related complaints, and such visits accounted for 28% of referrals to gastroenterologists.[100,101] Because symptoms often overlap, early IBD may be inappropriately labeled as IBS. At least one study reported that more than 25% of patients with Crohn's disease had been misdiagnosed as having IBS in the prodromal stages of their disease.[102] Attempts to define organic disease in patients with IBS inevitably results in the application of more invasive diagnostic imaging procedures and escalated healthcare costs.[6]

Calprotectin has been found to correlate closely with IBD activity[103] and provides a highly sensitive, specific, and noninvasive alternative for assessing inflammatory activity in IBD.[99,104] Fecal calprotectin levels have been shown to correlate significantly with histological and endoscopic assessments of disease activity in ulcerative colitis[105] and with indium-111–labeled white blood cells (the gold standard for assessing gut inflammation) in patients with Crohn's disease.[106] In one report, more than 95% of patients with IBD had elevated fecal calprotectin levels.[107]

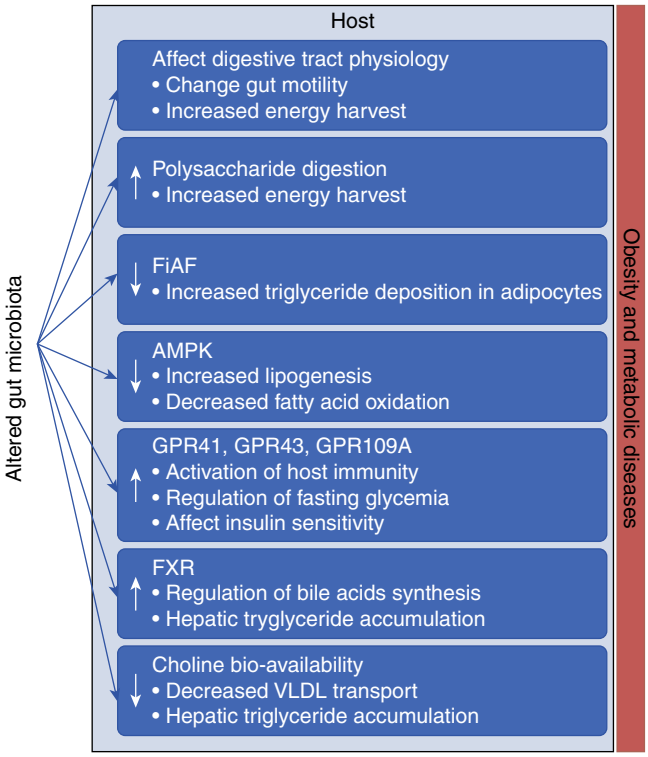

Fig. 28.2 Metabolic and immune interactions between gut microbes and the host in obesity and the metabolic syndrome. (From Boulangé CL, Neves AL, Chilloux J, et al. Impact of the gut microbiota on inflammation, obesity, and metabolic disease. *Genome Med.* 2016 Apr 20;8[1]:42. PMID: 27098727. Reproduced under the terms of the Creative Commons Attribution 4.0 International License [http://creativecommons.org/licenses/by/4.0/].)

Calprotectin has been used to predict relapse in patients with established IBD and to evaluate the effectiveness of therapeutic regimens as well.[83,108,109] In 2017 a systematic review was published in *Inflammatory Bowel Diseases,* which found that two consecutively elevated calprotectin values were associated with 53% to 83% likelihood of relapse within the next 2 to 3 months among asymptomatic patients with IBD.[110]

Because the severity of inflammation is indicated by varying levels of calprotectin, the treatment options and urgency of diagnostic intervention vary as well (Table 28.2).

Infectious Agents

Helicobacter pylori. *Helicobacter pylori* remains a prevalent worldwide infection, with infection rates in middle-aged adults reaching more than 80% in areas of low socioeconomic status and 20% to 50% in most industrialized countries.[111] *H. pylori* continues to be a causal link for the development of peptic ulcer disease (an estimated 10% to 20% lifetime risk in infected individuals),[112] as well as a variety of other GI concerns ranging in severity from dyspepsia to gastric malignancy.[113,114]

Several diagnostic options exist in assessing possible *H. pylori* infection. Although histological confirmation remains the gold standard, noninvasive measures such as urea breath testing, *H. pylori* stool antigen (HpSA) testing, and *H. pylori* polymerase chain reaction (PCR) are currently available. A 2018 Cochrane review found that at a 90% specificity, HpSA testing has a sensitivity of 83%, less accurate than urea breath testing for the diagnosis of infection.[115]

HpSA diagnostics have been approved by the US Food and Drug Administration for the detection of *H. pylori* pre- and posteradication therapy. This biomarker indicates the presence of *H. pylori* antigens shed directly into the stool and provides increased ease of clinical use as well as diagnostic performance characteristics comparable to urea breath testing in both adult and pediatric populations.[116,117] It has been shown to accurately indicate treatment failure at 7 days after completion of eradication therapy (compared with 4 weeks for urea breath testing),[117–119] an important consideration for directing additional clinical intervention in patients who remain symptomatic or develop recurrent symptoms posttherapy.

Although PCR testing for *H. pylori* is currently offered as a noninvasive diagnostic alternative to endoscopy and biopsy as well, concerns have been raised about the high degree of false-positive results with this methodology.[120,121]

Clostridium difficile. *Clostridium difficile* is an anaerobic, spore-forming, gram-positive bacterium that can be part of the normal intestinal flora. Although typically considered an opportunistic

TABLE 28.2 Calprotectin Levels, Inflammation Severity, and Clinical Intervention

<50 mcg/g	No inflammation
50–120 mcg/g	Mild inflammation
• Evaluate for dysbiosis, allergies, and infection.	
120–250 mcg/g	Moderate inflammation
• Evaluate aggressively for source of inflammation.	
>250 mcg/g	Severe inflammation
• Refer for diagnostic imaging (i.e., colonoscopy).	
• Begin treatment in patients with inflammatory bowel disease (IBD). Therapy should persist until biomarker indicates that inflammation has resolved and mucosal healing has occurred.	

infection occurring after antibiotic therapy, the epidemiology of *C. difficile* infection has shifted significantly. Its incidence has increased dramatically worldwide in the past decade, and new at-risk populations include individuals with community-acquired infection and no previous exposure to antibiotics, children, and pregnant women.[122]

C. difficile produces two toxins, A and B, which are its main virulence factors, and human infection can take many forms. These range from asymptomatic carrier states[123] and recurrent mild-to-moderate IBS-like manifestations to severe symptoms indistinguishable from colitis (cramping, diarrhea, urgency, mucus, and blood) that may result in a misdiagnosis of IBD.[124]

Parasitical Agents

Research suggests that parasitical organisms may also act as etiological agents of gut inflammation and dysfunction, including abdominal pain, diarrhea, and constipation.[125] One study found *Blastocystis hominis* to be present four times more frequently in patients with IBS compared with control subjects. In addition, symptoms resolved in 80% of subjects with IBS when *B. hominis* was treated.[126]

Other parasitical agents identified by stool analysis that have been isolated from patients with clinical symptomology include *Dientamoeba fragilis, Entamoeba* spp., *Endolimax nana,* and *Giardia lamblia.*[127–129] A review by an American diagnostic laboratory routinely surveying stool for parasitical agents found that 23.5% of nearly 14,000 clinical samples meeting *International Classification of Diseases,* 9th edition, criteria for IBS tested positive for the presence of at least one parasite.[130] *B. hominis* was the most commonly identified organism (12.5% of positive samples), followed by *D. fragilis* (3.8%), *Entamoeba* spp. (3.4%), *E. nana* (2.2%), and *G. lamblia* (0.7%). Similar results have been reported by laboratories outside of the United States as well.[131]

In 2017 a systematic review of 45 studies found that following infectious enteritis, more than 10% of individuals develop IBS, a more than fourfold increase in risk compared with those without infectious enteritis.[132]

GUT MICROFLORA BALANCE

At birth, the human GI tract is sterile. Bacterial colonization begins within days of delivery and evolves continuously over the first 1 to 2 years of life.[133] Early gut microflora development is affected by a variety of factors: location and type of birthing, breastfeeding versus formula-feeding, and antibiotic use in infancy and childhood.[134–137] *Bifidobacteria* are typically the first organisms to populate the newborn gut, and research suggests that any event that results in inadequate gut colonization during early life may lead to an increased risk of infectious, allergic, and autoimmune disorders later in life.[138] Once established, the bacterial composition of the gut tends to remain relatively constant over the lifetime of an adult,[139] although environmental (pharmaceuticals, toxins, infectious agents), lifestyle (stress), and dietary (glycemic load, fiber content, essential fatty acid composition, macronutrient/micronutrient composition, and pH balance) factors may induce shifts in commensal flora balance.[140,141]

Bacteria are present at every level of the GI tract and can be found in increasing density as one progresses from the upper gut (esophagus and stomach, 10^3 to 10^5 organisms/mL luminal content) to the lower gut (large intestine, 10^{10} to 10^{12} organisms/mL luminal content; feces, 10^9 to 10^{11} organisms/mL luminal content). In addition, the human gut hosts a massive diversity of microflora species—estimates range from 2000 to 35,000 bacterial species in the human gut; because many of these species are not cultivatable, it is difficult to derive a definitive estimate.[142,143] A recent project, the Metagenomics of the Human Intestinal Tract (MetaHit), cataloged nearly 10 million genes in the human gut microbiome.[144] Anaerobic species comprise the vast majority of the microbiome in healthy individuals; these include obligate anaerobes such as *Bacteroides, Bifidobacterium, Lactobacillus,* and *Clostridium,* as well as facultative anaerobes such as *Escherichia coli, Citrobacter, Enterobacter, Proteus,* and *Klebsiella.*[145] At counts of greater than 100 trillion bacteria colonizing the GI tract, these nonhuman cells vastly outnumber the total number of human cells in the body. With a metabolic capacity greater than the liver—and accounting for roughly 3 lb of body mass—this dynamic population of organisms could be considered a hidden organ in its own right.[146]

As noted previously, the bacteria that inhabit the human GI tract play a significant role in metabolic processes in the body. These include fermentation, SCFA and undigested dietary fiber metabolism, primary bile acid deconjugation, vitamin synthesis, and energy production. In addition, they are key immunomodulators, exert trophic effects on intestinal epithelia, and are a critical defense against pathogens—not only by competing for nutrients, space, and adherence intraluminally but also by producing bactericidal substances.[147] For this reason, alterations in gut microbial balance (dysbiosis) may result in health-related consequences at both the intestinal and extraintestinal levels.[80,148–150]

In dysbiosis, organisms of typically low intrinsic virulence, including bacteria, yeasts, and protozoa, may grow or migrate beyond their normal limitations. This can result in intensified microbial competition for nutrients, damage to the gut mucosal layer, and alterations of host immune function[151] and, as a consequence, may increase the risk for nutritional deficiencies, inflammation, autoimmune disorders, and neoplasia.[147,152–156]

Given the potential for disease that results from altered host–flora dynamics, restoration of balance as a means of restoring health has been a fundamental tenet of natural medicine and an increasing area of research in traditional medical spheres. However, the question should be asked: What defines optimal gut ecology?

Analysis of stool samples has been historically used to provide insight into the microbial composition of the gut. Specifically, levels of growth on plated culture media can be quantified and reflect the density of bacteria in the distal colon. Studies comparing electron microscopical evaluation of the microflora with fecal culture suggest that 50% to 80% of the total microscopic composition is recovered with stool culture methodologies. Limitations presented with the utilization of culture techniques include selectivity of growth based on media used and challenges posed by recovering strict anaerobes in a standard culture environment. Despite these limitations, the use of molecular probes suggests that there is good agreement on the degree of biodiversity when fecal culture is compared with 16S rDNA sequence analysis. In addition, biomarkers that reflect the metabolic activity of the GI microflora provide insight into the optimal functioning of the microbiome.[157]

With the advent of the Human Microbiome Project, increased focus has been placed on the use of molecular probe technology to characterize the microbial populations of the human body. A surprising 80% of the bacteria populating the human gut, previously unknown and thought to be unculturable, was revealed with these probe technologies.[158] What has emerged in recent years is the field of "culturomics," a revolution in bacterial culture technology that has permitted the isolation of hundreds of new bacterial species using multiple culture conditions and prolonged incubation times, combined with matrix-assisted laser desorption/ionization time of flight (MALDI-TOF) mass spectrometry and 16S rRNA sequencing. There are a number of

Fig. 28.3 All 2776 species isolated at least once from humans using culture. Using the online tool Wordle (http://www.wordle.net), the size of the name of each species is proportional to the number of times it occurs in the database. In this image, only the species name was taken into consideration, excluding the genus. (From Bilen M, Dufour JC, Lagier JC, et al. The contribution of culturomics to the repertoire of isolated human bacterial and archaeal species. *Microbiome*. 2018;May 24;6[1]:94. PMID: 29793532. Reproduced under the terms of the Creative Commons Attribution 4.0 International License [http://creativecommons.org/licenses/by/4.0/].)

techniques that have advanced culture technology, including the use of diffusion chambers (the use of membranes that allow nutrients to enter but confine bacterial cells); this alone increased the number of cultured colonies 300-fold.[159,160] Fig. 28.3 shows all 2776 species isolated from humans at least once using culture, an incredible and very recent increase in the number of culturable species.

Given ongoing evidence linking the GI microflora, health, and disease, these research initiatives have sought to identify a core gut microbiome. A limited number of common species have been demonstrated in the human intestinal microbiota to date, indicating the promise of applying molecular probe techniques in defining a beneficial bacterial composition. Given that research consistently demonstrates significant interindividual diversity and high intraindividual specificity, variability of microflora composition between individuals appears to be the norm, especially with aging.[161,162] In addition, although molecular probes have the capability of identifying the vast pool of species inhabiting the human gut, questions have been raised about the clinical relevance of such identification, as was noted previously with *H. pylori* PCR versus stool antigen testing. This is of particular concern when parasitical and/or pathogenic organisms are identified because probe technology does not currently have the capacity to differentiate between the DNA of living organisms (active infection) and DNA fragments indicative of past infectious processes or incidental exposure (the so-called "viability bias"). Additionally, metagenomic studies are limited by the extraction bias; that is, the diversity of the bacterial revealed is a function of the extraction protocol.[163] It seems likely that advanced culture methods combined with genomic analyses may provide the best overall picture of gut microbial diversity.

Ultimately, characterization of the microflora is undertaken to correct imbalances that may be contributing to acute or chronic states of illness. Supportive therapies such as prebiotics and probiotics (see Chapters 104 and 105 on prebiotics and probiotics) are standard clinical tools for optimizing gut health, and supplementation has been shown to be of benefit in an array of medical conditions, including atopic dermatitis,[145,164] acute infectious and antibiotic-associated diarrhea,[165–167] cancer prevention,[154] IBS,[168,169] prevention of necrotizing enterocolitis,[170] prevention and treatment of Pouchitis,[171] and ulcerative colitis.[172–175]

Although evidence exists that demonstrates clinical benefit, there is little consensus regarding what constitutes the most optimal therapeutic strain(s), concentrations, or timeline of treatment. With the emergence of molecular technology, there may be a point in the near future that allows individual targeting of probiotic therapies. Until that time, phenotypic markers that provide insight into the health of the microbiome—biomarkers reflecting digestion/absorption (D), immunology/inflammation/infectious processes (I), and gut microflora balance (G)—may be utilized to identify and monitor patients needing support.

BIOMARKERS FOR GASTROINTESTINAL MICROFLORA BALANCE AND METABOLIC FUNCTION

Beneficial Bacteria

Bifidobacterium, Lactobacillus, and nonpathogenic *E. coli* are the predominant strains of beneficial flora,[135] with the obligate anaerobic *Bifidobacteria* constituting about one fourth of the microbial flora found in adults.[176] In the distal colon, *Bifidobacteria* outnumber *Lactobacilli* by 1000:1.[177] Quantification of *Bifidobacteria* via stool culture typically demonstrates recovery in the 3+ or 4+ ranges in a healthy microbial milieu. The facultative aerobe *Lactobacilli* and nonpathogenic *E. coli* are both typically recovered in the 1+ or 2+ ranges.[178]

Adequate amounts of *Bifidobacterium, Lactobacillus,* and nonpathogenic *E. coli* are essential for the maintenance of optimal digestive functioning, and as such, these species are utilized in culture diagnostics as indicators of gut microflora health. Recovery of their numbers in less-than-optimal ranges suggests alterations in gut microbial balance and indicates a clinical need to ascertain the underlying etiology of the disruption and, ultimately, to assess the need for therapeutic support. The composition and distribution of the GI flora are affected by a variety of factors, as noted previously, including dietary intake, infectious agents, pharmaceuticals, and age. Stress also exerts a profound impact on gut flora and physiology, including increasing intestinal permeability, increasing bacterial adherence, and decreasing intraluminal levels of *Lactobacilli.*[141]

Restoration of balance and improvement of clinical symptoms may be achieved by probiotic supplementation. As indicated in the peer-reviewed literature, increasing levels of probiotic support may be required with increasing levels of disease state severity (Fig. 28.4).[179]

Additional Bacteria

Bacterial cultures are capable of identifying any number of additional organisms present in the individual human gut. These organisms may or may not exert a pathogenic effect depending on the state of balance or imbalance of the gut microbial milieu in toto. Putting it another way: sometimes these agents are the source of gut dysfunction, and sometimes their presence is merely a reflection of underlying gut dysfunction.

Overgrowth of additional bacteria may cause clinical and subclinical malabsorption and increase bowel permeability to large molecules. Abnormalities of the immune or mechanical barriers can lead to enhanced uptake of inflammatory luminal macromolecules and pathogenic bacteria. Bacterial antigens are capable of inducing antibodies, which cross-react with host antibodies, forming systemic immune complexes.[180,181] This process has been implicated in the etiology of chronic gut inflammation, as well as SLE and other connective tissue diseases.[182,183]

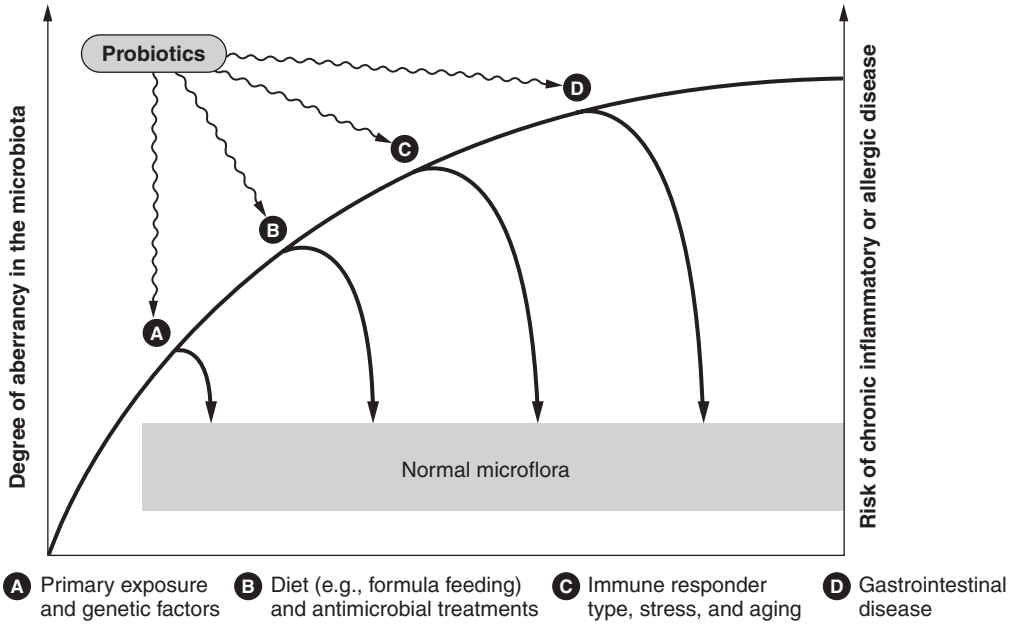

Fig. 28.4 Probiotic recommendations by disease. (From Isolauri E, Kirijavainen PV, Salminen S. Probiotics: a role in the treatment of intestinal infection and inflammation? *Gut.* 2002;50:iii54–iii59. http://gut.bmj.com/content/50/suppl_3/iii54.full.pdf. Used with permission from BMJ Publishing Ltd. Rights were not granted to include this figure in electronic media. Please refer to the printed book. 2012.)

Bacterial species such as *Klebsiella* and *Proteus* are not routinely surveyed as components of standard microbiological assessments, but both have demonstrated antigenic cross-reactivity to human leukocyte antigens (HLAs). *Klebsiella* has been associated with ankylosing spondylitis when cross-reactivity occurs with the HLA-B27 antigen. Similarly, *Proteus mirabilis* has been associated with rheumatoid arthritis and is known to cross-react with the HLA-DR4 antigen.[184,185]

Mycology

The GI tract in healthy individuals normally harbors small amounts of yeast. However, colonic yeast infections have attracted attention and controversy as a possible cause of chronic complex illnesses.[186] Investigators have hypothesized that *Candida albicans* may be involved in the etiology of allergic disorders such as scleroderma and asthma,[152,187] chronic fatigue,[188] chemical sensitivity,[186] and IBD.[189] For example, a recent analysis of 235 individuals with IBD found that the fungal microbiota is also shifted compared with healthy controls, including a reduced proportion of *Saccharomyces cerevisiae* and an increased proportion of *C. albicans.*[190]

Biomarkers for Microflora Metabolic Activity

As mentioned previously, biomarkers that reflect the metabolic activity of the GI microflora can provide an adjunctive assessment of the microbial status of the gut. Diagnostic assays utilized include those that evaluate SCFAs, β-glucuronidase, and bile acid metabolism.[165]

Beneficial Short-Chain Fatty Acids

SCFAs are produced by the anaerobic bacterial fermentation of primarily nonabsorbed dietary fiber.[191] The rate and amount of SCFA production depends on the composition and density of microflora present in the colon, the substrate source, and GI transit time.[192]

There are three primary beneficial SCFAs—acetate, n-butyrate, and propionate—yet most clinical and research emphasis has been placed on n-butyrate. Butyrate plays a major role in the physiology of the colonic mucosa and serves as the major energy source for the colonocyte.[193] In addition, research suggests that it may modulate inflammation in IBD via regulation of proinflammatory cytokines[194,195] and may play a role in the prevention of colon cancer.[196]

Beta-Glucuronidase

Beta-glucuronidase is an inducible enzyme elaborated by anaerobic *E. coli, Peptostreptococcus, Bacteroides,* and *Clostridium.*[197,198] By uncoupling glucuronides (xenobiotics and endogenous compounds detoxified via the glucuronidation pathway), this enzyme can deconjugate potential toxins, enhancing the formation of local carcinogens in the bowel[199] and promoting the enterohepatic recirculation of toxins, hormones,[200] and various drugs[201] in the body. For this reason, excess amounts of the enzyme may promote a higher risk of colon cancer. Both the incidence of colon cancer and levels of β-glucuronidase tend to be higher in individuals consuming Western diets (high in saturated fat, low in fiber) than in individuals consuming diets high in fiber and low in saturated fat.[202]

However, an adequate amount of β-glucuronidase activity is probably important to maintain normal enterohepatic recirculation of endogenous compounds, such as vitamin D,[203] thyroid hormone,[204] and estrogen.[205]

Bile Acids

The relationship between dietary fat and increased risk of colon cancer is believed to hinge on the excess production of bile acids and the bacterial conversion of conjugated primary bile acids to potentially dangerous unconjugated secondary bile acids.[206] Studies have found that a higher ratio of secondary bile acids, specifically, an elevated ratio of lithocholic acid to deoxycholic acid (LCA/DCA ratio), is associated with higher susceptibility to polyps and colorectal cancer.[207] Increased secondary bile acid excretion and a rise in the LCA/DCA ratio have also been observed in patients with gallstones.[208] An increase in secondary bile acids and a decrease in primary bile acids have recently been observed among patients with heart failure, with a tentative link to overall survival.[209]

BOX 28.1 Biomarkers for Stool Analysis: Clinical Vignettes

A 21-year-old woman presents with a history of intermittent recurrent abdominal cramping, bloating and/or gas, and occasional diarrhea over the past 2 years. She has been evaluated by her college health clinic on numerous occasions, has been told that her symptoms were primarily "stress related," and has been advised to cut back on her coffee intake during the day. She has recently been evaluated for complaints of fatigue and has been diagnosed with hypothyroidism (including elevated thyroid antibodies), for which she is now being treated. While home during a break, the patient was asked to submit a stool analysis by her primary care doctor, who was concerned that some underlying etiology had not been determined. Results were significant for the following:

Pancreatic elastase = 150 (normal level, more than 200)

- At this level, the pancreatic elastase clinically indicates moderate pancreatic insufficiency and the need for pancreatic enzyme support. Evaluation of the underlying cause of pancreatic insufficiency is warranted.

Calprotectin = 22 (normal level, less than 50)

- A normal calprotectin level indicates no inflammation due to neutrophilic activity in the gastrointestinal tract.

Eosinophil protein X = 13.1 (normal level, less than 7.0)

- An elevated eosinophil protein X may be associated clinically with celiac disease, parasitical infections, and/or immunoglobulin-E–mediated food allergies.

Microscopy = no evidence of parasite infection or altered gut flora

Given that celiac disease can be consistent with the patient's clinical symptoms and may be suggested on stool analysis by an elevated eosinophil protein X and compromised pancreatic exocrine function (low pancreatic elastase), the doctor decided to evaluate the patient for celiac disease. Blood serologies (positive tissue transglutaminase immunoglobulin-A and positive antiendomysial antibody) confirmed the diagnosis of celiac disease. The patient was placed on a gluten-free diet and given pancreatic digestive enzyme support. At follow-up, the patient reported that her symptoms had markedly improved—appearing only during times of dietary indiscretion.

BOX 28.2 Biomarkers for Stool Analysis: Clinical Vignette

A 42-year-old woman presents with a 3-year history of irregular bowel movements and intermittent lower abdominal pain, for which she has seen her primary care provider many times. She also has been diagnosed with depression and is currently using a tricyclic antidepressant, which she notes does not make a significant difference in her abdominal pain. She has used fiber, antidiarrheals, probiotics, and diet changes in the past to no avail. Upon evaluation, her new primary physician chooses to use stool analysis to evaluate the root cause of her illness. While waiting for the stool test to return, empiric use of probiotics at 10 billion colony-forming units per day has made no difference. The following results were noted:

Pancreatic elastase = 482 (normal level, more than 200)

- At this level, the pancreatic elastase clinically indicates normal pancreatic function and no need for pancreatic enzyme support.

Calprotectin = 286 (normal level, less than 50)

- This level of elevation of calprotectin indicates severe gastrointestinal tract inflammation and warrants referral to a specialist for further investigation (i.e., colonoscopy).

Microscopy = no evidence of parasitical infection or altered gut flora

The patient is referred for colonoscopy for inflammatory changes in the gastrointestinal tract. She is diagnosed with ulcerative colitis and placed on steroids and 5-aminosalicylic acid. For this patient, stool analysis allowed for early detection and appropriate referral to a gastroenterologist. Subsequent evaluations of gastrointestinal inflammation with the calprotectin biomarker can be used to monitor mucosal healing and determine whether repair is sufficient and/or complete or to monitor for relapse in patients with inflammatory bowel disease (IBD).

Bacterial overgrowth markedly increases the concentration of unconjugated bile acids, and this mechanism may play an important role in the pathophysiology of gut mucosal injury.[210] Probiotic treatment with *L. reuteri* has been demonstrated to lower the bioavailable concentration of toxic bile acids.[206]

SUMMARY

The philosophical framework that describes GI health to be the foundation of optimal health is not a new one. The *Sushruta Samhita,* an ancient Ayurvedic text, alludes to this in the following passage: "A person whose basic emotional and physical tendencies are in balance, whose digestive power is balanced, whose bodily tissues, elimination functions and activities are in balance, and whose mind, sense and soul are filled with vitality, that person is said to be healthy." If we hold this tenet to be true, then tools that allow us to diagnostically illuminate the imbalances that create symptoms and disease states in our patients—and ultimately lead to interventions to support them—are clinically important. Biomarkers for stool analysis provide a useful approach to identify the underlying pathologies that present as gut dysfunction, thus eliminating the need for costly diagnostic testing where unnecessary; highlighting those individuals specifically at risk for severe disease who do require significant diagnostic intervention; and identifying the source of gut dysfunction to apply simple, cost-effective treatments (Boxes 28.1 and 28.2).

Organic Acid Profiling

Michael J. Chapman, ND, Edward C. Wallace, ND, DC, and *Terry Arden Pollock, BS, MS*

OUTLINE

INTRODUCTION

In 1909 Dr. Archibald Garrod stood before the Royal College of Physicians in London and presented his concept of "inborn error of metabolism." He used his clinical expertise in childhood illness, combined with insight from his mentorship in genetics, to make the argument for biochemical individuality.[1] Garrod believed organic acidurias were an example of genetic inheritance that could be linked to biochemical individuality and illness.[2] His concept was extremely controversial at the time because Mendelian genetics had generated major opposition.[3]

More than 100 years later, a multitude of inborn errors have been characterized through advances in molecular genomics.[2] Although urine organic acid profiling remains a valuable diagnostic tool for screening genetic disorders (as in the 1900s),[4] a new utility for organic acid profiling has emerged. Enzyme dysfunction (such as seen in inborn errors) leads to abnormal organic acids in the urine. Profiling these acids has been shown to provide insight into altered enzyme function. This chapter discusses the multitude of factors that lead to enzyme dysfunction and demonstrates that organic acid profiling is not limited to only inborn errors. Instead, organic acids are clinically relevant to uncover any factor driving enzyme dysfunction, whether *genetic, nutritional,* or *environmental* in origin.

The human genome project has taken Dr. Garrod's concept of genetic individuality to a new level. This genomic revolution has led to extensive research into the subtle differences in genes, particularly through single-nucleotide polymorphisms (SNPs). We are learning more each day about how person-to-person genetic variation predisposes to enzymatic dysfunction.

Furthermore, enzyme function can be influenced by environmental factors such as nutritional inadequacies, dysbiosis, toxic exposure, mitochondrial dysfunction, hormone imbalance, inflammation, and chronic disease.[5–7] For example, vitamin B_{12} deficiency leads to the excretion of methylmalonic acid in the urine, mimicking the inborn error of metabolism known as methylmalonic aciduria.[8] The ability of the environment to influence enzyme production and activity is referred to as epigenetics.

With a new understanding of genetic individuality and epigenomics in mind, this chapter demonstrates how organic acid profiling can assist the clinician in assessing both endogenous and exogenous factors that limit metabolic pathways and shows that organic acid testing ultimately leads to opportunities for therapeutic intervention. Organic acid profiling aids the clinician in designing personalized and targeted therapeutic interventions by providing a direct analysis of metabolic pathways.

LABORATORY ORGANIC ACID PROFILES

Organic acids are compounds produced through normal metabolic processes. They are commonly measured by first-morning void urinalysis and are often categorized into groups based on their clinical relevance. Common organic acid categories include the following:

- Organic acids produced by gut microbiota
- Organic acids of mitochondrial dysfunction
- Organic acids related to neurotransmitter metabolism
- Organic acids related to vitamin-dependent pathways
- Organic acids from toxic exposures and detoxification pathways

Organic acid interpretation requires clinical insight into the array of factors that can precipitate abnormal findings. The human metabolism is an incredibly complex and dynamic system, and clinicians often place emphasis on both individual biomarkers and abnormal biomarker patterns that may provide clinical insight. The following sections review these main categories of organic acids and discuss the clinical utility of measuring these biomarkers and metabolic pathways. Although more than 300 organic acids have been reported in the literature, this chapter focuses only on those most frequently presented on laboratory profiles. Note that urine testing should be avoided in patients with renal compromise because it can lead to false-positive urine findings.

Organic Acids Produced by Gut Microbiota

The gastrointestinal microbiome plays an important role in health and disease progression. One role of the gut flora is to digest and ferment components from the food, such as fibers, fatty acids, phenols, and many other compounds.[9] When gut bacteria act on these compounds, they create by-products, such as B vitamins. Several organic acids are also produced by gut bacterial fermentation and are systemically absorbed by the body. Bacterially derived compounds (also referred to as bacterial metabolites) can have significant beneficial or harmful activity in the body. These bacterial metabolites can be detected

through urine organic acid testing, and they have been studied in a variety of conditions.

Clinically profiling bacterial metabolites can assist in the detection of unhealthy gut bacteria alterations, commonly called dysbiosis. Antibiotic use has been correlated with decreased excretion of bacterial organic acids.[10,11] Conversely, excessive bacterial growth in the gastrointestinal (GI) tract (such as in small intestinal bacterial overgrowth [SIBO]; see Chapter 9) may lead to a predictable global increase in bacterial metabolite production.[12] Evaluating bacterially derived organic acids can, therefore, provide insight into the relative abundance of GI microbiota and their metabolic activity.

Other factors, such as dietary habits, can strongly influence the urine levels of these organic acids. Accordingly, individual test results require careful interpretation and clinical correlation, including an assessment of the dietary factors present at the time of testing.

Malabsorption Markers (Tryptophan and Phenylalanine Metabolites)

Protein malabsorption can lead to excessive bacterial production of particular organic acids. Hartnup disease is a well-researched example of this phenomenon. In this condition, amino acid absorption (particularly tryptophan) is impaired in the intestine and leads to excessive bacterial fermentation of tryptophan to indole metabolites (indole-3-acetate).[13] Therefore Hartnup disease serves as a model for assessing bacterial fermentation products as markers of amino acid malabsorption.

Indoleacetic acid (IAA), or indole-3-acetate, is produced by gut bacterial fermentation of the amino acid tryptophan (as is seen in Hartnup disease).[14] Urinary IAA may also function as a biomarker for abnormal tryptophan metabolism, which is a characteristic feature in neurocognitive disorders.[15] IAA is considered to be systemically inflammatory, and the literature has correlated excessive IAA production with chronic diseases such as cardiovascular disease.[16] Indoleacetic aciduria has also been found in autistic patients, which is intriguing, given that autism is commonly associated with both dysbiosis and disordered tryptophan metabolism.[17]

IAA was previously thought to be primarily derived from the bacteria *Clostridia bartletti* or similar *Clostridia* species[18]; however, common gut microbes such as *Escherichia coli* and *Saccharomyces* spp. have demonstrated the ability to synthesize IAA.[19,20] Therefore IAA ultimately may be shown to be another way that gut bacteria can produce systemically-active compounds that can disrupt metabolic pathways.

Indican is another indole compound commonly correlated with protein malabsorption and has been used to assess dysbiosis and overgrowth.[21–23]

Phenylacetic acid and 4-hydroxyphenylacetic acid are also produced by gut bacterial fermentation of amino acids, similar to IAA.[11,18] Clinicians have used them as malabsorption markers alongside IAA; however, other dietary factors contribute to their production (Table 29.1). Therefore these markers should also be thought of as phenolic metabolites, which are discussed in the next section.

Dysbiosis Markers (Phenolic Metabolites): DHPPA3, 3-HPA, 4-HPA, PAA, HPHPA, Benzoic Acid, Hippuric Acid, D-Lactate

There are numerous organic acids that originate, at least in part, from gut microbiota. These acids have been used clinically as an indirect assessment of dysbiosis. Many of these bacterial metabolites originate from the fermentation of dietary phenols and flavonoids. Therefore the greater the bacterial numbers/activity in the GI tract, the higher the levels of bacterial metabolites found in the urine.

Diets high in polyphenols can be reflected as elevated urine levels in organic acid testing (Table 29.2). Specifically, bacteria easily metabolize dietary substrates such as flavonoids, catechins, and caffeic acids into these organic acids.[24] This understanding leads to an alternate clinical utility for the phenolic metabolites. In the absence of dysbiosis, levels of phenolic metabolites may serve as a marker for the intake of healthy, antioxidant-rich foods.

Clinically, urinary phenylacetic acid has been shown to inversely correlate to depressive symptoms.[25–27] There are similar findings for both **3-hydroxyphenylacetic acid** (3-HPAA) and **4-hydroxyphenylacetic acid** (4-HPAA).[7,28] All of these microbial by-products may exhibit COX-2 inhibition and free-radical–scavenging properties, which may reduce colon cancer risk. This lends further support to the utility of these markers as an indication of antioxidant consumption.[29–31] When these biomarkers are not suspected to be elevated due to dietary influence, abnormalities may be due to imbalances in gut flora which often lead clinicians to assess GI function and treat where appropriate.[7]

Bacterial metabolism of polyphenols results in the excretion of **benzoic acid** and **hippuric acid**. Urinary benzoic acid can also originate from foods containing the preservative sodium benzoate. Hippuric acid is formed when sodium benzoate is conjugated with glycine.[32] Elevated levels of urinary hippuric acid have been associated with several conditions that may be linked to dysbiosis.[33,34] For example, elevated urinary hippurate was associated with an increase in blood pressure, which is due to the direct effect of gut-microbial products on blood pressure. However in other studies low hippuric acid excretion has also been attributed to dysbiosis, which supports its use as a biomarker for gut microbial alterations.[35]

3,4-Dihydroxyphenylpropionic acid (DHPPA) is a fermentation by-product of dietary phenols that are produced by several bacteria (including some *Clostridia* spp.).[36–40] DHPPA and other bacterial metabolites were previously thought to identify the presence of specific dysbiotic bacteria. However, as with IAA, ongoing research has shown that there are more bacteria capable of synthesizing these metabolites than previously thought.

Similarly, 3-(3'-hydroxyphenyl)-3-hydroxypropionic acid (**HPHPA**) has been associated with *Clostridia* spp. and autism in a few small studies.[41] However, elevated urinary levels of this metabolite have also been found after the consumption of tea, grapes, and citrus foods (particularly orange juice).[42–45] In the absence of high dietary intake of phenol-rich foods, production of HPHPA may be due to alterations in gut bacteria and always warrant follow-up stool testing to confirm a clinical suspicion of dysbiosis or infection.

Urinary excretion of **D-lactate** has been used as a marker for carbohydrate malabsorption and small bowel dysbiosis.[46] There was initial debate around the origin of this metabolite. Early research suggested it was solely produced from gut bacteria (particularly *Lactobacillus* spp.).[47] The most prevalent GI condition associated with D-lactic acidosis is short bowel syndrome.[48,49] However, research now shows that D-lactate can also originate from human metabolism.[50] Elevated urinary excretion has been found in multiple disease conditions, including diabetes, inflammatory bowel disease (IBD), infection, and trauma, and may be relevant in chronic fatigue syndrome.[50] Therefore D-lactate may be a better indicator of metabolic disturbance from chronic disease progression than gut dysbiosis.

Yeast and Fungal Markers (Arabinose, Arabinitol, Citramalic Acid, Tartaric Acid)

Candidiasis is a controversial topic among integrative, functional, and natural medicine practitioners. Despite being a frequently used term, the diagnosis of "*Candida* overgrowth" or "systemic *Candida*" is still a topic of debate, except in invasive candidiasis, a fungal sepsis. That being said, *gastrointestinal yeast* is a relatively common finding that ultimately may or may not reflect dysbiosis and/or infection.

Clinicians have used organic acid findings (as an alternative to stool testing) in an effort to detect the presence of gastrointestinal yeast. **D-arabinitol** is a sugar alcohol that is produced specifically by

TABLE 29.1 Organic Acids and Common Metabolic Associations

Analyte	Metabolic Pathway	Clinical Associations
Indoleacetic acid	Gut bacterial metabolism	Chronic inflammation, neurocognitive disorders, cardiovascular disease
Indican	Gut bacterial metabolism	Protein malabsorption/intake
Phenylacetic acid	Gut bacterial metabolism	Polyphenol intake
3-Hydroxyphenylacetic acid	Gut bacterial metabolism	Polyphenol intake, COX-2 inhibition, reduced colon cancer risk
4-Hydroxyphenylacetic acid	Gut bacterial metabolism	Polyphenol intake, COX-2 inhibition, reduced colon cancer risk
Benzoic acid	Gut bacterial metabolism	Polyphenol intake, sodium benzoate intake
Hippuric acid	Gut bacterial metabolism	Polyphenol intake, sodium benzoate intake
3,4-DHPPA	Gut bacterial metabolism	Polyphenol intake
HPHPA	Gut bacterial metabolism	Flavanoid intake
D-lactate	Bacterial or human by-product	Small bowel dysbiosis, diabetes, IBD, infection, chronic fatigue syndrome
D-arabinitol	Yeast product	Systemic invasive candidiasis
Arabinose	Fruit sugar	Fruit intake
Citramalic acid	Fruit sugar	Fruit intake
Tartaric acid	Phenolic food compound	Polyphenol intake, food additive/preservative
Adipic acid	Fatty acid metabolism	Insulin resistance/diabetes, fasting, ketogenic diet
Suberic acid	Fatty acid metabolism	Insulin resistance/diabetes, fasting, ketogenic diet
Ethylmalonic acid	Fatty acid metabolism	Insulin resistance/diabetes fasting, ketogenic diet
Pyruvic acid	Glycolysis	High carbohydrate intake
Lactic acid	Anaerobic metabolism	Hypoxic states: anemia, sleep apnea, recent exercise
β-hydroxybutyric acid	Ketone production	Insulin resistance/diabetes, fasting, ketogenic diet
β-hydroxymethylglutaric acid	HMG pathway	Ketosis, statin therapy (theoretically)
Citric acid	Citric acid cycle	Diabetes/metabolic syndrome, depression, hypertension, fibromyalgia, cancer, IBD, ASD, mitochondrial dysfunction
Cis-aconitic acid	Citric acid cycle	Mitochondrial dysfunction
Isocitric acid	Citric acid cycle	Mitochondrial dysfunction
α-Ketoglutaric acid	Citric acid cycle	Mitochondrial dysfunction
Succinic acid	Citric acid cycle	Mitochondrial dysfunction
Malic acid	Citric acid cycle	Mitochondrial dysfunction
Vanilmandelic acid	Epi-/norepinephrine metabolism	Neuroendocrine tumors, psychological stress, PTSD
3-Methoxy-4-hydroxyphenylglycol	Epi-/norepinephrine metabolism	Mood disorder (low), behavioral disorders (low)
Homovanillic acid	Dopamine metabolism	Fatigue, sleep apnea, mood disorder (low), neuroblastoma
5-Hydroxyindoleacetic acid	Serotonin metabolism	SSRI/5-HTP supplementation, neuroendocrine tumors, chronic migraine, inflammation, metabolic syndrome, cardiovascular disease, IBS-D
Kynurenic acid	Tryptophan metabolism	Mood disorder, chronic inflammation, insulin resistance
Quinolinic acid	Tryptophan metabolism	Mood disorder, chronic inflammation, insulin resistance
α-Ketoisovaleric acid	Amino acid metabolism	Muscle catabolism, BCAA supplementation, insulin resistance, B-vitamin need
α-Ketoisocaproic acid	Amino acid metabolism	Muscle catabolism, BCAA supplementation, insulin resistance, B-vitamin need
α-Keto-β-methylvaleric acid	Amino acid metabolism	Muscle catabolism, BCAA supplementation, insulin resistance, B-vitamin need
Formiminoglutamic acid	Amino acid metabolism	Alcohol consumption, OCP use, nitrous oxide exposure, folate/vitamin B_{12} Need
Methylmalonic acid	Amino acid metabolism	Vitamin B_{12} deficiency, inborn error
Xanthurenic acid	Tryptophan metabolism	Inflammation, vitamin B_6 need
3-Hydroxyisovaleric acid	Amino acid metabolism	Biotin need
3-Hydroxypropionic acid	Amino acid metabolism	Small bowel dysbiosis
Glutaric acid	Amino acid metabolism	Inborn error
Isovalerylglycine	Amino acid metabolism	Inborn error
α-Ketophenylacetic acid	Styrene exposure	Oxidative damage
α-Hydroxyisobutyric acid	MTBE exposure	Oxidative damage
2-Methylhippuric acid	Xylene exposure	Oxidative damage
Glucaric acid	Phase I and II detox	Oxidative stress, antioxidant intake
P-hydroxyphenyllactic acid	Gut bacterial metabolism	Unknown
Orotic acid	Urea cycle	Alcoholism, allopurinol use, inborn error
Pyroglutamic acid	Glutathione pathway	Poor amino acid status, poor glycine intake
α-Hydroxybutyric acid	Glutathione pathway	Insulin resistance, smoking, alcohol intake

ASD, Autism spectrum disorder; *BCAA,* branch-chain amino acid; *3,4-DHPPA,* 3,4-dihydroxyphenylpropionic acid; *HMG,* β-hydroxymethylglutaric acid; *HPHPA,* 3-(3′-hydroxyphenyl)-3-hydroxypropionic acid; *IBD,* inflammatory bowel disease; *IBS-D,* irritable bowel syndrome, diarrhea predominant; *MTBE,* methyl tert-butyl ether; *OCP,* oral contraceptive pill; *PTSD,* posttraumatic stress disorder; *SSRI,* selective serotonin reuptake inhibitor.

TABLE 29.2 Common Dietary Sources of Gut Bacterial Metabolites

Urinary Metabolite	Common Dietary Sources
Indoleacetic acid, Indican	High tryptophan intake, green/black tea[61]
Phenylacetic acid	Wine/grapes[62]
3,4-Dihydroxyphenopropionic acid	Whole grains, chocolate, coffee, green/black tea, olives/olive oil, citrus fruits (animal studies)[36,38,40,63–69]
3-Hydroxyphenylacetic acid and 4-hydroxyphenlyacetic acid	Wine/grapes,[62,65] cranberries,[66] green/black tea,[40] berries,[67,68] orange juice,[69] grape seed extract[70]
Benzoic acid/hippuric acid	Orange juice[71], elderberry,[72] huckleberry,[73] food preservative,[74] berries,[75] other flavanoids[76]
Arabinose	Widely distributed, grains, commercial sweeteners[77]
Citramalic acid	Apples,[54,55] cranberries,[56] sugar beets[57]
Tartaric acid	Wine/grapes,[78] chocolate,[79] food additive/preservative

Candida spp., and high urinary levels have been found in individuals with systemic invasive candidiasis.[51,52] However, it is not known if urinary D-arabinitol levels correlate to GI *Candida* spp.

Conversely, **arabinose** is not made by *Candida* but, rather, is a pentose sugar that can be fermented by *Candida* into D-arabinitol. **Arabinose, citramalic acid**, and **tartaric acid** were reported to be elevated in one case study of children with autistic features.[53] However, there is no research, to date, correlating these markers to clinical candidiasis. Because these organic acids are likely dietary in origin (particularly fruit),[54–58] abnormal markers warrant follow-up stool testing to confirm a suspicion of gastrointestinal candidiasis.59 As these markers may come from fruit intake, and given that many clinicians anecdotally monitor fruit intake when suspecting GI candidiasis, the former organic acids can aid in the management of GI yeast; however, this hypothesis has not been fully evaluated in the literature.

Looking ahead, the field of metabolomic profiling has been analyzing organic acid patterns in multiple disease populations. As more becomes known, it may eventually lead to an expanded application of bacterial metabolite profiling. If we know which organic acids are of bacterial origin and what "organic acid footprint" is associated with a disease, we can then begin to unravel the role that our gut flora plays in the development or prevention of that specific disease.[60] At this time we work with non-specific indicators of the "bacterial organic acid footprint" to demonstrate the presence or absence of dysbiosis.

Organic Acids of Mitochondrial Dysfunction

Clinicians use these organic acids as indicators of mitochondrial function, and abnormalities can provide therapeutic opportunities to support cellular and metabolic energy.

Fatty Acid Oxidation (Adipic Acid, Suberic Acid, and Ethylmalonic Acid)

In the mitochondria, fatty acids are converted into fuel sources through a process called beta-oxidation. Beta-oxidation is a critical step in meeting cellular energy demands. The first step in beta-oxidation is the conversion of fatty acids into acetyl coenzyme A (acetyl-CoA), which is the fuel used by the citric acid cycle to generate adenosine triphosphate (ATP). Fatty acid conversion is dependent on carnitine because these fatty acids must be transported across the mitochondrial membrane via the "carnitine shuttle."[80]

When beta-oxidation is impaired, fats are increasingly metabolized by an alternate pathway (omega-oxidation), resulting in elevated levels of specific dicarboxylic acids, such as **adipic**, **suberic**, and **ethylmalonic acids**.[81,82] Impaired beta-oxidation can occur due to carnitine deficiency or dysfunction of the enzymes involved and may lead to an accumulation of these dicarboxylic acids.[83,84] These dicarboxylic acids are then excreted in the urine. Elevated adipic, suberic, or ethylmalonic acid excretion is also characteristic of ketosis, such as in insulin resistance/diabetes, fasting, or low carbohydrate intake.[84]

Beyond metabolic ketosis, free fatty acid accumulation is a significant independent clinical finding because these acids lead to mitochondrial dysfunction by injuring the cell membrane and increasing free-radical production.[80,85] Therefore monitoring these acids provides insight into mitochondrial impairment. Adipic acid excretion has been found to be elevated in chronic alcohol use in males, suggesting another source of mitochondrial dysfunction.[86] However, clinicians should be aware that a high intake of medium-chain triglycerides (MCT oil, coconut, etc.) could also lead to isolated elevations of fatty acid metabolites.[87]

The "carnitine shuttle" is critically important to beta-oxidation. Therefore carnitine supplementation may help attenuate mitochondrial dysfunction and improve ATP synthesis.[80,88] Vitamin B_2 and magnesium availability also play an important role in optimal beta-oxidation, making them viable intervention options for elevated urinary fatty acids (such as in glutaric aciduria).[89–91]

Mitochondrial dysfunction has been implicated as a characteristic in innumerable chronic diseases. Therefore organic acid profiling can be a method to uncover subclinical disruptions of beta-oxidation and is a valuable tool for investigating mitochondrial dysfunction in the clinical setting.[92] Nutritional intervention, including, but not limited to, B vitamins, antioxidants, and carnitine, may be helpful when laboratory signs of mitochondrial dysfunction are found.[93]

Glycolysis (Pyruvic Acid and Lactic Acid)

Carbohydrates are another source of the cellular fuel acetyl-CoA. Carbohydrates typically contain glucose as a component, which is converted into **pyruvic acid** by a large enzyme called the pyruvate dehydrogenase complex (PDC). PDC requires multiple cofactors derived from vitamins B_1, B_2, B_3, and B_5. Thiamine (vitamin B_1) appears to be particularly important to the PDC enzyme.[94] In cases of an increased rate of glycolysis, vitamin B_1 supplementation was able to decrease lactic acid and pyruvic acid.[95] Pyruvic acid is also metabolized by another enzyme named pyruvate carboxylase, which requires biotin as a cofactor. When elevated pyruvic acid is paired with elevated 3-hydroxyisovaleric acid (discussed later), clinicians may evaluate biotin needs.

Conversely, elevated lactic acid and pyruvic acid in the urine can be caused by several inborn errors, such as pyruvate carboxylase deficiency.[96,97] Elevated urinary **lactic acid** may also originate from impaired glycemic control, such as is seen in insulin resistance and alcohol dependence.[98–100] Furthermore, lactic acid increases during hypoxic states and has been found to be elevated in sleep apnea.[101] Lastly, lactic acid is produced during strenuous exercise and has been used as a biomarker for exercise exertion.[102]

Citric Acid Cycle Metabolites

The citric acid cycle, or tricarboxylic acid cycle (TCA cycle), is a group of biochemical interactions that occur in every living cell's mitochondria. This cycle of reactions provides the necessary molecules for oxidative phosphorylation and is the biggest source for producing ATP, the main cellular energy source (Fig. 29.1).[103,104] Each step of the citric acid cycle is dependent on nutrient cofactors to assist in catalyzing each chemical reaction.

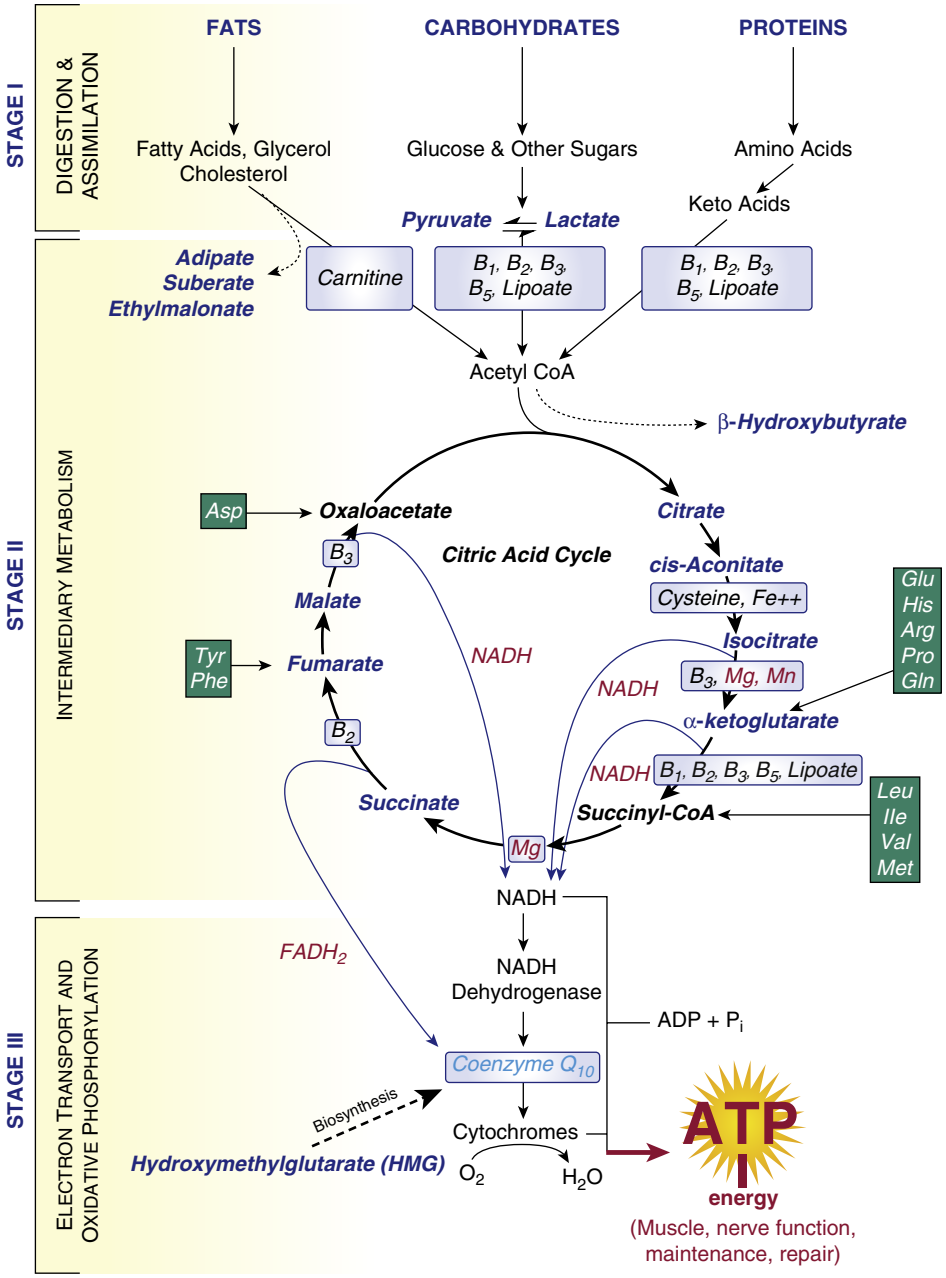

Fig. 29.1 Cellular energy pathways and commonly profiled organic acids.

β-hydroxybutyric acid (BHBA) is a ketone body. Ketones are generated in the liver when glucose metabolism is unable to meet energy demands. Heightened ketone production (ketosis) occurs during states such as prolonged fasting, exercise, and metabolic disease.[105] Elevations of β-hydroxybutyric acid can be used as an early risk indicator for diabetes, predicting impaired glucose tolerance and worsening glycemic control.[106–108] Low carbohydrate intake and ketogenic diets are likely to contribute to BHBA levels.

β-hydroxymethylglutaric acid (HMG) is another keto acid made from the molecule HMG-CoA and is a precursor to cholesterol and coenzyme Q_{10} synthesis. Inhibition of HMG-CoA (through statin therapy) may lead to higher circulating levels of HMG, showing up as elevated urinary HMG. Several inborn errors are known to produce 3-hydroxy-3-methylglutaric aciduria, with varying degrees of onset and clinical manifestations, ranging from neurodevelopmental disorders to cardiomyopathy.[109]

Citric acid cycle intermediates are tricarboxylic acids that make up the backbone of the TCA cycle. The predominance of literature surrounding abnormal citric acid cycle organic acid excretion is in the field of inborn errors of metabolism. However, advancing metabolomics research has begun to investigate metabolic "footprints" of various chronic diseases.[110–113] For example, altered urinary citric acid excretion has been demonstrated in metabolomics studies of diabetes/metabolic disease,[114–116] major depressive disorder,[28] hypertension,[117] fibromyalgia,[118] cancer,[119,120] and immune-mediated inflammatory disease (e.g., IBD).[121] Excretion of citric acid intermediates may also be abnormal in autism.[5,122,123] Furthermore, alterations in TCA cycle mechanics, leading to abnormal excretion of intermediates, has been associated with mitochondrial dysfunction,[124,125] linking them to conditions such as neurocognitive disease, diabetes, cancer, mood disorders, cardiovascular disease, and chronic fatigue syndrome.[92]

Many nutrient cofactors, particularly B vitamins and essential minerals, have demonstrated the capacity to protect mitochondrial function and are critical to the citric acid cycle.[94,126] Abnormal TCA cycle intermediates may reflect dysfunction of the TCA enzymes due to nutritional status, vitamin deficiency, toxicity, genetic polymorphism, or disease condition.[5,6,127–134] Abnormal urinary excretion of these acids may provide a window into various clinical conditions, as well as a potential therapeutic target to correct mitochondrial dysfunction.[103]

Genomics research may lead us to a greater understanding of how genetic individuality plays a role in the subclinical disruption of citric acid cycle mechanics. This information generates a novel utility for interpreting organic acids in the urine.[127] For example, homozygous enzyme defects of the citric acid cycle have been extensively studied. Recent studies suggest heterozygous defects may be tumorigenic.[131] If nutritional supplementation can attenuate these enzymatic weaknesses, whether they are genetic or acquired, clinical analysis of these metabolites may have vast clinical applications.[132] Attenuating subtle metabolic disruptions with adequate vitamin cofactor supplementation may significantly aid in chronic disease prevention or management.

Organic Acids of Neurotransmitter Metabolism

Neurotransmitter metabolites are an important group of organic acids. These compounds are breakdown products of neurotransmitter metabolism and can offer insight into neurotransmitter synthesis and degradation. Altered neurotransmitter metabolism can be due to enzyme impairment from chronic disease states, stress, genetic susceptibility, environmental toxins, and/or nutritional deficiencies.

Vanilmandelic acid (VMA) and **3-methoxy-4-hydroxyphenylglycol** (MHPG) originate from the breakdown of catecholamines, such as epinephrine and norepinephrine (Fig. 29.2). Catecholamines are integrally related to the stress response, both in the brain and peripherally. Therefore catecholamine metabolites have been used to assess sympathetic activity.[133] Much of the research on these markers has been focused on detecting neuroendocrine tumors and paragangliomas (particularly with VMA).[134–136] Elevated urinary VMA correlates to other physiological stress conditions, such as during competition, posttraumatic stress disorder (PTSD), and daily psycho-emotional stress.[137–140]

Low levels of catecholamine metabolites, particularly MHPG, have been found in mood and behavioral disorders.[141,142] Researchers have used this organic acid as an index for depression.[143] It is also interesting to note that because catecholamines are increased in response to exercise, MHPG has been explored as a method to evaluate the effectiveness of exercise as a therapeutic intervention in patients with affective disorders.[143,144]

Lower urinary MHPG has also been found in patients with attention deficit hyperactivity disorder (ADHD).[145,146] Disruption of catecholamine neurotransmission is a central hypothesis in ADHD, in both animal and human models.[147] Atomoxetine (a selective norepinephrine reuptake inhibitor) has efficacy in ADHD and may block norepinephrine in the central nervous system (CNS), allowing its breakdown and excretion.[148] Therefore urinary MHPG may be useful as a biomarker for serotonin–norepinephrine reuptake inhibitor (SNRI) therapy.[148,149]

Homovanillic acid (HVA) originates from dopamine. Similar to vanilmandelic acid, urinary HVA is elevated in neural crest tumors, such as neuroblastoma.[135,150] Dopamine is involved in learning and behavior modulation, and elevated urinary HVA has also been used as a dopamine turnover biomarker, seen in autism and other neurobehavioral disorders.[151] Dopamine also plays a role in the circadian rhythm, and elevated HVA correlates to dopamine-induced tiredness. For example, patients with obstructive sleep apnea present with varying degrees of sleepiness, and patients with apnea presenting with sleepiness and fatigue have much higher dopamine metabolite levels compared with patients with apnea with less sleepiness.[152] Conversely, low HVA levels may reflect low dopamine turnover in mood disorders, whereby medications that increase HVA correlate to therapeutic responsiveness.[153]

5-hydroxyindoleacetic acid (5-HIAA) is a metabolic by-product of serotonin.[154] Urinary 5-HIAA has been used as a predictive and prognostic biomarker for neuroendocrine tumors.[155–158] However, because it is a breakdown product of serotonin, patients taking over-the-counter 5-HTP, those taking psychiatric medications, or those who consume tryptophan-rich foods may anecdotally have high 5-HIAA levels in their urine.[158–160]

Aside from these factors, elevated 5-HIAA has been used as a marker of excess serotonin turnover in the periphery, which is associated with several clinical conditions. For example, higher levels have been associated with serotonin-induced infertility in men.[161] Similar risk associations have been found in chronic migraine, inflammation, metabolic syndrome, and cardiovascular disease.[162–164] Low urinary 5-HIAA levels has been found in some patient populations. One hypothesis of this association is that the need for niacin (vitamin B_3) shunts tryptophan away from serotonin production and into the kynurenine pathway which leads to NAD synthesis. Clinically, one may consider additional niacin support to correct this metabolic disturbance.[165]

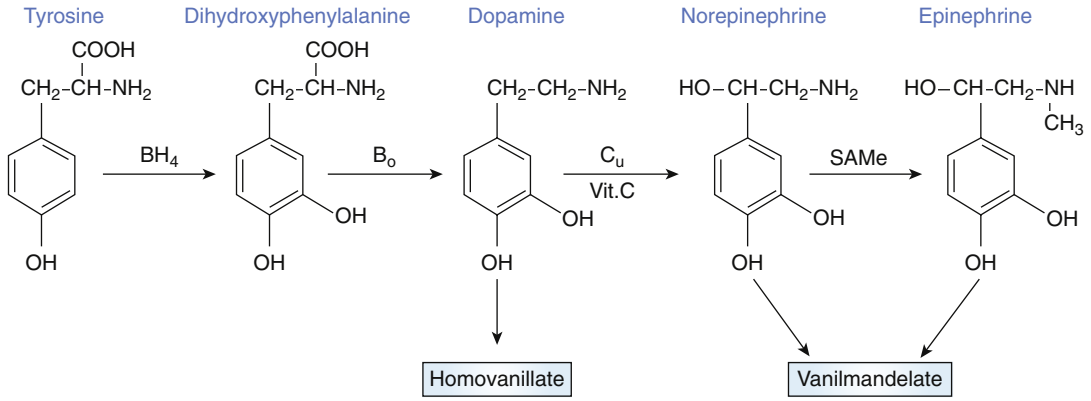

Fig. 29.2 Catecholamine metabolism and urinary metabolites.

The overwhelming majority of circulating serotonin is produced in the GI tract, not the central nervous system.[166] Therefore urinary 5-HIAA is primarily a reflection of gut-derived serotonin.[167,168] In the GI tract, alterations of serotonin metabolism have been associated with IBS. Higher urinary 5-HIAA was found in constipation-predominant irritable bowel syndrome (IBS),[169] whereas lower levels have been found in diarrhea-predominant IBS.[170] In a recent IBS study, 5-HTP supplementation led to increased turnover to 5-HIAA compared with controls (suggesting dysfunctional serotonin metabolism); however, supplementation ultimately improved intestinal barrier function.[171]

Tryptophan metabolism produces urinary **kynurenic acid** and **quinolinic acid**. Tryptophan is the amino acid precursor of serotonin. However, tryptophan is primarily metabolized in a different pathway, known as the *kynurenine pathway*. This alternate pathway is upregulated in response to inflammation and stress, which may cause deficient serotonin production.[172] Therefore urinary kynurenic acid and quinolinic acid are relevant in mood disorders and chronic inflammation.[173] Kynurenic acid can become further metabolized into quinolinic acid, which is an inflammatory and neurotoxic metabolite associated with depression.[174] Some laboratories calculate the ratio of kynurenic acid to quinolinic acid, whereby a low kyurenic:quinolinic ratio is suggestive of disturbed kynurenine metabolism leading to excessive quinolinic acid production (seen in mood disorders).[175] These metabolites also play a role in the development of insulin resistance and diabetes, which are common findings in depressed patients.[173]

The kynurenine pathway is particularly sensitive to vitamin B_6 deficiency, which has been shown to increase urinary kynurenic acid and xanthurenic acid (discussed in the next section).[176,177] Altered tryptophan metabolism and vitamin B_6 deficiency are suspected complications of the use of the oral contraceptive pill (OCP).[177,178] Vitamin B_6 supplementation has also been used to attenuate these alterations (at least partly); however, OCP use may disrupt tryptophan metabolism through other unknown mechanisms. Also, as previously mentioned, a major end-product of the kynurenine pathway is NAD, usually supplied by vitamin B_3. Therefore, clinicians may look at elevated kynurenine metabolites as an indication for needs for vitamin B_3.[165]

Organic Acids Related to Vitamin-Dependent Pathways

Some organic acids are used as specific markers to assess functional levels of vitamin cofactors. By examining pathways that are strongly influenced by nutrient availability, clinicians can home in on potential nutrient insufficiencies that can be targeted therapeutically.

Branch-Chain Amino Acid Intermediates (α-Keto Acids)

In the body, amino acids can be broken down to provide metabolites used in energy production. To do so, branch-chain amino acids (leucine, isoleucine, and valine) must be transported into the mitochondria via the carnitine shuttle. They are then converted into α-keto acids: **α-ketoisovaleric**, **α-ketoisocaproic**, and **α-keto-β-methylvaleric acids**.

After entering the mitochondria, α-keto acids are further metabolized by an enzyme complex known as the branch-chain α-keto acid dehydrogenase complex (BCKDC). BCKDC is the same enzyme responsible for the inborn metabolism error maple syrup urine disease. This enzyme complex requires multiple cofactors derived from vitamins B_1, B_2, B_3, and B_5 and lipoic acid. Because the breakdown of α-keto acids is dependent on BCKDC, deficiencies in the enzyme's cofactors may lead to increased α-keto acids in the systemic circulation and the urine (Fig. 29.3).[179]

Optimally functioning branch-chain amino acid (BCAA) metabolism is important in a variety of clinical conditions. As a group, BCAAs participate in protein synthesis, stimulate insulin release, spare lean muscle during weight loss or aging, and promote wound healing.[180] Elevated plasma BCAAs are associated with insulin resistance, which may be a result of decreased BCAA catabolism for energy production.[181] This metabolic disturbance could be compounded if nutrient deficiencies (such as vitamins B_1, B_2, B_3, and B_5) limit the activity of BCKDC.[179]

Therapeutically, B-vitamin support may be indicated with elevated urinary α-keto acids levels. In one study, supplementation demonstrated the ability to reduce α-keto acid excretion in healthy individuals, suggesting that elevated urinary α-keto acids is an indicator of the need for B vitamins.[182] Also, high BCAA turnover (such as in strenuous exercise, catabolic states, or BCAA supplementation) may contribute to the excretion of α-keto acids. The ability of B vitamins to attenuate these clinical states has not been fully researched.

Folate and B_{12} Markers: Formiminoglutamic Acid and Methylmalonic Acid

Formiminoglutamic acid (FIGlu) is the intermediate metabolite in the pathway that converts histidine to glutamic acid.[183] FIGlu metabolism depends on tetrahydrofolate (BH_4), a folate derivative, and accumulates with inadequate available folate. FIGlu accumulation is seen most dramatically in the inborn error formiminoglutamic aciduria. However, urinary FIGlu measurements have also been used as an indirect assessment of folate deficiency, dating back to the 1950s.[184] Initially called the "FIGlu test," patients with folate deficiency were shown to produce higher urinary FIGlu when given a large dose of L-histidine.[184]

In the literature, urinary FIGlu testing continues to be a marker for folate deficiency.[185,186] Compared with known folate-deficient patients, one study demonstrated that FIGlu has a high degree of specificity for

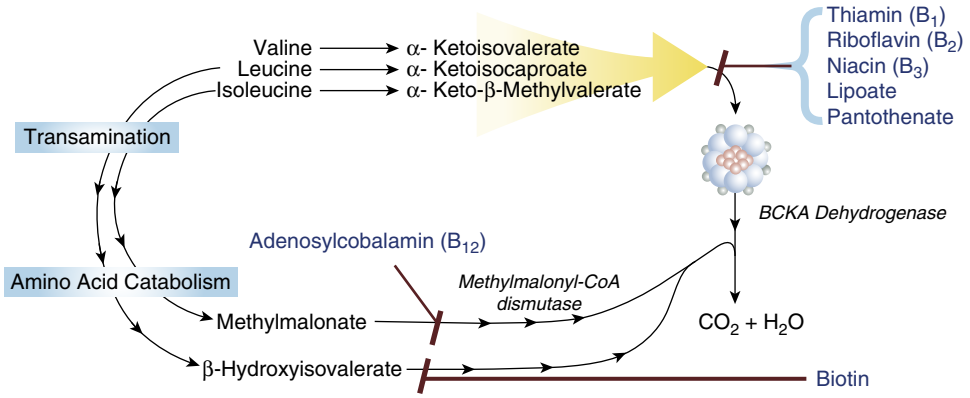

Fig. 29.3 Amino acid metabolism and B-vitamin cofactors.

detecting folate deficiency.[187] Multiple clinical conditions are associated with high urinary FIGlu, such as alcohol consumption, pregnancy, and birth control use.[188,189] Whether this is due to true folate depletion or another unknown mechanism is still debated.

Aside from folate evaluation, formiminoglutamic acid may reflect vitamin B_{12} status because folate recycling requires B_{12} as a cofactor. Vitamin B_{12} replacement decreased FIGlu levels in one study.[190] Both folate and vitamin B_{12} are critically important to methylation, which may support the utility of urinary FIGlu as a marker for disordered methylation capacity, as is seen in alcoholism.[191] Lending further clinical evidence, nitrous oxide (NO) is a known inhibitor of the enzyme that recycles folate (using B_{12}), and exposure to NO transiently increased urinary FIGlu, mimicking B_{12} deficiency.[192]

Methylmalonic acid (MMA) is an intermediate of methionine conversion to succinic acid for energy use. This pathway is vitamin B_{12} dependent, and MMA accumulation is indicative of the inborn error methylmalonic acidemia.[193] This inborn error can arise from variants in multiple genes, and it can present itself at any time in life, with varying degrees of severity.[194] Also, subtle genetic variants (SNPs) that can predispose individuals to B_{12} deficiency have been discovered.[195]

Because MMA conversion requires vitamin B_{12}, elevated levels of MMA are indicative of B_{12} deficiency.[196–199] Methylmalonic acid, as a functional biomarker, is considered a more sensitive index of B_{12} status compared with serum B_{12}.[200–204] Urinary MMA correlates with serum MMA, making the simple urine test a useful screening tool for B_{12} deficiency in at-risk populations, such as the elderly or patients with GI dysfunction.[196,202] Vitamin B_{12} therapy lowers MMA, and monitoring this metabolite may help prevent the consequences of B_{12} deficiency, such as cognitive decline and neuropathy.[204–206]

Other B-Vitamin Markers: Xanthurenic Acid, 3-Hydroxypropionic Acid, 3-Hydroxyisovaleric Acid, Glutaric Acid, Isovalerylglycine

Xanthurenic acid is a product of the tryptophan-kynurenine pathway discussed previously. Disturbances in this pathway have been evaluated in a variety of clinical conditions, including immune suppression, cancer progression, and immune/inflammatory reactions (such as in IBD).[207] The entire pathway is heavily dependent on vitamin B_6 availability; therefore xanthurenic acid has been studied as a biomarker for B_6 status.[208–210] Functional B_6 deficiency can be a consequence of dysglycemia, caused by inflammatory upregulation of the kynurenine pathway, ultimately leading to elevated levels of xanthurenic acid.[211] Also previously mentioned, kynurenine metabolites may become elevated when there are needs for vitamin B_3, which may lead clinicians to consider vitamin B_3 supplementation to address tryptophan-kynurenine abnormalities.[165]

Biotin, also referred to as vitamin B_7, is an essential vitamin cofactor in several enzymatic pathways. Certain clinical circumstances, such as pregnancy, vegetarianism, and anticonvulsant therapy, have been demonstrated to induce marginal biotin deficiency.[212,213] The organic acid **3-hydroxyisovaleric acid** is a functional marker for biotin status and can predict early biotin deficiency before serum biotin is affected.[213–216] **3-hydroxypropionic acid** is another biotin deficiency marker that has been studied; however, it does not appear to have the same diagnostic sensitivity.[217]

Glutaric acid and **isovalerylglycine** are two acids that are extremely elevated in inborn errors of acyl-CoA dehydrogenase. There are multiple forms of acyl-CoA dehydrogenase deficiencies, and most of them are diagnosed in neonates.[218] However, milder forms of this rare mitochondrial disorder exist, can have adult-onset presentation, and are responsive to riboflavin (vitamin B_2) and carnitine therapy.[218,219] Another interesting study demonstrated that elevated urinary levels of isovalerylglycine were found in anorexia nervosa patients. This is believed to be due to the effect of poor thyroid conversion of vitamin B_2 into active FAD, which is normalized in some patients after a refeeding program. Therefore vitamin B_2 need may be demonstrated by this urinary marker. Other causes of mitochondrial dysfunction may have a similar effect on beta-oxidation causing abnormalities of these markers.

Organic Acids From Toxic Exposures and Detoxification Pathways

Some organic acids relate to toxic exposure and detoxification capacity. These discrete biomarkers have increasing clinical utility in today's world (see Chapter 30, Urinary Porphyrins, and Chapter 35, Environmental Medicine). The following subsections provide a few examples of markers that help identify current exposures and the potential need for detoxification support.

Toxic Exposure Metabolites: α-Ketophenylacetic Acid, α-Hydroxyisobutyric Acid, 2-Methylhippurate

α-Ketophenylacetic acid (more commonly known as phenylglyoxylic acid) is a breakdown product of the petrochemical styrene. Styrene is a plastic ingredient found in numerous products, including insulation, fiberglass, carpet backing, pipes, and car and boat parts.[220] The most common source of styrene exposure is plastic food containers. Phenylglyoxylic acid (PGA) accounts for the majority of styrene detoxification in the body and serves as an exposure biomarker.[221] PGA can also originate from benzene, toluene, ethylbenzene, and xylene exposure.[222–224] Therefore high levels of urinary PGA warrant an investigation of any petrochemical contact because these chemicals are suspected to cause DNA damage.[221,224]

α-Hydroxyisobutyric acid is the major urinary metabolite of an industrial solvent called methyl tert-butyl ether (MTBE). MTBE was used as an additive to gasoline until the mid-2000s, when it was gradually phased out. However, considerable underground leakage has led to widespread groundwater and soil contamination.[225] Concerns about the tumorigenicity of chronic exposure to MTBE has been debated in the literature for a long time and played a significant role in removing MTBE from gasoline. However, it is still used in other industrial settings. Interestingly, MTBE is a powerful solvent, and injection of MTBE into the gallbladder has been a successful intervention to dissolve gallstones.[226,227]

Another organic acid commonly found in the urine is **2-methylhippurate**, which is a xylene-breakdown metabolite. Humans are exposed to xylene most commonly through volatile organic compounds (VOCs) from paints and varnish.[228] 2-methylhippuratue has also been found to be elevated in individuals exposed to pesticides.[229]

Detoxification Pathway Markers: Glucaric Acid, P-Hydroxyphenyllactic Acid, Orotic Acid, Pyroglutamic Acid, α-Hydroxybutyric Acid

Glucaric acid (or glucarate) is frequently used as an indirect marker for Phase I detoxification.[230–232] Many environmental chemicals, including pesticides and xenobiotics, are detoxified through Phase I enzymes. Therefore urinary glucaric acid is a valuable biomarker for exposure, as well as exposure-induced upregulation of detoxification enzymes.[233,234] Glucaric salts (such as calcium-D-glucarate), along with antioxidant-rich foods, are often used therapeutically to support detoxification. Therefore it is important to know that these therapies provide sources of glucaric acid that could influence urinary results.[235,236]

Traditionally, urine screening for elevated **orotic acid** was used to identify the inborn error orotic aciduria and as a means of evaluating other hyperammonemias.[237] Orotic acid has also been interpreted,

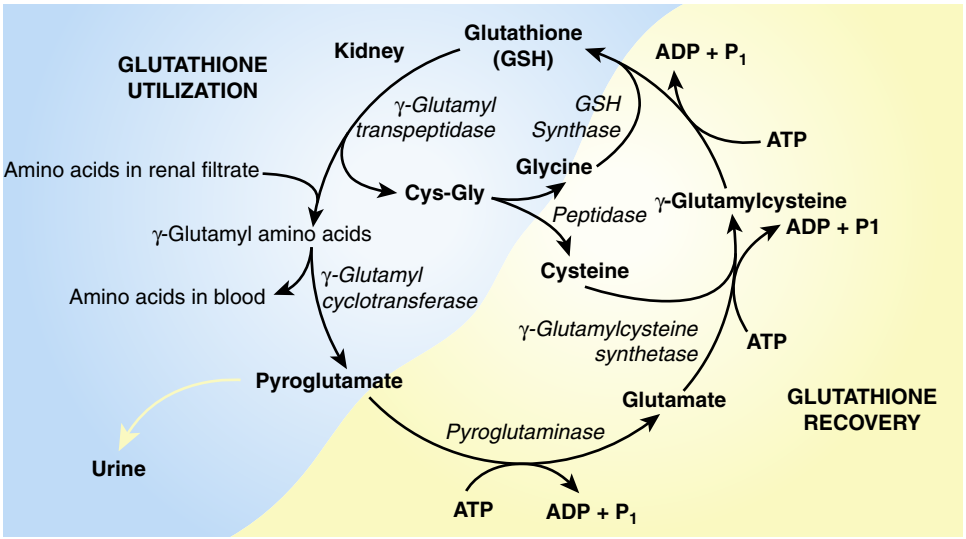

Fig. 29.4 The gamma-glutamyl cycle.

anecdotally, as a reflection of arginine status and urea cycle dysfunction; however, routine use of this biomarker to assess subclinical nutrient deficiency or hepatotoxicity is not well established in the literature.[238,239] Also, urinary orotic acid may arise from inhibition of other biochemical pathways. For example, the pyrimidine pathway used in nucleotide synthesis is inhibited by drug therapies such as allopurinol. This inhibition results in elevated urinary orotic acid.[240] Similar to orotic acid, urinary **sulfate** has also been used by clinicians to assess detoxification capacity. However, urinary sulfate has been shown to be heavily influenced by dietary habits, and therefore it is a relatively nonspecific biomarker.[241]

Pyroglutamic acid (also known as 5-oxoproline) is a metabolite of the gamma-glutamyl cycle. The gamma-glutamyl cycle is important because it assists in glutathione production and recycling (Fig. 29.4).[242] Glutathione is a powerful antioxidant, primarily responsible for cellular detoxification and redox balance.[242]

Glutathione is a tripeptide, consisting of three amino acids: glutamate, cysteine, and glycine. Glutathione synthesis requires sufficient availability of these amino acids, and deficiency of any of the three amino acids can affect glutathione production.[242] Elevated pyroglutamic acid may reflect nutritional needs for the amino acid glutathione precursors, particular glycine.[243,244] In individuals consuming low-protein/vegetarian diets, elevated pyroglutamic acid levels were significantly reduced when protein was supplemented.[245] To lend further support to pyroglutamic acid as a marker for glycine need, glycine supplementation has demonstrated the capacity to return high pyroglutamic acid excretion to normal and increase glutathione levels.[246]

Whereas the gamma-glutamyl cycle is responsible for recycling glutathione, it is the transsulfuration pathway that produces glutathione. The biomarker **α-hydroxybutyrate** (2-hydroxybuturic acid [2-HB]) is hypothesized to be a marker for upregulation of the transsulfuration pathway.[238] However, the majority of the literature demonstrates that 2-HB has a stronger correlation with dysglycemia. Some articles have suggested that it is one of the most significant biomarkers available for early determination of insulin resistance and metabolic disturbance.[247,248] Metabolic stress creates an imbalance in NADH/NAD ratios, which leads directly to the production of 2-HB.[249,250] 2-HB levels may be affected by smoking, alcohol consumption, exercise, and dietary habits. Thus 2-HB could prove to be a biomarker for unhealthy lifestyle habits.[251]

SUMMARY

Organic acid analysis is a powerful clinical tool. Originating as a way to diagnose inborn errors of metabolism, it now has been adopted into the evolving field of metabolomics, genomics, and personalized medicine. Clinicians aiming to target individual metabolic weaknesses use organic acid analysis as a backbone assessment. Numerous examples have been discussed in the medical profession of the dramatic positive clinical outcomes that have resulted from targeted treatments based on organic acid abnormalities.

Looking to the future, many more organic acids will likely be evaluated and added to current organic acid profiles. Organic acid profiling will continue to expand our understanding of the multitude of factors that precipitate individual susceptibility to chronic diseases and, therefore, guide the therapies that can help prevent them. Organic acid analysis provides insight into genetic metabolic weaknesses, environmental insults, and diet and lifestyle factors that limit optimal biochemical function. These abnormalities are likely at the root of innumerable chronic diseases, and correcting these abnormalities could have profound application in overall disease regression or prevention. Tomorrow's medicine will be an integration of Dr. Garrod's genetic individuality concept with functional profiling of biochemical pathways, ultimately making organic acid profiling critically important to clinicians focused on personalized medical care.

Urinary Porphyrins for the Detection of Heavy Metal and Toxic Chemical Exposure

Michael J. Chapman, ND

OUTLINE

INTRODUCTION

Today's world is one of unprecedented toxicity. The planet's increasing industrialization has led to the release of metals and the synthesis of new-to-nature chemicals that are designed to be difficult for biological systems to break down, which has resulted in substantial soil, water, food, and air contamination. Throughout this modernization, there have been instances of human exposures that have caused dramatic and immediate health consequences. However, little emphasis has been placed on how chronic low-level exposure contributes to chronic disease. Now, more than ever, there is a need to bring greater focus on the role of environmental exposures and to address the growing toxic burden of the entire population.[1]

One of the earliest discoveries relating to the role toxic metals play in disrupting homeostasis is the mechanism by which lead poisoning alters heme synthesis.[2–5] When heme synthesis is interrupted, heme metabolites, known as porphyrins, build up in tissues and are subsequently excreted in the urine at higher levels.[6] With this new understanding, the ability to measure porphyrins came into clinical practice as a tool that helps clinicians assess the contribution of toxic exposure to the disease process.

DESCRIPTION

Porphyrin urinary excretion, also referred to as porphyrinuria, has been an area of clinical investigation since the 1800s. Porphyrinuria was originally discovered as an inborn error of metabolism and led to the clinical characterization of congenital porphyria.[7] Eventually, porphyrins were uncovered as precursors of heme metabolism, and what was termed porphyrinuria is the result of a disruption in heme production. Since that time, the heme pathway has been extensively studied, along with the enzymes responsible for heme synthesis. As additional enzyme pathway defects became evident, the symptomatic presentation of each inherited metabolic error became collectively known as *porphyrias*.[8]

Urine porphyrin measurement has been an important tool for the clinical diagnosis of porphyrias, and its usage has largely remained relegated to this purpose. However, urine porphyrin quantitative assessment, not caused by an inborn error of metabolism, remains an area of intrigue in both the scientific literature and in clinical practice. Any factor that alters the functionality of one or more of the enzymes involved in heme metabolism may result in altered porphyrin excretion. This has been studied in metabolic dysfunction, drug responses, and toxic exposures.[9] Because the nature of clinical porphyrias is well established, the majority of this chapter's content is dedicated to the use of urinary porphyrin assessment to detect minor disturbances of heme metabolism.

HEME BIOSYNTHESIS

Heme is an indispensable protein in the body. It serves as the body's substrate for essential protein production, such as hemoglobin for oxygen exchange, and for the Phase I detoxification enzymes and the cytochromes (a, b, c, and P450) used in electron transport and detoxification. The heme-synthesis pathway involves eight enzymatic steps (Fig. 30.1). Flaws in any of these eight enzymes can ultimately impair heme synthesis, leading to increased heme precursors called porphyrinogens. These porphyrinogens are then quickly oxidized to the porphyrin form as they are removed from the body.[6]

However, in severe enzyme deficiency, porphyrins can accumulate in the body, leading to potentially life-threatening health complications as seen in acute and chronic porphyrias (Table 30.1).[8] Most of the enzyme defects that lead to porphyria are inherited conditions. Porphyrias have historically been clinically classified in multiple ways, either based on clinical presentation or by the nature of the inherited defect.[6,8] The urinary analysis of these porphyrins has been a great tool to aid in the diagnosis of porphyria.

In addition to aiding in the diagnosis of congenital and acquired porphyrias, urinary measurement has also been studied in cases of more subtle heme-synthesis errors. These include cases of toxic exposures, oxidative and metabolic stress, and specific clinical conditions such as autism.[6,9] By studying these cases, attempts have been made to characterize particular patterns of porphyrinuria to gain greater insight into the causes and consequences of disrupted heme biosynthesis.

PORPHYRINURIA IN ENVIRONMENTAL EXPOSURE

Lead exposure is one of the most famous and well-known porphyrinuria inducers. Lead affects three different enzymes in the heme pathway and can produce characteristic elevations in urinary porphyrins, which have been well described in the literature.[4] The typical pattern of porphyrin excretion seen in lead poisoning is an increase in δ-aminolevulinic acid (ALA) and coproporphyrin. This occurs as a result of inhibition of the heme-synthesis enzymes δ-aminolevulinate dehydratase and coproporphyrinogen oxidase, respectively.[2,4,6] Because of the consistency of this finding, it has been suggested that urinary

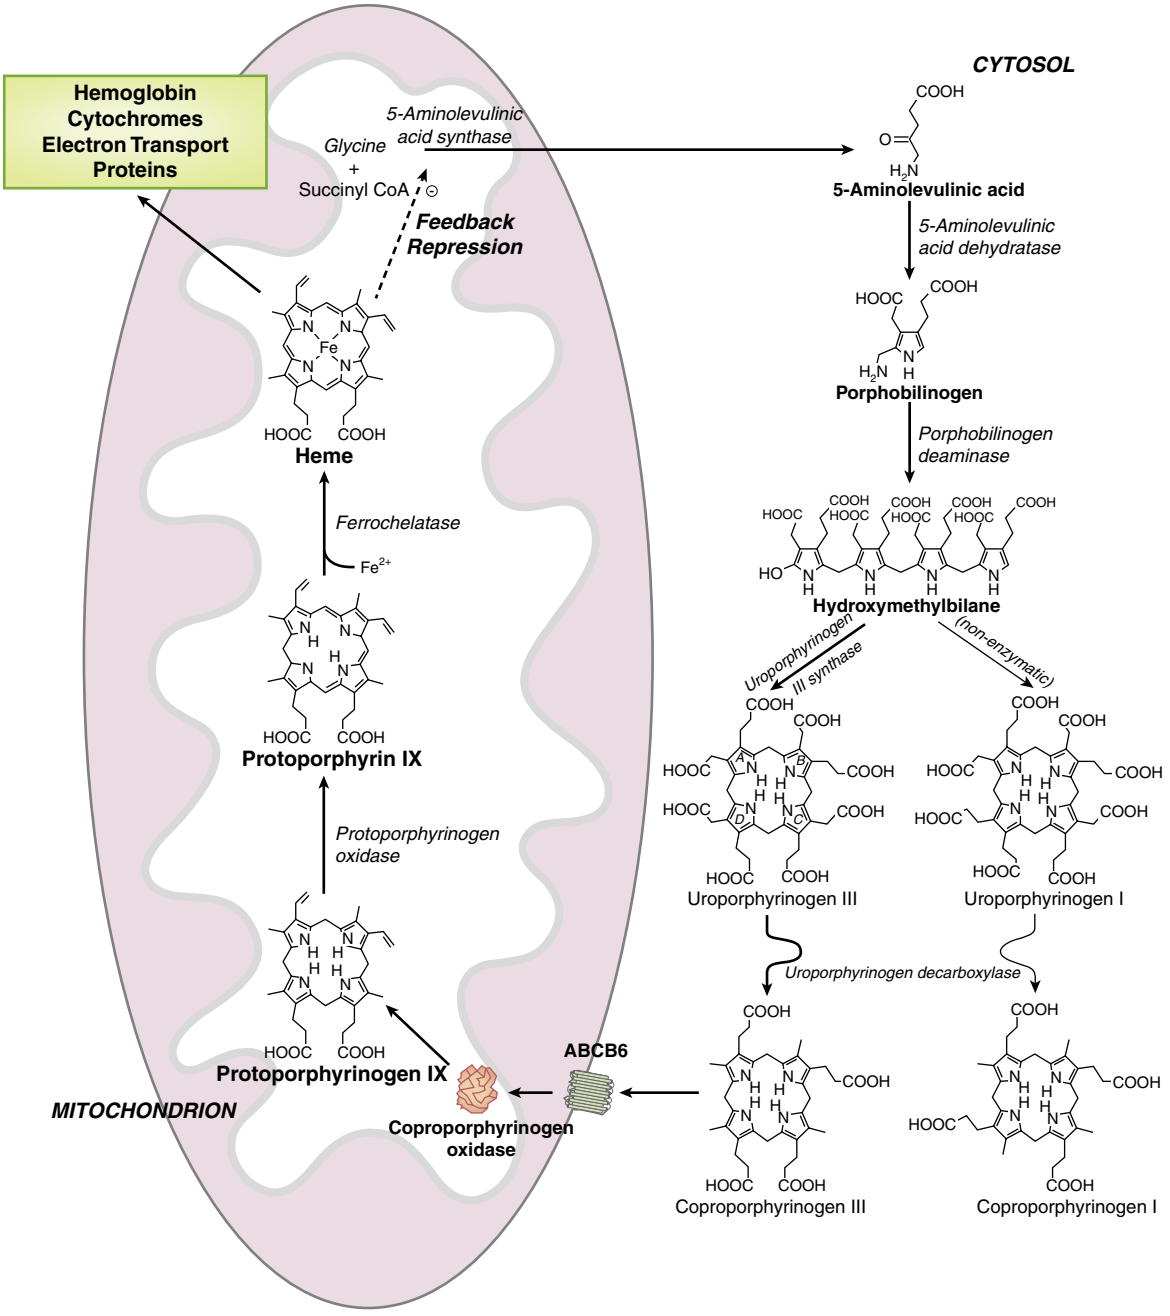

Fig. 30.1 Biosynthesis of heme.

TABLE 30.1 Types of Porphyrias

Porphyria	Enzyme Deficiency	Urine Findings[8]
Acute intermittent porphyria	Porphobilinogen deaminase	ALA, PBG, uroporphyrins
Hereditary coproporphyria	Coproporphyrinogen oxidase	ALA, PBG, coproporphyrins
Variegate porphyria	Protoporphyrinogen oxidase	ALA, PBG, coproporphyrins
Porphyria cutanea tarda	Uroporphyrinogen decarboxylase	Uroporphyrins, heptaporphyrins
Hepatoerythropoietic porphyria		
Protoporphyria	Fellochelatase	None
ALA dehydratase porphyria	ALA dehydratase	ALA, coproporphyrins
Congenital erythropoietic porphyria	Uroporphyrinogen III synthase	Uroporphyrins, heptaporphyrins

ALA, δ-aminolevulinic acid; *PGB,* porphobilinogen.

TABLE 30.2 Excretion Patterns in Common Environmental Exposures

Common Environmental Trigger	Common Urine Findings[a]
Lead	ALA, coproporphyrin III[4]
Mercury	Coproporphyrins, pentacarboxylporphyrin, precoproporphyrin
Arsenic	Uroporphyrins, coproporphyrins[28]
Alcohol	ALA, total porphyrins[32]
Numerous organic chemicals[b]	Uroporphyrins, coproporphyrins, total porphyrins[6]

ALA, δ-aminolevulinic acid.

Note: Certain environmental exposures have demonstrated particular patterns of porphyrin excretion. However, when interpreting urinary porphyrin testing, due diligence should be applied to rule out any inherited porphyria if suspected. Toxic metal analysis can aid in the diagnosis of metal toxicity.

[a]These patterns have been demonstrated in the literature and in clinical practice; however, it should be stated that these are general guidelines. Positive findings warrant further investigation into toxic exposure. Also, other factors (e.g., medications, liver disease, malignancy, and other chronic conditions) can contribute to altered porphyrin excretion.

[b]Porphyrin excretion patterns have been studied in a limited number of organic chemical exposures. A comprehensive workup is recommended when assessing any form of environmental toxic exposure.

porphyrin analysis may be considered as part of monitoring lead exposure in combination with blood lead levels.[10,11]

More recently, the use of urinary porphyrin profiles has been researched with respect to mercury exposure and toxicity. The bulk of this scientific exploration is attributed to Dr. James Wood's work at the Department of Environmental Health at the University of Washington.[12–19] In multiple animal and human studies, a pattern of porphyrin excretion was detected as a result of mercury exposure (Table 30.2). A statistically significant increase was seen in the excretion of three discrete porphyrins: coproporphyrin, pentacarboxylporphyrin, and an atypical porphyrin they referred to as precoproporphyrin.[12,13,15,19,20] This atypical porphyrin would later be renamed keto-isocoproporphyrin.[21,22] This pattern correlated with the dose and timing of mercury exposure. These three porphyrins were also elevated in dentists routinely exposed to mercury vapors, specifically in dentists with higher urinary mercury excretion.[19] Interestingly, in another study involving dentists, these three porphyrins were also significantly decreased after chelation therapy.[13] One study of dentists found that porphyrin excretion was better correlated with clinical symptoms associated with mercury toxicity than urine mercury levels.[23] Ultimately, a few published articles claimed that this porphyrin pattern was a useful biomarker for assessing the total body burden of mercury.[24–26] Additionally, these researchers suggested that porphyrin profiling may be more reliable than urine mercury testing for detecting subclinical mercury exposure correlating with the toxic neurological effects.[20,24]

Altered urinary porphyrin excretion has been documented in other environmental toxic exposures, such as arsenic,[27–31] cadmium, organic chemicals,[6] and alcohol,[32] and in combinations of multiple toxic exposures.[33] Many other toxicants may play a role in porphyrinuria and need further investigation. Although urinary porphyrin excretion appears to consistently correlate with toxic metal exposure, the degree to which an individual's detoxification capacity plays a role in susceptibility to toxins is still under investigation.[17,34] It may ultimately be determined that both increased environmental exposure and reduced detoxification contribute to the degree of heme-pathway disruption.

CLINICAL APPLICATIONS OF PORPHYRINURIA

Porphyrin profiles have been used clinically in assessing certain patient populations. The most recent intrigue regarding porphyrin assessment is in autism. Investigation into risk factors that might contribute to the rise in autism over recent years led to concern about the role mercury exposure plays in autism pathogenesis.[35–38] As more research began to implicate mercury exposure as a plausible factor in the development of autism spectrum disorders (ASDs), porphyrin testing was used as a noninvasive and independent method for assessing exposure.[39] Indeed, several studies of autism patients showed significant porphyrin excretion compared with controls, often corresponding to the porphyrin patterns characteristic of mercury exposure.[40] These results were replicated across multiple continents.[41,42] Clinically, porphyrin profiles are still used in this patient population to assess toxic metal body burden. However, reduced detoxification capacity and increased oxidative stress have also been suspected in autism.[43–45] Therefore the multifactorial nature of childhood neurobehavioral disorders should be strongly emphasized.[46] Reduction in porphyrin excretion after chelation therapy, along with emerging evidence surrounding mercury, ASD, and heme disturbances, makes porphyrin profiling an important clinical tool.[14,29,47]

Aside from managing autism and toxic exposures, the association between oxidative stress and porphyrin excretion is clinically significant. Knowing the amount of oxidative stressors the average patient encounters daily, clinicians must consider the role these exposures play in other chronic health complaints. With the growing understanding of genetic individuality and variation, porphyrin excretion may provide a window into genetic susceptibility to oxidative stress.[17] Further studies are needed to evaluate these roles in various patient populations, such as neurological disorders,[48] malignancy,[49] and mood disorders, to name a few.

CONCLUSION

Urine porphyrin profiling can be a noninvasive and valuable tool for chronic disease assessment and management. There is compelling evidence that environmental exposure, whether severe or nascent, has the potential to be a major contributing factor in the pathogenesis of chronic illness. Specific toxicants may also demonstrate unique patterns of porphyrin excretion because eof specific heme-synthesis enzyme abnormalities. Often, the difficulty in clinically assessing toxicity is the degree to which these toxins are stored in tissues rather than in the circulation, making it difficult to assess the total body burden. Because heme synthesis takes place in specific tissues (predominantly bone, kidney, and the liver), tissue toxins may affect heme synthesis, leading to porphyrinuria. It should be noted that many common medications can affect the heme pathway. Further studies are warranted to elucidate the triggers leading to altered urine porphyrin levels. Therefore clinical correlation and discretion are important when interpreting any given test result.

Finally, care and expertise should be applied in the management of environmental exposure and toxicity. The primary approach is the identification and removal of ongoing exposures. In addition to the physical examination, a thorough exposure history, combined with a well-designed environmental questionnaire, can help identify toxic triggers. Second, intake of antioxidant-rich nutrients and vitamins helps increase detoxification and elimination. Last, ensuring optimal detoxification via gastrointestinal elimination, appropriate skin care, and sweat depuration therapy goes a long way toward toxin removal.

31

Urine Indican Test (Obermeyer Test)

Dirk W. Powell, BS, ND

OUTLINE

INTRODUCTION

An increased level of urinary indican indicates bacterial dysbiosis or small intestine bacterial overgrowth (SIBO). Indole is produced when tryptophan, an essential amino acid, is converted to *2,3-benzopyrrole* by intestinal bacterial cleavage of the tryptophan side chain. The indole produced in the small intestine is mostly excreted in feces, but some is also absorbed into the systemic circulation.

Indole that is absorbed from the small intestine is converted to indican (*1H-indol-3-ol hydrogen sulfate ester*) in the liver. Indican is conjugated with potassium sulfate or glucuronic acid. After reentering the general circulation, indican is then excreted by the kidneys, and the concentration of indican can be measured in the urine (Fig. 31.1).

CLINICAL APPLICATION

Because most of the endogenous indoles have a side chain that prevents cleavage and are metabolized to skatole, the production of indicans (indoxyl potassium sulfate and indoxyl glucuronate) reflects bacterial activity in the gastrointestinal tract, particularly in the small intestine. Table 31.1 lists conditions where increased levels of indican are found.[1-4] Elevated levels of indican are considered an indicator of the overgrowth of anaerobic bacteria in the small intestine, impaired protein digestion, or excess protein (tryptophan) ingestion.

Procedure

The detection of indican depends on its oxidation to indigo blue by Obermeyer reagent and then the concentration of the indigo blue in a layer of chloroform for measurement.

Method

1. Place 5 mL of fresh urine in a test tube.
2. Add 5 mL of Obermeyer reagent.
3. Mix.
4. Add 2 mL of chloroform and invert several times.
5. Allow the chloroform to settle and observe.
6. The results are then rated by the color present in the chloroform layer.

The Obermeyer test requires the use of a hood to exhaust toxic fumes and caution to avoid skin contact with Obermeyer reagent.

Reagents

- Obermeyer reagent: dissolve 0.8 g ferric chloride in 100 mL concentrated hydrochloric acid (*caution:* caustic).
- Chloroform (*caution:* volatile and toxic; keep tightly capped)

Results

Most tests result in varying depths of blue, as shown in Table 31.2. However, some patients have as-yet-unidentified molecules that can modify the colors produced by this methodology. In Table 31.2, column 1 lists the ranking, column 2 shows the typical blue color, and column 3 lists color variants.

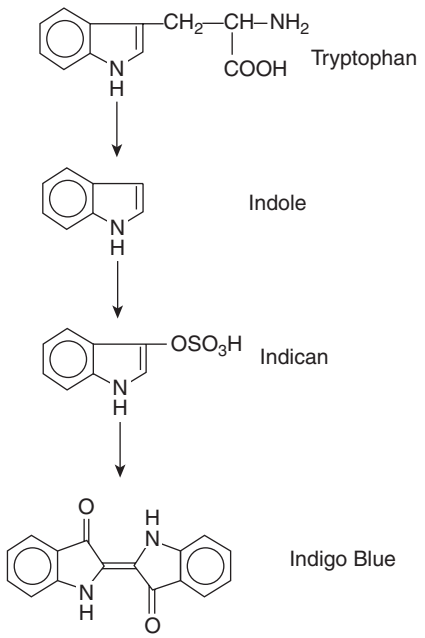

Fig. 31.1 Conversion of tryptophan to indican and indigo blue.

TABLE 31.1 Conditions Associated With Elevated Levels of Indican[1–4]

Hypochlorhydria (parietal cell dysfunction, antacids)
Pancreatic insufficiency (deficient trypsin, chymotrypsin, pepsin)
Excess protein intake
Increased GI transit time (gastroparesis, inefficient peristalsis)
Gastric ulcer or cancer
Inflammatory bowel disease
Celiac disease
Biliary and intestinal obstruction
Small intestine bacterial overgrowth
Gastrectomy or bariatric surgery
Jejunal diverticulosis
Scleroderma
Hartnup disease

GI, Gastrointestinal.

TABLE 31.2 Interpretation of Obermeyer Test Results

Toxic Level	Color	Color Variants
0		Urine color
1		Light blue or light green
2		Blue, green, or golden brown
3		Violet, indigo, or dark brown
4		Jet black

- Urine color: 0 (negative or normal)
- Light blue or light green: +1
- Blue, green, or golden brown: +2
- Violet, indigo, or dark brown: +3
- Jet black: +4

INTERPRETATION

A positive result can be associated with the disorders listed in Table 31.1, hypochlorhydria, pancreatic insufficiency, SIBO, an excessively high protein intake. The latter indication can be controlled by the institution of a diet with moderate protein (less than 60 g daily) for 2 days before testing.

CONCLUSION

The Obermeyer test is an in-office diagnostic test that can be used to identify gastrointestinal (GI) dysfunction or dysbiosis. A positive test may indicate the need for additional testing for gastrointestinal pathogens, SIBO, or altered GI function. The Obermeyer test for urine indican can be a clinically useful tool for identifying underlying causes of GI-related disorders and for optimizing GI health.

SECTION 3

Therapeutic Modalities and Practice Specialties

This section presents a historical, scientific, and clinical review of the schools of thought and modalities of natural medicine by its various names. We have compiled the work of experts in their fields into what we hope the reader will find a concise, yet useful, description of these practices, modalities, and specialties. Because of the clinically oriented and unconventional nature of these disciplines, the scientific evaluation of their theories and efficacy has been limited in the past. Happily, published research in natural medicine has increased dramatically since *A Textbook of Natural Medicine* was first published in 1985.

Although this textbook is strongly oriented to the scientific method and the use of the peer-reviewed research for documentation of the efficacy of a therapy, the widespread clinical use and long history of patient satisfaction demand that they be given far more clinical attention. Although the mechanisms of action of several have yet to be elicited, their research foundation continues to strengthen.

Acupuncture

Mark Harrison Nolting, ND, EAMP, and *John C. Reed, MD, MDiv*

OUTLINE

INTRODUCTION

This chapter presents acupuncture at a time when the practice has been increasingly recognizable and is a popular therapeutic practice around the world. Although research into the efficacy of acupuncture abounds, quality research studies that are acceptable to many in conventional medicine seem elusive. Professional skepticism of the practice of acupuncture is easy to find online. We intend for this chapter to inform and encourage the discussion of acupuncture within the current state of practice, promote understanding and consideration of the history of acupuncture, and explore the variety of practice options. Importantly, this chapter also serves as a presentation of updated research information, providing the basis for what we consider to be the availability of good evidence of efficacy.

Acupuncture needling is one of the most visual and widely practiced traditional medicine therapies in the world today.[1] Public acceptance and utilization of acupuncture as a profession and a therapeutic modality steadily increased across the globe between 1980 and 2018. In the United States, where the growth of acupuncture has been most impressive during these years, we have seen the numbers of licensed nonphysician practitioners and physician practitioners expand rapidly. In Washington State, for example, the number of acupuncture licensees jumped by 227% during the 10 years from 1997 to 2007, the most of any of the complementary and alternative (CAM) medicine practices, including chiropractic. The same report showed the growth of chiropractic licenses was only 14%, whereas that of physicians was 34%. Naturopathic physician licenses also increased considerably during the same period, by 134%.[2]

PROFESSIONAL ORGANIZATIONS

The following U.S.-based organizations were formed to guide, support, and monitor all aspects of acupuncture practice in the United States, from credentialing and professional practice to education and research:

- National Certification Commission for Acupuncture and Oriental Medicine (NCCAOM; founded in 1982): the nonprofit professional certifying agency for acupuncture and oriental medicine practice[3]
- American Association of Acupuncture and Oriental Medicine (AAAOM; founded in 1981): the largest acupuncturist professional trade organization[4]
- Council of Colleges of Acupuncture and Oriental Medicine (CCAOM; founded in 1982): the 501(c)(6) voluntary membership association for 57 acupuncture schools and programs in the United States[5]
- Accreditation Commission for Acupuncture and Oriental Medicine (ACAOM; 1989): the national organization recognized by the U.S. Department of Education to accredit acupuncture and Oriental medicine (AOM) schools and programs in the United States[6]
- American Board of Chiropractic Acupuncture (ABCA; founded in 2005): the nonprofit organization that is the sole chiropractic acupuncture credentialing organization recognized by the American Chiropractic Association[7]
- American Academy of Medical Acupuncture (AAMA; founded in 1987): the largest physician acupuncturist (MD, DO) professional trade organization[8]
- American Board of Medical Acupuncture (ABMA; founded in 2000): the nonprofit credentialing organization setting national standards in training and examination for diplomates in medical acupuncture[9]
- Society of Acupuncture Research (SAR; founded in 1993): an interprofessional organization of researchers and clinicians dedicated to improving the quality and increasing the awareness of research in acupuncture, herbal therapy, and other modalities of Oriental medicine[10]

BOX 32.1 Education

Acupuncture Training	Physician Training	Other
Licensed acupuncturist (LAc standard): • 3–4 years professional, post-bachelor's standard • 1500–2000 hours acupuncture specific • Advanced professional doctorate programs (PD and DAOM/Doctorate of Acupuncture and Oriental Medicine)	MD, DO, ND, DC: • 300 hours or less, acupuncture specific • 100 hours for chiropractic add-on	Physical therapist, nurse: • 40–50 hours of "dry needling" National Acupuncture Detox Association detoxification technicians: • 100 hours or less

TABLE 32.1 China TCM Statistics 2017

TCM professionals, total	613,000
TCM doctors	482,000
TCM interns	14,000
TCM pharmacy professionals	117,000
Acupuncture hospitals	6
TCM doctors per 10,000 population	2.69 (0.69–0.83, United States)
Chinese investment in TCM	1.7 billion yuan

TCM, Traditional Chinese medicine.

- National Acupuncture Detoxification Association (NADA; founded in 1985): a not-for-profit 501(c)(3) training and advocacy organization that encourages community wellness through the use of a standardized 5-point ear acupuncture protocol initially developed to assist in substance abuse withdrawal[11]
- American Society of Acupuncturists (ASA; founded in 2017): an umbrella organization that grew out of the informal Council of State [Acupuncture] Associations. This 501(c)(6) not-for-profit organization has 24 state associations with a total current membership of 4000. It seeks to provide resources for the promotion of professional acupuncture practitioners in their respective state practice situations.[12]

As a result of the ongoing work of these organizations, the following milestones had been achieved as of 2018[3,5,11]:

- Licensure: 47 states plus Washington, DC
- Licensed acupuncturists: estimated 25,000 to 30,000
- CCAOM schools and branches: 57
- NCCAOM diplomates since 1982: 22,000
- NADA-trained providers in 23 states

There are several types of providers who receive training in acupuncture,[3–9,11,12] as noted in Box 32.1.

On occasion, professionals such as medical doctors, naturopathic physicians, and chiropractors undergo extensive training in acupuncture, but it is more common to receive specific professional training composed of far fewer hours.

For perspective and comparative purposes, Table 32.1 provides traditional Chinese medicine (TCM) statistics from mainland China for the years 2007 and 2008. Acupuncture is considered a key component of the practice of "modern" TCM, along with herbal medicine, massage, nutrition, qigong, and health promotion.[13–19]

The World Health Organization stated in 2001 that "Chinese medicine, particularly acupuncture, is the most widely used traditional medicine. It is practiced in every region of the world."[20] Although this statement has not been revised as of 2018, there is every reason to believe that this remains true.

TERMINOLOGY

When it comes to discussing acupuncture in the context of its integration into Western health care systems, we should recognize that term *acupuncture* is ambiguous, and its meaning can differ based on its context of use. For clarification, the common different meanings of *acupuncture* are as follows:

1. Acupuncture is a physical medicine procedure involving the insertion of filiform needles into the body at specific points to effect therapeutic functional changes in nerve, connective tissue, muscular, and vascular structures and internal organ systems. Procedures that elicit these therapeutic responses through point stimulation using heat (moxibustion), pressure, laser light frequencies, sound frequencies, and electrical currents in the milli- to microampere range are best termed "acupuncture-related techniques," which can be more clearly described by adding clarifying terms, such as *electroacupuncture, sonopuncture, acupressure,* and so forth.[21]
2. Acupuncture is a multicomponent health care practice: The "practice of acupuncture" involves history taking, physical examination, diagnosis, patient education, and acupuncture procedure planning regarding point selection, stimulation intensity, and session frequency. In the practice of acupuncture, a practitioner typically incorporates other traditional or modern physical medicine interventions, such as heating of acupoints (traditional moxibustion), suction cupping, bleeding, soft tissue scraping, manual tissue and joint manipulation, electrostimulation, laser stimulation, and therapeutic exercise. The practice of acupuncture can be relevant to patient outcome goals, including goals in acute care, chronic illness care, and preventive or wellness care. The present-day theories and methods of the practice of acupuncture grew out of the health care traditions from China, Japan, Korea, and Vietnam and the dissemination of this practice through the West since the 17th century. Recent acupuncture basic science research is illuminating the biomedical correlations to aspects of acupuncture methods and practice that were previously only understood via translations of the metaphors used in the ancient Chinese acupuncture texts.[22]
3. The term *acupuncture* is used in many cases to refer to the distinct entry-level health profession that specializes in the practice of acupuncture and related techniques according to a licensed or registered scope of practice delimited by U.S. state laws. The designation of these "professional acupuncturists" varies, with the most familiar terms being licensed acupuncturist (LAc), certified acupuncturist (CA), East Asian medicine provider (EAMP), Oriental medical doctor (OMD), and doctor of acupuncture and oriental medicine (DAOM). Although the initial licensing authorities were concerned with the safety and competency of practitioners inserting needles into patients, most professional acupuncturists in the United States have been trained in East Asian traditional diagnostic and therapeutic models that are broader in scope than the traditional application of needle-based physical medicine treatments. This profession has worked to progressively expanded the legal scope of practice to reflect the practice of a comprehensive natural health care system.

In the state of California, for example, acupuncture licensure was expanded to reflect this trend within the professional acupuncturist community. "The theory and practice of acupuncture is based

on Asian medicine (also known as traditional, classical Chinese or Oriental medicine), a comprehensive natural health care system that has been in use in Asian countries for thousands of years to preserve health and diagnose, treat, and prevent illness."[23]

The practice of the California licensed acupuncture profession, according to Business and Professions Code Section 4937(b) of California, now legally includes the following: "to perform or prescribe the use of oriental massage, acupressure, breathing techniques, exercise, or nutrition, including the incorporation of drugless substances and herbs as dietary supplements to promote health."[24]

In this process of expanding the scope of practice beyond the physical medicine practice of acupuncture, the profession in Washington State redefined itself in legislation as *East Asian medical practitioners (EAMPs)*.

This expansion of the scope of professional acupuncturists beyond the clinical practice of a physical medicine–based needling procedure into a broad-based "natural medicine" scope involving herbal treatments, manual therapies, and lifestyle practices is likely a result of two factors: first, the perceived need among the public for more personalized, "natural," and gentler health services than those of typical biomedicine; and second, the creation of TCM as an organized diagnostic and treatment practice style in the modern Peoples Republic and the resulting export of TCM as the principal type of diagnosis and treatment approach taught in U.S. acupuncture programs and colleges. The TCM style is most compatible with the use of herbal treatments for internal medicine problems and with the use of needling as an adjunct therapy. For clarity, there are many styles of acupuncture practice. In Japan, for example, traditional Japanese medicine includes the acupuncture practitioners who use needles, moxa, and other tools to deal with the physical medicine aspects of health and illness and includes the 10,000+ regular medical doctors who use Kampo medicines (standardized herbal formulae) to complement pharmaceutical drugs and diet and lifestyle intervention for the care of internal medicine health problems.[25]

In November 1997, the National Institutes of Health (NIH) convened a consensus development conference on the subject of acupuncture. After discussion among a board of experts, the following working definition was included in the NIH Consensus Statement:

> *Acupuncture describes a family of procedures involving stimulation of anatomical locations on the skin by a variety of techniques. There are a variety of approaches to diagnosis and treatment in American acupuncture, which incorporates medical traditions from China, Japan, Korea, and other countries. The most studied mechanism of stimulation of acupuncture points employs penetration of the skin by thin, solid, metallic needles, which are manipulated manually or by electrical stimulation.*[26]

The NIH conference has had a lasting positive effect on the growth of acupuncture in the United States. The definitions and recommendations for further research have sparked wider acceptance within the medical profession and promoted the consensus that acupuncture as a procedure and as a mode of practice is ready to be incorporated into the education, research, and practice schemes of Western medicine. Because of the increasing basic and clinical research in acupuncture, the NIH conference documents kept the NIH definition of the practice of American acupuncture within definition levels 1 and 2 in the previous list. It did not include the diagnostic and therapeutic practices of TCM herbal internal medicine as part of the necessary model of "acupuncture practice."

We describe acupuncture and related physical medicine techniques as a standalone health care practice and also discuss the types of licensed providers who currently offer it within their scope of practice, including the LAc providers of East Asian natural medicine, the medical and osteopathic physicians, the chiropractic and naturopathic physicians, the physical therapists, and the drug detox technicians. All of these providers have been contributing to the dissemination of acupuncture throughout the health care system and to its accessibility to the general public. This chapter describes the various styles of acupuncture practice and the evidence-informed clinical applications of acupuncture so that readers will be better informed about effective clinical referrals based on patients' needs and desires.

CLINICAL APPLICATIONS

The clinical applications of acupuncture can be divided into three areas: biomechanical medicine, internal medicine, and mind–body medicine.

Biomechanical medicine refers to approaches that improve or restore the structure and functions of the muscles, nerves, connective tissue, ligaments, and bones that support pain-free movement and resilience to mechanical stress. Examples include low back pain, joint strains, radiculopathies, and sports injuries.

Internal medicine refers to disorders of internal organ systems and the neuroendocrine regulation of the body; examples are migraine headaches, diabetes, constipation, and infertility.

Mind–body medicine refers to psychological and emotional disorders ranging from stress reactions to anxiety, depression, cognitive dysfunction, and interpersonal and social adjustment disorders.

THEORY AND PRACTICE STYLES
