CUMBERLAND, **CUMBRIA**, so denominated from the *Cumbri* or Britons who inhabited it; one of the most northerly counties in England. It was formerly a kingdom extending from the vallum of Adrian to the city of Dumbrinton, now Dumbarton, on the frith of Clyde in Scotland. At present it is a county of England, which gives the title of *duke* to one of the royal family, and sends two members to parliament. It is bounded on the north and north-west by Scotland; on the south and south-east by part of Lancashire and Westmoreland; it borders on the east with Northumberland and Durham; and on the west is washed by the Irish sea. The length from north to south may amount to 55 miles, but the breadth does not exceed 40. It is well watered with rivers, lakes, and fountains; but none of its streams are navigable. In some places there are very high mountains. The air is keen and piercing on these mountains towards the north; and the climate is moist, as in all hilly countries. The soil varies with the face of the country; being barren on the moors and mountains, but fertile in the valleys and level ground bordering on the sea. In general the eastern parts of the shire are barren and desolate; yet even the least fertile parts are rich in metals and minerals. The mountains of Copland abound with copper: veins of the same metal, with a mixture of gold and silver, were found in the reign of queen Elizabeth among the fells of Derwent; and royal mines were formerly wrought at Kewick. The county produces great quantities of coal, some lead, abundance of the mineral earth called *black-lead*, several mines of lapis calaminaris; and an inconsiderable pear-fishery on the coast near Raven-glass.

CUMBERLAND (Richard), a very learned English divine in the latter end of the 17th century, was son of a citizen of London, and educated at Cambridge. In 1672, he published his excellent Treatise of the Laws of Nature; and in 1686, An Essay toward the Jewish

land.

Cuminum
||
Cuniculus.

Jewish Weights and Measures. After the revolution he was nominated by king William to the bishopric of Peterborough, without the least solicitation on his part. He pursued his studies to the last; and the world is obliged to him for clearing up several difficulties in history, chronology, and philosophy. After the age 83, he applied himself to the study of the Coptic language, of which he made himself master. He was as remarkable for humility of mind, benevolence of temper, and innocence of life, as for his extensive learning. He died in 1718.

CUMINUM, CUMIN: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order, *Umbellatæ*. The fruit is ovate and striated; there are four partial umbels, and the involucre are quadrifid. There is but one species, viz. the cuminum. It is an annual plant, perishing soon after the seed is ripe. It rises 9 or 10 inches high in the warm countries where it is cultivated; but seldom rises above four in Britain. It has sometimes flowered very well here but never brings its seeds to perfection. The leaves are divided into long narrow segments, like those of fennel, but much smaller: they are of a deep green, and generally turned backward at their extremity: the flowers grow in small umbels at the top of the stalks: they are composed of five unequal petals, of a pale bluish colour, which are succeeded by long, channelled, aromatic seeds. The plant is propagated for sale in the island of Malta. In Britain the seeds must be sown in small pots, and plunged in a very moderate hot-bed to bring up the plants. These, after, having been gradually inured to the open air, turned out of the pots, and planted in a warm border of good earth, preserving the balls of earth to their roots, will flower pretty well, and may perhaps even perfect a few seeds in warm seasons. These seeds have a bitterish warm taste, accompanied with an aromatic flavour, not of the most agreeable kind. They are accounted good carminatives; but not very often made use of. An essential oil of them is kept in the shops.

CUNÆUS (Peter), born in Zealand, in 1586, was distinguished by his knowledge in the learned languages, and his skill in the Jewish antiquities. He also studied law, which he taught at Leyden, in 1615; and read politics there till his death, in 1638. His principal work is a treatise, in Latin, on the republic of the Hebrews.

CUNEIFORM, in general an appellation given to whatever resembles a wedge.

CUNEIFORM-Bone, in anatomy, the seventh bone of the cranium, called also *os basilare*, and *os sphenoides*. See ANATOMY, n^o 16.

CUNEUS, in antiquity, a company of infantry drawn up in form of a wedge, the better to break through the enemy's ranks.

CUNICULUS, in zoology, See LEPUS.

CUNICULUS, in mining, a term used by authors in distinction from *puteus*, to express the several sorts of passages and cuts in these subterranean works. The *cuniculi* are those direct passages in mines where they walk on horizontally; but the *putei* are the perpendicular cuts or descents. The miners in Germany call these by the name *stollen*, *schachts*; the the first word

expressing the horizontal, and the second the perpendicular cuts.

CUNILA, in botany: A genus of the monogynia order, belonging to the monandria class of plants; and in the natural method ranking under the 42d order, *Verticillatæ*. The corolla is ringent, with its upper lip erect and plane; there are two filaments, castrated, or wanting antheræ; the seeds are four. There are three species, none of which has any remarkable property.

CUNINA, in mythology, a goddess who had the care of little children.

CUNITZ (Mary), one of the greatest geniuses in the 16th century, was born in Silesia. She learned languages with amazing facility; and understood Polish, German, French, Italian, Latin, Greek, and Hebrew. She attained a knowledge of the sciences with equal ease: she was skilled in history, physic, poetry, painting, music, and playing upon instruments; and yet these were only an amusement. She more particularly applied herself to the mathematics, and especially to astronomy, which she made her principal study, and was ranked in the number of the most able astronomers of her time. Her Astronomical Tables acquired her a prodigious reputation: she printed them in Latin and German, and dedicated them to the emperor Ferdinand III. She married Elias de Lewin, M. D.; and died at Pistehen, in 1664.

CUNNINGHAM, one of the four bailiwicks in Scotland; and one of the three into which the shire of Air is subdivided. It lies north-east of Kyle. Its chief town is Irvin.

CUNNINGHAM (Alexander), author of a History of Great Britain from the revolution to the accession of George I. was born in the south of Scotland about the year 1654, in the regency of Oliver Cromwell. His father was minister at Ettrick, in the presbytery and shire of Selkirk. He was educated, as was the custom among the Scottish presbyterian gentlemen of those times, in Holland; where he imbibed his principles of government, and lived much with the English and Scots refugees at the Hague before the revolution; particularly with the earls of Argyle and Sunderland. He came over to England with the prince of Orange, and enjoyed the confidence and intimacy of many leading men among the whig party, that is, the friends and abettors of king William and the revolution. He was employed at different times, in the character of a travelling companion or tutor; first, to the earl of Hyndford, and his brother Mr William Carmichael, solicitor general, in the reign of queen Anne, for Scotland; secondly, with the lord Lorne, afterwards so well known under the name of *John duke of Argyle*; and thirdly, with the lord viscount Londale. In his travels, we find him, at the German courts, in company with the celebrated Mr Joseph Addison, whose virtues he celebrates, and whose fortune, like that of our author, compelled him to.

“ ————become for hire,
“ A travel'ing tutor to a squire.”

Lord Lorne, at the same time was under the tuition of Mr Cunningham, though not seventeen years of age, was colonel of a regiment, which his father, the earl

Cunila

Cunningham.

Cunning-
ham.

of Argyle, had raised for his majesty's service in Flanders. Mr Cunningham's connection with the duke of Argyle, with whom he had the honour of maintaining an intimacy as long as he lived, together with the opportunities he enjoyed of learning, in his travels, what may be called *military geography*, naturally tended to qualify him for writing intelligibly on military affairs.

Mr Cunningham, both when he travelled with the noblemen abovementioned, and on other occasions, was employed by the English ministry in transmitting secret intelligence to them on the most important subjects. He was also, on sundry occasions, employed by the generals of the confederate armies, to carry intelligence, and to make representations to the court of Britain. In Carstairs's State-papers, published by Dr Macornick principal of the united college of St Andrew's in 1774, there are two letters from our author, dated Paris the 22d and 26th of August 1701, giving an account of his conferences with the marquis de Torey, the French minister, relative to the Scots trade with France. This commercial negotiation, from the tenor of Cunningham's letters compared with his history, appears to have been the only ostensible object of his attention; for he sent an exact account to king William, with whom he was personally acquainted, of the military preparations throughout all France.

Mr Cunningham's political friends, Argyle, Sunderland, Sir Robert Walpole, &c. on the accession of George I. sent him as British envoy to the republic of Venice. He arrived in that city in 1715; and continued there, in the character of resident, till the year 1720, when he returned again to London. He lived many years after, which he seems chiefly to have passed in a studious retirement. In 1735, he was visited in London by lord Hyndford, by the direction of his lordship's father, to whom he had been tutor, when he appeared to be very old. He seems to have lived about two years after; for the body of an Alexander Cunningham lies interred in the vicar chancel of St Martin's church, who died in the 83d year of his age, on the 15th day of May 1737; and who was probably the same person.

His "History of Great Britain, from the revolution in 1688 to the accession of George I." was published in two volumes 4to, in 1787. It was written by Mr Cunningham in Latin, but was translated into English by the reverend William Thomson, L. L. D. The original manuscript came into the possession of the reverend Dr Hollingberry, archdeacon of Chichester, some of whose relations had been connected with the author. He communicated it to the earl of Hardwicke, and to the reverend Dr Douglas now bishop of Carlisle, both of whom recommended the publication. In a short preface to the work, the archdeacon says, "My first design was to have produced it in the original; but knowing how few are sufficiently learned to understand, and how many are indisposed to read two quarto volumes in Latin, however interesting and entertaining the subject may be, I altered my purpose, and intended to have sent it into the world in a translation. A nervous fever depriving me of the power, defeated the scheme." But he afterwards transferred the undertaking to Dr Thomson; and Dr Holling-

berry observes, that Dr Thomson "has expressed the sense of the author with fidelity." The work was undoubtedly well deserving of publication. It contains the history of a very interesting period, written by a man who had a considerable degree of authentic information, and his book contains many curious particulars, not to be found in other histories. His characters are often drawn with judgment and impartiality: at other times they are somewhat tinged with prejudice. This is particularly the case with respect to bishop Burnet, against whom he appears to have conceived a strong personal dislike. But he was manifestly a very attentive observer of the transactions of his own time; his work contains many just political remarks; and the facts which he relates are exhibited with great perspicuity and often with much animation. Throughout his book he frequently intersperses some account of the literature, and of the most eminent persons of the age concerning which he writes; and he has also adorned his work with many allusions to the classics and to ancient history.

Alexander Cunningham, the author of the history of Great Britain, has been supposed to be the same person with Alexander Cunningham who published an edition of Horace at the Hague, in two volumes 8vo, in 1721, which is highly esteemed. But from the best information we have been able to collect, they were certainly different persons; though they were both of the same name, lived at the same time, had both been travelling tutors, were both said to have been eminent for their skill at the game of chess, and both lived to a very advanced age. The editor of Horace is generally said to have died in Holland, where he taught both the civil and canon laws, and where he had collected a very large library, which was sold in that country.

CUNUS, in anatomy, the *pubendum muliebre*, or the anterior parts of the genitals of a woman, including the *labia pudendi* and *mons veneris*.

CUNOCEPHALI, in mythology, (from *κυν*, "dog." and *κεφαλη*, "head,"), a kind of baboons, or animals with heads like those of dogs, which were wonderfully endowed, and were preserved with great veneration by the Egyptians in many of their temples. It is related that by their assistance the Egyptians found out the particular periods of the sun and moon; and that one half of the animal was often buried, while the other half survived; and that they could read and write. This strange history, Dr Bryant imagines, relates to the priests of Egypt, styled *cahen*, to the novices in their temples, and to the examinations they were obliged to undergo, before they could be admitted to the priesthood. The Egyptian colleges were situated upon rocks or hills, called *caph*, and from their consecration to the sun, *caph-el*; whence the Greeks deduced *κεφαλη*, and from *cahen-caph-el* they formed *κυνοκεφαλος*. So that *cahen-caph-el* was some royal feminary in Upper Egypt, whence they drafted novices to supply their colleges and temples. By this etymology he explains the above history. The death of one part, while the other survived, denoted the regular succession of the Egyptian priesthood. The *cunocephali* are also found in India and other parts of the world. These and the *acephali* were thus denominated from their place of residence and from their worship.

Cunning-
ham

Cunoce-
phali.

Cunodontes

Cupel.

CUNODONTES, a people mentioned by Solinus and Isidorus, and by them supposed to have the teeth of dogs. They were probably denominated, says Dr Bryant, from the object of their worship, the deity Chan-Adon, which the Greeks expressed *Kunodav*, and thence called his votaries *Cunodontes*.

CUNONIA, in botany: A genus of the digynia order, belonging to the decandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous; the calyx pentaphyllous; the capsule bilocular, acuminate, polyspermous; the styles longer than the flower.

CUOGOLO, in natural history, the name of a stone much used by the Venetians in glass-making, and found in the river Fesino. It is a small stone of an impure white, of a shattery texture, and is of the shape of a pebble.

CUP, a vessel of capacity of various forms and materials, chiefly to drink out of. In the Ephem. German. we have a description of a cup made of a common pepper-corn by Oswald Nerlinger, which holds 1200 other ivory cups, having each its several handle, all gilt on the edges; with room for 400 more.

CUP, in botany. See **CALYX**.

CUP-Galls, in natural history, a name given by authors to a very singular kind of galls found on the leaves of the oak and some other trees. They are of the figure of a cup, or drinking-glass without its foot, being regular cones adhering by their point or apex to the leaf; and the top or broad part is hollowed a little way, so that it appears like a drinking-glass with a cover, which was made so small as not to close it at the mouth, but fall a little way into it. This cover is flat, and has in the centre a very small protuberance, resembling the nipple of a woman's breast. This is of a pale green, as is also the whole of the gall, excepting only its rim that runs round the top: this is of a scarlet colour, and that very beautiful. Besides this species of gall, the oak leaves furnish us with several others, some of which are oblong, some round, and others flatted; these are of various sizes, and appear on the leaves at various seasons of the year. They all contain the worm of some small fly; and this creature passes all its changes in this its habitation, being sometimes found in the worm, sometimes in the nymph, and sometimes in the fly-state, in the cavity of it.

CUPANIA, in botany: A genus of the adelphia order, belonging to the monœcia class of plants; and in the natural method ranking under the 28th order, *Tricocca*. The calyx of the male is triphyllous; the corolla pentapetalous; the stamina five. The calyx of the female triphyllous; the corolla tripetalous; the style triid; and a pair of seeds. There is but one species, a native of America, and which possesses no remarkable property.

CUPEL, in metallurgy, a small vessel which absorbs metallic bodies when changed by fire into a fluid scoria; but retains them as long as they continue in their metallic state. One of the most proper materials for making a vessel of this kind is the ashes of animal bones; there is scarcely any other substance which so strongly resists vehement fire, which so readily imbibes metallic scoriæ, and which is so little disposed to

be vitrified by them. In want of these, some make use of vegetable ashes, freed by boiling in water from their saline matter, which would cause them melt in the fire.

The bones, burnt to perfect whiteness, so as that no particle of coaly or inflammable matter may remain in them, and well washed from filth, are ground into moderately fine powder; which, in order to its being formed into cupels, is moistened with just as much water as is sufficient to make it hold together when strongly pressed between the fingers; some direct glutinous liquids, as whites of eggs or gum-water, in order to give the powder a greater tenacity; but the inflammable matter, however small in quantity, which accompanies these fluids, and cannot be easily burnt out from the internal part of the mass, is apt to revive a part of the metallic scoria that has been absorbed, and to occasion the vessel to burst or crack. The cupel is formed in a brass ring, from three quarters of an inch to two inches diameter, and not quite so deep, placed upon some smooth support: the ring being filled with moistened powder, which is pressed close with the fingers; a round-faced pestle, called a *monk*, is struck down into it with a few blows of a mallet, by which the mass is made to cohere, and rendered sufficiently compact, and a shallow cavity formed in the middle: the figure of the cavity is nearly that of a sphere, that a small quantity of metal melted in it may run together into one bead. To make the cavity the smoother, a little of the same kind of ashes levigated into an impalpable powder, and not moistened, is commonly sprinkled on the surface, through a small fine sieve made for this purpose, and the monk again struck down upon it. The ring or mould is a little narrower at bottom than at top; so that by pressing it down on some of the dry powder spread upon a table, the cupel is loosened, and forced upwards a little; after which it is easily pushed out with the finger, and is then set to dry in a warm place free from dust.

CUPELLATION, the act of refining gold or silver by means of a cupel. For this purpose another vessel, called a *muffle*, is made use of, within which one or more cupels are placed. The muffle is placed upon a grate in a proper furnace, with its mouth facing the door, and as close to it as may be. The furnace being filled up with fuel, some lighted charcoal is thrown on the top, and what fuel is afterwards necessary is supplied through a door above. The cupels are set in the muffle; and being gradually heated by the successive kindling of the fuel, they are kept red-hot for some time, that the moisture which they strongly retain may be completely dissipated: for if any vapours should issue from them after the metal is put in, they would occasion it to sputter, and a part of it to be thrown off in little drops. In the sides of the muffle are some perpendicular slits, with a knob over the top of each, to prevent any small pieces of coals or ashes from falling in. The door, or some apertures made in it being kept open, for the inspection of the cupels, fresh air enters into the muffle, and passes off through these slits: by laying some burning charcoal on an iron plate before the door, the air is heated before its admission; and by removing the charcoal or supply-

Cupel,
Cupella-
tion.

Cupella-
tion.

ing more, the heat in the cavity of the muffle may be somewhat diminished or increased more speedily than can be effected by suppressing or exciting the fire in the furnace on the outside of the muffle. The renewal of the air also is necessary for promoting the scorification of the lead.

The cupel being of a full red heat, the lead cast into a smooth bullet, that it may not scratch or injure the surface, is laid lightly in the cavity: it immediately melts; and then the gold or silver to be cupelled are cautiously introduced either by means of a small iron ladle or by wrapping them in paper, and dropping them on the lead with a pair of tongs. The quantity of lead should be at least three or four times that of the fine metal: but when gold is very impure, it requires 10 or 12 times its quantity of lead for cupellation. It is reckoned that copper requires for its scorification about 10 times its weight of lead; that when copper and gold are mixed in equal quantities, the copper is so much defended by the gold as not to be separable with less than 20 times its weight of lead; and that when copper is in very small proportion, as a 20th or 30th part of the gold or silver, upwards of 60 parts of lead are necessary for one of the copper. The cupel must always weigh at least half as much as the lead and copper; for otherwise it will not be sufficient for receiving half the scoria: there is little danger, however, of cupels being made too small for the quantity of a gold assay.

The mixture being brought into thin fusion, the heat is to be regulated according to the appearances; and in this consists the principal nicety in the operation. If a various coloured skin rises to the top, which liquefying, runs off to the sides, and is there absorbed by the cupel, visibly staining the parts it enters; if a fresh scoria continually succeeds, and is absorbed nearly as fast as it is formed, only a fine circle of it remaining round the edge of the metal; if the lead appears in gentle motion, and throws up a fume a little way from its surface; the fire is of the proper degree, and the process goes on successfully.

Such a fiery brightness of the cupel as prevents its colour from being distinguished, and the fumes of the lead rising up almost to the arch of the muffle, are marks of too strong a heat: though it must be observed, that the elevation of the fumes is not always in proportion to the degree of heat; for if the heat greatly exceeds the due limits, both the fumes and ebullition will entirely cease. In these circumstances the fire must necessarily be diminished: for while the lead boils and smokes vehemently, its fumes are apt to carry off some part of the gold; the cupel is liable to crack from the hasty absorption of the scoria, and part of the gold and silver is divided into globules, which lying discontinued on the cupel after the process is finished, cannot easily be collected: if there is no ebullition or fumes, the scorification does not appear to go on. Too weak a heat is known by the dull redness of the cupel; by the fume not rising from the surface of the lead; and the scoria like bright drops in languid motion, or accumulated, or growing consistent all over the metal. The form of the surface affords also an useful mark of the degree of heat; the stronger the fire, the more convex is the surface; and the weaker, the more flat: in this point, however, regard must be

had to the quantity of metal; a large quantity being always flatter than a small one in an equal fire.

Towards the end of the process, the fire must be increased; for greatest part of the fusible metal lead being now worked off, the gold and silver will not continue melted in the heat that was sufficient before. As the last remains of the lead are separating, the rainbow colours on the surface become more vivid, and variously intersect one another with quick motions. Soon after, disappearing all at once, a sudden luminous brightness of the button of gold and silver shows the process to be finished. The cupel is then drawn forwards towards the mouth of the muffle; and the button, as soon as grown fully solid, taken out.

CUPPELLING FURNACE. See *Cupelling-FURNACE*.

CUPID, in pagan mythology, the god of love. There seem to have been two Cupids; one the son of Jupiter and Venus, whose delight it was to raise sentiments of love and virtue; and the other the son of Mars and the same goddess, who inspired base and impure desires. The first of these, called Eros, or true love, bore golden arrows, which caused real joy, and a virtuous affection; the other, called Anteros, had leaden arrows that raised a passion founded only on desire, which ended in satiety and disgust. Cupid was always drawn with wings, to represent his inconstancy; and naked, to show that he has nothing of his own. He was painted blind, to denote that love sees no fault in the object beloved; and with a bow and quiver of arrows, to show his power over the mind. Sometimes he is placed between Hercules and Mercury, to show the prevalence of eloquence and valour in love; and at others is placed near Fortune, to signify that the success of lovers depends on that inconstant goddess. Sometimes he is represented with an helmet on his head and a spear on his shoulder, to signify that love disarms the fiercest men; he rides upon the backs of panthers and lions, and uses their manes for a bridle, to denote that love tames the most savage beasts. He is likewise pictured riding upon a dolphin, to signify that his empire extends over the sea no less than the land.

CUPOLA, in architecture, a spherical vault, or the round top of a dome of a church, in the form of a cup inverted.

CUPPING, in surgery, the operation of applying cupping-glasses for the discharge of blood and other humours by the skin. See *SURGERY*.

CUPRESSUS, the CYPRESS-TREE: A genus of the monadelphia order, belonging to the monœcia class of plants; and in the natural method ranking under the 51st order, *Coniferae*. The male calyx is a scale of the catkin; there is no corolla; the antheræ are four, sessile, and without filaments. The calyx of the female is a scale of the strobilus, and uniflorous; instead of styles there are hollow dots; the fruit is an angulated nut. There are six species; the most remarkable are the following: 1. The sempervirens, with an upright straight stem, closely branching all around, almost from the bottom upwards, into numerous quadrangular branches; rising in the different varieties from 15 to 40 or 50 feet in height, and very closely garnished with small, narrow, erect evergreen leaves, placed imbricatum; and flowers and fruit from the sides of the branches. 2. The thvoides,

Cupelling
||
Cupressus.

Cupressus, thyoides, or evergreen American cypress, commonly called white cedar, hath an upright stem, branching out into numerous two edged branches, rising 20 or 30 feet high, ornamented with flat ever-green leaves imbricated like arbor vitæ, and small blue cones the size of juniper-berries. 3. The disticha, or deciduous American cypress, hath an erect trunk, retaining a large bulk, branching wide and regular; grows 50 or 60 feet high, fully garnished with small, spreading deciduous leaves, arranged distichous, or along two sides of the branches. All these species are raised from seeds, and will sometimes also grow from cuttings; but those raised from seeds prove the handsomest plants. The seeds are procured in their cones from the seedsmen, and by exposing them to a moderate heat, they readily open, and discharge the seeds freely. The season for sowing them is any time in March; and they grow freely on a bed or border of common light earth: especially the first and third species. The ground must then be dug, well broken, and raked smooth, then drawing an inch of earth evenly from off the surface into the alley, sow the seeds moderately thick, and directly sift the earth over them, half an inch deep. If in April and May the weather proves warm and dry, a very moderate watering will now and then be necessary, and the plants will rise in six or eight weeks. During the summer they must be kept clear from weeds, and in dry weather they must be gently watered twice a-week. In winter they must be occasionally sheltered with mats in the time of hard frost. In two years they will be fit for transplanting from the seed-bed, when they may be set in nursery-rows two feet asunder; and in three or four years they will be fit for the shrubbery.

The wood of the first species is said to resist worms, moths, and putrefaction, and to last many centuries. The coffins in which the Athenians were wont to bury their heroes were made, says Thucydides, of this wood; as were likewise the chests containing the Egyptian mummies. The doors of St Peter's church at Rome were originally of the same materials. These, after lasting upwards of 600 years, at the end of which they did not discover the smallest tendency to corruption, were removed by order of pope Eugenius IV. and gates of brass substituted in their place. The same tree is by many eminent authors recommended as improving and meliorating the air by its balsamic and aromatic exhalations; upon which account many ancient physicians of the eastern countries used to send their patients who were troubled with weak lungs to the island of Candia, where these trees grew in great abundance; and where, from the salubrious air alone, very few failed of a perfect cure. In the same island, says Miller, the cypress trees were so lucrative a commodity, that the plantations were called *dos filia*; the felling of one of them being reckoned a daughter's portion. Cypress, says Mr Pococke, is the only tree that grows towards the top of mount Lebanon, and being nipped by the cold, grows like a small oak. Noah's ark is commonly supposed to have been made of this kind of wood.

CUPRUM AMMONIACALE. See CHEMISTRY, N^o 1034. This preparation is recommended in some kinds of spasmodic diseases, given in the dose of one or two grains.

VOL. V.

CUPRUM, or COPPER. See COPPER.

CURACOA, or CURASSOW, one of the larger Antilles islands, subject to the Dutch; situated in W. Long. 68. 30. N. Lat. 12. 30. This island is little else than a bare rock, about ten leagues long and five broad; lying three leagues off the coast of Venezuela. It has an excellent harbour, but the entrance is difficult. The basin is extremely large, and convenient in every respect; and is defended by a fort skilfully constructed, and always kept in repair. The reason of forming a settlement on this barren spot was to carry on a contraband trade with the Spanish colonies on the continent; but after some time the method of managing this trade was changed. Curassow itself became an immense magazine, to which the Spaniards resorted in their boats to exchange gold, silver, vanilla, cocoa, cochineal, bark, skins, and mules for negroes, linen, silks, India stuffs, laces, spices, ribbands, quick-silver, steel, and iron-ware. These voyages, though continual, did not prevent a number of Dutch sloops from passing from Curassow to the continent. But the modern substitution of register-ships instead of galleons, has made this communication less frequent; but it will be revived whenever, by the intervention of war, the communication with the Spanish main shall be cut off. The disputes between the courts of London and Versailles also prove favourable to the trade of Curassow. At these times it furnishes provisions to the southern parts of St Domingo, and takes off all its produce. Even the French privateers, from the windward islands, repair in great numbers to Curassow, notwithstanding the distance. The reason is, that they find there all kinds of necessary stores for their vessels; and frequently Spanish, but always European goods, which are universally used. English privateers seldom cruize in these parts. Every commodity without exception, that is landed at Curassow, pays one *per cent.* port-duty. Dutch goods are never taxed higher: but those that are shipped from other European ports pay nine *per cent.* more. Foreign coffee is subject to the same tax, in order to promote the sale of that of Surinam. Every other production of America is subject only to a payment of three *per cent.*; but with an express stipulation that they are to be conveyed directly to some port belonging to the republic.

CURATE, the lowest degree in the church of England; he who represents the incumbent of a church, parson, or vicar, and officiates divine service in his stead: and in case of pluralities of livings, or where a clergyman is old and infirm, it is requisite there should be a curate to perform the cure of the church. He is to be licensed and admitted by the bishop of the diocese, or by an ordinary having episcopal jurisdiction: and when a curate hath the approbation of the bishop, he usually appoints the salary too; and in such case, if he be not paid, the curate hath a proper remedy in the ecclesiastical court, by a sequestration of the profits of the benefice; but if the curate is not licensed by the bishop, he is put to his remedy at common law, where he must prove the agreement, &c. A curate having no fixed estate in his curacy, not being instituted and inducted, may be removed at pleasure by the bishop or incumbent. But there are perpetual curates as well as temporary, who are appointed where tithes are improper, and no vicarage endowed: these are not

4 H

removeable,

Cupressus
|
Curate

Curatella removeable, and the impropietors are obliged to find them; some whereof have certain portions of the tithes settled on them. Every clergyman that officiates in a church (whether incumbent or substitute) in the liturgy is called a *curate*. Curates must subscribe the declaration according to the act of uniformity, or are liable to imprisonment, &c.

Curculio.

CURATELLA, in botany: A genus of the digynia order, belonging to the polyandria class of plants; and in the natural method ranking with those of which the order is doubtful. The calyx is pentaphyllous; the petals four; the styles two; the capsule bipartite, with the cells dispermous.

CURATOR, among the Romans, an office under the emperors, who regulated the price of all kinds of merchandize and vendible commodities in the cities of the empire. They had likewise the superintendance of the customs and tributes; whence also they were called *logistæ*.

CURATOR, among civilians, a trustee or person nominated to take care of the affairs and interests of a person emancipated or interdicted. In countries where the Roman law prevails, between the age of 14 and 24 years, minors have curators assigned them; till 14, they have tutors.

CURATOR of an University, in the United Provinces, is an elective office, to which belongs the direction of the affairs of the university; as, the administration of the revenues, the inspection of the professors, &c. The curators are chosen by the states of each province: the university of Leyden has three; the burghermasters of the city have a fourth.

CURB, in the manege, a chain of iron made fast to the upper part of the branches of the bridle in a hole called the *eye*, and running over the horse's beard. It consists of these three parts; the hook, fixed to the eye of the branch; the chain of SS's or links; and the two rings, or mailles. Large curbs, provided they be round, are always most gentle: but care is to be taken, that it rest in its proper place, a little above the beard, otherwise the bit-mouth will not have the effect that may be expected from it.

English watering bits have no curbs; the Turkish bits, called *genettes*, have a ring that serves instead of a curb. See **GENETTES**.

CURB, in farriery, is a hard and callous swelling on the hind part of the hock, attended with stiffness, and sometimes with pain and lameness. See **SPAVIN**.

CURCAS, a name given in Egypt to an esculent root, approaching to the taste and virtues of the colocasia. It is also a name used in Malabar for a small fruit of the shape and size of an hazel nut. Both these things have the credit of being strong provocatives; and it is very probable that the curcas of the East Indies may be the fruit called *bet* by Avicenna, and said to possess the same virtues. Garcias has been led into a very great error by this similarity of names and virtues; and supposes the curcas of Egypt the same with that of the East Indies.

Plate CLI.

CURCULIO, in zoology, a genus of insects belonging to the order of coleoptera. The feelers are subclavated, and rest upon the snout, which is prominent and horny. These insects are divided into the following families. 1. Those which have the rostrum longer than the thorax, and whose thighs are simple.

2. Those which have the rostrum longer than the thorax, and the thighs thicker and made for leaping.

3. Those which have the rostrum longer than the thorax and the thighs dentated. 4. Those which have dentated thighs, and a rostrum shorter than the thorax.

5. Those whose thighs are without teeth or spines, and the rostrum shorter than the thorax. There are no less than 95 species, principally distinguished by their colour.

The larvæ of the curculiones differ not from those of most coleopterous insects. They bear a resemblance to oblong soft worms. They are provided anteriorly with six scaly legs, and their head is likewise scaly. But the places where those larvæ dwell, and their transformations, afford some singularities. Some species of them, that are dreaded for the mischief they do in granaries, find means to introduce themselves, while yet small, into grains of corn, and there make their abode. It is very difficult to discover them, as they lie concealed within the grain. There they grow at leisure, enlarging their dwelling-place as they grow, at the expence of the interior meal of the grain on which they feed. Corn-lofts are often laid waste by these insects, whose numbers are sometimes so great as to devour and destroy all the corn. When the insect,

after having eat up the meal, is come to its full size, it remains within the grain, hidden under the empty husk, which subsists alone; and there transformed, it becomes a chrysalis, nor does it leave it till a perfect insect, making its way through the husk of the grain. It is no easy matter to discover by the eye the grains of corn thus attacked and hollowed out by these insects, as they outwardly appear large and full: but the condition the curculio has reduced them to, renders them much lighter: and if you throw corn infested by these insects into water, all the tainted grains will swim, and the rest sink to the bottom. Other larvæ of curculiones are not so fond of corn, but fix in the same manner on several other seeds. Beans, pease, and lentils, that are preserved dry, are liable to be spoiled by these little animals, which prey upon the inward part of the grain, where they have taken up their habitation, and do not come forth till they have completed their transformation, by breaking through the outward husk of the grain: this is discoverable by casting those grains into water; those that swim are generally perforated by the curculiones. Other species are lodged in the inside of plants. The heads of artichokes and thistles are often bored through and eaten away by the larvæ of large curculiones. Another species smaller, but singular, pierces and inwardly consumes the leaves of elms. It frequently happens that almost all the leaves of an elm appear yellow, and as it were dead towards one of their edges, while the whole remainder of the leaf is green. Upon inspecting those leaves, the dead part appears to form a kind of bag or small bladder. The two laminæ or outward pellicles of the leaf, as well above as below, are entire, but distant and separated from each other, whilst the parenchyma that lies between them has been consumed by several small larvæ of the curculio, that have made themselves that dwelling, in which they may be met with. After their transformation they come forth, by piercing the kind of bladder, and give being to a curculio that is brown, small, and hard to catch, by

Curculio.

Barbut on Insects.

reason

Curcuma reason of the nimbleness with which it leaps. The property of leaping, allotted to this single species, depends on the shape and length of its hinder legs.

||
Curetes.

CURCUMA, TURMERIC: A genus of the monogynia order, belonging to the monandria class of plants; and in the natural method ranking under the eighth order, *Scitamineæ*. It has four barren stamina, with a fifth fertile. The species are,

1. The rotunda, with a round root, hath a fleshy-jointed root like that of ginger, but round; which sends up several spear-shaped oval leaves, which rise upwards of a foot high, and of a sea green colour. From between these arises the flower-stalk, supporting a loose spike of flowers of a pale-yellowish colour, inclosed in several different spathæ, or sheaths, which drop off. The flowers are never succeeded by seeds in Britain. 2. The longa, hath long fleshy roots of a deep yellow colour, which spread under the surface of the ground like those of ginger; they are about the thickness of a man's finger, having many round knotty circles, from which arise four or five large spear-shaped leaves, standing upon long foot-stalks. The flowers grow in loose scaly spikes on the top of the foot-stalks, which arise from the larger knobs of the roots, and grow about a foot high; they are of a yellowish red colour, and shaped somewhat like those of the Indian reed.

These plants grow naturally in India, from whence the roots are brought to Europe for use. They are very tender; so will not live in Britain unless kept constantly in a stove. They are propagated by parting the roots. The root communicates a beautiful but perishable yellow dye, with alum, to woollen, cotton, or linen. In medicine it is esteemed aperient and emmenagogic; and of singular efficacy in the jaundice.

CURDISTAN, a country of Asia, seated between the Turkish empire and Persia, lying along the eastern coast of the river Tigris, and comprehends great part of the ancient Assyria. Some of the inhabitants live in towns and villages, and others rove from place to place, having tents like the wild Arabs, and are also robbers like them. Their religion is partly Christian, and partly Mahometanism; but they are very loose in regard to either.

CURDLING, the coagulating or fixing of any fluid body; particularly milk. See the article **CHEESE**.

Pausanias says, that Aristæus son of Apollo, and Cyrene daughter of the river Peneus, were the first who found the secret of curdling milk.

At Florence they curdle their milk for the making of cheese with artichoke flowers; in lieu of the rennet used for the same purpose among us.

The Bisaltæ, a people of Macedonia, Rochfort observes, live wholly upon curdled milk, *i. e.* on curds. He adds, that curds are the whole food of the people of Upper Auvergne in France, and whey their only drink.

CURETES, in antiquity, a sort of priests or people of the isle of Crete, called also *Corybantes*. See **CORYBANTES** and **CRETE**. The Curetes are said to have been originally of mount Ida in Phrygia; for which reason they were also called *Idæi Dactyli*. See **DACTYLI**

Lucian and Diodorus Siculus represent them as very expert in casting of darts; though other authors give them no weapons but bucklers and pikes: but all agree in furnishing them with tabors and castanets; and relate that they used to dance much to the noise and clashing thereof. By this noise, it is said, they prevented Saturn from hearing the cries of young Jupiter, whereby he was saved from being destroyed.

Some authors, however, give a different account of the Curetes. According to Pezron and others, the Curetes were, in the times of Saturn, &c. and in the countries of Crete and Phrygia, what the druids were afterwards among the Gauls, &c. *i. e.* they were priests who had the care of what related to religion and the worship of the gods. Hence, as in those days it was supposed there was no communication with the gods but by divinations, auguries, and the operations of magic; the Curetes passed for magicians and enchanters: to these they added the study of the stars, of nature, and poetry; and so were philosophers, astronomers, &c.

Vossius, *de Idolat.* distinguishes three kinds of Curetes; those of Ætolia, those of Phrygia, and those of Crete, who were originally derived from the Phrygians. The first, he says, took their name from *κῆρυξ*, *tonsure*; in regard, from the time of a combat wherein the enemy seized their long hair, they always kept it cut. Those of Phrygia and Crete, he supposes, were so called from *κῆρυξ*, *young man*; in regard they were young, or because they nursed Jupiter when he was young.

CURFEW, or **COURFEW**, a signal given in cities taken in war, &c. to the inhabitants to go to bed. Pasquin says, it was so called, as being intended to advertise the people to secure themselves from the robberies and debaucheries of the night.

The most eminent curfew in England was that established by William the Conqueror, who appointed, under severe penalties, that at the ringing of a bell at eight o'clock in the evening, every one should put out their lights and fires and go to bed: whence, to this day, a bell rung about that time is called a *curfew-bell*.

CURIA, in Roman antiquity, was used for the senate-house. There were several curiæ in Rome; as the *curia calabra*, said to be built by Romulus; the *curia hostilia*, by Tullus Hostilius; and the *curia pompeia*, by Pompey the Great.

CURIA also denoted the places where the curiæ used to assemble. Each of the 30 curiæ of old Rome had a temple or chapel assigned to them for the common performance of their sacrifices, and other offices of their religion; so that they were not unlike our parishes. Some remains of these little temples seem to have subsisted many ages after on the Palatine-hill, where Romulus first built the city, and always resided.

CURIA, among the Romans, also denoted a portion or division of a tribe. In the time of Romulus, a tribe consisted of ten curiæ, or a thousand men; each curia being one hundred. That legislator made the first division of his people into thirty curiæ. Afterwards, *curia*, or *domus curialis*, became used for the place where each curia held its assemblies. Hence also curia passed to the senate-house; and it is from hence

Curetes
|
Curia.

Curia
|
Curiosus.

the moderns come to use the word *curia*, "court," for a place of justice, and for the judges, &c. there assembled.

Varro derives the word from *cura*, "care;" *q. d.* an assembly of people charged with the care of public affairs. Others deduce it from the Greeks; maintaining, that at Athens they called *κῦρια* the place where the magistrate held his assizes, and the people used to assemble: *κῦρια*, again, may come from *κῦρος*, *authority, power*; because it was here the laws were made.

CURIA, in ancient customs.—It was usual for the kings of England to summon the bishops, peers, and great men of the kingdom, to some particular place, at the chief festivals in the year: and this assembly is called by historians *curia*; because there they consulted about the weighty affairs of the nation: whence it was sometimes also called *solemnis curia*, *generalis curia*, *augustalis curia*, and *curia publica*, &c. See *WITENA-MOT*.

CURIA Baronum. See *COURT-BARON*.

CURIA Claudenda, is a writ that lies against him who should fence and inclose the ground, but refuses or defers to do it.

CURIATII, three brothers of Alba, maintained the interest of their country against the Romans who had declared war against those of Alba. The two armies being equal, three brothers on each side were chosen to decide the contest: the Curiatii by those of Alba, and the Horatii by the Romans. The three first were wounded, and two of the latter killed: but the third, joining policy to valour, ran away; and having thus tired the Curiatii, he took them one after another and killed them all three.

CURING, a term used for the preserving fish, flesh, and other animal substances, by means of certain additions of things, to prevent putrefaction. One great method of doing this, is by smoking the bodies with the smoke of wood, or rubbing them with salt, nitre, &c.

CURIO, the chief and priest of a curia.—Romulus, upon dividing the people into curiæ, gave each division a chief, who was to be priest of that curia, under the title of *curio* and *flamen curialis*. His business was to provide and officiate at the sacrifices of the curia, which were called *curionia*; the curia furnishing him with a sum of money on that consideration, which pension or appointment was called *curionium*. Each division had the election of its curia; but all these particular curios were under the direction of a superior or general, called *curio maximus*; who was the head of the body, and elected by all the curios assembled in the comitia curialis.

All these institutions were introduced by Romulus, and confirmed by Numa, as Halicarnassicus relates it.

CURIOSUS, an officer of the Roman empire during the middle age, appointed to take care that no frauds and irregularities are committed; particularly no abuses in what related to the posts, the roads, &c. and to give intelligence to the court of what passed in the provinces. This made the curiosi people of importance, and put them in a condition of doing more harm than they prevented; on which account, Honorius cashiered them, at least in some parts of the empire, *anno 415*.

The curiosi came pretty near to what we call *con-*

trollers. They had their name from *cura*, "care;" *quod curis agendis & electionibus cursus publici inspicendis operam darent*.

CURLEW, in ornithology. See *SCOLEPAX*.

CURMI, a name given by the ancients to a sort of malt liquor or ale. It was made of barley, and was drunk by the people of many nations instead of wine, according to Dioicorides's account. He accuses it of causing pains in the head, generating bad juices, and disordering the nervous system. He also says, that in the western parts of Iberia, and in Britain, such a sort of liquor was in his time prepared from wheat instead of barley. See *ALE*.

CURNOCK, a measure of corn containing four bushels or half a quarter.

CURRANS, or CURRANTS, the fruit of a species of grossularia. See *GROSSULARIA*.

The white and red sort are mostly used; for the black, and chiefly the leaves, upon first coming out, are in use to flavour English spirits, and counterfeit French brandy. Currants greatly assuage drought, cool and fortify the stomach, and help digestion; and the jelly of black currants is said to be very efficacious in curing inflammations of the throat.

CURRANTS also signify a smaller kind of grapes, brought principally from Zant and Cephalonia. They are gathered off the bushes, and laid to dry in the sun, and so put up in large butts. They are opening and pectoral; but are more used in the kitchen than in medicine.

CURRENT, or COURANT, a term used to express the present time. Thus the year 1791 is the current year, the 20th current is the 20th day of the month now running.—With regard to commerce, the price current of any merchandize is the known and ordinary price accustomed to be given for it. The term is also used for any thing that has course or is received in commerce; in which course we say, *current coin*, &c.

CURRENT, in navigation, a certain progressive movement of the water of the sea, by which all bodies floating therein are compelled to alter their course or velocity, or both, and to submit to the laws imposed on them by the current.

In the sea, currents are either natural and general, as arising from the diurnal rotation of the earth about its axis; or accidental and particular, caused by the waters being driven against promontories, or into gulphs and straits, where wanting room to spread, they are driven back, and thus disturb the ordinary flux of the sea. Currents are various, and directed towards different parts of the ocean, of which some are constant, others periodical. The most extraordinary current of the sea, is that by which part of the Atlantic or African Ocean moves about Guinea from Cape Verd towards the curvature or bay of Africa, which they call *Fernando Poo*; *viz.* from west to east, contrary to the general motion. And such is the force of the current, that when ships approach too near the shore, it carries them violently towards that bay, and deceives the mariners in their reckoning. There is a great variety of shifting currents which do not last, but return at certain periods; and these do, most of them, depend upon and follow the anniversary winds or monsoons, which by blowing in one place may cause a current in another. Varenus informs us, that at Java,

Curlew
||
Current.

Current. Java, in the straits of Sunda, when the monsoons blow from the west, *viz.* in the month of May, the currents set to the eastward, contrary to the general motion. Between the island of Celebes and Madura, when the western monsoons set in, *viz.* in December, January, and February, or when the winds blow from the north-west, or between the north and west, the currents set to the south-east, or between the south and east. At Ceylon, from the middle of March to October, the currents set to the southward, and in the other parts of the year to the northward; because at this time the southern monsoons blow, and at the other the northern. Between Cochin-China and Malacca, when the western monsoons blow, *viz.* from April to August, the currents set eastward against the general motion; but the rest of the year they set westward, the monsoon conspiring with the general motion. They run so strongly in these seas, that unexperienced sailors mistake them for waves that beat upon the rocks, known usually by the name of *breakers*. So for some months after the 15th of February, the currents set from the Maldives towards India on the east, against the general motion of the sea. On the shore of China and Cambodia, in the months of October, November, and December, the currents set to the north-west, and from January to the south-west, when they run with such rapidity about the shoals of Parcel, that they seem swifter than an arrow. At Pulo Condore, upon the coast of Cambodia, though the monsoons are shifting, yet the currents set strongly towards the east, even when they blow to a contrary point. Along the coasts of the Bay of Bengal, as far as the Cape Romania, at the extreme point of Malacca, the current runs southward in November and December. When the monsoons blow from China to Malacca, the sea runs swiftly from Pulo Cambi to Pulo Condore on the coast of Cambodia. In the Bay of Sans Bras, not far from the Cape of Good Hope, there is a current particularly remarkable, where the sea runs from east to west to the landward; and this more vehemently as it is opposed by winds from a contrary direction. The cause is undoubtedly owing to some adjacent shore which is higher than this. In the straits of Gibraltar, the currents almost constantly drive to the eastward, and carry ships into the Mediterranean: they are also found to drive the same way into St George's channel.

The setting or progressive motion of the current may be either quite down to the bottom, or to a certain determinate depth. As the knowledge of the direction and velocity of currents is a very material article in navigation, it is highly necessary to discover both, in order to ascertain the ship's situation and course with as much accuracy as possible. The most successful method which has been hitherto practised by mariners for this purpose is as follows. A common iron pot, which may contain four or five gallons, is suspended by a small rope fastened to its ears or handles, so as to hang directly upright, as when placed upon the fire. This rope, which may be from 70 to 100 fathoms in length, being prepared for the experiment, is coiled in the boat, which is hoisted out of the ship at a proper opportunity, when there is little or no wind to ruffle the surface of the sea. The pot being then thrown overboard into the water, and

immediately sinking, the line is slackened till about 70 or 80 fathoms of the line run out; after which the line is fastened to the boat's stern, by which she is accordingly restrained, and rides as at an anchor. The velocity of the current is then easily tried by the log and half-minute glass, the usual method of discovering the rate of a ship's sailing at sea. The course of the stream is next obtained by the compass provided for this operation. Having thus found the setting and drift of the current, it next remains to apply this experiment to the purposes of NAVIGATION; for which see that article.

Under-CURRENTS are distinct from the upper or apparent, and in different places set or drive a contrary way. Dr Smith makes it highly probable, that in the Downs, in the straits of Gibraltar, &c. there is an under-current, whereby as much water is carried out as is brought in by the upper-currents. This he argues from the offing between the north and south Foreland, where it runs tide and half-tide, *i. e.* it is either ebb or flood in that part of the Downs three hours before it is so off at sea: a certain sign, that though the tide of flood runs aloft, yet the tide of ebb runs under-foot, *i. e.* close by the ground; and so at the tide of ebb it will flow under-foot. This he confirms by an experiment in the Baltic Sound, communicated to him by an able seaman present at the making it. Being there then with one of the king's frigates, they went with their pinnace into the mid-stream, and were carried violently by the current. Soon after that, they sunk a basket with a large cannon bullet to a certain depth of water, which gave check to the boat's motion; and sinking it still lower and lower, the boat was driven a-head to the windward against the upper current, the current aloft not being above four or five fathom deep. He added, that the lower the basket was let down, the stronger the under-current was found.

From this principle, it is easy to account for that continual in-draught of water out of the Atlantic into the Mediterranean through the straits of Gibraltar, a passage about 20 miles broad; yet without any sensible rising of the water along the coasts of Barbary, &c. or any overflowing of the lands, which there lie very low.—Dr Halley, however, solves the currents setting in at the straits without overflowing the banks by the great evaporation, without supposing any under-current.

CURRICULUS, in our ancient writers, denotes the year or course of a year. *Actum est hoc annorum Dominica incarnationis quater quinquagenis & quinquies, quinis lustris, & tribus curriculum; i. e.* in the year 1028: for four times fifty makes two hundred, and five times two hundred makes one thousand; five lustris are twenty-five years, and three curricula are three years.

CURRIERS, those who dress and colour leather, after it comes from the tan-yard. See TANNING.

CURRODREPANUS (formed of *currus*, "chariot," and *δρεπανον*, "scythe" or "sickle"), in antiquity, a kind of chariot armed with scythes. The driver of these chariots was obliged to ride on one of the horses, as there was no other seat for him; the usual place for him being all armed with knives, as was likewise the hinder part of the chariot. There were no scythes pointing down to the earth either from

Current
||
Currodrepanus.

Currying,
Curfing. from the beam or axle-tree; but these were fixed at the head of the axle-tree in such a manner as to be moveable by means of a rope, and thereby could be raised or let down, and drawn forward or let fall backward, by relaxing the rope.

CURRYING; the method of preparing leather with oil, tallow, &c.

The chief business is to soften and supple cow and calve-skins, which make the upper-leathers and quarters of shoes, covering of saddles, coaches, and other things which must keep out water. 1. These skins, after coming from the tanner's yard, having many fleshy fibres on them, the currier soaks them some time in common water. 2. He takes them out and stretches them on a very even wooden horse; then with a paring-knife he scrapes off all the superfluous flesh, and puts them in to soak again. 3. He puts them wet on a hurdle, and tramples them with his heels till they begin to grow soft and pliant. 4. He soaks them on train-oil, which by its unctuous quality is the best liquor for this purpose. 5. He spreads them on large tables, and fastens them at the ends. There, with the help of an instrument called a *pummel*, which is a thick piece of wood, the under side of which is full of furrows crossing each other, he folds, squares, and moves them forwards and backwards several times, under the teeth of this instrument, which breaks their too great stiffness. This is what is properly called *currying*. The order and number of these operations is varied by different carriers, but the material part is always the same. 6. After the skins are curried, there may be occasion to colour them. The colours are black, white, red, yellow, green, &c. the other colours are given by the skimmers, who differ from carriers in this, that they apply their colours on the flesh side; the carriers on the hair side. In order to whiten skins, they are rubbed with lumps of chalk or white-lead, and afterwards with pumice-stone. 7. When a skin is to be made black, after having oiled and dried it, he passes over it a puff dipt in water impregnated with iron; and after his first wetting, he gives it another in a water prepared with foot, vinegar, and gum-arabic. These different dyes gradually turn the skin black, and the operations are repeated till it be of a shining black. The grain and wrinkles, which contribute to the suppleness of calves and cows leather, are made by the reiterated folds given to the skin in every direction, and by the care taken to scrape off all hard parts on the colour side.

CURSING AND SWEARING, an offence against God and religion, and a sin of all others the most extravagant and unaccountable, as having no benefit or advantage attending it. By the last statute against this crime, 19 Geo. II. which repeals all former ones, every labourer, sailor, or soldier, profanely cursing or swearing, shall forfeit 1 s.; every other person under the rank of a gentleman, 2 s.; and every gentleman or person of superior rank, 5 s. to the poor of the parish; and, on a second conviction, double; and, for every subsequent offence, treble the sum first forfeited, with all charges of conviction: and, in default of payment, shall be sent to the house of correction for 10 days. Any justice of the peace may convict upon his own hearing, or the testimony of one witness; and any

constable or peace officer, upon his own hearing, may secure any offender and carry him before a justice, and there convict him. If the justice omits his duty, he forfeits 5 l. and the constable 40 s. And the act is to be read in all parish churches and public chapels the Sunday after every quarter-day, on pain of 5 l. to be levied by warrant from any justice. Besides this punishment for taking God's name in vain in common discourse, it is enacted by stat. 3. Jac. I. c. 21. that if in any stage-play, interlude, or show, the name of the Holy Trinity, or any of the persons therein, be jestingly or profanely used, the offender shall forfeit 10 l.; one moiety to the king, and the other to the informer.

CURSITOR, a clerk belonging to the court of chancery in England, whose business it is to make out original writs. In the statute 18 Edw. III. they are called *clerks of course*, and are 24 in number, making a corporation of themselves. To each of them is allowed a division of certain counties, into which they issue out the original writs required by the subject.

CURTATE DISTANCE, in astronomy, the distance of a planet from the sun to that point, where a perpendicular let fall from the planet meets with the ecliptic.

CURTATION, in astronomy, is the interval between a planet's distance from the sun and the curtate distance.

CURTEYN, CURTANA, was the name of Edward the Confessor's sword, which is the first sword carried before the kings of England at their coronation; and it is said the point of it is broken as an emblem of mercy.

CURTIN, CURTAIN, or *Courtin*, in fortification, is that part of the rampart of a place which is betwixt the flanks of two bastions, bordered with a parapet five feet high, behind which the soldiers stand to fire upon the covered way and into the moat.

CURTIUS (Marcus), a Roman youth, who devoted himself to the gods manes for the safety of his country, about 360 years before the Augustan age. A wide gap had suddenly opened in the forum, and the oracle had said that it never would close before Rome threw into it whatever it had most precious. Curtius immediately perceived that no less than an human sacrifice was required. He armed himself, mounted his horse, and solemnly threw himself into the gulf, which instantly closed over his head.

CURTIUS (Quintus), a Latin historian who wrote the life of Alexander the Great in 10 books, of which the two first are not indeed extant, but are so well supplied by Freinshemius, that the loss is scarcely regretted. Where this writer was born, or even when he lived, are points no one pretends to know. By his style he is supposed to have lived in or near the Augustan age; while some are not wanting, who imagine the work to have been composed in Italy about 300 years ago, and the name of *Quintus Curtius* to be fictitiously added to it. Cardinal du Perron was so great an admirer of this work, as to declare one page of it to be worth 30 of Tacitus; yet M. le Clerc, at the end of his Art of Criticism, has charged the writer with great ignorance and many contradictions. He has nevertheless many qualities as a writer, which will always make him admired and applauded.

Curfitor
||
Curtius.

Curvature CURVATURE OF A LINE, is the peculiar manner of its bending or flexure, by which it becomes a curve of such and such peculiar properties.

Curve CURVE, in geometry, a line which running on continually in all directions, may be cut by one right line in more points than one. See CONIC SECTIONS and FLUCTIONS.

Curvet, or **Corvet**, in the manege, an air in which the horse's legs are raised higher than in the demi volt: being a kind of leap up, and a little forwards, wherein the horse raises both his fore-legs at once, equally advanced, (when he is going straight forward, and not in a circle), and as his fore-legs are falling, he immediately raises his hind legs, equally advanced, and not one before the other: so that all his four legs are in the air at once: and as he sets them down, he marks but twice with them.

Curvilinear, or **Curvilinear**, is said of figures bounded by curves or crooked lines.

Curvirostra, in ornithology. See LOXIA.

Curule chair, in Roman antiquity, a chair adorned with ivory, wherein the great magistrates of Rome had a right to sit and be carried.

The curule magistrates were the ædiles, the prætors, censors, and consuls. This chair was fitted in a kind of chariot, whence it had its name. The senators who had borne the offices of ædiles, prætors, &c. were carried to the senate-house in this chair, as were also those who triumphed, and such as went to administer justice, &c. See ÆDILE, &c.

Curzola, an island in the gulf of Venice, lying on the coast of Dalmatia. It is about 20 miles long, and has a small town of the same name, with a bishop's see. It belongs to the Venetians. E. Long. 17. 15. N. Lat. 43. 6.

CUSA (Nicholas de), a learned cardinal, born of mean parentage, and named from Cusa, the place of his birth. He was made a cardinal in 1448; and being appointed governor of Rome by Pope Pius II. during his absence at Mantua, he was the chief concertor and manager of the war against the Turks. He founded a church, and a noble library of Greek and Latin authors, at Cusa; and left many excellent works behind him, which were collected and published in three volumes at Basil in 1565. In these he has made no scruple to detect the lying traditions and sophistries of the Roman church.

CUSCO, a large and handsome town of South America in Peru, formerly the residence of the Incas. It is seated at the foot of a mountain, and is built in a square form, in the middle of which there is the best market in all America. Four large streets terminate in this square, which are all as straight as a line, and regard the four quarters of the world. The Spaniards tell us wonderful things of the richness of the Inca's palace, and of the temple of the sun; but more sober travellers judging from what remains, think most of them to be fabulous. At present it contains eight large parishes, and five religious houses, the best of which belongs to the Jesuits; and the number of the inhabitants may be about 50,000, of which three-fourths are the original natives, Americans. From this town there is a very long road, which runs along the Cordaleim; and, at certain distances, there are small houses for resting places, some parts of which are so artificially

wrought, that it is surprising how a people who had no iron tools could perform such workmanship. There are streams of water run through the town, which are a great convenience in to hot a country where it never rains. It is 375 miles east of Lima. W. Long. 74. 37. S. Lat. 13. 0.

CUSCUTA, **DODDER**: a genus of the digynia order, belonging to the tetrandria class of plants; and in the natural method ranking under those of which the order is doubtful. The calyx is quadrifid; the corolla monopetalous; the capsule bilocular. There are two species; one of which is a native of Britain, viz. the *Europæa*, dodder, hell-weed, or devil's guts. This is a very singular plant, almost destitute of leaves, parasitical, creeping, fixing itself to whatever is next to it. It decays, at the root, and afterwards is nourished by the plant which supports it. Hops, flax, and nettles, are its common support; but principally the common nettle. Its blossoms are white. As soon as the shoots have twined about an adjacent plant, they send out from their inner surface a number of little vesicles or papillæ, which attach themselves to the bark or rind of the plant. By degrees the longitudinal vessels of the stalk, which appear to have accompanied the vesicles, shoot from their extremities, and make their way into the softer plant, by dividing the vessels and insinuating themselves into the tenderest part of the stalk; and so intimately are they united with it, that it is easier to break than to disengage them from it. The whole plant is bitter. It affords a pale reddish colour. Cows, sheep, and swine, eat it; horses refuse it; goats are not fond of it.

CUSH, the eldest son of Ham, and father of Nimrod; the other sons of Cush were Seba, Havilah, Sabtah, Raamah, and Sabrecha. Gen. x. 6—8. Though we know of no other person of scripture that is called by this name, yet there are several countries, that are called by it; whether the same man may have dwelt in them all at different times, or that there were some other men of this name, we are ignorant.

The Vulgate, Septuagint, and other interpreters, both ancient and modern, generally translate *Cushi*, *Ethiopia*: but there are many passages wherein this translation cannot take place.

Cush is the name of the country watered by the Araxes. They who in translating the situation of Eden, have made *Cush* Ethiopia, gave rise to that unwarrantable opinion which Josephus and several others have entertained of the river Gihon's being the Nile. In this place (Gen. ii. 13.) the LXX translation renders the word *Cush* by the name of Ethiopia; and in this mistake is not only here followed by our English version, but in the same particular in several other places.

Cush is the same as Cush. The Chaldees generally put the *tau* where the Hebrews use the *schin*; they say *cuth*, instead of *cush*. See CUTH.

But Ethiopia is frequently in the Hebrew called *Cush*; and Josephus says, that they called themselves by this name, and that the same name was given them by all Asia. St Jerom tells us, that the Hebrews call the Ethiopians by the same name, and the Septuagint give them no other. Jeremiah (xiii. 23.) says, "Can the Cushæan, or Ethiopian, change his colour." In Ezekiel (xxix. 10.) the Lord threatens to reduce
"Egypt

Cuscuta,
Cush.

Cushion || Custom and Habit. "Egypt to a desert, from the tower of Syene even unto the border of Cush, or Ethiopia;" and in Isaiah, (xi. 11.) he says, "he will recover the remnant of his people, which shall be left from Assyria, and from Egypt, and Pathros, and from Cush." All these marks agree with Ethiopia properly so called, which lies to the south of Egypt.

Bochart has shown very clearly that there was a country called "the land of *Cush*" in Arabia Petræa, bordering upon Egypt; that this country extended itself principally upon the eastern shore of the Red-Sea, and, at its extremity, to the point of this sea, inclining towards Egypt and Palestine.

Thus there are three countries of the name of Cush, described in scripture, and all confounded by interpreters under the general name of Ethiopia.

CUSHION, in engraving, is a bag of leather filled with sand, commonly about nine inches square, and three or four thick, used for supporting the plate to be engraved.

CUSHION, in gilding, is made of leather, fastened to a square board, from 14 inches square to 10, with a handle. The vacuity between the leather and board is stuffed with fine tow or wool, so that the outer surface may be flat and even. It is used for receiving the leaves of gold from the paper, in order to its being cut into proper sizes and figures.

CUSI, in natural history, a name given by the people of the Philippine islands to a very small and very beautiful species of parrot.

CUSP, *cusps*, properly denotes the point of a spear or sword; but is used in astronomy to express the points or horns of the moon, or any other luminary.

CUSP, in astrology, is used for the first point of each of the 12 houses, in a figure or scheme of the heavens. See HOUSE.

CUSPIDATED, in botany, are such plants whose leaves are pointed like a spear.

CUSPINIAN (John), a German, was born at Sweinfurt in 1473; and died at Vienna in 1529. He was first physician to the emperor Maximilian I. and employed by that prince in several delicate negotiations. We have of his in Latin, 1. A history of the Roman emperors from Julius Cæsar to the death of Maximilian I. Degory Wheare, in his *Methodus Legendæ Historiæ*, calls this "*luculentum sane opus, & omnium lectione dignissimum.*" 2. An history of Austria; being a kind of continuation of the preceding. 3. An history of the origin of the Turks, and of their cruelties towards Christians. Gerard Vossius calls Cuspinian *magnum suo ævo historia lumen.*

CUSTOM, a very comprehensive term, denoting the manners, ceremonies, and fashions, of a people, which having turned into a habit, and passed into use, obtain the force of laws; in which sense it implies such usages, as, though voluntary at first, are yet by practice become necessary.

Custom is hence, both by lawyers and civilians, defined *lex non scripta*, "a law or right not written," established by long usage, and the consent of our ancestors: in which sense it stands opposed to the *lex scripta*, or "the written law." See LAW, Part II. n° 38—41.

Custom and Habit, in the human economy. The former is often confounded with the latter. By *cu-*

stom we mean a frequent reiteration of the same act; and by *habit*, the effect that custom has on the mind or body. This curious subject falls to be considered first in a moral, and secondly in a physical, light. Custom and Habit.

I. *Influence of Custom and Habit, on the Mind, &c.* Custom hath such influence upon many of our feelings, by warping and varying them, that its operations demand the attention of all who would be acquainted with human nature. The subject, however, is intricate. Some pleasures are fortified by custom: and yet custom begets familiarity, and consequently indifference: *Kaimes's Elements of Criticism.*

If all the year were playing holidays,
To sport would be as tedious as to work:
But when they seldom come, they wish'd for come,
And nothing pleaseth but rare accidents. *Shakesp.*

In many instances, satiety and disgust are the consequences of reiteration: again, though custom blunts the edge of distress and of pain; yet the want of any thing to which we have been long accustomed is a sort of torture. A clue to guide us through all the intricacies of this labyrinth, would be an acceptable present.

Whatever be the cause, it is certain that we are much influenced by custom: it hath an effect upon our pleasures, upon our actions, and even upon our thoughts and sentiments. Habit makes no figure during the vivacity of youth: in middle age it gains ground; and in old age governs without controul. In that period of life, generally speaking, we eat at a certain hour, take exercise at a certain hour, go to rest at a certain hour, all by the direction of habit: nay, a particular seat, table, bed, comes to be essential; and a habit in any of these cannot be controlled without uneasiness.

Any slight or moderate pleasure, frequently reiterated for a long time, forms a peculiar connection between us and the thing that causes the pleasure. This connection, termed *habit*, has the effect to awaken our desire or appetite, for that thing when it returns not as usual. During the course of enjoyment, the pleasure rises insensibly higher and higher till a habit be established: at which time the pleasure is at its height. It continues not, however, stationary: the same customary reiteration which carried it to its height, brings it down again by insensible degrees, even lower than it was at first; but of that circumstance afterward. What at present we have in view is to prove by experiments, that those things which at first are but moderately agreeable, are the aptest to become habitual. Spirituous liquors, at first scarce agreeable, readily produce an habitual appetite: and custom prevails so far, as even to make us fond of things originally disagreeable, such as coffee, assafœtida, and tobacco.

A walk upon the quarter-deck, though intolerably confined, becomes however so agreeable by custom, that a sailor in his walk on shore confines himself commonly within the same bounds. The author knew a man who had relinquished the sea for a country-life: in the corner of his garden he reared an artificial mount with a level summit, resembling most accurately a quarter-deck, not only in shape but in size; and here he generally walked. In Minorca governor Kane made an excellent road the whole length of the island;

Custom
and Habit.

island; and yet the inhabitants adhere to the old road, though not only longer, but extremely bad. Play or gaming, at first barely amusing by the occupation it affords, becomes in time extremely agreeable; and is frequently prosecuted with avidity, as if it were the chief business of life. The same observation is applicable to the pleasures of the internal senses, those of knowledge and virtue in particular: children have scarce any sense of these pleasures; and men very little who are in the state of nature without culture: our taste for virtue and knowledge improves slowly: but is capable of growing stronger than any other appetite in human nature.

To introduce an active habit, frequency of acts is not sufficient without length of time: the quickest succession of acts in a short time is not sufficient; nor a slow succession in the longest time. The effect must be produced by a moderate sort of action, and a long series of easy touches, removed from each other by short intervals. Nor are these sufficient without regularity in the time, place, and other circumstances of the action: the more uniform any operation is, the sooner it becomes habitual. And this holds equally in a passive habit; variety in any remarkable degree, prevents the effect: thus any particular food will scarce ever become habitual where the manner of dressing is varied. The circumstances then requisite to augment a moderate pleasure, and at the long-run to form a habit, are weak uniform acts, reiterated during a long course of time, without any considerable interruption: every agreeable cause that operates in this manner will grow habitual.

Affection and aversion, as distinguished from passion on the one hand, and on the other from original disposition, are in reality habits respecting particular objects, acquired in the manner above set forth. The pleasure of social intercourse with any person, must originally be faint, and frequently reiterated, in order to establish the habit of affection. Affection thus generated, whether it be friendship or love, seldom swells into any tumultuous or vigorous passion; but is however the strongest cement that can bind together two individuals of the human species. In like manner, a slight degree of disgust often reiterated with regula-

VOL. V.

Custom and Habit.
rity, grows into the habit of aversion, which commonly subsists for life.

Objects of taste that are delicious, far from tending to become habitual, are apt by indulgence to produce satiety and disgust: no man contracts a habit of sugar, honey, or sweet-meats, as he doth of tobacco.

These violent delights have violent ends,
And in their triumphs die. The sweetest honey
Is loathsome in its own deliciousness,
And in the taste confounds the appetite;
Therefore love moderately, long love doth so;
Too swift arrives as tardy as too slow.

Romeo and Juliet, act 2. sc. 6.

The same observation holds with respect to all objects that being extremely agreeable raise violent passions: such passions are incompatible with a habit of any sort; and in particular they never produce affection or aversion: a man who at first sight falls violently in love, has a strong desire of enjoyment, but no affection for the woman (A): a man who is surprised with an unexpected favour, burns for an opportunity to exert his gratitude, without having any affection for his benefactor: neither does desire of vengeance for an atrocious injury involve aversion.

It is perhaps not easy to say why moderate pleasures gather strength by custom: but two causes concur to prevent that effect in the more intense pleasures. These, by an original law in our nature, increase quickly to their full growth, and decay with no less precipitation: and custom is too slow in its operation to overcome that law. The other cause is not less powerful: exquisite pleasure is extremely fatiguing; occasioning, as a naturalist would say, great expence of animal spirits; and of such the mind cannot bear so frequent gratification, as to superinduce a habit: if the thing that raises the pleasure return before the mind have recovered its tone and relish, disgust ensues instead of pleasure.

A habit never fails to admonish us of the wonted time of gratification, by raising a pain for want of the object, and a desire to have it. The pain of want is always first felt: the desire naturally follows; and upon presenting the object, both vanish instantaneously. Thus a man accustomed to tobacco, feels, at the end

4 I

of

(A) Violent love, without affection, is finely exemplified in the following story. When Constantinople was taken by the Turks, Irene, a young Greek of an illustrious family, fell into the hands of Mahomet II. who was at that time in the prime of youth and glory. His savage heart being subdued by her charms, he shut himself up with her, denying access even to his ministers. Love obtained such ascendant as to make him frequently abandon the army, and fly to his Irene. War relaxed, for victory was no longer the monarch's favourite passion. The soldiers, accustomed to booty, began to murmur, and the infection spread even among the commanders. The Basha Mustapha, consulting the fidelity he owed his master, was the first who durst acquaint him of the discourses held publicly to the prejudice of his glory. The sultan, after a gloomy silence, formed his resolution. He ordered Mustapha to assemble the troops next morning; and then with precipitation retired to Irene's apartment. Never before did that princess appear so charming; never before did the prince bestow so many warm caresses. To give a new lustre to her beauty, he exhorted her women next morning to bestow their utmost art and care on her dress. He took her by the hand, led her into the middle of the army, and pulling off her vail, demanded of the bashas with a fierce look, whether they had ever beheld such a beauty? After an awful pause, Mahomet with one hand laying hold of the young Greek by her beautiful locks, and with the other pulling out his scimitar, severed the head from the body at one stroke. Then turning to his grandees, with eyes wild and furious, "This sword (says he), when it is my will, knows to cut the bands of love." However strange it may appear, we learn from experience, that desire of enjoyment may consist with the most brutal aversion, directed both to the same woman. Of this we have a noted example in the first book of Sully's Memoirs; to which we choose to refer the reader, for it is too gross to be transcribed.

Custom
and Habit.

of the usual interval, a confused pain of want; which at first points at nothing in particular, though it soon settles upon its accustomed object: and the same may be observed in persons addicted to drinking, who are often in an uneasy restless state before they think of the bottle. In pleasures indulged regularly, and at equal intervals, the appetite, remarkably obsequious to custom, returns regularly with the usual time of gratification; not sooner, even though the object be presented. This pain of want arising from habit, seems directly opposite to that of satiety; and it must appear singular, that frequency of gratification should produce effects so opposite, as are the pains of excess and of want.

The appetites that respect the preservation and propagation of our species, are attended with a pain of want similar to that occasioned by habit: hunger and thirst are uneasy sensations of want, which always precede the desire of eating or drinking; and a pain for want of carnal enjoyment, precedes the desire of an object. The pain being thus felt independent of an object, cannot be cured but by gratification. Very different is an ordinary passion, in which desire precedes the pain of want; such a passion cannot exist but while the object is in view; and therefore, by removing the object out of thought, it vaniseth with its desire and pain of want.

The natural appetites abovementioned, differ from habit in the following particular: they have an undetermined direction toward all objects of gratification in general; whereas an habitual appetite is directed to a particular object: the attachment we have by habit to a particular woman, differs widely from the natural passion which comprehends the whole sex; and the habitual relish for a particular dish, is far from being the same with a vague appetite for food. That difference notwithstanding, it is still remarkable, that nature hath enforced the gratification of certain natural appetites essential to the species, by a pain of the same sort with that which habit produceth.

The pain of habit is less under our power than any other pain that arises from want of gratification: hunger and thirst are more easily endured, especially at first, than an usual intermission of any habitual pleasure: persons are often heard declaring, they would forego sleep or food, rather than tobacco. We must not however conclude, that the gratification of an habitual appetite affords the same delight with the gratification of one that is natural: far from it; the pain of want only is greater.

The slow and reiterated acts that produce a habit, strengthen the mind to enjoy the habitual pleasure in greater quantity and more frequency than originally; and by that means a habit of intemperate gratification is often formed: after unbounded acts of intemperance, the habitual relish is soon restored, and the pain for want of enjoyment returns with fresh vigour.

The causes of the present emotions hitherto in view, are either an individual, such as a companion, a certain dwelling-place, a certain amusement; or a particular species, such as coffee, mutton, or any other food. But habit is not confined to such. A constant train of trifling diversions may form such a habit in the mind, that it cannot be easy a moment without amusement; a variety in the objects prevents a habit

Custom
and Habit.

as to any one in particular; but as the train is uniform with respect to amusement, the habit is formed accordingly; and that sort of habit may be denominated a *generic habit*, in opposition to the former, which is a *specific habit*. A habit of a town-life, of country-sports, of solitude, of reading, or of business, where sufficiently varied, are instances of generic habits. Every specific habit hath a mixture of the generic; for the habit of any one sort of food makes the taste agreeable, and we are fond of that taste wherever found. Thus a man deprived of an habitual object, takes up with what most resembles it; deprived of tobacco, any bitter herb will do rather than want: a habit of punch makes wine a good resource: accustomed to the sweet society and comforts of matrimony, the man unhappily deprived of his beloved object, inclines the sooner to a second. In general, when we are deprived of a habitual object, we are fond of its qualities in any other object.

The reasons are assigned above, why the causes of intense pleasure become not readily habitual: but now we discover, that these reasons conclude only against specific habits. In the case of a weak pleasure, a habit is formed by frequency and uniformity of reiteration, which, in the case of an intense pleasure, produceth satiety and disgust. But it is remarkable, that satiety and disgust have no effect, except as to that thing singly which occasions them: a surfeit of honey produceth not a loathing of sugar; and intemperance with one woman produceth no disfrelish of the same pleasure with others. Hence it is easy to account for a generic habit in any intense pleasure: the delight we had in the gratification of the appetite, inflames the imagination, and makes us, with avidity, search for the same gratification in whatever other object it can be found. And thus uniform frequency in gratifying the same passion upon different objects, produceth at length a generic habit. In this manner one acquires an habitual delight in high and poignant sauces, rich dress, fine equipages, crowds of company, and in whatever is commonly termed *pleasure*. There concurs at the same time, to introduce this habit, a peculiarity observed above, that reiteration of acts enlarges the capacity of the mind, to admit a more plentiful gratification than originally, with regard to frequency as well as quantity.

Hence it appears, that though a specific habit cannot be formed but upon a moderate pleasure, a generic habit may be formed upon any sort of pleasure, moderate or immoderate, that hath variety of objects. The only difference is, that a weak pleasure runs naturally into a specific habit; whereas an intense pleasure is altogether averse to such a habit. In a word, it is only in singular cases that a moderate pleasure produces a generic habit; but an intense pleasure cannot produce any other habit.

The appetites that respect the preservation and propagation of the species, are formed into habit in a peculiar manner; the time as well as measure of their gratification are much under the power of custom; which, introducing a change upon the body, occasions a proportional change in the appetites. Thus, if the body be gradually formed to a certain quantity of food at stated times, the appetite is regulated accordingly; and the appetite is again changed, when a different habit

Custom
and Habit.

habit of body is introduced by a different practice. Here it would seem, that the change is not made upon the mind, which is commonly the case in passive habits, but upon the body.

When rich food is brought down by ingredients of a plainer taste, the composition is susceptible of a specific habit. Thus the sweet taste of sugar, rendered less poignant in a mixture, may, in course of time, produce a specific habit for such mixture. As moderate pleasures, by becoming more intense, tend to generic habits; so intense pleasures, by becoming more moderate, tend to specific habits.

The beauty of the human figure, by a special recommendation of nature, appears to us supreme, amid the great variety of beautiful forms bestowed upon animals. The various degrees in which individuals enjoy that property, render it an object sometimes of a moderate, sometimes of an intense, passion. The moderate passion, admitting frequent reiteration without diminution, and occupying the mind without exhausting it, turns gradually stronger till it becomes a habit. Nay, instances are not wanting, of a face at first disagreeable, afterward rendered indifferent by familiarity, and at length agreeable by custom. On the other hand, consummate beauty, at the very first glance, fills the mind so as to admit no increase. Enjoyment lessens the pleasure; and if often repeated, ends commonly in satiety and disgust. The impressions made by consummate beauty, in a gradual succession from lively to faint, constitute a series opposite to that of faint impressions waxing gradually more lively, till they produce a specific habit. But the mind when accustomed to beauty contracts a relish for it in general, though often repelled from particular objects by the pain of satiety; and thus a generic habit is formed, of which inconstancy in love is the necessary consequence; for a generic habit, comprehending every beautiful object, is an invincible obstruction to a specific habit, which is confined to one.

But a matter which is of great importance to the youth of both sexes, deserves more than a cursory view. Though the pleasant emotion of beauty differs widely from the corporeal appetite, yet when both are directed to the same object, they produce a very strong complex passion: enjoyment in that case must be exquisite; and therefore more apt to produce satiety than in any other case whatever. This is a never-failing effect, where consummate beauty in the one party, meets with a warm imagination and great sensibility in the other. What we are here explaining, is true without exaggeration; and they must be insensible upon whom it makes no impression: it deserves well to be pondered by the young and the amorous, who, in forming the matrimonial society, are too often blindly impelled by the animal pleasure merely, inflamed by beauty. It may indeed happen after the pleasure is gone, and go it must with a swift pace, that a new connection is formed upon more dignified and more lasting principles: but this is a dangerous experiment; for even supposing good sense, good temper, and internal merit of every sort, yet a new connection upon such qualifications is rarely formed: it commonly, or rather always happens, that such qualifications, the only solid foundation of an indissoluble

connection, are rendered altogether invisible by satiety of enjoyment creating disgust.

One effect of custom, different from any that have been explained, must not be omitted, because it makes a great figure in human nature: though custom augments moderate pleasures, and lessens those that are intense, it has a different effect with respect to pain; for it blunts the edge of every sort of pain and distress, faint or acute. Uninterrupted misery, therefore, is attended with one good effect: if its torments be incessant, custom hardens us to bear them.

The changes made in forming habits are curious. Moderate pleasures are augmented gradually by reiteration, till they become habitual; and then are at their height: but they are not long stationary; for from that point they gradually decay, till they vanish altogether. The pain occasioned by want of gratification, runs a different course: it increases uniformly; and at last becomes extreme, when the pleasure of gratification is reduced to nothing.

—————It so falls out,

That what we have we prize not to the worth,
While we enjoy it; but being lack'd and lost,
Why then we rack the value; then we find
The virtue that possession would not show us
Whilst it was ours.

Much ado about Nothing, act 4. sc. 2.

The effect of custom with relation to a specific habit, is displayed through all its varieties in the use of tobacco. The taste of that plant is at first extremely unpleasant: our disgust lessens gradually, till it vanishes altogether; at which period the taste is neither agreeable nor disagreeable: continuing the use of the plant, we begin to relish it; and our relish improves by use, till it arrive at perfection: from that period it gradually decays, while the habit is in a state of increment, and consequently the pain of want. The result is, that when the habit has acquired its greatest vigour, the relish is gone; and accordingly we often smoke and take snuff habitually, without so much as being conscious of the operation. We must except gratification after the pain of want; the pleasure of which gratification is the greatest when the habit is the most vigorous: it is of the same kind with the pleasure one feels upon being delivered from the rack. This pleasure however is but occasionally the effect of habit; and however exquisite, is avoided as much as possible because of the pain that precedes it.

With regard to the pain of want, we can discover no difference between a generic and a specific habit; but these habits differ widely with respect to the positive pleasure. We have had occasion to observe, that the pleasure of a specific habit decays gradually till it turn imperceptible: the pleasure of a generic habit, on the contrary, being supported by variety of gratification, suffers little or no decay after it comes to its height. However it may be with other generic habits, the observation certainly holds with respect to the pleasures of virtue and of knowledge: the pleasure of doing good has an unbounded scope, and may be so variously gratified that it can never decay; science is equally unbounded; our appetite for knowledge having an ample range of gratification, where discoveries are recommended by novelty, by variety, by utility, or by all of them.

Custom
and Habit.

Custom
and habit.

In this intricate inquiry, we have endeavoured, but without success, to discover by what particular means it is that custom hath influence upon us: and now nothing seems left, but to hold our nature to be so framed as to be susceptible of such influence. And supposing it purposely so framed, it will not be difficult to find out several important final causes. That the power of custom is a happy contrivance for our good, cannot have escaped any one who reflects, that business is our province, and pleasure our relaxation only. Now satiety is necessary to check exquisite pleasures, which otherwise would engross the mind and unqualify us for business. On the other hand, as business is sometimes painful, and is never pleasant beyond moderation, the habitual increase of moderate pleasure, and the conversion of pain into pleasure, are admirably contrived for disappointing the malice of fortune, and for reconciling us to whatever course of life may be our lot:

How use doth breed a habit in a man!
This shadowy desert, unfrequented woods,
I better brook than flourishing peopled towns.
Here I can sit alone, unseen of any,
And to the nightingale's complaining notes
Tune my distresses, and record my woes.

Two Gentlemen of Verona, act 5. sc. 4.

As the foregoing distinction between intense and moderate, holds in pleasure only, every degree of pain being softened by time, custom is a catholicon for pain and distress of every sort; and of that regulation the final cause requires no illustration.

Another final cause of custom will be highly relished by every person of humanity, and yet has in a great measure been overlooked; which is, that custom hath a greater influence than any other known cause, to put the rich and the poor upon a level: weak pleasures, the share of the latter, become fortunately stronger by custom; while voluptuous pleasures, the share of the former, are continually losing ground by satiety. Men of fortune, who possess palaces, sumptuous gardens, rich fields, enjoy them less than passengers do. The goods of Fortune are not unequally distributed; the opulent possess what others enjoy.

And indeed, if it be the effect of habit, to produce the pain of want in a high degree while there is little pleasure in enjoyment, a voluptuous life is of all the least to be envied. Those who are habituated to high feeding, easy vehicles, rich furniture, a crowd of valets, much deference and flattery, enjoy but a small share of happiness, while they are exposed to manifold distresses. To such a man, enslaved by ease and luxury, even the petty inconveniences in travelling, of a rough road, bad weather, or homely fare, are serious evils: he loses his tone of mind, turns peevish, and would wreak his resentment even upon the common accidents of life. Better far to use the goods of Fortune with moderation: a man who by temperance and activity hath acquired a hardy constitution, is, on the one hand, guarded against external accidents; and, on the other, is provided with great variety of enjoyment ever at command.

We shall close this branch of the subject with an article more delicate than abstruse, *viz.* what authority custom ought to have over our taste in the fine arts. One particular is certain, that we cheerfully abandon

to the authority of custom things that nature hath left indifferent. It is custom, not nature, that hath established a difference between the right hand and the left, so as to make it awkward and disagreeable to use the left where the right is commonly used. The various colours, though they affect us differently, are all of them agreeable in their purity: but custom has regulated that matter in another manner; a black skin upon a human being, is to us disagreeable; and a white skin probably not less so to a negro. Thus things, originally indifferent, become agreeable or disagreeable by the force of custom. Nor will this be surprizing after the discovery made above, that the original agreeableness or disagreeableness of an object, is, by the influence of custom, often converted into the opposite quality.

Proceeding to matters of taste, where there is naturally a preference of one thing before another; it is certain, in the first place, that our faint and more delicate feelings are readily susceptible of a bias from custom; and therefore that it is no proof of a defective taste, to find these in some measure influenced by custom: dress and the modes of external behaviour, are regulated by custom in every country: the deep red or vermilion with which the ladies in France cover their cheeks, appears to them beautiful in spite of nature; and strangers cannot altogether be justified in condemning that practice, considering the lawful authority of custom, or of the *fashion* as it is called: it is told of the people who inhabit the skirts of the Alps facing the north, that the swelling they universally have in the neck is to them agreeable. So far has custom power to change the nature of things, and to make an object originally disagreeable take on an opposite appearance.

But as to every particular that can be denominated proper or improper, right or wrong, custom has little authority, and ought to have none. The principle of duty takes naturally place in every other; and it argues a shameful weakness or degeneracy of mind, to find it in any case so far subdued as to submit to custom.

II. *Effects of Custom and Habit in the Animal Economy.* These may be reduced to five heads. 1. On the simple solids. 2. On the organs of sense. 3. On the moving power. 4. On the whole nervous power. 5. On the system of blood-vessels.

1. *Effects on the Simple Solids.* Custom determines the degree of flexibility of which they are capable. By frequently repeated flexion, the several particles of which these solids consist are rendered more supple and moveable on each other. A piece of catgut, *s. g.* when on the stretch, and having a weight appended to its middle, will be bended thereby perhaps half an inch; afterwards, by frequent repetitions of the same weight, or by increasing the weight, the flexibility will be rendered double. The degree of flexibility has a great effect in determining the degree of oscillation, provided that elasticity is not affected; if it go beyond this, it produces flaccidity. Again, custom determines the degree of tension; for the same elastic chord that now oscillates in a certain degree of tension, will, by frequent repetition of these oscillations, be so far relaxed, that the extension must be renewed in order to produce the same tension, and consequently the same

Cullen's Lectures on the Mat. Med. 1st edit.

vibra-

Custom and Habit. vibrations, as at first. This appears in many instances in the animal economy, as when different muscles concur to give a fixed point or tension to each other: and thus a weakly child totters as it walks; but by giving it a weight to carry, and by thus increasing the tension of the system, it walks more steadily. In like manner the fulness of the system gives strength, by distending the vessels every where, and so giving tension: hence a man, by good nourishment, from being weak, acquires a great increase of strength in a few days: and on the other hand, evacuations weaken by taking off the tension.

2. *Effects on the Organs of Sense.* Repetition gives a greater degree of sensibility, in so far only as it renders perception more accurate. Repetition alone gives lasting impression, and thus lays the foundation of memory; for single impressions are but retained for a short time, and are soon forgot. Thus a person, who at present has little knowledge of cloths, will, by frequently handling them, acquire a skill of discerning them, which to others seems almost impossible. Many are apt to mistake this for a nicer sensibility, but they are much mistaken; for it is an universal law, that the repetition of impression renders us less acute. This is well illustrated by the operation of medicines; for all medicines which act on the organs of sense must, after some time, be increased in their dose to produce the same effects as at first. This affords a rule in practice with regard to these medicines; it becoming necessary, after a certain time, to change one medicine even for a weaker of the same nature. Thus medicines, which even have no great apparent force, are found, by long use, to destroy the sensibility of the system to other impressions. But to this general rule, that, by repetition, the force of impressions is more and more diminished, there are some exceptions. Thus persons, by a strong emetic, have had their stomachs rendered so irritable, that 1-20th of the first dose was sufficient to produce the same effect. This, however, oftener takes place when the vomit is repeated every day; for if the same vomit be given at pretty considerable intervals the general rule is observed to hold good. Thus two contrary effects of habit are to be noted; and it is proper to observe, that the greater irritability is more readily produced when the first impression is great, as in the case first given of the strong emetic. This may be farther illustrated by the effect of fear, which is commonly observed to be diminished on repetition; which can only be attributed to custom: while, on the other hand, there are instances of persons, who having once got a great fright, have for ever after continued slaves to fears excited by impressions of the like kind, however slight, which must be imputed entirely to excess of the first impression, as has been already observed. To this head also belongs the association of ideas, which is the foundation of memory and all our intellectual faculties, and is entirely the effect of custom; with regard to the body also, these associations often take place. And sometimes, in producing effects on the body, associations seemingly opposite are formed, which, through custom, become absolutely necessary; *e. g.* a person long accustomed to sleep in the neighbourhood of a great noise, is so far from being incommoded on that account, that afterwards such noise becomes necessary to produce sleep.

It will be of use to attend to this in medical practice; Custom and Habit. for we ought to allow for, however opposite it may seem at the time, whatever usually attended the purpose we design to effect. Thus, in the instance of sleep, we must not exclude noise when we want to procure rest, or any causes which may seem opposite to such an effect, provided custom has rendered them necessary.

3. *Effects on the Moving Fibres.* A certain degree of tension is necessary to motion, which is to be determined by custom; *e. g.* a fencer, accustomed to one foil, cannot have the same steadiness or activity with one heavier or lighter. It is necessary also that every motion should be performed in the same situation, or posture of the body, as the person has been accustomed to employ in that motion. Thus, in any surgical operation, a certain posture is recommended; but if the operator has been accustomed to another, such a one, however awkward, becomes necessary afterwards to his right performance of that operation.

Custom also determines the degree of oscillation of which the moving fibres are capable. A person accustomed to strong muscular exertions is quite incapable of the more delicate. Thus writing is performed by small muscular contractions; but if a person has been accustomed to stronger motions with these muscles, he will write with much less steadiness.

This subject of tension, formerly attributed to the *simple fibres*, is probably more strictly applicable to the moving: for besides a tension from flexion, there is also a tension from irritation and sympathy; *e. g.* the tension of the stomach from food, gives tension to the whole body. Wine and spirituous liquors give tension *e. g.* a person that is so affected with tremor as scarcely to hold a glass of any of these liquors to his head, has no sooner swallowed it, than his whole body becomes steady; and after the system has been accustomed to such stimuli, if they are not applied at the usual time, the whole body becomes flaccid, and of consequence unsteady in its motions.

Again, custom gives facility of motion. This seems to proceed from the distension which the nervous power gives to the moving fibres themselves. But in whatever manner it is occasioned, the effect is obvious; for any new or unusual motion is performed with great difficulty.

It is supposed that sensation depends on a communication with the sensorium commune, by means of organs sufficiently distended with nervous influence. We have found, that sensibility is diminished by repetition. And we have now to observe, that in some cases it may be increased by repetition, owing to the nervous power itself flowing more easily into the part on account of custom. Attention to a particular object may also determine a greater influx into any particular part, and thus the sensibility and irritability of that particular part may be increased.

But with regard to facility of motion, the nervous power, no doubt, flows most easily into these parts to which it has been accustomed: yet facility of motion does not entirely depend on this, but in part also on the concurrence of the action of a great many muscles; *e. g.* Winslow has observed, that in performing any motion, a number of muscles concur to give a fixed point to those intended chiefly to act, as well as to others.

Custom
and Habit.

others that are to vary and modify their action. This, however, is assisted by repetition and the freer influx; as by experience we know the proper attitude for giving a fixed point in order to perform any action with facility and steadiness.

Custom gives a spontaneous motion also which seems to recur at stated periods, even when the exciting causes are removed. Thus, if the stomach has been accustomed to vomit from a particular medicine, it will require a much smaller dose than at first, nay, even the very sight or remembrance of it will be sufficient to produce the effect; and there are not wanting instances of habitual vomiting, from the injudicious administration of emetics. It is on this account that all spasmodic affections so easily become habitual, and are so difficult of cure: as we must not only avoid all the exciting causes, even in the smallest degree, but also their associations.

Custom also gives strength of motion; strength depends on strong oscillations, a free and copious influx of the nervous power, and on dense solids. But in what manner all these circumstances have been brought about by repetition, has been already explained. The effect of custom, in producing strength, may be thus illustrated: a man that begins with lifting a calf, by continuing the same practice every day, will be able to lift it when grown to the full size of a bull.

All this is of considerable importance in the practice of physic, though but too little regarded; for the recovery of weak people, in great measure, depends on the use of exercise, suited to their strength, or rather within it, frequently repeated and gradually increased. Farther, it is necessary to observe, that custom regulates the particular celerity with which each motion is to be performed: for a person accustomed, for a considerable time to one degree of celerity, becomes incapable of a greater; *e. g.* a man accustomed to slow-walking will be out of breath before he can run 20 paces. The train, or order, in which our motions are to be performed, is also established by custom; for if a man hath repeated motions, for a certain time in any particular order, he cannot afterwards perform them in any other. Custom also very frequently associates motions and sensations: thus, if a person has been in use of associating certain ideas with the ordinary stimulus which in health excites urine, without these ideas the usual inclination will scarce excite that excretion; and when these occur, will require it even in the absence of the primary exciting cause; *e. g.* it is very ordinary for a person to make urine when going to bed; and if he has been, for any length of time, accustomed to do so, he will ever afterwards make urine at that time, though otherwise he would often have no such inclination: by this means some secretions become, in a manner, subject to the will. The same may be said of going to stool: and thus affords us a good rule in the case of costiveness; for by endeavouring to fix a stated time for this evacuation, it will afterwards, at such time, more readily return. It is farther remarkable, that motions are inseparably associated with other motions: this, perhaps, very often proceeds from the necessary degree of tension; but it also often depends merely on custom, an instance of which we have in the uniform motions of our eyes.

4. *Effects on the whole Nervous Power.* We have

found, that, by custom, the nervous influence may be determined more easily into one part than another; and therefore, as all the parts of the system are strongly connected, the sensibility, irritability, and strength of any particular part, may be thus increased. Custom also has the power of altering the natural temperament, and of inducing a new one. It is also in the power of custom to render motions periodical, and periodically spontaneous. An instance of this we have in sleep, which is commonly said to be owing to the nervous power being exhausted, the necessary consequence of which is sleep, *e. g.* a rest of the voluntary motions to favour the recruit of that power: but if this were the case, the return of sleep should be at different times, according as the causes which diminish the nervous influence operate more or less powerfully; whereas the case is quite otherwise, these returns of sleep being quite regular. This is no less remarkable in the appetites, that return at particular periods, independent of every cause but custom. Hunger, *e. g.* is an extremely uneasy sensation; but goes off of itself, if the person does not take food at the usual time. The excretions are farther proofs of this, *e. g.* going to stool, which, if it depended on any particular irritation, should be at longer or shorter intervals according to the nature of the aliment. There are many other instances of this disposition of the nervous influence to periodical motions, as the story of the idiot of Stafford, recorded by Dr Plot (*Spectator*, n^o 447.), who, being accustomed to tell the hours of the church-clock as it struck, told them as exactly when it did not strike by its being out of order. Montaigne tells us of some oxen that were employed in a machine for drawing water, who, after making 300 turns, which was the usual number, could be stimulated by no whip or goad to proceed farther. Infants, also, cry for and expect the breast at those times in which the nurse has been accustomed to give it.

Hence it would appear, that the human economy is subject to periodical revolutions, and that these happen not oftener may be imputed to variety: and this seems to be the reason why they happen oftener in the body than mind, because that is subject to greater variety. We see frequent instances of this in diseases, and in their crises; intermitting fevers, epilepsies, asthmas, &c. are examples of periodical affections: and that critical days are not so strongly marked in this country as in Greece, and some others, may be imputed to the variety and instability of our climate; but perhaps still more to the less sensibility and irritability of our system; for the exhibition of medicine has little effect in disturbing the crises, though it be commonly assigned as a cause.

We are likewise subject to many habits independent of ourselves, as from the revolutions of the celestial bodies, particularly the sun, which determines the body, perhaps, to other daily revolutions besides sleeping and waking. There are also certain habits depending on the seasons. Our connections, likewise, with respect to mankind, are means of inducing habits. Thus regularity from associating in business, induces regular habits both of mind and body.

There are many diseases which, though they arose at first from particular causes, at last continue merely through custom or habit. These are chiefly of the nervous

Custom
and Habit.

Custom and Habit, Customs. nervous system. We should therefore study to counteract such habits; and accordingly Hippocrates, among other things for the cure of epilepsy, orders an entire change of the manner or life. We likewise imitate this in the chincough; which often resists all remedies till the air, diet, and ordinary train of life, are changed.

5. *Effects on the Blood-vessels.* From what has been said on the nervous power, the distribution of the fluids must necessarily be variously affected by custom, and with that the distribution of the different excretions; for though we make an estimate of the proportion of the excretions to one another, according to the climate and seasons, they must certainly be very much varied by custom.

On this head we may observe, that blood-letting has a manifest tendency to increase the quantity of the blood; and if this evacuation be repeated at stated times, such symptoms of repletion, and such motions are excited at the returning periods, as render the operation necessary. The same has been observed in some spontaneous hemorrhagies. These, indeed, at first, may have some exciting causes, but afterwards they seem to depend chiefly on custom. The best proof of this is with regard to the menstrual evacuation. There is certainly something originally in females, that determines that evacuation to the monthly periods. Constant repetition of this comes to fix it, independent of strong causes, either favouring or preventing repletion; e. g. blood-letting will not impede it, nor filling the body induce it: and indeed, so much is this evacuation connected with periodical motions, that it is little in our power to produce any effect by medicines but at those particular times. Thus if we would relax the uterine system, and bring back this evacuation when suppressed, our attempts would be vain and fruitless, unless given at that time when the menses should have naturally returned.

CUSTOMS, in political economy, or the duties, toll, tribute, or tariff, payable to a king or state upon merchandize exported and imported, form a branch of the perpetual taxes. See TAX.

“The considerations upon which this revenue (or the more ancient part of it, which arose only from exports) was invested in the king, were said to be two: 1. Because he gave the subject leave to depart the kingdom, and to carry his goods along with him. 2. Because the king was bound of common right to maintain and keep up the ports and havens, and to protect the merchant from pirates. Some have imagined they are called with us *customs*, because they were the inheritance of the king by immemorial usage and the common law, and not granted him by any statute: but Sir Edward Coke hath clearly shown, that the king’s first claim to them was by grant of parliament 3 Edw. I. though the record thereof is not now extant. And indeed this is in express words confessed by statute 25 Edw. I. c. 7. wherein the king promises to take no customs from merchants, without the common assent of the realm, “saving to us and our heirs the customs on wool, skins, and leather, formerly granted to us by the commonalty aforesaid.” These were formerly called *hereditary customs* of the crown; and were due on the exportation only of the said three commodities, and of none other: which were stiled the *staple* commodi-

ties of the kingdom, because they were obliged to be brought to those ports where the king’s staple was established, in order to be there first rated, and then exported. They were denominated in the barbarous Latin of our ancient records, *custuma*, (an appellation which seems to be derived from the French word *coustum*, or *colutum*, which signifies toll or tribute, and owes its own etymology to the word *coust*, which signifies price, charge, or, as we have adopted it in English, *cost*); not *consuetudines*, which is the language of our law whenever it means merely usages. The duties on wool, sheep-skins or woolfells, and leather exported, were called *custuma antiqua sive magna*: and were payable by every merchant, as well native as stranger; with this difference, that merchant-strangers paid an additional toll, viz. half as much again as was paid by natives. The *custuma parva et nova* were an impost of 3 d. in the pound due from merchant-strangers only, for all commodities as well imported as exported; which was usually called the *alien’s duty*, and was first granted in 31 Edw. I. But these ancient hereditary customs, especially those on wool and woolfells, came to be of little account when the nation became sensible of the advantages of a home manufacture, and prohibited the exportation of wool by statute 11 Edw. III. c. 1.

“Other customs payable upon exports and imports were distinguished into subsidies, tonnage, poundage, and other imposts. Subsidies were such as were imposed by parliament upon any of the staple commodities before mentioned, over and above the *custuma antiqua et magna*: tonnage was a duty upon all wines imported, over and above the prisage and butlerage aforesaid: poundage was a duty imposed *ad valorem*, at the rate of 12 d. in the pound, on all other merchandize whatsoever: and the other imposts were such as were occasionally laid on by parliament, as circumstances and times required. These distinctions are now in a manner forgotten, except by the officers immediately concerned in this department; their produce being in effect all blended together, under the one denomination of the *customs*.”

By these we understand, at present, a duty or subsidy paid by the merchant at the quay upon all imported as well as exported commodities, by authority of parliament; unless where, for particular national reasons, certain rewards, bounties, or drawbacks, are allowed for particular exports or imports. The customs thus imposed by parliament are chiefly contained in two books of rates, set forth by parliamentary authority; one signed by Sir Harbottle Grimston, speaker of the house of commons in Charles II.’s time; and the other an additional one signed by Sir Spenser Compton, speaker in the reign of George I. to which also subsequent additions have been made. Aliens pay a larger proportion than natural subjects, which is what is now generally understood by the *aliens duty*; to be exempted from which is one principal cause of the frequent applications to parliament for acts of naturalization.

These customs are then, we see, a tax immediately paid by the merchant, although ultimately by the consumer. And yet these are duties felt least by the people; and, if prudently managed, the people hardly consider that they pay them at all. For the merchant

Customs
||
Custos Bre-
vium.

merchant is easy, being sensible he does not pay them for himself; and the consumer, who really pays them, confounds them with the price of the commodity: in the same manner as Tacitus observes, that the emperor Nero gained the reputation of abolishing the tax of the sale of slaves, though he only transferred it from the buyer to the seller; so that it was, as he expresses it, *remissum magis specie, quam vi: quia, cum venditor pendere juberetur, in partem pretii emptoribus accrescebat*. But this inconvenience attends it on the other hand, that these imposts, if too heavy, are a check and cramp upon trade; and especially when the value of the commodity bears little or no proportion to the quantity of the duty imposed. This in consequence gives rise also to smuggling, which then becomes a very lucrative employment: and its natural and most reasonable punishment, viz. confiscation of the commodity, is in such cases quite ineffectual; the intrinsic value of the goods, which is all that the smuggler has paid, and therefore all that he can lose, being very inconsiderable when compared with his prospect of advantage in evading the duty. Recourse must therefore be had to extraordinary punishments to prevent it; perhaps even to capital ones: which destroys all proportion of punishment, and puts murderers upon an equal footing with such as are really guilty of no natural, but merely a positive, offence.

There is also another ill consequence attending high imposts on merchandize, not frequently considered, but indisputably certain; that the earlier any tax is laid on a commodity, the heavier it falls upon the consumer in the end; for every trader through whose hands it passes must have a profit not only upon the raw material and his own labour and time in preparing it, but also upon the very tax itself, which he advances to the government; otherwise he loses the use and interest of the money which he so advances. To instance in the article of foreign paper. The merchant pays a duty upon importation, which he does not receive again till he sells the commodity, perhaps at the end of three months. He is therefore equally intitled to a profit upon that duty which he pays at the custom house, as to a profit upon the original price which he pays to the manufacturer abroad; and considers it accordingly in the price he demands of the stationer. When the stationer sells it again, he requires a profit of the printer or bookseller upon the whole sum advanced by him to the merchants: and the bookseller does not forget to charge the full proportion to the student or ultimate consumer; who therefore does not only pay the original duty, but the profits of these three intermediate traders, who have successively advanced it for him. This might be carried much farther in any mechanical, or more complicated, branch of trade.

CUSTOM-HOUSE, an office established in the maritime cities, or port-towns for the receipt and management of the customs and duties of importation, and exportation, imposed on merchandises, and regulated by books of rates.

CUSTOS BREVIUM, the principal clerk belonging to the court of common pleas, whose business it is to receive and keep all the writs made returnable in that court, filing every return by itself; and, at the end of each term, to receive of the prothonotaries all the records of the nisi prius, called the *posteas*.

Custos Rotulorum, an officer who has the custody of the rolls and records of the sessions of peace, and also of the commission of the peace itself.

He usually is some person of quality, and always a justice of the peace, of the quorum, in the county where he is appointed.

Custos Spiritualium, he that exercises the spiritual jurisdiction of a diocese, during the vacancy of any see, which, by the canon-law, belongs to the dean and chapter; but at present, in England, to the archbishop of the province, by prescription.

Custos Temporalium, was the person to whom a vacant see or abbey was given by the king, as supreme lord. His office was, as steward of the goods and profits, to give an account to the escheator, who did the like to the exchequer.

CUT-A-FEATHER, in the sea-language. If a ship has too broad a bow, it is common to say, *she will not cut a feather*; that is, she will not pass through the water so swift as to make it foam or froth.

CUT Purse, in law; if any person *clam & secreta*, and without the knowledge of another, cut his purse or pick his pocket, and steal from thence above the value of twelve pence, it is felony excluded clergy.

Cut-purses or *saccularii*, were more severely punished than common thieves by the Roman and Athenian laws.

CUT Water, the sharp part of the head of a ship below the beak. It is so called because it cuts or divides the water before it comes to the bow, that it may not come too suddenly to the breadth of the ship, which would retard her.

CUTANEOUS, in general, an appellation given to whatever belongs to the cutis or skin. Thus, we say *cutaneous* eruptions; the itch is a *cutaneous* disease.

CUTH, or *CUTHAN* (anc. geog.), a province of Assyria, which, as some say, lies upon the Araxes, and is the same with Cush: but others take it to be the same with the country which the Greeks call *Susiana*, and which to this very day, says Dr Wells, is by the inhabitants called *Chusestan*. F. Calmet is of opinion that Cuthah and Scythia are the same place, and that the Cuthites who were removed into Samaria by Salmaneser (2 Kings xvii. 24.) came from Cush or Cuth, mentioned in Gen. ii. 13. See the article *CUSH*.—The Cuthites worshipped the idol Nergal. id. ibid. 30. These people were transplanted into Samaria in the room of the Israelites, who before inhabited it. Calmet is of opinion, that they came from the land of Cush, or Cuthah upon the Araxes; and that their first settlement was in the cities of the Medes, subdued by Salmaneser and the kings of Syria his predecessors. The scripture observes, that the Cuthites, upon their arrival in this new country, continued to worship the gods formerly adored by them beyond the Euphrates. Efarhaddon king of Assyria, who succeeded Sennacherib, appointed an Israelitish priest to go thither, and instruct them in the religion of the Hebrews. But these people thought they might reconcile their old superstition with the worship of the true God. They therefore framed particular gods for themselves, which they placed in the several cities where they dwelt. The Cuthites then worshipped both the Lord and their false gods together, and chose the lowest of the people to make priests

Custos Ro-
tularum
|
Cuth.

Cuticle ||
Cutting. priests of them in the high places; and they continued this practice for a long time. But afterwards they forsook the worship of idols, and adhered only to the law of Moses, as the Samaritans who are descended from the Cuthites do at this day.

CUTICLE, the scarf-skin. See ANATOMY, n^o 74.

CUTICULAR, the same with CUTANEOUS.

CUTIS, the skin. See ANATOMY, n^o 76.

CUTTER, a small vessel, commonly navigated in the channel of England. It is furnished with one mast, and rigged as a sloop. Many of these vessels are used in an illicit trade, and others are employed by government to take them; the latter of which are either under the direction of the admiralty or custom-house. See a representation of a cutter of this sort in the plate referred to from the article VESSEL.

CUTTER, is also a small boat used by ships of war.

CUTTER of the Tallies, an officer of the exchequer, whose business is to provide wood for the tallies, to cut or notch the sum paid upon them; and then to cast them into court, to be written upon. See TALLY.

CUTTING, a term used in various senses and various arts; in the general, it implies a division or separation.

CUTTING is particularly used in heraldry, where the shield is divided into two equal parts, from right to left, parallel to the horizon, or in the fesse-way.

The word also is applied to the honourable ordinaries, and even to animals and moveables, when they are divided equally the same way; so, however, as that one moiety is colour, the other metal. The ordinaries are said to be cut, couped, when they do not come full to the extremities of the shield.

CUTTING, in chirurgery, denotes the operation of extracting the stone out of the bladder by section. See LITHOTOMY.

CUTTING in coinage. When the laminæ or plates of the metal, be it gold, silver, or copper, are brought to the thickness of the species to be coined, pieces are cut out, of thickness, and nearly of the weight, of the intended coin; which are now called *planchets*, till the king's image hath been stamped on them. The instrument wherewith they cut, consists of two pieces of steel, very sharp, and placed over one another; the lower a little hollow, representing a mortar, the other a pestle. The metal put between the two, is cut out in the manner described under COINAGE.

Note. Medallions, where the relievo is to be great, are not cut, but cast or moulded.

CUTTING, in the manege, is when the horse's feet interfere; or when with the shoe of one foot he beats off the skin from the pattern joint of another foot. This is more frequent in the hind foot than the fore: the causes are either weariness, weakness in the reins, not knowing how to go, or ill shoeing.

CUTTING, in painting, the laying one strong lively colour over another, without any shade or softening. The cutting of colours has always a disagreeable effect.

CUTTING in wood, a particular kind of sculpture or engraving; denominated from the matter wherein it is employed.

It is used for various purposes; as for figured letters, head and tail-pieces of books; and even for schemes and other figures, to save the expence of en-

graving on copper: and for prints and stamps for paper, calicoes, linens, &c.

The invention of cutting in wood, as well as that in copper, is ascribed to a gold smith of Florence; but it is to Albert Durer and Lucas they are both indebted for their perfection. See ENGRAVING, and PRINTING.

One Hugo de Carpi invented a manner of cutting in wood, by means whereof the prints appeared as if painted in clear-obscure. In order to this, he made three kinds of stamps for the same design; which were drawn, after one another, though the presses for the same print: they were so conducted, as that one served for the grand lights, a second for the demi-teints, and a third for the outlines and the deep shadows.

The art of cutting in wood was certainly carried to a very great pitch above two hundred years ago; and might even vie, for beauty and justness, with that of engraving in copper. At present it is in a low condition, as having been long neglected, and the application of artists wholly employed on copper, as the more easy and promising province: not but that wooden cuts have the advantage of those in copper on many accounts; chiefly for figures and devices in books; as being printed at the same time and in the same press as the letters: whereas for the other, there is required a particular impression. In the representation of plants and flowers, and in designs for paper-hangings, where the outline only is wanted to be printed, in a bold full manner, this method will be found cheaper and more effectual than the use of copper-plates.

The cutters in wood begin with preparing a plank or block of the size and thickness required, and very even and smooth on the side to be cut: for this, they usually take beech, pear-tree, or box; though the latter is the best, as being the closest, and least liable to be worm eat. The wood being cut into a proper form and size, should be plained as even and truly as possible: it is then fit to receive the drawing or chalking of the design to be engraved. But the effect may be made more apparent, and the ink, if any be used in drawing, be prevented from running, by spreading thinly on the surface of the wood white lead tempered with water, by grinding with a brush pencil, and afterwards rubbing it well with a fine linen rag whilst it is wet: and when it is dry, brushing off any loose or powdery part with a soft pencil.

On this block they draw their design with a pen or pencil, just as they would have it printed. Those who cannot draw their own design, as there are many who cannot, make use of a design furnished them by another; fastening it upon the block with paste made of flour and water, with a little vinegar or gum tragacanth; the strokes or lines turned towards the wood.

When the paper is dry, they wash it gently over with a sponge dipped in water; which done, they take off the paper by little and little, still rubbing it a little first with the tip of the finger; till at length there be nothing left on the block but the strokes of ink that form the design, which mark out so much of the block as is to be spared or left standing. Figures are sometimes cut out of prints, by taking away all the white part or blank paper, and cemented with gum-water to the surface of the wood. The rest they

Cutting.

Cuttings cut off, and take away very curiously with the points of very sharp knives, or little chisels or gravers, according to the bigness or delicacy of the work; for they need no other instruments.

It differs from engraving in copper, because in the former, the impression comes from the prominent parts or strokes left uncut; whereas in the latter, it comes from the channels cut in the metal.

The manner of printing with wooden prints is much more expeditious and easy than that of copper-plate; because they require only to be dipt in the printing-ink, and impressed on the object in the same manner and with the same apparatus as the letter-printing is managed; and for purposes that do not require great correctness, the impression is made by the hand only, a proper handle being fixed to the middle of the print, by which it is first dipped in the ink, spread by means of a brush on a block of proportionable size covered with leather; and then lifted up instantly, and dropped with some little force on the paper which is to receive the impression.

CUTTINGS, or slips, in gardening, the branches or sprigs of trees or plants, cut or slipped off to set again; which is done in any moist fine earth.

The best season is from August to April; but care is to be taken when it is done, the sap be not too much in the top, least the cut die before that part in the earth have root enough to support it: nor yet must it be too dry or scanty; the sap in the branches assisting it to take root.

In providing the cuttings, such branches as have joints, knots, or burrs, are to be cut off two or three inches beneath them, and the leaves to be stripped off so far as they are set in the earth. Small top-branches, of two or three years growth, are fittest for this operation.

CUTTLE-FISH. See **SEPTA**. The bone of the cuttle-fish is hard on one side, but soft and yielding on the other; so as readily to receive pretty neat impressions from medals, &c. and afterwards to serve as a mould for casting metals, which thus take the figure of the original: the bone is likewise frequently employed for cleaning or polishing silver. This fish contains in a certain distinct vessel a fluid as black as ink: which it is said to shed when pursued, and thus to conceal itself by discolouring the water. The particular qualities of this liquor are not yet determined. Dr Leigh says, he saw a letter which had been written with it ten years before, and which still continued. Some report that the ancients made their ink from it; and others, that it is the basis of China, or India-ink: but both these accounts appear to have little foundation. Pliny, speaking of the inks made use of in his time, after observing that the cuttle-fish is in this respect of a wonderful nature, adds expressly, that ink was not made from it.

CUTTS (John lord), a soldier of most hardy bravery in king William's wars, was son of Richard Cutts, Esq; of Matching in Essex; where the family were settled about the time of Henry VI. and had a great estate. He entered early into the service of the duke of Monmouth, was aid-de-camp to the duke of Lorrain in Hungary, and signalized himself in a very extraordinary manner at the taking of Buda by the Imperialists in 1686; which important place had

been for near a century and a half in the hands of the Turks. Mr Addison, in a Latin poem worthy of the Augustan age, plainly hints at Mr Cutt's distinguished bravery at that siege. Returning to England at the revolution, he had a regiment of foot; was created baron of Gowran in Ireland, Dec. 6. 1690; appointed governor of the isle of Wight, April 14. 1693; was made a major general; and, when the assassination project was discovered, 1695-6, was captain of the king's guard. In 1698 he was complimented by Mr John Hopkins, as one to whom "a double crown was due," as a hero and a poet. He was colonel of the Coldstream, or second regiment of guards, in 1701; when Mr Steele, who was indebted to his interest for a military commission, inscribed to him his first work, "The Christian Hero." On the accession of queen Anne he was made a lieutenant-general of the forces in Holland; commander in chief of the forces in Ireland, under the duke of Ormond, March 23. 1704-5; and afterwards one of the lords justices of that kingdom, to keep him out of the way of action; a circumstance which broke his heart. He died at Dublin, Jan. 26. 1706-7, and is buried there in the cathedral of Christ church. He wrote a poem on the death of queen Mary; and published, in 1687, "Poetical exercises, written upon several occasions, and dedicated to her royal Highness Mary princess of Orange." It contains, besides the dedication signed J. Cutts, verses to that princess; a poem on Wisdom; another to Mr Waller on his commending it; seven more copies of verses (one of them called *La Muse Cavalier*, which had been ascribed to lord Peterborough, and as such mentioned by Mr Walpole in the list of that nobleman's writings), and 11 songs; the whole composing but a very thin volume; which is by no means so scarce as Mr Walpole supposes it to be. A specimen of his poetry (of which the five first lines are quoted by Steele in his fifth Tatler) is here added:

Only tell her that I love,
Leave the rest to her and fate;
Some kind planet from above
May perhaps her pity move;
Lovers on their stars must wait,
Only tell her that I love.
Why, oh, why should I despair?
Mercy's pictur'd in her eye:
If she once vouchsafe to hear,
Welcome hope, and welcome fear.
She's too good to let me die;
Why, oh, why should I despair?

CYATHUS, *κυαθος* (from the verb *χυειν*, to pour out), was a common measure among the Greeks and Romans, both of the liquid and dry kind. It was equal to an ounce, or the twelfth part of a pint. The cyathus was made with an handle like our punch-ladle. The Roman toppers were used to drink as many *cyathi* as there were muses, i. e. nine; also as many as there were letters in the patron's name. Thus, they had modes of drinking similar to the modern health-drinking or toasting. They say, that the cyathus of the Greeks weighed 10 drachms; and Galen says the same; though elsewhere he says, that a cyathus contains 12 drachms of oil, 13 drachms and one scruple of wine, water, or vinegar, and 18 drachms of honey. Galen says, that among the Veterinarii the cyathus contained two ounces.

CYAXARES, son of Phraortes, was king of Media

Cutts
|
Cyaxares.

Cyaxares | dia and Persia. He bravely defended his kingdom, which the Scythians had invaded. He made war against Alyattes king of Lydia; and subjected to his power all Asia beyond the river Halys. He died after a reign of 40 years, in the year of Rome 160.

CYAXARES II. is supposed by some to be the same as Darius the Mede. He was son of Astyages king of Media. He added seven provinces to his father's dominions, and made war against the Assyrians, whom Cyrus favoured.

CYBEBE, a name of Cybele, from *κυβηβειν*, because in the celebration of her festivals men were driven to madness.

CYBELE, in Pagan mythology, the daughter of Coelus and Terra, and wife of Saturn. She is supposed to be the same as Ceres, Rhea, Ops, Vesta, Bona Mater, Magna Mater, Berecynthia, Dindymene, &c. According to Diodorus, she was the daughter of a Lydian prince, and as soon as she was born she was exposed on a mountain. She was preserved by sucking some of the wild beasts of the forest, and received the Name of Cybele from the mountain where her life had been preserved. When she returned to her father's court, she had an intrigue with Atys, a beautiful youth whom her father mutilated, &c. All the mythologists are unanimous in mentioning the amours of Atys and Cybele. In Phrygia the festivals of Cybele were observed with the greatest solemnity. Her priests called *Corybantes*, *Galli*, &c. were not admitted in the service of the goddess without a previous mutilation. In the celebration of the festivals, they imitated the manners of madmen, and filled the air with shrieks and howlings mixed with the confused noise of drums, tabrets, bucklers, and spears. This was in commemoration of the sorrow of Cybele for the loss of her favourite Atys. Cybele was generally represented as a robust woman far advanced in her pregnancy, to intimate the fecundity of the earth. She held keys in her hand, and her head was crowned with rising turrets, and sometimes with the leaves of an oak. She sometimes appears riding in a chariot drawn by two tame lions: Atys follows by her side, carrying a ball in his hand, and supporting himself upon a fir tree which is sacred to the goddess. Sometimes she is represented with a sceptre in her hand, with her head covered with a tower. She is also seen with many breasts, to show that the earth gives aliments to all living creatures; and she generally carries two lions under her arms. From Phrygia the worship of Cybele passed into Greece, and was solemnly established at Eleusis under the name of the *Eleusinian mysteries of Ceres*. The Romans, by order of the Sibylline books, brought the statue of the goddess from Pessinus into Italy; and when the ship which carried it had run on a shallow bank of the Tiber, the virtue and innocence of Claudia was vindicated in removing it with her girdle. It is supposed that the mysteries of Cybele were first known about 257 years before the Trojan war, or 1580 years before the Augustan age. The Romans were particularly superstitious in washing every year, on the 6th of the kalends of April, the shrine of this goddess in the waters of the river Almon. There prevailed many obscenities in the observation of the festivals; and the priests themselves were the

most eager to use indecent expressions, and to show their unbounded licentiousness by the impurity of their actions.

CYBELICUM MARMOR, a name given by the ancients to a species of marble dug in a mountain of that name in Phrygia. It was of an extremely bright white, with broad veins of bluish black.

CYCAS, in botany: A genus of plants belonging to the first natural order, *Palmae*. The fruit is a dry plum with a bivalved kernel. There is but one species described by Linnæus, viz. the circinalis, or sago-tree, which grows spontaneously in the East Indies, and particularly on the coast of Malabar. It runs up with a straight trunk to 40 feet or more, having many circles the whole length, occasioned by the old leaves falling off; for they standing in a circular order round the stem, and embracing it with their base, whenever they drop, they leave the marks of their adhesion behind. The leaves are pinnated, and grow to the length of seven or eight feet. The pinnæ or lobes are long, narrow, entire, of a shining green, all the way of a breadth, lance-shaped at the point, are closely crowded together, and stand at right angles on each side the midrib, like the teeth of a comb. The flowers are produced in long bunches at the footstalks of the leaves, and are succeeded by oval fruit, about the size of large plums, of a red colour when ripe, and a sweet flavour. Each contains a hard brown nut, enclosing a white meat, which tastes like a chestnut.

This is a valuable tree to the inhabitants of India, as it not only furnishes a considerable part of their constant bread, but also supplies them with a large article of trade. The body contains a farinaceous substance, which they extract from it and make into bread in this manner: they saw the body into small pieces, and after beating them in a mortar, pour water upon the mass: this is left for some hours to settle. When fit, it is strained through a cloth, and the finer particles of the mealy substance running through with the water, the gross ones are left behind and thrown away. After the farinaceous part is sufficiently subsided, the water is poured off, and the meal being properly dried, is occasionally made into cakes and baked. These cakes are said to eat nearly as well as wheaten bread, and are the support of the inhabitants for three or four months in the year.

The same meal more finely pulverized, and reduced into granules, is what is called *Sago*, which is sent into all parts of Europe, and sold in the shops for a great strengthener and restorative.

There is a sort of sago made in the West Indies, and is sent to Europe in the same manner as that from the East; but the West India sago is far inferior in quality to the other. It is supposed to be made from the pith of the *areca oleracea*. See *ARECA*.

The *brood boom* (or bread-tree) of the Hottentots, a plant lately discovered by professor Thunberg, is described as a new species of this genus, by the name of *cycas Caffra*, in the *Nova Acta Reg. Soc. Scient. Ups.* vol. ii. p. 233. tab. V. The pith, or *medulla*, which abounds in the trunk of this little palm, Mr Sparman informs us, is collected and tied up in dressed calf or sheep-skins, and then buried in the earth for the space of several weeks, till it becomes sufficiently

Cybeli
cum,
Cycas.

Cyceon mellow and tender to be kneaded up with water into a paste, of which they afterwards make small loaves or cakes, and bake them under the ashes. Other Hottentots, not quite so nice, nor endued with patience enough to wait this tedious method of preparing it, are said to dry and roast the pith or marrow, and afterwards make a kind of brown frumenty of it.

||
Cyclamen.

CYCLON, from *κωκυθων*, "to mix;" a name given by the ancient poets and physicians to a mixture of meal and water, and sometimes of other ingredients. These constituted the two kinds of *cyceon*; the coarser being of the water and meal alone; the richer and more delicate composed of wine, honey, flour, water, and cheese. Homer, in the 11th Iliad, talks of *cyceon* made with cheese and the meal of barley mixed with wine, but without any mention either of honey or water; and Ovid, describing the draught of *cyceon* given by the old woman of Athens to Ceres, mentions only flour and water. Dioscorides understood the word in both these senses; but extolled it most in the coarse and simple kind: he says, when prepared with water alone, it refrigerates and nourishes greatly.

CYCINNIS, a Grecian dance, so called from the name of its inventor, one of the satyrs belonging to Bacchus. It consisted of a combination of grave and gay movements.

CYCLADES INSULAE; islands anciently so called, as Pliny informs us, from the *Cyclus* or orb in which they lie; beginning from the promontory *Geraestum* of *Embocca*, and lying round the island *Delos*, (Pliny).

Where they are, and what their number, is not so generally agreed. Strabo says, they were at first reckoned 12, but that many others were added: yet most of them lie to the south of *Delos*, and but few to the north, so that the middle or centre, ascribed to *Delos*, is to be taken in a loose, not a geometrical sense. Strabo recites them after *Artemidorus*, as follows: *Helena*, *Ceos*, *Cynthus*, *Seriphus*, *Melus*, *Siphus*, *Cimolus*, *Prepesinthus*, *Olearus*, *Naxus*, *Parus*, *Syrus*, *Myconus*, *Tenus*, *Andrus*, *Gyarus*; but he excludes from the number, *Prepesinthus*, *Olearus*, and *Gyarus*.

CYCLAMEN, SOWBREAD: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 21st order, *Preciæ*. The corolla is verticillated, with the tube very short, and the throat prominent; the berry is covered with the capsule. There are but two species: which, however, produce many beautiful varieties. They are low, herbaceous, flowery perennials of the tuberous rooted kind, with numerous, angular, heart-shaped, spotted, marbled leaves; with many fleshy foot-stalks six inches high, carrying monopetalous, five-parted reflexed flowers of various colours. All the varieties are extremely ornamental, and some of the flowers very fragrant. They may be planted in any of the common borders, but require to be sheltered from hard frosts by being covered with mats. They should also have a light dry soil, otherwise their roots are apt to rot. The species are propagated by seeds, and the particular varieties by dividing their roots.

The root of the cyclamen has, when fresh, an extremely acrimonious burning taste, which it loses almost entirely on being dried. It is recommended as

an errhine; in cataplasms for schirrous any cancerous tumors; and internally as a cathartic, detergent, and aperient. It operates very slowly, but with great virulence and inflaming the fauces and intestines.

CYCLE, in chronology, a certain period or series of numbers which regularly proceed from the first to the last, and then return again to the first, and so circulate perpetually. See **CHRONOLOGY**, n° 26.

Cycle of Indiction, a period of 15 years in use among the Romans. It has no connection with the celestial motion, but was instituted, according to Baronius, by Constantine; who having reduced the time which the Romans were obliged to serve to 15 years, he was consequently obliged every 15 years to impose, or *indicare* according to the Latin expression, an extraordinary tax for the payment of those who were discharged; and hence arose this cycle, which from the Latin word *indicare*, was styled *indiction*.

Cycle of the Moon, called also the *golden number*, and the *Metonic cycle* from its inventor Meton the Athenian, is a period of 19 years, which when they are completed, the new moons and full moons return on the same days of the month, so that on whatever days the new and full moons fall this year, 19 years hence they will happen on the very same days of the month, though not at the same hour, as Meton and the fathers of the primitive church thought; and therefore at the time of the council of Nice, when the method of finding the time for observing the feast of Easter was established, the numbers of the lunar cycle were inserted into the kalender, which upon the account of their excellent use, were set in golden letters, and the year of the cycle called the *golden number* of that year.

Cycle of the Sun, a revolution of 28 years, which being elapsed, the dominical or Sunday letters return to their former place, and proceed in the same order as before, according to the Julian kalender.

CYCLISUS, in surgery, an instrument in the form of a half moon, used in scraping the skull, in case of fractures of that part.

CYCLOID, a curve on which the doctrines of pendulums, and time measuring instruments, in a great measure depend; Mr Huygens demonstrated, that from whatever point or height a heavy body, oscillating on a fixed centre, begins to descend, while it continues to move in a cycloid, the time of its falls or oscillations will be equal to each other. It is likewise demonstrable, that it is the curve of quickest descent, *i. e.* a body falling in it, from any given point above, to another, not exactly under it, will come to this point in a less time than in any other curve passing through those two points.

CYCLOPÆDIA, or **ENCYCLOPÆDIA**, denotes the circle or compass of arts and sciences. A cyclopædia, say the authors of the French *Encyclopédie*, ought to explain as much as possible the order and connection of human knowledge.

CYCLOPS, in fabulous history, the sons of Neptune and Amphitrite; the principal of whom were Brontes Steropes, and Peracmon; but their whole number amounted to above an hundred. Jupiter threw them into Tartarus as soon as they were born; but they were delivered at the intercession of Tellus, and became

Cycle
||
Cyclops.

Cyclopterus. came the assistants of Vulcan. They were of prodigious stature, and had each only one eye, which was placed in the middle of their foreheads.

Some mythologists say, that the Cyclops signify the vapours raised in the air, which occasion thunder and lightning; on which account they are represented as forging the thunderbolts of Jupiter. Others represent them as the first inhabitants of Sicily, who were cruel, of a gigantic form, and dwelt round mount *Ætna*.

CYCLOPTERUS, the **SUCKER**, in ichthyology, a genus belonging to the order of amphibia nantes. The head is obtuse, and furnished with saw-teeth: there are four rays in the gills; and the belly-fins are connected together in an orbicular form. The species are,

1. The lumpus, or lump-fish, grows to the length of 19 inches, and weighs seven pounds. The shape of the body is like that of the bream, deep and very thick, and it swims edge-ways. The back is sharp and elevated; the belly flat, of a bright crimson colour. Along the body there run several rows of sharp bony tubercles, and the whole skin is covered with small ones. The pectoral fins are large and broad, almost uniting at their base. Beneath these is the part by which it adheres to the rocks, &c. It consists of an oval aperture, surrounded with a fleshy, muscular, and obtuse soft substance; edged with many small threaded appendages, which concur as so many clasps. The tail and vent-fins are purple. By means of this part it adheres with vast force to any thing it pleases. As a proof of its tenacity, it hath been known, that in flinging a fish of this species just caught into a pail of water, it fixed itself so firmly to the bottom, that on taking the fish by the tail, the whole pail by that means was lifted, though it held some gallons, without once making the fish quit its hold. These fish resort in multitudes during spring to the coast of Sutherland near the Ord of Caithness. The seals which swarm beneath, prey greatly upon them, leaving the skins; numbers of which, thus emptied, float ashore at that season. It is easy to distinguish the place where the seals are devouring this or any other unctuous fish, by a smoothness of the water immediately above the spot. This fact is now established; it being a tried property of oil to still the agitation of the waves and render them smooth. Great numbers of lump-fish are found in the Greenland seas during the months of April and May, when they resort near the shore to spawn. Their roe is remarkably large, which the Greenlanders boil to a pulp and eat. They are extremely fat, which recommends them the more to the natives, who admire all oily food. They call them *nipists* or *cat-fish*, and take quantities of them during the season. The fish is sometimes eaten in England, being stewed like carp; but is both flabby and insipid.

2. The liparis takes the name of *sea-snail* from the soft and unctuous texture of its body, resembling that of the land-snail. It is almost transparent, and soon dissolves and melts away. It is found in the sea near the mouths of great rivers, and hath been seen full of spawn in January. The length is five inches; the colour a pale brown, sometimes finely streaked with a darker. Beneath the throat is a round depression of

a whitish colour like the impression of a seal, surrounded by twelve small pale yellow tubercles, by which probably it adheres to the stones like the other species.

3. The lesser sucking-fish is found in different parts of the British seas. It is about four inches in length; the skin without scales, slippery, and of a dusky colour. It hath also an apparatus for adhering to stones and rocks similar to the others.

CYDER, or **CIDER**, an excellent drink made of the juice of apples, especially of the more curious table kinds; the juice of these being esteemed more cordial and pleasant than that of the wild or harsh kinds. In making this drink it hath long been thought necessary, in every part of England, to lay the harder cyder-fruits in heaps for some time before breaking their pulps; but the Devonshire people have much improved this practice. In other counties the method is to make these heaps of apples in a house, or under some covering inclosed on every side. This method hath been found defective, because, by excluding the free air, the heat soon became too violent, and a great perspiration ensued, by which in a short time the loss of juices was so great, as to reduce the fruit to half their former weight, attended with a general rottenness, rancid smell, and disagreeable taste. In the South-hams, a middle way has been pursued, to avoid the inconveniences and loss attending the above. They make their heaps of apples in an open part of an orchard, where, by the means of a free air and less perspiration, the desired maturity is brought about, with an inconsiderable waste of the juices and decay of the fruit, entirely free of rankness; and though some apples rot even in this manner, they are very few, and are still fit for use; all continue plump and full of juices, and very much heighten the colour of cyders, without ill taste or smell.

In pursuing the Devonshire method, it is to be observed, 1. That all the promiscuous kinds of apples that have dropped from the trees, from time to time, are to be gathered up and laid in a heap by themselves, and to be made into cyder after having so lain about ten days. 2. Such apples as are gathered from the trees, having already acquired some degree of maturity, are likewise to be laid in a heap by themselves for about a fortnight. 3. The later hard fruits, which are to be left on the trees till the approach of frost is apprehended, are to be laid in a separate heap, where they are to remain a month or six weeks, by which, notwithstanding frost, rain, &c. their juices will receive such a maturation, as will prepare them for a kindly fermentation, and which they could not have attained on the trees by means of the coldness of the season.

It is observable, that the riper and mellow the fruits are at the time of collecting them into heaps, the shorter should be their continuance there; and on the contrary, the harsher, immaturer, and harder they are, the longer they should rest.

These heaps should be made in an even and open part of an orchard, without an regard to covering from rain, dews, or what else may happen during the apples staying there; and whether they be carried in and broken in wet or dry weather, the thing is all the same. If it may be objected that during their having lain

Cyder
||
Cydnus.

lain together in the heap, they may have imbibed great humidity, as well from the air as from the ground, rain, dews, &c. which are mixed with their juices; the answer is, this will have no other effect than a kindly diluting, natural to the fruit, by which means a speedier fermentation ensues, and all heterogeneous humid particles are thrown off.

The apples are then ground, and the pumice is received in a large open-mouthed vessel, capable of containing as much thereof as is sufficient for one making, or one cheese. Though it has been a custom to let the pumice remain some hours in the vessel appropriated to contain it, yet that practice is by no means commendable; for if the fruits did not come ripe from the trees, or otherwise matured, the pumice, remaining in the vat too long, will acquire such harshness and coarseness from the skins as is never to be got rid of; and if the pumice is of well ripened fruit the continuing too long there will occasion it to contract a sharpness that very often is followed with want of spirit and pricking; nay, sometimes it even becomes vinegar, or always continues of a wheyish colour; all which proceeds from the heat of fermentation that it almost instantly falls into on lying together; the pumice therefore should remain no longer in the vat than until there may be enough broke for one pressing, or that all be made into a cheese, and pressed the same day it is broken.

In Plate CLIV. is a perspective view of the cyder-press and apple-mill.

A, B, the bottom or lower beam; C, D, the upper beam; 5, 6, 7, 8, 9, the uprights; 4, 4, e, e, spurs; Z, 2, 12, braces, or cross-pieces; a, b, capitals; X, blocks; g, the screw; E, the back or receiver; F, the cheese or cake of pumice, placed on the stage or bafon; G, the stage or bafon; 10, 10, beams that support the pieces of which the bafon is composed; 11, perpendicular pieces for supporting these beams; H, the buckler; R, S, Q, a circular trough of the apple-mill; T, L, V, compartments or divisions, for different sorts of apples; M, the mill-stone; L, M, axis of the mill stone; N, the spring-tree bar.

CYDER-Spirit, a spirituous liquor drawn from cyder by distillation, in the same manner as brandy from wine. The particular flavour of this spirit is not the most agreeable, but it may with care be divested wholly of it, and rendered a perfectly pure and insipid spirit upon rectification. The traders in spirituous liquors are well enough acquainted with the value of such a spirit as this: they can give it the flavours of some other kinds, and sell it under their names, or mix it in large proportion with the foreign brandy, rum, and arrack, in the sale, without any danger of a discovery of the cheat.

CYDIAS, a painter who made a painting of the Argonauts in the 11th Olympiad. This celebrated piece was bought by the orator Hortensius for 164 talents.

CYDNUS (anc. geog.), a river of Cilicia; rising in mount Taurus, to the north of Tarsus, through whose middle it ran, in a very clear and cold stream, which had almost proved fatal to Alexander on bathing in it; falling into the sea at a place called Rhegma, a breach, the sea breaking in there, and affording

the people of Tarsus a station or port for their ships. The water of the Cydnus is commended by Strabo, as of service in nervous disorders and the gout. Cydonia.

CYDONIA (anc. geog.), one of the three most illustrious cities of Crete, situated in the north-west of the island, with a locked port, or walled round. The circumstances of the founding of Cydon are uncertain. Stephen of Byzantium says, that it was at first named Apollonia from Cydon the son of Apollo. Pausanias ascribes the founding of it to Cydon the son of Tegetus, who travelled into Crete. Herodotus affirms, that it was founded by the Samians, and that its temples were erected by them. Alexander, in the first book of the Cretans, informs us, that it received its name from Cydon the son of Mercury. Cydon was the largest city in the island; and was enabled to hold the balance between her contending neighbours. She sustained some famous sieges. Phaleucus, general of the Phocceans, making an expedition into Crete with a fleet and a numerous army, invested Canea both by sea and land; but lost his army and his life before its walls. In succeeding times, when Metellus subdued the island, he assailed Cydon with all his forces; and after combating an obstinate resistance, subjected it to the power of Rome. Cydon occupied the present situation of Canea; only extending half a league farther towards St Odero; where on the sea shore the remains are still to be seen of some ancient walls which appear to have been of a very solid construction. See CANEA.

CYDONIA, the QUINCE; so called from Cydon, a town of Crete, famous for its abounding with this fruit. Linnæus has joined this genus to the apple and pear; but as there is such a remarkable difference between the fruits, we follow Mr Miller, who treats the quince as a genus by itself.

Species. 1. The oblonga, with an oblong fruit, lengthened at the base. 2. The maliforma, with oval leaves woolly on their under side, and lengthened at their base. 3. The lusitanica, with obverse oval leaves, woolly on their under side. There are some other varieties of this fruit propagated in fruit-gardens, and in the nurseries for sale; one of which is a soft eatable fruit, another very astringent, and a third with a very small fruit cottony all over, which is scarce worth keeping. These Mr Miller supposed to be feminal variations, but the three others to be distinct species. The Portugal quince is the most valuable: its pulp turns to a fine purple when stewed or baked, and becomes much softer and less austere than the others; so is much fitter for making marmalade. The trees are all easily propagated, either by layers, suckers, or cuttings; which must be planted in a moist soil. Those raised from suckers are seldom so well rooted as those which are obtained from cuttings or layers, and are subject to produce suckers again in greater plenty: which is not so proper for fruit-bearing trees. These trees require very little pruning; the chief thing to be observed is, to keep their stems clear from suckers, and cut off such branches as cross each other: likewise all upright luxuriant shoots from the middle of the tree should be taken off, that the head may not be too much crowded with wood, which is of ill consequence to all fruit-trees. These sorts may also be propagated by budding or grafting upon stocks raised by

Cygnus by cuttings; so that the best sorts may be cultivated this way in greater plenty than by any other method. These are also in great esteem to bud or graft pears upon; which for summer or autumn fruits are a great improvement to them, especially those designed for walls and espaliers; for the trees upon these stocks, do not shoot so vigorously as those upon free-stocks, and therefore may be kept in less compass, and sooner produce fruit: but hard winter-fruits do not succeed so well upon these stocks, their fruit being subject to crack, and are commonly stony, especially all the breaking pears: therefore these stocks are only fit for melting pears and a moist soil.

CYGNUS, or **SWAN**, in ornithology. See **ANAS**.

CYGNUS, the **SWAN**, in astronomy, a constellation of the northern hemisphere, between Lyra and Cepheus. The stars in the constellation Cygnus, in Ptolemy's catalogue, are 19; in Tycho's 18; in Hevelius's 47; in the Britannic catalogue 81.

CYLINDER, in geometry, a solid body supposed to be generated by the rotation of a parallelogram.

Rolling, or *Loaded CYLINDER*, a cylinder which rolls up an inclined plane; the phenomena of which are explained under **MECHANICS**.

CYLINDROID, in geometry, a solid body, approaching to the figure of a cylinder, but differing from it in some respects, as having the bases elliptical, but parallel and equal.

CYLINDRUS, in natural history, the name of a genus of shell-fish, of which there are many elegant and precious species.

CYMA, in botany, the tender stalks which herbs send forth in the beginning of the spring, particularly those of the cabbage kind.

CYMA, or **CYMATIUM**, in architecture, a member or moulding of the corniche, the profile of which is waved, that is, concave at top, and convex at bottom.

CYMBAL, *κυμβαλον*, a musical instrument in use among the ancients. The cymbal was made of brass, like our kettle drums, and, as some think, in their form, but smaller, and of different use. Ovid gives cymbals the epithet of *genialia*, because they were used at weddings and other diversions.

Cassiodorus and Isidore call this instrument *acetabulum*, the name of a cup or cavity of a bone wherein another is articulated; and Xenophon compares it to a horse's hoof; whence it must have been hollow: which appears, too, from the figure of several other things denominated from it: as a basin, caldron, goblet, cask, and even a shoe, such as those of Empedocles, which were of brass.

In reality, the ancient cymbals appear to have been very different from our kettle drums, and their use of another kind: to their exterior cavity was fastened a handle; whence Pliny compares them to the upper part of the thigh, and Rabanus to phials.

They were struck against one another, in cadence, and made a very acute sound. Their invention was attributed to Cybele; whence their use in feasts and sacrifices: setting aside this occasion, they were seldom used but by dissolute and effeminate people. M. Lampe, who has written expressly on the subject, attributes the invention to the Curetes, or inhabitants of mount Ida in Crete; it is certain these, as well as the Cory-

bantes or guards of the kings of Crete, and those of Rhodes and Samothracia, were reputed to excel in the music of the cymbal.

The Jews had their cymbals, or at least instruments which translators render cymbals; but as to their matter and form, critics are still in the dark. The modern cymbal is a mean instrument, chiefly in use among vagrants, gypsies, &c. It consists of steel wire, in a triangular form, whereon are passed five rings, which are touched and shifted along the triangle with an iron rod held in the left hand, while it is supported in the right by a ring, to give it the freer motion. Durandus says, that the monks used the word *cymbal* for the cloister-bell used to call them to the refectory.

CYME (anc. geog.), a city built by Pelops on his return from Greece. Cyme the Amazon gave its name, on expelling the inhabitants, according to Mela. Latin authors, as Nepos, Livy, Mela, Pliny, Tacitus, retain the appellation *Cyme*, after the Greek manner. It stood in Aeolia, between Myrina and Phocæa (Ptolemy); and long after, in Peutinger's map, is set down nine miles distant from Myrina.—From this place was the Sybilla Cumæa, called *Erythraea*, from *Erythra*, "a neighbouring place." It was the country of Ephorus. Helioid was a Cnecan originally (Stephanus); his father coming to settle at Ascra in Bœotia.

CYMENE, in botany, a name given by the ancient Greeks to a plant with which they used to dye woollen things yellow, and with which the women of those times used also to tinge the hair yellow, that being the favourite colour in those ages. The *cymene* of the Greeks is evidently the same plant with the *lutea herba* of the Latins; or what we call *dyer's weed*. See **RESEDA**.

CYNÆGIRUS, an Athenian, celebrated for his extraordinary courage. He was brother to the poet Æschylus. After the battle of Marathon, he pursued the flying Persians to their ships, and seized one of their vessels with his right hand, which was immediately severed by the enemy. Upon this he seized the vessel with his left hand, and when he had lost that also, he still kept his hold with his teeth.

CYNANCHE, a species of quinzy, in which the tongue is inflamed and swelled, so that it hangs out beyond the teeth.

CYNANCHUN, **BASTARD DOGSBANE**: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 30th order, *Contortæ*. The nectarium is cylindrical and quinque-dentated. There are six species; of which the following are the most remarkable. 1. The acutum, commonly called *Montpelier scammony*; and, 2. The monspeliacum, or round-leaved Montpelier scammony. They abound with a milky juice like the spurge, which issues out wherever they are broken, and this milky juice when concreted has frequently been sold for scammony. These plants propagate so fast by their creeping roots, that few people care to admit them into gardens.

CYNARA, the **ARTICHOKE**: A genus of the polygamia æqualis order, belonging to the syngeneia class of plants. The calyx is dilated, imbricated with cornous squamæ, and emarginated with a sharp point.

Off

Cyme
Cynara.

Cynara. Of this genus there are four species, but only two are cultivated for use.

1. The scolymus, or garden artichoke, hath large, thick, perennial roots, crowned by a considerable cluster of large pennatifid, erect leaves, two or three feet long. In the middle are upright stalks rising a yard high, on the top of which is a large rough scaly head, composed of numerous, oval, calycinal scales inclosing the florets, sitting on a broad fleshy receptacle, which, with the fleshy base of the scales, is the only eatable part of the plant. The varieties of this species are, (1.) The conical green-headed French artichoke, having the small leaves terminated by spines, a tall stalk, the head somewhat conical, and of a light green colour, with the scales pointed at top, opening and turning outward. (2.) The globular-headed red Dutch artichoke, having leaves without spines, a strong stalk, the head large, globular, a little compressed at top, and of a reddish-green colour; broad obtuse scales emarginated at top, growing close, and turning inward. Of these varieties the last is deservedly the most esteemed, both on account of its superiority in size and the agreeableness of its flavour. Both varieties are perennial in their root: but the leaves and fruit-stem die to the ground in winter; and their roots remaining, send up fresh leaves and stems every summer, producing a supply of artichokes for 20 years if required. The flowers and seed of all the plants of this genus are produced in the centre of the head; the scales of which are the proper calyx of the flower, which consists of numerous small bluish florets, succeeded by downy seeds sitting naked on the receptacle.

2. The cardunculus, or cardoon, greatly resembles the artichoke, but is of larger and more regular growth; the leaves being more upright, taller, broader, and more regularly divided; and the stalks of the leaves blanched are the only eatable parts of the plant.

Culture. Both the varieties of the artichoke are propagated by slips or suckers, arising annually from the stool or root of the old plants in spring, which are to be taken from good plants of any present plantation in March or the beginning or April, and planted in the open quarter of the kitchen-garden, in rows five feet asunder; and they will produce artichokes the same year in autumn. It should, however, be remarked, that though artichokes are of many years duration, the annual produce of their fruit will gradually lessen in the size of the eatable parts after the third or fourth year, so that a fresh plantation should be made every three or four years. The cardoon is a very hardy plant, and prospers in the open quarters of the kitchen-garden. It is propagated by seed sowed annually in the full ground in March; either in a bed for transplantation, or in the place where they are designed to remain. The plants are very large, so must stand at considerable distances from one another. By this means you may have some small temporary crops between the rows, as of lettuce, spinach, endive, cabbage, savoy, or broccoli plants. In the latter end of September, or in October, the cardoons will be grown very large, and their footstalks have acquired a thick substance; you must then tie up the leaves of each plant, to admit of earthing them closely all round for blanching, which will take up six or eight weeks; and thus the plants will come

in for use in November and December, and continue all winter.

CYNÆUS of Thessaly, the scholar of Demosthenes, flourished 275 years before Christ. Pyrrhus had so high an esteem for him, that he sent him to Rome to solicit a peace, and so vast was his memory, that the day after his arrival he saluted all the senators and knights by name. Pyrrhus and he wrote a Treatise of War, quoted by Tully.

CYNICS, a sect of ancient philosophers, who valued themselves upon their contempt of riches and state, arts and sciences, and every thing, in short, except virtue or morality.

The cynic philosophers owe their origin and institution to Antisthenes of Athens, a disciple of Socrates; who being asked of what use his philosophy had been to him, replied, "It enables me to live with myself." Diogenes was the most famous of his disciples, in whose life the system of his philosophy appears in its greatest perfection. He led a most wretched life, a tub having served him for a lodging, which he rolled before him wherever he went. Yet he was nevertheless not the more humble on account of his ragged cloak, bag, and tub; for one day entering Plato's house, at a time when there was a splendid entertainment there for several persons of distinction, he jumped up upon a very rich couch in all his dirt, saying, "I trample on the pride of Plato." "Yes (replied Plato), but with great pride, Diogenes." He had the utmost contempt for all the human race: for he walked the streets of Athens at noon day with a lighted lantern in his hand, telling the people, "He was in search of a man." Amongst many excellent maxims of morality, he held some very pernicious opinions; for he used to say, that the uninterrupted good fortune of Harpalus, who generally passed for a thief and a robber, was a testimony against the gods. He regarded chastity and modesty as weaknesses: hence Laertius observes of him, that he did every thing openly, whether it belonged to Ceres or Venus; though he adds, that Diogenes only ran to an excess of impudence to put others out of conceit with it. But impudence was the characteristic of these philosophers; who argued, that what was right to be done, might be done at all times and in all places. The chief principle of this sect, in common with the stoics, was, that we should follow nature. But they differed from the stoics in their explanation of that maxim; the cynics being of opinion, that a man followed nature that gratified his natural motions and appetites; while the stoics understood right reason by the word nature.

CYNIC Spasm, a kind of convulsion, wherein the patient imitates the howlings of dogs.

CYNIPS, in zoology, a genus of insects belonging to the hymenoptera order. The mouth is armed with jaws, but has no proboscis: the sting is spiral, and mostly concealed within the body. The *quercus folii*, or oak-leaf cynips, is of a burnished shining brown colour. The antennæ are black; the legs and feet of a chestnut-brown; and the wings white, but void of marginal spots. It is in the little smooth, round, hard galls, found under the oak-leaves, generally fastened to the fibres, that this insect is produced, a single one in each gall. These latter are ligneous, of a hard compact sub-

Cynus
||
Cynips.

Cynoc-
phalus
||
Cynofar-
ges.

Cynoc-
phala.
||
Cyperus.

substance, formed like the rest, by the extravasation of the sap of the leaf, occasioned by the puncture of the gall-fly when it deposits its eggs. Sometimes instead of the cynips, there is seen to proceed from the gall a larger insect of a brown colour, which is an ichneumon. This ichneumon is not the real inmate of the gall, or he that formed it. He is a parasite, whose mother deposited her egg in the yet tender gall; which, when hatched, brings forth a larva that destroys the larva of the cynips, and then comes out when it has undergone its metamorphosis and acquired its wings.

The quercus gemmæ, or oak-bud cynips, is of a very dark green, slightly gilded: its antennæ and feet are of a dun colour, rather deep. It deposits its eggs in the oak buds, which produces one of the finest galls, leaved like a rose-bud beginning to blow. When the gall is small, that great quantity of leaves is compressed, and they are set one upon another like the tiles of a roof. In the centre of the gall there is a kind of ligneous kernel, in the middle of which is a cavity; and in that is found the little larva, who feeds there, takes its growth, undergoes its metamorphosis, and breaks through the inclosure of that kind of cod in order to get out. The whole gall is often near an inch in diameter, sometimes more when dried and displayed; and it holds to a branch by a pedicle.

There are a great number of other species.

CYNOCEPHALUS, in zoology, the trival name of a species of SIMIA.

CYNOGLOSSUM, HOUND'S TONGUE: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 41st order, *Asperifoliae*. The corolla is funnel-shaped, with its throat closed up by little arches formed in it; the seeds depressed, and affixed to the style or receptacle only on their inner side. There are eight species, none of them remarkable for their beauty. The root of one of them, *viz.* the officinale, or common greater hound's tongue, was formerly used in medicine, and supposed to possess narcotic virtues; but it is discharged from the present practice. The smell of the whole plant is very disagreeable. Goats eat it; sheep, horses, and swine refuse it.

CYNOMETRA, in botany: A genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking with those of which the order is doubtful. The calyx is tetraphyllous; the antheræ bifid at top; the legumen carnos, crescent-shaped, and monospermous.

CYNOMORIUM, in botany: A genus of the monandria order, belonging to the monœcia class of plants; and in the natural method ranking under the 50th order, *Amentaceæ*. The male calyx is an imbricated catkin; there is no corolla: the calyx of the female is in the same catkin; no corolla; one style; and one roundish seed.

CYNOPHONTIS, in antiquity, a festival observed in the dog-days at Argos, and so called *απο της κυνας φονης*, *i. e.* from killing dogs; because it was usual on this day to kill all the dogs they met with.

CYNOREXY, an immoderate appetite, to the degree of a disease; called also *fames canina* and *bulimy*.

CYNOSARGES, a place in the suburbs of Athens, named from a white or swift dog, who snatched away part of the sacrifice offering to Hercules. It had a

gymnasium, in which strangers or those of the half-blood performed their exercises; the case of Hercules, to whom the place was consecrated. It had also a court of judicature, to try illegitimacy, and to examine whether persons were Athenians of the whole or half blood. Here Antisthenes set up a new sect of philosophers called *Cynics*, either from the place, or from the snarling or the impudent disposition of that sect.

CYNOSCEPHALÆ (anc. geog.), a place in Thessaly near Scotussa; where the Romans, under Q. Flaminius, gained a great victory over Philip, son of Demetrius king of Macedon. These Cynoscephalæ are small tops of several equal eminences; named from their resemblance to dogs heads, according to Plutarch.

CYNOSSEMA, the tomb of Hecuba, on the promontory Mastusia, over against Sigeum, in the south of the Chersonesus Thracia; named either from the figure of a dog, to which she was changed, or from her sad reverse of fortune (Pliny, Mela).

CYNOSURA, in astronomy, a denomination given by the Greeks to *ursa minor*, or "the little bear," by which sailors steer their course. The word is formed of *κυνος*, *q. d. the dog's tail*. This is the constellation next our pole, consisting of seven stars, four whereof are disposed like the four wheels of a chariot, and three lengthwise representing the beam; whence some give it the name of the *chariot*, or *Charles's wain*.

CYNOSURA, *Cynofuræ*, or *Cynofuris*, (anc. geog.), a place in Laconica; but whether maritime or inland, uncertain. Here Æsculapius, being thunderstruck, was buried (Cicero).

CYNOSURA was also the name of the promontory of Marathon in Attica, obverted to Eubœa.

CYNOSURA, in mythology, a nymph of Ida in Crete. She nursed Jupiter, who changed her into a star which bears the same name. It is the same as the *ursa minor*.

CYNOSURUS, in botany: A genus of the digynia order, belonging to the triandria class of plants; and in the natural method ranking under the 4th order, *Gramina*. The calyx is bivalved and multiflorous; the receptacle proper, unilateral, and foliaceous. There are ten species, four of which are natives of Britain, *viz.* the cristatus, or crested dog-tail grass; the echinatus, or rough dog-tail-grass; the cæruleus, or blue dog-tail grass; and the paniceus, or bearded dog-tail grass.

CYNTHIUS and CYNTHIA, in mythology, surnames of Appollo and Diana, derived from *Cynthia* the name of a mountain in the middle of the island of Delos.

CYNTHIUS (anc. geog.), a mountain of the island Delos, so high as to overshadow the whole island. On this mountain Latona brought forth Appollo and Diana: hence the epithet *Cynthius* (Virgil), and *Cynthia* (Lucan, Statius).

CYNURIA, or *CYNURIUS Ager*, (anc. geog.), a district of Laconica, on the confines of Argolis. A territory that proved a perpetual bone of contention between the Argives and Spartans (Thucydides). For the manner of deciding the dispute, see *THYREA*.

CYPERUS, in botany: A genus of the monogynia order, belonging to the triandria class of plants;

Cyphon
|
Cyprianus.

and in the natural method ranking under the 3d order, *Calamaria*. The glumes are paleaceous, and imbricated towards each side; the corolla is wanting, and there is one naked seed. There are 20 species; the only remarkable are the round and the long sweet cyperus. The former is a native of the East Indies, and grows by the sides of rivulets, ditches, and the like. The root is knotty, wrapped round with fibrous strings not easy to break, of a brown colour without and grey within; of a pleasant scent, especially when fresh and well dried; the leaves are green, and resemble those of the reed and leek. The latter, commonly called *English* or *Flemish cyperus*, grows in the water, and along banks and river sides. Its root is as thick as an olive, full of little knots or specks, of an oblong figure, grey colour, sweet and somewhat sharp taste, and almost without smell when it is newly taken out of the ground. The roots of both plants are esteemed cordial, diuretic, and cephalic, resistors of poisons, and expellers of wind. Long cyperus is much used by perfumers and glovers.

CYPHON, in antiquity, a kind of punishment used by the Athenians. It was a collar made of wood; so called because it constrained the criminal who had this punishment inflicted on him to bow down his head.

CYPHONISM, CYPHONISMUS, from *κυφω*, which has various significations; derived from *κυφος*, *crooked*: a kind of torture or punishment in use among the ancients.

The learned are at a loss to determine what it was. Some will have it to be that mentioned by St Jerom in his *Life of Paul the Hermit*, chap. 2. which consisted in smearing the body over with honey, and thus exposing the person, with his hands tied, to the warm sun, to invite the flies and other vermin to persecute him.

CYPRÆA, or GOWRIE, in zoology, a genus of insects belonging to the order of vermes testacea. It is an animal of the limax or snail kind; the shell is one involuted, subovated, obtuse, smooth valve. The aperture on each side is linear, longitudinal, and toothed. There are 44 species, distinguished by the form of their shells. The pediculus, or common gowrie, is represented on Plate CLIV.

This genus is called *cypræa venerea* from its being peculiarly dedicated to Venus; who is said to have endowed a shell of this genus with the powers of a *remora*, so as to impede the course of the ship which was sent by Periander tyrant of Corinth with orders to castrate the young nobility of Corcyra.

CYPRESS. See CUPRESSUS

CYPRIANUS (Thascius-Cæcilius), a principal father of the Christian church, was born at Carthage in Africa, at the latter end of the second or beginning of the third century. We know nothing more of his parents than that they were heathens; and he himself continued such till the last 12 years of his life. He applied himself early to the study of oratory; and some of the ancients, particularly Lactantius, inform us, that he taught rhetoric in Carthage with the highest applause. Cyprian's conversion is fixed by Pearson to the year 246; and was at Carthage, where, as St Jerome observes, he had often employed his rhetoric in the defence of paganism. It was brought about by one Cæcilius, a priest of the Church of Car-

thage, whose name Cyprian afterwards took; and between whom there ever after subsisted so close a friendship, that Cæcilius at his death committed to Cyprian the care of his family. Cyprian was also a married man himself; but as soon as he was converted to the faith, he resolved upon a state of continence which was thought a high degree of piety, as not being yet become general. Being now a Christian, he was to give the usual proof of the sincerity of his conversion; and that was by writing against paganism and in defence of Christianity. With this view he composed his piece *De Gratia Dei*, "or concerning the grace of God," which he addressed to Donatus. It is a work of the same nature with the Apologetic of Tertulian, and the Octavius of Minutius Felix. He next composed a piece *De Idolorum Vanitate*, or "upon the vanity of idols." Cyprian's behaviour, both before and after his baptism, was so highly pleasing to the bishop of Carthage, that he ordained him a priest a few months after. It was rather irregular to ordain a man thus in his very noviciate; but Cyprian was so extraordinary a person, and thought capable of doing such singular service to the church, that it seemed allowable in this case to dispense a little with the form and discipline of it. For besides his known talents as a secular man, he had acquired a high reputation of sanctity since his conversion; having not only separated himself from his wife, as we have observed before, which in those days was thought an extraordinary act of piety, but also consigned over all his goods to the poor, and given himself up entirely to the things of God. It was on this account no doubt, too, that when the bishop of Carthage died the year after, that is in the year 248, none was judged so proper to succeed him as Cyprian. The quiet and repose which the Christians had enjoyed during the last 40 years, had, it seems, greatly corrupted their manners; and therefore Cyprian's first care, after his advancement to the bishopric, was to correct disorders and reform abuses. Luxury was prevalent among them; and many of their women were not so strict as they should be, especially in the article of dress. This occasioned him to draw up his piece *De habitu virginum*, or "concerning the dress of young women;" in which, besides what he says on that particular head, he inculcates many lessons of modesty and sobriety. In the year 249, the emperor Decius began to issue out very severe edicts against the Christians, which particularly affected those upon the coast of Africa; and in the beginning of 250, the heathens in the circus and amphitheatre of Carthage, insisted loudly upon Cyprian's being thrown to the lions: a common method of destroying the primitive Christians. Cyprian upon this withdrew from his church at Carthage, and fled into retirement, to avoid the fury of the persecutions. He wrote in the place of his retreat, pious and instructive letters to those who had been his hearers; and also to the *libellatici*, a name by which those pusillanimous Christians were called, who procured certificates of the heathen magistrates, to show that they had complied with the emperor's orders in sacrificing to idols. At his return to Carthage he had several councils on the repentance of those who had fallen during this persecution, and other points of discipline; he opposed the schemes of Navatus and Novatianus;

Cyprianus.

Cyprinus. Novatianus; and contended for the rebaptizing of those who had been baptized by heretics. At last he died a martyr in the persecution of Valerian and Gallienus, in 258. Cyprian wrote 81 letters, and several treatises. The best edition of his works are those of Pamelius in 1568; of Rigaltius in 1648; and of Oxford in 1682. His works have also been translated into English by Dr Marshall.

CYPRINUS, in ichthyology; a genus of fishes, belonging to the order of abdominales. The mouth is toothless; there are three rays in the gill: the body is smooth and white; and the belly-fins have frequently nine rays. There are 31 species, principally distinguished by the number of rays in the vent-fin. The most remarkable are.

1. The carp, or carp. This was introduced into England about the year 1514, by Leonard Maschal, to whom we are also indebted for that excellent apple the *pepin*. Russia wants these fish at this day. Sweden has them only in the ponds of people of fashion. They chiefly abound in rivers and lakes of Polish Prussia, where they are sometimes taken of a vast size. They are there a great article of commerce, and sent in well-boats to Sweden and Russia. The merchants purchase them out of the waters, of the noblesse of the country, who draw a good revenue from this article. The ancients do not separate the carp from the sea-fish. They are sometimes found in the harbour of Dantzic between the town and a place called *Hela*.

Carp are very long-lived. Gefner brings an instance of one that was near 100 years old. They grow also to a very great size; some authors speak of carp weighing 200 pounds weight, and five feet in length. The carp is a prodigious breeder: its quantity of roe has been sometimes found so great, that when taken out and weighed against the fish itself, the former has been found to preponderate. From the spawn of this fish, caviare is made for the Jews, who hold the sturgeon in abhorrence. The carp is extremely cunning, and on that account is sometimes styled the *river-fox*. They will sometimes leap over the nets and escape that way; at other times they will immerse themselves so deep in the mud as to let the net pass over them. They are also very shy in taking a bait; yet at the spawning-time they are so simple as to suffer themselves to be tickled, handled, and caught by any body that will attempt it. This fish is apt to mix its milt with the roe of other fish; from which is produced a spurious breed, as has been observed in the offspring of the carp and tench, which bore the greatest resemblance to the first. The same has also been observed of the carp and bream.

In Polish Prussia, and many other parts of Germany, the sale of carp constitutes a part of the revenue of the nobility and gentry: so that the proper management of that fish is reduced to a kind of system, founded on the experience of several generations. Of the methods there practised, we have an account in the Philosophical Transactions for 1771, art. 37. communicated by Mr J. Reinhold-Forster: who says, he has seen carp treated and maintained according to those methods, "above a yard long, and of 25 pounds weight;" but had no opportunity of ascertaining their age. "In the pond, however, at Charlottenburg (he adds), a palace belonging to the king of Prussia, I saw more

than two or three hundred carp, between two and three feet long; and I was told by the keeper they were between 50 and 60 years standing. They were tame, and came to the shore in order to be fed; they swallowed with ease a piece of white bread of the size of half a halfpenny roll."—Mr Forster, in this paper, also vouches a most extraordinary circumstance, namely, the possibility of the carp's not only living for a considerable time out of water, but of its growing fat in its new element. The author has seen the experiment successfully tried, and attended to the whole process, in a nobleman's house where he then resided, in the principality of Anhalt-Deßau. The fish being taken out of the water, is wrapped up in a large quantity of wet moss, spread on a piece of net, which is then gathered into a purse; in such a manner, however, as to allow him room to breathe. The net is then plunged into water, and hung up to the ceiling of a cellar. At first the dipping must be repeated every three or four hours; but afterwards the carp need only to be plunged into the water once in about six or seven hours. Bread soaked in milk is first given him in small quantities. In a short time, the fish will bear more, and grow fat under this seemingly unnatural treatment. Mr Daines Barrington, in a note, confirms a part of the preceding account, by mentioning the practice of a certain fishmonger near Claremarket, who, in the winter, frequently exposes a bushel at least of carp and tench, for sale, in the same dry vessel, for six or seven hours; many of which are not sold, and yet continue in health, though breathing nothing but air, during the time abovementioned, for several days successively.

2. The barbus, or barbel, is so extremely coarse as to be overlooked by the ancients till the time of the poet Ausonius, who gives it no great character. They frequent the still and deep parts of rivers, and live in society, rooting like swine with their noses in the soft banks. It is so tame as to suffer itself to be taken by the hand; and people have been known to take numbers by diving for them. In summer they move about during night in search of food; but towards autumn, and during winter, confine themselves to the deepest holes. The barbel is about the length of three feet, and will weigh 18 pounds; the belly white; the dorsal fin is armed with a remarkable strong spine, sharply serrated, with which it can inflict a very severe and dangerous wound on the incautious handler, and even do much damage to nets. They are the worst and coarsest of fresh-water fish, and seldom eaten but by the poorer sort of people, who sometimes boil them with a bit of bacon to give them a relish. Their roe is very noxious, affecting those who unwarily eat of it with a nausea, vomiting, purging, and a slight swelling.

3. The tinca, or tench, was treated with the same disrespect by the ancients as the barbel; but is now in much more repute. It has by some been called the *physician* of the fish; and its slime has been said to be of so healing a nature, that the wounded fishes apply it as a styptic. In Britain it is reckoned a wholesome and delicious food; but the Germans are of a different opinion. By way of contempt they call it the *shoemaker*. Gefner even says, that it is insipid and unwholesome. It does not commonly exceed four or five

Cyprinus. pounds in weight, though some have been known to weighten or twenty. They love still waters, and are rarely found in rivers: they are very foolish and easily caught. The tench is thick and short in proportion to its length. The colour of the back is dusky; the dorsal and ventral fins of the same colour; the head, sides, and belly, of a greenish cast, most beautifully mixed with gold, which is in its greatest splendor when the fish is in the highest season.

4. The gudgeon is generally found in gentle streams, and is of a small size, the largest not exceeding half a pound weight. They bite eagerly; and are assembled by raking the bed of the river: to this spot they immediately crowd in shoals, in expectation of food.

5. The brama, or bream, is an inhabitant of lakes, or the deep parts of still rivers. It is a fish that is very little esteemed, being extremely insipid.

6. The rutilus, or roach, is a common fish, found in many of the deep still rivers of England. They are gregarious, keeping in large shoals. It has never been known to exceed five pounds in weight.

7. The leuciscus, or dace, like the roach is gregarious, haunts the same places, is a great breeder, very lively, and during summer is very fond of frolicking near the surface of the water. It never exceeds the weight of a pound and an half: the scales are smaller than those of the roach.

8. The cephalus, or chub, is a very coarse fish and full of bones. It frequents the deep holes of rivers; and in summer commonly lies on the surface beneath the shade of some tree or bush. It is very timid, sinking to the bottom on the least alarm, even at the passing of a shadow; but they will soon resume their former situation. It feeds on worms, caterpillars, grasshoppers, and other colcopterous insects that happen to fall into the water: and it will even feed on cray-fish. It will rise to a fly. Some of this kind have been known to weigh eight or nine pounds.

9. The alburnus, or bleak. These fish are very common in many of the rivers in England, and keep together in large shoals. At certain seasons they seem to be in great agonies: they tumble about near the surface of the water, and are incapable of swimming far from the place: but in about two hours they recover and disappear. Fish thus affected, the Thames fishermen call *mad* bleaks. They seem to be troubled with a species of *gordius*, or hair-worm, which torments them so, that they rise to the surface and then die. The bleak seldom exceeds five or six inches in length. Artificial pearls are made with the scales of this fish, and probably also with those of the dace. They are beat into a fine powder, then diluted with water, and introduced into a thin glass bubble, which is afterwards filled with wax. The French were the inventors of this art. During the month of July there appear in the Thames, near Blackwall and Greenwich, innumerable multitudes of small fish, known to the Londoners by the name of *white bait*. They are esteemed very delicious when fried with fine flour, and occasion, during the season, a vast resort of the lower order of epicures to the taverns at the places where they are taken at. There are various suppositions concerning these fishes, all of which terminate in reckoning them the fry of some other fish. Mr Pennant thinks they are

of the carp kind, though he cannot determine the species to which they belong. They have a greater simularity to the bleak than to any other, but he thinks they cannot be the young fry of this species; because the bleak is found in many of the British streams, but the white bait only in the Thames. The usual length of this fish is only two inches.

10. The auratus, or golden fish, a small fish domesticated by the Chinese, and generally kept for ornament by great people in their courts and gardens. They breed them in small ponds made for the purpose, in basons, and even in porcelain vessels. This fish is no larger than our pilchard. The male is of a bright red colour from the top of the head to the middle of the body: the rest is of a gold-colour; but it is so bright and splendid, that the finest gilding, according to F. le Comte, cannot approach it. The female is white: but its tail and half of its body resemble the lustre of silver. F. du Halde, however, observes, that a red and white colour are not always the distinguishing marks of the male and female; but that the females are known by several white spots which are seen round the orifices that serve them as organs of hearing, and the males, by having these spots much brighter. Gold-fish are light and lively; they love to sport on the surface of the water, soon become familiarised, and may even be accustomed to come and receive their food on sounding a small rattle. Great care is necessary to preserve them; for they are extremely delicate, and sensible of the least injuries of the air: a loud noise, such as that of thunder or cannons; a strong smell, a violent shaking of the vessel, or a single touch, will oft-times destroy them. These fish live with little nourishment: those small worms which are engendered in the water, or the earthy particles that are mixed with it, are sufficient for their food. The Chinese, however, take care, from time to time, to throw into the basons and reservoirs where they are kept small balls of paste, which they are very fond of when dissolved; they give them also lean pork dried in the sun and reduced to a fine and delicate powder, and sometimes snails: the slime which these insects leave at the bottom of the vessel is a great delicacy for them, and they eagerly hasten to feed on it. In winter they are removed from the court to a warm chamber, where they are kept generally shut up in a porcelain vessel. During that season they receive no nourishment; however, in spring, when they are carried back to their former bason, they sport and play with the same strength and liveliness as they did the preceding year.

In warm countries these fish multiply fast, provided care be taken to collect their spawn, which floats on the water, and which they almost entirely devour. This spawn is put into a particular vessel exposed to the sun, and preserved there until vivified by the heat: gold-fish, however, seldom multiply when they are kept in close vases, because they are then too much confined. In order to render them fruitful, they must be put into reservoirs of considerable depth in some places at least, and which are constantly supplied with fresh water. At a certain time of the year, a prodigious number of barks may be seen in the great river *Yang-tse-kiang*, which go thither to purchase the spawn of these fish.

*Grozier's
Description
of China.*

Cyprinus fish. Towards the month of May, the neighbouring inhabitants shut up the river in several places with mats and hurdles, which occupy an extent of almost nine or ten leagues; and they leave only a space in the middle sufficient for the passage of barks. The spawn of the fish, which the Chinese can distinguish at first sight, although a stranger could perceive no traces of it in the water, is stopped by these hurdles. The water mixed with spawn is then drawn up, and after it has been put into large vessels, it is sold to merchants, who transport it afterwards to every part of the empire. This water is sold by measure, and purchased by those who are desirous of stocking their ponds and reservoirs with fish.

Notwithstanding the tenderness of these fish even in their native climate, they are now naturalized in Britain, where they even breed. They were first introduced into England about the year 1691; but were not generally known till 1728, when a great number were brought over, and presented first to Sir Matthew Dekker, and by him circulated round the neighbourhood of London, from whence they have been distributed to most parts of the country.

Nothing can be more amusing than a glass bowl containing such fishes: the double refractions of the glass and water represent them, when moving, in a shifting and changeable variety of dimensions, shades, and colours; while the two mediums, assisted by the concavo convex shape of the vessel, magnify and distort them vastly: not to mention that the introduction of another element and its inhabitants into our parlours engages the fancy in a very agreeable manner. Some people exhibit this sort of fish in a very fanciful way; for they cause a glass bowl to be blown with a large hollow space within that does not communicate with it. In this cavity they put a bird occasionally; so that you may see a goldfinch or a linnet hopping as it were in the midst of the water, and the fishes swimming in a circle round it. The simple exhibition of the fishes is agreeable and pleasant; but in so complicated a way becomes whimsical and unnatural, and liable to the objection due to him.

Qui variare cupit rem prodigialiter unam.

CYPRIPEDIUM, the LADY'S SLIPPER, in botany: A genus of the diandria order, belonging to the gynandria class of plants; and in the natural method ranking under the 7th order, *Orchidææ*. The nectarium is ventricose, inflated, and hollow. There are three species: of which only one, viz, the calceolus is a native of Britain. It grows in rough ground in different parts of the island. The other species are natives of America. None of them are easily propagated in gardens, and therefore must be transplanted from those places where they are natives.

CYPRUS, an island situated in the Levant, or most easterly part of the Mediterranean sea, between 33 and 36 degrees of east longitude, and 30 and 34 of north latitude. In ancient times this island was known by the name of Acamis, Ceraftis, Aspalia, Amathus, Macaria, Cryptos, Colinia, Sphecia, Paphia, Salaminia, Ærofa, and Cyprus. The etymologies of these names are neither very easily found, nor are they of much importance. The name by which it was most generally known is that of *Cyprus*, said to be derived from *cypros*, the name of a shrub or tree with which the island abounded; supposed to be the cypress.

Cyprus, according to Eratosthenes, was first discovered by the Phœnicians, two or three generations before the days of Asterius and Minos kings of Crete; that is, according to Sir Isaac Newton's computation, 2006 years before the Christian era. It was at that time so full of wood that it could not be tilled, and the Phœnicians first cut down that wood for melting copper, with which the island abounded; and afterwards, when they began to sail without fear on the Mediterranean, that is, after the Trojan war, they built great natives of the wood produced on the island. Josephus, however, informs us, that the descendants of *Cittim*, the son of Javan, and grandson of Japhat, were the original inhabitants of Cyprus. According to his account, *Cittim*, seeing his brother Tarshish settled in Cilicia where he built the city of Tarsus, settled with his followers in this opposite island; and either he or his descendants laid the foundations of the city of *Citium*, which, according to Ptolemy, was the most ancient in the island. As Cyprus was too narrow to contain the great numbers who attended him, he left here as many as might serve to people the country, and with the rest passed over into Macedon.

The island of Cyprus was divided among several petty kings till the time of Cyrus the Great. He subdued them all; but left each in possession of his kingdom, obliged them only to pay him an annual tribute, and to send supplies of men, money, and ships, when required. The Cyprian princes lived thus subject to the Persians till the reign of Darius Hystaspes, when they attempted to shake off the yoke, but with bad success; their forces being entirely defeated, and themselves again obliged to submit. They made another more successful attempt about the year before Christ 357; but, however, could never totally free themselves from their subjection. It is very probable that they submitted to Alexander the Great, though historians are silent as to that event. On the death of the Macedonian conqueror, the dominion of Cyprus was disputed by Antigonus and Ptolemy the son of Lagus. At last Antigonus prevailed, and the whole island submitted to him about 304 years before Christ. He and his son Demetrius kept possession of it for 11 years, when it was recovered by Ptolemy, and quietly possessed by him and his descendants till 58 years before Christ, when it was most unjustly seized by the Romans. In the time of Augustus, it began to be ranked among the proconsular provinces, and to be governed by magistrates sent thither by the senate. In the year 648 it was conquered by the Saracens; but recovered by the Romans in 957. They held it, however, but for a very short time, and the barbarians kept possession of it till the time of the croisades. It was then reduced by the croisaders: and Richard I. of England gave it to the princes of the Lusignan family, who held it till the year 1570. They divided it into 12 provinces, in each of which was a capital city from which the province was denominated. So considerable was the island at this time, that besides the cities abovementioned, and others of less note, it contained 800 villages. In 1570 it was taken by the Turks, and though it hath ever since continued under their tyrannical yoke, is still so considerable as to be governed by a beglerbeg, and seven sangaics under him.

The air in this island is for the most part very unwholesome,

Cyrano, Cyrenaica. wholefome, on account of the many fens and marfhes with which the country abounds. The foil is an excellent fertile clay; and would produce all the neceffaries of life in abundance, if properly cultivated. There are but few fprings or rivers in this ifland; fo that when the rains do not fall plentifully at the ufual feafons, the inhabitants are much diftreffed by the fcarcity of water. By reafon of the uncultivated ftate of the country, they are alfo greatly infefted with poifonous reptiles of various kinds. The people are extremely ignorant and lafcivious, as indeed they are remarked to have been from the remoteft antiquity. Anciently the worfhip of Venus was eftablifhed in this ifland, whence her title among the poets of the *Cyprian queen*; and fuch an inclination had the inhabitants to become the votaries of this goddefs, both in theory and practice, that the young women ufed to prostitute themfelves in her temple in order to raife themfelves portions. Nor are their fucceffors faid to be much better at this day. The exports of the ifland are filks, oil, cotton, wine, falt, and turpentine: the imports are French and Venetian broad cloths; and fometimes a few bales of Englifh manufacture, cutlery wares, fugar, tin, lead, &c.

Knights of Cyprus, an order inflituted by Guy de Lusignan, titular king of Jerufalem, to whom Richard I. of England, after conquering this ifland, made over his right.

CYRANO (Bergerac), a French author, born in Gascony, about the year 1620. He firft entered into the army, where his natural courage engaged him frequently in duels in the quality of a fecond: which, with other rash actions, procured him the title of the *Interpid*. But the little profpect he faw of preferment made him renounce the trade of war for the exercife of wit. His comic hiftories of the ftates and empires in the fun and moon, fhew him well acquainted with the Cartesian philofophy, and to have a lively imagination. Lord Orrery claffes him with Swift for his turn of humour, which he fays the latter adopted and purfued.

CYRENAICA, an ancient kingdom of Africa, correfponding to the prefent kingdom and defert of Barca and Tripoli. It was originally inhabited by a number of barbarous nations differing little from great gangs of robbers. Afterwards fome colonies from Greece fettled here, and Cyrenaica became fo powerful a ftate, that it waged war with Egypt and Carthage, often with fuccefs. In the time of Darius Hyftafpes, Arcefilaus, the reigning prince in Cyrenaica, was driven from the throne; on which his mother Pheretima applied for affiftance to the king of Cyprus. Her fon afterwards returning to Barca, the chief city of Cyrene, was there affaffinated, together with his father-in-law. Pheretima finding herfelf difappointed by the king of Cyprus, applied to Darius Hyftafpes, and by the affiftance of the Perfians reduced Barca. Here ſhe behaved with the utmoft cruelty, caufing all thofe who had been concerned in her fon's death to be impaled, and the breasts of their wives to be cut off and affixed near them. She is faid to have been afterwards devoured by worms; which was looked upon as a divine judgment for her exceffive cruelty. The prifoners in the mean time were ſent to Darius, who fettled them in a diftrict of Baetria, from them called

Barca. Cyrenaica, however, ſeems to have remained free till the time of Alexander the Great, who conquered it along with Egypt. Soon after his death the inhabitants recovered their liberty; but were in a ſhort time reduced by Ptolemy king of Egypt. Under thefe kings it remained till Ptolemy Phyſcon made it over to his baftard fon Apian, who in the 658th year of Rome left it by will to the Romans. The ſenate permitted all the cities to be governed by their own laws; and this immediately filled the country with tyrants, thofe who were moſt potent in every city or diftrict endeavouring to aſſume the ſovereignty of it. Thus the kingdom was thrown into great confuſion; but Lucullus in a good meafure reſtored the public tranquillity on his coming thither during the firſt Mithridatic war. It was found impoſſible, however, totally to ſuppreſs theſe diſturbances till the country was reduced to the form of a Roman province, which happened about 20 years after the death of Apian, and 76 before Chriſt. Upon a revolt, the city of Cyrene was ruined by the Romans; but they afterwards rebuilt it. In proceſs of time it fell to the Arabs; and then to the Turks, who are the prefent maſters of it.

CYRENAICS, a ſect of ancient philoſophers, ſo called from their founder Ariſtippus of Cyrene, a diſciple of Socrates.

The great principle of their doctrine was, that the ſupreme good of man in this life is pleaſure; whereby they not only meant a privation of pain, and a tranquillity of mind, but an aſſemblage of all mental and ſenſual pleaſures, particularly the laſt.

Cicero makes frequent mention of Ariſtippus's ſchool; and ſpeaks of it as yielding debauchees. Three diſciples of Ariſtippus, after his death, divided the ſect into three branches; under which diviſion it languiſhed and ſunk; the firſt called the *Hegefiac* ſchool; the ſecond the *Anniverian*; and the third the *Theodoran*; from the names of their authors.

CYRENE (anc. geog.), the capital of Cyrenaica, and one of the cities called *Pentapolis*, diſtant from Apollonia its ſea-port, 10 miles, ſituated on a plain, of the form of a table, according to Strabo. A colony of the Thereans. Though they were deſcendants of the Lacedemonians, yet they differed from them in their turn of mind or diſpoſition, applying themſelves to philoſophy; and hence aroſe the Cyrenaic ſect, at the head of which was Ariſtippus, who placed all happineſs in pleaſure. The Cyreneans were a people much given to aurigation, or the uſe of the chariot, from their excellent breed of horſes, (Pindar, Ephorus, Strabo.)

CYRIL (St) biſhop of Jeruſalem, ſucceeded Maximus in 350. He was afterwards depoſed for the crime of expoſing to ſale the treaſures of the church, and applying the money to the ſupport of the poor during a great famine. Under Julian he was reſtored to his ſee, and was firmly eſtabliſhed to all his old honours and dignities under Theodoſius; in which he continued unmoleſted to his death in 386. The remains of this father conſiſt only of 23 catecheſes, and one letter to the emperor Conſtantius.

CYRILL (St) patriarch of Alexandria, ſucceeded Theophilus, his uncle, in 412. Scarce was he inſtalled, when he began to exert his authority with great vigour; he drove the Novatians and Jews from Alexandria,

Cyrenaica
Cyrill.

Cyrus. andria, permitting their wealth and synagogues to be taken from them. This proceeding highly displeased Orestes, the governor of the city, who saw that if the bishop's authority was not soon suppressed it might grow too strong for that of the magistrate. Upon which a kind of civil war broke out between Orestes and the bishop; many tumults were raised, and some battles fought in the very streets of Alexandria. St Cyrill also distinguished himself by his zeal against Nestorius bishop of Constantinople, who, in some of his homilies, had asserted that the Virgin Mary ought not to be called the mother of God. The dispute at first proved unfavourable to Cyrill, whose opinion was not only condemned, but himself deprived of his bishopric and thrown into prison. But he was soon after released, and gained a complete victory over Nestorius, who in 431 was deposed from his see of Constantinople. Cyrill returned to his see at Constantinople, where he died in 444. St Cyrill also wrote against Theodorus of Mopsuesta, Diodorus of Tarsus, and Julian the apostate. He composed commentaries on St John's gospel, and wrote several other books. His works were published in Greek and Latin in 1638, in six volumes folio.

CYRUS, the son of Cambyfes the Persian, by Mandane the daughter of Astyages king of the Medes. The two chief historians, who have written the life of Cyrus, are Herodotus and Xenophon; but their accounts of him are different, in as much as the latter makes his father a king of Persia, and the former a meaner man. The account of Herodotus, as Dr Prideaux observes, indeed contains narratives that are much more strange and surprising, and consequently more diverting and agreeable to the reader: and for this reason more have chose to follow him than Xenophon.

Herodotus informs us, that Astyages king of the Medes, dreamed, that a vine sprung from the womb of his daughter Mandane, the branches whereof overshadowed all Asia; whereupon having consulted the soothsayers, he was told that this dream portended the future power and greatness of a child who should be born of his daughter; and further, that the same child should deprive him of his kingdom. Astyages, to prevent the accomplishment of this prediction, instead of marrying his daughter to some powerful prince, gave her to Cambyfes a Persian of mean condition, and one who had no great capacity for forming any important design, nor for supporting the ambition of his son, by his own riches and authority. Nor did Astyages stop here; the apprehensions he was under, lest Mandane's son might perhaps find that assistance in his own courage, or some lucky circumstances which his family was not able to supply him with, induced him to take a resolution of dispatching the child, if there should be any. As soon, therefore, as he understood his daughter was with child, he commanded one of his officers, whose name was Harpagus, to destroy the infant as soon as it came into the world. Harpagus, fearing the resentment of Mandane, put the child into the hands of one who was the king's shepherd, in order to expose him. The shepherd's wife was so extremely touched with the beauty of Cyrus, that she desired her husband rather to expose her own son, who was born some time before, and preserve the young prince. Af-

ter this manner Cyrus was preserved and brought up among the king's shepherds.

One day, as the neighbouring children were at play together, Cyrus was chosen king; and having punished one of his little play-fellows with some severity, for disobeying his commands, the child's parent complained of Cyrus to Astyages. This prince sent for young Cyrus, and observing something great in his air, his manner and behaviour, together with a great resemblance of his daughter Mandane, he made particular inquiry into the matter, and discovered, that, in reality, Cyrus was no other than his grandson. Harpagus, who was the instrument of preserving him, was punished with the death of his own son: however, Astyages believing that the royalty which the soothsayers had promised to the young prince, was only that which he had lately exercised among the shepherds children, troubled himself no more about it. Cyrus being grown up, Harpagus disclosed the whole secret of his birth to him, together with the manner wherein he had delivered him from the cruel resolution of his grandfather. He encouraged him to come into Media, and promised to furnish him with forces in order to make him master of the country, and depose Astyages. Cyrus hearkened to these propositions, engaged the Persians to take arms against the Medes, marched at the head of them to meet Astyages, defeated him, and possessed himself of Media. He carried on many other wars; and at length sat down before Babylon, which after a long siege he took.

The relation of Cyrus's life from Xenophon is as follows: Astyages king of Media married his daughter Mandane to Cambyfes king of Persia, son to Achæmenes king of the same nation. Cyrus was born at his father's court, and was educated with all the care his birth required. When he was about the age of 12 years, his grandfather Astyages sent for him to Media, together with his mother Mandane. Some time after, the king of Assyria's son having invaded Media, Astyages, with his son Cyaxares and his grandson Cyrus, marched against him. Cyrus distinguished himself in this war, and defeated the Assyrians. Cambyfes afterwards recalled him, that he might have him near his own person; and Astyages dying, his son Cyaxares, uncle by the mother's side to Cyrus, succeeded him in the kingdom of Media.

Cyrus, at the age of 30 years, was, by his father Cambyfes, made general of the Persian troops; and sent at the head of 30,000 men to the assistance of his uncle Cyaxares, whom the king of Babylon with his allies the Cappadocians, Carians, Phrygians, Cilicians, and Paphlagonians, were preparing to attack. Cyaxares and Cyrus prevented them, by falling upon them and dispersing them. Cyrus advanced as far as Babylon, and spread terror throughout the country. From this expedition he retired to his uncle, towards the frontiers of Armenia and Assyria, and was received by Cyaxares in the tent of the Assyrian king whom he had defeated.

After this, Cyrus carried the war into the countries beyond the river Halys, entered Cappadocia, and subdued it entirely. From thence he marched against Croesus king of Lydia, beat him in the first battle; then besieged him in Sardis his capital; and after a
siege

Cyrus.

siege of fourteen days obliged him to surrender. See CROESUS. After this, Cyrus having almost reduced all Asia, repassed the Euphrates, and made war upon the Assyrians. He marched directly to Babylon, took it, and there prepared a palace for his uncle Cyaxares, whether he might retire, if at any time he had an inclination to come to Babylon; for he was not then in the army. After all these expeditions, Cyrus returned to his father and mother into Persia, where they were still living; and going some time after to his uncle Cyaxares into Media he married his cousin the only daughter and heiress of all Cyaxares's dominions, and went with her to Babylon, from whence he sent men of the first rank and quality to govern all the several nations which he had conquered. He engaged again in several wars, and subdued all the nations which lie between Syria and the Red Sea. He died at the age of 70 years, after a reign of 30: but authors differ very much concerning the manner of his death. Herodotus, Justin, and Valerius Maximus relate, that he died in the war against the Scythians; and that falling into an ambush which queen Tomyris had laid for him, she ordered his head to be cut off, and cast into a vessel full of blood, saying, "Thou hast always thirsted after human blood, now glut thyself with it." Diodorus the Sicilian says, that he was taken in an engagement and hanged. Ctesias assures us, that he died of a wound which he received in his thigh: but by Xenophon's account he died peaceably in his bed, amidst his friends and servants; and certain it is, that in Alexander's time his monument was shown at Pasargarda in Persia.

From all this, it is easy to conclude that we are but imperfectly acquainted with the history of this great prince, the founder of the Persian, and destroyer of the Chaldean empire. We learn fewer particulars of it from scripture, but then they are more certain than any that we have produced. Daniel (viii. 3—20.) in the famous vision wherein God showed him the ruin of several great emperors, which were to precede the birth of the Messiah, represents Cyrus to us under the idea of "a ram, which had two horns: and the two horns were high, but the one was higher than the other, and the higher came up last. This ram pushed westward, and northward, and southward, so that no beasts might stand before him; neither was there any that could deliver out of his hand, but he did according to his will, and became great." The ram's two horns signify the two empires which Cyrus reunited in his person; that of the Medes, and that of the Persians. The last was greater and more powerful than the empire of the Medes: or otherwise, these two horns signify the two branches of Cyrus's successors. His son Cambyfes dying, the empire was transferred to Darius the son of Hystaspes, and was continued down to Darius Codomannus, who, as Calmet thinks, is the great horn which the he-goat, that denotes Alexander, run against. In chap. vii. 5. Daniel compares Cyrus to a bear, with three ribs in the mouth of it, to which it was said, "Arise, devour much flesh." Cyrus succeeded his father Cambyfes in the kingdom of Persia, and Darius the Mede, by Xenophon called Cyaxares, and Astyages in the apocryphal chapter (xiii. 1.) of Daniel, in the kingdom of the Medes and empire of Babylon. He was monarch of

all the East; or as he speaks (2 Chr. xxxvi. 22, 23, and Ezr. i. 1. 2.) "of all the earth," when he permitted the Jews to return into their own country, in the year of the world 3466, before Jesus Christ 538. The enemies of the Hebrews, making use of this prince's affection to his own religion, prevailed with him to put a stop by his orders to the building of the temple at Jerusalem; (Ezr. iv. 5.) The prophets frequently foretold the coming of Cyrus; and Isaiah (xliv. 28.) has been so particular as to declare his name 200 years before he was born. Josephus (Antiq. 1. II. c. 2.) says, that the Jews of Babylon showed this passage of the prophet to Cyrus; and that this prince, in the edict which he granted them for their return, acknowledged that he received the empire of the world from the God of Israel; and that the same God had described him by name in the writings of the prophets, and foretold that he should build a temple to him at Jerusalem. Cyrus is pointed out in scripture under the name of the righteous man and the shepherd of Israel, (Isaiah xli. 2. 10. xlv. 11. and xlv. 23.) Notwithstanding this, God says of him, (Isa. xlv. 5.) "I girded thee, though thou hast not known me." And Jeremiah calls Cyrus and his people, who overthrew the Babylonish empire, thieves and robbers. The taking of Babylon by Cyrus is clearly set down by the prophets, and may be seen under the articles BABYLON and BELSHAZZAR. Archbishop Usher fixes the birth of Cyrus to the year of the world 3405; his first year at Babylon to 3466, and his death to 3475. The eastern people will have it, that Cyrus by the mother's side was descended from some of the Hebrew prophets; as also that his wife was a Jew, which is the reason (say they), that this prince so attached himself to the Jews, to whom he was so nearly allied.

CYRUS II. was the younger son of Darius Nothus, and the brother of Artaxerxes. He was sent by his father at the age of 16 to assist the Lacedemonians against Athens. Artaxerxes succeeded to the throne at the death of Nothus; and Cyrus, who was of an aspiring soul, attempted to assassinate him. He was discovered, and had been punished with death, had not his mother Parysatis saved him from the hands of the executioners by her tears and intreaties. This circumstance did not in the least check the ambition of Cyrus: he was appointed over Lydia and the sea-coasts, where he secretly fomented rebellion and levied troops under various pretences. At last he took the field with an army of 100,000 barbarians, and 13,000 Greeks under the command of Clearchus. Artaxerxes met him with 900,000 men near Cunaxa. The battle was long and bloody; and Cyrus might have perhaps obtained the victory, had not his uncommon rashness proved his ruin. It is said that the two royal brothers met in person, and their engagement ended in the death of Cyrus, 401 years before the Augustan age. Artaxerxes was so anxious of its being universally reported that his brother had fallen by his hand, that he put to death two of his subjects for boasting that they had killed Cyrus. The Greeks who were engaged in the expedition, obtained much glory in the battle; and after the death of Cyrus, they remained victorious in the field without a commander. They were not discouraged though at the distance of above

Cyrus.

600 leagues from their country, and surrounded on every side by a powerful enemy. They unanimously united in the election of commanders, and traversed all Asia, in spite of the continual attacks of the Persians; and nothing is more truly celebrated in ancient history than the bold retreat of the ten thousand. The journey that they made from the place of their first embarkation till their return has been calculated at 1155 leagues performed in the space of 15 months, including all the time which was devoted to take rest and refreshment. This retreat has been celebrated by Xenophon, who was one of their leaders, and among the friends and supporters of Cyrus.

CYST, the bag or tunic including all incysted tumors, as the scirrhus, atheroma, steotoma, meliceres, &c.

CYSTIC, in anatomy, a name given to two arteries and two veins.

CYSTIC DUCT. See ANATOMY, n° 97.

CYTHERA, *orum*, (anc. geog.) an island opposite to Mallea a promontory, and to Boiæ a town of Laconica; with a cognominal town, which has an excellent port called *Scundea*. The island was sacred to Venus, with a very ancient temple of that goddess exhibited in armour at Cythera, as in Cyprus. Now *Cerigo*.

CYTHEREA, in mythology, the surname of Venus, so called from Cytheræ an island, where she had a temple esteemed the most ancient in Greece, and on the shores of which she was believed to be borne by the Zephyrs, surrounded by the Loves, the Tritons, and Nereides, reclining in a languishing posture in a seashell. They give the name of Cytheriades to the Graces which attended her on the shore without quitting her, except on those occasions when she rather chose to be waited on by the Pleasures.

CYTINUS, in botany: A genus of the dodecandria order, belonging to the gynandria class of plants; and in the natural method ranking under the 11th order, *Sarmentacea*. The calyx is quadrifid, superior; there is no corolla; the antheræ are 16, and sessile; the fruit an octolocular polyspermous berry.

CYTISUS, TREE TREFOIL: A genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, *Papilionacea*. The calyx is bilabiated, with the upper lip bifid; inferior, tridentate; the legumen attenuated at the base. There are 11 species; of which the most remarkable are, 1. The laburnum, or large deciduous cytissus, hath a large upright tree-stem, branching into a full-spreading head, 20 or 30 feet high, having smooth greenish branches, oblong oval entire leaves, growing by threes on long slender foot-stalks; and from the sides of all the branches numerous yellow flowers collected into long spikes, hanging loosely downward, and appearing in May. 2. The sessilifolius, often called *cytissus secundus clusii*, have a low shrubby stem dividing into numerous erect brownish branches, forming a bushy head five or six feet high, garnished with small oval leaves growing by threes; some on very short foot-stalks, others sitting close; and bright yellow flowers in short erect spikes at the ends of the branches, appearing in June. 3. The nigricans grows with a short shrubby stem, dividing low into many erect slender branches, forming a bushy

VOL. V.

head for our five feet high, with oblong, oval, trifoliate leaves, and yellow flowers, terminating all the branches in upright spikes, appearing in July. 4. The hirsutus, or hairy evergreen Neapolitan cytissus, rises with an upright shrubby grey stem, sending out many erect greenish hairy branches, forming a fine head six or eight feet high, closely garnished with small hairy trifoliate leaves on short footstalks, and yellow flowers from the sides of the branches in short pendulous spikes, appearing in June. 5. The Austriacus, Austrian, or Tartarian evergreen cytissus, hath a shrubby stem, dividing low into many greenish branches, forming a bushy head three or four feet high, having smooth whitish-green leaves, and bright yellow flowers in close umbellate heads at the ends of the branches, having a cluster of leaves under each head. These flowers appear in May,

Culture, &c. All the sorts are hardy, and will prosper in any common soil and exposure: though, as the hirsutus is sometimes affected by severe frost, it should have a dry soil, and a somewhat sheltered situation. They may all be propagated by seeds or cuttings, and all the culture they require in the nursery is to have the ground kept clear from weeds, and dug annually between the rows. Though they are generally considered only as ornamental shrubs, yet the first species, if originally trained to a stem, and suffered to stand, will grow to the size of pretty large timber trees. They grow naturally on the Alps, the mountains of Dauphine, and the highlands of Scotland; and the timber being very hard, and taking a fine polish, is frequently used for making chairs, tables, bedsteads, and other furniture; and is said to equal the finest mahogany in beauty. A species of cytissus, called by Linnæus *cytissus cajan*, is known in the West Indies, where it is a native, by the name of the *pigeon-pea*, from the seeds being the common food for these birds in that part of the world. These seeds are also sometimes used as food for the human species; and as they are of a very binding quality, afford a wholesome nourishment during the wet season, when dysenteries are so frequent.

CYZICENS, CYZICENA, among the ancient Greeks, were a sort of magnificent banqueting-houses, always looking towards the north, and usually opening upon gardens.

They had their name from Cyzicus, a city very considerable for the grandeur of its buildings; situated in an island of Myfia, bearing the same name.

CYZICUM, or CYZICUS (anc. geog.), one of the noblest cities of the Hither Asia; situated in a cognominal island of the Propontis, on the coast of Myfia; joined to the continent by two bridges (Strabo); the first by Alexander: the city, a colony of the Milesians (Pliny). Rendered famous by the siege of Mithridates, which was raised by Lucullus.—The inhabitants were made a free people by the Romans, but forfeited their freedom under Tiberius. It was adorned with a citadel and walls round it; had a port and marble towers; and three magazines, one for arms, another for warlike engines, and a third for corn. Cyziceni, the people; noted by the ancients for their timidity and effeminacy: hence the proverb in Zenodotus and others, *Tinctura Cyzenica*, applied to persons guilty of an indecency through fear: but *Stateres Cy-*

thurn, fection.

Czar. **CZACKTHURN**, a strong town of Germany, in Austria, and near the frontiers of Hungary. It is seated between the rivers Drave and Muhr. in E. Long. 17. 19. N. Lat. 46. 24.

CZAR, a title of honour, assumed by the grand-dukes, or, as they are now styled emperors of Russia.

The natives pronounce it *tzar*, or *zaar*; and this, by corruption (it has been fancied) from *Cæsar* "emperor," from some imagined relation to the Roman emperors. But this etymology does not seem correct. When the czar Peter formally required of the European courts an acknowledgement of his imperial titles, and that the appellation of *Emperor* should never be omitted, there was great difficulty made about it, especially at the court of Vienna; which occasioned him to produce the famous letter, written in the German tongue, from Maximilian I. emperor of Germany, to Vassili Ivanovitch, confirming a treaty of alliance offensive and defensive against Sigismund king of Poland. In this dispatch, which is dated August the 4th, 1514, and is ratified with the seal of the golden-bull, Maximilian addresses Vassili by calling him *Kayser* and *Herrscher aller Russen*; "emperor and ruler of all the Russias." But independently of this document, there could be no doubt that the foreign courts, in their intercourse with that of Moscow, styled the sovereigns indiscriminately *Great Duke*, *Czar*, and *Emperor*. With respect to England in particular, it is certain, that in Chancellor's Account of Russia, so early as the middle of the 16th century, Ivan Vassilievitch II. is called *Lord and Emperor of all Russia*; and in the English dispatches, from the reign of Elizabeth to that of Anne, he is generally addressed under the same appellation. When the European powers, however, styled the czar *Emperor of Muscovy*, they by no means intended to give him a title similar to that which was peculiar to the emperor of Germany; but they bestowed upon him that appellation as upon an Asiatic sovereign, in the same manner as we now say the emperors of China and Japan. When Peter, therefore, determined to assume the title of emperor, he found no difficulty in proving that it had been conferred upon his predecessors by most of the

European powers; yet when he was desirous of affixing to the term the European sense, it was considered as an innovation, and was productive of more negotiations than would have been requisite for the termination of the most important state affair. At the same time it occasioned a curious controversy among the learned, concerning the rise and progress of the titles by which the monarchs of this country have been distinguished. From their researches, it appeared that the early sovereigns of Russia were called great duke, and that Vassili Ivanovitch was probably the first who styled himself *tzar*, an expression which in the Slavonian language signifies *king*; and that his successors continued to bear within their own dominions that title as the most honourable appellation, until Peter the Great first took that of *Povelitel* or emperor. After many delays and objections, the principal courts of Europe consented, about the year 1722, to address the sovereign of Russia with the title of emperor; without prejudice, nevertheless, to the other crowned heads of Europe.

CZASLAU, a town of Bohemia, and capital of a circle of the same name. Here is the highest tower in all Bohemia; and near this place the king of Prussia gained a victory over the Austrians in 1742. It is seated on the river Crudenka, in E. Long. 15. 33. N. Lat. 49. 50.

CZENSTOKOW, a town of Poland in the palatinate of Cracovia, with a fort, in which they keep a rich treasure, called "the treasure of the virgin Mary." The pilgrims flock hither so much for the sake of a convent near it, that it is called the *Loretto* of Poland. The town is situated on the river in Warthe, E. Long. 19. 15. N. Lat. 50. 48.

CZERNIC, a town of Carniola, in Austria, situated in E. Long. 15. 0. N. Lat. 46 12. It is remarkable for its lake; for a particular description of which see the article **CIRCHNITZER**.

CZERNIKOU, a considerable town of Muscovy, and capital of a duchy of the same name, with a castle. It is seated on the river Dezna, in E. Long. 32. 13. N. Lat. 51. 20.

CZONGRODT, a town of Upper Hungary, and capital of a territory of the same name, at the confluence of the rivers Teisse and Keres. E. Long. 20. 57. N. Lat. 45. 50.

D A C

D.

D A C

D
Dacca.

Dacca,
Dace.

D, THE fourth letter of the alphabet, and the third consonant.

Grammarians generally reckon D among the lingual letters, as supposing the tongue to have the principal share in the pronunciation thereof; though the Abbot de Dangeau seems to have reason in making it a palate letter. The letter D is the fourth in the Hebrew, Chaldee, Samaritan, Syriac, Greek; and Latin alphabets; in the five first of which languages it has the same name, though somewhat differently spoke, e. g. in Hebrew and Chaldee *Daleth*, in Syriac *Dolet*, and in Greek *Delta*.

The form of our D is the same with that of the Latins, as appears from all the ancient medals and inscriptions; and the Latin D is no other than the Greek Δ, rounded a little, by making it quicker and at two strokes. The Δ of the Greeks, again, is borrowed from the ancient character of the Hebrew *Daleth*; which form it still retains, as is shown by the Jesuit Souciat, in his Dissertation on the Samaritan Medals.

D is also a numeral letter, signifying *five hundred*; which arises hence, that, in the Gothic characters, the D is half the M, which signifies a *thousand*. Hence the verse,

Litera D velut A quingentos significabit.

A dash added a-top, \overline{D} , denotes it to stand for five thousand.

Used as an abbreviation, it has various significations: thus D stands for Doctor; as, M. D. for Doctor of Medicine; D. T. Doctor of Theology; D. D. implies Doctor of Divinity, or "dono dedit;" D. D. D. is used for "dat, dicat, dedicat;" and D. D. D. D. for "dignum Deo donum dedit."

DAB, in ichthyology, the English name of a species of PLEURONECTES.

DABUL, a town of Asia, in the East Indies, on the coast of Malabar, and to the south of the gulf of Cambaye, on a navigable river. It was formerly very flourishing, but is now much decayed. It belongs to the Portuguese, and its trade consists principally in pepper and salt. E. Long. 73. 55. N. Lat. 17. 30.

DACCA, a town of Asia, in the kingdom of Bengal in the East Indies, situated in E. Long. 89. 10. N. Lat. 24. 0.—The advantages of the situation of this place, and the fertility of the soil round it, have long since made it the centre of an extensive commerce. The courts of Delhi and Muxadavad are furnished from thence with the cottons wanted for their own consumption. They each of them maintain an agent on the spot to superintend the manufacture of them; and he has an authority, independent of the magistrate, over the brokers, weavers, embroiderers, and all the workmen whose business has any relation to the object of his commission. These unhappy people are forbidden, under pecuniary and corporal penalties, to sell, to any person whatever, a piece exceeding the value of

three guineas: nor can they, but by dint of money, relieve themselves from this oppression.

In this, as in all the other markets, the Europeans treat with the Moorish brokers settled upon the spot, and appointed by the government. They likewise lend their name to the individuals of their own nation, as well as to Indians and Armenians living in their settlements, who, without this precaution, would infallibly be plundered. The Moors themselves, in their private transactions, sometimes avail themselves of the same pretence, that they may pay only two, instead of five *per cent*. A distinction is observed, in their contracts, between the cottons that are bespoke and those which the weaver ventures, in some places, to manufacture on his own account. The length, the number of threads, and the price, of the former are fixed: nothing further than the commission for the latter is stipulated, because it is impossible to enter into the same detail. Those nations that make a point of having fine goods, take proper measures that they may be enabled to advance money to their workmen at the beginning of the year. The weavers, who in general have but little employment at that time, perform their work with less hurry than in the months of October, November, and December, when the demand is pressing.

Some of the cottons are delivered unbleached, and others half-bleached. It were to be wished that this custom might be altered. It is very common to see cottons that look very beautiful, go off in the bleaching. Perhaps the manufacturers and brokers foresee how they will turn out; but the Europeans have not so exquisite a touch, nor such an experienced eye to discern this. It is a circumstance peculiar to India, that cottons, of what kind soever they are, can never be well bleached and prepared but in the place where they are manufactured. If they have the misfortune to get damage before they are shipped for Europe, they must be sent back to the places from whence they came.

DACE, in ichthyology, a species of CYPRINUS.

This fish is extremely common in the rivers in Britain, and gives the expert angler great diversion. The dace will bite at any fly; but he is more than ordinarily fond of the stone caddis, or May-fly, which is plentiful in the latter end of April and the whole month of May. Great quantities of these may be gathered among the reeds or sedges by the water-side; and on the hawthorn bushes near the waters. These are a large and handsome bait; but as they last only a small part of the year in season, recourse is to be had to the ant-fly. Of these the black ones found in large mole-hills or ant-hills are the best. These may be kept alive a long time in a bottle, with a little of the earth of the hill, and some roots of grass; and they are in season throughout the months of June, July, August, and September. The best season of all is when they swarm, which is in the

Dachaw
Dacier.

end of July or beginning of August; and they may be kept many months in a vessel washed out with a solution of honey in water, even longer than with the earth and grafs-roots in the vial; though that is the most convenient method with a small parcel taken for one day's fishing. In warm weather this fish very seldom refuses a fly at the top of the water; but at other times he must have the bait sunk to within three inches of the bottom. The winter fishing for dace requires a very different bait: this is a white maggot with a reddish head, which is the produce of the eggs of the beetle, and is turned up with the plough in great abundance. A parcel of these put in any vessel, with the earth they were taken in, will keep many months, and are an excellent bait. Small dace may be put into a glass jar with fresh water; and there preserved alive for a long time, if the water is properly changed. They have been observed to eat nothing but the animalcula of the water. They will grow very tame by degrees.

DACHAW, a town of Bavaria in Germany. It is pretty large, well built, and seated on a mountain, near the river Amber. Here the elector has a palace and fine gardens. E. Long. 11. 30. N. Lat. 48. 20.

DACIA (anc. geog.), a country which Trajan, who reduced it to a province, joined to Moesia by an admirable bridge. This country lies extended between the Danube and the Carpathian mountains, from the river Tibiscus, quite to the north bend of the Danube; so as to extend thence in a direct line to the mouth of the Danube and to the Euxine; on the north-side next the Carpates, terminated by the river Hieratus, now the Pruth; on the west by the Tibiscus or Teis; comprising a part of Upper Hungary, all Transylvania and Walachia, and a part of Moldavia. *Daci*, the people; a name which Strabo takes to be the same with the *Davi* of Comedies: neighbours, on the west, to the *Getae*; an appellation common also in Comedies. Josephus mentions a set of religious men among the *Daci*, whom he calls *Plisti*, and compares with the *Esseni*; of these *Plisti* no other author makes any mention. *Dacicus*, the epithet; assumed by some emperors, (Juvenal.) There was a *Dacia Aureliani*, a part of Illyrium, which was divided into the eastern and western; Sirmium being the capital of the latter, and Sardica of the former. But this belongs to the lower age.

DACIER, (Andrew), born at Castres in Upper Languedoc, 1651, had a great genius and inclination for learning, and studied at Saumur under Tannegui le Fevre, then engaged in the instruction of his daughter, who proved afterwards an honour to her sex. This gave rise to that mutual tenderness which a marriage of 40 years could never weaken in them. The duke of Montausier hearing of his merit, put him in the list of commentators for the use of the dauphin, and engaged him in an edition of Pompeius Festus, which he published in 1681. His edition of Horace printed at Paris in 10 vols in 12mo, and his other works, raised him a great reputation. He was made a member of the academy of inscriptions in 1695. When the history of Louis XIV. by medals was finished, he was chosen to present it to his majesty; who being informed of the pains which he had taken in it, settled upon him a pension of 2000 livres, and appointed him keep-

er of the books of the king's closet in the Louvre. When that post was united to that of library-keeper to the king, he was not only continued in the privileges of his place during life, but the survivance was granted to his wife, a favour of which there had been no instance before. But the death of Madam Dacier in 1720, rendered this grant, which was so honourable to her, ineffectual. He died September 18. 1722, of an ulcer in the throat. In his manners, sentiments, and the whole of his conduct, he was a complete model of that ancient philosophy of which he was so great an admirer, and which he improved by the rules and principles of Christianity.

DACIER (Anne), daughter of Tannegui le Fevre, professor of Greek at Saumur in France. She early showed a fine genius, which her father cultivated with great care and satisfaction. After her father's death she went to Paris, whither her fame had already reached; she was then preparing an edition of Callimachus, which she published in 1674. Having shown some sheets of it to Mr Hus, preceptor to the dauphin, and to several other men of learning at the court, the work was so highly admired, that the duke of Montausier made a proposal to her of publishing several Latin authors for the use of the dauphin. She rejected this proposal at first, as a task to which she was not equal. But the duke insisted upon it; so that at last he gained her consent; upon which she undertook an edition of Florus, published in 1674. Her reputation being now spread over all Europe, Christina queen of Sweden ordered count Konigsmark to make her a compliment in her name: upon which Mademoiselle le Fevre sent the queen a Latin letter, with her edition of Florus: to which her majesty wrote an obliging answer; and not long after sent her another letter, to persuade her to abandon the Protestant religion, and made her considerable offers to settle at her court. In 1683 she married Mr Dacier; and soon after declared her design to the duke of Montausier and the bishop of Meaux of reconciling herself to the church of Rome, which she had entertained for some time: but as Mr Dacier was not yet convinced of the reasonableness of such a change, they retired to Castres in 1684, where they had a small estate, in order to examine the points of controversy between the Protestants and the Roman Catholics. They at last determined in favour of the latter, and made their public abjuration in 1685. After this, the king gave both husband and wife marks of his favour. In 1693, she applied herself to the education of her son and daughter, who made a prodigious progress: the son died in 1694, and the daughter became a nun in the abbey of Longchamp. She had another daughter, who had united in her all the virtues and accomplishments that could adorn the sex; but she died at 18. Her mother has immortalized her memory in the preface to her translation of the Iliad. Madam Dacier was in a very infirm state of health the two last years of her life: and died, after a very painful sickness, August 27. 1720, aged 69. She was remarkable for her firmness, generosity, equality of temper, and piety.

DACTYL, *daçtylus*, a foot in the Latin and Greek poetry, consisting of a long syllable, followed by two short ones: as *carmivè*

Some say it is derived from *δακτυλος*, "a finger," because

Dacier,
Daçtyl.

Dactylus because it is divided into three joints, the first of which is longer than the other two.

Dactylic. The dactyl is said to have been the invention of Dionysius or Bacchus, who delivered oracles in this measure at Delphos, before Apollo. The Greeks call it *δακτυλικός*. The dactyl and spondee are the most considerable of the poetical feet; as being the measures used in heroic verse, by Homer, Virgil, &c. These two are of equal time, but not equal motion. The spondee has an even, strong, and steady pace, like a trot: the dactyl resembles the nimbler strokes of a gallop.

DACTYLUS was also a sort of dance among the ancient Greeks, chiefly performed, Hesychius observes, by the *athletæ*.

DACTYLS also denote the fruit of the palm-tree, more usually called *dates*.

DACTYLI IDÆI; the *Fingers of Mount Ida*. Concerning these, Pagan theology and fable give very different accounts. The Cretans paid divine worship to them, as those who had nursed and brought up the god Jupiter; whence it appears, that they were the same as the Corybantes and Curetes. Nevertheless Strabo makes them different; and says, that the tradition in Phrygia was, that "Curetes and Corybantes were descended from the Dactyli Idæi: that there were originally an hundred men in the island, who were called *Dactyli Idæi*; from whom sprang nine Curetes, and each of these nine produced ten men, as many as the fingers of a man's two hands; and that this gave the name to the ancestors of the Dactyli Idæi." He relates another opinion, which is, that there were but five Dactyli Idæi; who, according to Sophocles, were the inventors of iron: that these five brothers had five sisters, and that from this number they took the name of *fingers of mount Ida*, because they were in number ten; and that they worked at the foot of this mountain. Diodorus Siculus reports the matter a little differently. He says "the first inhabitants of the island of Crete were the Dactyli Idæi, who had their residence on mount Ida: that some said they were an hundred; others only five, in number equal to the fingers of a man's hand, whence they had the name of *Dactyli*: that they were magicians, and addicted to mystical ceremonies: that Orpheus was their disciple, and carried their mysteries into Greece: that the Dactyli invented the use of iron and fire, and that they had been recompensed with divine honours."

Diomedes the Grammarian says, The Dactyli Idæi were priests of the goddess Cybele: called *Idæi*, because that goddess was chiefly worshipped on mount Ida in Phrygia; and *Dactyli*, because that, to prevent Saturn from hearing the cries of infant Jupiter, whom Cybele had committed to their custody, they used to sing certain verses of their own invention, in the Dactylic measure. See **CURETES** and **CORYBANTES**.

DACTYLIC, something that has a relation to dactyls.

Anciently, there were dactylic as well as spondaic flutes, *tibia dactylica*. The dactylic flutes consisted of unequal intervals; as the dactylic foot does of unequal measures.

DACTYLIC Verses are hexameter verses, ending in a dactyl instead of a spondee; as spondaic verses are those which have a spondee in the fifth foot instead of a dactyl.

An instance of a dactylic verse we have in Virgil: *Dactylio.*
Bis patria cecidere manus: quin protinus omnia
Per legerent oculis — *ÆN.* vi. 33. *isancy*

DACTYLIOMANCY, DACTYLIOMANTIA, a sort of divination performed by means of a ring. The word is composed of the Greek *δακτυλιος* "ring," of *δακτυλος* "finger," and *μαντια* "divination."

Dactyliomancy consisted principally in holding a ring, suspended by a fine thread, over a round table, on the edge whereof were made divers marks with the twenty-four letters of the alphabet. The ring in shaking, or vibrating over the table, stopped over certain of the letters, which, being joined together, composed the answer required. But the operation was preceded and accompanied by several superstitious ceremonies; for first the ring was to be consecrated with a great deal of mystery: the person who held it was to be clad in linen garments to the very shoes; his head was to be shaved all round; and in his hand he was to hold vervain. And before he proceeded on any thing, the gods were first to be appeased by a formulary of prayers, &c. Ammianus Marcellinus gives the process at large in his 29th book.

DACTYLIS, COCK'S-FOOT GRASS: A genus of the digynia order, belonging to the triandria class of plants; and in the natural method ranking under the 4th order, *Gramina*. The calyx is bivalved and compressed, and the one valve longer than the other, carinated, or having the rachis prominent and sharp. There are two species, the cynosuroides or smooth cock's-foot grass, and the glomeratus or rough cock's-foot grass. Both are natives of Britain: the first grows in marshy places, and the latter is common in meadows and pasture-grounds. This last is eat by horses, sheep, and goats; but refused by cows.

DACTYLUS, in zoology, a name given by Pliny to the **PHOLAS**.

DADUCHI, in antiquity, priests of Ceres. That goddess having lost her daughter Proserpine, say mythologists, began to make search for her at the beginning of the night. In order to do this in the dark, she lighted a torch, and thus set forth on her travels throughout the world: for which reason it is that she is always seen represented with a lighted torch in her hand. On this account, and in commemoration of this pretended exploit, it became a custom for the priests, at the feasts and sacrifices of the goddess, to run about in the temple, with torches after this manner; one of them took a lighted torch from off the altar, and holding it with his hand, ran with it to a certain part of the temple, where he gave it to another, saying to him, *Tibi trado*: this second ran after the like manner to another part of the temple, and gave it to the third, and so of the rest. From this ceremony the priests became denominated *daduchi*, *δαδυχοι* *q. d.* "torch-bearers;" from *das*, "an unctuous resinous wood, as pine, fir, &c." whereof the ancients made torches; and *εχω*, "I have, I hold." — The Athenians also gave the name *deduchus* to the high-priest of Hercules.

DÆDALA, a mountain and city of Lycia, where Dædalus was buried, according to Pliny. — Also two festivals in Læotia, so called; one of them, observed at Alalcomenes by the Plataeans in a large grove, where they exposed in the open air pieces of boiled flesh, and carefully observed whether the crows that came to prey

Dædala.

Dædala,
Dædalus.

prey upon them directed their flight. All the trees upon which any of these birds alighted were immediately cut down, and with them statues were made, called *Dædala*, in honour of Dædalus. The other festival was of a more solemn kind. It was celebrated every 60 years by all the cities of Bœotia, as a compensation for the intermission of the smaller festivals for that number of years, during the exile of the Platæans. Fourteen of the statues called *Dædala* were distributed by lot among the Platæans, Lebadæans, Coroncans, Orchomenians, Thespians, Thebans, Tanagræans, and Chæroneans, because they had effected a reconciliation among the Platæans, and caused them to be recalled from exile about the time that Thebes was restored by Cassander the son of Antipater. During this festival a woman in the habit of a bride-maid accompanied a statue which was dressed in female garments, on the banks of the Eurotes. This procession was attended to the top of mount Cithæron by many of the Bœotians, who had places assigned them by lot. Here an altar of square pieces of wood cemented together like stones was erected, and upon it were thrown large quantities of combustible materials. Afterwards a bull was sacrificed to Jupiter, and an ox or heifer to Juno, by every one of the cities of Bœotia, and by the most opulent that attended. The poorest citizens offered small cattle; and all these oblations, together with the *Dædala*, were thrown into the common heap and set on fire, and totally reduced to ashes. They originated in this: When Juno, after a quarrel with Jupiter, had retired to Eubœa, and refused to return to his bed, the god, anxious for her return, went to consult Cithæron king of Platæa, to find some effectual measure to break her obstinacy. Cithæron advised him to dress a statue in woman's apparel, and carry it in a chariot, and publicly to report it was Platæa the daughter of Afopus, whom he was going to marry. The advice was followed; and Juno, informed of her husband's future marriage, repaired in haste to meet the chariot, and was easily united to him, when she discovered the artful measures he made use of to effect a reconciliation.

DÆDALUS, an Athenian, son of Eupalamus, descended from Erechtheus king of Athens. He was the most ingenious artist of his age; and to him we are indebted for the invention of the wedge, and many other mechanical instruments, and the sails of ships. He made statues which moved of themselves, and seemed to be endowed with life. Talus his sister's son promised to be as great as himself by the ingenuity of his inventions; and therefore from envy he threw him down from a window and killed him. After the murder of this youth, Dædalus, with his son Icarus, fled from Athens to Crete, where Minos king of the country gave him a cordial reception. Dædalus made a famous labyrinth for Minos, and assisted Pasiphae the queen to gratify her unnatural passion for a bull. For this action Dædalus incurred the displeasure of Minos, who ordered him to be confined in the labyrinth which he had constructed. Here he made himself wings with feathers and wax, and carefully fitted them to his body and that of his son, who was the companion of his confinement. They took their flight in the air from Crete; but the heat of the sun melted the wax on the wings of Icarus, whose flight was too

high, and he fell into that part of the ocean which from him has been called the *Icarian Sea*. The father by a proper management of his wings alighted at Cumæ, where he built a temple to Apollo, and thence directed his course to Sicily, where he was kindly received by Cocalus, who reigned over part of the country. He left many monuments of his ingenuity in Sicily, which still existed in the age of Diodorus Siculus. He was dispatched by Cocalus, who was afraid of the power of Minos, who had declared war against him because he had given an asylum to Dædalus. The flight of Dædalus from Crete with wings is explained by observing that he was the inventor of sails, which in his age might pass at a distance for wings. He lived 1400 years before the Christian era. There were two statues of the same name; one of Sicyon son of Patroclus; the other a native of Bithynia.

DÆMON Δαίμων, a name given by the ancients to certain spirits or genii, which they say appeared to men, either to do them service or to hurt them.

The Greek word *δαίμων* is derived (according to Plato, in his *Cratylus*, p. 398. *ed. Sarani*, vol. i.) from *δαίμων*, "knowing or intelligent;" but according to others from *δαίνομαι*, "to distribute;" (see the Scholiast on Homer, II. i. ver. 222). Either of these derivations agrees with the office ascribed to dæmons by the ancient heathens, as the spirit intrusted with the inspection and government of mankind. For, according to the philosophers, dæmons held a middle rank between the celestial gods and men on earth, and carried on all intercourse between them; conveying the addresses of men to the gods, and the divine benefits to men. It was the opinion of many, that the celestial divinities did not themselves interpose in human affairs, but committed the entire administration of the government of this lower world to these subaltern deities: *Neque enim pro majestate deum celestium fuerit, hæc curare;* (Apuleius *de deo Socratis*, p. 677). *Cuncta celestium voluntate, numine & autoritate, sed dæmonum obsequio, & opera, & ministerio fieri arbitrandum est;* (*Id.* p. 675.) Hence they became the objects of divine worship. "If idols are nothing," says Celsus (*apud Origen con. Cels.* lib. viii. p. 393.), "what harm can there be to join in the public festivals? If they are dæmons, then it is certain that they are gods, in whom we are to confide, and to whom we should offer sacrifices and prayers, to render them propitious."

Several of the heathen philosophers held, that there were different kinds of dæmons; that some of them were spiritual substances of a more noble origin than the human race, and that others had once been men.

But those dæmons who were the more immediate objects of the established worship amongst the ancient nations were human spirits, such as were believed to become dæmons or deities after their departure from their bodies. Plutarch teaches (*Vit. Romul.* p. 36. *ed. Paris*) "that according to a divine nature and justice, the souls of virtuous men are advanced to the rank of dæmons; and that from dæmons, if they are properly purified, they are exalted into gods, not by any political institutions, but according to right reason." The same author says in another place (*de Is. & Osir.* p. 361.), "that Isis and Osiris were, for their virtue, changed from good dæmons into gods, as were Hercules

Dæmon

Dæmoniac. cules and Bacchus afterwards, receiving the united honours both of gods and dæmons." Hesiod and other poets who have recorded the ancient history or traditions on which the public faith and worship were founded, assert, that the men of the golden age, who were supposed to be very good, became dæmons after death, and dispensers of good things to mankind.

Though *dæmon* is often used in a general sense as equivalent to a *deity*; and is accordingly applied to *fate* or *fortune*, or whatever else was regard as a god: yet those dæmons who were the more immediate objects of divine worship amongst the heathens were human spirits; as is shown in Farmer on Miracles, chap. iii. sect. 2.

The word *dæmon* is used indifferently in a good and in a bad sense. In the former sense, it was very commonly used among the ancient heathens. "We must not (says Menander) think any dæmon to be evil, hurtful to a good life, but every god to be good." Nevertheless, those are certainly mistaken who affirm, that *dæmon* never signifies an evil being till after the times of Christ. Pythagoras held dæmons who sent diseases to men and cattle (*Diogen. Laert. Vit. Pythagor. p. 514. ed. Amstel.*) Zaleucus, in his preface to his Laws (*apud Stobæum, Serm. 42.*) supposes that an evil dæmon might be present with a man, to influence him to injustice. The dæmons of Empedocles were evil spirits, and exiles from heaven; (*Plutarch, Περὶ τῆς μὴ δεῖν δαίμωνι ζῆσθαι*). And in his life on Dion (p. 958) he says, "It was the opinion of the ancients, that evil and mischievous dæmons, out of envy and hatred to good men, oppose whatever they do." Scarce did any opinion more generally prevail in ancient times than this, *viz.* that as the departed souls of good men became good dæmons, so the departed souls of bad men became evil dæmons.

It has been generally thought, that by *dæmons* we are to understand *devils*, in the Septuagint version of the Old Testament. Others think the word is in that version certainly applied to the ghosts of such dead men as the heathens deified, in Deut. xxxii. 17. Ps. cvi. 37. That *dæmon* often bears the same meaning in the New Testament, and particularly in Acts xvii. 18. 1 Cor. x. 21. 1 Tim. iv. 1, Rev. ix. 13. is shown at large by Mr Joseph Mede (*Works, p. 623, et seq.*). That the word is applied *always* to human spirits in the New Testament, Mr Farmer has attempted to show in his Essay on Dæmoniacs p. 208. *et seq.* As to the meaning of the word *dæmon* in the fathers of the Christian church, it is used by them in the same sense as it was by the heathen philosophers, especially the latter Platonists; that is sometimes for departed human spirits, and at other times for such spirits as had never inhabited human bodies. In the fathers, indeed, the word is more commonly taken in an evil sense, than in the ancient philosophers. Besides the two forementioned kinds of dæmons, the fathers, as well as the ancient philosophers, held a third, *viz.* such as sprang from the congress of superior beings with the daughters of men. In the theology of the fathers, these were the worst kind of dæmons.

Different orders of dæmons had different stations and employments assigned them by the ancients. Good dæmons were considered as the authors of good to mankind; evil dæmons brought innumerable evils both

upon men and beasts. Amongst evil dæmons there was a great distinction with respect to the offices assigned them; some compelled men to wickedness, others stimulated them to madness. See DEMONIAIC.

Much has been said concerning the dæmon of Socrates. He pretended to his friends and disciples, and even declared to the world, that a friendly spirit, whom he called his *dæmon*, directed him how to act on every important occasion in his life, and restrained him from imprudence of conduct.

In contemplating the character of this great philosopher, while we admire him as the noblest pattern of virtue and moral wisdom that appeared in the heathen world, we are naturally led to inquire, whether what he gave out concerning his dæmon were a trick of imposture, or the reverie of a heated imagination, or a sober and true account of a favour which heaven designed to confer on so extraordinary a man.

To ascertain in this case the object of our inquiries, is by no means so easy as the superficial thinker may be apt to imagine. When we consider the dignity of sentiment and simplicity of manners which Socrates displayed through the general tenor of his life, we cannot readily bring ourselves to think that he could be capable of such a trick of imposture. Nothing of the wildness of an enthusiast appears in his character; the modesty of his pretensions, and the respect which in his conversation and conduct he uniformly testified for the ordinary duties of social life, sufficiently prove that he was free from the influence of blind enthusiasm: we cannot infer, therefore, that, like the astronomer in Rasseias, he was deceived with respect to his dæmon by an over-heated imagination. It is no less difficult to believe, that God would distinguish an heathen in so eminent a manner, and yet leave him uninstructed in the principles of true religion. Surely, if ever scepticism be reasonable, it must be in such matters as the present.

Yet, if it be still insisted, that some one of these three notions concerning the dæmon of Socrates must be more probable than the others; we would rather esteem Socrates an enthusiast in this instance, than degrade him to the base character of an impostor, or suppose that a spiritual being actually revealed himself to the philosopher, and condescended to become his constant attendant and counsellor. People are often under the influence of an over-heated imagination with regard to some one thing, and cool and sober as to every thing else.

DÆMONIAC (from *dæmon*), a human being whose volition and other mental faculties are overpowered and restrained, and his body possessed and actuated, by some created spiritual being of superior power.

Such seems to be the determinate sense of the word; but it is disputed whether any of mankind ever were in this unfortunate condition.

It is generally agreed, that neither good nor evil spirits are known to exert such authority at present over the human race: but in the ancient heathen world, and among the Jews, particularly in the days of our Saviour, evil spirits, at least, are thought by many to have been more troublesome.

The Greeks and Romans imagined, that their deities, to reveal future events, frequently entered into the prophet or prophets who was consulted, the prophet or prophets who was consulted, overpowered

Dæmoniac.

Definition.

2

Dispute concerning dæmoniacs.

3

Notions of the Greeks and Ro-

mans concerning possessions.

Dæmoniac. powered their faculties, and uttered responses with their organs of speech. Apollo was believed to enter into the Pythones, and to dictate the prophetic answers received by those who consulted her. Other oracles besides that of Delphi were supposed to unfold futurity by the same machinery. And in various other cases, either malignant dæmons or benevolent deities were thought to enter into and to actuate human beings. The *Lymphatici*, the *Ceriti*, the *Larvati*, of the Romans, were all of this description; and the Greeks, by the use of the word *δαίμονιοι*, show that they referred to this cause the origin of madness. Among the ancient heathens, therefore, it appears to have been a generally received opinion, that superior beings entered occasionally into men, overpowered the faculties of their minds, and actuated their bodily organs. They might imagine that this happened in instances in which the effects were owing to the operation of different causes; but an opinion so generally prevalent had surely some plausible foundation.

4
Of the
Jews.

The Jews too, if we may trust the sacred writings or Josephus, appear to have believed in dæmoniacal possession. The case of Saul may be recollected as one among many in which superior created beings were believed by the Jews to exert in this manner their influence over human life. The general tenor of their history and language, and their doctrines concerning good and evil spirits, prove the opinion of dæmoniacal possession to have been well known and generally received among them.

5
Of man-
kind in ge-
ral in the
days of our
Saviour.

In the days of our Saviour, it would appear that dæmoniacal possession was very frequent among the Jews and the neighbouring nations. Many were the evil spirits whom Jesus is related in the gospels to have ejected from patients that were brought unto him as possessed and tormented by those malevolent dæmons. His apostles too, and the first Christians, who were most active and successful in the propagation of Christianity, appear to have often exerted the miraculous powers with which they were endowed on similar occasions. The dæmons displayed a degree of knowledge and malevolence which sufficiently distinguished them from human beings: and the language in which the dæmoniacs are mentioned, and the actions and sentiments ascribed to them in the New Testament, show that our Saviour and his apostles did not consider the idea of dæmoniacal possession as being merely a vulgar error concerning the origin of a disease or diseases produced by natural causes.

6
Jesus
Christ and
his apostles
must have
believed
dæmonia-
cal posses-
sion to be
real.

The more enlightened cannot always avoid the use of metaphorical modes of expression; which though founded upon error, yet have been so established in language by the influence of custom, that they cannot be suddenly dismissed. When we read in the book of Joshua, that the sun on a certain occasion stood still, to allow that hero time to complete a victory; we easily find an excuse for the conduct of the sacred historian, in accommodating his narrative to the popular ideas of the Jews concerning the relative motions of the heavenly bodies. In all similar instances, we do not complain much of the use of a single phrase, originally introduced by the prevalence of some groundless opinion, the falsity of which is well known to the writer.

But in descriptions of characters, in the narration of

facts, and in the laying down of systems of doctrine, Dæmoniac. we require different rules to be observed. Should any person, in compliance with popular opinions, talk in serious language of the existence, dispositions, declarations, and actions of a race of beings whom he knew to be absolutely fabulous, we surely could not praise him for candid integrity: we must suppose him to be either exulting in irony over the weak credulity of those around him, or taking advantage of their weakness, with the dishonesty and the selfish views of an impostor. And if he himself should pretend to any connection with this imaginary system of beings; and should claim, in consequence of his connection with them, particular honours from his contemporaries; whatever might be the dignity of his character in all other respects, nobody could hesitate even for a moment to brand him as an impostor of the basest character.

Precisely in this light must we regard the conduct of our Saviour and his apostles, if the idea of dæmoniacal possession were to be considered merely as a vulgar error. They talked and acted as if they believed that evil spirits had actually entered into those who were brought to them as possessed with devils, and as if those spirits were actually expelled by their authority out of the unhappy persons whom they had possessed. They expected, they demanded too, to have their professions and declarations believed, in consequence of their performing such mighty works, and to be honoured as having thus triumphed over the powers of hell. The reality of dæmoniacal possession stands upon the same evidence with the gospel system in general.

7
Reasona-
bleness of
this doc-
trine.

Neither is any thing absurd or unreasonable in this doctrine. It does not appear to contradict those ideas which the general appearances of nature and the series of events suggest concerning the benevolence and wisdom of the Deity, and the counsels by which he regulates the affairs of the universe. We often fancy ourselves able to comprehend things to which our understanding is wholly inadequate: we persuade ourselves, at times, that the whole extent of the works of the Deity must be well known to us, and that his designs must always be such as we can fathom. We are then ready, whenever any difficulty arises to us, in considering the conduct of Providence, to model things according to our own ideas; to deny that the Deity can possibly be the author of things which we cannot reconcile; and to assert, that he must act on every occasion in a manner consistent with our narrow views. This is the pride of reason; and it seems to have suggested the strongest objections that have been at any time urged against the reality of dæmoniacal possession. But the Deity may surely connect one order of his creatures with another. We perceive mutual relations and a beautiful connection to prevail through all that part of nature which falls within the sphere of our observation. The inferior animals are connected with mankind, and subjected to their authority, not only in instances in which it is exerted for their advantage, but even where it is tyrannically abused to their destruction. Among the evils to which mankind have been subjected, why might not their being liable to dæmoniacal possession be one? While the Supreme Being retains the sovereignty of the universe,

Dæmoniac. universe, he may employ whatever agents he thinks proper in the execution of his purposes: he may either commission an angel or let loose a devil; as well as bend the human will, or communicate any particular impulse to matter.

All that revelation makes known, all that human reason can conjecture, concerning the existence of various orders of spiritual beings, good and bad, is perfectly consistent with, and even favourable to, the doctrine of dæmoniacal possession. It was generally believed through the ancient heathen world; it was equally well known to the Jews, and equally respected by them; it is mentioned in the New Testament in such language, and such narratives are related concerning it, that the gospels cannot well be regarded in any other light than as pieces of imposture, and Jesus Christ must be considered as a man who dishonestly took advantage of the weakness and ignorance of his contemporaries, if this doctrine be nothing but a vulgar error; it teaches nothing inconsistent with the general conduct of Providence; it is not the caution of philosophy, but the pride of reason, that suggests objections against this doctrine.

8
Arguments of the Antidæmonists. Those, again, who are unwilling to allow that angels or devils have ever intermeddled so much with the concerns of human life, urge a number of specious arguments in opposition to these.

9
The cases in which the Greeks and Romans supposed dæmoniacal possession, was only instances of madness, &c. The Greeks and Romans of old, say they, did believe in the reality of dæmoniacal possession. They supposed that spiritual beings did at times enter into the sons or daughters of men, and distinguish themselves in that situation by capricious freaks, deeds of wanton mischief, or prophetic enunciations. But in the instances in which they supposed this to happen, it is evident that no such thing took place. Their accounts of the state and conduct of those persons whom they believed to be possessed in this supernatural manner, show plainly that what they ascribed to the influence of dæmons were merely the effects of natural diseases. Whatever they relate concerning the *larvati*, the *cerriti*, and the *lymphatici*, shows that these were merely people disordered in mind, in the same unfortunate situation with those madmen and idiots and melancholy persons whom we have among ourselves. Festus describes the *Larvati* as being *furiosi et mente moti*. Horace says,

*Hellade percussâ, Marius cum præcipitat se,
 Cerritus fuit?*

Plato, in his *Simæus*, says, *αδεις γαρ ενους εφαιπεται μαντικης ενθουου, αληθους.* Lucian describes dæmoniacs as lunatic, and as staring with their eyes, foaming at the mouth, and being speechless.

10
The same is true of the Dæmoniacs of the New Testament. It appears still more evidently, that all the persons spoken of as possessed with devils in the New Testament, were either mad or epileptic, and precisely in the same condition with the madmen and epileptics of modern times. The Jews, among other reproaches which they threw out against our Saviour, said, *He hath a devil, and is mad; why hear ye him?* The expressions *he hath a devil, and is mad*, were certainly used on this occasion as synonymous. With all their virulence, they would not surely ascribe to him at once two things that were inconsistent and contradictory. Those who thought more favourably of the character of Jesus, asserted concerning his discourses, in reply to

his adversaries, *These are not the words of him that hath a demon*; meaning, no doubt, that he spoke in a more rational manner than a madman could be expected to speak. The Jews appear to have ascribed to the influence of dæmons, not only that species of madness in which the patient is *raving and furious*, but also *melancholy madness*. Of John, who secluded himself from intercourse with the world, and was distinguished for abstinence and acts of mortification, they said, *He hath a demon*. The youth, whose father applied to Jesus to free him from an evil spirit, describing his unhappy condition in these words, *Have mercy on my son, for he is lunatic and sore vexed with a demon; for oft times he falleth into the fire, and oft into the water*, was plainly epileptic. Every thing indeed that is related in the New Testament concerning dæmoniacs, proves that they were people affected with such natural diseases as are far from being uncommon among mankind in the present age. When the symptoms of the disorders cured by our Saviour and his apostles as cases of dæmoniacal possession, correspond so exactly with those of diseases well known as natural in the present age, it would be absurd to impute them to a supernatural cause. It is much more consistent with common sense and sound philosophy to suppose, that our Saviour and his apostles wisely, and with that condescension to the weakness and prejudices of those with whom they conversed, which so eminently distinguished the character of the Author of our holy religion, and must always be a prominent feature in the character of the true Christian, adopted the vulgar language in speaking of those unfortunate persons who were groundlessly imagined to be possessed with dæmons, though they well knew the notions which had given rise to such modes of expression to be ill-founded, then to imagine that diseases, which arise at present from natural causes, were produced in days of old by the intervention of dæmons, or that evil spirits still continue to enter into mankind in all cases of madness, melancholy or epilepsy.

Besides, it is by no means a sufficient reason for receiving any doctrine as true, that it has been generally received through the world. Error, like an epidemical disease, is communicated from one to another. In certain circumstances, too, the influence of imagination predominates, and restrains the exertions of reason. Many false opinions have extended their influence through a very wide circle, and maintained it long. On every such occasion as the present, therefore, it becomes us to enquire, not so much how generally any opinion has been received, or how long it has prevailed, as from what causes it has originated, and on what evidence it rests.

When we contemplate the frame of nature, we behold a grand and beautiful simplicity prevailing thro' the whole: Notwithstanding its immense extent, and though it contains such numberless diversities of being; yet the simplest machine constructed by human art does not display easier simplicity, or an happier connection of parts. We may therefore venture to draw an inference, by analogy, from what is observable of the order of nature in general to the present case. To permit evil spirits to intermeddle with the concerns of human life, would be to break through that order which the Deity appears to have established through his

11
Inference from the analogy of nature.

Dæmoniæcs works; it would be to introduce a degree of confusion unworthy of the wisdom of Divine Providence.

¶ Daille.

Such are the most rational arguments that have been urged on both sides in this controversy. Perhaps the dæmonianists have the stronger probabilities on their side; but we will not presume to take upon ourselves the office of arbitrators in the dispute.

DÆMONIACS, in church-history, a branch of the Anabaptists; whose distinguishing tenet is, that the devils shall be saved at the end of the world.

DAFFODIL. See **NARCISSUS**.

DAGNO, a town of Turkey in Europe, in Albania, with a bishop's see. It is the capital of the district of Ducagini, and is seated on the rivers Drino and Nero, near their confluence. It is 15 miles south-east of Scutari, and 15 north-east of Alessio. E. Long. 19. 48. N. Lat. 42. 0.

DAGO, or **DAGNO**, an island in the Baltic Sea, on the coast of Livonia, between the gulf of Finland and Riga. It is of a triangular figure, and may be about 20 miles in circumference. It has nothing considerable but two castles, called *Dagger-wort* and *Paden*. E. Long. 22 30. N. Lat. 58. 48.

* See 1 Sam. Chap. V.

DAGON, the false god of Ashdod*, or, as the Greeks call it, *Azotus*. He is commonly represented as a monster, half man and half fish; whence most learned men derive his name from the Hebrew *dag*, which signifies "a fish." Those who make him to have been the inventor of *bread-corn*, derive his name from the Hebrew *Dagan*, which signifies *frumentum*; whence Philo Biblius calls him *Zeus Αραρπειος*, *Jupiter Aratrius*.

This deity continued to have a temple at Ashdod during all the ages of idolatry to the time of Maccabees: for the author of the first book of Maccabees tells us, that "Jonathan, one of the Maccabees, having beaten the army of Apollonius, Demetrius's general, they fled to Azotus, and entered into Bethdagon (the temple of their idol); but that Jonathan set fire to Azotus, and burnt the temple of Dagon and all those who were fled into it."

Dagon, according to some, was the same with Jupiter, according to others Saturn, according to others Venus, and according to most Neptune.

DAHGESTAN, a country of Asia, bounded by Circassia on the north, by the Caspian Sea on the east, by Chirvein a province of Persia on the south, and by Georgia on the west. Its chief towns are Tarku and Derbent, both situated on the Caspian Sea.

DAHOME, a kingdom of Africa, on the coast of Guinea, to the north of Whidah, or Fida. The king of this country conquered Whidah, and very much disturbed the slave-trade of the Europeans.

DAILLE (John), a Protestant minister near Paris, was one of the most learned divines of the 17th century, and was the most esteemed by the Catholics of all the controversial writers among the Protestants. He was tutor to two of the grandsons of the illustrious Mr Du Plessis Mornai. Mr Daille having lived 14 years with so excellent a master, travelled into Italy with his two pupils: one of them died abroad; with the other he saw Italy, Switzerland, Germany, Flanders, Holland, and England, and returned in 1621. He was received minister in 1623, and first exercised his office in the family of Mr Du Plessis Mornai; but

this did not last long, for that lord died soon after. The memoirs of this great man employed Mr Daille the following year. In 1625 he was appointed minister of the church of Samur, and in 1626 removed to Paris. He spent all the rest of his life in the service of this last church, and composed several works. His first piece was his masterpiece, and an excellent work, *Of the Use of the Fathers*, printed 1631. It is a strong chain of reasoning, which forms a moral demonstration, against those who would have religious disputes decided by the authority of the fathers. He died in 1670, aged 77.

DAIRI, or **DAIRO**, in the history of Japan, is the sovereign pontiff of the Japanese; or, according to Kæmper, the hereditary ecclesiastical monarch of Japan. In effect, the empire of Japan is at present under two sovereigns, *viz.* an ecclesiastical one called the *dairo*, and a secular one who bears the title of *kubo*. The last is the emperor, and the former the oracle of the religion of the country.

DAIRY, in rural affairs, a place appropriated for the management of milk, and the making of butter, cheese, &c. See **BUTTER**, **CHEESE**, &c.

The dairy-house should always be kept in the neatest order, and so situated as that the windows or lattices never front the south, south-east, or south-west. Lattices are also to be preferred to windows, as they admit a more free circulation of the air than glazed lights possibly can do. It has been objected, that they admit cold air in winter and the sun in summer; but the remedy is easily obtained, by making a frame the size of or somewhat larger than the lattice, and constructing it so as to slide backward and forward at pleasure. Packthread strained across this frame, and oiled cap paper pasted thereon, will admit the light, and keep out the sun and wind.

It is hardly possible in the summer to keep a dairy-house too cool; on which account none should be situated far from a good spring or current of water. They should be neatly paved either with red brick or smooth hard stone; and laid with a proper descent, so that no water may lodge. This pavement should be well washed in the summer every day, and all the utensils belonging to the dairy should be kept perfectly clean. Nor should we ever suffer the churns to be scalded in the dairy, as the steam that arises from hot water will injure the milk. Nor should cheese be kept therein, nor rennet for making cheese, nor a cheese-press be fixed in a dairy, as the whey and curd will diffuse their acidity throughout the room.

The proper receptacles for milk are earthen pans, or wooden vats or trundles; but none of these should be lined with lead, as that mineral certainly contains a poisonous quality, and may in some degree affect the milk: but if people are so obstinate as to persist in using them, they should never forget to scald them, scrub them well with salt and water, and to dry them thoroughly, before they deposit the milk therein. Indeed all the utensils should be cleaned in like manner before they are used; and if after this they in the least degree smell sour, they must undergo a second scrubbing before they are fit for use.

DAKIR, in English statutes, is used for the twentieth part of a last of hides. According to the statute of

Dairi
||
Dakir.

Dais 51 Hen. III. *De compositione ponderum & mensurarum*, a last of hides consists of twenty dakirs, and every dakir of ten hides. But by 1 Jac. cap. 33. one last of hides or skins is twelve dozen. See DICKER.

DAIS, in botany: A genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 31st order, *Veprecula*. The involucre is tetraphyllous; the corolla quadrifid or quinquefid; the fruit a monospermous berry.

DAISY. See BELLIS.

DALACA, an island of the Red Sea, over-against the coast of Abex, about 72 miles in length and 15 in breadth. It is very fertile, populous, and remarkable for a pearl fishery. The inhabitants are negroes, and great enemies to the Mahometans. There is a town of the same name seated over-against Abassia.

DALBERGIA, in botany; a genus of the octandria order, belonging to the diadelphia class of plants. There are two filaments or stamina quadrifid at top. The fruit is pedicellated, not gaping, leguminous, membrano-compressed, and bearing seeds.

DALEA, a province of Sweden, bounded on the north by Dalecarlia, on the east by the Wermeland and the lake of Wener, on the south by Gothland, and on the north by Norway and the sea.

DALEBURG, a town of Sweden, and capital of the province of Dalia, seated on the western bank of the lake Wener, 50 miles north of Gottenburg. E. Long. 13. 0. N. 59. 0.

DALECARLIA, a province of Sweden, so called from a river of the same name, on which it lies, near Norway. It is divided into three parts, which they call *valleys*; and is about 175 miles in length and 100 in breadth. It is full of mountains, which abound in mines of copper and iron, some of which are of a prodigious depth. The towns are very small, and Idra is the capital. The inhabitants are rough, robust, and warlike; and all the great revolutions in Sweden had their rise in this province. The river rises in the Dofrine mountains; and, running south-east thro' the province, falls into the gulph of Bothnia.

DALECHAMP (James), a physician in Normandy, in the 16th century, wrote a History of Plants, and was well skilled in polite learning. He wrote notes on Pliny's Natural History, and translated Athenæus into Latin. He practised physic at Lyons from 1552 to 1558, when he died, aged 75.

DALECHAMPIA, in botany: A genus of the adelphia order, belonging to the monœcia class of plants; and in the natural method ranking under the 38th order, *Tricocœa*. The involucre of the male is common and quadripartite; the calyces hexaphyllous; corolla none; the nectarium laminated or scaly; the stamina monodelphous or coalited at the base, and polyandrous or numerous. The female involucre is common and triphyllous; corolla none; style one; the capsule tricocous.—There is but one species, *viz.* the scandens, a native of Jamaica. It is a climbing plant, which rises to a considerable height; and is remarkable for nothing but having its leaves armed with bristly hairs, which sting the hands of those who unwarily touch them.

DALEM, a town of the United Provinces, and capital of a district of the same name. It was taken by

the French in 1672, who demolished the fortifications. It is seated on the river Bervine, five miles north-east of Liege. E. Long. 5. 59. N. Lat. 50. 40.

D'ALEMBERT. See ALEMBERT.

DALLEN (Cornelius Van), an eminent engraver, who flourished about the year 1640. He was a native of Holland; but under what master he learned the art of engraving, is uncertain. It is difficult to form a proper judgment of his merit; for sometimes his prints resemble those of Cornelius Vischer, of Lucas Vosterman, of P. Pontius, of Bolswert, and other masters. A set of antique statues, engraved by him, are in a bold, free style, as if founded upon that of Goltzius; others, again, seem imitations of that of Francis Poilly. In all these different manners he has succeeded; and they plainly manifest the great command he had with his graver, for he worked with that instrument only. He engraved a great variety of portraits, some of which are very valuable, and form the best as well as the larger part of his works.

DALKEITH, a town of Scotland, in Mid-Lothian, six miles south-east of Edinburgh; W. Long. 2. 20. N. Lat. 55. 50. It is the principal residence of the Duke of Buccleugh, who has here a noble house and extensive parks. In this house, which at the time was the head-quarters of General Monk, the restoration of Charles II. was planned.—The Duke's eldest son has the title of Earl of Dalkeith. Here is a considerable market weekly on Thursdays, which supplies in part both Edinburgh and Glasgow.

DALMATIA, a province of Europe, bounded on the north by Bosnia, on the south by the gulph of Venice, on the east by Servia, and on the west by Morlachia. Spalatro is the capital of that part belonging to the Venetians; and Ragusa, of a republic of that name; the Turks have a third, whose capital is Herzegovina. The air is wholesome, and the soil fruitful; and it abounds in wine, corn, and oil.

DALTON, a town of Lancashire, in England. It is seated on the spring-head of a river, in a champaign country, not far from the sea; and the ancient castle is made use of to keep the records, and prisoners for debt in the liberty of Furnes. W. Long. 3. 0. N. Lat. 54. 18.

DALTON (John), D.D. an eminent divine and poet, was the son of the Rev. Mr John Dalton rector of Dean near Whitehaven in Cumberland, where he was born in 1709. He was educated at Queen's College, Oxford; and became tutor or governor to the Lord Beauchamp, only son of the Earl of Hertford, late Duke of Somerset; during which time he adapted Milton's admirable *Mask of Comus* to the stage, by a judicious insertion of several songs and different passages selected from other of Milton's works, as well as of several songs and other elegant additions of his own, suited to the characters and to the manner of the original author. During the run of this piece he industriously sought out a grand-daughter of Milton's, oppressed both by age and poverty; and procured her a benefit from it, the profits of which amounted to a very considerable sum. He was promoted by the king to a prebend of Worcester; where he died on the 22d of July 1763. Besides the above, he wrote a descriptive poem, addressed to two ladies at their return from view-

Dam ing the coal-mines near Whitehaven; and Remarks on
 12 historical designs of Raphael, and the *Museum Gra-*
 Damascus. *cum & Egyptiacum.*

DAM, a boundary or confinement, as to *dam* up or
dam out. *Infra damnum suum*, within the bounds or
 limits of his own property or jurisdiction.

DAMA, in zoology. See CERVUS.

DAMAGE, in law, is generally understood of a hurt
 or hindrance attending a person's estate: but, in com-
 mon law, it is part of what the jurors are to inquire
 of in giving verdict for the plaintiff or defendant in a
 civil action, whether real or personal; for after giving
 verdict on the principal cause, they are likewise asked
 their consciences touching costs and damages, which
 contain the hindrances that one party hath suffered
 from the wrong done him by the other. See COSTS.

DAMAN, a maritime town of the East Indies, at
 the entrance into the gulph of Cambay. It is divided
 by the river Daman into two parts; one of which is
 called *New Daman*, and is a handsome town, well
 fortified, and defended by a good Portuguese garrison.
 The other is called *Old Daman*, and is very ill built.
 There is a harbour between the two towns, defended
 by a fort. It was taken by the Portuguese in 1535.
 The Mogul has attempted to get possession of it several
 times, but always without effect. E. Long. 72. 35.
 N. Lat. 21. 5.

DAMASCENUS (John), an illustrious father of
 the church in the 8th century, born at Damascus,
 where his father, though a Christian, enjoyed the office
 of counsellor of state to the Saracen caliph; to which
 the son succeeded. He retired afterwards to the mo-
 nastery of St Sabas, and spent the remainder of his life
 in writing books of divinity. His works have been often
 printed: but the Paris edition in 1712, 2 vols folio, is
 esteemed the best.

DAMASCIUS, a celebrated heathen philosopher,
 born at Damascus in the year 540, when the Goths
 reigned in Italy. He wrote the life of his master Isi-
 dorus; and dedicated it to Theodora, a very learned
 and philosophical lady, who had also been a pupil to
 Isidorus. In this life, which was copiously written, he
 frequently made oblique attacks on the Christian reli-
 gion. We have nothing remaining of it but some ex-
 tracts preserved by Photius. Damascius succeeded
 Theon in the rhetorical school, and Isidorus in that of
 philosophy, at Athens.

DAMASCUS, a very ancient city of Syria in A-
 sia, seated in E. Long. 47. 18. N. Lat. 35. 0. Some
 of the ancients suppose this city to have been built by
 one Damascus, from whom it took its name; but the
 most generally received opinion is, that it was found-
 ed by Uz the eldest son of Aram. It is certain, from
Gen. xiv. 5. that it was in being in Abraham's time,
 and consequently may be looked upon as one of the
 most ancient cities in the world. In the time of king
 David it seems to have been a very considerable place;
 as the sacred historian tells us, that the Syrians of Da-
 mascus sent 20,000 men to the relief of Hadadezer
 king of Zobah. We are not informed whether at that
 time it was governed by kings, or was a republic. Af-
 terwards, however, it became a monarchy which pro-
 ved very troublesome to the kingdom of Israel, and
 would even have destroyed it entirely, had not the Deity
 miraculously interposed in its behalf. At last this

monarchy was destroyed by Tiglath Pileser king of
 Assyria, and Damascus was never afterwards governed
 by its own kings. From the Assyrians and Babylonians
 it passed to the Persians, and from them to the Greeks
 under Alexander the Great. After his death he belong-
 ed, with the rest of Syria, to the Seleucidæ; till their
 empire was subdued by the Romans about 70 years be-
 fore Christ. From them it was taken by the Saracens
 in 633; and it is now in the hands of the Turks.—
 Notwithstanding the tyranny of the Turkish govern-
 ment, Damascus is still a considerable place. It is si-
 tuated in a plain of so great extent, that one can but
 just discern the mountains which compass it on the
 other side. It stands on the west side of the plain,
 about two miles from the head of the river Barrady,
 which waters it. It is of a long, strait figure, extend-
 ing about two miles in length, adorned with mosques
 and steeples, and encompassed with gardens computed
 to be full 30 miles round. The river Barrady, as soon
 as it issues from the clefts of the Antilibanus into the
 plain, is divided into three streams, whereof the mid-
 dlemost and biggest runs directly to Damascus, and is
 distributed to all the cisterns and fountains of the city.
 The other two seemed to be artificial; and are drawn
 round, one to the right, and the other to the left, on
 the borders of the gardens, into which they are let by
 little currents, and dispersed every where. The houses
 of the city, whose streets are very narrow, are all built
 on the outside either with sun-burnt brick, or Flemish
 wall: and yet it is no uncommon thing to see the
 gates and doors adorned with marble portals, carved,
 and inlaid with great beauty and variety; and within
 these portals to find large square courts beautified with
 fragrant trees and marble fountains, and compassed
 round with splendid apartments. In these apartments
 the ceilings are usually richly painted and gilded; and
 their duans, which are a sort of low stages seated in the
 pleasantest part of the room, and elevated about 16 or
 18 inches above the floor, whereon the Turks eat, sleep,
 say their prayers, &c. are floored, and adorned on the
 sides with variety of marble mixed in mosaic knots and
 mazes, spread with carpets, and furnished all round
 with bolsters and cushions, to the very height of luxu-
 ry. In this city are shown the church of John the Bap-
 tist, now converted into a famous mosque; the house
 of Ananias, which is only a small grotto or cellar
 wherein is nothing remarkable; and the house of Ju-
 das with whom Paul lodged. In this last is an old
 tomb, supposed to be that of Ananias; which the
 Turks hold in such veneration, that they keep a lamp
 continually burning over it. There is a castle belong-
 ing to Damascus, which is like a little town, having
 its own streets and houses; and in this castle a maga-
 zine of the famous Damascus steel was formerly kept.
 The fruit-tree called the *damascene*, and the flower
 called the *damask rose*, were transplanted from the gar-
 dens belonging to this city; and the silks and linens
 known by the name of *damasks*, were probably invented
 by the inhabitants.

DAMASCUS-steel. See DAMASK.

DAMASIA (anc. geog.), a town of Vindelicia on
 the Licus. Afterwards called *Augusta*. Now *Augs-*
burg in Suabia, on the Lech. E. Long. 10. 50.
 N. Lat. 48. 20.

DAMASK, a sort of silken stuff, having some parts
 raised.

Damascus
 Damasia.

Damask raised above the ground, representing flowers or other figures. **Damask** should be of dressed silks, both in warp and woof. It has its name from its being originally brought from Damascus in Syria.

Damietta.

There is also a stuff in France called the *caffart damask*, made in imitation of the true damask, having woof of hair, coarse silk, thread, wool, or cotton. Some have the warp of silk and the woof of thread; others are all thread or all wool.

DAMASK is also a kind of wrought linen, made in Flanders, so called, because its large flowers resemble those of damasks. It is chiefly used for tables; a table-cloth and a dozen of napkins are called a *damask-service*.

DAMASK is also applied to a very fine steel, in some parts of the Levant, chiefly at Damascus in Syria; whence its name. It is used for sword and cutlass blades, and is finely tempered.

DAMASKEENING, or **DAMASKING**, the art or operation of beautifying iron, steel, &c. by making incisions therein, and filling them up with gold or silver wire; chiefly used for adorning sword-blades, guards, and gripes, locks of pistols, &c.

Damasking partakes of the mosaic, of engraving, and of carving: like the mosaic, it has inlaid work; like engraving, it cuts the metal, representing divers figures; and, as in chasing, gold and silver is wrought in relievo. There are two ways of damasking; the one, which is the finest, is when the metal is cut deep with proper instruments, and inlaid with gold and silver wire: the other is superficial only.

DAMELOPRE, a kind of bilander, used in Holland for conveying merchandise from one canal to another; being very commodious for passing under the bridges.

DAMIANISTS, in church-history, a branch of the ancient acephali-severitæ. They agreed with the catholics in admitting the VIth council, but disowned any distinction of persons in the Godhead; and professed one single nature, incapable of any difference: yet they called God "the Father, Son, and Holy Ghost."

DAMIETTA, a port-town of Egypt, situated on the eastern mouth of the river Nile, four miles from the sea, and 100 miles north of Grand Cairo. E. Long. 32. and N. Lat. 31. The present town stands upon a different site from the ancient Damietta so repeatedly attacked by the European princes. The latter, according to Abulfeda, was a "town surrounded by walls, and situated at the mouth of the eastern branch of the Nile." Stephen of Byzantium inform us, that it was called *Thamiatis* under the government of the Greeks of the lower empire, but that it was then very inconsiderable. It increased in importance every day, in proportion as Pelusium, which was frequently plundered, lost its power. The total ruin of that ancient town occasioned the commerce of the eastern parts of the Delta to be transferred to Damietta. It was, however, no longer a place of strength, when, towards the year 238 of the Hegira, the emperors of Constantinople took possession of it a second time. The importance of a harbour so favourably situated opened the eyes of the caliphs. In the year 244 of the Hegira, Elmetouakkel surrounded it with strong

walls. This obstacle did not prevent Roger king of Sicily from taking it from the Mahometans in the year 550 of the Hegira. He did not, however, long enjoy his conquest. Salah Eddin, who about that period mounted the throne of Egypt, expelled the Europeans from Damietta. Fifteen years after they returned to besiege it; but this able sultan baffled all their efforts. Notwithstanding their land army was supported by a fleet of 1200 sail, they were obliged to make a disgraceful retreat.

It was the fate of this place to be constantly besieged. In the year 615 of the Hegira, under the reign of Eladel, the crusaders attacked it with a very considerable force. They landed on the western shore of the Nile; and their first care was to surround their camp with a ditch and pallisado. The mouth of the river was defended by two towers, furnished with numerous garrisons. An enormous iron chain, stretching from one side to the other, hindered the approach of vessels. The crusaders carried by storm the tower on the same side with their camp, broke the chain, and opened the entrance of the river for their fleet. Nejm Eddin, the sultan's son, who was encamped near Damietta, covered it with an army. To stop the enemies vessels he threw a bridge over the Nile. The Franks overturned it, and the prince adopted the measure of choking up the mouth of the river, which he almost rendered impassable by several large boats he sunk there. After alternate and various successes, many bloody battles, and a siege of 17 months, the Christian princes took Damietta by storm. They did not, however, long enjoy the fruit of so much blood split, and of an armament which had cost immense sums. Completely invested near the canal of Achmoun, by the waters of the Nile and by the Egyptian army, they purchased their lives and their liberty by the sacrifice of their conquest.

One-and-thirty years after this defeat St Louis carried Damietta without striking a stroke. The Arabs, however, soon recovered it; but tired of keeping a place which continually drew upon them the most warlike nations of Europe, they totally destroyed it, and rebuilt it further up in the country. This modern Damietta, first called *Menchié*, as Abulfeda tells us, has preserved the memory of its origin in a square still called by that name. Writers in general have confounded these two towns, ascribing to the one the attributes of the other. The modern Damietta is rounded in a semicircle on the eastern bank of the Nile, two leagues and a half from the mouth of it. The eye, placed at one of the extremities of the crescent, takes in its whole extent. It is reckoned to contain 80,000 souls. It has several squares, the most considerable of which has retained the name of *Menchié*. The bazars are filled with merchants. Spacious *okals*, or *khans*, collecting under their porticos the stuffs of India, the silks of mount Lebanon, sal ammoniac, and pyramids of rice, proclaim that it is a commercial town. The houses, those in particular which are on the banks of the river, are very lofty. They have in general handsome saloons built on the top of their terraces, which are cheerful belvideres, open to every wind, where the Turk, effeminately reclining on a sofa, passes his life in smoking,

Damietta. king, in looking on the sea, which bounds the horizon on one side, on the great lake that extends itself on the other, and on the Nile, which running between them, traverses a rich country. Several large mosques, adorned with lofty minarets, are dispersed over the town. The public baths, lined with marble, are distributed in the same manner as those of Grand Cairo. The linen you are served with is clean, and the water very pure. The heat and the treatment in them, so far from injuring the health, serve to strengthen, nay even to improve it, if used with moderation. This custom, founded on experience, is general in Egypt.

The port of Damietta is continually filled with a multitude of boats and small vessels. Those called *Scherms* serve to convey the merchandize on board the ships in the road, and to unload them; the others carry on the coasting trade. This town carries on a great trade with Syria, with Cyprus, and Marseilles. The rice called *Mizelaoui*, of the finest quality there is in Egypt, is cultivated in the neighbouring plains. The exports of it amount annually to about six millions of livres. The other articles of the produce of the country are linens, sal-ammoniac, corn, &c. A ruinous policy for the country prohibits the exportation of this last article; but the law is evaded, and it passes under the name of rice.

The Christians of Aleppo and Damascus, settled in this town, have for several ages carried on its principal commerce. Turkish indolence, content with extorting from them from time to time, suffers them to become rich. The exportation of rice to foreign countries is prohibited; but by means of some *douceurs* to the customhouse officers, the people of Provence load annually several ships with it. The *Bogaz* preventing them from entering the Nile, their cargoes are conveyed on board by the boats of the country. This inconvenience is the source of endless vexation and abuses. The boat, which is loaded in the evening with rice of the first quality, is frequently not that which arrives at the ship; an inferior quality is substituted for it during the night. The Marseilles captains, aware of these rogueries, without being able to prevent them, endeavour to play off trick against trick, so that this commerce has become a general scene of knavery. But the badness of the port is still more detrimental to Damietta. The road where the vessels lie being exposed to every wind, the slightest gale obliges the captains to cut their cables and take shelter at Cyprus, or to stand off to sea. It would be easy, by cutting a canal only of half a league, to open a passage for ships into the Nile, where there is deep water. This work, which might be executed at very little expence, would render Damietta a noble harbour; but despotism, insensible to the interest of the people, is always surrounded by destruction in its progress, and wants both the will and the power to create.

The tongue of land on which Damietta is situated, straitened on one side by the river, and on the other by the western extremity of lake *Menzalé*, is only from two to six miles wide from east to west. It is intersected by innumerable rivulets in every direction, which render it the most fertile spot in Egypt. The soil there produces, *communibus annis*, 80 bushels of rice for

one. The other produce is in the same proportion. It is there that nature, lavishing profusely her pomp and riches, presents flowers, fruits, and harvests, at every season of the year. Winter never deprives it of these advantages; its beauties are never impaired by summer. Destructive heats, as well as chilling colds, are equally unknown in that happy spot. The thermometer varies only from 9 to 24 degrees above the freezing point. Damietta is indebted for this charming temperature to the immense quantity of water with which it is surrounded. The verdure is no where so fresh; the trees are no where covered with such quantities of fruit. The rivulets around the fields of rice are lined with several kinds of reeds, some of which rise to a great height. The reed *calamus* is here found in abundance, which is made use of for writing by the orientals. Its slender stalk bears long narrow leaves, which hang gracefully, and spreading branches covered with white flowers. Here also are to be seen forests of papyrus, of which the ancient Egyptians made their paper. Strabo, who calls it *Biblus*, gives an accurate description of it. It is here also that the *Lotus*, of which the Arabs have preserved the primitive name of *Nuphar*, exalts its lofty stalk above the waters. Its large calyx blows either of an azure blue or of a brilliant white, and it appears with the majesty of the king of the aquatic plants. The marshes and the canals in the interior parts of country are filled with this superb flower, which diffuses a most agreeable odour.

There are a great many villages around Damietta, in most of which are manufactures where the most beautiful linens of the country are fabricated. The finest napkins in particular are made there, fringed with silk. You are served at table with them, but especially on ceremonial visits, when the slave presents you with one to wipe your mouth with, after you have drank your sherbet, or eat the sweetmeats, which are carried round on a silver plate to all the company. These small towns, generally surrounded with little woods, or trees promiscuously planted, form a whimsical and picturesque assemblage. By the side of the sycamore and the melancholy tamarind, one sees the elegant cassia tree, with its clusters of yellow flowers, like those of the cytissus. The top of the date-tree, loaded with enormous bunches, rises above the grove. The cassia, with its sweet-scented flower, grows under its shade. The orange and lemon trees cover the labourer's cabin with their golden fruit. The banana-tree with its long leaves, the pomegranate with its scarlet flower, and the fig-tree with its sugary fruit, throw a vast variety into these landscapes.

DAMNII, anciently a people of Britain: situated between the Selgovæ to the south and the Caledonii to the north. Now *Clydesdale*.

DAMNONII. See DANMONII.

DAMOCLES, one of the flatterers of Dionysius the Elder of Sicily. He admired the tyrant's wealth, and pronounced him the happiest man on earth. Dionysius prevailed upon him to undertake for a while the charge of royalty, and he was convinced of the happiness which a sovereign enjoyed. Damocles ascended the throne, and while he gazed upon the wealth and splendor that surrounded him, he perceived a sword hanging

Damietta,
Damocles.

Damon | ing over his head by a horse hair. This so terrified
Damps. | him that all his imaginary felicity vanished at once, and
 he begged Dionysius to remove him from a situation
 which exposed his life to such fears and dangers.

DAMON, the name of several illustrious ancients; particularly of a Pythagorean philosopher very intimate with Pythias. When he had been condemned to death by Dionysius, he obtained from the tyrant leave to go and settle his domestic affairs, on promise of returning at a stated hour to the place of execution. Pythias pledged himself to undergo the punishment which was to be inflicted on Damon, should he not return in time, and he consequently delivered himself into the hands of the tyrant. Damon returned at the appointed moment, and Dionysius was so struck with the fidelity of those two friends, that he remitted the punishment, and intreated them to permit him to share their friendship and enjoy their confidence.

DAMPIER (William), a famous navigator, descended from a good family in Somersetshire in England, was born in 1652. Losing his father when very young, he was sent to the sea, where he soon distinguished himself, particularly in the South Sea. His voyage round the world is well known, and has gone through many editions. He appears afterward to have engaged in an expedition concerted by the merchants of Bristol to the South Sea, commanded by Captain Woods Rogers; who sailed in August 1708, and returned in September 1711: but we have no further particulars of his life or death.

DAMPS, in natural history (from the Saxon word *damp*, signifying vapour or exhalation), are certain noxious exhalations issuing from some parts of the earth, and which prove almost instantly fatal to those who breathe them.

These damps are chiefly observed in mines and coal-pits: though vapours of the same kind often issue from old lavas of burning mountains; and, in those countries where volcanoes are common, will frequently enter houses, and kill people suddenly without the least warning of their approach. In mines and coal-pits they are chiefly of two kinds, called by the miners and colliers the *choke* and *fire-damps*; and both go under one general name of *foul airs*. The *choke-damp* is very much of the nature of fixed air; and usually infests those places which have been formerly worked, but long neglected, and are known to the miners by the name of *wastes*. No place, however, can be reckoned safe from this kind of damps, except where there is a due circulation of air; and the procuring of this is the only proper means of preventing accidents from damps of all kinds. The *choke-damp* suffocates the miners suddenly, with all the appearances found in those that are suffocated by fixed air. Being heavy, it descends towards the lowest parts of the workings, and thus is dangerous to the miners, who can scarce avoid breathing it. The *fire-damp*, which seems chiefly to be composed of inflammable air, rises to the roof of the workings, as being specifically lighter than the common atmosphere; and hence, though it will suffocate as well as the other, it seldom proves so dangerous in this way as by its inflammable property, by which it often takes fire at the candles, and explodes with extreme violence.

In the Phil. Trans. n° 119. there is an account of

some explosions by damps of this kind, on which we have the following observations. 1. Those who are in the place where the vapour is fired, suddenly find themselves surrounded with flames, but hear little or no noise; though those who are in places adjacent, or above ground, hear a very great one. 2. Those who are surrounded by the inflamed vapour feel themselves scorched or burnt, but are not moved out of their places, though such as unhappily stand in the way of it are commonly killed by the violence of the shock, and often thrown with great force out at the mouth of the pit; nor are the heaviest machines found able to resist the impetuosity of the blast. 3. No smell is perceived before the fire, but a very strong one of brimstone is afterwards felt. 4. The vapour lies towards the roof, and is not perceived if the candles are held low; but when these are held higher, the damp descends like a black mist, and catches hold of the flame, lengthening it to two or three handfuls; and this appearance ceases when the candles are held nearer the ground. 5. The flame continues in the vault for several minutes after the crack. 6. Its colour is blue, something inclining to green, and very bright. 7. On the explosion of the vapour, a dark smoke like that proceeding from fired gunpowder is perceived. 8. Damps are generally observed to come about the latter end of May, and to continue during the heat of summer. They return several times during the summer season, but observe no certain rule.

Besides these kinds of damps, which are very common, we find others described in the Philosophical Transactions, concerning the nature of which we can say nothing. Indeed the account seems somewhat suspicious. They are given by Mr Jessop, from whom we have the foregoing observations concerning the fire-damp, and who had these from the miners in Derbyshire. After describing the common damp, which consists of fixed air, "They call the second sort (says he) the *pease-bloom damp*, because, as they say, it smells like pease-bloom. They tell me it always comes in the summer-time; and those grooves are not free which are never troubled with any other sort of damps. I never heard that it was mortal; the scent, perhaps, freeing them from the danger of a surprisè: but by reason of it many good grooves lie idle at the best and most profitable time of the year, when the subterraneous waters are the lowest. They fancy it proceeds from the multitude of red-trefoil flowers, by them called *honeysuckles*, with which the limestone meadows in the Peake do much abound. The third is the strongest and most pestilential of any; if all be true which is said concerning it. Those who pretend to have seen it (for it is visible) describe it thus: In the highest part of the roof of those passages which branch out from the main groove, they often see a round thing hanging, about the bigness of a foot-ball, covered with a skin of the thickness and colour of a cob-web. This, they say, if it is broke by any accident, as the splinter of a stone, or the like, disperseth itself immediately, and suffocates all the company. Therefore, to prevent casualties, as soon as they have espied it, they have a way, by the help of a stick and long rope, of breaking it at a distance; which done, they purify the place well with fire, before they dare enter it again. I dare not avouch

Damps.

Damps. vouch the truth of this story in all its circumstances, because the proof of it seems impossible, since they say it kills all that are likely to bear witness to the particulars: neither dare I deny but such a thing may have been seen hanging on the roof, since I have heard many affirm it."—Some damps, seemingly of the same nature with those last mentioned, are noticed by the author of the Chemical Dictionary, under the word *Damps*. "Amongst the noxious mineral exhalations (says he), we may place those which are found in the mines of Sal-gem in Poland. These frequently appear in form of light flocks, threads, and spiders webs. They are remarkable for their property of suddenly catching fire at the lamps of the miners with a terrible noise and explosion. They instantly kill those whom they touch. Similar vapours are found in some mines of fossil coal."

With regard to the formation of damps we have as yet no certain theory; nor, though the experiments of aerologists are abundantly able to show the composition and manner of forming these noxious airs artificially, have they yet thrown much light on the method by which nature prepares them on a large scale. There are two general ways in which we may suppose this to be done; one by the stagnation of atmospheric air in old waste places of mines and coal-pits, and its conversion into these mephitic exhalations; the other by their original formation from the phlogistic or other materials found in the earth, without any interference of the atmosphere. In favour of the former opinion it may be urged, that old wastes are never free from damps, especially those of the kind resembling fixed air; nor are they always deficient in the inflammable kind. The same is also true of old wells, or even cellars, and in short in every place where the air stagnates for any considerable time. But, on the other hand, we have many instances of fixed air coming out of the earth, and that in vast quantities, where no considerable stagnation of the atmosphere could be suspected; as for instance, in the grotto del Cani in Italy, where a continual stream of it has issued from time immemorial. The same seems to be the case with the tops of some high mountains, particularly Mount Blanc, the highest in Europe; on the top of which M. Saussure found the atmosphere so much impregnated with fixed air, that lime-water exposed to it very quickly gathered a crust on its surface. Sir William Hamilton, in his account of the eruptions of Vesuvius, informs us, that the inhabitants in the neighbourhood of that mountain are infested with a kind of pestilential vapours named by them *mosfetes*, which issue from the old lavas thrown out by the volcano. These are of the nature of the damps in the mines or coal-pits, and issue forth in such quantity as either to infect the atmosphere for a very considerable way round, or to do mischief by being carried from place to place by the atmospheric currents, which are not strong enough to dissipate them for some time. From some late accounts, the *samiel* (or scorching winds, as they have been represented) in the eastern countries, seem to be no other than streams of fixed air of considerable extent, which exert their usual and fatal effects on those who breathe them. A strong argument in favour of this opinion is, that these winds

cannot cross a river, it being the nature of water to absorb fixed air, and thus destroy them.

Hence it is rendered probable that these mephitic vapours are often to be met with in the open atmosphere, and consequently cannot always be the effect of stagnation; nor indeed does it at all appear that mere stagnation can affect the quality of the atmosphere either one way or other. This fluid cannot have its properties altered but by something immersed in it upon which it can act, and by means of which action its component parts may be changed or separated. While this process is going on, there is generally, if not always, an *absorption* of air, accompanied indeed frequently with an emission of some aerial fluid equal in quantity to that which is absorbed. Mr Scheele, in his Essay on Fire, has shown by a number of experiments the effect of exposing certain substances to the action of air, both on the substances themselves and on the aerial fluid. The result of all these is no other than what we might expect from a very slow combustion, and which perhaps may on inquiry be found to be the only way by which air can be decomposed. If the substance exposed to the air was capable of absorbing that part of the fluid which had undergone a change, there was always an evident diminution, but not otherwise. Thus, on inclosing some caustic fixed alkali in a phial of atmospheric air, a considerable diminution took place; and the alkali, by becoming saturated with fixed air, showed that a decomposition had taken place, and that the dephlogisticated part of the air had separated from the other, attached itself to the fixed alkali, and become fixed air by uniting with a certain proportion of phlogistic matter. Hence we may conceive, that in any place where the air was confined over a vast quantity of caustic alkaline salt, it would soon become unfit for the purposes of animal life, and we might say that a *damp* would be formed. But this would be a damp of a very different kind from that usually met with in mines; for here the dephlogisticated part of the atmosphere being converted into fixed air, and absorbed by the salt, only the poisonous mephitic, or as it is commonly called *phlogisticated*, air would remain, so that no fixed air could ever be separated from it.

Let us now suppose, that instead of the alkaline salt a quantity of burning charcoal is confined in a place where there is not a proper circulation of air, and we will soon see that a damp of the very same kind with that called by miners the *choke-damp* will be formed. But this, according to the late discoveries, takes place by reason of the dissipation of the charcoal by heat, and its union with the dephlogisticated part of the atmosphere, which always constitutes fixed air.* In this case, however, the damp must be but of short continuance, and will soon be dissipated after the charcoal is extinguished; but if, instead of the charcoal, we substitute a large quantity of fermenting liquor, from whence the fixed air is naturally emitted, a damp will be formed much more difficult to be dissipated than the former, because it renews itself in a very short time; and, unless there is a very constant circulation of air, it will be dangerous to enter the place where it is.

From the last example we may form an idea of the manner

Damps.

* See Aerology and Fixed Air.

Damps. manner in which these damps, consisting chiefly of fixed air, are formed. We know not indeed thoroughly the nature of fermentation; but we are assured, that it is always accompanied by an internal heat; which, in some cases, is raised to the utmost height, insomuch that large quantities of moist vegetable substances, packed together, will sometimes burst out into flame. It is not, however, at all times necessary for the extrication of fixed air, that the heat should come to this extremity. The example of fermenting liquors shows, that in some cases a very moderate heat is sufficient for the purpose. Now, though the comparison may seem somewhat inadequate between the solid substance of the earth and a fermenting liquid, yet we know that a gentle heat constantly takes place in the bowels of the earth; and that almost all terrestrial substances will emit fixed air on being exposed to heat. It is not at all improbable, therefore, that, on the large scale of nature, the quantity of materials may compensate for the weakness of the heat, and thus occasion a constant emission of fixed air; which, though slow in comparison of what is effected in our experiments by a violent artificial heat, may yet accumulate in the narrow spaces of mines in such a manner as to be very troublesome. In volcanic countries, where the heat of the earth is much greater, the emission of fixed air is in proportion; and thus we may account for that continual stream of it, which issues from the grotto del Cani, and perhaps other places. The *mosfets*, which are said to proceed from old lavas, can only be accounted for by supposing the heat, which originally took place in them, to be, in some measure renewed; or that they have been again, by some means or other, disposed to take fire as formerly: but this we offer merely as a conjecture; there not being as yet sufficient data to determine any thing positively upon the subject.

It may be objected to the hypothesis just now laid down, that, if there is a continual disposition in the earth to produce fixed air, the whole surface of it must pour out such a quantity as would destroy every living creature upon it. This indeed might be granted, were the surface of the earth quite bare, and destitute of vegetation: but we know that fixed air is composed of the dephlogisticated kind and phlogiston; and that these two ingredients, after being once joined, may be separated from each other, and reassume their proper characters. There is no absurdity, therefore, in supposing that the fixed air may be continually decomposed by the vegetables which grow all over the surface of the earth; and the atmosphere not only thus preserved from any taint from it, but supplied with a quantity of pure dephlogisticated air, which it is certain that vegetables do emit. It is also certain, that wherever the atmosphere is suffered to be in contact with the bare surface of the ground for some time, a considerable quantity of fixed air will be produced, unless there is a constant circulation of atmospherical air to carry off the former before it has time to produce any sensible effect. Hence we may account for the damps in wells, cellars, and even in the confined places of old castles and ruinous buildings, where the air is not in contact with the surface of the ground itself, but with mere heaps of rubbish and old walls.

Vol. V.

Damps. With regard to what is called the *fire-damp*, the case seems to be more plain. In the Phil. Trans. n^o 136, we have the following account of one of this kind which seemed evidently to issue from the earth. "This work is upon a coal of five yards in thickness, and hath been begun upon about six or eight and thirty-years ago. When it was first found, it was extremely full of water, so that it could not be wrought down to the bottom of the coal; but a *witchet*, or cave, was driven out of the middle of it, upon a level, for gaining room to work, and drawing down the spring of water that lies in the coal to the eye of the pit. In driving of which witchet, after they had gone a considerable way under ground, and were scared of wind, the fire-damps did begin by little and little to breed, and to appear in crevices and flits of the coal, where water had lain before the opening of the coal, with a small bluish flame, working and moving continually; but not out of its first seat, unless the workmen held their candles to it; and then being weak, the blaze of the candle would drive it with a sudden fizz away to another crevice, where it would soon after appear blazing and moving as formerly. This was the first knowledge of it in this work, which the workmen made but a sport of; and so partly neglected, till it had gotten some strength; and then upon a morning, the first collier that went down, going forwards in the witchet with his candle in his hand, the damp presently darted out so violently at his candle, that it struck the man clear down, singed all his hair and cloths, and disabled him from working for a while after. Some other small warnings it gave them, insomuch that they resolved to employ a man on purpose that was more resolute than the rest, to go down a while before them every morning, to chase it from place to place, and so to weaken it. His usual manner was to put on the worst rags he had, and to wet them all in water, and when he came within the danger of it, then he fell down groveling upon his belly, and so went forward, holding in one hand a long wand or pole, at the head whereof he tied candles burning, and reached them by degrees towards it; then the damp would fly at them, and if it missed of putting them out, would quench itself with a blast, and leave an ill-scented smoke behind. Thus they dealt with it till they had wrought the coal down to the bottom, and the water following, and not remaining as before in the body of it, among sulphureous and brassy metal that is in some veins of the coal, the fire-damp was not seen nor heard of till the latter end of the year 1675, which happened as followeth.

"After long working of this coal, it was found upon the rising grounds that there lay another roach of coal at the depth of 14 yards under it, which proved to be 3 $\frac{1}{2}$ yards thick, and something more sulphureous. This encouraged us to sink in one of the pits we had formerly used on the five-yards coal.—As we sunk the lower part of it, we had many appearances of the fire-damp in the watery crevices of the rocks we sunk through, flashing and darting from side to side of the pit, and showing rainbow-like colours upon the surface of the water in the bottom; but upon drawing up of the water with buckets, which stirred the air in the pit, it would leave burning, till the colliers at work, with their breath and sweat, and the smoke of their candles, thickened

Damps. thickened the air in the pit, and then it would appear again; they lighted their candles at it sometimes when they went out; and so in this pit it did no further harm."

In another pit, however, it soon appeared, and at last produced a most terrible explosion. This was occasioned by one of the workmen going imprudently down with a lighted candle, after a cessation of work for some days, and the force exerted by it seemed equal to that of gun-powder.

The formation of inflammable air in mines cannot be attributed to any vitiation of the atmosphere; for there is no natural process with which we are acquainted, by which such a change could be accomplished. In one instance, however, we have an example of a fire-damp being produced, not only without any considerable stagnation of atmospherical air, but where there is the best circulation imaginable. This is in large bellows used in metallurgic works, which are sometimes burst by an explosion of inflammable matter proceeding from the rancid matters with which the leather is greased. Dr Priestley has shown, that inflammable air is composed of pure elementary fire, charcoal or phlogiston, and a little water; and that this composition may take place even *in vacuo*. All these materials are to be met with in the bowels of the earth. Coal, a bituminous substance, is abundantly able to supply the phlogiston; the natural moisture of the earth affords water, and the heat, however gentle, which constantly exists in the bowels of the earth, may be sufficient to produce a quantity of inflammable air, which gradually accumulating in those places where there is not a constant stream of atmospherical air to carry it off, will soon produce the dreadful effects already mentioned.

A much more important consideration than the formation of damps, however, is the proper method of avoiding their pernicious effects. The inflammability of one kind affords an easy method of preventing it from accumulating, viz. by setting fire to it. This may be done with safety, unless it has been suffered to go too far before the experiment is made: for the inflammable air, being much lighter than any other kind, will naturally rise to the top; so that a man, lying flat on the ground to avoid the force of the explosion, and holding up a lighted candle fixed upon a pole, may at once free the mine from such a troublesome guest. But where it has been allowed to accumulate in too great quantity, so that this method cannot be used, or in the other kind, which is not inflammable, the method commonly practised is to produce a constant circulation of air as much as possible through all parts of the mine. To procure this, they make a perpendicular opening which they call a *shank* or *shaft*, so that the mine may have two or more openings; and thus by reason of the difference of temperature between the open atmosphere and that in the mine, there is a continual draught of air through them both. This current will always be stronger in proportion to the difference between the external atmosphere and that of the mine: and likewise in proportion to the difference between the depth of the two shafts. But as the temperature of the atmosphere is variable, it happens, at certain seasons of the year, that there is not a sufficient difference between that

of the atmosphere and in the mine to produce the necessary circulation. This happens principally in the spring and autumn; at which seasons it is necessary to light fires in the shafts, which are always efficacious for the purpose desired.

Among the other uses to which dephlogisticated air might be applied, Mr Cavallo reckons that of securing people from the dangerous effects of damps in mines, and other subterraneous places. "If a large bladder," says he, "into which a solution of lime in water is introduced, be filled with dephlogisticated air, and a small wooden or glass pipe be adapted to its neck, a man may hold that pipe in his mouth, and may breathe the dephlogisticated air; and thus equipped he may enter into these subterranean places, amidst the various elastic fluids contained in them. A large bladder of dephlogisticated air will serve for above a quarter of an hour, which is a length of time sufficient for various purposes; besides, if longer time is required to be spent in these places, a person may have two or more bladders of dephlogisticated air along with him, and may shift as soon as the air of one is contaminated. Without the necessity of any more complicated apparatus, the bladders full of dephlogisticated air may be kept stopped by putting corks into the glass or wooden pipes that are tied to their necks. This air might also be used for diving-bells."

DAMSEL, from the French *damoisel* or *damoiseau*, an appellation anciently given to all young people of either sex, that were of noble or genteel extraction, as the sons and daughters of princes, knights, and barons: thus we read of Damsel Pepin, Damsel Louis le Gros, Damsel Richard prince of Wales.

From the sons of kings this appellation first passed to those of great lords and barons, and at length to these of gentlemen who were not yet knights.

At present damsel is applied to all maids or girls not yet married, provided they be not of the vulgar.

DAN, or JOR-DAN, which last literally denotes "the river Dan;" so named from the people where it has its source, which is a lake called *Phiala*, from its round figure, to the north of its apparent rising from the mountain Panium or Paneum, as was discovered by Philip, Tetrarch of Trachonites; for on throwing light bodies into the Phiala, he found them to emerge again at Paneum (Josephus). From Paneum it runs in a direct course to a lake called *Samachonites*; as far as which it is called *Jordan the Less*; and thence to the lake Genesareth, or of Tiberias, where it comes increased by the lake Samachonitis and its springs, and is called the *Greater Jordan*; continuing its direct course southwards, till it falls into the Asphaltites.

DAN (anc. geog.), a town to the west of the source of the Jordan; formerly called *Lais* (Joshua, Judges, Josephus). This was the north, as Beerseba was the south, boundary of the Israelites; as appears from the common expression in Scripture, from *Dan* to *Beerseba*. At Dan Jeroboam erected one of the golden calves (1 Kings xii.).

DAN, the tribe, extended itself westward of Judah, and was terminated by Azotus and Dora on the Mediterranean (Josephus).

DANAE, in antiquity, a coin somewhat more than an obolus, used to be put into the mouths of the dead, to pay their passage over the river Acheron.

Damsel
||
Danae.

DANAE,

Danae
|
Danaus.

DANAË, in fabulous history, was the daughter of Acrisius king of Argos, by Eurydice. She was confined in a brazen tower by her father, who had been told by an oracle that his daughter's son would put him to death. His endeavours to prevent Danae from becoming a mother proved fruitless; and Jupiter, who was enamoured of her, introduced himself to her bed by changing himself into a golden shower. From his embraces Danae had a son, with whom she was exposed on the sea by her father. The wind drove the bark which carried her to the coasts of the island of Seriphus; where she was saved by some fishermen, and carried to Polydeutes king of the place, whose brother, called *Dietyis*, educated the child called *Perseus*, and tenderly treated the mother. Polydeutes fell in love with her; but as he was afraid of her son, he sent him to conquer the Gorgons, pretending that he wished Medusa's head to adorn the nuptials which he was going to celebrate with Hippodamia the daughter of Genomaus. When Perseus had victoriously finished his expedition, he retired to Argos with Danae to the house of Acrisius, whom he inadvertently killed. Some suppose that it was Proetus the brother of Acrisius who introduced himself to Danae in the brazen tower; and instead of a golden shower, it was maintained that the keepers of Danae were bribed by the gold of her seducer. Virgil mentions that Danae came to Italy with some fugitives of Argos, and that she founded a city called *Ardea*.

DANAIDES (fab. hist.), the fifty daughters of Danaus king of Argos. When their uncle Ægyptus came from Egypt with his fifty sons, they were promised in marriage to their cousins; and before the celebration of their nuptials, Danaus, who had been informed by an oracle that he was to be killed by the hands of one of his sons-in-law, made his daughters solemnly promise that they would destroy their husbands. They were provided with daggers by their father; and all except Hypermnestra stained their hands with the blood of their consins the first night of their nuptials; and as a pledge of their obedience to their father's injunctions, they presented him each with the head of the murdered sons of Ægyptus. Hypermnestra was summoned to appear before her father, and answer for her disobedience in suffering her husband Lynceus to escape; but the unanimous voice of the people declared her innocent, and she dedicated a temple to the goddess of Persuasion. The sisters were purified of this murder by Mercury and Minerva by order of Jupiter; but according to the more received opinion, they were condemned to severe punishment in hell, and were compelled to fill with water a vessel full of holes, so that the water ran out as soon as poured into it; and therefore their labour was infinite, and their punishment eternal. The heads of the sons of Egyptus were buried at Argos; but their bodies were left at Lerna, where the murder had been committed.

DANAUS (fab. hist.), a son of Belus and Anchinoe, who after his father's death reigned conjointly with his brother Ægyptus on the throne of Egypt. Some time after, a difference arose between the brothers, and Danaus set sail with his fifty daughters in quest of a settlement. He visited Rhodes, where he consecrated a statue to Minerva, and arrived safe on the coast of Gelanor, where he was hospitably received by Gela-

nor king of Argos. Gelanor had lately ascended the throne, and the first years of his reign were marked with dissensions with his subjects. Danaus took advantage of Gelanor's unpopularity, and obliged him to leave the crown. In Gelanor, the race of the Inachidæ was extinguished, and the Belides began to reign at Argos in Danaus. Some authors say, that Gelanor voluntarily resigned the crown to Danaus, on account of the wrath of Neptune, who had dried up all the waters of Argolis, to punish the impiety of Inachus. The success of Danaus invited the fifty sons of Ægyptus to embark for Greece. They were kindly received by their uncle; who either apprehensive of their number, or terrified by an oracle, which threatened his ruin by one of his sons-in-law, caused his daughters, to whom they were promised in marriage, to murder them the first night of their nuptials. His orders were executed. Hypermnestra alone spared the life of Lynceus: (See DANAIDES). Danaus at first persecuted Lynceus with unremitted fury; but he was afterwards reconciled to him, and he acknowledged him for his son-in-law and successor after a reign of 50 years. He began his reign about 1586 years before the Christian era; and after death he was honoured with a splendid monument in the town of Argos, which still existed in the age of Pausanias. According to Æschylus, Danaus left Egypt, not to be present at the marriage of his daughters with the sons of his brother, a connection which the deems unlawful and impious.

DANCE, or DANCING, as at present practised, may be defined, "an agreeable motion of the body, adjusted by art to the measures or tune of instruments, or of the voice."—But, according to what some reckon more agreeable to the true genius of the art, dancing is "the art of expressing the sentiments of the mind, or the passions, by measured steps or bounds that are made in cadence by regulated motions of the body, and by graceful gestures; all performed to the sound of musical instruments or of the voice."

There is no account of the origin of the practice of dancing among mankind. It is found to exist among all nations whatever, even the most rude and barbarous; and, indeed, however much the assistance of art may be necessary to make any one perfect in the practice, the foundation must certainly lie in the mechanism of the human body itself.

The connection that there is between certain sounds and those motions of the human body called *dancing*, hath seldom or never been inquired into by philosophers, though it is certainly a very curious speculation. The power of certain sounds not only over the human species, but even over the inanimate creation, is indeed very surprising. It is well known, that the most solid walls, nay the ground itself, will be found to shake at some particular notes in music. This strongly indicates the presence of some universally diffused and exceedingly elastic fluid, which is thrown into vibrations by the concussions of the atmosphere upon it, produced by the motion of the sounding body.—If these concussions are so strong as to make the large quantity of elastic fluid vibrate that is dispersed through a stone wall or a considerable portion of earth, it is no wonder they should have the same effect upon that invisible and exceedingly subtle matter that pervades and seems to reside in our nerves.

Dance.

Dance.

Some there are that have their nerves constructed in such a manner, that they cannot be affected by the sounds which affect others, and some scarce with any, while others have such an irritability of the nerves in this case, that they cannot, without the greatest difficulty, sit or stand still when they hear a favourite piece of music played.

It is conjectured by very eminent philosophers, that all the sensations and passions to which we are subject do immediately depend upon the vibrations excited in the nervous fluid abovementioned. Hence, musical sounds have the greatest power over those people who are of a delicate sensible frame, and who have strong passions. If it be true, therefore, that every passion in the human nature immediately depends upon a certain affection of the nervous system, or a certain motion or vibration in the nervous fluid, we shall immediately see the origin of the different dances among different nations. One kind of vibration, for instance, raises the passions of anger, pride, &c. which are indispensably necessary in warlike nations. The sounds, for such there are, capable of exciting a similar vibration, would naturally constitute the martial music among such nations, and dances conformable to it would be instituted. This appears to be the case particularly among barbarous nations, as we shall presently have occasion to remark. Other vibrations of the nervous fluid produce the passions of joy, love, &c.; and sounds capable of exciting these particular vibrations will immediately be formed into music for dances of another kind.

As barbarous people are observed to have the strongest passions, so they are also observed to be the most easily affected by sounds and the most addicted to dancing. Sounds to us the most disagreeable, the drumming with sticks upon an empty cask, or the noise made by blowing into reeds incapable of yielding one musical note tolerable to us, is agreeable music to them. Much more are they affected by the sound of instruments which have any thing agreeable in them. Mr Gallini informs us, that "The spirit of dancing prevails almost beyond imagination among both men and women in most parts of Africa. It is even more than instinct, it is a rage, in some countries in that part of the globe.—Upon the gold coast especially, the inhabitants are so passionately fond of it, that in the midst of their hardest labour, if they hear a person sing, or any musical instrument played, they cannot refrain from dancing.—There are even well attested stories of some negroes flinging themselves at the feet of an European playing on a fiddle, intreating him to desist, unless he had a mind to tire them to death; it being impossible for them to cease dancing while he continued playing."—The same thing is found to take place in America, though, as the inhabitants of that continent are found to be of a more fierce and barbarous nature than the African nations, their dances are still more uncouth and barbarous than those of the negroes. In Mexico, says Gallini, they have also their dances and music, but in the most uncouth and barbarous style. For their symphony they have wooden drums, something in form of a kettle-drum, with a kind of pipe or flagelet, made of a hollow cane or reed, but very grating to an European ear. It is observed they love every thing that makes a noise, how disagreeable soever the

found is. They will also hum over something like a tune when they dance 30 or 40 in a circle, stretching out their hands, and laying them on each others shoulders. They stamp and jump, and use the most antic gestures for several hours, till they are heartily weary. And one or two of the company sometimes step out of the ring to make sport for the rest, by showing feats of activity, throwing their lances up into the air, catching them again, bending backwards, and springing forwards with great agility."

The origin of dancing among the Greeks was most certainly the same as among all other nations; but as they proceeded a certain length in civilization, their dances were of consequence more regular and agreeable than those of the more barbarous nations. They reduced dancing into a kind of regular system; and had dances proper for exciting, by means of the sympathy abovementioned, any passion whatever in the minds of the beholders. In this way they are said to have proceeded very great lengths, to us absolutely incredible. At Athens, it is said, that the dance of the Eumenides or Furies on the theatre had so expressive a character as to strike the spectators with irresistible terror: men grown old in the profession of arms trembled; the multitude ran out; women with child miscarried; people imagined they saw in earnest those terrible deities commissioned with the vengeance of heaven to pursue and punish crimes upon earth.

The Greeks had martial dances, which they reckoned to be very useful for keeping up the warlike spirit of their youth; but the Romans, though equally warlike with the Greeks, never had any thing of the kind.—This probably may be owing to the want of that romantic turn for which the Greeks were so remarkable. The Romans had no heroes among them, such as Hercules, Achilles, or Ajax; nor does the whole Roman history furnish an example of a general that made war after the manner of Alexander the Great. Though their soldiers were as valiant as ever the Greeks could pretend to be, the object with them was the honour of the republic, and not their own personal praise. Hence there was less fury, and much more cool deliberate valour, exercised by the Romans, than any other nation whatever. The passions of pride, resentment, obstinacy, &c. were excited in them, not by the mechanical means of music and dancing, but by being taught that it was their chief honour to fight for the republic.—It does not however appear, that the Romans were at all less capable of being affected in this mechanical manner than the Greeks. When dancing, was once introduced, it had the very same effects at Rome as at Athens.

Among the Jews, dancing seems to have made a part of the religious worship on some occasions, as we learn from some passages in the Psalms, though we do not find either that or singing positively enjoined as a divine precept.—In the Christian churches mentioned in the New Testament, there is no account of dancing being introduced as an act of worship, though it is certain that it was used as such in after ages. Mr Gallini tells us, that "at Limoges, not long ago, the people used to dance the round in the choir of the church which is under the invocation of their patron saint; and at the end of each psalm, instead of the *Gloria Patri*, they sung as follows: *St Marcel, pray for us, and we will dance in honour of you.*"—Though dan-

Dance.

Dance. dancing would now be looked upon as the highest degree of profanation in a religious assembly, yet it is certain, that dancing, considered as an expression of joy, is no more a profanation than singing, or than simple speaking; nor can it be thought in the least more absurd, that a Christian should dance for joy that Jesus Christ is risen from the dead, than that David danced before the ark when it was returned to him after a long absence.

Plato reduces the dances of the ancients to three classes. 1. The military dances, which tended to make the body robust, active, and well-disposed for all the exercises of war. 2. The domestic dances, which had for their object an agreeable and innocent relaxation and amusement. 3. The mediatorial dances, which were in use in expiations and sacrifices.—Of military dances there were two sorts: the *gymnopedique* dance, or the dance of children; and the *enoptian*, or armed dance. The Spartans had invented the first for an early excitation of the courage of their children, and to lead them on insensibly to the exercise of the armed dance. This childrens dance used to be executed in the public place. It was composed of two choirs: the one of grown men, the other of children; whence, being chiefly designed for the latter, it took its name. They were both of them in a state of nudity. The choir of the children regulated their motions by those of the men, and all danced at the same time, singing the poems of Thales, Aleman, and Dionysodorus.—The *enoptian* or *pyrrhic* was danced by young men armed cap-a-pee, who executed, to the sound of the flute, all the proper movements either for attack or for defence. It was composed of four parts.—The first, the *polysis* or footing; which consisted in a quick shifting motion of the feet, such as was necessary for overtaking a flying enemy, or for getting away from him when an overmatch.—The second part was the *xiphisis*; this was a kind of mock-fight, in which the dancers imitated all the motions of combatants; aiming a stroke, darting a javelin, or dexterously dodging, parrying, or avoiding a blow or thrust. The third part, called the *komos*, consisted in very high leaps or vaultings, which the dancers frequently repeated, for the better using themselves occasionally to leap over a ditch, or spring over a wall. The *tetrakomos* was the fourth and last part: this was a square figure, executed by slow and majestic movements; but it is uncertain whether this was every where executed in the same manner.

Of all the Greeks, the Spartans were those who most cultivated the Pyrrhic dance. Athenæus relates, that they had a law by which they were obliged to exercise their children at it from the age of five years. This warlike people constantly retained the custom of accompanying their dances with hymns and songs. The following was sung for the dance called *trichoria*, said to be instituted by Lycurgus, and which had its name from its being composed of three choirs, one of children, another of young men, and the third of old. The old men opened the dance, saying, “In time past we were valiant.” The young men answered, “We are so at present.” “We shall be still more so when our time comes,” replied the chorus of children. The Spartans never danced but with real arms. In process of time, however, other nations came to use only wea-

pons of wood on such occasions. Nay, it was only so late as the days of Athenæus, who lived in the second century, that the dancers of the Pyrrhic, instead of arms, carried only staves, ivy-bound wands (*thyrsus*) or reeds. But, even in Aristotle’s days, they had begun to use thyrsuses instead of pikes, and lighted torches in lieu of javelins and swords. With these torches they executed a dance called the *conflagration of the world*.

Of the dances for amusement and recreation, some were but simply gambols, or sportive exercises, which had no character of imitation, and of which the greater part exist to this day. The others were more complex, more agreeable, figured, and were always accompanied with singing. Among the first or simple ones was the *ascoliasmus*; which consisted in jumping, with one foot only, on bladders filled with air or with wine, and rubbed on the outside with oil. The *dypollum* was jumped with both feet close. The *kyballos* was what is called in England the *johnny*.—Of the second kind was that called the *whirl-wind*, of which there is a description in Longinus, and the Ionian dances: these last, in the original of their institution, had nothing but what was decent and modest; but, in time, their movements came to be so depraved, as to be employed in expressing nothing but voluptuousness, and even the grossest obscenity.

Among the ancients there were no festivals nor religious assemblies but what were accompanied with songs and dances. It was not held possible to celebrate any mystery, or to be initiated, without the intervention of these two arts. In short, they were looked upon to be so essential in these kinds of ceremonies, that to express the crime of such as were guilty of revealing the sacred mysteries, they employed the word *khoisra*, “to be out of the dance.” The most ancient of these religious dances is the *Bacchic*; which was not only consecrated to Bacchus, but to all the deities whose festival was celebrated with a kind of enthusiasm. The most grave and majestic was the *hyperbœmatic*: it was executed to the lyre, and accompanied with the voice.—At his return from Crete, Theseus instituted a dance at which he himself assisted at the head of a numerous and splendid band of youth round the altar of Apollo. The dance was composed of three parts; the *strophe*, the *antistrophe*, and the *stationary*. In the *strophe*, the movements were from the right to the left; in the *antistrophe*, from the left to the right. In the *stationary*, they danced before the altar; so that the *stationary* did not mean an absolute pause or rest, but only a more slow or grave movement. Plutarch is persuaded, that in this dance there is a profound mystery. He thinks, that by the *strophe*, is indicated the motion of the world from east to west; by the *antistrophe*, the motion of the planets from the west to the east; and by the *stationary*, the stability of the earth. To this dance Theseus gave the name of *geranos*, or “the crane;” because the figures which characterised it bore a resemblance to those described by cranes in their flight.

With regard to the modern practice of dancing as an art, there are few directions that can be of much service. The following is extracted from Mr Gallini’s description of the several steps or movements.

“The dancing (says he) is generally on a theatre, or in a saloon or room. At the theatre there are four parts to be considered. 1. The nearest front to the spectators.

Dance. spectators. 2. and 3. The two sides or wings. 4. The furthest front from the spectators.

“ In a saloon or room, the place in which are the spectators decides the appellation respectively to them of right and left. The dancer should place himself in as advantageous a point of view to them as possible.

“ In the dance itself, there are to be distinguished, the attitude of the body, the figure, the positions, the bends, the risings or leaps, the steps, the cabriole, the fallings, the slides, the turns of the body, the cadences.

“ The *attitude* of the body requires the representing one's self in the most graceful manner to the company.

“ The *figure* is to follow the track prescribed to the steps in the dance.

“ The *position* is that of the varied attitudes, which must be at once striking and easy, as also of the different exertions of the legs and feet in dancing.

“ The *bends* are inflexions of the knees, of the body, of the head, or the arms.

“ The *risings* are the contrast to the bends, the extension of the knee. One of these two motions necessarily precedes the other.

“ The *step* is the motion by the foot or feet from one place to another.

“ The *leap* is executed by springing up into the air; it begins with a bend, and proceeds with a quick extension of the legs, so that both feet quit the ground.

“ The *cabriole* is the crossing, or cutting of capers, during the leap, before the return of the feet to the ground.

“ The *falling* is the return of the feet to the ground, by the natural gravitation of the body.

“ The *slide* is the action of moving the foot along the ground without quitting it.

“ The *turn* is the motion of the body towards either side, or quite round.

“ The *cadence* is the knowledge of the different measures, and of the times of movement the most marked in the music.

“ The *track* is the line marked by the dance: it may be either straight or curve, and is susceptible of all the inflexions correspondent to the various designs of the composer.—There are the right, the diametral line, the circular line, and the oblique line. The *right* line is that which goes lengthwise, reckoning from one end of the room towards the other. The *diametral* line is across the room, from one side to the other. The *circular* line is waving, or undulatory, from one place to another. The *oblique* line proceeds obliquely from one quarter of the room towards another.—Each of these lines may directly or separately form the dancer's track, diversified with steps and positions.

“ The *regular* figure is when two or more dancers move in contrary directions; that is to say, that when one moves towards the right, the other moves to the left.—The *irregular* line is when the couples figuring together are both on the same side.

“ Commonly the man gives the right hand to the lady in the beginning or ending of the dance, as we see in the *minuet*, *lowre*, &c.

“ When a greater number of dancers figure together, they are to execute the figure agreeably to the composition of the dance, with special attention to keep an eye constantly on the partner.—When, in any given dance, the dancers have danced for some time in the

same place, the *track* is only to be considered as the conductor of the *steps*, but not of the *figure*; but when the dance continues, without being confined to the same place, then the *track* must be considered as the conductor both of the steps and of the figure.

“ Now, to observe the figure, the dancer must have placed himself at the beginning of the track upon which he is to dance, and comprehend the figure before he himself begins it. He is to remark and conceive whether the figure is right, diametral, circular, or oblique; if it is progressive or retrogressive, or towards the right or left. He should have the air played or sung to him, to understand the movement.—Where the tracks cross one another, the steps of each of the couples must leave a sufficient distance between them not to confuse the figure.

“ There are commonly reckoned ten kinds of positions, which are divided into *true* and *false*, five each.—There are three principal parts of the foot to be observed; the toes, the heel, and the ankle.

“ The *true* positions are when the two feet are in a certain uniform regularity, the toes turned equally outwards.—The *false* are divided into regular and irregular. They differ from the true, in that the toes are either both turned inwards; or if the toes of one foot are turned outwards, the others are turned inward.

“ In the first of the true positions, the heels of the two feet are close together, so that they touch; the toes being turned out. In the second, the two feet are open in the same line, so that the distance between the two heels is precisely the length of one foot. In the third, the heel of one foot is brought to the ankle of the other, or seems to lock in with it. In the fourth, the two feet are the one before the other a foot's length, distance between the two heels, which are on the same line. In the fifth, the two feet are across, the one before the other; so that the heel of one foot is directly opposite to the toes of the other.

“ In the first of the false positions, the toes of both feet are turned inwards, so that they touch, the heels being open. The second is, when the feet are asunder at a foot's distance between the toes of each, which are turned inward, the heels being on a line. The third is, when the toes of one foot are turned outwards, the other inwards, so that the two feet form a parallel. The fourth is, when the toes of the two feet are turned inwards: but the toes of one foot are brought nearer the ankle of the other. The fifth is, when the toes of the two feet are turned inwards, but the heel of one foot is opposite to the toes of the other.

“ There are mixed positions, composed of the true and false in combination; which admit of such an infinite variety, and are in their nature so unsusceptible of description by words, that it is only the sight of the performance that can give any tolerable idea of them.

“ Of the bends of the knee there are two kinds; the one *simple*, the other *forced*. The simple bend is an inflexion of the knees without moving the heel, and is executed with the foot flat to the ground. The forced bend is made on the toes with more force and lower.

“ Much is to be observed on the head of *steps*. First, not to make any movement before having put the body in an upright posture, firm on the haunches.

“ Begin with the inflexion of the knee and thigh; advance one leg foremost; with the whole foot on the ground,

Danc. ground, laying the stress of the body on the advanced leg.

“ There are some who begin the step by the point of the toes; but that has an air of theatrical affectation. Nothing can be more noble than a graceful ease and dignity of step. The quantity of steps used in dancing are almost innumerable; they are nevertheless reducible under five denominations, which may serve well enough to give a general idea of the different movements that may be made by the leg, viz. the direct step, the open step, the circular step, the twisted step, and the cut step.

“ The *direct* step is when the foot goes upon a right line, either forwards or backwards.

“ The *open* step is when the legs open. Of this step there are three kinds: one when they open outwards; another, when, describing a kind of circle, they form an in-knee'd figure; a third, when they open sideways; this is a sort of right step, because the figure is in a right line.

“ The *round* step, is when the foot, in its motion, makes a circular figure, either inwards or outwards.

“ The *twisted* step, or *pas tortille*, is when the foot in its motion turns in and out. There are three kinds of this step: one forwards, another backwards, the third sidelong.

“ The *cut* step is when one leg or foot comes to strike against the other. There are also three sorts of this step; backwards, forwards, and sidelong.

“ The steps may be accompanied with bendings, risings, leaps, cabrioles, fallings, slidings, the foot in the air, the tip-toe, the rest on the heel, quarter-turns, half-turns, three-quarter turns, and whole-turns.

“ There may be practised three kinds of bends, or sinkings, in the steps; viz. bending before the step proceeds, in the act of stepping, and at the last of the steps.

“ The beginning or initial sink-pace is at the first setting off, on advancing the leg.

“ The bend in the act of stepping continues the march or walk.

“ The final sink-pace closes the march.

“ The rising is just the reverse of the bend, or sink-pace, which shall have preceded it.

“ Some great masters in the art of dancing, having observed that music, which is inseparable from it, was capable of being preserved and conveyed by the musical characters, imagined by analogy, that the like advantage could be procured to the composition of dances. Upon this plan they attempted what is called the *chorography*, an art which they suppose was either utterly unknown to the ancients, or not transmitted to us from them.

“ It may indeed be easily allowed, that the track or figure of a dance may be determined by written or engraved lines; but those lines will necessarily appear so perplexing, so intricate, so difficult, if not impossible to seize, in their various relations, that they are only fit to disgust and discourage, without the possibility of their conveying a satisfactory or retainable instruction. —Thence it is, that the article of *Chorography* in the French *Encyclopédie* is universally exploded as unintelligible and useless: though nothing more than an ele-

mentary indication of the art; and an explanation, such as it is, of some of the technical terms of it.”

Stage-DANCES. The Greeks were the first who united the dance to their tragedies and comedies; not indeed as making part of those spectacles, but merely as an accessory.

The Romans, as usual, copied after the Greeks; but in the reign of Augustus they left their instructors far behind them. Two very extraordinary men made their appearance at that time: they invented a new species of entertainment, and carried it to an astonishing degree of perfection. Nothing was then talked of but the wonderful talents and amazing performances of Pylades and Bathylus, who were the first to introduce among the Romans what the French call the *ballet d'action*, wherein the performer is both actor and dancer.

Pylades undertook the hard task of representing, with the assistance of the dance alone, strong and pathetic situations. He succeeded perhaps beyond his own expectation, and may be called the father of that style of dancing which is known to us by the name of *grave* or *serious pantomime*.

Bathylus an Alexandrian, and a freedman of Mecenas, took upon himself to represent such subjects as required a certain liveliness and agility. He was handsome in his person; and the two great scourges of Roman follies, Persius and especially Juvenal, speak of him as the gallant of every woman in Rome. The latter, in his cynic style, even goes so far as to say, that when Bathylus performed the dance called, after the name of a celebrated female dancer, *Chiremenos-Leda*, the gravest matron was turned off her guard, and the young virgin longed for the dancer's addresses.

Nature had been excessively partial to those two men. They were endowed with genius, and all the exterior charms that could captivate the eye. By their study, application, and a desire to establish a lasting reputation, they displayed to the greatest advantage all the resources which the art of dancing could supply. These, like two phenomena, disappeared, and never did the world see “their like again.” Government withdrew her protection, the art gradually sunk into obscurity, and became even entirely forgotten on the accession of Trajanus to the empire.

Thus buried with the other arts in entire oblivion, dancing remained uncultivated till about the 15th century, when ballets were revived in Italy at a magnificent entertainment given by a nobleman of Lombardy at Tortona on account of the marriage between Galeas Duke of Milan and Isabella of Arragon. Every resource that poetry, music, dancing, and machinery could supply, was employed and exhausted on the occasion. The description given of so superb an entertainment excited the admiration of all Europe, and excited the emulation of several men of genius, who improved the hint to introduce among their countrymen a kind of spectacle equally pleasing and noble.

It would seem, however, that at first the women had no share in the public or theatrical dance; at least we do not see them mentioned in the various entertainments given at the opera in Paris till the 21st of January 1681. when the then Dauphiness, the princess of Conti, and some other ladies of the first distinction in the court of Louis XIV. performed a ballet with the opera.

Dance.

Dance. opera called *Le Triomphe de l'Amour*. This union of the two sexes served to enliven and render the spectacle more pleasing and far more brilliant than it ever was at any other period. It was received with so much applause, that on the 16th of May following, when the same opera was acted in Paris at the theatre of the Palais Royal, it was thought indispensable for the success of that kind of entertainment to introduce female dancers. They have continued ever since to be the principal support of the opera.

The dance is now in such commendation, that, particularly in France, the opera-house seems rather an academy for dancing than calculated for the representation of lyric poems. The disgusting and immoderate length of their recitatives is one of the chief causes of that general taste for dancing which prevails amongst them. A wit being asked one day what could be done to keep up an opera threatened with a most complete damnation? "Do! (says he); why, lengthen the dances and shorten the petticoats." So evident it is, that singing, though apparently the chief purpose of an opera, is by no means the most pleasing part of the entertainment to the spectators.

Thus, what was at first introduced as a mere accessory to the musical performance, became in process of time its only support; and this circumstance excited the emulation of several eminent ballet-masters. The art, however, of composing those grand dances, which are now so much admired, was for many years in a state of infancy, till Monsieur Noverre stepped forth and gave it that degree of perfection which it seems impossible to exceed. This celebrated ballet-master and performer, in a work lately published, has with great elegance and ingenuity delineated the nature, objects, and powers of dancing, enumerated the proper requisites to give it effect, and shown how much it may be ennobled by an acquaintance with the kindred arts.

Ballets, he observes, have hitherto been the faint sketch only of what they may be one day. An art entirely subservient, as this is, to taste and genius, may receive daily variation and improvements. History, painting, mythology, poetry, all join to raise it from that obscurity in which it lies buried; and it is truly surprising, that composers have hitherto disdained so many valuable resources.

According to our author, the reason why this art has remained so long in its infancy, is because its effects have been restrained to the transitory ones of fire-works calculated only to please the eye; and it never was supposed to have powers sufficient to speak to the heart: whereas it may vie, he says, with the best dramatic pieces, prove equally interesting, and captivate the spectator by the charms of the most complete illusion.

If ballets, therefore, says he, "are for the most part uninteresting and uniformly dull; if they fail in the characteristic expression which constitutes their essence, the defect does not originate from the art itself, but should be ascribed to the artists. Are then the latter to be told, that dancing is an imitative art? I am indeed inclined to think that they know it not, since we daily see the generality of composers sacrifice the beauties of the dance, and give up the graceful *naïveté* of sentiment, to become the servile copiers of a certain number of figures, known and hackneyed for

above a century; so that the ballets of Phaeton, or of any ancient opera, revived by a modern composer, would prove so very similar to former ones, that one would think they have undergone no alterations, and are the same in every step.

"Ballet-masters should consult the productions of the most eminent painters. This would bring them nearer to nature, and induce them to avoid, as often as possible, that symmetry of figures, which, by repeating the object, present two different pictures on one and the same canvas.

"Those symmetrical figures from right to left, according to my judgment, are supportable only in the entrées, which are not meant to express any thing in particular, but are only calculated to afford some relief to the principal dancers. They may be introduced in a general dance at the conclusion of an entertainment, they may also be admitted in the *pas* of four, six, &c. though in my opinion it be ridiculous even in this case to prefer the display of bodily strength and agility to expression and sentiment. But such figures must give way to nature in what we term *ballets d'action*. An instance, though perhaps not very forcible, may serve to elucidate and support my argument.

"At the sudden and unexpected appearance of some young fauns, a troop of nymphs take themselves to flight with equal affright and precipitation. The former are in pursuit of the latter with that eagerness which the very hope of pleasure can inspire. Now they stop to observe what impression they have made on the nymphs; these at the same time, and for a similar reason, check their career: with fear they survey their pursuers, endeavour to guess at their intentions, and provide for a retreat to some spot, where they may rest secure from the dangers that threaten them. Both troops now join, the nymphs resist, defend themselves, and at last effect their escape with no less swiftness than dexterity.

"This I call a busy active scene in which the dance, as it were, should speak with energy. Here studied and symmetrical figures cannot be introduced without a manifest violation of the truth, without destroying the rules of probability, and without weakening the action and lessening its effect.—This scene should be conspicuous; for its beautiful disorder, and the art of the composer, must here be the handmaid of nature.

"A ballet-master, devoid of taste and discernment, will make of this a mechanical piece of dancing, and thus deprive it of the effect it was calculated to produce for want of entering into the spirit of it. His nymphs and fauns will be arranged upon a parallel line, he will place the former in attitudes awkwardly uniform, and insist on the latter holding up their arms to an even altitude; rather than deviate from the beaten path, and the antique rules of opera dancing, he will cautiously avoid to have, on the right and left, his nymphs placed in unequal numbers, but will reduce a scene of action, which ought to be supported with spirit, to an exercise equally affected and uninteresting.

"Perhaps some ill-disposed critics, so far strangers to the art as not to judge of it from its various effects, will maintain, that the above scene should present only two different objects, the one portrayed in the love-sick

Dance. sick fauns, the other expressed by the affright of the nymphs. But how many shades may serve to embellish these pictures? how varied may be the strokes of the pencil? how opposite the lights? and what a number of tints ought to be employed in order to draw from this twofold situation a multiplicity of images, each more lively and spirited than the other?

“As all men share the same passions, and these differ in proportion to their sensations and feelings, they may therefore be worked upon more or less powerfully in proportion as they manifest themselves outwardly with more or less force and impetuosity. This principle once acknowledged, and nature indeed enforces it daily, it would certainly be more to the purpose to diversify the attitudes and vary the expression; for then the pantomime action of each personage would be divested of a disgusting uniformity. The truth of imitation and the skill of the painter would conspicuously appear in giving a different aspect to the features, some of them expressive of a kind of ferocity, others betraying less eagerness, these casting a more tender look; and to the rest, the languishing air of voluptuousness. The sketch of this first picture naturally leads to the composition of the second: here some nymphs appear divided between fear and desire; there some others express by the contrast of their attitudes the various emotions of their soul. Some are more scornful than their companions, whilst others betray a curiosity equal to their fears. This ensemble gives life to the whole picture, and is the more pleasing that it is perfectly consistent with nature. From this exposition, you will not hesitate to agree with me, that symmetry, the offspring of art itself, should never find place in the ballets d’action.”

“I shall beg leave to enquire of all those who reason from habitual prejudice, whether they will look for their favourite symmetry in a herd of sheep flying from the wolf, or amongst wretched peasants leaving their huts and fields, in order to shelter themselves from the fury of a party of enemies? By no means. But the art lies in concealing art itself; my aim is by no means to introduce disorder and confusion; on the contrary, I will have regularity even in irregularity. What I most insist upon is, the introducing of well concerted groups, situations forcibly expressed, but never beyond nature, and above all, a certain ease in composition, which betrays not the labour of the composer. As for the figures, they are likely to please only in proportion as they quickly succeed each other, and are devised with equal taste and elegance.”

A ballet perfect in all its parts, our author proceeds to observe, is a picture, drawn from life, of the manners, dresses, ceremonies, and customs of all nations. It must therefore be a complete pantomime, and through the eyes speak, as it were, to the very soul of the spectator. If it wants expression, if it be deficient in point of situation and scenery, it degenerates into a spectacle equally flat and monotone.

According to Plutarch, a ballet is, if the expression may be allowed, a mute conversation, or a speaking and animated picture, whose language consists of motions, figures, and gestures.—These figures, says our author, are unlimited in their number, because there are a thousand things that the ballet may express.

Phrynica, one of the oldest tragedy writers, says, that he could find in our ballet as many figures as the sea rolls waves in a high winter tide.

Dance.

A well composed ballet, therefore, may do without the assistance of words: M. Noverre even remarks, that these only serve to weaken the action, and partly destroy its effects. He has no opinion of a pantomime which, in order to be understood, must borrow the help of a verbal explanation. “Any ballet whatever (says he), destitute of intrigue, action, and interest, displaying nothing more than the mechanical beauties of the art, and, though decorated with a pompous title, unintelligible throughout, is not unlike those portraits and pictures to which the painters of old subscribed the names of the personages and action they meant to represent: because they were imperfect in point of imitation, the situations weakly expressed, the outlines incorrect, and the colours unseemly.”

“When dancers shall feel, and, Proteus like, transform themselves into various shapes to express to the life the conflict of passions; when their features, their very looks, shall speak their inward feelings; when, extending their arms beyond the narrow circle prescribed by the rigid rules of pedantry, and with equal grace and judgment giving them a fuller scope, they shall by proper situations describe the gradual and successive progress of the passions; when, in fine, they call good sense and genius to the assistance of their art, then they may expect to distinguish themselves: explanatory speeches will become useless; a mute but powerful eloquence will be substituted to much better effect; each motion will be a sentence; every attitude will pourtray a situation; each gesture convey a thought, and each glance a new sentiment: every part will please, because the whole will be a true and faithful imitation of nature.”

A ballet, in whatever style it may be, should, according to Aristotle, be composed, as well as poetry, of two different parts, which he calls parts of quality and parts of quantity. Nothing exists in nature without matter, form, and figure; the ballet therefore becomes a mere nonentity, if it be deficient in any of those essential parts, which mark and constitute the being of any one thing animate or inanimate. The matter here is the subject intended for representation; its form consists in the ingenious distribution of the plan; and the various compounding parts constitute its figure. Form therefore contains the parts of quality, and the extent the parts of quantity.

Thus it appears, that ballets are in some degree subject to the rules of poetical composition. They, nevertheless, differ from tragedies and comedies, in that the former are not subject to the three unities of time, place, and action: Yet they require an unity of plot, in order that the various scenes may meet and end on the same point.—The ballet, therefore, may be termed the brother of the drama; though not restrained to its stricter rules: which only serve to cramp the imagination, check its flight, and confine genius; and if adhered to, must set aside all thought of composition of ballets, by depriving them of their chief ornament, pleasing variety.

M. Noverre considers tragedy as the subject most suitable for the art of dancing. The former abounds in noble incidents, situations, &c. and these produce

Dance. the best stage effects. Besides, the passions are more forcibly expressed by great characters than by common men: the imitation is of course less difficult, the action in the pantomime more significant, natural, and intelligible.

“ The business of a skilful master (he observes), is to foresee, as it were, at one glance, the general effect that may result from the ensemble, and never give the preference to one single part over the whole. The only way for him to bestow his thoughts on the greatest number, is to forget for a while the principal characters of the drama; if his whole attention should entirely be taken up with the parts of his first dancers of both sexes, the action is suspended, the scenes are slow in their progress, and the whole performance must fall short of its desired effect.

In the tragedy of *Merope*, by Voltaire, the principal characters are, *Merope*, *Polifonte*, *Egiste*, and *Narbas*: But although the parts of the inferior actors are not of equal importance, yet they all concur to the general action, and to the progression of the drama, which would appear deficient in some parts, should either of those characters be wanting in the representation. No useless personage should be obtruded on the stage. Every thing therefore that may tend to weaken the effect of the drama ought to be carefully avoided, and only that number of actors introduced which is barely requisite for the execution of the performance.

“ A ballet is a production of the same kind. It must be divided into acts and scenes, each of which, as well as the act itself, must have its beginning, its middle, and its end; that is, in other words, exposition, plot, and denouement.

“ I have observed above, that the principal performers in a ballet should be forgotten for a while: My reason is, that, in my opinion, it is easier to give striking parts to *Hercules* and *Omphale*, *Ariadne* and *Bacchus*, *Ajax* and *Ulysses*, &c. than to 24 persons in their retinue: If these have nothing to say, they are superfluous, and of course ought to be rejected; but, if they are to speak, let their conversation be consonant with that of the principal characters.

“ The difficulty, therefore, does not lie in assigning a primary and distinctive part to *Ajax* or *Ulysses*; since it springs naturally from the importance of their situation in the play; but in introducing the figures in a becoming style, giving them parts of more or less importance, connected with the action of the two heroes; in introducing women, some of whom will appear concerned for *Ajax*, and the greater number showing their partiality for *Ulysses*. The triumph of the latter, the former's death, present to the man of genius a series of images that vie with each other in point of interesting and picturesque situations. These, by means of colouring skilfully contrasted, cannot but produce the most lively sensations. In fine, a ballet pantomime should be dramatic in all its parts; and the figure-dancers, who succeed to the principal performers, ought to continue the scene, not by a number of symmetrical figures and studied steps, but by that kind of animated expression which keeps up the attention of the spectators to the main subject for which the preceding actors have prepared the audience.

“ Yet, either through ignorance or in consequence of a vitiated habit, there are but few well supported ballets. Dance is introduced for the mere purpose of dancing: the end is supposed to be answered by the mechanical motions of the feet, or by high jumping, and that the idea which people of real taste may have of a ballet is fully answered, when inactive performers are introduced in it, who mix and jostle each other, presenting a confused heap of pictures, sketched without taste, awkwardly grouped, and totally devoid of that harmony and expression, the offspring of the soul, which alone can embellish art by giving it life.”

M. Noverre, in considering the knowledge necessary for attaining perfection in the present art, observes, that mythology, ancient poetry, and chronology, ought to be the primary studies of a ballet-master; who ought also to possess a genius for poetry and painting, since the art borrows all its charms from a perfect imitation of nature.

A slight knowledge of geometry cannot but prove very advantageous, as it will help the master to introduce his figures in due proportion, to calculate exactly, and execute with precision. By means of that unerring guide, he will retrench every superfluous accessory, and thus enliven the performance. Taste will introduce elegance, genius create variety, and judgment direct the whole.

What is a ballet but a piece of more or less complicated machinery, which strikes or surprises the beholder by its various effects, only in proportion as those are diversified and sudden? That chain and connection of figures, those motions succeeding each other with rapidity, those various forms turning contrary ways, that mixture of different incidents, the ensemble and harmony which mark the steps and accompany the exertions of the dancers; do not all these give you the idea of a mechanism most ingeniously contrived?

Ballets are often built on preternatural subjects: several of them require the assistance of machinery. For instance, few of the subjects taken from *Ovid* will be fit for representation, without a change of scenery, flights through the air, metamorphoses, &c. This author therefore must never be taken for a model, unless the ballet-master himself be an expert mechanist. None are to be found out of the capital but journeymen and stage-sweepers, whom the patronage of some mighty son of the sock has preferred by degrees to that employment. The talents of those upstarts consist in, and reach not beyond, the capacity of putting up the lights which they were wont to snuff for many years, or letting down awkwardly a glory of the most wretched style. The theatres in Italy are not remarkable for their machinery; those of Germany, built upon the same plan, are not less deficient in point of that enchanting part of stage-exhibition; so that a ballet-master must, in these countries, find himself greatly embarrassed, if unskilled in the mechanical arts, he cannot convey his ideas with perspicuity, by building for that purpose small models, which are better understood by the generality of workman than the clearest verbal explanation.

The theatres of Paris and London are the best supplied with these resources. The English are very ingenious: their stage machinery is more simplified than the French: and of course produce a quicker effect.

Dance. Amongst them all these kinds of works are, most exquisitely finished; that neatness, care, and exactitude, which is remarkable throughout every part, greatly contribute to the precision of the whole. Those chief-d'œuvres of mechanism particularly display themselves in their pantomimes; which, however, are low and trivial, devoid of taste and interest, and built upon the meanest incidents. It may be said that this kind of entertainment, which, is got up at a prodigious expence, is only calculated to please those eyes which are shocked at nothing; and that it would meet with no success on the French theatres, where no other pleafantry is permitted but such as is not incompatible with decency, abounds with delicacy and wit, and is no ways levelled against morals and humanity.

A composer who wishes to rise superior to the generality of ballet-masters, should study the painters, and trace them in their various manners of drawing and composing. Both arts have the same object in view whether it be for taking likenesses, mixing the colours, and preserving the clear-obsure; or for grouping the figures properly; laying on the draperies, throwing the former into elegant attitudes, and giving them life and expression.

Upon the same principal, the knowledge of anatomy will serve to render more clear and intelligible the precepts which he has to lay down for his pupils. It will be an easy matter for him to distinguish properly between the natural and habitual defects in their conformation. These are the greatest obstacles that so often impede the progress of young beginners. Thus once knowing the cause, he will be able to remedy the evil; as his lesson and precepts will then be the result of strict attention, they never can fail of becoming profitable.

Drawing is too useful in the composition of ballets for the master not to pay a serious attention to that art; it will contribute to the beauty of the forms; it will give to the figures an air of novelty and elegance, animate the groups, throw the body into graceful positions, and show the attitudes in a just precision.

A ballet-master who is no proficient in music, will make a bad choice of his airs. He will not enter into the spirit or character of them. The motions of his dancers will not beat time with that precision and delicacy which are absolutely necessary, unless he is endowed with that sensibility of organ which is more commonly the gift of nature than the result of art, and is far above what may be acquired by long practice and steady application.

A good choice of music is as essential to dancing as the choice of words and the phrasing of a speech is to eloquence. It is the tune and time of the music that fix and determine the motions of the dancers. If the former be uniform and devoid of taste, the ballet will, like its model, be dull and unmeaning.

By this immediate connection between music and dancing, it clearly appears, that, from a practical knowledge of the former, the ballet-master will derive the greatest advantages. He will then be able to impart his thoughts to the composer; and if taste and knowledge combine together, he will either set the music himself, or at least furnish the composer with the principal outlines, to characterise the action of the dancer; as this will be varied and expres-

sive, the ballet cannot fail of being equally so. Music well composed should paint and speak; and the dance set to those sounds, will be, as it were, the echo to repeat the words. If on the contrary it be mute, if it speak not to the ear of the dancer, then all sentiment and expression are banished from the performance.

As nothing can appear trifling to the man of genius, nothing should seem so to the ballet-master. It is impossible for him to distinguish himself in his profession, unless he applies to study those arts which have been just mentioned. Yet to insist that he should be master of them all in that degree of perfection which is attainable only by those who give themselves entirely up to the study of each of them in particular, would be requiring a mere impossibility.

All that can be deemed strictly requisite, therefore, is a general knowledge, a slight tincture of those sciences which, by the connection they have with each other, are likely to contribute to the improvement of the art and to its reputation. From the natural union, however, that subsists between the arts, and from the harmony which reigns amongst them, that ballet-master will ennoble his composition with the most fire, spirit, liveliness, and interest, who has most genius and imagination, and whose knowledge is most extensive.

As to performers, and their personal qualifications: The first point to which it is directed to pay attention when one takes up the profession of a dancer (at least so soon as he becomes capable of reflection), is his bodily formation: If one is conscious of any natural defects which seem irremediable by art, it will be best immediately to renounce every idea that may have been formed of the advantage arising from popular approbation. But where personal defects can be reformed by application, study, or the advice and assistance of judicious masters, then it becomes an essential concern quickly to exert every effort, before the parts to be corrected have acquired strength and consistence, before nature has unalterably taken her bent, and the error becomes too habitual and inveterate.

Among other personal defects, there are two which deserve particular notice: The first is that of being *jarreté*, "knock-knee'd"; the other of being *arqué* or "bow-legged."

A man is said to be *jarreté* or in-knee'd when the haunches are straight, and incline inwardly, the thighs lie near, and the knees are protuberant, and so close that they touch and knock together at every step even when the feet are at a distance; so that such a person, from the knees to the feet, makes the figure of a triangle: in people of this formation, likewise, there is a clumsiness in the instep of the ankle, a great elevation in the instep, while the *tendo Achillis* is not only very slender, but much extended in the articulation.

The other defect, of being *arqué* or bow-legged, is the opposite of the former; and exists in the same parts, namely, from the haunches to the feet, which describe a sort of bow or arch; for the haunches being in this case hollow, the thighs and knees stand open, and at a distance, and produce the same effect in the lower extremities, so that they can never be brought in proper contact like those of a well-shaped person; their

Dance.

their feet also are long and flat, the ankle juts out, and the *tendo Achillis* is large and closely inserted. A single view of these diametrically opposite defects, prove more forcibly than any arguments, that the instructions which might correct the errors of one of those sort of dancers, would tend only to increase the defects of the other; and that consequently their aim and study ought to be correspondently opposite.

The dancer whose defect is of the first kind, that of being *jarreté*, must use the means which art furnishes him with, to separate and widen the too closely connected parts. The first step to this end is to turn the thighs outwardly, endeavouring to move them in that position, by taking the advantage of the free rotation which the thigh bone has in the *cotiloïdal* cavity of the haunches: assisted by this exercise, the knees will follow the same direction, and return as it were to their proper position. The kneecap (which seems intended to prevent the knee from being thrown too far backward from its insertion) will stand perpendicular over the point of the foot, while the thigh and leg thus placed describe a line that will ensure firmness and stability to the whole body.

The second remedy to be used is, to keep the knees in a constant bend, and to make them appear very much stretched, without their being really so. This must be the result of long and constant practice; but when the habit is firmly contracted, it is impossible to return to the former vicious position, without causing an insupportable pain and numbness. Some dancers have been able to conceal this defect so artfully, that it was entirely undiscoverable unless in dancing *strait-capers* or in very quick movements. The reason of its becoming visible at such times is, that the contraction of the muscles in the effort of leaping makes them stiff about the articulation, and forces every part into its former and natural situation; the knees thus strained, turn inwardly and (for the time) regain their usual protuberance, which becomes an obstacle to the display of the *entre-chat*. The more these parts connect, to the greater distance will the lower extremities be thrown; hence the legs, neither being able to beat nor cross, remain motionless at the time of the knees rolling over each other, while the *entre-chat*, being neither cut, beat, nor crossed by the feet, is deprived of that life and brilliancy which are its chief merit.

A person thus formed, should entirely renounce the *entre-chat*, *cabrioles*, and every kind of dance that requires very quick and complicated movements, as it will infallibly render him weak and powerless; for the haunches being so strait, the muscles that are attached to them (whereon the motions of the trunk depend), have not a proper and easy play, which will be always in proportion to the dimension of these bones, because then the muscles shoot out or divide from a point more distanced from the centre of gravity: therefore the grander sort of dancing, and *terra à terre*, is the best adapted to such dancers; and we may add, that whatever they lose on the score of strength, they regain in elegance and address. They are luxuriant and shining in the simplest parts; easy, even in difficult ones, where no great efforts are required; just in their execution; elegant in their display; and their spring is always exerted with an infinity of grace, as they dexterously employ every resource with the motion of the instep

can give them. These are advantages which atone for want of personal strength; and in dancing agility and address are always preferable to the mere efforts of force

The art of concealing or overcoming the defect of such performers as we have characterised by being *arqué* or bow-legged, is in a great measure the opposite of the former; namely; by endeavouring to bring together the parts that are too much separated, and lessening that vacancy which is particularly observable between the knees. These require no less exercise than the former in turning the thighs outwardly, and generally are less able to disguise their faults; for being more robust and vigorous, there is less pliability in their muscles, and their joints move less easily. And it must be added, if the deformity results from a natural distortion of the bone, labour will be as useless as all the aids of art will be impotent.

It was remarked, that dancers of the first class, or *jarreté*, should preserve a slight genuflexion or bend in their performance; while these, for the opposite reason, ought to keep their limbs either extended or stretched, and to cross more closely, by that means diminishing the vacancy occasioned by the natural separation. Such dancers are nervous, lively, and brilliant in all cases which require more strength than elegance; vigour and agility may be inferred from their muscular force, and the firmness and resistance of their articular ligaments; lively in their dancing, because they cross low rather than high; and requiring on that account less space in beating time, they perform it with more liveliness: they display more brilliancy, because the light becomes visible between the limbs at the moment of crossing and recrossing: and this is precisely the *clair-obscur* of dancing; for if the time in the *entre-chat* or cross-caper is neither cut nor beat, but rolled or huddled over, there is no light to give distinction to the shadows, and the limbs so closely joined, present an indistinct and effectless mass.

These dancers have less address than the others, as they generally depend on their strength; and indeed their strength is a constant obstacle to ease and pliancy; if it forsakes them a single moment, they appear awkward and ridiculous: nor can they conceal their situation by any trifling display; that requiring mere address, would give them time to recover, which their want of natural elasticity otherwise prevents.

Dancers who are *jarretés*, are weak, slender, and delicate; the others, strong and vigorous, large made and nervous. It is a common opinion, that stout, squat-built men, are heavy and sluggish; which they doubtless are in respect of bodily weight: but the notion is erroneous so far as regards dancing; for activity owes its very existence to muscular strength, and every man who has not a requisite share of that will always fall heavy. The reason is evident; the weak parts, in the instant of falling, not being able to resist the stronger (that is the weight of the body, which acquires a *momentum* in proportion to the height it falls or descends from), yield and bend; and it is at the moment of relaxation or flexion that the noise of the fall is heard; a circumstance greatly lessened, or rather entirely avoided, when the body is able to maintain itself in a perpendicular direction; and while the muscular spring is sufficient to oppose that descending force.

Dance.

Dance. force, and vigorously resist a shock which would otherwise destroy it.

Nature has not exempted the fair sex from those imperfections we have been taking notice of; but art, and the use of petticoats, come fortunately to the help of the female dancer. The hoop conceals a multitude of defects, which the critic's curious eye cannot ascend to discover. Most of them dance with their knees open, as if they were naturally *arques*; but, thanks to this bad habit, and to the petticoats, they appear more brilliant than the men; because, as they beat from the lower part of the leg, they perform the time quicker than men, who, concealing nothing from the spectator, are obliged to beat at a greater extent, and to do it originally from the haunch.

The vivacity of the sex contributes much to the brilliancy of their execution; though certainly not less is owing to the petticoats, which, by concealing the length of the limbs, catch the attention, and fix it more advantageously: thus all the fire of the beats being united in one point, appears more lively and brilliant; while the eye embraces one object only, without being hurried and confused, in proportion to the space it has to overlook.

To perfection in dancing, Mr Noverre observes, nothing is more necessary than the outward turn of the thigh; yet nothing is more natural to mankind than the contrary position: it is born with us. It will be superfluous, in establishing this truth, to cite for example the Asiatics, the Africans, or any people who dance, or rather leap and move, without art or principle. If we attend only to children, or the rustic inhabitants of the villages, we shall see that they all turn their feet inwardly. The other position is purely invention; and a proof, far from equivocal, of this fault being an imaginary one, is, that a painter would transgress as much against nature as the rules of his art, were he to place the feet of his portrait in the situation of a dancer's. It is plain, then, that to dance elegantly, walk gracefully, or address ourselves with ease and manliness, we must absolutely reverse the nature of things; and force our limbs, by artificial applications equally tedious and painful, to assume a very different situation from what they originally received.

Such a change, however necessary in this art, can only be accomplished by laying its foundation in the earliest stages of infancy, when every bone and muscle is in a state of pliability, and capable of receiving any direction which we choose to give them.

The difficulty of attaining the outward position of the limbs is owing to our ignorance of the proper arts to be employed. Most beginners persuade themselves that it is to be acquired by forcing the feet to turn outward; and though this part may readily take such a direction, from their suppleness, and being so easily moved at their articulation with the leg; yet this method is so far false, as it tends to displace the ankle-bones, and besides has not any effect upon either the knees or thighs.

Neither is it possible to throw the knees outwardly without the assistance of the thigh. The knees have only two motions, bending and extension; the one drawing the leg backward, the other throwing it forward: they have no power, therefore, of themselves to determine or assume an outward position; but must

eventually depend on the thigh, which entirely commands all the lower parts of the body, and turns them in consequence of its own rotatory motion; so that, in fact, whatever motion or position that takes, the knee, foot, and leg, are obliged to follow.

M. Noverre condemns the *tourne-haunch* as a clumsy and useless invention, which, instead of producing any good effect, serves only to lame those who use it, by giving a distortion to the waist, much more disagreeable than what it was intended to remove.

The simplest and most natural means are those which reason and good sense ought to adopt; and of these a moderate but continual exercise is indispensable: the practice of a circular motion or turning of the legs, both inwardly and outwardly, and of boldly beating at full extent from the haunch, is the only certain exercise to be preferred. It insensibly gives freedom, spring, and pliancy; while the motions acquired by using the machine have more an air of constraint, than of that liberty and ease which should shine conspicuous in them.

It has been maintained, that a strong and vigorous person ought to spring higher and better than a slender or weaker man. But experience (says M. Noverre) daily proves the contrary. We see many dancers, who cut the time very strong, who beat with much vigour and firmness, and yet cannot spring to any considerable perpendicular elevation: for an oblique elevation, or on one side, ought here to be distinguished from the former; the latter is faint, and depends entirely upon address in the dancer. There are others, again, whose slender form renders their execution less bold, and rather elegant than forcible, rather lively than nervous, but who can rise to an extraordinary height: it is to the shape and formation of the foot, and to the length and elasticity of the tendon, that this power of elevation is originally owing; the knees, the loins, and the arms, all co-operate in this action; the stronger the pressure upon the muscles, the greater is the re-action, and the spring or leap is proportionably high. The alternate motion of the knees participate with those of the instep and *tendo Achillis*, though the latter are still the most essential auxiliaries; the muscles of the trunk lend their assistance, and preserve the body in a perpendicular direction; while the arms, running imperceptibly to the mutual assistance of all the parts, serve as wings to counterbalance the machine.

Observe all those animals that have long and slender ancles, as stags, roebucks, sheep, cats, monkeys, &c. and you will perceive that they have a quickness and facility of springing and leaping, which animals differently formed in that part can never obtain.

But were a man endowed with all the other qualities essential to the perfection of the art, yet still without strength and firmness in his loins he never can be a good dancer. This strength is certainly the gift of nature; but it may be much improved by the assiduity of an able teacher. We daily see dancers who have neither perpendicularity nor firmness, and whose performance is altogether unstable and irregular: and we likewise see others, who, though they possess not so great a degree of native force, have all the appearance of sinewy firmness and muscular strength, in their haunches, back, and loins. Art has furnished a substitute for nature, in the lessons of some excellent teachers,

Dance.

Dance.

teacher, who has convinced them, that when once they forego an attention to the loins, it is impossible to keep themselves in a right perpendicular line; and therefore all their exertions will be devoid of taste: that all wavering and instability in this part is inconsistent with perpendicularity and firmness, and will certainly cause distortion of the shape and waist: that the depresso and sinking of the body deprives the lower parts of that liberty which is necessary to their easy motion: that hence the body is undetermined in its positions; frequently drags the limbs; and constantly loses the centre of gravity; and therefore cannot recover an equilibrium, but after various efforts and contortions totally repugnant to the graceful and harmonious motion of good dancing.

Such is the performance of those dancers who have no strength in their loins, or at least do not exert what they possess. In order to dance well, the body should be firm and steady; it should particularly be motionless and free from wavering while the legs are in exertion; for when the body follows the actions of the feet, it displays as many grimaces and distortions as the legs execute different steps; the performance is then robbed of its ease, uniformity, harmony, exactness, firmness, perpendicularity, and equilibrium; in a word, of all those beauties and graces which are so essential to make dancing give pleasure and delight.

Many dancers are of opinion, that to be soft and luxuriant, the knees must be bent very low. But in this they are most certainly mistaken; for a more than ordinary flexion of the knees gives rather a dryness and insipidity to dancing; and a dancer may be very inelegant, and jerk, as it were, all his movements, as well in bending very low as in not bending at all. The reason will appear natural and evident, when we reflect, that the time and motions of the dancer are strictly subordinate to the time and movements of the music: pursuing this principle, it is not to be doubted, that when the flexion of the knees is greater than what the air or time of the dance requires, the measure then drawls along, languishes, and is lost. To recover and catch again the time which this unnecessary flexion had destroyed, the extension of the knee must be equally quick; and it is this sudden transition which gives such a harshness and sterility to the execution, and renders it as disgusting as the opposite fault of stiffness and inflexibility.

That luxuriant softness requires more to its perfection than merely an exact flexion and extension of the knees; the spring of the instep must add its assistance, while the loins must balance the body to preserve these springs in proper bounds. It is this rare harmony of motion (says M. Noverre) which has procured the celebrated Dupré the glorious title of the *God of Dance*.

There are many dancers, and of an inferior class only, who can display a great variety of steps, badly enough chosen to be sure, and often displayed without either judgment or taste; but it is very uncommon to find among them that exactness of ear (that rare but innate talent of a dancer), which gives life to and stamps a value upon steps, and which diffuses over all their motions a spirit that animates and enlivens them.

There are some ears stupid and insensible even to the most simple, plain, and striking movements; there are

Dance.

others, more cultivated or refined, that can feel and comprehend the measure, but cannot seize its intricacies; and there are others again to whom the most difficult airs and movements are easy and intelligible, and at once comprehended. It is nevertheless certain, that a dancer may have a very perfect and nice feeling, and yet not make his feelings intelligible to the audience, if he has not the art of commanding those resources which depend upon a proper exertion of the *coup-de-pied*: awkwardness becomes visible where the exactest proportion was necessary; and every step which would have been becoming, and produced the happiest effect, had it been smartly introduced at the conclusion of the measure, will now be cold and lifeless, if all the limbs are in motion at once. It requires more time to move the whole body than to exert any single member; the flexion and extension of the instep is more readily and quickly made than the reciprocal motion of all the joints. This principle allowed, that the dancer is destitute of precision, who (supposing he possesses a musical ear) knows not how to time his steps; the elasticity of the instep, and the more or less active play of the muscles, add to the natural sensibility of the ear, and stamp value and brilliancy on the dance. The joint charms of the harmony springing from the movements of the music, and the motions of the dancer, captivates even those whose ears are the most insensible and least susceptible of musical impression.

There are some countries where the inhabitants in general are endowed with this innate musical taste. The Palatinate, Wintemberg, Saxony, Brandenburg, Austria, and Bohemia, supply the orchestres of the German princes with many excellent musicians and eminent composers. The Germans, indeed, are born with a very lively and just taste for music, and have in them the seeds of true harmony; nothing is more common than to hear concerts, both in the streets and in the shops of their mechanics, performed with the greatest skill and exactness.

Such a natural and native taste of music as we have been mentioning, is usually accompanied by, or includes in it, a similar one for dancing; they are kindred arts; the tender and harmonious accents of the one excites and produces the agreeable and expressive motions of the other, and their union entertains the eye and ear with animated pictures of sentiment; these two senses, again, convey to the heart the interesting images which affect them, while the heart, in its turn, communicates them to the mental faculty: thus the pleasure resulting from the harmony and intelligence of these two arts, enchants the spectator, and fills him with the most seducing pleasures of voluptuousness.

Dancing is probably no where varied to such a degree as in the provinces of Germany; where the well known dances of one village are strangers in the adjacent hamlet; their songs of mirth and merriment have no less different airs and movements, though they are all marked with that of gaiety. Their dances are pleasing and engaging, because the offspring of simple nature; their motions express joy and pleasure; and the exactness with which the whole is performed, gives a peculiar agreeableness to their steps, gestures, and attitudes. Do they spring?—a hundred persons, assembled round an oak, or some ancient pillar, seize
the

Dance. the time at one instant, bound up, and descend with the same exactness. Do they wish to mark the measure by a *coup-de-pied*?—all strike with one consent; or when they catch up their women, you see them all in the air at an equal height, nor do they descend but at the precise note that marks the time.

The counter-point, which is doubtless the touchstone of a delicate ear, is to them an object of no difficulty; hence their dance is so particularly animated, and the nicety of that organ has the effect of giving their different motions an air of gaiety and variety altogether exquisite.

A dancer whose ear is untuned to harmony, displays his steps without order or regularity, wanders from his part, and pursues the measure without being able to reach it: devoid of judgment, his dancing has neither sentiment nor expression; and the music which should direct his motions, regulate his steps, and guide his time, serves only to expose his imperfections and insufficiency. The study of music should therefore be applied to for the purpose of obviating this defect, and giving more sensibility and exactness to the organs of hearing.

It will not be expected that we should proceed to give a description of all the intricacies and combinations of steps that are or can be exerted in dancing; or enlarge upon the mechanical particulars of the art. A dissertation on the latter would be insipid and disgusting; for the language of the feet and limbs is addressed to the eyes, not to the ears: and a detail of the former would be endless, since every dancer has his peculiar manner of joining or varying the time. It may be sufficient just to mention on this point, that it is in dancing as in music, and with dancers as with musicians: Dancing does not abound with more fundamental steps than music with notes; but there are octaves, breves, semibreves, minims, crotchets, double and treble crotchets; times to count and measures to follow. This mixture, however, of a small number of steps, and a few notes, furnishes dancers with a multitude of connections and a variety of figures: taste and genius will always find a source of novelty in arranging them in different manners, and to express various ideas. Slow and lengthened, or quick and precipitate steps, and the time correspondently varied, give birth to this endless diversity.

Country-DANCE. See *COUNTRY-Dance.*

Country-Dance, commonly so written, and hence seeming to imply a rustic way of dancing borrowed from country people or peasants, is by others supposed to be a corruption of the French *Contre-danse*, where a number of persons placing themselves opposite one to another begin a figure.

Rope-DANCER, *schœnobates*, a person who walks, leaps, dances, and performs several other feats upon a small rope or wire.

The ancients had their rope-dancers as well as we. These had four several ways of exercising their art: The first vaulted, or turned round the rope like a wheel round its axis, and there hung by the heels or neck. The second flew or slid from above, resting on their stomach, with the arms and legs extended. The third ran along a rope stretched in a right line or up and down. Lastly, the fourth not only walked on the rope, but made surprising leaps and turns thereon.

They had likewise, the *cremnobates* and *orobates*; that is, people who walked on the brinks of precipices: Nay more, Suetonius in *Gauba*, c. 6. Seneca in his 85th Epistle, and Pliny, *lib. viii. c. 2.* make mention of elephants that were taught to walk on the rope. *St Vitus's DANCE.* See *MEDICINE-Index.*

DANCETTE, in heraldry, is when the outline of any bordure, or ordinary, is indented very largely, the largeness of the indentures being the only thing that distinguishes it from indented.

DANCING. See *DANCE.*

DANCING-Girls of Egypt. See *ALME.*

Dancing-girls are employed all over the east, as affording great diversion at all public entertainments. They are all prostitutes; and by the laws of their society are bound to refuse no one for their price, which is rated according to their beauty and other accomplishments. There are even particular sets of them appropriated to the service of the Gentoo temples and the use of the bramín priests who attend them. These poor creatures say that they were first debauched by their *god*, and afterwards by him consigned over to the use of the priests who belong to his temples.

These dancing-girls, whether in a settled or unsettled condition, live in a band or community under the direction of some superannuated female of the same profession, under whom they receive a regular education, and are trained up in all the arts of love and leasing, like scholars in an academy. Thus they acquire the art of captivating the affections of the other sex to such a degree, that nothing is more common than for one of the princes or chief people of the country to take a liking to one of these girls, and waste immense sums on her, though at the same time their own haram is stocked with beauties far superior, and who are besides possessed of the natural modesty of the sex, to which the others have not the smallest pretensions. Thus some of these girls acquire immense wealth. In the neighbourhood of Goa, for instance, on a part of the continent bordering on the district of that island, the dancing girls founded a village, after being driven from Goa by the zeal of the archbishop. Here they reside in a body corporate, and attend the parties of pleasure of the noblemen and principal inhabitants, for it is not every one's purse that can afford them. Here many of them acquire considerable fortunes by this scandalous traffic, and throw it into a common stock for the sake of carrying on merchandise; being concerned in shipping and the most profitable voyages, for which they have regular factors and brokers.

The dress of these women varies according to the country they live in; but in all it is the most gorgeous imaginable. They are loaded with jewels, literally from top to toe, since even on their toes they wear rings. Their necks are adorned with carcanets, their arms with bracelets, and their ancles with chains of gold and silver, often enriched with precious stones. They also wear nose-jewels, which at first have an odd appearance, but to which the eye is soon reconciled. In Indostan, these dancing-girls, as well as the other women of the country, have a peculiar method of preserving and managing their breasts, which at the same time makes no inconsiderable part of their fire.

They

Dance.
||
Dancing.

Dancing. They inclose them in a pair of hollow cases, exactly fitted to them; made of very light wood, linked together, and buckled at the back. These at once confine their breasts so that they cannot grow to any disgustfully exuberant size; though, from their smoothness and pliancy, they play so freely with every motion of the body, that they do not crush the tender texture of the flesh in that part, like the stiff whalebone stays in use among the Europeans. The outside of them is spread over with a thin plate of gold or silver, or set with gems, if they can afford it. Another occasional ornament the dancing-girls put on, particularly when they resort to their gallants, viz. a necklace of many loose turns, composed of flowers strung together, which they call *negrees*, somewhat resembling Spanish double jessamy, but of a much stronger and more agreeable fragrant odour, and far preferable to any perfumes. "They have nothing (says Mr Grose) of that nauseous boldness which characterises the European prostitutes, their style of seduction being all softness and gentleness."

With regard to the performances of these women as dancers, we have various accounts. The author of *Memoirs of the late War in Asia*, acquaints us, "that their attitudes as well as movements are not ungraceful. Their persons are delicately formed, gaudily attired, and highly perfumed. By the continuation of wanton attitudes, they acquire, as they grow warm in the dance, a frantic lasciviousness themselves, and communicate, by a natural contagion, the most voluptuous desires to the beholders." Mr Ives seems to have been very cool on this subject. "I could not (says he) see any thing in their performance worthy of notice. Their movements are more like tumbling or showing postures than dancing. Their dress is thin and light; and their hair, necks, ears, arms, wrists, fingers, legs, feet, and even the toes, are covered with rings of gold and silver, made after a clumsy manner. They wear two rings in their noses; and by their staring looks and odd gesticulations, you would rather suspect them to be mad women than morris-dancers. The band of music that attends them is not less singular in its way: it is chiefly composed of three or four men, who hold two pieces of bell metal in their hands, with which they make an incessant noise; another man beats what he is pleased to call a drum; and that they may not want vocal music to complete the band, there are always two others appointed to sing. These last generally lay in their mouths a good loading of beetel nut before they begin; which, after having been well chewed, tinges the saliva with such a redness, that a stranger would judge them to bleed at the mouth by too violent an exertion of their voice. These gentry are called *ticky-taw* boys, from the two words *ticky-taw*, which they continually repeat, and chant with great vehemence. The dancing-girls are sometimes made use of in their religious ceremonies, as when the priests bring forth the images of their gods into the open fields on a car ornamented with lascivious figures, these girls dance before the images amidst a great crowd of people; and having been selected for their superior beauty, are very profitable to their masters, the priests, who are said to prostitute them to all comers."

Mr Grose informs us, that "these dances would hardly at first relish with Europeans, especially as they

are accompanied with a music far from delightful, consisting of little drums called *gungums*, cymbals, and a sort of fife, which make a hideous din, and are played on by men, whose effeminacy, grimaces, and uncouth shrivelled features, all together shock the eye and torture the ear. However, by use we become reconciled to the noise, and may observe some not unpleasing airs, with which the dancers keep time: the words often express the matter of a pantomime dance, such as a lover courting his mistress; a procurer bringing a letter, and endeavouring to seduce a woman from one gallant in favour of another; a girl timorous and afraid of being caught in an intrigue. All these love-scenes the girls execute in character dances, and with no despicable expression, if they are proficient in their art; for then their gestures, air, and steps, are marking and well adapted. In some of their dances, even in public, modesty is not much respected by the lascivious attitudes into which they throw themselves, without exposing any nudity; being richly clad and bedecked with jewels after their manner. But in private parties to which they are called, as in gardens, they give themselves a greater loose, and have dances in reserve; in which, though still without any grossness in discovering their bodies, they are mistresses of such motions and lewdness of looks and gestures as are perhaps more provoking.

DANDELION, in botany. See LEONTODON.

DANDINI (Pietro), an eminent painter, was born at Florence in 1646, and received his first instruction in the art of painting from Valerio Spada, who excelled in small drawings with a pen. Whilst he was under the care of that artist, he gave such evident proofs of a ready genius, that he was then placed as a disciple with his uncle Vincentio Dandini, a master of great reputation through all Italy, who had been bred up under Pietro da Cortona. He afterwards travelled through most of the cities of Italy, studying the works of those who were most distinguished; and resided for a long time at Venice, where he copied the paintings of Titian, Tintoretto, and Paolo Veronese. He next visited Parma and Modena, to design the works of Correggio; omitting no opportunity that might contribute to improve his hand or his judgment. When he returned to Florence, the grand duke Cosmo III. the grand duchess Victoria, and the prince Ferdinand, kept him perpetually employed, in fresco painting as well as in oil; his subjects being taken not only from sacred or fabulous history, but from his own invention and fancy, which frequently furnished him with such as were odd and singular, and especially with whimsical caricatures. He died in 1712.—This master had a most extraordinary talent for imitating the style of even the most celebrated ancient painters of every school, particularly Titian, Veronese, and Tintoretto; and with a force and elegance, equal to his subjects of history, he painted portraits, landscapes, architecture, flowers, fruit, battles, animals of all kinds, and likewise sea-pieces; proving himself an universal artist, and excellent in every thing he undertook.

He had a son, Octavio, who proved not inferior to him in any branch of his profession, and was an honour to his family and his country.

DANDINI (Cæsar), history painter, was born at Florence

Danegelt Florence; and was the elder brother and first instructor of Vincentio Dandini the uncle of Pietro. This master had successively studied as a disciple with Cavalier Curradi, Passignano; and Christofano Allori: from whom he acquired a very pleasing manner of designing and colouring. He was extremely correct in his drawing, and finished his pictures highly. Several noble altar-pieces in the churches of Florence are of his hand; and one, which is in the chapel l'Annonciata, is particularly admired.

DANEGELT, an annual tax laid on the Anglo-Saxons, first of 1 s. afterwards 2 s. for every hide of land through the realm, for maintaining such a number of forces as were thought sufficient to clear the British seas of Danish pirates, which heretofore greatly annoyed the coasts.

DANEGELT was first imposed as a standing yearly tax on the whole nation, under king Ethelred, A. D. 991. That prince, says Camden, *Britan.* 142. much distressed by the continual invasions of the Danes, to procure a peace, was compelled to charge his people with heavy taxes, called *danegelt*.—At first he paid 10,000 l. then 16,000 l. then 24,000 l. after that 36,000 l. and lastly 48,000 l.

Edward the Confessor remitted this tax: William I. and II. reassumed it occasionally. In the reign of Henry I. it was accounted among the king's standing revenues; but king Stephen, on his coronation-day, abrogated it for ever.

No church or church-land paid a penny to the *danegelt*; because, as is set forth in an ancient Saxon law, the people of England placed more confidence in the prayers of the church than in any military defence they could make.

DANDOLO (Henry), doge of Venice, a brave admiral and politician. With a Venetian fleet he took Constantinople in 1203, and had the moderation to refuse to be emperor. He died in 1250.

DANET (Peter), abbot of St Nicholas de Verdun, was one of the persons chosen by the duke of Montaufer to write on the classics for the use of the dauphin. He had a share in Phædrus, which he published with notes and explications in Latin. He also wrote a dictionary in Latin and French, and another in French and Latin. He died at Paris in 1709.

DANIEL, the fourth of the greater prophets, was born in Judea of the tribe of Judah, about the 25th year of the reign of Josiah. He was led captive to Babylon, with other young Hebrew lords, after the taking of Jerusalem by Nebuchadnezzar, who took them into his service. That prince gave them masters to instruct them in the language and sciences of the Chaldeans, and ordered them to be fed with the most delicate viands; but they, fearing that they should eat meat forbidden by the law of Moses, desired the king's officers to allow them only pulse. The wisdom and conduct of Daniel pleasing Nebuchadnezzar, that prince gave him several posts of honour. It is commonly believed, that this prophet when but 12 years of age, made known the innocence of the chaste Susannah; but the learned are not agreed, that the young Daniel, who confounded the old men, was the same with this prophet. However, he explained Nebuchadnezzar's dream of the mysterious statue, which foretold the four great monarchies; on which account he was

made prefect of the province of Babylon. In the reign of Darius the king of the Medes, he refused to adore the golden statue of the king, and was cast into the lions den, when those beasts, tho' pinched with hunger, did him no manner of hurt. And he explained the characters written on the wall of the room where Belshazzar was feasting.

It is believed that Daniel died in Chaldea, and that he did not take advantage of the permission granted by Cyrus to the Jews of returning to their own country. St Epiphanius says he died at Babylon; and herein he is followed by the generality of historians.

The prophecies of Daniel concerning the coming of the Messiah, and the other great events of after-times, are so clear and explicit, that, as St Jerom tells us, Porphyry objected to them, that those which related to the kings of Syria and Egypt, chap. xi. must have been written after the times of Antiochus Epiphanes; whereas this prophecy was translated into Greek 100 years before his time, and the translation was in the hands of the Egyptians, who had no great kindness for the Jews and their religion. And those prophecies foretelling the successes of Alexander, chap. viii. 5. xi. 3. were shown to Alexander by the Jews, in consequence of which they obtained several privileges from him; (*Ant. lib. xi. c. 8.*) The style of Daniel is not so lofty and figurative as that of the other prophets; it is clear and concise, and his narrations and descriptions simple and natural: in short, he writes more like a historian than a prophet.

The Jews do not reckon Daniel among the prophets; part of his book, that is, from the fourth verse of his second chapter to the end of the seventh chapter, was originally written in the Chaldee language; the reason of which was, that in that part he treats of the Chaldee or Babylonish affairs: all the rest of the book is in Hebrew. The six first chapters of the book of Daniel are a history of the kings of Babylon, and what befel the Jews under their government. In the six last he is altogether prophetic, foretelling not only what should happen to his own church and nation, but events in which foreign princes and kingdoms were concerned.

DANIEL (Samuel), an eminent poet and historian, was born near Taunton in Somersetshire in the year 1562, and educated at Oxford: but leaving that university without a degree, he applied himself to English history and poetry under the patronage of the earl of Pembroke's family. He was afterwards tutor to the lady Ann Clifford; and, upon the death of Spencer was created poet-laureat to queen Elizabeth. In king James's reign he was appointed gentleman extraordinary, and afterwards one of the grooms of the privy-chamber to the queen consort, who took great delight in his conversation and writings. He wrote an history of England, several dramatic pieces, and some poems; and died in 1619.

DANIEL (Gabriel), a celebrated Jesuit, and one of the best French historians, was born at Rouen in 1649. He taught polite literature, philosophy, and divinity, among the Jesuits; and was superior of their house at Paris, where he died in 1728. There are a great number of his works published in French, of which the principal are, 1. An History of France, of which he also wrote an abridgement in nine volumes 12mo.

Danmonii,
Dante.

2. An History of the French Militia, in 2 vols 4to.
3. An Answer to the Provincial Letters. 4. A Voyage to the World of Descartes. 5. Letters on the Doctrines of the Theorists, and on Probability. 6. New difficulties relating to the knowledge of Brutes: And, 7. A theological treatise on the Efficacy of Grace.

DANMONII, an ancient British nation, supposed to have inhabited that tract of country which is now called Cornwall and Devonshire, bounded on the south by the British Ocean, on the west by St George's Channel, on the north by the Severn Sea, and on the east by the country of the Durotriges. Some other British tribes were also seated within these limits; as the Cossini and Ostidamni, which were probably particular clans of the Danmonii; and, according to Mr Baxter, they were the keepers of their flocks and herds. As the several tribes of the Danmonii submitted without much resistance to the Romans, and never joined in any revolt against them, that people were under no necessity of building many forts, or keeping many garrisons in their country. This is the reason why so few Roman antiquities have been found in that country, and so little mention is made of it and its ancient inhabitants by Roman writers. Ptolemy names a few places, both on the sea-coasts and in the inland parts of this country, which were known to, and frequented by, the Romans. The most considerable of these places are the two famous promontories of Bolerium and Oerinum, now the Landsead and the Lizard; and the towns of Isca Danmoniorum and Tamare, now Exeter and Saltash. As the Danmonii submitted to tamely to the Romans, they might perhaps permit them to live, for some time at least, under their own princes and their own laws; a privilege which we know they granted to some other British states. In the most perfect state of the Roman government in Britain, the country of the Danmonii made a part of the province called Flava Cæsariensis, and was governed by the president of that province. After the departure of the Romans, kingly government was immediately revived amongst the Danmonii in the person of Vortigeru, who was perhaps descended from the race of their ancient princes, as his name signifies in the British language a chieftain or the head of a family.

DANTE (Aligheri), one of the first poets of Italy, was born at Florence in 1265, of an ancient and honourable family. Boccaccio, who lived in the same period, has left a very curious and entertaining treatise, on the life, the studies, and manners of this extraordinary poet; whom he regarded as his master, and for whose memory he professed the highest veneration. This biographer relates, that Dante, before he was nine years old, conceived a passion for the lady whom he has immortalized in his singular poem. Her age was near his own; and her name was Beatrice, the daughter of Folco Portinari, a noble citizen of Florence. The passion of Dante, however, like that of his successor Petrarch, seems to have been of the chaste and platonic kind, according to the account he has himself given of it, in one of his early productions intitled *Vita Nuova*; a mixture of mysterious poetry and prose; in which he mentions both the origin of his affection and the death of his mistress, who, according to Boccaccio, died at the age of 24. The same author asserts, that Dante fell into a deep melancholy in con-

sequence of this event, from which his friends endeavoured to raise him, by persuading him to marriage. After some time he followed their advice, and repented it; for he unfortunately made choice of a lady who bore some resemblance to the celebrated Xanippe. The poet, not possessing the patience of Socrates, separated himself from her with such vehement expressions of dislike, that he never afterwards admitted her to his presence, though she had born him several children. In the early part of his life he gained some credit in a military character: distinguishing himself by his bravery in an action where the Florentines obtained a signal victory over the citizens of Arezzo. He became still more eminent by the acquisition of civil honours; and at the age of 35 he rose to be one of the chief magistrates of Florence, when that dignity was conferred by the suffrages of the people. From this exaltation the poet himself dated his principal misfortunes, as appears from the fragment of a letter quoted by Lionardo Bruni, one of his early biographers, where Dante speaks of his political failure with that liberal frankness which integrity inspires. Italy was at that time distracted by the contending factions of the Ghibellins and the Guelphs; the latter, among whom Dante took an active part, were again divided into the Blacks and the Whites. Dante, says Gravina, exerted all his influence to unite these inferior parties: but his efforts were ineffectual, and he had the misfortune to be unjustly persecuted by those of his own faction. A powerful citizen of Florence, named Corso Donati, had taken measures to terminate these intestine broils, by introducing Charles of Valois, brother to Philip the Fair king of France. Dante, with great vehemence, opposed this disgraceful project, and obtained the banishment of Donati and his partizans. The exiles applied to the pope (Boniface VIII.), and by his assistance succeeded in their design. Charles of Valois entered Florence in triumph, and those who had opposed his admission were banished in their turn. Dante had been dispatched to Rome as the ambassador of his party; and was returning, when he received intelligence of the revolution in his native city. His enemies, availing themselves of his absence, had procured an iniquitous sentence against him, by which he was condemned to banishment, and his possessions were confiscated. His two enthusiastic biographers, Boccaccio and Manetti, express the warmest indignation against this injustice of his country. Dante, on receiving the intelligence, took refuge in Siena, and afterwards in Arezzo, where many of his party were assembled. An attempt was made to surprize the city of Florence, by a small army which Dante is supposed to have attended: the design miscarried, and our poet is conjectured to have wandered to various parts of Italy, till he found a patron in the great Candella Scala, prince of Verona, whom he has celebrated in his poem. The high spirit of Dante was ill suited to courtly dependence; and he is said to have lost the favour of his Veroneze patron by the rough frankness of his behaviour. From Verona he retired to France, according to Manetti; and Boccaccio affirms that he disputed in the theological schools of Paris with great reputation. Bayle questions his visiting Paris at this period of his life; and thinks it improbable, that a man, who had been one of the chief magistrates of Florence, should

Dante.

Dante. should condescend to engage in the public squabbles of the Parisian theologians; but the spirit both of Dante and the times in which he lived sufficiently account for this exercise of his talents; and his residence in France at this season is confirmed by Boccaccio, in his life of our poet, which Bayle seems to have had no opportunity of consulting.

The election of Henry count of Luxemburgh to the empire, in November 1308, afforded Dante a prospect of being restored to his native city, as he attached himself to the interest of the new emperor, in whose service he is supposed to have written his Latin treatise *De Monarchia*, in which he asserted the rights of the empire against the encroachments of the Papacy. In the year 1311, he instigated Henry to lay siege to Florence; in which enterprise, says one of the biographers, he did not appear in person, from motives of respect towards his native city. The emperor was repulsed by the Florentines; and his death, which happened in the succeeding year, deprived Dante of all hopes concerning re-establishment in Florence. After this disappointment, he is supposed to have passed some years in roving about Italy in a state of poverty and distress, till he found an honourable establishment at Ravenna, under the protection of Guido Novello da Polenta, the lord of that city, who received this illustrious exile with the most endearing liberality, continued to protect him through the few remaining years of his life, and extended his munificence to the ashes of the poet.

Eloquence was one of the many talents which Dante possessed in an eminent degree. On this account he is said to have been employed on fourteen different embassies in the course of his life, and to have succeeded in most of them. His patron Guido had occasion to try his abilities in a service of this nature, and dispatched him as his ambassador to negotiate a peace with the Venetians, who were preparing for hostilities against Ravenna. Manetti asserts that he was unable to procure a public audience at Venice, and returned to Ravenna by land, from his apprehensions of the Venetian fleet; when the fatigue of his journey, and the mortification of failing in his attempt to preserve his generous patron from the impending danger, threw him into a fever, which terminated in death on the 14th of September 1321. He died, however, in the palace of his friend; and the affectionate Guido paid the most tender regard to his memory. This magnificent patron (says Boccaccio) commanded the body to be adorned with poetical ornaments, and, after being carried on a bier through the streets of Ravenna by the most illustrious citizens, to be deposited in a marble coffin. He pronounced himself the funeral oration, and expressed his design of erecting a splendid monument in honour of the deceased: a design which his subsequent misfortunes rendered him unable to accomplish. At his request, many epitaphs were written on the poet: the best of them (says Boccaccio) by Giovanni del Virgilio of Bologna, a famous author of that time, and the intimate friend of Dante. Boccaccio then cites a few Latin verses, not worth transcribing, six of which are quoted by Bayle as the composition of Dante himself, on the authority of Paul Jovius. In 1483 Bernardo Bembo, the father of the celebrated cardinal,

raised a handsome monument over the neglected ashes of the poet, with the following inscription:

Dante.

Exigua tumuli Danthes hic sorte jacebas
Squalenti nulli cognita pæne situ;
At nunc marmoreo subnixus conderis arcu,
Omnibus et cultu splendidiore nites:
Nimirum tæmibus, Mulsis incensus Etruscis.
Hoc tibi, quem in primis hæc coluere, dedit.

Before this period the Florentines had vainly endeavoured to obtain the bones of their great poet from the city of Ravenna. In the age of Leo X. they made a second attempt, by a solemn application to the pope for that purpose; and the great Michael Angelo, an enthusiastic admirer of Dante, very liberally offered to execute a magnificent monument to the poet. The hopes of the Florentines were again unsuccessful. The particulars of their singular petition may be found in the notes to Codrivi's Life of Michael Angelo.

At what time, and in what place, he executed the great and singular work which has rendered him immortal, his numerous commentators seem unable to determine. Boccaccio asserts, that he began it in his 35th year, and had finished seven cantos of his *Inferno* before his exile; that in the plunder of his house, on that event, the beginning of his poem was fortunately preserved, but remained for some time neglected, till its merit being accidentally discovered by an intelligent poet named Dino, it was sent to the marquis Marcello Malespina, an Italian nobleman, by whom Dante was then protected. The marquis restored these lost papers to the poet, and intreated him to proceed in a work which opened in so promising a manner. To this incident we are probably indebted for the poem of Dante, which he must have continued under all the disadvantages of an unfortunate and agitated life. It does not appear at what time he completed it; perhaps before he quitted Verona, as he dedicated the *Paradise* to his Veronese patron. The critics have variously accounted for his having called his poem *Comedia*. He gave it that title (said one of his sons), because it opens with distress and closes with felicity. The very high estimation in which this production was held by his country, appears from a singular institution. The republic of Florence, in the year 1373, assigned a public stipend to a person appointed to read lectures on the poem of Dante: Boccaccio was the first person engaged in this office; but his death happening in two years after his appointment, his comment extended only to the seventeen first cantos of the *Inferno*. The critical dissertations that have been written on Dante are almost as numerous as those to which Homer has given birth; the Italian, like the Grecian bard, has been the subject of the highest panegyric, and of the grossest invective. Voltaire has spoken of him with that precipitate vivacity, which so frequently led that lively Frenchman to insult the reputation of the noblest writers. In one of his entertaining letters, he says to an Italian abbé, "Je fais grand cas du courage, avec lequel vous avez osé dire que Dante étoit un fou, et son ouvrage un monstre.—Le Dante pourra entrer dans les bibliothèques des curieux, mais il ne fera jamais lu." But more temperate and candid critics have not been wanting to display the merits of this original poet. Mr Warton has introduced into his last volume on English poetry,

Dante,
Dantzic.

poetry, a judicious and spirited summary of Dante's performance.

DANTE (John Baptist), a native of Perugia, an excellent mathematician, called the *new Dædalus*, for the wings he made himself, and with which he flew several times over the lake Thrasymenus. He fell in one of his enterprises; the iron work with which he managed one of his wings having failed; by which accident he broke his thigh: but it was set by the surgeons, and he was afterwards called to Venice to profess mathematics.

DANTZIC, the capital of Polish Prussia, standing on a branch of the Vistula, about four miles above where it falls into the Baltic; in E. Long. 18. 36. N. Lat. 54. 20. This city is famous in history on many accounts, particularly that of its being formerly at the head of the Hanseatic association, commonly called the *Hanse-towns*. It is large, beautiful, populous, and rich; its houses generally are five stories high; and many of its streets are planted with chestnut-trees. One of the suburbs is called *Scotland*; and the Scots have great privileges in consequence of their gallant defence of the town, under one of the family of Douglas, when it was besieged by the Poles. It is said there are upwards of 30,000 pedlars of that nation in Poland who travel on foot, and some with three, four, or five horses. In king Charles II.'s time they were about 53,000: in that reign Sir John Denham and Mr Killigrew were sent to take the number of them, and to tax them by the poll, with the king of Poland's licence; which having obtained, they brought home L. 10,000 Sterling, besides their charges in the journey. Dantzic has a fine harbour; and is still a most eminent commercial city, although it seems to be somewhat past its meridian glory, which was probably about the time that the president de Thou wrote his much esteemed *Historia sui Temporis*, wherein, under the year 1607, he so highly celebrates its commerce and grandeur. It is a republic, claiming a small adjacent territory about forty miles round it, which were under the protection of the king and the republic of Poland. Its magistracy, and the majority of its inhabitants, are Lutherans; although the Romanists and Calvinists be equally tolerated in it. It has 26 parishes, with many convents and hospitals. The inhabitants have been computed to amount to 200,000; but later computations fall very considerably short of it, as appears by its annual bill of mortality, exhibited by Dr Busching, who tells us, that in the year 1752, there died but 1846 persons. Its own shipping is numerous; but the foreign ships constantly resorting to it are more so, whereof 1014 arrived there in the year 1752; in which year also 1288 Polish vessels came down the Vistula, chiefly laden with corn, for its matchless granaries; from whence that grain is distributed to many foreign nations, Poland being justly deemed the greatest magazine of corn in all Europe, and Dantzic the greatest port for distributing it every where: besides which, Dantzic exports great quantities of naval stores, and vast variety of other articles. Dr Busching affirms, that it appears from ancient records, as early as the year 997, that Dantzic was a large commercial city, and not a village or inconsiderable town, as some pretend. The inhabitants of Dantzic have often changed their masters, and have sometimes been un-

der the protection of the English and Dutch; but generally have shown a great predilection for the kingdom and republic of Poland, as being less likely to rival them in their trade, or abridge them of their immunities, which reach even to the privilege of coining money. Though strongly fortified, and possessed of 150 large brass cannon, it could not, through its situation, stand a regular siege, being surrounded with eminences. In 1724, the inhabitants discovered a remarkable attachment and fidelity towards Stanislaus king of Poland, not only when his enemies, the Russians, were at their gates, but even in possession of the city. This city was exempted by the late king of Prussia from those claims which he made on the neighbouring countries; notwithstanding which, his Prussian majesty soon after thought proper to seize on the territories belonging to Dantzic, under pretence of their having been formerly part of Polish Prussia. He then proceeded to possess himself of the port-duties belonging to that city, and erected a custom-house in the harbour, where he laid arbitrary and insupportable duties upon goods exported or imported. To complete the system of oppression, custom-houses were erected at the very gates of Dantzic, so that no persons could go in or out of the town without being searched in the strictest manner. Such is the treatment which the city of Dantzic has received from the king of Prussia, though few cities have ever existed which have been comprehended in so many general and particular treaties, and whose rights and liberties have been so frequently secured, and guaranteed by so many great powers, and by such a long and regular succession of public acts, as that of Dantzic has been. In the year 1784, it was blockaded by his troops on various pretences; but by the interposition of the empress of Russia and of the king of Poland, they were withdrawn; and a compromise having taken place, the city was restored to its former immunities. Nevertheless, its trade has since been rather upon the decline, the merchants choosing to settle where their property may be more secure.

DANUBE, the largest and most considerable river in Europe, rising in the Black Forest, near Zunberg; and running N. E. through Swabia by Ulm, the capital of that country; then running E. through Bassaria and Austria, passes by Ratisbon, Passau, Ens, and Vienna. It then enters Hungary, and runs S. E. from Presburg to Buda, and so on to Belgrade; after which it divides Bulgaria from Molachia and Moldavia, discharging itself by several channels into the Black Sea, in the province of Bessarabia. Towards the mouth, it was called the *Ister* by the ancients; and it is now said, that four of the mouths are choaked up with sand, and that there are only two remaining. It begins to be navigable for boats at Ulm, and receives several large rivers as it passes along. It is so deep between Buda and Belgrade, that the Turks and Christians have had men of war upon it; and yet it is not navigable to the Black Sea, on account of the cataracts. The Danube was generally supposed to be the northern boundary of the Roman empire in Europe. It was worshipped as a deity by the Scythians.

DAPHNE, a daughter of the river Peneus by the goddess Terra, of whom Apollo became enamoured. This passion had been raised by Cupid; with whom

Dantzic
||
Daphene.

Daphne. who! Apollo, proud of his late conquest of the serpent Python, had disputed the power of his darts. Daphne heard with horror the addresses of the god, and endeavoured to remove herself from his importunities by flight. Apollo pursued her, and Daphne, fearful of being caught, intreated the assistance of the gods, who changed her into a laurel. Apollo crowned his head with the leaves of the laurel, and for ever ordered that that tree should be sacred to his divinity. Some say that Daphne was admired by Leucippus, son of Cœnomaus king of Pisa, who to be in her company disguised his sex and attended her in the woods in the habit of a huntress. Leucippus gained Daphne's esteem and love; but Apollo, who was his powerful rival, discovered his sex, and Leucippus was killed by the companions of Diana. Daphne was also the name of a daughter of Tiresias, priestess in the temple of Delphi. She was consecrated to the service of Apollo by the Epigoni, or according to others by the goddess Tellus. She was called *Sibyl* on account of the wildness of her looks and expressions when she delivered oracles. Her oracles were generally in verse; and Homer, according to some accounts, has introduced much of her poetry in his compositions.

DAPHNE (anc. geog.), a small village near to, or in the suburbs of, Antiochia of Seleucis in Syria; with a large grove, well watered with springs: In the middle of the grove stood the temple of Apollo and Diana. Its extent was 80 stadia or 10 miles; the distance from the city five miles: A place pleasant and agreeable, from the plenty of water and the temperature of the air, and its soft breathing breezes. The grove was of bay-trees, intermixed with cypresses; which last multiplied so fast, as to occupy the whole of it. Pompey gave some land for enlarging the grove. Antiochus Epiphanes built a very large temple of Daphnæus Apollo. The place at length became so infamous, that people of modesty and character avoided resorting thither: so that *Daphnici mores* became proverbial.

DAPHNE (anc. geog.), a small district on the lake Samachonitis, in the Higher Galilee, very pleasant and plentifully watered with springs, which feed the Lesh Jordan; whence its name seems to arise, probably in imitation of that near Antioch of Syria on the river Orontes.

DAPHNE, *Spurge-laurel*; a genus of the monogynia order, belonging to the octandria class of plants; and in the natural method ranking under the 31st order, *Vepreculæ*. There is no calyx; the corolla is quadri-lobed and marcescent, inclosing the stamina. The fruit is a monospermous berry. There are 15 species; of which the following are the most remarkable.

1. Mezereum, the mezereon or spurge-olive, is a low deciduous shrub. It is a native of Germany, and has been also discovered in England in some woods near Andover in Hampshire. Of this elegant plant there are four varieties: 1. The white; 2. The pale-red; 3. The crimson; and, 4. The purple-flowering.—Hanbury is very lavish of his praise of these shrubs. He says, “they have each every perfection to recommend them as flowering-shrubs. In the first place, they are of low growth, seldom arising to more than three or four feet in height, and therefore are proper even for the smallest gardens. In the next place, they

will be in bloom when few trees, especially of the shrubby tribe, present their honours. It will be in February, nay, sometimes in January; then will the twigs be garnished with flowers all around from one end to the other. Each twig has the appearance of a spike of flowers of the most consummate lustre; and as the leaves are not yet out, whether you behold this tree near or at a distance, it has a most enchanting appearance. But this is not all; the sense of smelling is peculiarly regaled by the flowers; their spicy sweetness is diffused around, and the air is perfumed with their odours to a considerable distance. Many flowers, deemed sweet, are not liked by all; but the agreeable inoffensive sweetness of the mezereon has ever delighted the sense of smelling, whilst the lustre of its bloom has feasted the eye. Neither is this the only pleasure the tree bestows: for besides the beauty of the leaves, which come out after the flowers are fallen, and which are of a pleasant green colour and an oblong figure, it will be full of red berries in June, which will continue growing till the autumn. Of these berries the birds are very fond; so that whoever is delighted with those songsters, should have a quantity of them planted all over the outskirts of his wilderness quarters.”

2. Gnidium, the flax-leaved daphne, is a low deciduous shrub; native of Italy, Spain, and about Montpellier. This species seldom grows higher than three feet. The branches are very slender, and ornamented with narrow, spear-shaped, pointed leaves, much like those of the common flax. The flowers are produced in panicles at the ends of the branches: They are small, come out in June, but are rarely succeeded by seeds in England.

3. Cneorum, the spear-leaved daphne or cneorum, is a very low deciduous shrub; native of Switzerland, Hungary, the Alps, and Pyrenean mountains. This rises with a shrubby, branching stalk, to about a foot or a foot and an half high. The leaves are narrow, spear-shaped, and grow irregularly on the branches. The flowers are produced in clusters at the ends of the little twigs: They make their appearance in March, are of a purple colour, and possessed of a fragrance little inferior to that of the mezereon; but they are seldom succeeded by seeds in England.

4. Tartonraira, the oval leaved daphne or tartonraira, a very low deciduous shrub, is a native of France and Italy. This rises with a woody stalk to the height of about two feet. The branches are numerous, irregular, tough, and covered with a light-brown-coloured bark. The leaves are oval, very small, soft to the touch, and shining. The flowers are produced in clusters from the sides of the stalks: They are white, come out in June, and are succeeded by roundish berries which seldom ripen in England. This sort should have a dry soil and warm situation.

5. Alpina, the alpine daphne or chamelæa, is a low deciduous shrub native of the Alps, Geneva, Italy, and Austria. This will grow up to the height of about a yard. The leaves are spear-shaped, obtuse, and hoary underneath. The flowers come out in clusters from the sides of the branches, and are very fragrant: They appear in March, and are succeeded by red berries that ripen in September.

6. Thymelæa, the milkwort-leaved daphne or the thymelæa;

Daphne. thymelæa; a low deciduous shrub, native of Spain and the south of France. The thymelæa will grow up to the height of a yard. The stalks of this species are upright, branched, and covered with a light-brown bark. The leaves are spear-shaped, smooth, and in some respect resemble those of milk-wort. The flowers are produced in clusters from the sides of the stalks: They are of a greenish colour, have no foot-stalks, appear in March, and are succeeded by small yellowish berries, which will be ripe in August. This sort requires a dry soil and a warm situation.

7. Vilosa, the hairy-leaved daphne, a very low deciduous shrub, native of Spain and Portugal. The stalks are ligneous, about two feet high, and send forth branches alternately from the sides. The leaves are spear-shaped, plane, hairy on both sides, and grow on very short footstalks. The flowers have very narrow tubes, are small and make no great show: They come out in June, and are not succeeded by ripe seeds in England. This shrub, in some situations, retains its leaves all winter in such beauty as to cause it to be ranked among the low-growing evergreens; but as in others it is sometimes shattered with the first bleak winds, it is left to the gardener whether to place this shrub among the deciduous trees or evergreens.

8. Laureola, the spurge laurel or evergreen daphne; a low evergreen shrub, common in some parts of England, also in Switzerland and France. This shrub seldom grows more than a yard or four feet high; it sends out many branches from the bottom, and these are covered with a smooth light-brown bark that is very thick. The bark on the younger branches is smooth and green; and these are very closely garnished with leaves of a delightful strong lucid green colour. These leaves sit close to the branches, and are produced in such plenty, that they have the appearance, at a small distance, of clusters at the ends of the branches. They are spear-shaped, shining, smooth, and thick: their edges are entire. Hanbury extols this plant with a degree of enthusiasm: continuing, "and this is another excellent property of this tree, that it is thus possessed of such delightful leaves for its ornament. These leaves, when growing under the drip of trees, spread open, and exhibit their green pure and untarnished, in its natural colour; when planted singly in exposed places, they naturally turn back with a kind of twist, and the natural green of the leaf is often alloyed with a brownish tinge. This shrub is also valuable on account of its flowers; not because they make any great show, but from their fragrance, and the time they appear; for it will be in blow the beginning of January, and will continue so until the middle or latter end of April before the flowers fall off; during which time they never fail to diffuse abroad their agreeable odours which are refreshing and inoffensive. In the evenings especially, they are more than commonly liberal; insomuch that a few plants will often perfume the whole end of a garden; and when this happens early, before many flowers appear, the unskilful in flowers, perceiving an uncommon fragrance, are at once struck with surprize, and immediately begin enquiring from whence it can proceed. Neither are its odours confined to a garden only; but, when planted near windows, they will enter parlours, and ascend even into bed-chambers, to the great com-

fort of the possessor, and surprize of every fresh visitor." These flowers make but little show; for they are small, and of a greenish-yellow. They are produced amongst the leaves from the sides of the stalks, in small clusters, and will often be so hid by them, as to be unnoticed by any but the curious. They are succeeded by oval berries, which are first green, and afterwards black when ripe. These berries will be in such plenty as to be very ornamental; but will soon be eaten up by the birds; which is another good property of this tree, as it invites the different sorts of whistling birds to flock where it is planted in great plenty.

Propagation. The mezereon ripens its seeds in Britain, which may at any time be easily obtained, if they are secured from birds. Previous therefore to sowing, the healthiest and most thriving trees of the white, the pale, and the deep-red sorts, should be marked out, and as soon as the berries begin to alter from green, they must be covered with nets, to secure them from the birds, which would otherwise devour them all. The berries will be ripe in July; and due observance must be had to pick them up as they fall from the trees, and to keep the sorts separate. As soon as they are all fallen, or you have enough for your purpose, they may then be sown. The best soil for these plants is a good fat black earth, such as is found in kitchen-gardens that have been well manured and managed for many years. In such soil as this they will not only come up better, but will grow to a greater height than in any other. No particular regard need be paid to the situation; for as this tree is a native of the northern parts of Europe, it will grow in a north border, and flourish there as well as in a south; nay, if there be any difference the north border is more eligible than the south. The ground being made fine, and cleared of roots of all sorts, the seeds should be sown hardly half an inch depth. The mould being riddled over them that depth, let the beds be netted up, and they will want no other attention until the spring. These seeds will sometimes remain in the ground two years; but for the most part they come up the spring after sowing; and the seedlings will require no other care during the summer than weeding, and gentle watering in dry weather. After they have been in the seed-bed one year, the strongest may be drawn out, and planted in the nursery, to make room for the others; though, if they do not come up very close, it would be as well to let them remain in the seed-bed until the second autumn: when they should be taken up with care, and planted in beds at a foot asunder each way. This will be distance enough for these low-growing shrubs. October is the best month for planting them out finally; for although they will grow if removed any time between then and spring, yet that will certainly be a more proper season than when they are in full blow. Such is the culture of this shrub. The other species of this genus require a different management.

The spurge laurel is propagated by seeds, in the same manner, as the common mezereon. The seeds must be preserved from the birds by nets, until they are ripe. Soon after, they must be sown as is directed for the mezereon. They will often be two years before they come up; during which time, and afterwards, they may have the same management as has
been

Daphne. been laid down for the common mezereon until they be finally set out. This shrub will grow in almost any soil or situation, but flourishes most under the shade and drip of taller plants, giving a peculiar cheerfulness to the bottoms of groves and clamps in winter.

All the other sorts are with some difficulty propagated and retained. They will by no means bear removing, even when seedlings; and if ever this is attempted, not one in an hundred must be expected to grow. They are raised by seeds, which are received from the places where they grow naturally; and he who is desirous of having these plants, must manage them in the following manner: Let a compost be prepared of these equal divisions; one-fourth part of lime-rubbish; one-fourth part of drift or sea sand; another of splinters of rocks, some broad and others smaller; and the other part of maiden earth from a rich pasture. Let these be mixed all together, and filled into largish pots. In each of these pots put a seed or two, about half an inch deep, in the finest of the mould. We receive the seeds in the spring; so that there is little hopes of their coming up until the spring following: Let, therefore, the pots be set in the shade all the summer, and in the autumn removed into a warm situation, where they may enjoy every influence of the sun's rays all winter. In March let them be plunged into a moderate hot-bed, and the plants will soon after appear. This bed will cause them to be strong plants by the autumn; and when all danger of frost is over, they may be uncovered wholly, and permitted to enjoy the open air. In the autumn, they should be removed into the greenhouse, or set under an hot-bed frame all winter; and in spring they should be placed where they are to continue, moulding them up the height of the pot; the pots being sufficiently broken to make way for their roots as they shoot, and then left to nature.—The situation of the four tenderer sorts must be well sheltered: and if it be naturally rocky, sandy, and dry, it will be the better; for in the places where they grow naturally, they strike into the crevices of rocks, and flourish where there is hardly any appearance of soil.

This is one method of obtaining these shrubs. Another way is, by sowing the seeds in the places where they are to remain. The situation and nature of the soil should be as near that above described as possible; and the mould should be made fine in some places, and a seed or two sown in each. After this, pegs should be stuck down on each side of them, to direct to the places where they are sown. The exactest care must be observed, all summer to pull up the weeds as often as they appear; for if they are permitted to get strong, and have great roots they will pull up the seeds with them. In the spring following, if the seeds are good, the plants will appear. During the summer, they should be watered in dry weather; and, for the first winter or two, should have some furze-bushes pricked all round them, at a proper distance, which will break the keen edge of the frosty winds, and preserve the young plants until they are strong enough to defend themselves.

The cneorum and the alpine chamelæa are very hardy, and will grow in the coldest situation; but the other sorts should have a warm soil, and a well-sheltered

site, or they will be subject to be destroyed in bad weather.

Medicinal properties. The root of the mezereon was long used in the Lisbon diet-drink for venereal complaints, particularly nodes and other symptoms resisting the use of mercury; but with the composition of this article we were unacquainted, till an account of it was published in the Edinburgh Physical Essays, by Dr Donald Monro of London. On chewing it a little, it proves very pungent, and its acrimony is accumulated about the fances, and is very durable. It is employed chiefly under the form of decoction; and it enters the decoctum sarsaparillæ compositum of the London college; but it has also been used in powder combined with some inactive one, as that of liquorice root. It is apt to occasion vomiting and purging; so must be begun in grain-doses, and gradually increased. It is often usefully combined with mercury. The bark of the root contains most acrimony, though some prefer the woody part. Mezereon has also been used with good effects in tumors and cutaneous eruptions not venereal. The whole plant is very corrosive. Six of the berries will kill a wolf. A woman gave 12 grains of the berries to her daughter who had a quartan ague; she vomited blood, and died immediately.

DAPHNEPHORIA, a festival in honour of Apollo, celebrated every ninth year by the Bœotians. It was then usual to adorn an olive bough with garlands of laurel and other flowers, and placed on the top a brazen globe, on which were suspended smaller ones. In the middle was placed a number of crowns, and a globe of inferior size, and the bottom was adorned with a saffron coloured garment. The globe on the top represented the sun or Apollo. That in the middle was an emblem of the moon, and the others of the stars. The crowns, which were 65 in number, represented the sun's annual revolution. This bough was carried in solemn procession by a beautiful youth of an illustrious family, and whose parents were both living. The youth was dressed in rich garments which reached to the ground, his hair hung loose and dishevelled, his head was covered with a golden crown, and he wore on his feet shoes called *Iphicratida*, from Iphicrates an Athenian, who first invented them. He was called *Δαφνηφορες*, laurel-bearer; and at that time he executed the office of priest of Apollo. He was preceded by one of his nearest relations, bearing a rod adorned with garlands, and behind him followed a train of virgins with branches in their hands. In this order the procession advanced as far as the temple of Apollo, surnamed Ismenius, where supplicatory hymns were sung to the god.—This festival owes its origin to the following circumstance: When an oracle advised the Ætolians, who inhabited Arne and the adjacent country, to abandon their ancient possessions and go in quest of a settlement, they invaded the Theban territories, which at that time were pillaged by an army of Pelasgians. As the celebration of Apollo's festival was near, both nations, who religiously observed it, laid aside all hostilities, and according to custom cut down laurel boughs from mount Helicon, and in the neighbourhood of the river Melas, and walked in procession in honour of the divinity. The day that this solemnity was observed, Polematus the general of the Bœotian army saw a youth in a dream, that presented him with a complete suit of armour, and commanded

Daphne,
Daphne-
phoria.

Dapifer commanded the Bœotians to offer solemn prayers to Apollo, and walk in procession with laurel boughs in their hands every ninth year. Three days after this dream, the Bœotian general made a sally and cut off the greatest part of the besiegers, who were compelled by this blow to relinquish their enterprise. Polematas immediately instituted a novennial festival to the god, who seemed to be the patron of the Bœotians.

DAPIFER, the dignity or office of grand-master of a prince's household. This title was given by the Emperor of Constantinople to the Czar of Russia as a testimony of favour. In France the like officer was instituted by Charlemagne, under the title of *dapiferat*; and the dignity of dapifer is still subsisting in Germany, the elector of Bavaria assuming the title of *arch dapifer of the empire*, whose office is, at the coronation of the emperor, to carry the first dish of meat to table on horseback.

DAPPLE-BAY, in the manege: When bay horses have marks of a dark bay, they are called *dapple-bays*.

DAPPLE Black: When a black horse has got spots or marks more black or shining than the rest of his skin, he is called a *dapple-black*.

DARANTASIA, (anc. geog.), called *Forum Glau-dii* by the Romans; a town of the Centrones in Gallia Narbonensis, situated between Lemincum and Augusta Prætoria. Now *Mousters*, and *Mousters en Tarantaise*, in Savoy.

DARAPTI, among logicians, one of the modes of syllogisms of the third figure, whose premises are universal affirmatives, and the conclusion is a particular affirmative: thus,

DAR- Every body is divisible;

AP- Every body is a substance;

TI, Therefore, some substance is divisible.

DARDA, a town and fort of Lower Hungary, built by the Turks in 1686, and taken by the Imperialists the next year, in whose hands it remains. It is seated on the rive Draw, 10 miles from its confluence with the Danube, and at the end of the bridge of Esfeck. E. Long. 19. 10. N. Lat. 45. 45.

DARDANELLES, two ancient and strong castles of Turkey, one of which is in Romania, and the other in Natolia, on each side the canal formerly called the *Hellespont*. This keeps up a communication with the Archipelago, and the Propontis or sea of Marmora. The mouth of the canal is four miles and a half over: and the castles were built in 1659, to secure the Turkish fleet from the insults of the Venetians. The ships that come from Constantinople are searched at the castle on the side of Natolia, to see what they have on board.

DARDANIA, (anc. geog.), a district of Moesia Superior to the South. Now the south part of Servia, towards the confines of Macedonia and Illyricum, *Dardani* was the name of the people, who seem to have been descendants of the *Dardani* of Troas. Also a small district of Troas, along the Hellespont, (Mela, Virgil.) — And the ancient name of *Samothracia*, (Pliny); from *Dardanus*, who removed thither.

DARDANIUM PROMONTORIUM, (Pliny); *Dardanis*, (Strabo): A promontory of Troas, near Abydos, running out into the Hellespont; with a cognominal town at it, called also *Dardanus* and *Dardanium*: All which give name to the *Dardanelles*.

DARDANUS, a son of Jupiter and Electra, who, after the death of his brother Jason, left Samothrace his country, and passed into Asia Minor, where he married Batia, the daughter of Teucris, king of Teucris. After the death of his father-in-law he ascended the throne, and reigned 62 years. He built the city of Dardania, and was reckoned the founder of the kingdom of Troy. He was succeeded by Erichthonius. According to some, Corybas, his nephew, accompanied him to Teucris, where he introduced the worship of Cybele. Dardanus taught his subjects to worship Minerva, and he gave them two statues of the goddess, one of which is well known by the name of *Palladium*. According to Virgil, Dardanus was an Italian by origin.

DARE, in ichthyology, the same with dace. See **DACE**.

DARES, a Phrygian, who lived during the Trojan war, in which he was engaged, and of which he wrote the history in Greek. This history was extant in the age of Ælian; the Latin translation, now extant, is universally believed to be spurious, though it is attributed by some to Cornelius Nepos. This translation first made its appearance A. D. 1477, at Milan. Homer speaks of him, *Il. v. 10. 2nd 27.*

DARIC, in antiquity, a famous piece of gold, first coined by Darius the Mede about 538 years before Christ; probably during his stay at Babylon, out of the vast quantity of gold which had been accumulated in the treasury. From thence it was dispersed over the east, and also into Greece; so that the Persian daric, which was also called *stater*, was the gold coin best known in Athens in ancient times. According to Dr Bernard, it weighed two grains more than one of our guineas; but as it was very fine, and contained little alloy, it may be reckoned worth about 25s. sterling. Plutarch informs us, that the darics were stamped on one side with an archer clothed in a long robe, and crowned with a spiked crown, holding a bow in his left hand and an arrow in his right; and on the other side with the effigies of Darius. All the other pieces of gold of the same weight and value that were coined by the succeeding kings, both of the Persian and Macedonian race, were called *darics*, from Darius, in whose reign this coin commenced. Of these there were whole darics and half darics; and they are called in those parts of Scripture written after the Babylonish captivity, *adarkonim*; and by the talmudists, *darkonoth*. Greaves says that the daric is still found in Persia; but it is certainly very scarce and perhaps of doubtful antiquity.

DARIEN, or the Isthmus of Panama, is a province between South and North America, being a narrow isthmus, or neck of land, which joins them together. It is bounded on the north by the North Sea, on the South by the South Sea, on the east by the gulph or river of Darien, and on the west by another part of the South Sea and the province of Veragua. It lies in the form of a bow, or crescent, about the great bay of Panama, in the South Sea; and is 300 miles in length and 60 in breadth. This province is not the richest, but is of the greatest importance to Spain, and has been the scene of more actions than any other in America. The wealth of Peru is brought hither, and from hence exported to Europe. This has induced many enterprising people to make attempts on Panama,

Dardanus
||
Darien.

Darien. nama, Porto-Bello, and other towns of this province, in hopes of obtaining a rich booty.

The Scotch got possession of part of this province in 1699, and attempted to form an establishment which would have proved one of the most useful and important that ever was projected. Of the rise, progress, and catastrophe, of this well-imagined, but ill-fated, undertaking, Sir John Dalrymple, in the 2d volume of his *Memoirs of Great Britain and Ireland*, has given a very interesting account, authenticated in every particular by unquestionable documents. The projector and leader of the Darien expedition was a clergyman of the name of *Paterfon*; who having a violent propensity to see foreign countries, he made his profession the instrument of indulging it by going to the new western world, under the pretence of converting the Indians to the religion of the old. In his courts there he became acquainted with Cap. Dampier and Mr Waffer, who afterwards published, the one his *Voyages* and the other his *Travels*, in the region where the separation is narrowest between the Atlantic and the South Seas; and both of whom, particularly the first, appear by their books to have been men of considerable observation. But he got much more knowledge from men who could neither write nor read, by cultivating the acquaintance of some of the old Buccaneers, who after surviving their glories and their crimes, still in the extremity of age and misfortune, recounted with transport the ease with which they had passed and repassed from the one sea to the other, sometimes in hundreds together, and driving strings of mules before them loaded with the plunder of friends and of foes. Paterfon having examined the places, satisfied himself, that on the Isthmus Darien there was a tract of country running across from the Atlantic to the South Sea, which the Spaniards had never possessed, and inhabited by a people continually at war with them; that along the coast, on the Atlantic side, there lay a string of islands called the *Sambaloos*, uninhabited and full of natural strength and forests, from which last circumstance one of them was called the *island of the Pines*; that the seas there were filled with turtle and the manatee or sea-cow; that midway between Porto-Bello and Carthagena, but near 50 leagues distant from either, at a place called *Ata*, in the mouth of the river of Darien, there was a natural harbour, capable of receiving the greatest fleets, and defended from storms by other islands which covered the mouth of it, and from enemies by a promontory which commanded the passage, and by hidden rocks in the passage itself; that on the other side of the isthmus, and in the same tract of country, there were natural harbours, equally capacious and well defended; that the two seas were connected by a ridge of hills, which by their height, created a temperate climate in the midst of the most sultry latitudes, and were sheltered by forests, yet not rendered damp by them, because the trees grew at a distance from each other, having very little under-wood; that, contrary to the barren nature of hilly countries, the soil was of a black mould two or three feet deep, and producing spontaneously the fine tropical fruits and plants, and roots and herbs; that roads could be made with ease along the ridge, by which mules, and even carriages, might pass from the one sea to the other in the space

VOL. V.

of a day; and consequently this passage seemed to be pointed out by the finger of nature, as a common centre to connect together the trade and intercourse of the universe.

Paterfon knew that ships which stretch in a straight line from one point to another, and with one wind, run less risks, and require fewer hands, than ships which pass through many latitudes, turn with many coasts, and require many winds; in evidence of which, vessels of seven or eight hundred tons burden are often to be found in the South Seas, navigated by no more than eight or ten hands, because these hands have little else to do than to set their sails when they begin their voyage, and to take them in when they end it; that as soon as ships from Britain got so far south as to reach the trade-wind, which never varies, that wind would carry them to Darien, and the same wind would carry ships from the bay of Panama, on the opposite side of the isthmus, to the East-Indies; that as soon as ships coming from the East-Indies to the bay of Panama got so far north as the latitude of 40, to reach the westerly winds, which, about that latitude, blow almost as regularly from the west as the trade-winds do from the east, these winds would carry them, in the track of the Spanish Acapulco ships, to the coast of Mexico; from whence the land-wind, which blows for ever from the north to the south, would carry them along the coast of Mexico into the bay of Panama. So that in going from Britain, ships would encounter no uncertain winds, except during their passage south into the latitude of the trade-wind; in coming from India to the bay of Panama no uncertain winds, except in their passage north to the latitude of the westerly winds; and in going from the other side of the isthmus to the east, no uncertain wind whatsoever. —Gold was seen by Paterfon in some places of the isthmus; and hence an island on the Atlantic side was called the *Golden Island*, and a river on the side to the South Sea was called the *Golden River*; but these were objects which he regarded not at that time, because far greater were in his eye; the removing of distances, the drawing nations near to each other, the preservation of the valuable lives of seamen, and the saving in freight, so important to merchants, and in time so important to them, and to an animal whose life is of so short a duration as that of man.

By this obscure Scotsman, a project was formed to settle, on this neglected spot, a great and powerful colony; not as other colonies have for the most part been settled, by chance, and unprotected by the country from whence they went; but by system, upon foresight, and to receive the ample protection of those governments to whom he was to offer his project. And certainly no greater idea has been formed since the time of Columbus.

Paterfon's original intention was to offer his project to England, as the country which had most interest in it, not only from the benefit common to all nations, of shortening the length of voyages to the East Indies, but by the effect which it would have had to connect the interests of her European, West Indian, American, African, and East Indian trade. But Paterfon having few acquaintance, and no protection in London, thought of drawing the public eye upon him, and ingratiating himself

4 R

himself

Darien.

Darien. himself with monied men, and with great men, by assisting them to model a project, which was at that time in embryo, for erecting the Bank of England. But that happened to him which has happened to many in his situation: the persons to whom he applied made use of his ideas, took the honour of them to themselves, were civil to him for a while, and neglected him afterwards. He therefore communicated his project of a colony only to a few persons in London, and these few discouraged him.

He next made offer of his project to the Dutch, the Hamburghers, and the Elector of Braudenburgh; because, by means of the passage of the Rhine and Elbe through their states, he thought, that the great additional quantities of East Indian and American goods, which his colony would bring into Europe, would be distributed through Germany. The Dutch and Hamburgh merchants, who had most interest in the subject of his visit, heard him with indifference: The Elector, who had very little interest in it, received him with honour and kindness. But court-arts and false reports lost him even that prince's favour.

Paterfon, on his return to London, formed a friendship with Mr Fletcher of Salton, whose mind was inflamed with the love of public good, and all of whose ideas to procure it had a sublimity in them. Fletcher brought Paterfon down to Scotland with him, presented him to the Marquis of Tweeddale, then Minister for Scotland; and then, with that power which a vehement spirit always possesses over a diffident one, persuaded the Marquis, by arguments of public good, and the honour which would redound to his administration, to adopt the project. Lord Stair and Mr Johnston, the two secretaries of state, patronised those abilities in Paterfon which they possessed in themselves: and the Lord Advocate Sir James Stuart, the same man who had adjusted the Prince of Orange's declaration at the Revolution, whose son was married to a niece of Lord Stair, went naturally along with his connections. These persons, in June 1695, procured a statute from parliament, and afterwards a charter from the crown in terms of it, for creating a trading company to Africa and the new world, with power to plant colonies and build forts, with consent of the inhabitants, in places not possessed by other European nations.

Paterfon, now finding the ground firm under him, and that he was supported by almost all the power and talents of his country, the character of Fletcher, and the sanction of an act of parliament and royal charter, threw his project boldly upon the public, and opened a subscription for a company. The frenzy of the Scots nation to sign the solemn league and covenant never exceeded the rapidity with which they ran to subscribe to the Darien Company. The nobility, the gentry, the merchants, the people, the royal burghs without the exception of one, most of the other public bodies, subscribed. Young women threw their little fortunes into the stock, widows sold their jointures to get the command of money for the same purpose. Almost in an instant L. 400,000 were subscribed in Scotland, altho' it be now known, that there was not at that time above L. 800,000 of cash in the kingdom. The famous Mr Law, then a youth, afterwards confessed, that the facility with which he saw the passion of speculation com-

municate itself from all to all, satisfied him of the possibility of producing the same effect from the same cause, but upon a larger scale, when the Duke of Orleans, in the year of the Mississippi, engaged him against his will to turn his bank into a bubble. Paterfon's project, which had been received by strangers with fears when opened to them in private, filled them with hopes when it came to them upon the wings of public fame: For Colonel Erskine, son to Lord Cardross, and Mr Haldane of Gleneagles, the one a generous branch of a generous stem, and the other a country gentleman of fortune and character, having been deputed to receive subscriptions in England and on the continent, the English subscribed L. 300,000, and the Dutch and Hamburghers L. 200,000 more.

In the mean time the jealousy of trade (continues our author), which has done more mischief to the trade of England than all other causes put together, created an alarm in England; and the Houses of Lords and Commons, without previous inquiry or reflection, on the 13th of December 1695, concurred in a joint address to the King, against the establishment of the Darien Company as detrimental to the interest of the East India company. Soon after, the commons impeached some of their own countrymen for being instrumental in erecting the company and also some of the Scots nation, one of whom was a peer, Lord Belhaven; that is to say, they arraigned the subjects of another country for making use of the laws of their own. Among 600 legislators, not one had the happy ray of genius to propose a committee of both parliaments, to inquire into the principles and consequences of the establishment; and if these should, upon inquiry, be found that the benefit of it should be communicated, by a participation of rights, to both nations. The king's answer was, "That he had been ill advised in Scotland." He soon after changed his Scottish ministers, and sent orders to his resident at Hamburgh to present a memorial to the senate, in which he disowned the company and warned them against all connections with it. The senate sent the memorial to the assembly of merchants, who returned it with the following spirited answer: "We look upon it as a very strange thing, that the King of Britain should offer to hinder us, who are a free people, to trade with whom we please; but are amazed to think that he would hinder us from joining with his own subjects in Scotland, to whom he had lately given such large privileges, by so solemn an act of parliament." But merchants, though mighty prone to passion, are easily intimidated: The Dutch, Hamburg, and London merchants withdrew their subscriptions.

The Scots, not discouraged, were rather animated by this oppression; for they converted it into a proof of the envy of the English, and of their consciousness of the great advantages which were to flow to Scotland from the colony. The company proceeded to build six ships in Holland, from 36 to 60 guns, and they engaged 1200 men for the colony; among whom were younger sons of many of the noble and most ancient families of Scotland, and 60 officers who had been disbanded at the peace, who carried with them such of their private men, generally raised on their own, or the estates of their relations, as they knew to be faithful and brave; and most of these were Highlanders. The Scots.

Darien.

Darien. Scots parliament, on the 5th August 1698, unanimously addressed the King to support the company. The Lord President Sir Hugh Dalrymple, brother to Lord Stair and head of the bench, and the Lord Advocate Sir James Stuart, head of the bar, jointly drew memorials to the King, able in point of argument, information, and arrangement; in which they defended the rights of the company upon the principles of constitutional and of public law. And neighbouring nations, with a mixture of surprise and respect, saw the poorest kingdom of Europe sending forth the most gallant and the most numerous colony that had ever gone from the old to the new world.

On the 26th day of July of the year 1698, the whole city of Edinburgh poured down upon Leith, to see the colony depart, amidst the tears and prayers and praises of relations and friends and of their countrymen. Many seamen and soldiers, whose services had been refused, because more had offered themselves than were needed, were found hid in the ships, and, when ordered ashore, clung to the ropes and timbers, imploring to go without reward with their companions. Twelve hundred men sailed in five stout ships, and arrived at Darien in two months, with the loss of only 15 of their people. At that time it was in their power, most of whom were well born, and all of them hardily bred, and inured to the fatigues and dangers of the late war, to have gone from the northmost part of Mexico to the southmost of Chili, and to have overturned the whole empire of Spain in the South Seas: But modest, respecting their own and their country's character, and afraid of being accused that they had plunder, and not a settlement, in view, they began with purchasing lands from the natives, and sending messages of amity to the Spanish governors within their reach: and then fixed their station at Acta, calling it *New St Andrew*, from the name of the tutelar saint of Scotland, and the country itself *New Caledonia*. One of the sides of the harbour being formed by a long narrow neck of land which ran into the sea, they cut it across so as to join the ocean and the harbour. Within this defence they erected their fort, planting upon it 50 pieces of cannon. On the other side of the harbour there was a mountain a mile high, on which they placed a watch-house, which, in the rarefied air within the tropics, so favourable for vision, gave them an immense range of prospect, to prevent all surprise. To this place, it was observed, that the Highlanders often repaired, to enjoy a cool air, and to talk of their friends they had left behind in their hills; friends whose minds were as high as their mountains. The first public act of the colony was to publish a declaration of freedom of trade and religion to all nations. This luminous idea originated with Paterson.

But the Dutch East India Company having pressed the king, in concurrence with his English subjects, to prevent the settlement at Darien, orders had been sent from England to the governors of the West Indian and American colonies, to issue proclamations against giving assistance, or even to hold correspondence with the colony; and these were more or less harshly expressed, according to the tempers of the different governors. The Scots, trusting to far different treatment, and to the supplies which they expected from those colonies, had not brought provisions enough

with them, they fell into diseases from bad food and from want of food. But the more generous savages, by hunting and fishing for them, gave them that relief which fellow Britons refused. They lingered eight months, awaiting, but in vain, for assistance from Scotland; and almost all of them either died out or quitted the settlement. Paterson, who had been the first that entered the ship at Leith, was the last who went on board at Darien.

During the space of two years, while the establishment of this colony had been in agitation, Spain had made no complaint to England or Scotland against it. The Darien council even averred in their papers (which are in the Advocates Library), that the right of the company was debated before the king, in presence of the Spanish ambassador, before the colony left Scotland. But now, on the 3d of May 1696, the Spanish ambassador at London presented a memorial to the king, which complained of the settlement at Darien as an inroad on the rights of his master.

The Scots, ignorant of the misfortunes of their colony, but provoked at this memorial, sent out another colony soon after of 1300 men, to support an establishment which was now no more. But this last expedition having been more hastily prepared than the first, was unlucky in its passage. One of the ships was lost at sea, many men died on ship-board, and the rest arrived at different times, broken in their health and dispirited, when they heard the fate of those who had gone before them.—Added to the misfortunes of the first colony, the second had a misfortune peculiar to itself: The General Assembly of the Church of Scotland sent out four ministers, with orders, “to take charge of the souls of the colony, and to erect a presbytery, with a moderator, clerk, and record of proceedings: to appoint ruling elders, deacons, overseers of the manners of the people, and assistants in the exercise of church discipline and government, and to hold regular kirk-sessions.” When they arrived, the officers and gentlemen were occupied in building houses for themselves with their own hands, because there was no help to be got from others; yet the four ministers complained grievously that the council did not order houses to be immediately built for their accommodation. They had not had the precaution to bring with them letters of recommendation from the directors at home to the council abroad. On these accounts, not meeting with all the attention they expected from the higher, they paid court to the inferior ranks of the colonists, and by that means threw divisions into the colony. They exhausted the spirits of the people, by requiring their attendance at sermon four or five hours at a stretch, relieving each other by preaching alternately, but allowing no relief to their hearers. The employment of one of the days set aside for religious exercise, which was a Wednesday, they divided into three parts, thanksgiving, humiliation, and supplication, in which three ministers followed each other. And as the service of the church of Scotland consists of a lecture with a comment, a sermon, two prayers, three psalms, and a blessing, the work of that day, upon an average of the length of the service of that age, could not take up less than twelve hours: during which space of time the colony was collected, and kept close together in the guard-room, which was used as

Darien.

Darien. a church, in a tropical climate, and in a sickly season. They presented a paper to the council, and made it public, requiring them to set aside a day for a solemn fasting and humiliation, and containing their reasons for their requisition; in which, under pretence of enumerating the sins of the people, they poured abuse on their rulers. They damped the courage of the people, by continually presenting hell to them as the termination of life to most men, because most men are sinners. Carrying the presbyterian doctrine of predestination to extremes, they stopped all exertions, by showing that the consequence of them depended not on those by whom they were made. They converted the numberless accidents to which soldiers and seamen are exposed, into immediate judgments of God against their sins. And having resolved to quit the settlement, they, in excuse for their doing so, wrote bitter letters to the General Assembly against the characters of the colonists, and the advantages of the colony itself.

One of them, in a kind of history of the colony which he published, with a savage triumph exulted over the misfortunes of his countrymen in the following words:—"They were such a rude company, that I believe Sodom never declared such impudence in sinning as they. Any observant eye might see, that they were running the way they went: hell and judgment was to be seen upon them, and in them, before the time: Their cup was full; it could hold no more: They were ripe; they must be cut down with the sickle of the wrath of God."

The last party that joined the second colony at Darien, after it had been three months settled, was Captain Campbell of Finab, with a company of the people of his own estate, whom he had commanded in Flanders, and whom he carried to Darien in his own ship. On their arrival at New St Andrew, they found intelligence had been lately received, that a Spanish force of 1600 men, which had been brought from the coast of the South Sea, lay encamped at Tubucantee, waiting there till a Spanish squadron of eleven ships which was expected should arrive, when they were jointly to attack the fort. The military command was offered to Captain Campbell, in compliment to his reputation and to his birth, who was descended from the families of Breadalbane and Athole. In order to prevent a joint attack, he resolved to attack first; and therefore, on the second day after his arrival, he marched with 200 men to Tubucantee, before his arrival was known to the enemy, stormed the camp in the night-time, dissipated the Spanish force with much slaughter, and returned to the fort the fifth day: But he found the Spanish ships before the harbour, their troops landed, and almost all hopes of help or provision cut off; yet he stood a siege near six weeks, till almost all the officers were dead, the enemy by their approaches had cut off his wells, and his balls were so far expended, that he was obliged to melt the pewter dishes of the garrison into balls. The garrison then capitulated, and obtained not only the common honours of war and security for the property of the company, but, as if they had been conquerors, exacted hostages for performance of the conditions. Captain Campbell alone desired to be excepted from the capitulation, saying, he was sure the Spaniards could not forgive him the mischief which he so lately had done them. The brave, by their cou-

rage, often escape that death which they seem to provoke: Captain Campbell made his escape in his vessel, and, stopping nowhere, arrived safely at New York, and from thence to Scotland, where the company presented him with a gold medal, in which his virtue was commemorated, to inflame his family with the love of heroic actions. And the Lord Lyon King at Arms, whose office it is in Scotland (and such offices should be every where) to confer badges of distinction according to the rules of heraldry upon honourable actions, give him a Highlander and an Indian for supporters to his coat of arms.

A harder fate attended those whom Captain Campbell left at Darien. They were so weak in their health as not to be able to weigh up the anchors of the Rising Sun, one of their ships, which carried 60 guns: But the generous Spaniards assisted them. In going out of the harbour she ran aground: The prey was tempting; and to obtain it, the Spaniards had only to stand by and look on: but showed that mercy to the Scots in distress, which one of the countrymen of those Scots, General Elliot, returned to the posterity of the Spaniards at the end of the late conflagration at the siege of Gibraltar. The Darien ships being leaky and weakly manned, were obliged in their voyage to take shelter in different ports belonging to Spain and England. The Spaniards in the new world showed them kindness; the English governments showed them none; and in one place one of their ships was seized and detained. Of these only Captain Campbell's ship and another small one were saved: The Royal Sun was lost on the bar of Charlestown; and of the colony, not more than 30, saved from war, shipwreck, or disease, ever saw their country again.

Paterfon, who had stood the blow, could not stand the reflection of misfortune. He was seized with a lunacy in his passage home after the ruin of the first colony; but he recovered in his own country, where his spirit, still ardent and unbroke, presented a new plan to the company, founded on the idea of King William, that England should have the joint dominion of the settlement with Scotland.

He survived many years in Scotland, pitied, respected, but neglected. After the union of the two kingdoms, he claimed reparation of his losses from the equivalent-money given by England to the Darien Company, but got nothing; because a grant to him from a public fund would have been only an act of humanity, not a political job.

Thus ended the colony of Darien. Men look into the works of poets for subjects of satire; but they are more often to be found in the records of history. The application of the Dutch to King William against the Darien Company, affords the surest of all proofs, that it was the interest of the British islands to support it. England, by the imprudence of ruining that settlement, lost the opportunity of gaining and continuing to herself the greatest commercial empire that probably ever will be upon earth. Had she treated with Scotland, in the hour of the distress of the company, for a joint possession of the settlement, or adopted the union of the kingdoms, which the sovereign of both proposed to them, that possession could certainly have been obtained. Had she treated with Spain to relinquish an imaginary right, or at least to give a passage

Darien. across the isthmus, upon receiving duties so high as to overbalance all the chance of loss by a contraband trade, she had probably obtained either the one or the other. Had she broke with Spain for the sake of gaining by force one of those favours, she would have lost far less than she afterwards did by carrying a war into that country for many years, to force a king upon the Spaniards against their will. Even a rupture with Spain for Darien, if it had proved successful, would have knit the two nations together by the most solid of ties, their mutual interest: for the English must then have depended upon Spain for the safety of their caravans by land, and the Spaniards upon England for the safety of their fleets by sea. Spain and England would have been bound together as Portugal and England have long been; and the Spanish treasures have failed, under the wings of English navies, from the Spanish main to Cadiz, in the same manner as the treasures of Portugal have failed under the same protection, sacred and untouched, from the Brazils to Lisbon.

It has been made a question, Whether King William behaved with his ordinary sincerity and steadiness, in the assurances of favour which he gave more than once to the company during their distresses. The following anecdote makes it probable, that there was a struggle in his breast between the part which he was obliged to act to please his English and Dutch at the expence of his Scots subjects and his own feelings. A provision ship of the first colony, in which were 30 gentlemen passengers, and some of them of noble birth, having been shipwrecked at Carthage, the Spaniards believing, or pretending to believe, that they were smugglers, cast them into a dungeon and threatened them with death. The company deputed Lord Basil Hamilton from Scotland to implore King William's protection for the prisoners. The king at first refused to see him, because he had not appeared at court when he was last in London. But when that difficulty was removed by explanation, an expression fell from the king which showed his sense of the generous conduct of another, although influenced by the English and Dutch East India Companies, he could not resolve to imitate it in his own. For Lord Basil's audience having been put off from time to time, but at last fixed to be in the council-chamber after a council was over, the king, who had forgot the appointment, was passing into another room, when Lord Basil placed himself in the passage, and said, "That he came commissioned by a great body of his majesty's subjects to lay their misfortunes at his feet; that he had a right to be heard, and would be heard." The king returned, listened with patience, gave instant orders to apply to Spain for redress; and then turning to those near him, said, "This young man is too bold, if any man can be too bold in his country's cause." I had this anecdote from the present Earl of Selkirk, grandson to Lord Basil.

King William's desertion of a company erected upon the faith of his own charter, and the English oppressions of it, were the reasons why so many of the Scots, during four successive reigns, disliked the cause of the Revolution and of the Union. And that dislike, joined to English discontents, brought upon both countries two rebellions, the expenditure of many millions of money, and (which is a far greater loss) the downfall of many of their noblest and most ancient fami-

lies.—*Sir John Dalrymple's Memoirs of Great Britain and Ireland*, vol. ii.

DARII, in logic, one of the modes of syllogism of the first figure, wherein the major proposition is an universal affirmative, and the minor and conclusion particular and affirmative: thus,

DA- Every thing that is moved, is moved by another;

RI- Some body is moved;

I, Therefore, some body is moved by another.

DARIORIGUM (anc. geog.), a town of the Veneti in Gallia Celtica; called in the Notitia Lugdunensis, *Civitas Venetum*, after the manner of the lower age. Now *Vannes*, or *Vennes*, in Brittany. W. Long. 2. 37. Lat. 47. 40.

DARIUS, the name of several kings of Persia. See (*History of*) **PERSIA**.

DARKING, a market-town of Surrey in England, situated ten miles east of Guilford. The market is noted for corn and provisions, more especially for fowls. W. Long. 8. 20. N. Lat. 51. 18.

DARKNESS, the absence, privation, or want of natural light. "Darkness was upon the face of the deep" (Gen. i. 2.); that is to say, the chaos was plunged in thick darkness, because hitherto the light was not created. One of the most terrible sorts of darkness was that which Moses brought upon Egypt as a plague to the inhabitants of it. The Septuagint, our translation of the Bible, and indeed most others, in explaining Moses's account of this darkness, render it, "a darkness which may be felt;" and the Vulgate has it, "a palpable darkness;" that is, a darkness consisting of black vapours and exhalations, so condensed that they might be perceived by the organs of feeling or seeing; but some commentators think that this is carrying the sense too far, since in such a medium as this mankind could not live an hour, much less for the space of three days, as the Egyptians are said to have done during the time this darkness lasted; and therefore they imagine, that instead of a darkness that may be felt, the Hebrew phrase may signify a darkness wherein men went groping and feeling about for every thing they wanted. Le Clerc is of this opinion, and thinks that Philo, in his life of Moses, understood the passage in its right sense. "For in this darkness (says he), whoever were in bed, durst not get up; and such as their natural occasions compelled to get up, went feeling about by the walls, or any thing they could lay hold on, as if they had been blind." What it was that occasioned this darkness, whether it was in the air or in the eyes; whether it was a suspension of light from the sun in that country, or a black thick vapour which totally intercepted it, there is reason to think that the description which the author of the book of Wisdom (xvii. 1, 2, 3, &c.) gives us of their inward terrors and consternation, is not altogether conjectural, viz. that they were not only prisoners of darkness, and fettered with the bonds of a long night, but were horribly astonished likewise, and troubled with strange apparitions; for while over them was spread an heavy night, they were to themselves more grievous than darkness.

During the last three hours that our Saviour hanged upon the cross, a darkness covered the face of the earth, to the great terror and amazement of the people present at his execution. This extraordinary alteration in the

Darii
||
Darkness.

Darlington the face of nature (says Dr Macknight, in his *Harmony of the Gospels*), was peculiarly proper, whilst the Sun of righteousness was withdrawing his beams from the land of Israel and from the world; not only because it was a miraculous testimony borne by God himself to his innocence; but also because it was a fit emblem of his departure and its effects, at least till his light shone out anew with additional splendour in the ministry of his apostles. The darkness which now covered Judea and the neighbouring countries, beginning about noon and continuing till Jesus expired, was not the effect of an ordinary eclipse of the sun: for that can never happen but at the new moon, whereas now it was full moon; not to mention, that the total darkness occasioned by eclipses of the sun never continues above twelve or fifteen minutes; wherefore it must have been produced by the divine power, in a manner we are not able to explain. Accordingly, Luke (xxiii. 44, 45.), after relating that there was darkness over all the earth, adds, "and the sun was darkened;" which perhaps may imply, that the darkness of the sun did not occasion, but proceeded from, the darkness that was over all the land. Further, the Christian writers, in their most ancient apologies to the Heathens, affirm, that as it was full moon at the passover when Christ was crucified, no such eclipse could happen by the course of nature. They observe also, that it was taken notice of as a prodigy by the Heathens themselves.

DARLINGTON, a town of the county of Durham, situated on a flat on the river Skerne, which falls into the Tees. It is a pretty large place, has several streets, and a spacious market-place. It gives title of earl to the Vane family. W. Long. 1. 15. N. Lat. 54. 30.

DARMSTADT, a town of Germany in the circle of the Upper Rhine, and capital of the Langravate of Heise-Darmstadt, with a handsome castle, where its own prince generally resides. It is seated on a river of the same name, in Long. 8. 40. N. Lat. 49. 50.

DARNEL, in botany. See **LOLIUM**.

DARNLEY (Lord). See (*History* of) **SCOTLAND**.

DARTFORD, a town of the county of Kent in England, seated on the river Darent not far from its influx into the Thames. E. Long. 0. 16. N. Lat. 51. 25.

DARTMOUTH, a sea-port town in Devonshire, seated on the river Dart, near its fall into the sea. It is a well frequented and populous place, having a commodious harbour, and a considerable trade by sea. The town is large and well built; but the streets are narrow and bad, though all paved. It has the title of an earldom, and sends two members to parliament. W. Long. 4. 0. N. Lat. 50. 25.

DARTOS, in anatomy, one of the coats which form the scrotum. It is called the *dartos muscle*; but Dr Hunter says, that no such muscle can be found, and Albinus takes no notice of it in his tables.

DASYPUS, the **ARMADILLO** or *Tatu*, in zoology; a genus of quadrupeds, belonging to the order of bruta. The dasypus has neither foreteeth nor dogteeth; it is covered with a hard bony shell, intersected with distinct moveable zones or belts: this shell covers

the head, the neck, the back, the flanks, and extends even to the extremity of the tail; the only parts to which it does not extend, are the throat, the breast, and the belly, which are covered with a whitish skin of a coarse grain, resembling that of a hen after the feathers are pulled off. The shell does not consist of one entire piece, like that of the tortoise; but is divided into separate belts, connected to each other by membranes, which enable the animal to move it, and even to roll itself up like a hedge-hog. The number of these belts does not depend on the age of the animal, as some have imagined; but is uniformly the same at all times, and serves to distinguish the different species. All the species of this animal were originally natives of America: they were entirely unknown to the ancients; and modern travellers mention them as peculiar to Mexico, Brasil, and the southern parts of America; though some indeed have confounded them with two species of manis or shell-lizard, which are found in the East Indies: others report that they are natives of Africa, because some of them have been transported from Brasil to the coast of Guinea, where a few have since been propagated: but they were never heard of in Europe, Asia, or Africa, till after the discovery of America.—They are all endowed with the faculty of extending and contracting their bodies, and of rolling themselves up like a ball, but not into so complete a sphere as the hedge-hog. They are very inoffensive animals, excepting when they get into gardens, where they devour the melons, potatoes, and others roots. They walk quickly; but can hardly be said to run or leap, so that they seldom escape the pursuit either of men or dogs. But nature has not left them altogether defenceless. They dig deep holes in the earth; and seldom go very far from their subterraneous habitations: upon any alarm they immediately go into their holes; but, when at too great a distance, they require but a few moments to make one. The hunters can hardly catch them by the tail before they sink their body in the ground; where they stick so close, that the tail frequently comes away and leaves the body in the earth; which obliges the hunters, when they want to take them alive and immutilated, to dilate the sides of the hole. When they are taken, and find that there is no resource, they instantly roll themselves up, and will not extend their bodies unless they are held near a fire. When in deep holes, there is no other method of making them come out, but by forcing in smoke or water. They keep in their holes through the day, and seldom go abroad in quest of subsistence but in the night. The hunters usually chase them with small dogs, which easily come up with them. When the dogs are near, the creatures instantly roll themselves up, and in this condition the hunters carry them off. However, if they be near a precipice they often escape both the dogs and hunters: they roll themselves up, and tumble down like a ball, without breaking their shell, or receiving any injury. The dasypus is a very fruitful animal: the female generally brings forth four young ones every month; which is the reason why the species are so numerous, notwithstanding they are so much fought after on account of the sweetness of their flesh. The Indians likewise make baskets, boxes, &c. of the shells which cover their heads.

Linnæus enumerates six species of dasypus, principally

Dasypus.

Data ||
Dative. pally distinguished by the number of their moveable belts. See Plate CLV.

DATA, among mathematicians, a term for such things or quantities as are given or known, in order to find other things thereby that are unknown. Euclid uses the word *data* (of which he hath a particular tract) for such spaces, lines, and angles as are given in magnitude, or to which we can assign others equal.

From the primary use of the word *data* in mathematics, it has been transplanted into other arts; as philosophy, medicine, &c. where it expresses any quantity, which, for the sake of a present calculation, is taken for granted to be such, without requiring an immediate proof for its certainty; called also the *given* quantity, number, or power. And hence also such things as are known, from whence either in natural philosophy, the animal mechanism, or the operation of medicines, we come to the knowledge of others unknown, are now frequently in physical writers called *data*.

DATE, an addition or appendage in writings, acts, instruments, letter, &c. expressing the day and month of the year when the act or letter was passed or signed; together with the place where the same was done. The word is formed from the Latin *datum* "given," the participle of *do* "I give."

Ancient deeds had no dates, but only the month and year, to signify that they were not made in haste, or in the space of a day, but upon longer and more mature deliberation. The king's grants began with these words, *Præsentibus & futuris*, &c. but the grants of private persons with *Omniibus præsentis literas inspecturis*, &c.

A deed is good, though it mentions no date or hath a false date; or even if it hath an impossible date, as the 30th of February; provided the real day of its being dated or given, that is, delivered, can be proved. *Blackst. Com. vol. ii. p. 304.*

DATE, the fruit of the great palm-tree. See **PHOENIX**.

DATI (Carlo), professor of polite learning at Florence. His native country became very famous, as well on account of his works as of the eulogies which have been bestowed on him by learned men. The chief work to which Dati applied himself, was *Della Pittura Antica*, of which he published an essay in the year 1667. He died in 1675, much lamented, as well for his humanity and amiable manners as for his parts and learning.

DATISCA, in botany: A genus of the dodecandria order, belonging to the dioecia class of plants; and in the natural method ranking under the 54th order, *Miscellaneæ*. The male calyx is pentaphyllous; there is no corolla; the antheræ are sessile, long, and 15 in number. The female calyx is bidented; no corolla; the styles three; the capsule triangular, three-horned, unilocular, pervious, polyspermous, inferior.

DATISI, in logic, a mode of syllogisms in the third figure, wherein the major is an universal affirmative, and the minor and conclusion particular affirmative propositions. For example,

DA- All who serve God are kings;

TI- Some who serve God are poor;

SI, Therefore, some who are poor are kings.

DATIVE, in grammar, the third case in the de-

clension of nouns; expressing the state or relation of a thing to whose profit or loss some other thing is referred. See **GRAMMAR**.

It is called *dative*, because usually governed by a verb implying something to be given to some person. As, *commodare Socrati*, "to lend to Socrates;" *utilis republicæ*, "useful to the commonwealth;" *perniciosus ecclesiæ*, "pernicious to the church."

In English, where we have properly no cases, this relation is expressed by the sign *to*, or *for*.

DATUM, or **DARUS**, (anc. geog.), a town of Thrace, situated between Neapolis and the river Nestus: A colony of the Thracians, according to Eustathius: who places it on the sea-coast, near the Strymon, in a rich and fruitful soil, famous for ship-building and mines of gold; hence the proverb *Δατος Αγαθον*, denoting prosperity and plenty, (Strabo.) Appian describes it as seated on a steep eminence, the whole of which it covered. It was taken by Philip of Macedon, who changed its name to Philippi, being originally called Crenides on account of its springs. It was afterwards famous for the defeat of Brutus and Cassius by Augustus and Antony.

DATURA, the **THORN-APPLE**, in botany: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 23th order, *Luridæ*. The corolla is funnel-shaped, and plaited; the calyx tubular, angulated, and deciduous; the capsule quadrivalved. There are six species. The stramonium, or common thorn-apple, rises a yard high, with an erect, strong, round, hollow, green stalk, branching luxuriantly, having the branches widely extended on every side; large, oval, irregularly angulated, smooth, dark-green leaves; and from the divisions of the branches, large white flowers singly, succeeded by large, oval, prickly capsules, growing erect, commonly called *thorn-apples*. At night the upper leaves rise up and inclose the flowers. The blossoms have sometimes a tinge of purple or violet. The flowers consist of one large, funnel-shaped petal, having a long tube, and spreading pentagonal limb, succeeded by large roundish capsules of the size of middling apples, closely beset with sharp spines. An ointment prepared from the leaves gives ease in external inflammations and in the hæmorrhoids. The seeds were lately recommended by Dr Storck to be taken internally in cases of madness; but they seem to be a very unsafe remedy. Taken even in a small dose, they bring on a delirium, and in a large one would certainly prove fatal. Cows, horses, sheep, and goats, refuse to eat this plant.

DAUCUS, the **CARROT**, in botany: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order, *Umbellatæ*. The corolla is a little radiated, all hermaphrodite. The fruit bristly with short hairs. There are five species; but the only one which merits attention is the carota or common carrot. This is so well known as to need no description. There are several varieties, as the white, the orange, and the purple carrot; but of these the orange carrot is the most esteemed. It grows longer, larger, and is commonly more handsome than the others, being often 15 or 18 inches long in the eatable part, and from two to four in diameter at top. Carrots are propagated by seeds, which

Datum
|
Daucus.

Daucus. which are sown at different seasons of the year, in order to procure a supply of young roots for the table at all times. The season for sowing for the earliest crop is soon after Christmas. They should be sown in an open situation, but near a wall; though if they are sown close under it they will be apt to run up to seed too fast, and give no good roots; about eight inches distance is the most proper. They delight in a warm sandy soil, which should be light, and well dug to a good depth, that the roots may meet with no obstruction in running down, so as to make them forked, and shoot out lateral branches. This will happen especially when the ground has been too much dunged the same year that the seeds were sown, which will also occasion them to be worm-eaten. The hairyness of these seeds makes the sowing of them difficult, on account of their being so apt to stick together. Before sowing, therefore, they should be put through a fine chaff sieve; and a calm day should be chosen for sowing them. When sown, they should be trod in with the feet, and the ground raked level over them. When they first come up they should be cut up to four inches distance, and a month after this they are to be cleared again; and if drawn while young, they are now to be left at six inches distance every way; if they are to stand to grow large, they must be separated to ten inches distance. The second season for sowing carrots is in February. This must be done under a wall or hedge, on warm banks: but those which are to be on open large quarters should not be sown till the beginning of March. In July, carrots may be sown for an autumnal crop; and lastly, in the end of August, for those which are to stand the winter. These last will be fit for use in March, before any of the spring ones; but they are seldom so tender or well tasted. In order to preserve carrots for use all winter, they are to be dug up in the beginning of November, and laid in a dry place in sand; and these roots being again planted in February, will ripen seeds in August for succeeding crops: the longest and straightest roots are to be chosen for this purpose.

Under the article AGRICULTURE, n^o 44. we have taken notice of the good properties of carrots as a food for cattle. They have been greatly recommended as proper for fattening hogs; but from some experiments mentioned in the *Georgical Essays*, it appears, that though the bacon thus fed is of excellent quality, the feeding is considerably dearer than that fed with pease, pollard, &c. In the same essays, the following experiment is mentioned by Dr Hunter, concerning the propriety of raising carrots for the use of the distiller. "In the month of October (1773), I took 24 bushels of carrots. After being washed, topped, and tailed, I put them into a large brewing copper with four gallons of water; and covering them up with cloths to hasten the maceration, I ordered a fire to be kindled underneath, which in a short time reduced the whole into a tender pulp. They were then put into a common screw-press, and the juice taken from them; which, together with the liquor left in the copper, was run through a flannel bag. The juice was then returned into the copper; and as it was my design to make it into ale, I put to it a proportionable quantity of hops. The liquor was then boiled about an hour, when it ac-

quired both the colour and taste of wort. It was next put into a cooler, and afterwards into the working vessel, where the yeast was added to it. It worked kindly, and in all respects was treated as ale. I allowed it to remain in the cask about four months, when I broached it, but found it of a thick, muddy appearance. I attempted to fine it, but in vain. The taste was by no means displeasing, as it much resembled malt liquor. My first intention being frustrated, I threw it into the still, being about 40 gallons in measure, and by two distillations obtained four gallons of a clean proof spirit. It had, however, contracted a flavour from the hop, which should be left out when the intention is to reduce the liquor into spirit. From a gross calculation, I am induced to think that a good acre of carrots manufactured in this manner, will leave a profit of L. 40. after deducting the landlord's rent, cultivation, distillation, and other incidental expences. In this calculation, I presume that the spirit is worth six shillings per gallon, and not excised. An acre of barley will by no means produce so much spirit. A rich sandy loam is the best land for carrots; which, after the crop is removed, will be in high cultivation for corn."

Attempts have also been made to prepare sugar from carrots, but without success; a thick syrupy matter like treacle being only obtainable.—Raw carrots are given to children troubled with worms. They pass through most people but little changed.—A poultice made of the roots hath been found to mitigate the pain and abate the stench of foul and cancerous ulcers.—Crickets are very fond of carrots; and are easily destroyed by making a paste of powdered arsenic, wheat-meal, and scraped carrots, which must be placed near their habitations.—By their strong antiseptic qualities, a marmalade made from carrots has also been found useful in preventing and curing the sea scurvy.—The seeds have been reckoned carminative and diuretic; and were formerly much used as a remedy for the stone, but are at present disregarded.—Carrots were first introduced into England by the Flemings, in the reign of queen Elizabeth.

DAVENANT (Sir William), an eminent poet in the 17th century, was born at Oxford in 1606. After some stay at the university, he entered into the service of Frances first duchess of Richmond, and afterward of Fulke Grevil, lord Brook; who having an excellent taste for poetry, was much charmed with him. He got great esteem by writing poems and plays; and upon the death of Ben Johnson was created poet-laureat. He wrote his poem Gondibert at Paris. He formed a design for carrying over a considerable number of artificers, especially weavers, to Virginia, by the encouragement of Henrietta Maria, the queen-mother of England, who obtained leave for him of the king of France. But he and his company were seized by some parliament ships, and he carried prisoner first to the isle of Wight, and then to the Tower of London; but, by the Mediation of Milton and others, he got his liberty as a prisoner at large. At this time tragedies and comedies being prohibited, he contrived to set up an Opera, to be performed by declamations and music. This Italian opera began in Rutland-house in Charter-house-yard, 1656; but was afterwards removed to the

Cock-

Davenant Cock-Pit in Drury-Laue, was much frequented for many years. In 1648, his *Madagascar*, with other poems, were printed. He died in 1668.

Davidists.

DAVENANT (Doctor Charles), an eminent civilian and writer, eldest son of the preceding, and educated in Cambridge: he wrote several political tracts; and likewise plays. He was (1685) impowered, with the master of the revels, to inspect the plays designed for the stage, that no immoralities might be presented. His *Essays on Trade* are in high esteem; and were reprinted in 5 vols. 8vo, in 1771. Doctor Davenant was inspector-general of exports and imports; and died in 1712.

DAVENTRY, or **DAINTRY**, a handsome town of Northamptonshire in England, situate on the side of a hill on the great road to Chester and Carlisle. W. Long. 1. 15. N. Lat. 52. 12.

DAUGHTER, (*filia*), a female child. See the article **CHILDREN**.

Daughters, among the ancients, were more frequently exposed than sons, as requiring greater charge to educate and settle them in the world. See *Exposing of Children*. Those who had no legitimate sons were obliged, by the Athenian laws, to leave their estates to their daughters, who were confined to marry their nearest relations, otherwise to forfeit their inheritance; as we find to have been practised likewise among the Jews, many of whose laws seem to have been transcribed by Solon.

If an heiress happened to be married before her father's death, this did not hinder the nearest relation to claim the inheritance, and even to take the woman from her husband; which is said to have been a common case.

DAVID, king of Israel, and Hebrew poet, was born at Bethlehem 1085, and died 1014 years B. C. His history is particularly recorded in the sacred writings.

St DAVID's, an episcopal town of Pembroke-shire, in S. Wales; but has neither market nor fair. It is seated in a barren soil on the river Hen, not a mile from the sea-shore. It was once a considerable place, and had walls, which are now demolished; but it is small at present, and thinly inhabited; however, the cathedral is a pretty good structure. From the capé, near this place, there is a prospect into Ireland. W. Long. 5. 20. N. Lat. 52. 0.

St DAVID's, a town and fort of Asia, in the peninsula on this side the Ganges, and on the coast of Coromandel; 80 miles S. of Fort St. George. E. Long. 79. 55. N. Lat. 11. 30. On the taking of Madras by the French in 1746, the presidency of all the English settlements on the Coromandel coast was removed to Fort St David, and continued there till about the year 1752, when it was removed back to Madras. In June 1758, the fort was taken and demolished by the French, and has never been rebuilt since.

DAVIDISTS, **DAVIDICI**, or **DAVID GEORGIANS**, a sect of heretics, the adherents of David George, a native of Delft, who, in 1525, began to preach a new doctrine; publishing himself to be the true Messiah; and that he was sent thither to fill heaven, which was quite empty for want of people to deserve it. He is likewise said to have denied the existence of angels, good and evil, of heaven and hell, and to have rejected

the doctrine of a future judgment. He rejected marriage, with the Adamites; held, with Manes, that the soul was not defiled by sin; and laughed at the self-denial so much recommended by Jesus Christ. Such were his principal errors. He made his escape from Delft, and retired first into Friesland and then to Basil, where he changed his name, assuming that of John Bruck, and died in 1556.

He left some disciples behind him, to whom he promised, that he would rise again at the end of three years. Nor was he altogether a false prophet herein; for the magistrates of that city, being informed, at the three years end, of what he had taught, ordered him to be dug up and burnt, together with his writings, by the common hangman.

There are still some remains of this ridiculous sect in Holstein, Friesland, and other countries; whose temper and conduct seem to discredit the exaggerated account which some writers have given of their founder. He was probably a deluded fanatic and mystic.

DAVILA (Henry Catherine), a celebrated historian, was the youngest son of Antonio Davila, grand constable of Cyprus, who on the taking of that island by the Turks in 1570, had been obliged to retire into Spain, whence this family supposed they had derived their name and origin. From Spain Antonio repaired to the court of France, and settled his son Louis and two daughters under the patronage of Catherine of Medicis; whose name he afterwards gave to the young historian, born 1576, at an ancient castle in the territories of Padua, though generally called a native of Cyprus. The little Davila was brought early into France; and at the age of 18, he signalized himself in the military scenes of that country. His last exploit there was at the siege of Amiens, where he fought under Henry IV. and received a wound in the knee, as he relates himself in his history. After peace was established in France, he withdrew into Italy, and entered into the service of the Venetians. Davila, while he was at Venice, wrote his admirable *History of the Civil Wars of France*, which contains every thing worth notice that passed from the death of Henry II. in 1559, to the peace of Vervins in 1598. He continued to serve the republic of Venice with great reputation, till a most unfortunate adventure put an end to his life in 1631. Passing through Verona with his wife and family, on his way to Crema, which he was appointed to defend, and demanding, according to the usual custom of persons in his station, a supply of horses and carriages for his retinue, a brutal Veronese, called *il Turco*, entered the room where he and his family were at supper, and being mildly reprimanded for his intrusion by Davila, discharged a pistol at the historian, and shot him dead on the instant. His accomplices also killed the chaplain of Davila, and wounded many of his attendants. But his eldest son Antonio, a youth of 18, revenged the death of his father, by killing the murderer on the spot. All the confederates were secured next morning, and publicly executed at Verona. It is very remarkable, that Davila passed no censure on the massacre of St Bartholomew. His character of the queen mother has that partiality, which it was natural for him to show to the patroness of his family; but his general veracity is confirmed by

Davila.

Davis
|
Davit.

the great authority of the first duke of Epernon, who (to use the words of lord Bolingbroke) "had been an actor, and a principal actor too, in many of the scenes that Davila recites." Girard, secretary to this duke, and no contemptible biographer, relates, that this history came down to the place where the old man resided in Gascony, a little before his death; that he read it to him; that the duke confirmed the truth of the narrations in it; and seemed only surpris'd by what means the author could be so well informed of the most secret councils and measures of those times.

DAVIS (Sir John), an eminent lawyer and poet, born about the year 1570. He first distinguished himself by his poem *Nosce Teipsum* on the Immortality of the Soul. He became attorney-general, and speaker of the house of commons in Ireland; and afterward was appointed lord chief justice of the court of King's Bench in England, but died before his installation, in 1626. He published many law tracts; but was esteemed more of a scholar and a wit than of a lawyer.

DAVIS (John), a famous navigator in the 16th century, was born at Sandridge, near Dartmouth in Devonshire; and distinguished himself by making three voyages to the most northern parts of America, in order to discover a north-west passage to the East Indies; in which he discovered the Straits which bear his name. He afterwards performed five voyages to the East Indies; in the last of which he was slain in a desperate fight with some Japanese, near the coast of Malacca, on the 27th of December 1605. He wrote an account of his second voyage for the discovery of the north-west passage; a Voyage to the East-Indies; and other tracts.

DAVIS'S Straits. See *NEW BRITAIN*.

DAVIT, in a ship, a long beam of timber, represented by *a, a*, Plate CLXV. and used as a crane whereby to hoist the flukes of the anchor to the top of the bow, without injuring the sides of the ship as it ascends; an operation which, by mariners, is called *fluking the anchor*. The anchors being situated on both the bows, the davit may be occasionally shifted, so as to project over either side of the ship, according to the position of that anchor on which it is employed. The inner end of the davit is secured by being thrust into a square ring of iron *b*, which is bolted to the deck, and forelocked under the beams. This ring, which is called the *span-shackle*, exhibited at large by fig. 9. is fixed exactly in the middle of the deck, and close behind the foremast. Upon the outer end of the davit is hung a large block *c*, through which a strong rope traverses, called the *fish-pendent*, *d*; to whose foremost end is fitted a large iron hook *e*, and to its after-end a tackle or complication of pulleys *f*; the former of which is called the *fish-hook*, and the latter the *fish tackle*.

The davit, therefore; according to the sea-phrase, is employed to *fluk the anchor*; which being previously *catted* the fish-hook is fastened upon its flukes; and the effort of the tackle being transmitted to the hook, by means of the fish-pendent, draws up that part of the anchor sufficiently high upon the bow to fasten it, which is done by the *shank-painter*. See that article. — There is also a davit of a smaller kind occasionally

fixed in the long-boat, and employed to weigh the anchor therein. Dauphin.

DAUPHIN is a title given to the eldest son of France, and presumptive heir of the crown; on account of the province of Dauphiné, which in 1343 was given to Philip de Valois, on this condition, by Humbert dauphin of the Viennois. The Dauphin, in his letters patent, styles himself, *By the grace of God, eldest son of France, and dauphin of Viennois*.

DAUPHIN was anciently the title or appellation of the prince of Viennois in France.

Most authors who have sought the origin of the name *Dauphin* and *Dauphiné*, seem to have given too much loose to conjecture. Du-Chesne is of opinion, that it was the grandson of Guy the Fat who first bore the name of *dauphin*. Chorier observes, that William, canon of Notre Dame at Grenoble, who has written the life of Margaret, daughter of Stephen earl of Burgundy married with Guy, son of Guy the Fat, calls the latter simply Guy the Old, and the former always count Dauphin; and adds, that no record, no monument, ever attributes the title of dauphin to Guy the Fat or any of his predecessors: so that it must necessarily have taken its rise in his son, all whose successors so constantly assumed it, that it became the proper name of the family. He died in 1142, in the flower of his youth; so that it must be about the year 1120 that the title commenced; and without doubt, adds he, on some illustrious occasion. He observes farther, that this prince was of a military disposition, and delighted in nothing but war; and again, that it was the custom of the cavaliers to deck their caps, coats of arms, and the housing of their horses, with some figure or device peculiar to themselves, whereby they were distinguished from all others engaged in the same combat or tournament. From all these circumstances he conjectures, that this Guy chose the dolphin for his signature; that this was the crest of his helmet; and that he bore it on his coat in some notable tournament or battle, wherein he distinguished himself. And this, Chorier makes no doubt, is the real origin of the appellation. Nothing was more common in those times than to make proper names become the names of families or dignities. Witness the Ademars, Arthands, Aynards, Ailemans, Berengers, and infinite others; who all owe their names to some one of their ancestors, from whom it has been transmitted throughout the family.

The seigneurs or lords of Auvergne have likewise borne the appellation of *dauphin*; but the dauphins of Auvergne had it not till a good while after those of the Viennois, and even received it from them. The manner was this: Guy VIII. dauphin of Viennois, had by his wife Margaret, daughter of Stephen earl of Burgundy, a son and two daughters. The son was Guy IX. his successor. Beatrix, one of the daughters, was married to the count d'Auvergne, who, according to Blondel, was William V. or rather, as Chorier and others hold, Robert VI. father of William V. This prince lost the greatest part of the county Auvergne, which was taken from him by his uncle William, assisted by Louis the Young; and was only left master of the little canton whereof Vodable is the capital. He had a son whom he called Dauphin, on account of Guy, or Guigues, his nucle by the mother's side.

From

Dauphin
Day.

From his time his successors, holding the same petty canton of Auvergne, styled themselves *Dauphins of Auvergne*, and bore a dolphin for their arms.

DAUPHINS, or *Delphins*, in literary history, a name given to the commentators on the ancient Latin authors, who were employed by order of Louis XIV. of France, for the benefit of the prince, under the care and direction of M. de Montaulier his governor, Bosfuet and Huet his preceptors. They were 39 in number.

DAUPHINY, a province of France, bounded on the west by the river Rhone, on the north by the Rhone, and Savoy, on the south by Provence, and on the east by the Alps. Hence the presumptive heir of France is called the DAUPHIN. In some places it is very fertile; and produces corn, wine, olives, woad, copperas, silk, crystal, iron, and copper. But the greatest part of this province is barren, and the inhabitants are obliged to go into other countries for subsistence. The mountains abound in simples and game of all sorts; and here are fir-trees proper for masts. The principal rivers are, the Rhone, the Durance, the Isere, and the Drome. There is a great number of mineral springs; and Grenoble is the capital town.

DAURAT (John), an eminent French poet, born in 1507. In the reign of Henry II. he was preceptor to the king's pages, and Charles IX. who took great delight in his conversation, and honoured him with the title of his poet; but his generosity and want of management placed him in that class of learned men who have been very near starving. Conformable to the taste of the age, he had so much skill in making anagrams, that several illustrious persons gave him their names to anagrammatise: he also undertook to explain the Centuries of Nostradamus. Making verses was a disease in him: for no book was printed, nor did any person of consequence die, but Daurat made some verses on the occasion; as if he had been poet in ordinary, or his muse had been a hired mourner to the whole kingdom. Scaliger tells us, that he spent the latter part of his life in endeavouring to find all the bible in Homer. He died in 1588.

DAY, according to the most natural and obvious sense of the word, signifies that space of time during which it continues to be light; in contradistinction to night, being that partition of time wherein it is dark; but the space of time in which it is light, being somewhat vague and indeterminate, the time between the rising and the setting of the sun is usually looked on as the day; and the time which lapses from its setting to its rising again the night.

The word *day* is often taken in a large sense, so as to include the night also; or to denote the time of a whole apparent revolution of the sun round the earth; in which sense it is called by some a natural day, and by others an artificial one: but, to avoid confusion, it is usual to call it in the former sense simply the *day*, and in the latter a *nychthemeron*; by which term that appellation of it is aptly denoted, as it implies both day and night.

The *nychthemeron* is divided into twenty-four parts, called *hours*; which are of two sorts, equal and unequal or temporary. See the article HOUR.

Different nations begin their day at a different hour. Thus the Egyptians begin their day at midnight; from

whom Hippocrates introduced that way of reckoning into astronomy, and Copernicus and others have followed him: But the greatest part of astronomers reckon the day to begin at noon, and so count twenty-four hours, till the noon of the next day; and not twice twelve, - according to the vulgar computation. The method of beginning the day at midnight prevails also in Great Britain, France, Spain, and most parts of Europe.

The Babylonians began their day at sun-rising: reckoning the hour immediately before its rising again, the twenty-fourth hour of the day; from whence the hours reckoned in this way are called the *Babylonic*. In several parts of Germany, they begin their day at sun-setting, and reckon on till it sets next day, calling that the *twenty-fourth hour*: these are generally termed *Italian hours*. The Jews also began their *nychthemeron* at sun-setting; but then they divided it into twice twelve hours, as we do; reckoning twelve for the day, be it long or short, and twelve for the night, so that their hours continually varying with the day and night, the hours of the day were longer than those of the night for one half year, and the contrary the other; from whence their hours are called temporary: those at the time of the equinoxes became equal, because then those of the day and night are so. The Romans also reckoned their hours after this manner, as do the Turks at this day.

This kind of hours is called *planctry*, because the seven planets were anciently looked upon as presiding over the affairs of the world, and to take it by turns each of these hours according to the following order: Saturn first, then Jupiter, Mars, the Sun, Venus, Mercury, and last of all the Moon: hence they denominated each day of the week from that planet whose turn it was to preside the first hour of the *nychthemeron*. Thus, assigning the first hour of Saturday to Saturn, the second will fall to Jupiter, the third to Mars, and so the twenty-second of the same *nychthemeron* will fall to Saturn again, and therefore the twenty-third to Jupiter, and the last to Mars: so that on the first hour of the next day, it will fall to the sun to preside; and by the like manner of reckoning, the first hour of the next will fall to the Moon; of the next, to Mars; and the next, to Mercury; of the next, to Venus: hence the days of the week came to be distinguished by the Latin names of *Dies Saturni, Solis, Lunæ, Martis, Mercurii, Jovis, and Veneris*; and among us, by the names of Saturday, Sunday, Monday, &c.

Day-Coal, in natural history, a name given by the miners of England, and the common people who live in coal-countries, to that seam or stratum of the coal which lies uppermost in the earth. The same vein or stratum of coal usually runs a great way through the country, and dips and rises in the earth at different places; so that this upper stratum, or day-coal, is, in the various parts of the same stratum, sometimes near the surface and sometimes many fathoms deep. The subterranean fires found in some of our coal-countries feed principally on this coal; and are nearer to or farther from the surface as it rises or sinks.

Day-Fly. See EPHEMERIS.

Day-Net, among fowlers. See NET.

Days of Grace, are those granted by the court at the prayer of the defendant or plaintiff, in whose delay it is.

Day.

Day
||
Deacon.

Days of grace, in commerce, are a customary number of days allowed for the payment of a bill of exchange, &c. after the same becomes due.

Three days of grace are allowed in Britain; ten in France and Dantzic; eight at Naples; six at Venice, Amsterdam, Rotterdam, and Antwerp; four at Francfort; five in Leipzig; twelve at Hamburg; six in Portugal; fourteen in Spain; thirty in Genoa, &c.

In Britain the days of grace are given and taken as a matter of course, the bill being only paid on the last day: but in other countries, where the time is much longer, it would be reckoned dishonourable for a merchant to take advantage of it; bills are therefore paid on the very day they fall due.

Day's-Man, in the north of England, an arbitrator or person chosen to determine an affair in dispute.

Intercalary Days. See *INTERCALARY Days*.

Day's-Work, among seamen, the reckoning or account of the ship's course during 24 hours, or between noon and noon, according to the rules of trigonometry. See *DEAD-Reckoning*.

DAZE, in natural history, a name given by our miners to a glittering sort of stone, which often occurs in their works; and, as it is an unprofitable substance, is one of those things they call *weeds*. The word *daze* takes in with them every stone that is hard and glittering; and therefore it comprehends the whole genus of the telangia or stony nodules, which have the flakes of talk in their substance: these, according to the colour of the stony matter they are bedded in, and their own colour, give the names of *black daze*, *white*, *red*, and *yellow daze*, to these stones.

DEACON, **DIACONUS**, a person in the lowest degree of holy orders, whose business is to baptise, read in the church, and assist at the celebration of the eucharist. The word is formed from the Latin *Diaconus*, of the Greek *διακονος*, minister, servant. Deacons were instituted seven in number, by the apostles, *Acts* chap. vi. which number was retained a long time in several churches. Their office was to serve in the Agapæ, and to distribute the bread and wine to the communicants. Another part of the office of deacons, was to be a sort of monitors and directors to the people in the exercise of their public devotions in the church; for which purpose they made use of certain known forms of words, to give notice when each part of the service began. Whence they are sometimes called *cirokerukes*; "the holy cryers of the church."

Deacons had by licence and authority from the bishop, a power to preach, to reconcile penitents and grant them absolution, and to represent their bishops in general councils. Their office out of the church was to take care of the necessitous, such as orphans, widows, prisoners, and all the poor and sick who had any title to be maintained out of the revenues of the church; to inquire into the morals and conversation of the people, and to make their report thereof to the bishop. Whence, on account of the variety of business, it was usual to have several deacons in the same church.

In the Romish church, it is the deacons office to incense the officiating priest or prelate; to lay the corporal on the altar; to receive the pattern or cup from the subdeacon, and to present them to the person officiating; to incense the choir; to receive the pax from the officiating prelate, and carry it to the subdeacon; and

at the pontifical mass, when the bishops gives the blessing, to put the mitre on his head, and to take off the archbishop's pall and lay it on the altar. In England, the form of ordaining deacons, declares that it is their office to assist the priest in the distribution of the holy communion: in which, agreeably to the practice of the ancient church, they are confined to the administering the wine to the communicants. A deacon in England is not capable of any ecclesiastical promotion; yet he may be a chaplain to a family, curate to a beneficed clergyman, or lecturer to a parish-church. He may be ordained at 23 years of age, *anno currente*; but it is expressly provided, that the bishop shall not ordain the same person a priest and deacon in the same day. Deacons, according to St Paul, should be chaste, sincere, and blameless; neither great drinkers, nor given to filthy lucre: they should hold the mystery of the faith in a pure conscience; and should be well approved before they are admitted to the ministry. In the church of Scotland, the deacon's office is only to take care of the poor.

DEACONESS, *a female deacon*; an order of women who had their distinct offices and services in the primitive church. The office appears as ancient as the apostolical age; for St Paul calls Phebe a servant of the church of Cenchrea. The original word is *διακονος*, answerable to the Latin word *ministra*. Tertullian calls them *vidua*, widows, because they were commonly chosen out of the widows of the church; and, for the same reason, Epiphanius, and the council of Laodicea, calls them *πρεσβυτιδας*, elderly women, because none but such were ordinarily taken into this office. For, indeed, by some ancient laws, these four qualifications were required in every one that was to be admitted into this order. 1. That she should be a widow. 2. That she should be a widow that had born children. 3. A widow that was but once married. 4. One of a considerable age, 40, 50, or 60 years old. Though all these rules admitted of exceptions. Concerning their ordination, whether it was always performed by imposition of hands, the learned are much divided in their sentiments. Earonius and Valesius think they were not, and make no other account of them than as mere lay-persons. But the author of the constitutions, speaking of their ordination, requires the bishop to use imposition of hands, with a form of prayer which is there recited. We are not, however, to imagine, that this ordination gave them any power to execute any part of the sacerdotal office. They were only to perform some inferior services of the church, and those chiefly relating to the women for whose sakes they were ordained. One part of their office was to assist the minister at the baptizing of women, to undress them for immersion, and to dress them again, that the whole ceremony might be performed with all the decency becoming so sacred an action. Another part of their office was to be private catechists to the women-catechumens who were preparing for baptism. They were likewise to attend the women that were sick and in distress; to minister to martyrs and confessors in prison; to attend the womens gate in the church; and lastly, to assign all women their places in the church, regulate their behaviour, and preside over the rest of the widows; whence in some canons they are styled *πρεκατδεμενας*, "governesses." This order, which since
the

Deaconess.

Deaconry the 10th or 12th century has been wholly laid aside, was not abolished every where at once, but continued in the Greek church longer than in the Latin, and in some of the Latin churches longer than in others.

DEACONRY, DIACONATE, the order or ministry of a deacon or deaconess. See **DEACON** and **DEACONESS**.

DEACONRY, Diaconia, is also a name still reserved to the chapels and oratories in Rome, under the direction of the several deacons, in their respective regions or quarters.

To the deaconries were annexed a sort of hospitals or boards for the distribution of alms, governed by the regent deacons, called *cardinal deacons*, of whom there were seven, answering to the seven regions, there chief being called the *archdeacon*.

The hospital adjoining to the church of the deaconry had an administrator for the temporal concerns, called the *father of the deaconry*, who was sometimes a priest and sometimes a layman.

At present there are fourteen of these deaconries or hospitals at Rome, which are reserved to the cardinals. Du-Cange gives us their names: as, the deaconry of St Maria in the broad-way, the deaconry of St Eustachio near the Pantheon, &c.

DEAD LANGUAGES. See **PHILOLOGY**, chap. iii.

Preservation of DEAD Bodies. See **EMBALMING**.

Feast of the DEAD. See **FEAST of the Dead**.

DEAD-Lights, certain wooden ports which are made to fasten into the cabin windows, to prevent the waves from gushing into the ship in a high sea. As they are made exactly to fit the windows, and are strong enough to resist the waves, they are always fixed in on the approach of a storm, and the glass lights taken out, which must otherwise be shattered to pieces by the surges, and suffer great quantities of water to enter the vessel.

DEAD-Mens-Eyes, in the sea language, a kind of blocks with many holes in them, but no sheevers, whereby the shrouds are fastened to the chains: the crow feet reeve also through these holes: and, in some ships, the main-stays are set tight in them; but then they have only one hole, through which the lanyards are passed severaltimes. See **PLATE CLXV**.

DEAD's Part. See **LAW**, N° lxxxii, 6.

DEAD-Reasoning, in navigation, the judgment or estimation which is made of the place where a ship is situated; without any observation of the heavenly bodies. It is discovered by keeping an account of the distance she has run by the log, and of her course steered by the compass; and by rectifying these data by the usual allowances for drift, lee-way, &c. according to the ship's known trim. This reckoning, however, is always to be corrected, as often as any good observation of the sun can be obtained.

DEAD-Sea, in geography, a lake of Judea, into which the river Jordan discharges itself; being about 70 miles long and 20 broad. See **ASPHALTITES**.

DEAD-Tops, a disease incident to young trees, and cured by cutting off the dead parts close to the next good twig or shoot, and claying them over as in grafting.

DEAD-Water, at sea, the eddy-water just astern of a ship; so called, because it does not pass away so swift as the water running by her sides does. They say that

a ship makes much dead-water when she has a great eddy following her stern.

DEADLY-CARROT. See **THAPSIA**.

DEADLY-Feud, in English law-books, a profession of irreconcilable enmity, till a person is revenged by the death of his enemy. The word *feud* is derived from the German *Fehd*; which, as Hottoman observes, signifies *modo bellum, modo capitales inimicitias* *. Such enmity and revenge was allowed by law in the time of the Saxons, viz. If any man was killed, and a pecuniary satisfaction was not made to the kindred, it was lawful for them to take up arms to revenge themselves on the murderer; which was called *deadly feud*. And this probably was the original of an **APPEAL**.

DEAFNESS, the state of a person who wants the sense of hearing: or the disease of the ear, which prevents its due reception of sounds. See **MEDICINE-Index**.

Deafness generally arises either from an obstruction or a compression of the auditory nerve; or from some collection of matter in the cavities of the inner ear; or from the auditory passage being stopped up by some hardened excrement; or lastly, from some excrescence, a swelling of the glands, or some foreign body introduced within it.

Those born deaf are also dumb, as not being able to learn any language, at least in the common way. However, as the eyes in some measure serve them for ears, they may understand what is said by the motion of the lips, tongue, &c. of the speaker: and even accustom themselves to move their own, as they see other people do, and by this means learn to speak.— Thus it was that Dr Wallis taught two young gentlemen born deaf to know what was said to them, and to return pertinent answers. Digby gives us another instance of the same within his own knowledge; and there was a Swiss physician lately living at Amsterdam, one John Conrad Amman, who effected the same in several children born deaf with surprising success. He has reduced the thing to a fixed art or method, which he has published in his *Surdus Loquens*, Amstelod. 1692, and *de Loquela*, ibid. 1700.

In the Phil. Trans. N° 312. we have an account by Mr Waller, R. S. Sec. of a man and his sister, each about 50 years old, born in the same town with Mr Waller, who had neither of them the least sense of hearing: yet both of them knew, by the motion of the lips only, whatever was said to them, and would answer pertinently to the question proposed. It seems they could both hear and speak when children, but lost their sense afterwards; whence they retained their speech, which though uncouth, was yet intelligible.

Such another instance is that of Mr Goddy's daughter, minister of St Gervais in Geneva, related by Bishop Burnet. "At two years old they perceived she had lost her hearing; and ever since though she hears great noises, yet hears nothing of what is said to her. But by observing the motions of the mouth and lips of others, she acquired so many words, that out of these she hath formed a sort of jargon, in which she can hold conversation whole days with those that can speak her language. She knows nothing that is said to her unless she see the motion of their mouths that speak to her, so that in the night they are obliged to light candles to speak to her. One thing will appear the strangest

Deadly-
Carrot,
||
Deafness:

* Sec. Feuds

Deal
Dean.

strangest part of the whole narration : she has a sister, with whom she has practised her language more than with any body else ; and in the night, by laying her hand on her sister's mouth, she can perceive by that what she saith, and so can discourse with her in the dark." *Burn. Let. IV. p. 248**.

* See further the article Dumbness.

It is observable that deaf persons, and several others thick of hearing, hear better and more easily if a loud noise be raised at the time when you speak to them : which is owing, no doubt to the greater tension of the ear-drum on that occasion. Dr Wallis mentions a deaf woman, who if a drum were beat in the room could hear any thing very clearly ; so that her husband hired a drummer for a servant, that by this means he might hold conversation with his wife. The same author mentions another, who living near a steeple, could always hear very well if there was a ringing of three or four bells, but never else.

DEAL, a thin kind of fir-planks, of great use in carpentry. They are formed by sawing the trunk of a tree into a great many longitudinal divisions, of more or less thickness according to the purposes they are intended to serve.

A very good method of seasoning planks of deal and fir is to throw them into salt water as soon as they are sawed ; and keep them there three or four days, frequently turning them. In this case they will be rendered much harder, by drying afterwards in the air and sun : but neither this, nor any other method yet known will preserve them from shrinking.

Rods of deal expand laterally, or cross the grain, in moist weather, and contract again in dry ; and thence have been found to make an useful hygrometer.

DEAL, a town of Kent in England, lying between Dover and Sandwich, in E. Long. 1. 30. N. Lat. 51. 16. is supposed to be the *Dola* of Nennius, and is situated on a flat and level coast. This town, according to Dr Campbell, justifies an observation he had made in favour of situations of this kind *viz.* that they are less liable than others to be injured by the sea. The town of Deal, as far as we are able to judge, except it may be the sea's shrinking a little from it, is in much the same condition in which it ever was, even from the earliest accounts. The learned Dr Halley has proved, *Miscellanea Curiosa*, vol. iii. p. 426, that Julius Cæsar landed here, August 26th, the year before the coming of Christ 55.—The great conveniency of landing has been of infinite service to the place ; so that it is large and populous, divided into the upper and lower towns, adorned with many fair buildings, and is in effect the principal place on the Downs.

DEAN, an ecclesiastical dignitary in cathedral and collegiate churches, and head of the chapter.

Rural Dean, called also *Arch presbyter*, originally exercised jurisdiction over ten churches in the country, and afterwards became only the bishop's substitute, to grant letters of administration, probate wills, &c. ; to convocate the clergy ; and to signify to them sometimes by letters the bishop's will, and to give induction to the archdeacon. Their office is now lost in that of the archdeacons and chancellor.

DEAN of a Monastery, was a superior established under the abbot, to ease him in taking care of ten monks ; whence he was called *decanus*.

DEAN and Chapter, are the council of the bishop, to

assist him with their advice in affairs of religion, and also in the temporal concerns of his see. When the rest of the clergy were settled in the several parishes of each diocese, these were reserved for the celebration of divine service in the bishop's own cathedral ; and the chief of them, who presided over the rest, obtained the name of *decanus* or *dean*, being probably at first appointed to superintend ten canons or prebendaries.

All ancient deans are elected by the chapter by *conge d'eslire* from the king, and letters missive of recommendation, in the same manner as bishops ; but in those chapters that were founded by Henry VIII. out of the spoils of the dissolved monasteries, the deanery is donative, and the installation merely by the king's letters patent. The chapter, consisting of canons or prebendaries, are sometimes appointed by the king, sometimes by the bishop, and sometimes elected by each other.

The dean and chapter are the nominal electors of a bishop. The bishop is their ordinary and immediate superior ; and has, generally speaking, the power of visiting them, and correcting their excesses and enormities. They had also a check on the bishop at common law ; for till the statute 32 Hen. VIII. c. 28. his grant or lease would not have bound his successors, unless confirmed by the dean and chapter.

DEAN of Guild. See LAW, N^o clviii. II.

DEANERY, the office of a DEAN.—Deaneries and prebends may become void, like a bishopric, by death, by deprivation, or by resignation either to the king or bishop. If a dean, prebendary, or other spiritual person, be made a bishop, all the preferments of which he was before possessed are void ; and the king may present to them in right of his prerogative royal. But they are not void by the election, but only by the consecration.

DEATH, is generally considered as the separation of the soul from the body ; in which sense it stands opposed to life, which consists in the union thereof.

Physicians usually define death by a total stoppage of the circulation of the blood, and a cessation of the animal and vital functions consequent thereon ; as respiration, sensation, &c.

An animal body, by the actions inseparable from life, undergoes a continual change. Its smallest fibres become rigid ; its minute vessels grow into solid fibres no longer pervious to the fluids ; its greater vessels grow hard and narrow ; and every thing becomes contracted, closed, and bound up : whence the dryness, immobility, and extenuation, observed in old age. By such means the offices of the minuter vessels are destroyed ; the humours stagnate, harden, and at length coalesce with the solids. Thus are the subtilist fluids in the body intercepted and lost, the concoction weakened, and the reparation prevented ; only the coarser juices continue to run slowly through the greater vessels to the preservation of life, after the animal functions are destroyed. At length, in the process of these changes, death itself becomes inevitable, as the necessary consequence of life. But it is rare that life is thus long protracted, or that death succeeds merely from the decays and impairment of old age. Diseases, a long and horrid train, cut the work short.

The signs of death are in many cases very uncertain. If we consult what Winslow or Bruchier have said on this

Dean
||
Death.

Death. this subject, we shall be convinced, that between life and death the shade is so very undistinguishable, that even all the powers of art can scarcely determine where the one ends and the other begins. The colour of the visage, the warmth of the body, and suppleness of the joints, are but uncertain signs of life still subsisting; while, on the contrary, the paleness of the complexion, the coldness of the body, the stiffness of the extremities, the cessation of all motion, and the total insensibility of the parts, are but uncertain marks of death begun. In the same manner also, with regard to the pulse and breathing; these motions are often so kept under, that it is impossible to perceive them. By bringing a looking-glass near to the mouth of the person supposed to be dead, people often expect to find whether he breathes or not. But this is a very uncertain experiment: the glass is frequently sullied by the vapour of the dead man's body; and often the person is still alive, though the glass is no way tarnished. In the same manner, neither burning nor scarifying, neither noises in the ears nor pungent spirits applied to the nostrils, give certain signs of the discontinuance of life; and there are many instances of persons who have endured them all, and afterwards recovered without any external assistance, to the astonishment of the spectators. This ought to be a caution against hasty burials, especially in cases of sudden death, drowning, &c.

DEATH in Law. In law, there is a natural death and a civil death: natural, where nature itself expires; civil, where a person is not actually dead, but adjudged so by law. Thus, if any person, for whose life an estate is granted, remains beyond sea, or is otherwise absent, seven years, and no proof made of his being alive, he shall be accounted naturally dead.

Brothers of DEATH, a denomination usually given to the religious of the order of St Paul, the first hermit. They are called *brothers of death*, *fratres a morte*, on account of the figure of a death's head, which they were always to have with them, in order to keep perpetually before them the thoughts of death. This order, by its constitutions made in 1620, does not seem to have been established long before Pope Paul V. Louis XIII. in 1621, permitted them to settle in France. The order was probably suppressed by Pope Urban VIII.

LAW of DEATHBED. See Law, N^o cixxxi. 38—41.

DEATH-Watch, in natural history, a little insect famous for a ticking noise, like the beat of a watch, which the vulgar have long taken for a presage of death in the family where it is heard: whence it is also called *pediculus*, *fatidicus*, *mortifaga*, *pulsatorius*, &c.

There are two kinds of death-watches. Of the first we have a good account in the Phil. Transf. by Mr Allen. It is a small beetle, $\frac{5}{8}$ of an inch long, of a dark-brown colour, spotted; having pellucid wings under the vagina, a large cap or helmet on the head, and two antennæ proceeding from beneath the eyes, and doing the office of proboscides. The part it beats withal, he observed, was the extreme edge of the face, which he chooses to call the upper-lip, the mouth being protracted by this bony part, and lying underneath out of view.

This account is confirmed by Dr Derham; with this difference, that instead of ticking with the upper-lip, he observed the insect to draw back its mouth, and beat with its forehead. That author had two death-

watches, a male and a female, which he kept alive in a box several months; and could bring one of them to beat whenever he pleased, by imitating its beating. By this ticking noise he could frequently invite the male to get up upon the other in the way of coition. When the male found he got up in vain, he would get off again, beat very eagerly, and then up again: Whence the ingenious author concludes those pulsations to be the way whereby these insects woo one another, and find out and invite each other to copulation.

The second kind of death-watch is an insect in appearance quite different from the first. The former only beats seven or eight strokes at a time, and quicker; the latter will beat several hours together without intermission; and his strokes are more leisurely, and like the beat of a watch. This latter is a small greyish insect, much like a louse when viewed with the naked eye.

It is very common in all parts of the house in the summer-months: it is very nimble in running to shelter, and shy of bearing when disturbed; but will beat very freely before you, and also answer the beating, if you can view it without giving it disturbance, or shaking the place where it lies, &c. The author cannot say whether they beat in any other thing, but he never heard their noise except in or near paper. As to their noise, the same person is in doubt whether it be made by their heads, or rather snouts, against the paper; or whether it be not made after some such a manner as grasshoppers and crickets make their noise. He inclines to the former opinion. The reason of his doubt is, that he observed the animal's body to shake and give a jerk at every beat, but could scarce perceive any part of its body to touch the paper. But its body is so small and near the paper, and its motion in ticking so quick, that he thinks it might be, yet he not perceive it. The ticking, as in the other, he judges to be a wooing act; as having observed another, after much beating, come and make offers to the beating insect, who, after some offers, left off beating, and got upon the back of the other. When they were joined, he left off again; and they continued some hours joined tail to tail, like dog and bitch in coition. Whether this insect changes its shape and becomes another animal or not, he cannot say; though he has some cause to suspect that it becomes a sort of fly. It is at first a minute white egg, much smaller than the nits of lice; though the insect is near as big as a louse. In March it is hatched, and creeps about with its shell on. When it first leaves its shell, it is even smaller than its egg; though that be scarce discernible without a microscope. In this state it is perfectly like the mites in cheese. From the mite-state they grow gradually to their mature perfect state. When they become like the old ones, they are at first very small, but run about much more swiftly than before.

DEBENTURE, a term of trade used at the custom-house for a kind of certificate signed by the officers of the customs, which intitles a merchant exporting goods to the receipt of a bounty or draw-back. In Britain all merchandises that are designed to be taken on board for that voyage being entered and shipped, and the ship being regularly cleared out, and sailed out of port on her intended voyage, debentures may be made out from the exporter's entries, in order to obtain the drawbacks, allowances, bounties, or premiums; which debentures

Death.
Debenture.

Debenture
||
Decade.

debentures for foreign goods are to be paid within one month after demand. And in making out these debentures, it must be observed, that every picce of vellum, parchment, or paper, containing any debenture for drawing back customs or duties, must, before writing, be stamped, and pay a duty of 8d.

The forms of debentures vary according to the merchandise exported. In the execution of debentures for tobacco, it must be particularly observed, 1. That debentures for the same quantity may be made on one or more parchments. 2. That the exporter's oath must be printed, specifying whether he acts for himself or on commission. 3. If exported to any other foreign ports than Ireland, the word *Ireland* must be added to the oath after *Great Britain*. 4. That as no tobacco may be consumed on board of ships of war in Europe but what has paid full duties, and been manufactured in Great Britain, no drawback is to be allowed for tobacco exported in any man of war. 5. That the eight pounds *per* hoghead of 350 pounds, or more, allowed for draught at importation, must not be deducted on exportation. 6. That debentures for tobacco exported to Ireland must not be paid till a certificate be produced, testifying the landing thereof. 7. That no persons may swear to the exportation but such as are permitted to swear to debentures for other goods. In debentures for all other foreign goods, no person may be admitted to swear to the exportation but the true exporter, either as a proprietor, or who, being employed by commission, is concerned in the direction of the voyage. All kinds of debentures, before delivered or paid to the exporters, are entered into a separate book kept for that purpose by the collector and comptroller of the customs.

DEBITA FUNDI. See LAW, N^o clxvi. 1.

DEBITA Fructuum. See LAW, N^o clxx. 17.

DEBILITY, among physicians, a relaxation of the solids, occasioning oftentimes weaknesses and faintings.

DEBIR (anc. geog.), a sacerdotal city of Palestine, near Hebron; but neither distance, nor point of the compass on which it lies, can be determined. It was anciently called *Kariath-sepher* or *Kirjath-sepher*, and *Kirjath-sanna* (Joshua).—Another *Debir* in the tribe of Gad, beyond Jordan.

DEBRECHEN, a town of Upper Hungary, about 77 miles east of Buda. E. Long. 21. 10. N. Lat. 47. 45.

DEBRUIZED, in heraldry, a term peculiar to the English, by which is intimated the grievous restraint of any animal, debarred of its natural freedom, by any of the ordinaries being laid over it.

DEBT, in law, any thing due to another, whether it be money, goods, or services; or the action brought for recovering the same.

National DEBT. See FUNDS and NATIONAL Debt.

DEBTOR, a person who owes any thing to another; in contradistinction to creditor, which is he to whom the debt is owing.

DEBTOR, in merchants accounts. See BOOK-KEEPING.

DECAGON, in geometry, a plane figure with ten sides and ten angles.

DECADE, a word used by some old writers for the number ten, and *decades* for an enumeration by

tens. The word is formed from the Latin *decas*, which is derived from a Greek word of the same import. The word has been more peculiarly appropriated to the number of books, *q. d. decades*, into which the Roman History of Titus Livius is divided. Hence also came *decadal* arithmetic, the Decameron of Boecacio, &c.

DECAGYNIA (from *deka ten*, and *gyn a woman*), the name of an order, or secondary division, in the class decandria, of the sexual method, consisting of plants whose flowers are furnished with ten stamina and the same number of styles; which last are considered by Linnæus and sexualists as the female organs of generation in plants. Neurada and American nightshade furnish examples.

DECALOGUE, the ten precepts or commandments delivered by God to Moses, after engraving them on two tables of stone.

The Jews, by way of excellence, call these commandments the *ten words*, from whence they had afterwards the name of *decalogue*: but it is to be observed, that they joined the first and second into one, and divided the last into two. They understand that against stealing to relate to the stealing of men, or kidnapping; alleging, that the stealing one another's goods or property is forbidden in the last commandment.

The emperor Julian objected to the decalogue, that the precepts it contained (those only excepted which concern the worship of false gods, and the observation of the sabbath) were already so familiar to all nations, and so universally received, that they were unworthy, for that very reason, to be delivered, by so great a legislator, to so peculiar a people. The church of Rome has struck the second commandment quite out of the decalogue; and to make their number complete, hath split the tenth into two: The reason of which may be easily conceived.

DECAN, a kingdom of Asia, in the peninsula on this side the Ganges, bounded on the south by the kingdom of Bisnagar, on the west by the ocean, on the north by Mogulistan, and on the east by the mountains which separate it from Golconda.

DECANDRIA (*deka ten*, and *andros a husband*), Linnæus's tenth class, comprehending those hermaphrodite plants which bear flowers with ten stamina. See BOTANY, p. 430.

DECANTATION, among chemists, &c. the gently pouring off a liquor from its fæces, by inclining the lip or canthus of the vessel; whence the name.

DECANUS, in Roman antiquity, an officer who presided over the other ten officers, and was head of the contubernium, or serjeant of a file of soldiers.

DECAPOLIS (anc. geog.), a district beyond Jordan, almost all of it belonged to the half tribe of Manasseh; before the captivity, called *Bethsan*; but after occupied by heathens, who could not be driven out. It comprised, as the name denotes, ten principal cities on the other side the Jordan, if we except Scythopolis, which stood on this side, but its territory on the other.

DECAPROTI, DECEMPRIMI, in Roman antiquity, officers for gathering the tributes and taxes.

The decaproti were also obliged to pay for the dead, or to answer to the emperor for the quota parts of such as died out of their own estates.

DECASPERMUM, in botany: a genus of the monogynia order, belonging to the icosandria class of plants.

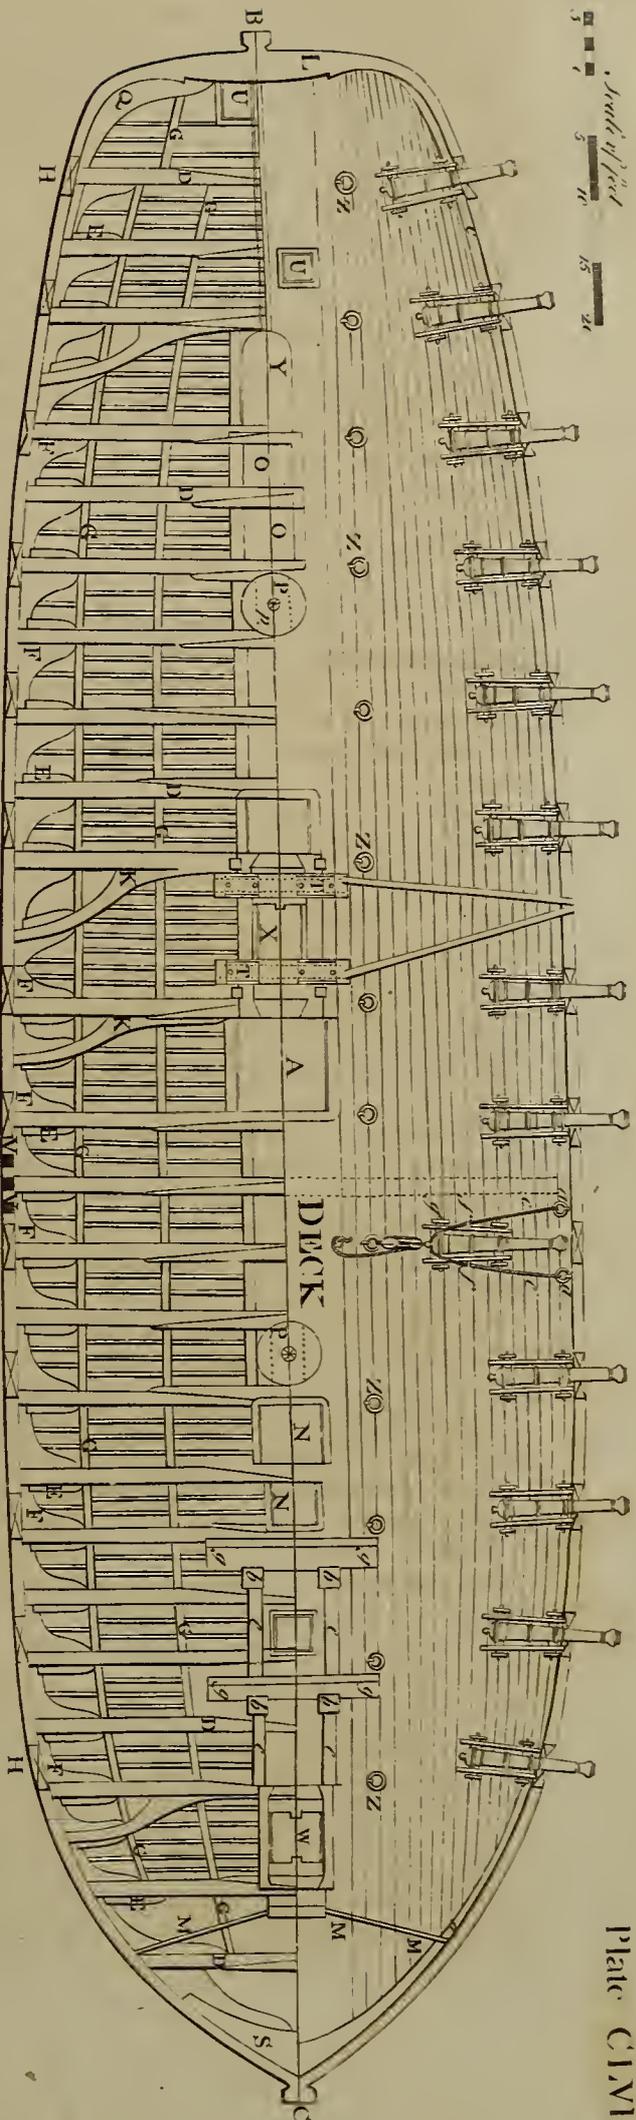

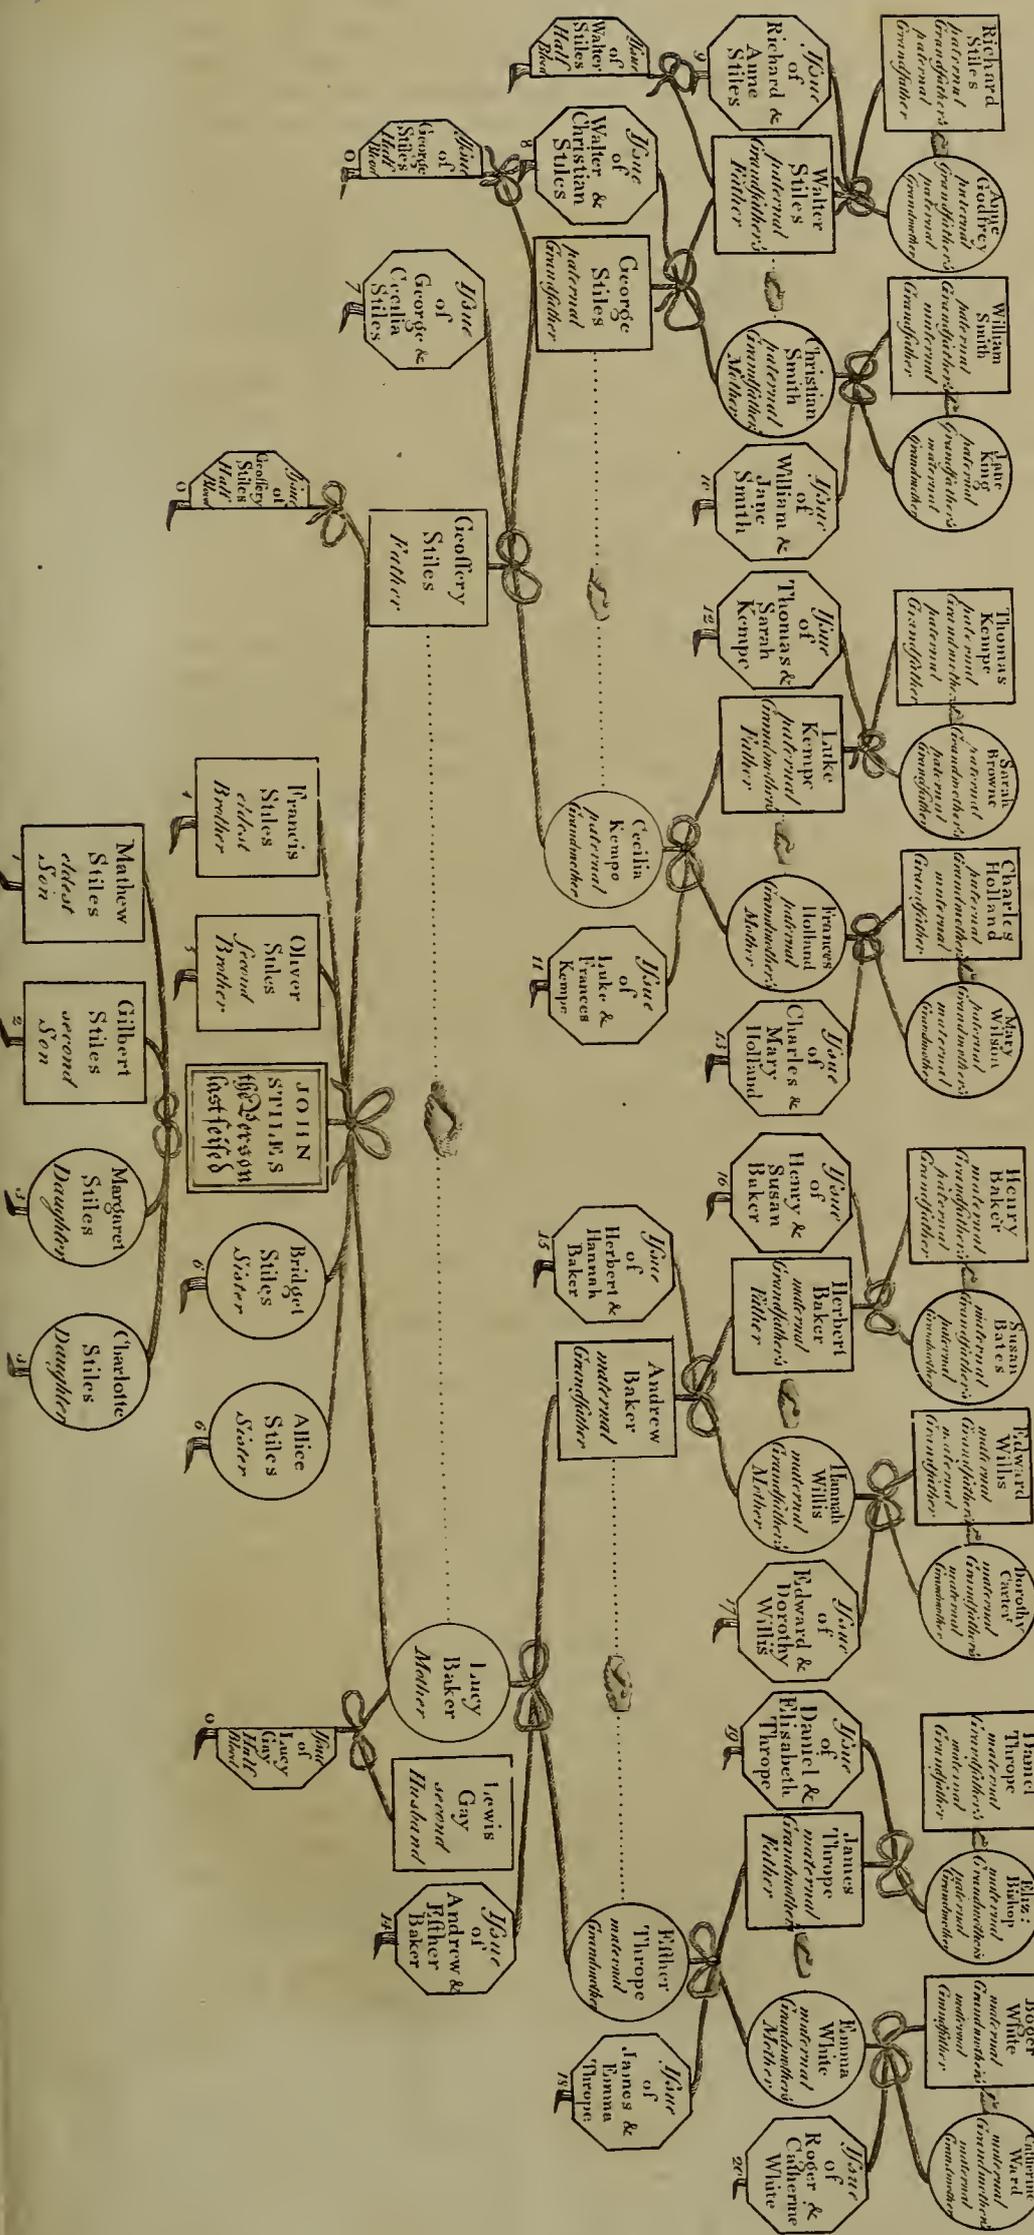

Plate CIVL.

TABLE OF DESCENDENTS

Decastyle plants. The calyx is a turbinated perianthium, quinquefid at the apex. The corolla has five roundish petals. The stamina are many filiform filaments, a little shorter than the corolla. The pericarpium is a dry, globular, decemlocular berry, with solitary egg-shaped seeds.

DECASTYLE, in the ancient architecture, a building with an ordnance of ten columns in front, as the temple of Jupiter Olympius was.

DECEIT, in law, a subtle trick or device, to which may be added all manner of craft and collusion, or underhand practice, used to defraud another, by any means whatever.

DECEMBER, the last month of the year, wherein the sun enters the tropic of Capricorn, and makes the winter solstice.

In Romulus's year, December was the tenth month, whence the name, *viz.* from *decem* "ten:" for the Romans began their year in March.

The month of December was under the protection of Vesta. Romulus assigned it 30 days, Numa reduced it to 29, which Julius Cæsar increased to 31.

Under the reign of Commodus, this month was called, by way of flattery, *Amazonius*, in honour of a courtesan whom that prince passionately loved, and had got painted like an Amazon; but it only kept the name during that emperor's life.

At the latter end of this month they had the *juveniles ludi*; and the country people kept the feast of the goddess Vacuna in the fields, having then gathered in their fruits and sown their corn; whence seems to be derived our popular festival called *harvest-home*.

DECEM PAGI (anc. geog.), a town of Belgica: Now *Dieuse*, in Lorraine, on the rivulet Seille or Selna, near the lake Lindre, about seven German miles to the north-east of Nancy.

DECEMPEDA, *Δεκαπους*, *ten-feet rod*, an instrument used by the ancients in measuring.

The decempeda was a rule or rod divided into ten feet: whence its name, from *decem* "ten," and *pes*, *pedis*, "foot." The foot was subdivided into twelve inches, and each inch into ten digits. The decempeda was used both in measuring of land, like the chain among us; and by architects to give the proper dimensions and proportions to the parts of their buildings, which use it still retains. Horace, lib. ii. od. 15. blaming the magnificence and delicacy of the buildings of his time, observes, that it was otherwise in the times of Romulus and Cato; that in the houses of private persons there were not then known any porticoes measured out with the decempeda, nor turned to the north to take the cool air.

DECEMVIRI, ten magistrates of absolute authority among the Romans. The privileges of the patricians raised dissatisfaction among the plebeians; who, though freed from the power of the Tarquins, still saw that the administration of justice depended upon the will and caprice of their superiors, without any written statute to direct them, and convince them that they were governed with equity and impartiality. The tribunes complained to the senate, and demanded that a code of laws might be framed for the use and benefit of the Roman people. This petition was complied with; and three ambassadors were sent to Athens and all the other Grecian states, to collect the laws of So-

lon and of all the other celebrated legislators of Greece. **Decemviri** Upon the return of the commissioners it was universally agreed, that ten new magistrates called *Decemviri*, should be elected from the senate to put the project into execution. Their power was absolute, all other offices ceased after their election, and they presided over the city with regal authority. They were invested with the badges of the consul, in the enjoyment of which they succeeded by turns; and only one was preceded by the fasces, and had the power of assembling the senate and confirming decrees. The first decemvirs were Appius Claudius, T. Genutius, P. Sextus, Sp. Veturius, C. Julius, A. Manlius, Ser. Sulpitius, Pluriatius, T. Romulus, Sp. Posthumius, in the year of Rome 302. Under them the laws which had been exposed to public view, that every citizen might speak his sentiments, were publicly approved of as constitutional, and ratified by the priests and augurs in the most solemn and religious manner. They were ten in number, and were engraved on tables of brass; two were afterwards added, and they were called the laws of the twelve tables, *leges duodecim tabularum*, and *leges decemvirales*. The decemviral power, which was beheld by all ranks of people with the greatest satisfaction, was continued; but in the third year after their creation the decemvirs became odious on account of their tyranny, and the attempt of Ap. Claudius to ravish Virginia totally abolished the office. The people were so exasperated against them, that they demanded them from the senate to burn them alive. Consuls were again appointed, and tranquillity re-established in the state.—There were other officers in Rome called decemvirs, who were originally appointed in the absence of the prætor to administer justice. Their appointment became afterwards necessary, and they generally assisted at sales called *subhastationes*, because a spear, *hasta*, was fixed at the door of the place where the goods were exposed to sale. They were called *decemviri litibus judicandis*. The officers whom Tarquin appointed to guard the Sibylline books were also called *decemviri*. They were originally two in number, called *duumviri*, till the year of Rome 388, when the number was increased to ten, five of which were chosen from the plebeians and five from the patricians. Sylla increased their number to fifteen, called *quindecimvirs*.

DECENNALIA, ancient Roman festivals, celebrated by the emperors every tenth year of their reign, with sacrifices, games, and largesses for the people. The emperor Augustus first instituted these solemnities, in which he was imitated by his successors. At the same time the people offered up vows for the emperor, and for the perpetuity of the empire; which were therefore called *vota decennialia*. Augustus's view in establishing the decennialia was to preserve the empire and the sovereign power without offence or restraint to the people. For during the celebration of this feast, that prince used to surrender up all his authority into the hands of the people; who filled with joy, and charmed with the goodness of Augustus immediately delivered it him back again.

DECHALES (Claudius Francis Milliet), an excellent mathematician, mechanic, and astronomer, descended from a noble family, and born at Chamberry in 1611. His principal performances are an edition of Euclid's elements of geometry in which the unservice-

Deciates
||
Decius.

able propositions are rejected, and the uses of those retained, annexed; a discourse on fortification; and another on navigation. These with others have been collected first in 3 vols folio, and afterwards in 4, under the title of *Mundus Mathematicus*: being indeed a complete course of mathematics. He died in 1672, professor of mathematics in the university of Turin.

DECIATES, or *Deciati*, (anc. geog.) a people of Gallia Narbonensis, next the borders of Italy, on the Mediterranean. Now the diocese of Grasse and Antibes. *Deciatum oppidum*, was a town situated between Antibes and Nice.

DECIDUOUS, an appellation chiefly used in respect of plants: thus, the calyx or cup of a flower is said to be *deciduous*, when it falls along with the flower-petals; and, on the contrary, it is called *permanent*, when it remains after they are fallen. Again, deciduous leaves are those which fall in autumn; in contradistinction to those of the ever-greens, which remain all the winter. See DEFOLIATION.

DECIL, in astronomy, an aspect or position of two planets, when they are distant from each other a tenth part of the zodiac.

DECIMAL ARITHMETIC, the art of computing by decimal fractions. See ARITHMETIC.

DECIMATION, a punishment inflicted by the Romans, on such soldiers as quitted their posts, or behaved themselves cowardly in the field. The names of the guilty were put into an urn or helmet, and as many were drawn out as made the tenth part of the whole number, and those were put to the sword, and the others saved. This was called *decimare*; a word of the ancient Roman militia, who, to punish whole legions, when they had failed in their duty, made every tenth soldier draw lots, and put him to death for an example to the others.

As the Romans had their *decimatio*, they had also the *vicefimatio*, and even *centesimatio*, when only the 20 or 100th man suffered by lot.

DECIPHERING, the art of finding the alphabet of a cipher. For the art both of CIPHERING and Deciphering, see the article CIPHER.

DECIUS MUS, a celebrated Roman consul, who, after many glorious exploits, devoted himself to the gods manes for the safety of his country in a battle against the Latins; about 340 years before the Augustan age. His son Decius imitated his example, and devoted himself in like manner in his fourth consulship, when fighting against the Gauls and Samnites. His grandson also did the same in the war against Pyrrhus and the Tarentines. This action of devoting oneself was of infinite service to the state. The soldiers were animated by the example, and induced to follow with intrepidity a commander who, arrayed in an unusual dress, and addressing himself to the gods with solemn invocation, rushed into the thickest part of the enemy to meet his fate.

DECIUS (Cn. Metius, Q. Trajanus), a native of Pannonia, sent by the Emperor Philip to appease a sedition in Mœsia. Instead of obeying his master's command, he assumed the imperial purple, and soon after marched against him, and at his death became the only emperor. He signalized himself against the Persians; and when he marched against the Goths, he pushed his horse into a deep marsh, from which he could not

extricate himself, and he perished with all his army by the darts of the barbarians, A. D. 251, after a reign of two years.

Deck.

DECK of a SHIP, (from *decken*, Dan. to cover); the planked floors of a ship, which connect the sides together, and serve as different platforms to support the artillery and lodge the men, as also to preserve the cargo from the sea in merchant vessels. As all ships are broader at the lower deck than on the next above it, and as the cannon thereof are always heaviest, it is necessary that the frame of it should be much stronger than that of the others; and for the same reason the second or middle deck ought to be stronger than the upper deck or fore-castle.

Ships of the first and second rates are furnished with three whole decks, reaching from the stem to the stern, besides a fore-castle and a quarter-deck, which extends from the stern to the main-mast; between which and the fore-castle a vacancy is left in the middle, opening to the upper deck, and forming what is called the *waist*. There is yet another deck above the hinder or aftmost part of the quarter-deck, called the *poop*, which also serves as a roof for the captain's cabin or couch.

The inferior ships of the line of battle are equipped with two decks and a half; and frigates, sloops, &c. with one gun-deck and a half, with a spar-deck below to lodge the crew.

The decks are formed and sustained by the beams, the clamps, the water-ways, the carlings, the ledges, the knees, and two rows of small pillars called *flanchions*, &c. See those articles.

That the figure of a deck, together with its corresponding parts, may be more clearly understood, we have exhibited a plan of the lower-deck of a 74 gun ship in Plate CLVI. And as both sides of the deck are exactly similar, the pieces by which it is supported appear on one side, and on the other side the planks of the floor of which it is composed, as laid up on those upper pieces.

A, the principal or main hatch-way.

B, the stern-post.

C, the stem.

D, the beams, composed of three pieces, as exhibited by D, in one of which the dotted lines show the arrangement of one of the beams under the other side of the deck.

E, part of the vertical or hanging knees.

F, the horizontal or lodging knees, which fasten the beams to the sides.

G, the carlings ranging fore and aft, from one beam to another.

H, the gun-ports.

I, the pump-dales, being large wooden tubes, which return the water from the pumps into the sea.

K, the spurs of the beams, being curved pieces of timber serving as half-beams to support the decks, where a whole beam cannot be placed on account of the hatchways.

L, the wing-transom, which is bolted by the middle to the stern-post, and whose ends rest upon the fashion-pieces.

M, the bulk-head or partition, which incloses the manger, and prevents the water which enters at the hawse-holes from running aft between decks.

NN,

Deck,
Declama-
tion.

NN, the fore hatch-way.
OO, the after hatch-way.
P, the drum-head of the gear capstern.
P p, the drum-head of the main capstern.
Q, The wing-transom knee.
R, one of the breast-hooks under the gun-deck.
S, the breast-hook of the gun-deck.
TT, the station of the chain-pumps.
V, the breadth and thickness of the timbers at the height of the gun-deck.
UU, scutes leading to the gunner's store-room, and the bread-room.
W, the station of the fore-mast.
X, the station of the main-mast.
Y, the station of the mizen-mast.
Z, the ring-bolts of the decks, used to retain the cannon whilst charging.

a a, The ring-bolts of the sides whereon the tackles are hooked that secure the cannon at sea.

c a a d, The water-ways, through which the scupper holes are pierced, to carry the water off from the deck into the sea.

b b, Plan of the foremost and aftmost cable-bits, with their cross-pieces g g, and their standards c e.

Thus we have represented on one side all the pieces which sustain the deck with its cannon; and on the other side, the deck itself, with a tier of 32 pounders planted in battery thereon. In order also to show the use of the breeching and train-tackle, one of the guns is drawn in as ready for charging.

The number of beams by which the decks of ships are supported, is often very different, according to the practice of different countries; the strength of the timber of which the beams are framed; and the service for which the ship is calculated.

As the deck which contains the train of a fire-ship is furnished with an equipage peculiar to itself, the whole apparatus is particularly described in the article *FIRE-ship*.

Flush-DECK implies a continued floor laid from stem to stern, upon one line, without any stops or intervals.

Half-DECK, a space under the quarter-deck of a ship of war, contained between the foremost bulk-head of the steerage and the fore-part of the quarter-deck. In the colliers of Northumberland the steerage itself is called the *half-deck*, and is usually the habitation of the crew.

DECLAMATION, a speech made in public, in the tone and manner of an oration, uniting the expression of action to the propriety of pronunciation, in order to give the sentiment its full impression upon the mind. According to the manners and customs of the present age, public harangues are made only, 1. In the pulpit. 2. In the senate, in council, or other public assembly. 3. By public professors. 4. On the theatre.

I. With regard to the declamation of the pulpit, the dignity and sanctity of the place, and the importance of the subject, require the preacher to exert the utmost powers of his voice to produce a pronunciation that is perfectly distinct and harmonious, and that he observe a deportment and action which is expressive and graceful. No man, therefore, who is destitute of a voice, should ascend the pulpit, and there act the part of a

pantomime before his audience. The preacher should not, however, roar like a common cryer, and rend the ear with the voice of thunder; for such kind of declamation is not only without meaning and without persuasion, but highly incongruous with the meek and gentle expressions of the gospel. He should likewise take particular care to avoid a monotony; his voice should rise from the beginning, as it were by degrees, and its greatest strength should be exerted in the application. Each inflexion of the voice should be adapted to the phrase, and to the meaning of the words; and each remarkable expression should have its peculiar inflexion. The dogmatic requires a plain, uniform tone of voice only; and the menaces of the gospel demand a greater force than do its promises and rewards; but the latter should not be pronounced in the soft tone of a flute, nor the former with the loud sound of a trumpet. The voice should still retain its natural tone in all its various inflexions. Happy is that preacher, to whom nature has given a voice that is at once strong, flexible, and harmonious.

An air of complacency and benevolence, as well as devotion, should be constantly visible in the countenance of the preacher. But every appearance of affectation must be carefully avoided: for nothing is so disgusting to an audience, as even the semblance of dissimulation. Eyes constantly rolling, turned towards heaven, and streaming with tears, rather denote a hypocrite, than a man possessed of the real spirit of religion, and that feels the true import of what he preaches. An air of affected devotion infallibly destroys the efficacy of all that the preacher can say, however just and important it may be. On the other hand, he must avoid every appearance of mirth or raillery, or of that cold unfeeling manner which is so apt to freeze the hearts of his hearers.

The body should be in general erect, and in a natural and easy attitude. The perpetual movement, or contortion, of the body, has a ridiculous effect in the pulpit, and makes the figure of a preacher and a harlequin much too similar. But, on the other hand, he ought not to remain constantly upright and motionless, like a speaking statue.

The motions of the hands give a strong expression to a discourse; but they should be constantly decent, grave, noble, and expressive. The preacher, who is incessantly in action, who is perpetually clasping his hands, or who menaces with a clenched fist, or counts his arguments on his fingers, will only excite mirth among his auditory. In a word, declamation is an art that the sacred orator should study with the utmost assiduity. The design of a sermon is to convince, to affect, and to persuade. The voice, the countenance, and the action, which are to produce this triple effect, are therefore the objects to which the preacher should particularly apply himself.

II. The declamation of a minister or statesman in the senate, in council, or other public assembly, is of a more unconfined nature. To persuade, to move the passions, and gain an ascendancy in a public assembly, the orator should himself feel the force of what he says, and the declamation should only express that internal sensation. But nothing should be carried to excess. A suavity in the tone of voice, a dignity of deportment, a graceful action, and a certain tranquillity of countenance

Declama-
tion.*Bielfield's*
Elements.

Declama-
tion.

nance, should constantly accompany the statesman when he speaks in public, even when he is most earnestly engaged in debate, or when he is addressing his sovereign in person. A pleasing tone of voice, and a distinct pronunciation, prejudice the hearers greatly in the speaker's favour. A young man may improve these to a surprising degree. Demosthenes, who had a natural impediment in his speech, was accustomed to go to the sea-shore, and partly filling his mouth with pebbles, he declaimed with a loud voice. The stones by degrees gave a volubility to his tongue, and the roaring of the waves reconciled him insensibly to the noise of the multitude.

III. The principal object of a public professor is the instruction of the studious youth: for which purpose, he is to convince and persuade. Every tone of voice, every expression of the countenance, or action of the body, which can produce this effect by enforcing the words, should therefore be employed by those who are to teach the sciences. There is, moreover, one very essential reflection which every professor ought to make, and which is, that the chair, from which he harangues, is surrounded by young students, naturally possessed with vivacity, not unfrequently ludicrous, and for the most part previously instructed in the preparatory sciences. They are therefore constantly inclined to criticise, to jest, and to ridicule: for which reason, the professor should endeavour to inspire them with respect and attention, by a grave, commanding, and venerable countenance; and carefully avoid all appearance of grimace in his action, and every kind of affectation in his discourse, that he may not afford the least opportunity for pleasantry.

IV. We are now come to *theatric declamation*.

1. This was very different among the ancients from what it is, and ought to be, with us, from the nature of the thing itself, and from the difference of circumstances. Numberless passages in Quintilian, and other ancient historians, critics, grammarians, and commentators, evidently prove, that the ancient dramatic declamation was subservient to the rules of the musical rhythmus; and by this, according to Aristides*, their action, as well as recital, was regulated. But to explain this seeming paradox, it will be necessary to make here some preliminary remarks. The ancients gave a much more extensive signification than we do to the word *music* (*musica*), which they derived from the muses, or at least from some of them. It is for this reason, that the same Aristides and Quintilian define it to be "An art that teaches all that relates to the use of the voice, and the manner of performing all the motions of the body with grace:" *Ars decoris in vocibus & motibus*. Therefore poetry, declamation, dancing, pantomimes, and many other gestures and exercises, were subservient to this art.

2. That part of general music which taught the art of declamation and gesture according to the rules of an established method (and which we perform by instinct, or at most by the aid of common sense), was distinguished by the name of *hypocritic music*: and this musical art was called by the Greeks *orchesis*; and by the Romans *saltatio*. It was, however, so far from being an advantage to the ancients to have had this art, which we have not, that it was, on the contrary, a mark of great imperfection. For, in the first place, it was an

instance of high absurdity to represent a tragedy, or comedy, before an audience of twenty thousand people, the far greatest part of whom could neither hear nor see what passed to any good purpose, unless they were possessed of organs which we have not. The theatres of London and Paris may conveniently contain about a thousand persons; and that is found sufficient in the most populous cities, where there are several places of entertainment on the same day, and where the people are reasonable enough to succeed each other in their diversions. As the features of the face could not be distinguished at so great a distance, and still less the alteration of countenance in order to represent the different passions, they were obliged to have recourse to *masks*; a wretched, childish invention, that destroyed all the strength and variety of expression. Their action became extravagant; and, at the same time, subservient to a regular mechanism, which prevented all the refinement, and all the pleasure of surprise, in the performance; and must have had an effect horribly disagreeable to those who were placed near the stage.

3. The egregious imperfection of their language likewise, which consisted of syllables long and short, whose duration was determined by a set measure of time, and their manner of tuning syllables, after the method of the *orchesis* of the Greeks, was another disadvantage. For by this means they determined by notes and characters placed after the long and short syllables, not only the nature, but the duration, of each action. Now, nothing could be more affected, more constrained and disgusting, than such method of declaiming. How far superior in this respect are the moderns, who consult nature alone in their *theatric declamation*; who can make the audience hear each sigh; who can accompany it with a proper attitude; who can incessantly vary their action; who can seize the lucky moment, and make the countenance fully express the sensations of the mind? Nature does all here; and art, infinitely inferior to nature, did all among the ancients. Modern declamation cannot be subservient to a musical rhythmus, seeing we speak rapidly, and without affectation. Our actors learn their art without art, from nature itself, assisted by reflection; and they arrive at a degree of excellence infinitely greater than that of the ancients, by a method far more simple, and by efforts incomparably more easy.

4. We do not, moreover, precisely know what the *theatric declamation* of the ancients was; nor what were the musical instruments which accompanied that declamation. The title to the *Eunuch* of Terence says, for example, "That Flaccus, the freedman of Clandius, made the music of that piece, in which he employed the two flutes, the right and the left." These flutes, it is likely, gave the tone to the actor; which must have had a very odd effect on the audience. Most of the ancient pieces have similar titles. They who would be particularly informed of the art of declaiming among the Greeks and Romans, may read to advantage the *Critical Reflections on Poetry and Painting* by the Abbé du Bos. The third part of that work consists entirely of learned researches and ingenious reflections on this silly practice of the ancients. But as this art has happily no place in modern declamation, and can at best serve only to make a parade

Declama-
tion.

* *De Musica*,
lib. i.

Declama-
mation. of erudition, we shall say no more of it, but pass to matters of real utility.

5. We think there is good reason to believe, moreover, that the most polished nations of modern Europe do not accompany their discourses, in general, with so many gesticulations, as did the Greeks, the Romans, and other inhabitants of warm climates. They appear to have found the method of animating a discourse, and giving it an expression, by the simple inflections of the voice, and by the features of the countenance; which is far more decent, more just, and rational, than all those contortions which perpetually derange the natural attitude of the body and its members, and give the speaker the air of a harlequin.

6. *Expression*; therefore, forms at once the essence and the end of declamation; and the means of producing it consists in a pronunciation that is sonorous, distinct, and pleasing, supported by an action that is decent and proper to the subject. If the best dramatic poet has need of a good declaimer or actor to make his writing produce its proper effect, the actor has likewise need of a good poet to enable him to please and affect by his action: for it is to little purpose that he endeavours to charm his auditory by uniting, with nature, all the powers of art, if the poet has not furnished him with sentiments that are rational and affecting.

7. The actor, in studying his part before a large mirror, where he can see his whole figure, in order to determine the most proper expression for every thought, should consult nature, and endeavour to imitate her. But, in this imitation, he should take care not to make too servile a copy. He has this to observe, in common with his colleagues, the masters in all the polite arts: The theatre is intended to exhibit an imitation of nature, and not nature itself. Tragedy and comedy form pictures of human life; but these pictures are also pieces of perspective, which require strokes somewhat stronger than nature, that they may be discerned at a distance. The actor is elevated to a considerable height from the ground; he is surrounded by scenery, he is separated from the audience by the orchestra, and he speaks in verse; all this is not natural: but the spectator is to accede to this necessary illusion, in order to promote his own pleasure, which would not be so great as it is were all these matters otherwise disposed. Declamation, therefore, should somewhat exceed, but never lose sight of, nature.

8. The tone of the actor's voice should be natural, but regulated by the extent of the theatre; sufficiently loud to be heard by all the audience, but not so violent as to rend their ears. A pure and graceful pronunciation, without any provincial accent, is likewise a great merit in an actor; and he should also habituate himself to speak in a manner perfectly distinct. It is a capital point in the pronouncing of verse, not to separate the two hemistichs, by resting too long on the *caesura* in the middle, or dwelling on the end of each hemistich: for, by so doing, the actor falls into a monotony, an insufferable uniformity of cadence, in a piece that consists of some thousand verses. The gradations of the voice demand also a very judicious observance. The speaker, who begins in a high tone, will find it very difficult to sustain it through the whole piece; and he, who clamours incessantly, will find his

lungs fail him in those parts where the vehemence of passion requires the strongest efforts. If we may be allowed the expression, the strongest touches, the boldest figures, will not there stand out from the picture in a striking manner.

9. The deportment of an actor should be constantly graceful, decent, and proper to the character he represents. An old man has a different position of body from a young *petit maitre*; an aged queen from a young princess; a noble gallant from a valet de chambre. A rational observance of nature, and an imitation of the best actors, are here the surest guides. The same may be said of the action of the hands, the theatrical step, &c. An inanimated figure, a body in the position of a statue, and hands immovable, are as displeasing in the scene as a player whose incessant gesticulation resembles the action of a puppet.

10. Every actor who aspires to make his art something more than merely mechanical, will begin by enabling himself readily to repeat his part, that the defect of his memory may not embarrass his action. When he is so far a master of it, he will make it the subject of serious reflection in his closet; endeavour to seize the true sense of the author; and to find out that expression of each sentiment and passion, which is the most natural, the most striking, and best adapted to the stage; and which he will cultivate by repeated essays; till he is able to render it in its full force.

DECLARATORY ACTION. See LAW, N^o clxxxii. 21.

DECLENSION, in, grammar, an inflection of nouns according to their divers cases; as nominative, genitive, dative, &c. See GRAMMAR.

DECLINATION, in astronomy, the distance of any celestial object from the equinoctial, either northward or southward. It is either true or apparent, according as the real or apparent place of the object is considered. See ASTRONOMY, N^o 409, 410.

DECLINATION of the Sea-Compass or Needle, is its variation from the true meridian of any place.

DECLINATION of a Wall or plane for Dials, is an arch of the horizon, contained either between the plane and the prime vertical circle, if you reckon it from the east or west; or else between the meridian and the plane, if you account from the north or south. See DIAL.

DECLINATORIES, are instruments for taking the declinations, inclinations, and reclinations of planes; and they are of several kinds.

The best sort for taking the declination consists of a square piece of brass or wood, with a limb accurately divided into degrees; and every fifth minute, if possible, having a horizontal dial moving on the centre made for the latitude of the place it is to serve in; and which has a small bit of fine brass fixed on its meridian line, like a fiducial edge, to cut the degrees of the limb: for at any time when the sun shines, by having the hour of the day, you may find the declination of any wall or plane by this instrument.

DECLINATURE of JUDGES. See LAW, N^o clvi. 12.

DECLIVITY denotes the reverse of ACCLIVITY.

DECOCTION, usually signifies either the action of boiling a substance in water, or the water itself in which the substance has been boiled. It is only applicable

Declarato-
ry
Decoction.

Decollation || **Decoration**
 cable to matters containing some principles soluble in water; such particularly are animal and vegetable matters. Decoction ought not to be used with such substances as contain any volatile principles, as they would be dissipated in the air during the process. But it may be safely used, nay even becomes necessary, when the matters to be treated are solid, and of a close and compact texture; because then the water could not extract its principles without a boiling heat. Most soft animal matters, as flesh, skin, tendons, may be conveniently boiled in water; because they contain no principle volatile with a boiling heat. Water extracts from them nothing but a gelatinous substance, and some oily parts which float on the surface of the water. All vegetable matters which are inodorous, and particularly those which are hard, as roots, barks, &c. are generally boiled, when an extraction of their principles by water is required.—To this rule, however, there are some exceptions. Peruvian bark, for instance, gives its strength to cold water better than to such as is boiling hot. Many other vegetables also have the same property of yielding less to boiling than to cold water. And therefore a general rule may be established, that decoction ought not to be employed but when absolutely necessary; that is, when the same principles, or the same quantities of those principles, cannot be obtained by an infusion, and that without heat, if it can be so done, considering that the proximate principles of vegetables are generally so delicate, and so susceptible of change and decomposition, that frequently the most gentle heat changes much their nature and properties.

DECOLLATION, BEHEADING, a term seldom used but in the phrase *decollation* of St John Baptist; which denotes a painting, wherein is represented the Baptist's head struck off from his trunk; or the feast held in honour of that martyr.

DECOMPOSITION, in chemistry, usually signifies the disunion or separation of the constituent parts of bodies.—It differs from mere mechanical division, in that when a body is chemically decomposed, the parts into which it is resolved are essentially different from the body itself; but though a mechanical force is applied to it ever so long, or with ever so much violence, the minutest particles into which the body may be reduced, still retain their original nature.—Thus, for example, though we suppose nitre, or any other salt, to be reduced to ever so fine powder, each particle retains the nature of nitre, as much as the largest unpounded mass; but if oil of vitriol is applied, a decomposition takes place, and one of the component parts of the nitre rises in the form of a smoking acid spirit, which never could have been suspected to lie hid in the mild neutral salt.

DECORATION, in architecture, any thing that adorns and enriches a building, church, triumphal arch, or the like, either without side or within.

The orders of architecture contribute greatly to the decoration; but then the several parts of those orders must have their just proportions, characters, and ornaments; otherwise the finest order will bring confusion rather than richness. See **ARCHITECTURE**.

Decorations in churches, are paintings, vases, festoons, &c. occasionally applied to the walls; and with so much conduct and discretion, as not to take off any

thing from the form of the architecture: as is much practised in Italy at the solemn feasts.

DECORATION is more particularly applied to the scenes of theatres.

In operas, and other theatrical performances, the decorations must be frequently changed conformably to the subject.

The ancients had two kinds of decorations for their theatres: the first, called *versatiles*, having three sides, or faces, which were turned successively to the spectators: the other called *ductiles*, showing a new decoration by drawing or sliding another before it.—This latter sort is still used, and apparently with much greater success than among the ancients, who were obliged to draw a curtain whenever they made a change in the decoration; whereas on our stage the change is made in a moment, and almost without being perceived.

DECORUM, in architecture, is the suitableness of a building, and the several parts and ornaments thereof, to the station and occasion.

DECOUPLE, in heraldry, the same as uncoupled: thus a chevron decouple, is a chevron wanting so much of it towards the point, that the two ends stand at a distance from one another, being parted and uncoupled.

DECOY, in naval affairs, a stratagem employed by a ship of war to betray a vessel of inferior force into an uncautious pursuit, till she has drawn her within the range of her cannon, or what is called within *gun-shot*. It is usually performed by painting the stern and sides in such a manner as to disguise the ship, and represent her either much smaller and of inferior force, or as a friend to the hostile vessel, which he endeavours to ensnare, by assuming the emblems and ornaments of the nation to which the stranger is supposed to belong. When she has thus provoked the adversary to chase, in hopes of acquiring a prize, she continues the decoy, by spreading a great sail, as endeavouring to escape; at the same time that her course is considerably retarded by an artful alteration of her trim till the enemy approaches. Decoying is also performed to elude the chase of a ship of a superior force in a dark night, by throwing out a lighted cask of pitch into the sea, which will burn for a considerable time and misguide the enemy. Immediately after the cask is thrown out, the ship changes her course, and may easily escape if at any tolerable distance from the foe.

DECOY, among fowlers, a place made for catching wild-fowl. A decoy is generally made where there is a large pond surrounded with wood, and beyond that a marshy and uncultivated country: if the piece of water is not thus surrounded, it will be attended with the noise and other accidents which may be expected to frighten the wild-fowl from a quiet haunt, where they mean to sleep, during the day-time, in security. If these noises or disturbances are wilful, it hath been held that an action will lie against the disturber.—As soon as the evening sets in, the decoy *rises* (as they term it), and the wild-fowl feed during the night. If the evening is still, the noise of their wings, during their flight, is heard at a very great distance, and is a pleasing though rather melancholy sound. This *rising* of the decoy in the evening, is in Sommersetshire called *radding*.

Decoration
 |
Decoy.

Decoy.

The decoy-ducks are fed with hempseed, which is thrown over the screens in small quantities, to bring them forwards into the pipes or canals, and to allure the wild-fowl to follow, as this seed is so light as to float.

There are several pipes, as they are called, which lead up a narrow ditch that closes at last with a funnel-net. Over these pipes (which grow narrower from their first entrance) is a continued arch of netting suspended on hoops. It is necessary to have a pipe or ditch for almost every wind that can blow, as upon this circumstance it depends which pipe the fowl will take to; and the decoy-man always keeps on the leeward side of the ducks, to prevent his effluvia reaching their sagacious nostrils. All along each pipe, at certain intervals, are placed screens made of reeds, which are so situated, that it is impossible the wild-fowl should see the decoy man, before they have passed on towards the end of the pipe, where the purse-net is placed. The inducement to the wild-fowl to go up one of these pipes is, because the decoy-ducks trained to this lead the way, either after hearing the whistle of the decoy-man, or enticed by the hempseed; the latter will dive under water, whilst the wild-fowl fly on, and are taken in the purse.

It often happens, however, that the wild-fowl are in such a state of sleepiness and dozing, that they will not follow the decoy-ducks. Use is then generally made of a dog, who is taught his lesson: he passes backwards and forwards between the reed-screens (in which are little holes, both for the decoy-man to see, and the little dog to pass through); this attracts the eye of the wild-fowl, who, not choosing to be interrupted, advance towards the small and contemptible animal, that they may drive him away. The dog all the time, by the direction of the decoy-man, plays among the screens of reeds, nearer and nearer the purse-net: till at last, perhaps, the decoy-man appears behind a screen, and the wild-fowl not daring to pass by him in return, nor being able to escape upwards on account of the net-covering, rush on into the purse-net. Sometimes the dog will not attract their attention, if a red handkerchief, or something very singular, is not put about him.

The general season for catching fowl in decoys, is from the latter end of October till February: the taking of them earlier is prohibited in Britain by an act 10. Geo. II. c. 32. which forbids it from June 1st till October 1st, under the penalty of five shillings for each bird destroyed within that space.

The Lincolnshire decoys are commonly set at a certain annual-rent, from 5 to 20 pounds a-year: and there is one in Somersetshire that pays 30l. The former contribute principally to supply the markets in London. Amazing numbers of ducks, wigeons, and teal, are taken: by an account sent us * of the number caught a few winters past, in one season, and in only ten decoys, in the neighbourhood of Wainfleet, it appeared to amount to 21,200, in which are included several other species of ducks: it is also to be observed, that, in the above particular, wigeon and teal are reckoned but as one, and consequently sell but at half price of the ducks. This quantity makes them so cheap on the spot, that we have been assured, several decoy-men would be content to contract for years to deliver their ducks at Boston, for 10d. per couple. The account of

* Pennant's Brit. Zool. ii. 595.

the numbers here mentioned, relates only to those that were sent to the capital.

It was customary formerly to have in the fens an annual driving of the young ducks before they took wing. Numbers of people assembled, who beat a vast tract, and forced the birds into a net placed at the spot where the sport was to terminate. A hundred and fifty dozens have been taken at once: but this practice being supposed to be detrimental, has been abolished by act of parliament.

DECREE, an order made by a superior power for the regulation of an inferior.

DECREE, in the civil law, is a determination which the emperor pronounces upon hearing a particular cause between the plaintiff and defendant.

DECREES of Councils, are the laws made by them, to regulate the doctrine and policy of the church.

DECREES in Chancery, are the determination of the lord-chancellor, upon a full hearing of the merits of a cause.

DECREET, in the law of Scotland, a final decree or judgment of the lords of session, from which an appeal only lies to parliament.

DECREET-Arbitral, in Scots law, the sentence or judgment of one to whom parties voluntarily submit the determination of any question betwixt them*.

DECREMENT, in heraldry, signifies the wane of the moon from the full to the new. The moon in this state is called moon decrescant, or in *decuris*; and when borne in coat armour, faces to the left side of the escutcheon, as she does to the right side when in the increment.

DECREPITATION, in chemistry, signifies the quick separation of the parts of a body, occasioned by a strong heat, and accompanied with noise and crackling. This effect is most frequently produced by water contained betwixt the parts of the decrepitating body, when these parts have a certain degree of adhesion together. This water being quickly reduced into vapour by the heat suddenly applied to it, rarifies, and bursts with noise the parts which compress it. The bodies most subject to decrepitation are certain salts, such as common salt, vitriolated tartar, nitre of lead, &c. the decrepitation of all which proceeds from the water of their crystallization. Clays which are not perfectly dry, and flints, are also subject to decrepitation.

DECREPITUDE, in medicine, the consequence of the infirmities of old age; which by degrees leads to death. See DEATH.

DECRETAL, in the canon law, a letter of a Pope determining some point or question in the ecclesiastical law. The decretals compose the second part of the canon law. The first genuine one, acknowledged by all the learned as such, is a letter of Pope Siricius, written in the year 385, to Himerus bishop of Tarragona, in Spain, concerning some disorders which had crept into the churches of Spain. Gratian published a collection of decretals, containing all the ordinances made by the popes till the year 1150. Gregory IX. in 1227, following the example of Theodosius and Justinian, formed a constitution of his own, collecting into one body all the decisions and all the causes which served to advance the papal power; which collection of decretals was called the *pentateuch*, because it contains five books.

DECUMARIA,

Decumaria
||
Dedication.

DECUMARIA, in botany: A genus of the monogynia order, belonging to the dolecandria class of plants; and in the natural method ranking under those of which the order is doubtful. The calyx is decapphyllous, superior; the petals ten; the fruit unknown.

DECUMATES AGRI, tithed fields, or granted on a tithe, as appears from Tacitus, to that rabble of Gauls who succeeded the Mercomanni, that had till then proved a check to the Roman conquests up the Rhine; and hence probably their name, people living on the marches or limits of the empire. In Cicero we have Ager Decumanus, which is of the same import with the Ager Decumas of Tacitus.

DECUPLE PROPORTION, that of ten to one.

DECURIO, a subaltern officer in the Roman armies. He commanded a decuria, which consisted of ten men, and was the third part of a turma, or the 30th part of a legio of horse which was composed of 380 men. There were certain magistrates in the provinces called *decuriones municipales*, who formed a body to represent the Roman senate in free and corporate towns. They consisted of ten; whence the name and their duty extended to watch over the interests of their fellow citizens, and to increase the revenues of the commonwealth. Their court was called *curia decurionum* and *minor senatus*; and their decrees, called *decreta decurionum*, were marked with two D. D. at the top. They generally styled themselves *civitatum patres curiales* and *honorati municipiorum senatores*. They were elected with the same ceremonies as the Roman senators; they were to be at least 25 years of age, and to be possessed of a certain sum of money. The election happened in the kalends of March.

DECURRENT LEAF. See BOTANY, p. 440.

DECURY, ten persons ranked under one chief or leader, called the *decurio*.

The Roman cavalry was divided into decuries, which were subdivisions of a century, each century containing ten decuries.

DECUSSATION, a term in geometry, optics, and anatomy, signifying the crossing of two lines, rays, or nerves, when they meet in a point, and then go on separately from one another.

DECUSSORIUM, a surgeon's instrument, which, by pressing gently on the dura mater, causes an evacuation of the pus collected between the cranium and the before mentioned membrane, through the perforation made by the trepan.

DEDHAM, a town of Essex in England, consisting of about 400 lofty houses. The streets are not paved, but very clean, occasioned by their lying pretty high. It has one large old church, remarkable for a fine Gothic steeple, with a great deal of carved work about it, but much injured by time. E. Long. 1. 10. N. Lat. 52. 5.

DEDICATION, the act of consecrating a temple, altar, statue, palace, &c. to the honour of some deity.

The use of dedications is very ancient both among the worshippers of the true God and among the heathens: the Hebrews call it *הַנְּחִיחַ* *hnanuchah*, "imitation;" which the Greek translators render *Επιμανια*, and *Επιμανισμος*, "renewing."

In the scripture we meet with dedications of the tabernacle, of altars, of the first and second temple, and even of the houses of private persons. There are also

dedications of vessels, and garments of the priests and Levites, and even of the men themselves. Dedication,
Dec.

The heathens had also dedications of temples, altars, and images of their gods, &c. Nebuchadnezzar held a solemn dedication of his statue, *Dan. iii. 2*. Pilate dedicated gilt bucklers at Jerusalem to Tiberius, *Philo de legat.* Petronius would have dedicated a statue to the emperor in the same city, *ibid. p. 791*. Tacitus, *Hist. lib. iv. c. 53*. mentions the dedication of the capitol, upon rebuilding it by Vespasian, &c.

The Jews celebrated the anniversary of the dedication of their temple every year for eight days. This was first enjoined by Judas Maccabeus, and the whole synagogue, in the year of the Syro-Macedonian era 148, *i. e.* 164 years before Christ. The heathens had the like anniversaries, as that of the dedication of the temple of Parthenope, mentioned by Lycophron. Under Christianity, dedication is only applied to a church; and is properly the consecration thereof performed by a bishop, with a number of ceremonies prescribed by the church.

The Christians finding themselves at liberty under Constantine, in lieu of their ruinous churches, built new ones in every place; and dedicated them with a deal of solemnity. The dedication was usually performed in a synod; at least they assembled a number of bishops to assist at the service. We have the description of those of the churches at Jerusalem and Tyre in Eusebius, and many others in later writers.

DEDICATION, in literature, is an address prefixed to a book, soliciting patronage, or testifying respect for the person to whom it is made. The dedication of the fourth part of Mr Edwards's History of Birds, is curious: *To GOD! the ONE eternal! the incomprehensible! the omnipresent! omniscient and almighty Creator of all things that exist! from orbs immeasurably great to the minutest points of matter, this Atom is dedicated and devoted, with all possible gratitude, humiliation, and worship, and the highest adoration both of body and mind, by his most resigned, low, and humble creature, G. E.*

DEE (John), a famous mathematician and astrologer, was born (July 1527) in London, where his father was a wealthy vintner. In 1542, he was sent to St John's college, Cambridge. After five years close application to mathematical studies, particularly astronomy, he went to Holland, in order to visit several eminent mathematicians on the continent. Having continued abroad near a year, he returned to Cambridge; and was there elected one of the fellows of Trinity college, then first erected by king Henry VIII. In 1548, he took the degree of master of arts; and, in the same year, left England a second time; his stay at home being rendered uneasy to him, by the suspicions that were entertained of his being a conjuror; arising partly from his application to astronomy, but especially on account of a piece of machinery in the *Ερπνη* of Aristophanes, which he exhibited to the university, and in which he represented the Scarabeus flying up to Jupiter, with a man and a basket of victuals on its back. These suspicions he could never after shake off: nor did his subsequent conduct, as we shall see, tend to clear him of the imputation; for if he was not actually a conjuror, it was not for want of endeavours.

Upon leaving England, he went to the university of Louvain; where he was much esteemed, and visited by several

Dec. several persons of high rank. Here he resided about two years, and then set out for France; where, in the college of Rheims, he read lectures of Euclid's elements with vast applause. In 1551, he returned to England, and was introduced by the secretary Cecil to king Edward, who assigned him a pension of 100 crowns, which he afterwards relinquished for the rectory of Upton, upon Severn: but soon after the accession of queen Mary, having some correspondence with the lady Elizabeth's servants, he was accused of practising against the queen's life by enchantment. On this account he suffered a tedious confinement, and was several times examined; till, in the year 1555, he obtained his liberty by an order of council.

When queen Elizabeth ascended the throne, our astrological Dee was consulted by lord Dudley, concerning a propitious day for her majesty's coronation. He was on this occasion introduced to the queen, who made him great promises, which were never performed, though she condescended to receive his instructions relative to the mystical interpretation of some of his unintelligible writings, which he published about this time. In 1564, he made another voyage to the continent; in order to present a book which he had dedicated to the emperor Maximilian. He returned to England in the same year; but in 1571, we find him in Lorraine; where, being dangerously ill, the queen sent over two physicians to his relief. Having once more returned to his native country, he settled at Mortlake in Surrey, where he continued his studies with unremitting ardor, and collected a considerable library of curious books and manuscripts, with a variety of instruments; most of which were afterwards destroyed by the mob, as belonging to one who dealt with the devil. In 1578, the queen being much indisposed, Mr. Dee was sent abroad to consult with German physicians and philosophers (astrologers no doubt) on the occasion. We now behold him again in England, where he was soon after employed in a more rational service. Her majesty, desirous to be informed concerning her title to those countries which had been discovered by her subjects, commanded Mr. Dee to consult the ancient records, and furnish her with proper geographical descriptions. Accordingly, in a short time he presented to the queen, in the gardens at Richmond, two large rolls, in which the discovered countries were geographically described and historically illustrated. These rolls are preserved in the Cotton library, *Augustus I.* His next employment was the reformation of the kalendar, on which subject he wrote a rational and learned treatise, preserved in the Ashmolean library at Oxford.

Hitherto the extravagancies of our eccentric philosopher seem to have been counterpoised by a tolerable proportion of reason and science; but henceforward we consider him as a mere necromancer and credulous alchymist. In the year 1581, he became acquainted with one Edward Kelley, by whose assistance he performed diverse incantations, and maintained a frequent imaginary intercourse with spirits. He was particularly intimate, it seems, with the angels Raphael and Gabriel. One of them made him a present of a black speculum, in which his angels and demons appeared as often as he had occasion for them; they answered

VOL. V.

his questions, and Kelley's business was to record their dictates:

Kelley did all his feats upon
The devil's looking-glass, a stone.

HUDIB. part ii. canto iii. v. 631.

In 1583, they were both introduced to a certain Polish nobleman, then in England, named *Albert Laski*, palatine of Siradia, a person equally addicted to the same ridiculous pursuits. He was so charmed with Dee and his companion, that he persuaded them to accompany him to his native country. They embarked for Holland in Sept. 1583; and travelling over land, arrived at the town of Laski in February following. Their patron, however, finding himself abused by their idle pretensions, persuaded them to pay a visit to Rodolph king of Bohemia; who, though a credulous man, was soon disgusted with their nonsense. They were afterwards introduced to the king of Poland, but with no better success. Soon after this, they were invited by a rich Bohemian nobleman to his castle of Trebona, where they continued for some time in great affluence; owing, as they asserted, to their art of transmutation by means of a certain powder in the possession of Kelley.

Dee, now quarrelling with his companion in iniquity, quitted Bohemia, and returned to England, where he was once more graciously received by the queen; who, in 1595, made him warden of Manchester college, in which town he resided several years. In 1604, he returned to his house at Mortlake, where he died in the year 1608, aged 81; leaving a large family, and many works, behind him.—The black stone into which Dee used to call his spirits, was in the collection of the earls of Peterborough, whence it came to lady Elizabeth Germaine. It was next the property of the late duke of Argyle, and is now Mr. Walpole's. It appears upon examination to be nothing but a polished piece of cannel-coal.—That Dee was a man of considerable acquirements, is beyond a doubt; his mathematical knowledge is generally allowed: but unless we suppose him a wicked impostor, which is by no means improbable, we must transmit him to posterity as one of the most foolish, superstitious, necromancers of his time. Nevertheless, the celebrated Dr. Hook, many years after Dee's death, took it into his head to prove that his journal, published by Casauban, was entirely cryptographical, concealing his political transactions, and that he was employed by queen Elizabeth as a spy.

DEE, the name of several rivers in Scotland and England; as those whereon the cities of Chester in England, and New Aberdeen in Scotland, are situated. The river Dee in Aberdeenshire abounds with salmon, so as to form one of the greatest salmon-fishings in Scotland.—Over this river there is a bridge of seven arches, built by a bishop of Aberdeen, who left for its support a revenue, which is now so large, that in order to exhaust the fund, a person has a salary to sweep the bridge once a-day.

DEED, an instrument written on paper or parchment, comprehending some contract, bargain, or agreement between the parties thereto, in relation to the matter therein contained.

DEEMSTERS, or DEMSTERS; (from the Saxon *dema*,

4 U

dema,

Dec
Deemsters.

Deeping *dema*, judge or umpire). All controversies in the Isle of Man are decided without process, writings, or any charges, by certain judges, chosen yearly from among themselves, called *deemsters*; there being two of them for each division of the island: they sit judges in all courts, either for life or property; and with the advice of 24 keys, declare what is law in uncommon emergencies.

DEEPING, a town of Lincolnshire in England, seated on the river Weland, in a fenny ground. W. Long. o. 20. N. Lat. 52. 35.

DEER, in zoology. See CERVUS.—The method of hunting the deer in the island of Ceylon is very particular. The huntsmen go out in the night, and only two usually go together: the one of these carries upon his head an earthen vessel, in which there is some fire burning and flaming; the ingredients are generally small sticks cut into pieces, and common rosin. Of this the other man carries a supply about him to replenish the pot when it grows low. The person who has the fire upon his head, carries in one hand a staff, on which there are fixed eight bells; and the larger these are the better. This man goes first into the woods, and the other follows close behind with a spear in his hand. As soon as the deer hears the noise of the bells, he turns towards the place where the sound comes; and seeing the fire, he eagerly runs up to it, and stands gazing at a small distance: the second man has then nothing to do but to kill him with the spear; for he sees neither of them.—Not only deer, but even elks and hares, are thus taken; for they gaze at the fire, and never see the men. The profits of this sort of hunting are very large, and the danger nothing; for though there are numbers of tygers, elephants, and wild boars, in these woods, the huntsmen are in no danger from them while the fire burns, for they all run away from it.

DE FACTO, something actually in fact, or existing; in contradistinction to *de jure*, where a thing is only so in justice, but not in fact: as a king *de facto*, is a person who is actually in possession of a crown, but has no legal right to the same; and a king *de jure*, is the person who has a just right to the crown, though he is out of possession thereof.

DEFAMATION, the speaking slanderous words of another; for which the slanderer is punishable, according to the nature of his offence, either by action upon the case at common law, or by statute in the ecclesiastical court.

DEFAULT, in law, is generally taken for non-appearance in court, at a day assigned; but imports any omission of that which we ought to do, for which judgment may be given against the defaulter.

DEFEASANCE, or DEFEISANCE, in law, a condition relating to some certain deed, which being performed, the deed is defeated and rendered void, as if it had never been made. The difference between a common condition and a defeasance is, that the condition is annexed to, or inserted in, the deed; and a defeasance is a deed by itself, concluded and agreed on between the parties, and having relation to another deed.

DEFECATE, in chemistry, a term applied to a body freed and purged from fæces and impurities.

DEFECTION, the act of abandoning or relinquishing a party or interest a person had been engaged in.—The word is formed of the Latin *deficio*, to fall off.

DEFECTIVE, in general, an appellation given to things which want some of the properties that naturally they ought to have. Thus,

DEFECTIVE or *Deficient Nouns*, in grammar, are such as want either a whole number, a particular case, or are totally indeclinable. See NOUN.

The term *defective* is also applied to a verb that has not all its moods and tenses. See VERB, MOOD, &c.

DEFENCE, in fortification, all sorts of works that cover and defend the opposite posts, as flanks, casements, parapets, and faussebrays. See FORTIFICATION.

Line of DEFENCE, a supposed line drawn from the angle of the curtain, or from any other part in the curtain, to the flanked angle of the opposite bastion.

DEFEND, in general, signifies much the same with protecting, or keeping off injuries offered to any person either by enemies or otherwise.

DEFEND, in our ancient laws and statutes, signifies to prohibit or forbid: as, *Usuarius defendit quoque rex Edwardus ne remaneret in regno*. L. L. Edw. Conf. c. 37. & 5 Rich. 2. c. 7. In which sense Chaucer also uses it in the following passage:

“Where can you in any manner age,
“That ever God defended marriage.”

In 7 Edw. I. there is a statute intitled, “*Statutum de defensione portandi arma*,” &c. And, “it is defended by law to distrain on the highway;” *Coke on Littleton*, fol. 161.

DEFENDANT, in law, the person sued in an action personal; as *tenant* is he who is sued in an action real. See ACTION.

DEFENDER of the FAITH (*Fidei Defensor*), a peculiar title belonging to the king of England; as *Catholicus* to the king of Spain, and *Christianissimus* to the king of France, &c. These titles were given by the popes of Rome. That of *Fidei Defensor* was first conferred by Leo X. on king Henry VIII. for writing against Martin Luther; and the bull for it bears date *quinto idus Octob. 1521*. It was afterwards confirmed by Clement VII. But the pope, on Henry's suppressing the houses of religion at the time of the Reformation, not only deprived him of his title, but deposed him from his crown also: though in the 35th year of his reign, his title, &c. was confirmed by parliament; and hath continued to be used by all succeeding kings to this day.—Chamberlayne says, the title belonged to the kings of England before that time; and for proof hereof appeals to several charters granted to the university of Oxford. So that pope Leo's bull was only a renovation of an ancient right.

DEFENDERS, were anciently notable dignitaries both in church and state, whose business was to look to the preservation of the public weal, to protect the poor and helpless, and to maintain the interests and causes of churches and religious houses. See PROTECTOR.—The council of Chalcedon, can. 2. calls the defender of a church *Εκδικος*. Codin, *de officiis aulae Const.* makes mention of defenders of the palace. There were also a defender of the kingdom, *defensor regni*;

Defection
||
Defender.

Defile *regni*; defenders of cities, *defensores civitatis*; defenders of the people, *defensores plebis*; of the poor, fatherless, widows, &c.

Deflagration. About the year 420, each patriarchal church began to have its defender; which custom was afterwards introduced into other churches, and continued to later days under other names; as those of *Advocate* and *Advowee*.

In the year 407, we find the council of Carthage asking the emperor for defenders, of the number of *Scholastici*, i. e. advocates who were in office; and that it might be allowed them to enter and search the cabinets and papers of the judges and other civil magistrates, whenever it should be found necessary for the interest of the church.

DEFILE, in fortification, a straight narrow passage, through which a company of horse or foot can pass only in a file, by making a small front.

DEFINITE, in grammar, is applied to an article that has a precise determinate signification; such as the article *the* in English, *le* and *la* in French, &c. which fix and ascertain the noun they belong to, to some particular; as *the king*, *le roi*: whereas, in the quality of *king*, *de roi*, the articles *of* and *de* mark nothing precise, and are therefore indefinite.

DEFINITION, in general, a short description of a thing by its properties; or, in logic, the explication of the essence of a thing by its kind and difference.

DEFINITIVE, a term applied to whatever terminates a process, question, &c.; in opposition to provisional and interlocutory.

DEFLAGRATION, in chemistry, the kindling or setting fire to a salt or mineral, &c. either alone or mixed for that purpose with a sulphureous one, in order to purify it.

This short process has been often recommended to the world as of great use in trying the strength of brandies and other vinous spirits, and has been greatly improved in this respect by Mr. Geoffroy.

The common way of trying spirits by deflagration, is to measure out any quantity of it, then to heat it, and set it on fire. If, after it will no longer burn, the remainder is half as much as the quantity measured out for the trial was, then the spirit tried is found to consist of half water, and half totally inflammable spirit; that is, it is somewhat below what we understand by the term *perfect proof*.—This method is much more certain than that by the crown of bubbles which arises upon shaking the spirit in a vial. Mons. Geoffroy's method is this: Take a cylindric vessel two inches high, and as much in diameter, consisting of thin plate silver, that metal being much less liable to rust than copper; this vessel must be fitted with a little rectangular gage exactly graduated into lines, half lines, &c. then the vessel being set level upon a copper case made to contain it, a parcel of the brandy to be examined is poured in, to the height of 16 lines. This height is to be exactly hit by pouring in more than enough at first, and then sucking out the overplus with a very small tube. Then the vessel being heated a little, so as just to make the liquor fume, it is to be set on fire, and left to go out of itself; at the instant when the flame expires, the gage is plunged perpendicularly into the vessel, and the line and quarters exactly noted

which the liquor wants of its former height: this difference gives the precise quantity of alcohol or pure spirit contained in the liquor. Thus, if eight lines of phlegm are found remaining, this being the half of the 16 lines of the original filling, it is plain, that the liquor contained one half spirit, or was something below proof. If only four lines remained, it was nearly double proof, or of a middle nature betwixt alcohol and common proof-spirit.

DEFLECTION of the RAYS of LIGHT, a property which Dr. Hook observed in 1675, and read an account of before the Royal Society, March 18, the same year. He says he found it different both from reflection and refraction, and that it was made towards the surface of the opaque body, perpendicularly. This is the same property which Sir Isaac Newton calls **INFLECTION**.

DEFLORATION, or **DEFLOWERING**, the act of violating or taking away a woman's virginity. See **VIRGINITY**.—Death, or marriage, are decreed by the civil law in case of defloration.

The ancients had so much respect for virgins, that they would not put them to death till they had first procured them to be deflowered. It is said, the natives of the coast of Malabar pay strangers to come and deflower their brides.

In Scotland, and the northern parts of England, it was a privilege of the lords of the manor, granted them by king Ewen, that they should have the first night's lodging with their tenant's wives. King Malcolm III. allowed the tenants to redeem this service at a certain rate, called *marcheta*, consisting of a certain number of cows. Buchanan says it was redeemed with half a mark of silver. The same custom had place in Wales, Flanders, Friesland, and some parts of Germany.

DEFLUXION, in medicine, the falling of the humours from a superior to an inferior part of the body.

DE FOE (Daniel), a writer famous for politics and poetry, was bred a hosier; which profession however he soon forsook, and became one of the most enterprising authors that any age produced. When discontents ran high at the Revolution, and king William was obliged to dismiss his Dutch guards, De Foe, who had true notions of civil liberty, ridiculed the enemies of government in his well-known poem, called *The True-born Englishman*, which had a prodigious sale. The next satire he wrote was intitled, *Reformation of Manners*; aimed at some persons of high rank, who rendered themselves a disgrace to their country. When the ecclesiastics in power breathed too much of a spirit of persecution, De Foe wrote a tract called *The Shortest Way with the Dissenters*; for which he was called to account, and explained himself with great firmness. He was afterwards sentenced to the pillory for attacking some public measures; which so little intimidated him, that, in defiance of their usage, he wrote *A Hymn to the Pillory*. It would be endless to enumerate all his publications; but the following are the principal: *The History of the Plague in 1665*; a novel intitled *The History of Colonel Jack*; *A new Voyage round the World by a Company of Merchants*, printed for Bettesworth, 1725; *The History of Roxana*; *Memoirs of a Cavalier*; *The History of Moll Flanders*; a book intitled *Religious Courtship*, which has undergone upwards of 20 editions; and the *Life and Adventures of Robinson Crusoe*,

Deflection
||
De Foe.

Defoliation an admirable performance, of which there have been editions without number, but concerning which there is an anecdote that does the author of it no credit as to the better part of a writer's character, honesty. When captain Woods Rogers touched at the island of Juan Fernandez, in the South Sea, he brought away Alexander Selkirk, a Scots sailor, who had been left ashore there, and had lived on that desolate place above four years. When Selkirk came back to England, he wrote a narrative of his adventures, and put the papers into the hands of De Foe, to digest for publication; who ungenerously converted the materials into the History of Robinson Crusoe, and returned Selkirk his papers again! A fraud for which, in a humane view, the distinguished merit of that romance can never atone. Daniel De Foe died at Illington, in 1731. All his productions of the romantic species, but especially the two last mentioned, are much in vogue amongst country readers; and, on account of their moral and religious tendency, may very probably in some measure counteract the pernicious effects produced by the too general circulation of modern novels, those occasional vehicles of impiety and infidelity.

DEFOLIATION, (from *de* and *folium* a leaf); the fall of the leaves. A term opposed to *frondescentia*, the annual renovation of the leaves, produced by the unfolding of the buds in spring. See FRONDESCENTIA.

Most plants in cold and temperate climates shed their leaves every year: this happens in autumn, and is generally announced by the flowering of the common meadow saffron. The term is only applied to trees and shrubs; for herbs perish down to the root every year, losing stem, leaves, and all.

All plants do not drop their leaves at the same time. Among large trees, the ash and walnut, although latest in unfolding, are soonest divested of them: the latter seldom carries its leaves above five months.

On the oak and horn-beam, the leaves die and wither as soon as the colds commence; but remain attached to the branches till they are pushed off by the new ones, which unfold themselves the following spring. These trees are doubtless a kind of ever-greens: the leaves are probably destroyed only by cold; and perhaps would continue longer on the plant, but for the force of the spring-sap, joined to the moisture.

In mild and dry seasons, the lilac, privet, yellow jessamine of the woods, and maple of Crete, preserve their leaves green until spring, and do not drop them till the new leaves are beginning to appear. The fig-tree, and many other trees that grow between the tropics, are of this particular class of ever-greens. The trees in Egypt, says Doctor Hasselquist, cast their leaves in the latter end of December and beginning of January, having young leaves ready before all the old ones are fallen off; and to forward this operation of nature, few of the trees have buds: the sycamore and willow, indeed, have some, but with few and quite loose *stipulae* or scales. Nature did not imagine buds so necessary in the southern as in the northern countries; this occasions a great difference between them.

Lastly, some trees and shrubs preserve their leaves

constantly through the whole year: and are not in the least influenced by the clemency or inclemency of seasons. Such are the firs, juniper, yew, cedar, cypress, and many other trees, hence denominated *ever-greens*. These preserve their old leaves a long time after the formation of the new, and do not drop them at any determinate time. In general, the leaves of ever-greens are harder, and less succulent, than those which are renewed annually. The trees are generally natives of warm climates; as the alaternutes of France and Italy, the ever-green oak of Portugal and Suabia.

Some herbaceous perennials, as the house-leeks and navel-worts, enjoy the same privilege with the ever-green trees, and resist the severities of winter: some even can dispense with the earth for some time; being replete with juices, which the leaves imbibe from the humidity of the atmosphere, and which, in such plants, are, of themselves, sufficient for effecting the purposes of vegetation. It is for this reason, that, unless in excessive hot weather, gardeners are seldom wont to water fat succulent plants, as the aloes, which rot when they are moistened, if the sun does not quickly dry them up.

The leaves of all the ever-green shrubs and trees, have a thin compact skin or cover over their surface; as is easily discovered by macerating them in water, in order to separate the parenchyma, or pulp, from the vessels of the leaves; which cannot be effected in any of these ever-greens till a thin parchment-like cover is taken off. These trees and shrubs are found by experiment to perspire but little, when compared with others which shed their leaves; and it is, perhaps, principally owing to this close covering, as also to the small proportion of moisture contained in their vessels, that they retain their verdure, and continue through the winter on the trees. The nutritive juices of these plants always abound, more or less, with an oily quality, which secures them from being injured by severe frosts; so that many of these ever-green trees are adapted to grow in the coldest parts of the habitable world.

With respect to deciduous trees, the falling off of the leaves seems principally to depend on the temperature of the atmosphere, which likewise serves to hasten or retard the appearance in question. An ardent sun contributes to hasten the dropping of the leaves.—Hence in hot and dry summers, the leaves of the lime-tree and horse-chestnut turn yellow about the first of September; whilst in other years, the yellowness does not appear till the beginning of October. Nothing, however, contributes more to hasten the fall of the leaves, than immoderate cold or moist weather in autumn; moderate droughts, on the other hand, serve to retard it. As a proof of this position, Mr. Adanson relates, that in the year 1759, the leaves of the elm-tree, which generally fall off about the 25th of November, continued in verdure and vigour at Paris, where the autumn was remarkably dry, till the 10th of the following month.

The following table, respecting the mean times in which different trees shed their leaves, is founded upon observations.

Goose-

Defoliation Deformity.	Gooseberry-tree and bladder-	Generally quit their leaves about	October 1st.
	Walnut and ash,		15th.
	Almond-tree, horse-chestnut,		20th.
	and lime-tree,		25th.
	Maple, hazle-nut, black-pop-		November 1st.
	lar, and aspen-tree,		10th.
	Birch, plane-tree, mountain-		15th.
	ofter, false-acacia, pear, and		20th.
	apple-tree,		
	Vine, mulberry, fig, sumac,		
	and angelica-tree,		
	Elm-tree and willow,		
	Apricot and elder trees,		

Milne's
Bot. Dict.

It deserves to be remarked, that an ever-green tree grafted upon a deciduous, determines the latter to retain its leaves. This observation is confirmed by repeated experiments; particularly by grafting the laurel, or cherry-bay, an evergreen, on the common cherry; and the ilex or ever-green oak, on the oak.

DEFORCEMENT, in law, the casting any one out of his land, or with-holding of lands and tenements by force from the right owner.

DEFORCEMENT, in Scots law, the opposing or resisting of the officers of the law in the execution of their office. See LAW, N^o cixxxvi. 15.

DEFORMITY, the want of that uniformity necessary to constitute the beauty of an object. See BEAUTY.

Deformity is either natural or moral. These are both referred by Mr Hutcheson to an internal sense; and our perceptions of them, as he supposes, arises from an original arbitrary structure of our own minds, by which certain objects, when observed, are rendered the occasions of certain sensations and affections.

That many objects give no pleasure to our sense is obvious. Many are certainly void of beauty; but then, says this author, there is no form which seems necessarily disagreeable of itself, when we dread no other evil from it, and compare it with nothing better of the kind. Many objects are naturally displeasing and distasteful to our external senses, as well as others pleasing and agreeable; as smells, tastes, and some separate sounds: but with regard to our sense of beauty, no composition of objects which give not unpleasent simple ideas, seems positively unpleasent or painful of itself, had we never observed any thing better of the same kind.

Had there been a species of the form which we now denominate *ugly* or *deformed*, and had we never seen or expected greater beauty, we should have received no disgust from it; though the pleasure would not have been so great in this form as in those we now admire. Our sense of beauty seems designed to give us positive pleasure; but not positive pain or disgust, any farther than what arises from disappointment.

There are indeed many faces which at first view are apt to raise dislike. But this is generally not from any positive deformity; but either from want of expected beauty, or from the carrying some natural indications of morally bad dispositions, which we all acquire a faculty of discerning in countenances, airs, and gestures. That this is not occasioned by any form positively disgusting, appears hence, that if, upon long acquaintance, we are sure of finding sweetness of tem-

per, humanity, and cheerfulness, though the body Deformity. form continues, it shall give us no disgust. There are horrors raised by some objects, which are only the effect of fear for ourselves, or compassion towards others, when either reason, or some foolish association of ideas, makes us apprehend danger; and not the effect of any thing in the form itself. For we find, that most of those objects which excite horror at first, when experience or reason has removed the fear, may become the occasion of pleasure.

The casual conjunction of ideas gives us disgust, where there is nothing disagreeable in the form itself. And this, in effect, is the cause of most of our fantastic aversions to the figures of divers animals, &c. Thus serpents of all kinds, and many insects, really beautiful enough, are beheld with aversion by many people, who have got some accidental ideas of mischief associated to them. A similar reasoning is applied to our perception of moral beauty and deformity. *Inquiry into the Original of our Ideas of Beauty and Virtue*, passim.

But it is more just to distinguish between the sentiments of delight or disgust, excited in us by beautiful or deformed objects, which are effects of some causes, and the natural and real qualities of the perceived objects by which they are produced. There are objects, says an excellent writer, which have a natural aptitude to please or offend, or between which and the contemplating mind there is a necessary congruity or incongruity; and though the actual perception of the understanding, and consequent feeling of the heart, in contemplating the actions and affections of moral agents, may exist in very different degrees, on account of the incidental obstructions arising from bodily indisposition, mental prejudices and biases, and the association of ideas; yet, to every rational mind properly disposed, morally good actions must for ever be acceptable, and can never of themselves offend; and morally evil actions must for ever be disagreeable, and can never of themselves please. What is right in actions and characters is beautiful and amiable, and gives pleasure; what is wrong is deformed and odious, and excites disgust: right and pleasure, wrong and pain, are as distinct as cause and effect. It is no less absurd to maintain, that the perception of virtue is nothing distinct from the reception of the pleasure resulting from it, than to infer, with some metaphysicians, that solidity, extension, and figure, are only particular modes of sensation, because attended, whenever they are perceived, with some sensations of sight or touch. Thus does this author show, that moral beauty and deformity are real qualities of certain actions; in which consists their aptitude to please or disgust. With respect to natural beauty, he observes, that uniformity amidst variety pleases, because of the natures of variety and uniformity, which are such, that whenever united, they are adapted to please every free unbiassed mind that discerns them. He accounts for the pleasure they afford, without referring them to an arbitrary internal sense, by the following circumstances that attend them. They are more easily comprehended by the mind: order and symmetry give things their stability and strength, and subserviency to any valuable purpose; regularity and order evidence art and design. Disorder and confusion, whence deformity arises, denote only the negation of regularity and

Deformity and order; or any arrangement and disposition of things, which are not according to a law, rule, or plan, and prove not design. These are not positively displeasing; except where we previously expected order, or where impotence or want of skill appear, and the contriver has either failed of his design or executed it ill.

In the Fugitive Pieces, is preserved an excellent essay on Bodily Deformity by the late William Hay, Esq; who was himself what he describes, and who, while he rallies his own figure with great pleasantry, discusses the general subject in a manner equally instructive and agreeable. He considers, 1. The natural consequences of bodily deformity; 2. How it affects the outward circumstances; and, 3. What turn it gives to the mind.

1. It is certain, that the human frame, being warped and disproportioned, is lessened in strength and activity, and rendered less fit for its functions. Scarron had invented an engine to take off his hat; "and I wish (says our author) I could invent one to buckle my shoe, or to take up a thing from the ground, which I can scarce do without kneeling, for I can bend my body no farther than it is bent by nature. For this reason, when ladies drop a fan or glove, I am not the first to take it up; and often restrain my inclination to perform those little services, rather than expose my spider-like shape. And I hope it will not be construed as pride, if I do not always rise from my seat when I ought: for if it is low, I find some trouble in it; and my centre of gravity is so ill placed, that I am often like to fall back. Things hanging within the reach of others are out of mine; and what they can execute with ease, I want strength to perform. I am in danger of being trampled upon or stifled in a crowd, where my back is a convenient lodgment for the elbow of any tall person that is near. I can see nothing, and my whole employment is to guard my person. I have forborne to attend his Majesty in the house of peers since I was like to be squeezed to death there against the wall. I would willingly comethither when his majesty commands, but he is too gracious to expect impossibilities. Besides, when I get in, I can never have the pleasure of seeing on the throne one of the best princes who ever sat on it. These, and many others, are the inconveniences continually attending a figure like mine. They may appear grievous to persons not used to them, but they grow easier by habit; and though they may a little disturb, they are not sufficient to destroy the happiness of life; of which, at an average, I have enjoyed as great a share as most men. And perhaps one proof of it may be my writing this Essay; not intended as a complaint against Providence for my lot, but as an innocent amusement to myself and others."

As to what effect deformity may have on the health, it appears natural to imagine, that as the inward parts of the body must in some measure comply with the outward mould, so the form of the latter being irregular, the first cannot be so well placed and disposed to perform their functions; and that generally deformed persons would not be healthy or long-lived. But this is a question best determined by facts; and in this case the instances are too few or unobserved, to draw a general conclusion from them: and health is more than

is commonly thought in a man's own power, and the reward of temperance more than the effect of constitution; which makes it still more difficult to pass a judgment. Æsop could not be young when he died; and might have lived longer, if he had not been murdered at Delphi. The Prince of Orange scarce passed the meridian of life, and the Duke of Luxemburg died about the age of 67. The Lord Treasurer Burleigh lived to 78; but his son the Earl of Salisbury, who died about 15 years after him, could not reach near that age. It is said that Mr Pope's father was deformed, and he lived to 75; whereas the son died in middle age, if he may be said to die whose works are immortal. "My (father adds our author) was not deformed, but active, and my mother a celebrated beauty; and I, that am so unlike them have lived to a greater age, and daily see my acquaintance, of a stronger frame, quitting the stage before me."

But whether deformity, abstractedly considered, be really prejudicial to health, in its consequences it appears to be most commonly an advantage. Deformed persons have a less share of strength than others, and therefore should naturally be more careful to preserve it; and as temperance is the great preservative of health, it may incline them to be more temperate. Another great preservative of health is moderate exercise, which few deformed persons can want strength to perform. As a deformed person is not formed for violent exercise, he is less liable to such disorders as are the natural consequence of it. He will also escape many accidents, to which men of athletic make, and who glory in their strength, are always exposing themselves to make trial and proof of it. If he cannot carry an ox, like Milo, he will not, like Milo, be handcuffed in the oak by attempting to rend it. He will not be the man that shall ride from London to York in a day, or to Windsor in an hour, for a wager: or that shall be perpetually performing surprising long journeys in a surprising short time, for no earthly business but the pleasure of relating them. Conscious of his own weakness, he will be cautious of running into places or occasions of danger. Nature, too, warns deformed persons to be careful not to offer such affronts as may call them forth into the field of false honour, where they cannot acquit themselves well for want of strength and agility; and they are securer from such affronts themselves, since others will consider the little credit they will gain, by compelling them to appear on that scene. On the whole, therefore, it may be concluded, that deformity is a protection to a man's health and person; which (strange as it may appear) are better defended by feebleness than strength.

2. The influence of bodily deformity on a man's fortune may next be considered. Among the lower class, he is cut off from many professions and employments. He cannot be a soldier, he is under standard; he cannot be a sailor, he wants activity to climb the rigging; he cannot be a chairman or porter, he wants strength to bear the burden. In higher life, he is all qualified for a lawyer, he can scarce be seen over the bar; for a divine, he may drop from his hassock out of sight in his pulpit. The improvement of his mind is his proper province, and his business only such as depends on ingenuity. If he cannot be a dancing-master to adjust the heels, he may be a schoolmaster to instruct

Deformity. instruct the head : he cannot be a graceful actor on the stage ; but he may produce a good play : he would appear ill as a herald in a procession ; but may pass as a merchant on the exchange : he cannot undergo the fatigue of the campaign ; but he may advise the operations of it ; he is designed by nature rather to sleep on Parnassus, than to descend on the plains of Eolis : he cannot be crowned at the Olympic games ; but may be the Pindar to celebrate them : he can acquire no glory by the sword : but he may by the pen, and may grow famous by only relating those exploits which are beyond his power to imitate.

Lord Bacon (that extensive and penetrating genius, who pointed out every part of nature for examination), in his Essay on Deformity, says, "that in their superiors it quencheth jealousy towards them, as persons that they think they may at pleasure despise ; and it layeth their competitors and emulators asleep, as never believing they should be in a possibility of advancement till they see them in possession." But it is much to be doubted whether this is not more than counterbalanced by the contempt of the world, which it requires no mean parts to conquer ; for if (as has been said) a good person is a letter of recommendation, deformity must be an obstruction in the way to favour. In this respect, therefore, deformed persons set out in the world to a disadvantage ; and they must first surmount the prejudices of mankind before they can be upon a par with others, and must obtain by a course of behaviour that regard which is paid to beauty at first sight. When this point is once gained, the tables are turned, and then the game goes in their favour : for others, sensible of their injustice to them, no sooner find them better than they expected, than they believe them better than they are ; whereas in the beautiful person they sometimes find themselves imposed upon, and are angry that they have worshipped only a painted idol. For (again take lord Bacon's words) "neither is it almost seen, that very beautiful persons are otherwise of great virtue ; they prove accomplished, but not of great spirit ; and study rather behaviour than virtue. Whereas deformed persons, if they be of spirit, will free themselves from scorn, which must be either by virtue or malice ; and therefore let it not be marvelled if they sometimes prove excellent persons, as was Agellanus, Zanger the son of Solomon, Æsop, Gasca president of Peru ; and Socrates may likewise go amongst them, with others." Nay, he says, "in a great wit deformity is an advantage to rising." And in another part of his works, "that they who by accident have some inevitable and indelible mark on their persons or fortunes, as deformed people, bastards, &c. if they want not virtue, generally prove fortunate."

Osborn, in his Historical Memoirs of Queen Elizabeth, informs us, that "she chose the goodliest persons for her household servants : but in her counsellors did not put by sufficiency, though accompanied with a crooked person ; as it chanced in a father and a son of the Cecils, both incomparable for prudence." It is well known the Queen would make the father

(Burleigh) sit in her presence ; telling him, that she did Deformity. not use him for his legs, but his head. But the son (afterwards lord treasurer and Earl of Salisbury) was not so civilly treated by the populace ; and is an instance, not only that envy pursues a great man, but that the highest post cannot redeem a deformed one from contempt : it attends him like his shadow, and like that too is ever reminding him of his ill figure, which is often objected for want of real crimes. For the same writer says of the same great man, "that the misfortunes accompanying him from his birth did not a little add to that cloud of detraction that fell upon all that he said or did ; a mulct in nature, like an optic spectacle, multiplying much in the sight of the people the apparitions of ill." Nor was this contempt buried with him : it trampled on his ashes, and insulted his grave ; as appears by an epitaph, which Osborn cites, as void of wit as it is full of scurrility ; in one line of which there is an epithet, not so elegant, as descriptive of his person, *viz*, "Little Bossive Robin, that was so great."

Such contempt in general, joined with the ridicule of the vulgar, is another certain consequence of bodily deformity ; for men naturally despise what appears less beautiful or useful, and their pride is gratified when they see such foils to their own persons. It is this sense of superiority which is testified by laughter in the lower sort ; while their betters, who know how little any man whatsoever hath to boast of, are restrained by good sense and good breeding from such an insult. But it is not easy to say why one species of deformity should be more ridiculous than another, or why the mob should be more merry with a crooked man, than with one that is deaf, lame, squinting, or purblind. It is a back in alto relievo that bears all the ridicule ; tho' one would think a prominent belly a more reasonable object of it, since the last is generally the effect of intemperance and of a man's own creation. Socrates was ugly, but not contemned ; and Philopœmen (A) of very mean appearance, and though contemned on that account, not ridiculed : for Montaigne says, "Ill features are but a superficial ugliness, and of little certainty in the opinion of men ; but a deformity of limbs is more substantial, and strikes deeper in." As it is more uncommon, it is more remarkable ; and that perhaps is the true reason why it is more ridiculed by the vulgar.

3. The last consideration on this subject relates to those passions and affections which most naturally result from deformity. Lord Bacon observes, that "deformed persons are commonly even with nature ; for as nature hath done ill by them, so do they by nature, being for the most part (as the scripture saith) *void of natural affection.*" But (says Mr Hay) "I can neither find out this passage in scripture, nor the reason of it ; nor can I give my assent or negative to a proposition, till I am well acquainted with the terms of it. If by natural affection is here meant universal benevolence, and deformity necessarily implies a want of it, a deformed person must then be a complete monster. But however

(A) Coming to an inn, where he was expected, before his attendants, the mistress of the house seeing a plain person of very mean aspect, ordered him to assist in getting things ready for Philopœmen. His attendants finding him so employed, he told them that he was then paying the tribute of his ugliness. *Plutarch.*

Deformity. however common the case may be, my own sensations inform me that it is not universally true. If by natural affection is meant a partial regard for individuals, I believe the remark is judicious, and founded in human nature. Deformed persons are despised, ridiculed, and ill-treated by others; are seldom favourites, and commonly most neglected by parents, guardians, and relations; and therefore, as they are not indebted for much fondness, it is no wonder if they repay but little. It is the command of scripture, *Not to set our affections on things below*; and it is the voice of reason, not to overvalue what we must soon part with: therefore, to be so fond of others as not to be able to bear their absence, or to survive them, is neither a religious nor moral duty, but a childish and womanish weakness; and I must congratulate deformed persons, who, by example, are early taught another lesson. And I will now lay open my own heart to the reader, that he may judge if Lord Bacon's position is verified in me.

"I hope it proceeds not from a malignity of heart; but I never am much affected with the common accidents of life, whether they befall myself or others. I am little moved when I hear of death, loss, or misfortune; I think the case is common.

(*Titus, & e medio fortuna ductus acerbo*.)

Juv. Sat. xiii.

And as it is always likely to happen, I am not surprised when it does. If I see a person cry or beat his breast on any such occasion, I cannot bear him company; but am not a Democritus to laugh at his folly. I read of battles and fields covered with slain; of cities destroyed by sword, famine, pestilence, and earthquake; I do not shed a tear: I suppose it is, because they are the usual storms, to which the human species are exposed, proceeding from the just judgments of God, or the mistaken and false principles of rulers. I read of persecutions, tortures, murders, massacres: my compassion for the sufferers is great, but my tears are stopped by resentment and indignation against the contrivers and perpetrators of such horrid actions. But there are many things that bring tears into my eyes whether I will or no; and when I reflect, I am often at a loss in searching out the secret source from whence they flow. What makes me weep (for weep I do) when I read of virtue or innocence in distress; of a good man helpless and forsaken, unmoved by the greatest insults and cruelties, or courageously supporting himself against oppression in the article of death? I suppose it is, to see vice triumphant, and virtue so ill rewarded in this life. May I judge by myself, I should imagine that few sincere Christians could read the sufferings of their Saviour, or Englishmen those of a Cranmer, Ridley, or Latimer, without tears; the first dying to establish his religion, the last to rescue it from corruption. When I read of Regulus returning to torment, and John of France to imprisonment, against the persuasion of friends, to keep faith with their enemies, I weep to think there is scarce another instance of such exalted virtue. Those who often hear me read, know that my voice changes, and my eyes are full, when I meet with a generous and heroic saying, action, or character, especially of persons whose example or command may influence mankind. I weep when I hear a Titus say, that he had lost the day in which he did no good; when Adrian tells his enemy, that he had escaped by

his being emperor; or Louis XII. that he is not to revenge the affront of the duke of Orleans. These are the first instances that happen to occur to me: I might recollect many, too many to insert in his essay; yet all are but a few, compared to instances of cruelty and revenge: perhaps I am concerned that they are so rare; perhaps too I inwardly grieve that I am not in a situation to do the like. I am entertained, but not moved, when I read Voltaire's History of Charles XII.: but I melt into tears on reading Hanway's character of his antagonist Peter the Great. The first is a story of a madman; the other of a father, friend, and benefactor of his people; whose character (as the author observes in the conclusion of it) will command the admiration of all succeeding generations; and I suppose I lament, that God is pleased to advance to royalty so few such instruments of good to mankind.

Again: "I am uneasy when I see a dog, a horse, or any other animal ill treated: for I consider them as endued with quick sense, and no contemptible share of reason; and that God gave man dominion over them, not to play the tyrant, but to be a good prince, and promote the happiness of his subjects. But I am much more uneasy at any cruelty to my own species; and heartily wish Procrustes disciplined in his own bed, and Phalaris in his bull. A man bruised all over in a boxing match, or cut to pieces in fighting a prize, is a shocking spectacle; and I think I could with less horror see a thousand fall in battle, than human nature thus depreciated and disgraced. Voilencé, when exerted in wantonness or passion, is brutality: and can be termed bravery only when it is sanctioned by justice and necessity.

"I have been in a situation to see not a little of the pomp and vanity, as well as of the necessity and misery, of mankind: but the last only affect me; and if, as a magistrate, I am ever guilty of partiality, it is in favour of the poor. When I am at church among my poor but honest neighbours in the country; and see them serious in performing the ceremonies prescribed; tears sometimes steal down my cheek, on reflecting, that they are doing and hearing many things they do not understand, while those who understand them better neglect them: that they, who labour and live hard, are more thankful to heaven than those who fare luxuriously on the fruits of their labour; and are keeping and repeating the fourth commandment at the very instant the others are breaking it.

"These are some of the sensations I feel; which I have freely and fairly disclosed, that the reader may judge, how far I am an instance of a deformed person wanting natural affection. And I am a good subject of speculation; because all in me is nature; for to own the truth, I have taken but little pains (though I ought to have taken a great deal), to correct my natural defects.

"Lord Bacon's next position is, 'That deformed persons are extremely bold: first in their own defence, as being exposed to scorn; but in process of time by a general habit.' This, probably, is so among the inferior sort, who are in the way of continual insults; for a return of abuse is a natural weapon of self-defence, and in some measure justified by the law of retaliation: To upbraid a man with a personal defect, which he cannot help, is also an immoral act; and he who does it, has reason to expect no better quarter than to hear
af

Deformity

Deformity. of faults, which it was in his own power not to commit. But I find this observation far from being verified in myself: an unbecoming bashfulness has been the consequence of my ill figure, and of the worse management of me in my childhood. I am always uneasy, when any one looks steadfastly on so bad a picture; and cannot look with a proper confidence in the face of another. I have ever reproached myself with this weakness, but am not able to correct it. And it may be a disadvantage to a man in the opinion of those he converses with; for though true modesty is amiable, the false is liable to misconstruction: and when a man is out of countenance for no reason, it may be imagined, that he has some bad reason for being so. In point of assurance, I am indeed a perfect riddle to myself; for I, who feel a reluctance in crossing a drawing room, or in opening my mouth in private company before persons with whom I am not well acquainted, find little in delivering my sentiments in public, and exposing my discourse, often as trifling as my person, to the ears of a thousand. From what cause this proceeds, I know not: it may be partly from hopes of wiping off any ill impressions from my person by my discourse, partly from a sense of doing my duty, and partly from a security in public assemblies from any gross personal reflections.

“ Lord Bacon compares the case of deformed persons to that of eunuchs; ‘in whom kings were wont to put great trust as good spies and whisperers; for they that are envious towards all, are more obnoxious and officious towards one.’ But with submission to so good a judge of human nature, I own I can discover no uncommon qualification in them for spies; and very few motives to envy peculiar to themselves. Spies submit to that base and ungenerous office, either for the sake of interest or power: if for interest, it is to gratify their covetousness: if for power, their ambition or revenge, which passions are not confined to the eunuch or deformed, but indiscriminately seize all classes of men. Envy too may prompt a man to mean actions, in order to bring down the person envied to his own level; but if it is on account of superiority of fortune, it will operate alike on men of all shapes. Eunuchs have but one peculiar motive to envy: but that (as Lord Bacon expresses it) makes them envious towards all; because it is for a pleasure which all but themselves may enjoy. Deformed persons are deprived only of beauty and strength, and therefore those alone are to be deemed the extraordinary motives to their envy; for they can no more be beautiful or strong than eunuchs be successful lovers. As to myself, whatever sparks of envy might be in my constitution, they are now entirely extinguished; for, by frequent and serious reflection, I have long been convinced of the small value of most things which men value the most.

“ There is another passion to which deformed per-

VOL. V.

sons seem to be more exposed than to envy; which is jealousy: for being conscious that they are less amiable than others, they may naturally suspect that they are less beloved. I have the happiness to speak this from conjecture, and not from experience; for it was my lot, many years ago, to marry a young lady, very piously educated, and of a very distinguished family, and whose virtues are an honour to her family and her sex: so that I had never any trial of my temper, and can only guess at it by emotions I have felt in my younger days; when ladies have been more liberal of their smiles to those whom I thought in every respect, but person, my inferiors.”

The most useful inference from all this to a deformed person is, to be upon his guard against those frailties to which he is more particularly exposed; and to be careful, that the outward frame do not distort the soul. *Orandum est* (says Juvenal), *ut sit mens sana in corpore sano*; “ Let us pray for a sound mind in a healthy body;” and every deformed person should add this petition, *ut sit mens recta in corpore curvo*, for “ an upright mind in a crooked one.” And let him frequently apply to himself this article of self-examination, *Lenior et melior fis, accedente senectâ?* As age approaches, do your temper and morals improve? It is a duty peculiarly incumbent: for if beauty adds grace to virtue itself, vice must be doubly hideous in deformity.

Ridicule and contempt are a certain consequence of deformity; and therefore what a person cannot avoid, he should learn not to regard. He should bear it like a man; forgive it as a Christian; and consider it as a philosopher. And his triumph will be complete, if he can exceed others in pleasantry on himself. Wit will give over when it sees itself outdone; and so will malice when it finds it has no effect: And if a man’s behaviour afford no cause of contempt, it will fall upon those who condemn him without cause.

Instead of repining, therefore, a deformed person ought to be thankful to Providence for giving him such a guard to his virtue and repose. Thousands are daily ruined by a handsome person; for beauty is a flower that every one wants to gather in its bloom, and spares no pains or stratagem to reach it. All the poetical stories concerning it have their moral. A Helen occasions war and confusion: the Hyacinths and Ganymedes are seized on for Catamites; the Eudymions and Adonises for gallants; Narcissus can admire nobody but himself, and grows old before he is cured of that passion. Who is a stranger to the story of Lucretia killing herself for her violated chastity, or of Virginia killed by her father to preserve it? In those circumstances, says Juvenal, she might wish to change persons with Rutila; the only lady we know among the ancients celebrated for a hump-back. The handsomest men are chosen for eunuchs and gallants; and when they are caught in exercising the last function, both (A) Horace and Juvenal inform you of the penalties

4 X

(A) Hic se præcipitem tecto dedit; ille flagellis

Deformity. penalties and indignities they undergo. Silius (B) was converted by the insatiable Messalina into a husband; and Sporus, by the monster Nero, into a wife. The last mentioned poet shows, that praying for beauty is praying for a curse; and (c) Persius refuses to join in such a prayer: And has not the deformed person reason to thank his stars, which have placed him more out of danger than even virtue could? for that could not guard a Joseph, an (D) Hippolytus, a Bellerophon, and others, against the revenge of slighted love.

Another great advantage of deformity is, that it tends to the improvement of the mind. A man that cannot shine in his person, will have recourse to his understanding; and attempt to adorn that part of him, which alone is capable of ornament. When his ambition prompts him to begin, with Cowley, to ask himself this question,

What shall I do to be for ever known,
And make the age to come my own?

on looking about him, he will find many avenues to the temple of fame barred against him; but some are still open through that of virtue; and those, if he has a right ambition, he will most probably attempt to pass. The more a man is inactive in his person, the more his mind will be at work; and the time which others spend in action, he will pass in study and contemplation: by these he may acquire wisdom; and by wisdom, fame. The name of Socrates is as much founded as those of Alexander and Cæsar; and is recorded in much fairer characters. He gained renown by wisdom and goodness; they by tyranny and oppression: he by instructing, they by destroying, mankind: and happy it is, that their evil deeds were confined to their lives; while he continues to instruct us to this day. A deformed person will naturally consider where his strength and his foible lie: and as he is well acquainted with the last, he will easily find out the first; and must know, that (if it is any where) it is not, like Samson's, in the hair; but must be in the lining of the head. He will say to himself, "I am weak in person: unable to serve my country in the field, I can acquire no military glory; but I may, like Socrates, acquire reputation by wisdom and probity; let me therefore be wise and honest. My figure is very bad; and I should appear but ill as an orator either in the pulpit or at the bar: let me therefore pass my time in my study, either in reading what may improve myself, or in writing what may entertain or instruct others. I have not the strength of Hercules, nor can I rid the world of so many monsters; but perhaps I may get rid of some that infest myself. If I cannot draw out Cacus from his den, I may pluck the villain from my own breast. I cannot cleanse the stable of Augeas: but I may cleanse my own heart from filth and impurity; I may demolish the hydra of vices

within me: and should be careful too, that while I lop off one, I do not suffer more to grow up in its stead. Let me be serviceable in any way that I can: and if I am so, it may, in some measure, be owing to my deformity; which at least should be a restraint on my conduct, lest my conduct make me more deformed."

Deformity
↓
Degradation.

Few persons have a house entirely to their mind; or the apartments in it disposed as they could wish. And there is no deformed person, who does not wish that his soul had a better habitation; which is sometimes not lodged according to its quality. Lord Clarendon says of Sir Charles Cavendish (brother to the marquis of Newcastle), that he was a man of the noblest and largest mind, though of the least and most inconvenient body that lived. And every body knows, that the late prince of Orange had many amiable qualities. Therefore, in justice to such persons, we must suppose that they did not repine that their tenements were not in a more regular style of architecture. And let every deformed person comfort himself with reflecting, that though his soul hath not the most convenient and beautiful apartment, yet that it is habitable; that the accommodation will serve as an inn upon the road; that he is but tenant for life, or (more properly) at will; and that, while he remains in it, he is in a state to be envied by the deaf, the dumb, the lame, and the blind.

DEFOSSION, (DEFOSSIO), the punishment of burying alive, inflicted among the Romans on vestal virgins guilty of incontinency. It is also a custom among the Hungarians to inflict this punishment on women convicted of adultery. Heretics were also punished in this manner. See *BURYING-Alive*.

DEGENERATION, or DEGENERATING, in general, denotes the growing worse, or losing some valuable qualities whereof a thing was formerly possessed. Some naturalists have been of opinion, that things are capable of degenerating into quite a distinct species; but this is a mere chimera. All that happens in the degeneration of a plant, for instance, is the losing its usual beauty, colour, smell, &c. a circumstance entirely owing to its being planted in an improper soil, climate; &c.

DEGLUTITION, the action of swallowing. See ANATOMY, n^o 104.

DEGRADATION, in English law-books called *disgradation* and *deposition*, the act of depriving or stripping a person for ever of a dignity or degree of honour, and taking away the title, badge, and privileges thereof.

The degradations of a peer, a priest, a knight, a gentleman, an officer, &c. are performed with divers ceremonies. That which anciently obtained in degrading a person from his nobility is very curious. It was practised in the time of Francis I. upon Captain Fangel.

Degrada-
tion.

Fangel, who had in a cowardly manner given up Fontarabia, whereof he was governor. On this occasion, 20 or 30 cavaliers, without blemish or reproach, were assembled; before whom the gentleman was accused of treason and breach of faith by a king at arms. Two scaffolds were erected; the one for the judges, heralds, and pursuivants; and the other for the guilty cavalier, who was armed at all points, and his shield placed on a stake before him, reversed with the point upwards. On one side assisted 12 priests in surplices, who sung the vigils of the dead. At the close of each psalm they made a pause, during which the officers of arms stripped the condemned of some piece of his armour, beginning with the helmet, and proceeding thus till he was quite disarmed; which done, they broke his shield in three pieces with a hammer. Then the king at arms emptied a basin of hot water on the criminal's head; and the judges, putting on mourning habits, went to the church. This done, the degraded was drawn from off the scaffold with a rope tied under his arm-pits, laid on a bier, and covered with mortuary clothes; the priest singing some of the prayers for the dead; and then he was delivered to the civil judge and the executioner of justice.

For a more domestic instance: Sir Andrew Harclay, earl of Carlisle, being attainted and convicted of treason, 18 Edw. II. *coram rege*; after judgment was pronounced on him, his sword was broken over his head, and his spurs hewn off his heels; Sir Anthony Lucy the judge saying to him, "Andrew, now thou art no knight, but a knave." By stat. 13 Car. II. William Lord Monson, Sir Henry Mildmay, and others, were degraded from all titles of honour, dignities, and pre-eminences, and prohibited to bear or use the title of lord, knight, esquire, or gentleman, or any coat of arms, for ever afterwards. It has been maintained that the king may degrade a peer; but it appears from later authorities, that he cannot be degraded but by act of parliament.

As to ecclesiastics, we have an instance of degradation before condemnation to death, in the eight century, at Constantinople. It is in the person of the patriarch Constantine, whom Constantine Copronymus caused to be executed. He was made to ascend the ambo; and the patriarch Nicetas sent some of his bishops to strip him of the pallium, and anathematized him: then they made him go out of the church backwards.

But we have a much later instance in English history: When Cranmer, archbishop of Canterbury, was degraded by order of queen Mary, they dressed him in episcopal robes, made only of canvas, put the mitre on his head, and the pastoral staff in his hand; and in this attire showed him to the people. Which done, they stripped him again piece by piece. At present they do not stand so much on the ceremony of degradation in order to the putting a priest to death: by reason of the delays and difficulties that it would occasion. Pope Boniface pronounced that six bishops were required to degrade a priest; but the difficulty of assembling so many bishops rendered the punishment frequently impracticable. In England, a priest, after having been delivered to his ordinary, if he cannot purge himself of the crime laid at his door, his gown and other robes are stripped over his ears by the common

hangman; by which he is declared divested of his orders.

It is decided, however, that degradation does not efface the priestly character. Degradation only seems to differ from deposition in a few ignominious ceremonies which custom has added thereto. Accordingly, in the business of Arnoul archbishop of Rheims, sentenced in the council of Orleans in 991, it was deliberated what form they should follow in the deposition; whether that of the canons, that is, simple deposition; or that of custom, viz. degradation. And it was declared, that he should surrender the ring, pastoral staff, and pallium; but that his robes should not be torn off. In effect, the canons prescribe no more than a mere reading of the sentence. It is the rest, therefore, added thereto by custom, viz. the stripping off the ornaments and the tearing the pontifical vestments, that properly constitutes degradation.

DEGRADATION, in painting, expresses the lessening the appearance of distant objects in a landscape, in the same manner as they would appear to an eye placed at that distance from them.

DEGREE, in geometry, a division of a circle, including a three hundred and sixtieth part of its circumference.

DEGREE of Latitude. See LATITUDE.

DEGREE of Longitude. See LONGITUDE.

A degree of the meridian on the surface of the globe is variously determined by various observers. Mr Picart measured a degree in the latitude of $49^{\circ} 21'$, and found it equal to 57060 French toises. But the French mathematicians, who have lately examined Mr Picart's operations, assure us, that the degree in that latitude is 57183 toises. In England, Mr Norwood, measured the distance between London and York, and found it 905751 English feet; and finding the difference of latitudes $2^{\circ} 28'$, determined the quantity of one degree to be 367196 English feet, or 69 English miles and 288 yards. Mr Maupertuis measured a degree in Lapland, in the latitude of $66^{\circ} 20'$, and found it 57438 toises. A degree was likewise measured at the equator by other French mathematicians, and found to contain 56767-8 toises. Whence it appears, that the earth is not a sphere, but an oblate spheroid.

DEGREE, in civil and canon law, denotes an interval in kinship, by which proximity and remoteness of blood are computed. See CONSANGUINITY and DESCENT.

DEGREES, in music, are the little intervals whereof the concords or harmonical intervals are composed.

DEGREE, in universities, denotes a quality conferred on the students or members thereof, as a testimony of their proficiency in the arts or sciences, and intitling them to certain privileges.

DEJANIRA, in fabulous history, daughter of Oeneus king of Ætolia, and wife to Hercules. The centaur Nessus endeavouring to ravish her, was slain by Hercules with a poisoned arrow. Nessus, when dying, gave his bloody shirt to Dejanira; assuring her, that it was a sovereign remedy to cure her husband if ever he proved unfaithful. Some time after, Dejanira thinking she had reason to suspect his fidelity, sent him the shirt; which he had no sooner put on, than he was seized with the most excruciating torments. Being unable to support his pains, he retired to mount

Oeta, and erecting a pile of wood set fire to it, and threw himself into the flames; upon which Dejanira killed herself in despair.

DEJECTION, in medicine, the act of voiding the excrements by the anus. See ANATOMY, n^o 93.

DEIFICATION, in antiquity. See APOTHEOSIS.

DEIPHON, in fabulous history, a brother of Triptolemus son of Cereus and Metanira. When Ceres travelled over the world, she stopped at his father's court and undertook to nurse him and bring him up. To reward the hospitality of Cereus, the goddess began to make his son immortal, and every evening she placed him on burning coals to purify him from whatever mortal particles he still possessed. The uncommon growth of Deiphon astonished Metanira, who wished to see what Ceres did to make him so vigorous. She was frightened to see her son on burning coals; and the shrieks that she uttered disturbed the mysterious operations of the goddess, and Deiphon perished in the flames.

DEISCAL, in the ancient British customs, the name of a ceremony originally used in the druidical worship, and retained in many places down to a very late period as a civil ceremony towards persons of particular distinction. The temples of the ancient Britons were all circular; and the druids, in performing the public offices of their religion, never neglected to make three turns round the altar, accompanied by all the worshippers. This practice was so habitual to the ancient Britons, that it continued in some places many ages after the druids and their religion were both destroyed. In the Scottish isles, the vulgar never come to the ancient sacrificing and fire-hallowing cairns, but they walk three times round them from east to west, according to the course of the sun. This sanctified tour, or round by the south, is called *deiscal*, from *deas* or *deas*, "the right hand," and *soil* or *ful*, "the sun;" the right-hand being ever next the heap or cairn. In the same isles it is the custom and fashion of the people to testify their respect for their chieftains, the proprietors of their several isles, and other persons of distinction, by performing the deiscal round them in the same manner. A gentleman giving an account of his reception in one of the western islands, of which he was proprietor, describes the ceremony of the deiscal in this manner: "One of the natives would needs express his high esteem for my person, by making a turn round about me sun-ways, and at the same time blessing me, and wishing me all happiness. But I bid him let alone that piece of homage, telling him I was sensible of his good meaning towards me. But this poor man was very much disappointed, as were also his neighbours; for they doubted not but this ancient ceremony would have been very acceptable to me; and one of them told me that this was a thing due to my character from them, as to their chief and patron; and that they could not, and would not, fail to perform it."

DEISM, the doctrine or belief of the deists. Deism, from *θεός*, *God*, may properly be used to denote natural religion, as comprehending those truths which have a real foundation in reason and nature; and in this sense it is so far from being opposite to Christianity, that it is one great design of the gospel to illu-

strate and enforce it. Thus some of the deistical writers have affected to use it. But deism more precisely signifies that system of religion, relating both to doctrine and practice, which every man is to discover for himself by the mere force of natural reason, independent of all revelation, and exclusive of it; and this religion Dr Tindal and others pretend is so perfect, as to be incapable of receiving any addition or improvement even from divine revelation.

DEISTS, a class of people, known also under the denomination of *Free-thinkers*, whose distinguishing character it is, not to profess any particular form or system of religion; but only to acknowledge the existence of a God, and to follow the light and law of nature, rejecting revelation, and opposing Christianity.

This name seems to have been first assumed as the denomination of a party about the middle of the 16th century, by some gentlemen in France and Italy, who were desirous of thus disguising their opposition to Christianity by a more honourable appellation than that of atheists. Viret, an eminent reformer, mentions certain persons in his epistle dedicatory prefixed to the second tome of his *Instruction Chretienne*, published in 1563, who called themselves by a new name, that of *Deists*. These, he tells us, professed to believe in God, but showed no regard to Jesus Christ, and considered the doctrine of the apostles and evangelists as fables and dreams. He adds, that they laughed at all religion, though they outwardly conformed to the religion of those with whom they lived, or whom they wished to please, or feared to offend. Some, he observes, professed to believe the immortality of the soul; others denied both this doctrine and that of providence. Many of them were considered as persons of acute and subtil genius, and took pains in disseminating their notions.

The deists hold, that, considering the multiplicity of religions, the numerous pretences to revelation, and the precarious arguments generally advanced in proof thereof, the best and surest way is to return to the simplicity of nature and the belief of one God; which is the only truth agreed to by all nations. They complain, that the freedom of thinking and reasoning is oppressed under the yoke of religion; and that the minds of men are ridden and tyrannized by the necessity imposed on them of believing inconceivable mysteries; and contend that nothing should be required to be assented to or believed but what their reason clearly conceives.

The distinguishing character of modern deists is, that they reject all revealed religion, and discard all pretences to it as the effects of imposture or enthusiasm. They profess a regard for natural religion, though they are far from being agreed in their notions concerning it. They are classed by some of their own writers into mortal and immortal deists: the latter acknowledging a future state; and the former denying it, or representing it as very uncertain.

Dr Clarke distinguishes four sorts of deists. 1. Those who pretend to believe the existence of an eternal, infinite, independent, intelligent Being, who made the world, without concerning himself in the government of it. 2. Those who believe the being and natural providence

Deists.

Deists. providence of God, but deny the difference of actions as morally good or evil, resolving it into the arbitrary constitution of human laws; and therefore they suppose that God takes no notice of them. With respect to both these classes, he observes that their opinions can consistently terminate in nothing but downright atheism. 3. Those who having right apprehensions concerning the nature, attributes, and all-governing providence of God, seem also to have some notion of his moral perfections; though they consider them as transcendent, and such in nature and degree, that we can form no true judgment, nor argue with any certainty concerning them: but they deny the immortality of human souls; alleging that men perish at death, and that the present life is the whole of human existence. 4. Those who believe the existence, perfections, and providence of God, the obligations of natural religion, and a state of future retribution, on the evidence of the light of nature, without a divine revelation: such as these, he says, are the only true deists; but their principles, he apprehends, should lead them to embrace Christianity; and therefore he concludes that there is now no consistent scheme of deism in the world.

The first deistical writer of any note that appeared in England was Herbert baron of Cherbury. He lived and wrote in the last century. His book *De Veritate* was first published at Paris in 1624. This, together with his book *De Causis Errorum*, and his treatise *De Religione Laici*, were afterwards published in London. His celebrated work *De Religione Gentilium* was published at Amsterdam in 1663 in 4to, and in 1700 in 8vo, and an English translation of it was published at London in 1705. As he was one of the first that formed deism into a system, and asserted the sufficiency, universality, and absolute perfection, of natural religion, with a view to discard all extraordinary revelation as useless and needless, we shall subjoin the five fundamental articles of this universal religion. They are these: 1. That there is one supreme God. 2. That he is chiefly to be worshipped. 3. That piety and virtue are the principal part of his worship. 4. That we must repent of our sins; and if we do so, God will pardon them. 5. That there are rewards for good men, and punishments for bad men, both here and hereafter. Our own age has produced a number of advocates in the same cause; and however they may have differed among themselves, they have been agreed in their attempts of invalidating the evidence and authority of divine revelation. We might mention Hobbes, Blount, Toland, Collins, Woolston, Tindal, Morgan, Chubb, Lord Bolingbroke, Hume, &c. Some have also added Lord Shaftesbury to the number.

But the friends of Christianity have no reason to regret the free and unreserved discussion which their religion has undergone. Objections have been stated and urged in their full force, and as fully answered; argument and rallery have been repelled; and the controversy between Christians and deists has called forth a great number of excellent writers, who have illustrated both the doctrines and evidence of Christianity in a manner that will ever reflect honour on their names, and be of lasting service to the cause of genuine religion and the best interests of mankind.

DEITY, *Godhead*; a common appellation given to God; and also by the poets to the heathen gods and goddesses.

DELAWARE, one of the United States of America, is situated between $38^{\circ} 29' 30''$, and $39^{\circ} 54'$ of north latitude. It extends from nearly the same longitude with the city of Philadelphia, to about $40'$ west. It is about one hundred miles in length, and the southern part of the state is about forty miles wide. The northern part is greatly narrowed by the course of the bay and river, and therefore the mean width may be estimated at about twenty-four miles.

The state of Delaware is bounded on the east by the bay and river of the same name, and by the Atlantic ocean; on the south by a line from Fenewick's Island, in latitude $38^{\circ} 29' 30''$, drawn west till it intersects what is commonly called the tangent line, dividing it from the state of Maryland; on the west, by the said tangent line, passing northwards up the peninsula, till it touch the western part of the territorial circle; and thence on the north, by the said circle, described with a radius of twelve miles about the town of New-Castle. The contents of the state will amount to about 1,200,000 acres.

About the year 1497, John Cabot and his son Sebastian, who were Venetians, in the service of Henry the seventh, made a general discovery of the American coast, which lies along the north-east of the continent. This was before the discoveries of Columbus had extended further than to a few of the West India islands. No settlement appears to have been effected here, until many years after the voyage of the Cabots. About the year 1608, this country was visited by Henry Hudson, who directed his endeavours to a more particular and accurate discovery of New-York, New-Jersey, Delaware-bay, and the adjacent country. Soon after this discovery, the Dutch are said to have purchased from Hudson any right which he might have acquired to the country by the discovery, and immediately sent a colony to form a settlement. At what time their first establishments began in America is not known with certainty. However, 'tis pretty well ascertained that in 1623, they had possession on the east side of the bay, and erected a fortification, which they called Nassau, at the place now known by the name of Gloucester.

In the year 1627, this country was visited by a colony of Swedes and Finns, under the command of William Useling, a respectable Swedish merchant. They landed, and at first settled at Cape-Henlopen, which they called Paradise-point. About the year 1631, they built a fort near Wilmington, to which they gave the name of Christain, or Christiana. There also they laid out a small town, which was afterwards demolished by the Dutch. The state of opposition between the two colonies, for some time, required the erection of fortifications all through the country. The Swedes built one at Chester, one upon Tenecum-Island, which they called New-Gottenburgh, and others at different places. The Dutch erected one at New-Castle, called Fort Casimir, and one at Lewis, called Whorekill. Soon after the arrival of the Swedes they were governed by Peter Minuit, under a commission from the queen of Sweden.—Sometime after this, the Swedish colony was committed to the government of John Printz; and on his being obliged to return home in 1654, his son-

Delaware. in-law, John Pappoia, was deputed to the administration.

In the year 1655, the Dutch in this settlement were considerably recruited by the arrival of seven vessels from New-Amsterdam, now New-York, having on board 6 or 700 men. They immediately dispossessed the Swedes of their forts on the river, then under the command of Suen-Scutz; and having obliged them all to surrender, on articles of capitulation, they carried the officers and principal inhabitants prisoners to New-York, and from thence to Holland. Those of that nation who remained, being without protection or assistance, were glad to unite with the Dutch and submit to their government. From this time the west side of the Delaware river was occupied by the two colonies, now grown into one under the Dutch government, until the first of October 1664, when it was surrendered on articles of capitulation to Sir Robert Carr, for his royal highness the duke of York, who was afterwards king James the second. Four years after this Col. Nichols, governor of New-York, appointed a council of six persons to assist captain Carr in the administration of the government*.

* *European settlements in America* vol. ii. p. 185.
† *Smith's New-Yersey.*

In the year 1672, the town of New-Castle was incorporated by the government of New-York, and was to be subject to the direction of a bailiff and six assistants †. After the first year the four eldest were to be removed from office, and four others were to be elected. The bailiff was president of the corporation, and entitled to a double vote. They had power to try causes, not exceeding the value of ten pounds, without an appeal from their jurisdiction. The office of scout, who had been chief of the council of six, was here converted into sheriff, who had jurisdiction within the corporation and along the river, and was annually elected. From this new constitution, the inhabitants were entitled to a free trade, without being obliged to make entry at New-York as had formerly been the practice.

During the earlier periods of the settlement of Delaware *wampum* was the principal currency of the country. Governor Lovelace of New-York, by proclamation, ordered that four white grains and three black ones should circulate for the value of a stiver or penny. This proclamation was published at New-York, Albany, Long-Island, Delaware, and the adjacent countries under the government of the Dutch. Large parcels of land had been purchased from the Indian proprietors by the Dutch, previously to the conquest by captain Carr. And after the establishment of the English government under the duke of York, the governors, deputy-governors, and the different county-courts, granted considerable quantities of land, on the west side of the bay and river, as far northerly as Upland, now called Chester, reserving a quit-rent of a bushel of wheat for every hundred acres. In this situation the government continued until the commencement of a war between the English and the states general; in which the whole country being retaken, became again subjected to the Dutch. But their possession was of short duration: for at the termination of the war in 1667, by the treaty of Breda, it was agreed, that the New-Netherlands, then supposed to include the Delaware colony, should be restored to the English in exchange for Surinam, a province of Guiana in South America. This article of the treaty was considered at the time as a very disad-

vantageous one to the British government. The value of Surinam was estimated much higher than all that tract of country, which now includes the states of New-York, New-Jersey, and Delaware. This was then viewed as a principal part of the disgrace attending the peace of Breda, which closed a war in which the national character of bravery had shone out with lustre, but where the misconduct of the government was no less apparent ‡.

From the restoration of this country to the English in 1667, until the beginning of Mr Dennis's administration in 1682, the counties of New-Castle, Kent, and Sussex were held as forming an appendage to the government of New-York; of course, the public affairs of the colony were conducted nearly as they had been previously to the capture of the country by the Dutch. Sir Edmund Andros now governed the duke of York's territory, and exercised jurisdiction over all the settlements on both sides the Delaware. His arbitrary impositions began to make his government and his character odious.—The inhabitants remonstrated against his conduct, but their efforts proved ineffectual.

The title of the duke of York to the New-Netherlands depended on a grant from the crown, dated the 12th of March, 1663-4. In the duke's settlement of the country, and forming a government under his grant, the Delaware colony was included, as it was supposed to be a part of the New-Netherlands. This idea seems to have originated, and to have been continued, in a voluntary deception, or rather from views of direct encroachment and usurpation. The very words of the grant are in direct opposition to such an extension of claim or jurisdiction. When Mr Penn in 1680, petitioned the crown for the grant of Pennsylvania, in consideration of large public debts due to his father's estate, this question naturally presented itself, and was fully discussed. The petition was referred to the lords of the committee of foreign plantations. From the importance of the subject, on the 8th of November 1680, they chose to submit it to the consideration of the attorney general of England. His report to them, on an examination of the subject, was, "that the patents granted to his royal highness of New-York, was bounded westward by the east side of Delaware Bay." In the year 1685, this question received a still more formal adjudication. On lord Baltimore's opposition to Mr Penn's settlement under his grant, it was brought before a committee of the privy-council a second time. And after full argument and examination, their lordships reported, among other things, "that they did then adjudge the land called Delaware to belong to his majesty."

In the settlement of the Delaware colony, under two deeds of feoffment from the duke of York in 1682, William Penn became involved in a territorial contest with lord Baltimore, which eventually became tedious, troublesome, and expensive to their representatives. The dispute was terminated in 1685, by an order "that for the avoiding of further differences, the tract of land lying between the river and bay of Delaware and the eastern sea, on the one side, and Chesapeake bay on the other, be divided in two equal parts, by a line from the latitude of Cape Henlopen, to the fortieth degree of northern latitude; and that one-half

Annexed to New-York.

4
Baltimore's claim.

Delaware. half thereof, lying toward the bay of Delaware and the eastern sea, be adjudged to belong to his majesty, and that the other half remain to the lord Baltimore, as comprised within his charter." This decision was founded on the principle that the king was deceived in his grant; that Delaware colony came within the exception by which the patent was restricted, as that part of the country was proved to have been previously possessed and settled by the Swedes and Dutch.

⁵ Delaware joined with Penn and the duke of York, expressed in the two deeds of feoffment, the former assumed the government of the Delaware colony, and in affairs of legislation, connected it with Pennsylvania. After this union of the province and the three lower counties, the representatives held their first session of assembly at Chester, on the fourth day of the tenth month, 1682. They enacted a law confirming the union, and delineating the particulars of the plan which was adopted. By this act, all the benefits and advantages before granted to the province were now extended to the colony of Delaware. They were from that time to be considered as the same people, and subject to the same laws. The freemen both of the province and of Delaware were summoned to attend this assembly *in person*: but they chose to elect twelve members in each county, amounting in all to seventy-two, the precise number which by the frame of government was to compose one house only. The representatives were accompanied with petitions to the governor importing, "that the fewness of the people, their inability in estate, and unskilfulness in government, would not permit them to serve in so large a council and assembly; and therefore it was their desire that the twelve now returned from each county, might serve both for provincial council and general assembly, with the same powers and privileges, which by the charter were granted to the whole."

† *Historical Review*, &c. 16.

§ *Life of Penn.*

The members were accordingly distributed into two houses; three out of each county made a council, consisting of eighteen, and the remaining part formed an assembly of fifty-four.

In the settlement of this country under the government of Mr Penn, the lands were purchased, and not forcibly taken from the natives; with whom it was observable that every new purchase considerably enhanced their estimation of the land. But the practice of contracting with the natives of America, for the lands on which settlements were made, is by no means peculiar to Mr Penn. Previously to his coming into Delaware the Dutch had adopted a similar practice; and large purchases had been made from the Indians, in different parts of America, and particularly in Massachusetts.

¶ *Ibid.*

During the time of William Penn's residence in his own province, the administration of the government was conducted safely and happily. There were no important altercations between the council and the assembly, or between either of them and the proprietary. But as the dispute between him and lord Baltimore recalled him to England, in less than three years after his arrival in the province, it soon lost the benefit of his personal assistance, and the repose of government was of short duration.

|| *Historical Review*, 18

On Mr Penn's leaving the province, we find disorders arising in every department of government. A certain Mr Moore, a chief in the proprietary's administration, was impeached by the assembly before the provincial council. He was represented, in an address to Mr Penn, as "an aspiring and corrupt minister of state." Mr John White, a representative from Delaware, who had signed the address as speaker, was soon arrested and committed to prison, and by a variety of artifices, the granting a *habeas corpus* was evaded*. There being no steady hand to hold the balance between the council and the assembly, they soon fell into controversy, in the construction of their respective powers and privileges;—and there had like to have been a very serious contest between the assembly and their absent proprietor, on his requiring from them a dissolution of their frame of government.—At the time of Mr Penn's departure, he had committed the administration of the government to five commissioners of state, taken out of the provincial council, who were to preside in his place. Soon disgusted with their disputes, and with the mode of conducting business in his absence, the proprietor removed the five commissioners from authority, and appointed for his deputy John Blackwell, an officer trained under Cromwell, and completely versed in the arts of intrigue. He commenced his administration in December 1688, by a display of unauthorised powers, and by endeavouring to sow discord among the people.

Delaware

Mr Penn returns to England.
7
Disorders the province.

* *Historical Review*, 19.

† *Life of Penn.*

Misfortunes now seemed to crowd on Mr Penn, in his own government and in England. In about six months after his arrival, the death of Charles brought James II. to the throne; a prince to whom he had been particularly known and particularly attached by obligations if not by principles. A variety of circumstances induced pointed suspicions against the proprietor. His taking lodgings in the neighbourhood of the court, at Kensington; his aiding the king's outrageous attack on Magdalen college; at this critical period, his writing a book on liberty of conscience, and vindicating the duke of Buckingham—all these circumstances conspired in forming the general prejudice against him as a *court instrument*.

After the abdication of James, both the province and its proprietor fell under the royal displeasure. Their laws had not been presented for approbation, and the new king and queen had not been proclaimed in the province for a long time after their accession; but the administration of the government was continued in the name of the exiled monarch. At what time the alteration took place is not ascertained; but in the year 1692, the government was assumed by the crown; and col. Fletcher, governor of New-York, administered both provinces. In consequence of these suspicions, Mr Penn not only lost his government for a time, but was several times publicly accused and prosecuted; and at length, to avoid the effects of the general unfavourable impressions, he was obliged to conceal himself for several years. In the latter end of the year 1693, on a hearing before the king and council, he was acquitted, and his government restored. After the proprietor's restoration, William Markham was appointed lieutenant-governor; and in the time of his administration, in 1696, another frame of government was proposed and adopted. This continued to be the constitution of Pennsylvania and Delaware, during the

Delaware, whole time of their union in legislation. For when the next charter was accepted by the province, in October 1701, it was totally rejected by the members of the three lower counties; and immediately a breach ensued, which eventually terminated in an entire separation.

* *Historical Review &c.*

9
Delaware separated from Pennsylvania.

This disunion does not appear to have been the effect of unreasonable caprice. By the new charter which was offered to their consideration, the principles of the first constitution were essentially mutilated. The people had no longer the election of the council; they were to be nominated by the governor, and were to serve on his terms. Instead of having but three voices in seventy-two, he was left single in the executive, and at liberty to restrain the legislative by refusing his assent to their bills whenever he thought fit. There were other articles, in the changing of which the people were advantaged. But whatever might have been the cause of this separation, it is certain by this act the Delaware colony avoided a great degree of altercation and political disorder.

For a great number of years after the separation, the political repose of the lower counties remained nearly undisturbed. At last, the contests between the two proprietaries revived. After this contest had continued for half a century, and when the claimants were exhausted with expence, anxiety and trouble; on the tenth of May 1732, for the purpose of adjusting all differences, they entered into articles of agreement, ascertaining the mode of settlement, and appointing commissioners to complete the contract. Those articles made a particular provision for adjusting the controversy, by drawing part of a circle about the town of New-Castle, and a line to ascertain the boundaries between Maryland and the Delaware colony.

From several other circumstances, as well as delays on the part of the Maryland proprietor, the execution of those articles and the decree thereon, were postponed until they were superseded by another agreement between Frederic lord Baltimore, son and heir of Charles lord Baltimore, and the proprietaries of Pennsylvania, which was made on the 4th of July, 1760, and was likewise confirmed by decree on the 6th of March, 1762. Those articles and decrees were immediately put in execution. The commissioners appointed and authorized by the respective proprietors, surveyed the several lines, as mentioned and described in the agreement, designated those lines by visible stones, pillars, and other landmarks, and made a return thereof under their hands and seals, with an exact plan or map of their work annexed. But from several causes, there never was a complete change of jurisdiction until the publication of Mr Penn's proclamation for that purpose, on the 8th of April 1775. This was finally carried into operation, the laws extended, and the boundaries of the counties and hundreds established, by an act of the Delaware legislature, passed the 2d of September 1775.

The separation from Pennsylvania, which has already been remarked, appears to have had a happy effect on the tranquillity of Delaware. It was involved in few political disturbances of importance, except the wars which it was obliged to participate from its connection with Great Britain. In the war which commenced in 1755, the exertions of the colonies were

excited in proportion to their respective degrees of patriotism and wealth. In this proportion, the Delaware colony was inferior to none of them in furnishing the necessary supplies of every kind. Major Wells was placed at the head of the military of this colony, and marched to the seat of war, in the western country, a large number of able-bodied, brave, and well disciplined troops.

In the year 1762, the expenditures and supplies of Delaware had far exceeded its regular proportion with the other provinces, and at that time the agent for the colony in England, received from the lords of the treasury, in consequence of a parliamentary grant, nearly four thousand pounds sterling, as a partial reimbursement of those expences. This was a sum much larger, according to the abovementioned proportion, than was granted to any of the other provinces.

Long before the settlement of the territorial contest between the two proprietors, so interesting to the Delaware counties, the dispute between Britain and America had commenced, and was hastening to a state when it was to attract the attention of the world. This small district from the first moment of opposing British usurpation, had felt and discovered a patriotic ardor equally with most of the colonies. So early as October 1765, representatives were deputed from Delaware to attend the first congress, which was held at New-York, for the purpose of obtaining a repeal of some of the most obnoxious British statutes. Cæsar Rodney and Thomas M'Kean, esquires, were the delegates who attended on the part of the Delaware counties. In the year 1773, the measures of Britain excited more than common attention. The legislature considered the crisis a very interesting one. They therefore "resolved that a standing committee of correspondence and enquiry be appointed, to consist of five members, whose business it shall be to obtain the most early and authentic intelligence of all such acts and resolutions of the British parliament, or proceedings of administration, as may relate to, or affect the British colonies in America; and to keep up a correspondence and communication with our sister colonies, respecting these important considerations."—Nor were those acts of patriotism and public spirit confined to legislative resolves: When the town of Boston, by the operation of the port-bill, was reduced to great distress, supplies from different parts of the colony, were voluntarily collected and forwarded for their relief.

During the subsequent periods of the war, there was no relaxation in the spirit and exertions of this state. Their supplies of every kind requisite to the public service, attested their attachment to the common cause; and the Delaware regiment was notoriously one of the finest and most efficient in the continental army. In the spring of 1776, it marched to join the American troops near New-York; being then commanded by col. John Haslet, an officer much distinguished for all the talents that can display a great civil and military character. He continued in the command of his regiment, and serving with unusual applause, until the ensuing winter, when at the battle of Princeton, his lamented death added one more victim to the great cause which he so cordially advocated. From this place his remains were conveyed to Philadelphia, and honorably interred; and some time afterwards,

Delaware. afterwards, the general assembly of the Delaware state, "remembering his virtues as a man, his merits as a citizen, and his services as a soldier," caused a monumental stone to be placed near his grave.

Through the remaining campaigns, the Delaware Troops preserved their uniform tenor of brave magnanimous conduct. In the southern states their character for military prowess was much distinguished. The commendation of them and the intrepid *Kirkwood*, by general Green, was singularly honourable. During the continuance of the war the distresses of Delaware, from various sources, were very destructive to both individual and general prosperity. The upper district of the state sustained for a long time the ravages and desolations of the British army. And after both armies advanced into Pennsylvania, the bay and river being in possession of the enemy, the armed vessels belonging to the British and the refugees, carried on a destructive predatory war on the coast, intercepting vessels, annoying the trade, burning houses, and kidnapping the citizens of Delaware. Those causes effectually arrested the progress of improvement in every different direction. The academies of *New-Ark* and *Wilmington* had become celebrated through the neighbouring states, and had interested and secured very extensive patronage. But the sciences were compelled to give place to the ravages of war. The approaches of the two armies dispersed their students, and the depreciation of the continental currency demolished their funds. Since the peace, learning appears to revive and flourish, as if confident of the aid and support of a permanent efficient government.

Just before the commencement of the war, a work of considerable importance was begun at Lewes, in the southern division of the state, viz. the erection of a bridge and causeway, from the town, over the creek and marsh to the opposite cape. This was an expensive and difficult undertaking. It was just finished when the British ships first came into the road off Lewes; when, in order to prevent too easy a communication, they were obliged partially to remove it, and afterwards so to neglect it, as that it was, before the conclusion of the war, nearly demolished. Within a year or two past they have begun to erect another bridge, nearly on the same plan, but entirely on a new foundation. It was begun, carried on, and is now finished, solely at the expence of individuals. It extends about a quarter of a mile from the town to the beach over a wide creek and marsh. The inhabitants are well compensated for their trouble and expence, by the facility of communication between the town and cape. The advantages attending it are too obvious and numerous to mention. While we are at this place it may be proper to observe, that the situation of the town and creek of Lewes must, at some future time, make them considerably important. Placed at the entrance of a bay, which is crowded with vessels from all the commercial world, and which is frequently closed with ice nearly through the winter season, necessity seems to require, and nature seems to suggest, the forming this port into a harbour for shipping. Nothing has prevented this heretofore but the deficiency of water in the creek. This want could be cheaply and easily supplied by a small canal, so as to afford a passage for the

VOL. V.

waters of Rehoboth into Lewes-creek, which would ensure an adequate supply. Delaware.

Since the war, the light-house, near the town of Lewes, which had been burnt in the year 1777, has been completely and handsomely repaired. This is a fine stone structure, about eight stories high; the annual expence of which is estimated at about 650 pounds.

The state of Delaware is divided into three counties, called New-Castle, Kent, and Suffex; and those again are subdivided into hundreds. The chief towns are New-Castle in the county of New-Castle, Dover in the county of Kent, and Lewes in the county of Suffex. ¹⁰ Civil divisions.

Previously to the late revolution, this district of country was denominated the *the three lower counties on Delaware*. Its former connection with Pennsylvania has been sufficiently remarked. In September 1776, the present constitution was established by a convention of representatives, chosen for that express purpose; and at that time it assumed the name of the *Delaware State*. The legislature is formed of two distinct branches, which together are called the *general assembly of Delaware*. One of the branches of the legislature is called the *house of assembly*; and consists of seven representatives, chosen for each county annually, who are to be freeholders of the county for which they are chosen. The other branch is called the *council*; and consists of nine members, three for each county, who are to be freeholders of the county for which they are chosen, and must be upwards of twenty-five years of age. A rotation of counsellors is established, by displacing one member for each county in every year, whereby they remain in trust for three years. All money-bills must originate in the house of assembly; but they may be altered, amended, or rejected by the legislative council. ¹¹ Constitution.

A president is chosen by the joint ballot of both houses, and continues in office three years, and until the sitting of the next general assembly. After this he is ineligible for the three next succeeding years. In case of the death, absence, or inability of the president, the speaker of the legislative council is vice-president for the time; and in his absence, the powers of the president devolve upon the speaker of the assembly. A privy council, consisting of four members, two elected by each house of the general assembly, is constituted to assist the president in the administration of the government.

The three justices of the supreme court, a judge of admiralty, and four justices of the common pleas and orphans courts, are appointed by the joint ballot of the president and general assembly, and commissioned by the president, and are to hold their offices during good behaviour. The president and privy council appoint the secretary, the attorney-general, registers for the probate of wills; registers in chancery, prothonotaries of the common pleas, clerks of the orphans courts, and clerks of the peace, who hold their offices for five years, unless sooner removed for mal-conduct. The house of assembly names twenty-four persons in each county for justices of the peace, from which number the president and his council commission twelve, who serve for

Delaware. seven years, unless sooner dismissed for mal-administration. The members of the legislative and privy councils, are justices of the peace for the whole state.

The justices of the common pleas have the power of holding inferior courts of chancery.

The clerks of the supremecourt are appointed by the chief justice, and the recorders of deeds, by the justices of common pleas—to hold their respective appointments for five years, if they behave themselves well. The general assembly appoints the generals and field-officers, and all other officers in the army or navy of this state.

The court of *appeals* consists of seven persons, the president, who is a member, and presides by virtue of his office, and six others; three to be chosen by the legislative council, and three by the house of assembly. This court receives appeals from the supreme court in all matters of law and equity. The judges continue in office during good behaviour.

The justices of the several courts, the members of the privy council, the secretary, the trustees of the loan-office, prothonotaries of the common pleas, and all persons concerned in army or navy contracts, are ineligible to either branch of the legislature. Every member before taking his seat, and all officers before they enter on the execution of their offices, must take the oath of allegiance, and subscribe a religious test, declaring their belief in God the Father, in Jesus Christ, and the Holy Ghost, and in the inspiration of the scriptures.

The house of assembly have the power of impeaching delinquent officers of government; such impeachment to be prosecuted by the attorney-general, or such person as the house of assembly shall appoint before the legislative council. The punishment may extend to temporary or perpetual disability to hold offices under government, or to such other penalties as the law shall direct.

The common law of England, as well as so much of statute law, as was adopted in practice in this state previous to the revolution, still remain in force, unless altered by particular acts of the legislature.—No religion is established in this state in preference to another; and no clergyman or preacher of the gospel of any denomination is capable of holding any civil office in this state, or of being a member of either branch of the legislature, while they continue in the exercise of the pastoral function.

This is a comprehensive abstract of the present constitution of Delaware. It has for several years been considered by the citizens of that state as essentially defective. In the administration of it they have sustained many inconveniences, which have greatly diminished the happiness of the people and the reputation of the government. From this cause, there has arisen a very general wish to alter or amend the constitution. An election of deputies in convention for this purpose has already taken place.

The state of Delaware, excepting the upper parts of the county of New-Castle, is, in general, extremely level and low. Large quantities of stagnant water, at particular seasons of the year, overspreading a great proportion of the land, render it equally unfit for the purposes of agriculture, and injurious to the health of the inhabitants.

The eastern side of the state is indented with a Delaware large number of creeks or small rivers, which generally have a short course, slimy and oozy banks, numerous shoals, are skirted with very extensive marshes, and empty into the river and bay of Delaware. The southern and western sides give origin to the head waters of Pocomoke, Wicomico, Nanticoke, Choptank, Chester, Sassafras, and Bohemia rivers, all of which fall into the bay of Chesapeake.

The spine, or highest ridge of the peninsula runs through the state of Delaware, inclined to the eastern or Delaware side. It is designated in Suffex, Kent, and part of New-Castle county, by a remarkable chain of swamps, from which the waters descend on each side, passing on the east to the Delaware, and on the west to the Chesapeake. Many of the shrubs and plants, growing in these swamps, are similar to those found on the highest mountains.

The soil along the Delaware, and for about eight or ten miles into the interior country, is commonly a rich and fertile clay, producing large timber, and well adapted to the various purposes of agriculture; thence to the abovementioned swamps it is chiefly light, sandy, and of inferior quality.

A question, concerning the origin of the flat and low lands of this and the neighbouring states, has been the subject of much curious speculation. The whole Peninsula, lying between the bays of Delaware and Chesapeake, as well as a large tract of the adjacent country, has many appearances of *made ground*. To enumerate these, or to adduce the reasonings in support of such opinion, would far exceed our necessary limits. But admitting the fact, it still remains difficult to account for the precise manner in which this vast tract of land has been acquired from the ocean. It has been conjectured, with some degree of probability, that it may have been formed by earth, washed down from the high grounds and mountains lying westward, aided, in a small degree, by the accumulation of soil from the decay of vegetable substances. This conjecture receives much confirmation from the aspect of a large extent of the country eastward of the great range of Alleghany mountains. The features of violence and confusion are deeply impressed on the surface of this tract. The irregularity of the strata of stones, earths and minerals; the position of the layers of lime-stone, almost universally vertical, instead of horizontal; all these are the vestiges of the operation of a power which must have convulsed the earth to its centre. On the contrary, when we take our view from the western ridge of those mountains we seem to survey a vast extended plain; all the various strata of stone appear to have lain undisturbed in the situation in which they were originally formed. The layers of sand, clay, and coal are nearly horizontal.

It is well known that several of the largest rivers, in the middle states, viz, the Hudson, the Delaware and the Patowmac, with some others of inferior size, in their course to the ocean, make their way through the ridges of high mountains. The clefts, through which these majestic currents roll, discover every appearance of violence and disrapture. The broken ragged faces of the mountains, on each side of the respective rivers; the tremendous rocks, which

over-

12
Face of the
country,
climate,
soil, &c.

Delaware. overhang the passage, and constantly seem ready to fall for want of support; the obstruction of the beds of the rivers, for several miles below, by rocks and loose stones; all these things, taken together, seem to be so many traces of a war of the elements, and the ravages of a power which nothing could oppose.

It has been supposed, that, in the extended plain behind these mountains, there was formerly collected a vast lake of water; that continuing from time to time to rise higher, it at length broke over, and tore the mountain down from its summit to its base.

The torrent, thus breaking forth, must have produced a convulsion more awful than we can imagine, and fully adequate to all the effects we behold. The quantity of rocks, stones, sand, clay and mud, thus set in motion by such an immense power, was probably sufficient to give a new face to the lower country. Nothing but the restoration of equilibrium, between these oceans of fresh and salt water, could have abated the fury of the torrent, or diminished the overwhelming drift of earth and sand upon the low lands.

The nature of the soil, from the feet of the mountains to the sea-shores, exactly corresponds with this opinion of its formation. The lower country seems to be made up of a variety of light substances, washed from higher grounds by torrents and floods, and afterwards deposited when those waters became stagnant. Gradations of soil are easily observable from the mountains to the sea. Near the mountains we find rocks of large dimensions; these are succeeded by others of smaller size; then the soil becomes stony, afterwards gravelly, and, last of all, we meet a light clay, sand and mud. Throughout the whole extent of country we can readily remark, that the deposition seems regularly to have taken place in the order of the respective specific gravities of these earthy bodies.

From the foregoing description of the low and level soil of a great part of the state of Delaware, it follows that it must be a sickly country. The diseases arising from the nature of the soil, chiefly prevail during the summer and autumn, and consist of intermittent and remittent fevers, and disorders of the stomach and bowels. They generally commence at the beginning of July, sooner or later, according to the degree and duration of the heats, and course of the winds; and commonly continue till the frosts and plentiful rains of the month of October.

These diseases fall, with peculiar violence, on strangers and infants. Happily for the human system it possesses a wonderful faculty of accommodation, and speedily acquires the power of resisting the most noxious causes. This *seasoning*, according to circumstances, is more or less severe, and occupies a longer or shorter time.

It has been commonly supposed, that this widely spreading epidemic originates from the combination of heat and moisture in producing an extensive putrefaction of those animal and vegetable substances which overspread so large a proportion of the surface of a fenny country. The want of brisk ventilation, and a deficiency of the sources of pure air, inseparable evils of a level and low country, may also be enumerated among the causes of these diseases. It must, however, be confessed, that this source of disease,

though extremely interesting to the science and practice of medicine, has never been investigated with the diligence it deserves; and that many important *desiderata* might still be enumerated.

The character of insalubrity belongs not to the whole state of Delaware. The high grounds, in the upper parts of New-Castle county, are as much distinguished by the purity of their air as by the charms of their extensive and delightful prospects. Wilmington, and its beautiful environs, has long been celebrated for health, and much resorted to by invalids from the lower and more sickly parts of the state. Many of the other districts of the county of New-Castle, and indeed a large proportion of the whole county, must be considered rather as healthful than otherwise.

Kent and Sussex are much more unhealthy. These two counties form one extended plain, abound in low and swampy grounds, and, with respect to their interior parts, are deprived of almost all the best sources of pure air. But asylums of health are by no means wanting in these counties; and we may, with great propriety, apply to them an observation which has been made with respect even to some of the most unwholesome countries in the world, viz. that healthy spots are interspersed over a great portion of them, and probably might be selected in larger number, and greater perfection, if proper attention were bestowed on the subject.

The western parts of the state bordering on Maryland, where extensive forests and uncleared swamps occupy a considerable extent of the country, excluding the sun's access to the stagnant waters, and absorbing noxious exhalations, enjoy a situation comparatively healthy.

On the other hand, places situated on the river and bay, enjoying a free exposure to the brisk and salutary breezes from the ocean, possess advantages of health, and purity of air, which are universally observed and acknowledged. In consequence of this, during the sickly season, the shores of the bay and river are much frequented by invalids for the recovery of health, and by the healthy for the prevention of disease. Here is a convenient pleasant retreat from noxious air, to which almost every individual, if situated in the most sickly parts of the state, can easily have access. Perhaps a more perfect refuge from disease might be obtained by sailing out on the bay, but for common purposes the shores are sufficient. No instances can be produced of places permanently unwholesome which have a free opening to the river or bay.

The intermediate space, therefore, between the forests on the one side, and the shores of the bay or river, to a small distance into the country, on the other, constitutes that tract in which the summer and autumnal diseases are chiefly prevalent and fatal.

These disorders have been observed, in many districts, for several years past, manifestly to increase with the disforestation of the country; and to be as remarkably diminished in others, by more extended openings, by draining stagnant waters, and by an improved state of agriculture. And we may safely venture to predict, that, when the high state of cultivation of this country shall have taken place, to which the fertility and other advantages of the soil strongly solicit the husbandman; when the sources of morbid exhalations shall have been

Delaware.

Delaware. better ascertained, and the means of correcting them more accurately understood and generally diffused; the state of Delaware will be as much distinguished for its purity of air and progressive populousness, as for its wealth and advantages of situation.

Delaware is chiefly an agricultural state. It includes a very fertile tract of country; and scarcely any part of the union can be selected more adapted to the different purposes of agriculture, or in which a greater variety of the most useful productions can be so conveniently and plentifully reared.

The general aspect of the country is extremely favourable to the processes of tillage. Excepting some of the upper parts of the county of New-Castle, the surface of the state is very little broken or irregular. The heights of Christiana are lofty and commanding; some of the hills of Brandywine are rough and stony; but descending from these, and a few others, the lower country is so little diversified as almost to form one extended plain.

In the county of New-Castle, the soil consists of a strong clay; in Kent, there is a considerable admixture of sand; and in Suffex, the quantity of sand altogether predominates.

Wheat is the staple of this state. It grows here, and in the greatest part of the peninsula between the two bays, in such perfection as not only to be particularly sought by the manufacturers of flour throughout the union, but also to be distinguished and preferred, for its superior qualities, in foreign markets. This wheat possesses an uncommon softness and whiteness, very favourable to the manufacture of superfine flour, and in this respect, far exceeds the hard and flinty grain raised in general on the high lands.

Besides wheat, this state generally produces plentiful crops of indian corn, barley, rye, oats, flax, buckwheat, and potatoes. It abounds in natural and artificial meadows, containing a large variety of grasses. Hemp, cotton, and silk, if properly attended to, doubtless would flourish very well.

The agricultural conveniences of the state are much enhanced by its vicinity to excellent markets for all its productions, and the facility of obtaining water-carriage within a short distance from every farm.

There is no part of America, perhaps no part of the known world, where the manufacture of flour is carried to a higher degree of perfection. Besides numerous mills of excellent construction all over the state, the celebrated collection of mills at Brandywine deserves particular notice. Here are to be seen, in one view, thirteen mills, with double that number of pairs of stones, all of superior dimensions and construction, capable of grinding between two and three thousand bushels of wheat per diem.

The county of Suffex, besides producing a considerable quantity of grain, particularly of indian corn, possesses excellent grazing lands. This county also exports very large quantities of lumber, obtained chiefly from an extensive swamp, called the *Indian River*, or *Cypress Swamp*, lying partly within this state, and partly in the state of Maryland. This morass extends six miles from east to west, and nearly twelve from north to south, including an area of nearly fifty thousand acres of land. The whole of this swamp is a high and level basin, very wet, though undoubtedly the high-

Delaware. est land betwixt the sea and the bay, whence the *Pocomoke* descends on one side, and *Indian River* and *St. Martin's* on the other.

Among the plants, shrubs, trees, quadrupeds, birds, and reptiles of this vast swamp, might probably be observed a thousand curiosities, very interesting to the philosophic enquirer. Its recesses have never yet been explored with the accurate views of botany and natural history. The vegetables to be found in it, almost universally possess strong sensible qualities; they are chiefly resinous, aromatic, or bitter. It is extremely probable, that many valuable medicinal substances, deserving investigation and experiment, lie concealed amidst these wilds. Wild animals, in considerable number and variety, find shelter in this swamp; among these may be reckoned bears, wolves, foxes, wild cats, and many other kinds. The birds of prey are observed to be here very numerous, and of prodigious size.

In the county of Suffex, among the branches of *Nanticoke River*, large quantities of bog-ore of iron are to be found. This ore was worked to considerable extent, prior to the late revolution; it was thought to be of good quality, and peculiarly adapted to the purposes of castings. The works have chiefly fallen into decay.

According to the census lately taken, by order of the United States, the inhabitants of the state of Delaware were found to amount to near sixty thousand.

In this state we find a variety of religious denominations. Of the Presbyterian communion, there are 24 churches—of the Episcopal, 14—of the society called *Quakers*, 6—of the Baptists, 4—of the Methodists, a considerable number, especially in the two lower counties of Kent and Suffex, the number of churches not exactly ascertained.

DELAWARE, a bay and river of the United States, which flows chiefly between Delaware and Pennsylvania on the west, and New-Jersey, with some part of New-York, on the east. It rises in lake *Ustyantho*, not far from Albany, in the state of New-York. From its source it takes a south-west direction, until it passes into the state of Pennsylvania, in latitude 42°. Thence it proceeds southwardly, dividing New-York from Pennsylvania, until it strikes the northwest corner of New-Jersey in latitude 41° 24'. Thence it continues its course through New-Jersey, Pennsylvania, and Delaware, until it passes into the ocean between *Cape-Henlopen* and *Cape-May*.

The width of the bay, between the two Capes, is something more than twenty miles; at the entrance of the river, about four or five miles; and from Philadelphia to the opposite shore of the Jersey, is about one mile.—*Reedy-Island*, near the mouth of the river, is the rendezvous of outward bound ships in autumn and spring, while waiting for a favourable wind. The course from this to the sea is about south-south-east; so that a north-west wind, which generally prevails at these seasons, is fair for vessels to put to sea. The navigation of this bay, in common seasons, is easy and safe, if conducted by persons of skill and attention. There are several extensive shoals, pretty near the mouth of the bay, which absolutely require this precaution. Of those, the *Over-Falls*, the *Brown*, and the *Brandywine* are the most dangerous.

The distance from the city of Philadelphia to *Cape-Henlopen*, by the ship-channel of the Delaware, is about

Delegate. about one hundred and twenty miles. So far there is a sufficient depth of water for a seventy-four gun ship. From Philadelphia to Trenton-Falls is thirty five miles; and this terminates the sloop navigation. The river is navigable for boats of eight or nine tons burthen forty miles further; and for Indian canoes, rafts of timber, plank, &c. two hundred miles above the city, by the course of the river. At *Easton* it receives the *Lehigh* from the west, which is navigable about thirty miles. The tide sets up as high as Trenton-Falls, and at Philadelphia generally rises about six feet. It flows about the rate of four miles an hour. In severe winters the Delaware is frequently closed with ice. Sometimes it extends very far down the bay; and it is said, that in the winter of 1739-40, the ice in the bay opposite the town of Lewes, extended as far as the eye could discover. If the river be frozen over, during the season, it is seldom completely navigable until the last of February or the beginning of March.

The name of *Delaware*, appears to be derived from the celebrated Lord *Delawar**, who completed the settlement of Virginia. 'Tis supposed his lordship put into this bay at his first arrival on the American-coast. The name has been communicated to the neighbouring state on the east.

DELEGATE, in a general sense, a deputy or commissioner.

DELEGATES, in Britain, commissioners appointed by the king, under the great seal, to hear and determine appeals from the ecclesiastical court.

Court of DELEGATES, the great court of appeal in all ecclesiastical causes. These delegates are appointed by the king's commission under his great seal, and issuing out of chancery, to represent his royal person, and hear all appeals to him made by virtue of the statute 25 Henry VIII. c. 19. This commission is usually filled with lords spiritual and temporal, judges of the courts at Westminster, and doctors of the civil law. Appeals to Rome were always looked upon by the English nation, even in the times of Popery, with an evil eye, as being contrary to the liberty of the subject, the honour of the crown, and the independence of the whole realm; and were first introduced in very turbulent times, in the 16th year of king Stephen (A. D. 1151), at the same period (Sir Henry Spelman observes) that the civil and canon laws were first imported into England. But in a few years after, to obviate this growing practice, the constitutions made at Clarendon, 11 Hen. II. on account of the disturbances raised by archbishop Becket and other zealots of the holy see, expressly declare, that appeals in causes ecclesiastical ought to lie from the archdeacon to the diocesan; from the diocesan to the archbishop of the province; and from the archbishop to the king; and are not to proceed any farther without special license from the crown. But the unhappy advantage that was given in the reign of king John, and his son Hen. III. to the encroaching power of the Pope, who was ever vigilant to improve all opportunities of extending his jurisdiction to Britain, at length rivetted the custom of appealing to Rome in causes ecclesiastical so strongly, that it never could be thoroughly broken off, till the grand rupture happened in the reign of Hen. VIII. when all the jurisdiction usurped by the Pope in matters ecclesiastical was restored to the crown, to which

it originally belonged: so that the statute 25 Hen. VIII. Delegation was but declaratory of the ancient law of the realm. But in case the king himself be party in any of these suits, the appeal does not then lie to him in chancery, which would be absurd; but, by the 24 Henry VIII. c. 12. to all the bishops of the realm, assembled in the upper house of convocation.

DELEGATION, a commission extraordinary given by a judge to take cognisance of and determine some cause which ordinarily does not come before him.

DELEGATION, in Scots law. See Law, n^o clxxvii. 8.

DELEN (Dirk Van), an eminent painter of architecture and perspective, was born at Heusden, but in what year is not known. He was a disciple of Francis Hals, in whose school he practised to paint those particular subjects which were most esteemed by that master, such as portraits and conversations; and by that means he acquired the skill to design figures with a great deal of spirit, and correctness.

DELETERIOUS, an appellation given to things of a destructive or poisonous nature. See POISON.

DELFT, a town of the united provinces, and capital of Delftland in Holland. It is a pretty large place, very clean and well built, with canals in the streets, planted on each side with trees. The public buildings, especially the town-house, are very magnificent. Here are two churches: in one is the tomb of the prince of Orange, who was assassinated; and in the other, that of admiral Tromp. It has a fine arsenal, well furnished; is about two miles in circumference, and is defended against inundations by three dams or dikes. Here is made a prodigious quantity of fine earthenware called *delft-ware*; but the town has no other trade. It is pleasantly situated among the meadows on the river Shie, in E. Long. 4. 13. N. Lat. 32. 6.

DELFT-Ware, a kind of pottery of baked earth, covered with an enamel, or white glazing, which gives it the appearance and nearness of porcelain.—Some kinds of this enamelled pottery differ much from others, either in their sustaining sudden heat without breaking, or in the beauty and regularity of their forms, of their enamel, and of the painting with which they are ornamented. In general, the fine and beautiful enamelled potteries, which approach the nearest to porcelain in external appearance, are at the same time those which least resist a brisk fire. Again, those which sustain a sudden heat, are coarse, and resemble common pottery.

The basis of this pottery is clay, which is to be mixed, when too fat, with such a quantity of sand, that the earth shall preserve enough of its ductility to be worked, moulded, and turned easily; and yet that its fatness shall be sufficiently taken from it, that it may not crack or shrink too much in drying or in baking. Vessels formed of this earth must be dried very gently to avoid cracking. They are then to be placed in a furnace to receive a slight baking, which is only meant to give them a certain consistence or hardness. And, lastly, they are to be covered with an enamel or glazing; which is done, by putting upon the vessels thus prepared, the enamel, which has been ground very fine, and diluted with water.

As vessels on which the enamel is applied are but slightly baked, they readily imbibe the water in which the enamel is suspended, and a layer of this enamel ad-

heres

Delft.

heres to their surface: these vessels may then be painted with colours composed of metallic calces, mixed and ground with a fusible glass. When they are become perfectly dry, they are to be placed in the furnace, included in cases of baked earth called *seggars*, and exposed to a heat capable of fusing uniformly the enamel which covers them.—This heat given to fuse the enamel being much stronger than that which was applied at first to give some consistence to the ware, is also the heat necessary to complete the baking of it. The furnace and the colours used for painting this ware, are the same as those employed for PORCELAIN. The glazing, which is nothing but white enamel, ought to be so opaque as not to show the ware under it. There are many receipts for making these enamels; but all of them are composed of sand or flints, vitrifying salts, calx of lead, and calx of tin; and the sand must be perfectly vitrified, so as to form a glass considerably fusible. Somewhat less than an equal part of alkaline salt, or twice its weight of calx of lead, is requisite to effect such vitrifications of sand. The calx of tin is not intended to be vitrified, but to give a white opaque colour to the mass; and one part of it is to be added to three or four parts of all the other ingredients taken together. From these general principles, various enamels may be made to suit the different kinds of earths. To make the enamel, lead and tin are calcined together with a strong fire; and the sand is also to be made into a fritt with the salts or ashes. The whole is then to be well mixed and ground together. This matter is then to be placed under the furnace, where it is melted and vitrified during the baking of the ware. It is next to be ground in a mill, and applied as above directed.

Chim. Dict.

The preparation of the white enamel is a very essential article in making delft-ware, and one in which many artists fail. M. Bosc. d'Antic, in a Memoir concerning this kind of ware, published in the *Mem. des Scavans Etrang. tom. 6.* recommends the following proportions. An hundred pounds of calx of lead are to be mixed with about a seventh part of that quantity of calx of tin for common delft-ware, or a fourth part of calx of tin for the finest kind; an hundred, or an hundred and ten, pounds of fine sand; and about twenty or thirty pounds of sea salt.—Concerning the earth of which the ware is made, he observes, that pure clay is not a proper material when used alone. Different kinds of earths mixed together are found to succeed better. Pieces of ware made of clay alone, are found to require too much time to dry; and they crack, and lose their form, unless they are made exceedingly thick. An addition of marle diminishes the contraction of the clay; renders it less compact; and allows the water to escape, without altering the form of the ware in drying. It affords also a better ground for the enamel; which appears more glossy and white than when laid on clay alone.—The kinds of clay which are chiefly used in the composition of delft-ware, are the blue and green. A mixture of blue clay and marle would not be sufficiently solid, and would be apt to scale, unless it were exposed to a fire more intense than what is commonly used for the burning of delft-ware. To give a greater solidity, some red clay is added: which, on account of its ferruginous matter, possesses the requisite binding quality. The proportions of these in-

redients vary in different works, according to the different qualities of the earths employed. Three parts of blue clay, two parts of red clay, and five parts of marle, form the composition used in several manufactories. M. d'Antic thinks, that the best delft-ware might be made of equal parts of pure clay and pure calcareous earth; but this composition would require that the fire should be continued twice as long as it generally is.

DELIA, in antiquity, a festival celebrated every fifth year in the island of Delos, in honour of Apollo. It was first instituted by Theseus, who at his return from Crete placed a statue there, which he had received from Ariadne. At the celebration they crowned the statue of the goddess with garlands, appointed a choir of music, and exhibited horse-races. They afterwards led a dance, in which they imitated by their motions the various windings of the Cretan labyrinth, from which Theseus had extricated himself by Ariadne's assistance.—There was another festival of the same name yearly celebrated by the Athenians in Delos. It also was instituted by Theseus, who, when he was going to Crete, made a vow, that if he returned victorious he would yearly visit in a solemn manner the temple of Delos. The persons employed in this annual procession were called *Deliaistæ* and *Theori*. The ship, the same which carried Theseus, and had been carefully preserved by the Athenians, was called *Theoria* and *Delias*. When the ship was ready for the voyage, the priest of Apollo solemnly adorned the stern with garlands, and an universal lustration was made all over the city. The *Theori* were crowned with laurels, and before them proceeded men armed with axes, in commemoration of Theseus, who had cleared the way from Troezen to Athens, and delivered the country from robbers. When the ship arrived at Delos, they offered solemn sacrifices to the god of the Island, and celebrated a festival to his honour. After this they retired to their ship and sailed back to Athens, where all the people of the city ran in crowds to meet them. Every appearance of festivity prevailed at their approach, and the citizens opened their doors and prostrated themselves before the *Deliaistæ* as they walked in procession. During this festival it was unlawful to put to death any malefactor, and on that account the life of Socrates was prolonged for thirty days.

DELIA, a surname of Diana, because she was born in Delos.

DELIAC, DELIACUS, among the ancients, denoted a poulterer, or a person who sold fowls, fatted capons, &c. The traders in this way were called *Deliaci*; the people of the isle of Delos first practised this occupation. They also sold eggs, as appears from Cicero, in his Academic Questions, lib. iv. Pliny, lib. x. cap. 30. and Columella, lib. viii. cap. 8. likewise mention the *Deliaci*.

DELIBAMENTA, in antiquity, a libation to the infernal gods always offered by pouring downwards.

See Libation.

Jus DELIBERANDI. See LAW, N^o clxxx. 23.

DELIBERATIVE, an appellation given to a kind or branch of rhetoric, employed in proving a thing, or convincing an assembly thereof, in order to persuade them to put it in execution.

To have a DELIBRATIVE voice in the assembly, is when a person has a right to give his advice and his vote

Delia
||
Deliberative.

Delict ||
Delirium. vote therein. In councils, the bishops have deliberative voices; those beneath them have only consultative voices.

DELICT, in Scots law, signifies such small offences or breaches of the peace as are punishable only by fine or short imprisonment.

DELIMA, in botany: A genus of the monogynia order, belonging to the polyandria class of plants; and in the natural method ranking with those of which the order is doubtful. There is no corolla; the calyx is five-leaved, with a two-seeded berry.

DELINQUENT, a guilty person, or one who has committed some fault or offence for which he is punishable. See **BRITAIN**, n^o 97.

DELIQUESCENCE, in chemistry, signifies the property which certain bodies have of attracting moisture from the air, and becoming liquid thereby. This property is never found but in saline substances, or matters containing them. It is caused by the great affinity which these substances have with water. The more simple they are, according to Mr. Macquer, the more they incline to deliquescence. Hence, acids, and certain alkalis, which are the most simple, are also the most deliquescent salts. Mineral acids are so deliquescent, that they strongly imbibe moisture from the air, even though they are already mixed with a sufficient quantity of water to be fluid. For this purpose, it is sufficient that they be concentrated only to a certain degree.—Many neutral salts are deliquescent, chiefly those whose bases are not saline substances. Salts formed by the vitriolic acid, with fixed or volatile alkalis, earths, or most metallic substances, are not deliquescent; although this acid is the strongest of all, and, when disengaged, attracts the moisture of the air most powerfully.

Though the immediate cause of deliquescence is the attraction of the moisture of the air, as we have already observed; yet it remains to be shown why some salts attract this moisture powerfully, and others, though seemingly equally simple, do not attract it at all. The vegetable alkali, for instance, attracts moisture powerfully; the mineral alkali, though to appearance equally simple, does not attract it at all. The acid of tartar by itself does not attract the moisture of the air; but if mixed with borax, which has a little attraction for moisture, the mixture is exceedingly deliquescent.—Some theories have been suggested, in order to account for these and other similar facts; but we are as yet too little acquainted with the nature of the atmosphere, and the relation its constituent parts have to those of terrestrial substances, to determine any thing with certainty on this head,

DELIQUIUM, or *DELIQUIUM Animi* (from *delinquo*, “I swoon”), a swooning or fainting away; called also *syncope*, *lipothymia*, *lipopsychia*, *eclipsis*, and *asphyxia*.

DELIQUIUM (from *deliquesco*, “to be dissolved”), in chemistry, is the dissolution or melting of a salt or calx by suspending it in a moist cellar.

Salt of tartar, or any fixed alkali, set in a cellar or other cool moist place, and in an open vessel, resolves or runs into a kind of liquor called by the chemists oil of tartar *per deliquium*.

DELIRIUM (from *deliro*, “to rave or talk idly”). When the ideas excited in the mind do not correspond

VCL. V.

to the external objects, but are produced by the change induced on the common sensory, the patient is said to be delirious. See **MEDICINE-Index**.

DELIVERY, or **CHILD-BIRTH**. See **MIDWIFERY**.

DELLI, or **DELHI**, a kingdom and city of the Mogul's empire, in Asia. The city is one of the capitals of the empire. The road between it and *Agra*, the other capital, is that famous alley or walk planted with trees by Jehin Ghir, and 150 leagues in length. Each half league is marked with a kind of turret; and at every stage there are little sarays or caravanseras for the benefit of travellers. The road, though pretty good, has many inconveniences. It is not only frequented by wild beasts, but by robbers. The latter are so dextrous at casting a noose about a man's neck, that they never fail, if within reach, to seize and strangle him. They gain their means likewise by means of handsome women; who, feigning great distress, and being taken up behind the unwary traveller, choke him with the same snare.—The capital consists of three cities, built near one another. The first, now quite destroyed, is said to have had 52 gates: and to have been the residence of king Porus, conquered by Alexander the Great. The second, which is also in ruins, was demolished by Shah Jehan, to build *Jehan-abad* with the materials. This makes the third city, and joins the ruins of the second. The city stands in an open plain country, on the river *Jamna*, which rises in this province. It is encompassed with walls, except towards the river. These are of brick, flanked with round towers; but without a ditch, and terraced behind, four or five feet thick. The circumference of the walls may be about nine miles. The fortress, which is a mile and an half in circuit, has good walls and round towers, and ditches full of water, faced with stone. It is surrounded with fine gardens, and in it is the Mogul's palace. See **INDOSTAN**. E. Long. 79. 25. N. Lat. 28. 20.

DELMENHORST, a strong town of Germany, in the circle of Westphalia, and county of Oldenburgh, belonging to Denmark; seated on the river Delm near the Weser. E. Long. 8. 37. N. Lat. 53. 10.

DELLOS, an island of the Archipelago, very famous in ancient history. Originally it is said to have been a floating island, but afterwards it became fixed and immoveable. It was held sacred on account of its being the birth-place of Apollo and Diana.—Anciently this island was governed by its own kings. Virgil mentions one Anias reigning here in the time of the Trojan war. He was, according to that poet, both king and high-priest of Apollo, and entertained Æneas with great kindness. The Persians allowed the Delians to enjoy their ancient liberties after they had reduced the rest of the Grecian islands. In after ages, the Athenians made themselves masters of it; and held it till they were driven out by Mithridates the Great, who plundered the rich temple of Apollo, and obliged the Delians to side with him. Mithridates was in his turn driven out by the Romans, who granted the inhabitants many privileges, and exempted them from all sorts of taxes. At present it is quite abandoned; the lands being covered with ruins and rubbish, in such a manner as to be quite incapable of cultivation. The inhabitants of Mycone hold it now, and pay but ten crowns land-tax to the Grand Signior for an island

Delos.

Delos

which was once one of the richest in the world.—Strabo and Callimachus tell us that the island of Delos was watered by the river Inapus; but Pliny calls it only a spring; and adds, that its waters swelled and abated at the same time with those of the Nile. At present there is no river in the island, but one of the noblest springs in the world; being twelve paces in diameter, and inclosed partly by rocks and partly by a wall. Mount Cynthus, whence Apollo had the surname of *Cynthius*, is by Strabo placed near the city, and said to be so high, that the whole island was covered by its shadow; but our modern travellers speak of it as an hill of a very moderate height. It is but one block of granite of the ordinary sort, cut on that side which faced the city into regular steps, and inclosed on both sides by a wall. On the top of the mountain are still to be seen the remains of a stately building, with a mosaic pavement, many broken pillars, and other valuable monuments of antiquity. From an inscription discovered there some time ago, and which mentions a vow made to Serapis, Isis and Anubis, some have conjectured, that on this hill stood a temple dedicated to these Egyptian deities, though nowhere mentioned in history.—The city of Delos, as is manifest from the magnificent ruins still extant, took up that spacious plain reaching from one coast to the other. It was well peopled, and the richest city in the Archipelago, especially after the destruction of Corinth; merchants flocking thither from all parts, both in regard of the immunity they enjoyed there, and of the convenient situation of the place between Europe and Asia. Strabo calls it one of the most frequented empories in the world; and Pliny tells us, that all the commodities of Europe and Asia were sold, purchased, or exchanged, there. It contained many noble and stately buildings; as, the temples of Apollo, Diana, and Latona; the porticoes of Philip of Macedon, and Dionysius Eutyches; a gymnasium; an oval basin made at an immense expense, for the representation of sea-fights; and a most magnificent theatre. The temple of Apollo was, according to Plutarch, begun by *Eryfichton* the son of Cecrops; but afterwards enlarged and embellished at the common charges of all the states of Greece. Plutarch tells us, that it was one of the most stately buildings in the universe; and speaks of an altar in it, which, in his opinion, deserved a place among the wonders of the world. It was built with the horns of various animals, so artificially adapted to one another, that they hanged together without any cement. This altar is said to have been a perfect cube; and the doubling it was a famous mathematical problem among the ancients. This went under the name of *Problema Deliacum*; and is said to have been proposed by the oracle, for the purpose of freeing the country from a plague. The distemper was to cease when the problem was solved.—The trunk of the famous statue of Apollo, mentioned by Strabo and Pliny, is still an object of great admiration to travellers. It is without head, feet, arms, or legs; but from the parts that are yet remaining, it plainly appears, that the ancients did not exaggerate when they commended it as a wonder of art. It was of a gigantic size, though cut out of a single block of marble; the shoulders being six feet broad, and the thighs nine feet round. At a small distance from this statue lies, amongst confused heaps

of broken columns, architraves, bases, chapiters, &c. a square piece of marble 15½ feet long, ten feet nine inches broad, and two feet three inches thick; which undoubtedly served as a pedestal for this colossus. It bears in very fair characters this inscription in Greek, “The Naxians to Apollo.” Plutarch tells us, in the life of Nicias, that he caused to be set up near the temple of Delos, an huge palm-tree of brass, which he consecrated to Apollo; and adds, that a violent storm of wind threw down this tree on a colossian statue raised by the inhabitants of Naxos. Round the temple were magnificent porticoes built at the charge of various princes, as appears from inscriptions which are still very plain. The names of Philip king of Macedon, Dionysius Eutyches, Mithridates Euergetes, Mithridates Eupator, kings of Pontus, and Nicomedes king of Bithynia, are found on several pedestals.—To this temple the inhabitants of the neighbouring islands sent yearly a company of virgins to celebrate, with dancing, the festival of Apollo and his sister Diana, and to make offerings in the name of their respective cities.

So very sacred was the island of Delos held by the ancients, that no hostilities were practised here, even by the nations that were at war with one another, when they happened to meet in this place. Of this Livy gives an instance. He tells us, that some Roman deputies being obliged to put in at Delos, in their voyage to Syria and Egypt, found the galleys of Perseus king of Macedon, and those of Eumenes king of Pergamus, anchored in the same harbour, though these two princes were then making war upon one another.—Hence this island was a general asylum, and the protection extended to all kinds of living creatures; for this reason it abounded with hares, no dogs being suffered to enter it. No dead body was suffered to be buried in it, nor was any woman suffered to lie-in there; all dying persons, and women ready to be delivered, were carried over to the neighbouring island of Rhœnæa.

DELPHI, (anc. geog.), a town of Phocis situated on the south-west extremity of mount Parnassus. It was famous for a temple and oracle of that god, of which the following was said to be the origin: A number of goats that were feeding on mount Parnassus came near a place which had a deep and long perforation. The steam which issued from the hole seemed to inspire the goats, and they played and frisked about in such an uncommon manner, that the goat-herd was tempted to lean on the hole, and see what mysteries the place contained. He was immediately seized with a fit of enthusiasm, his expressions were wild and extravagant, and passed for prophecies. This circumstance was soon known about the country, and many experienced the same enthusiastic inspiration. The place was revered; a temple was soon after erected in honour of Apollo; and a city built, which became the chief and most illustrious in Phocis. The influence of its god has controlled the councils of states, directed the course of armies, and decided the fate of kingdoms. The ancient history of Greece is full of his energy, and an early register of his authority. The circumjacent cities were the stewards and guardians of the god. Their deputies composed the famous Amphictyonic assembly, which once guided Greece.

The temple of Apollo, it is related, was at first a kind

Delos
Delphi.

Delphi. kind of cottage covered with boughs of laurel: but he was early provided with a better habitation. An edifice of stone was erected by Trophonius and Agamemdes, which subsisted about 700 years, and was burned in the year 636 after the taking of Troy, and 543 before Christ. It is mentioned in the hymn to Apollo ascribed to Homer. An opulent and illustrious family, called *Alcæonidae*, which had fled from Athens and the tyrant Hippias, contracted with the deputies for the building of a new temple, and exceeded their agreement. The front was raised with Parian marble, instead of the stone called *porus*; which resembled it in whiteness, but was not so heavy. A Corinthian was the architect. The pediments were adorned with Diana, and Latona, and Apollo, and the Muses; the setting of Phœbus or the sun; with Bacchus, and the women called *Thyades*. The architraves were decorated with golden armour; bucklers suspended by the Athenians after the battle of Marathon, and shields taken from the Gauls under Brennus. In the portico were inscribed the celebrated maxims of the seven sages of Greece. There was an image of Homer, and in the cell was an altar of Neptune, with statues of the Fates, and of Jupiter and Apollo, who were surnamed *Leaders of the Fates*. Near the hearth before the altar, at which Neoptolemus the son of Achilles was slain by a priest, stood the iron chair of Pindar. In the sanctuary was an image of Apollo gilded. The inclosure was of great extent, and filled with treasuries, in which many cities had consecrated tenths of spoil taken in war, and with the public donations of renowned states in various ages. It was the grand repository of ancient Greece, in which the labours of the sculptor and statuary, gods, heroes, and illustrious persons, were seen collected and arranged; the inequalities of the area or acclivity contributing to a full display of the noble assemblage.

The oracles were delivered by a priestess called Pythia, who received the prophetic influence in the following manner. A lofty tripod, decked with laurel, was placed over the aperture, whence the sacred vapour issued. The priestess, after washing her body, and especially her hair, in the cold water of Castalia, mounted on it, to receive the divine effluvia. She wore a crown of laurel, and shook a sacred tree, which grew by. Sometimes she chewed the leaves; and the frenzy which followed may with probability be attributed to this usage, and the gentler or more violent symptoms to the quantity taken. In one instance the paroxysm was so terrible, that the priests and suppliants ran away, and left her alone to expire, it was believed of the god. Her part was unpleasant; but, if she declined acting, they dragged her by force to the tripod. The habit of her order was that of virgins. The rules enjoined temperance and chastity, and prohibited luxury in apparel. The season of enquiry was in the spring, during the month called *Buſius*; after which Apollo was supposed to visit the altars of the Hyperboreans.

The city of Delphi arose in the form of a theatre, upon the winding declivity of Parnassus, whose fantastic tops overshadowed it, like a canopy, on the north, while two immense rocks rendered it inaccessible on the east and west, and the rugged and shapeless mount *Cirphis* defended it on the south. The foot of the

last-named mountain was washed by the rapid *Pliſtus*, which discharged itself into the sea at the distance of only a few leagues from the sacred city. This inaccessible and romantic situation, from which the place derived the name of Delphi (signifying, as explained in the glossaries, *solitary alone*), was rendered still more striking, by the innumerable echoes which multiplied every sound, and increased the ignorant veneration of visitants for the god of the oracle. The artful ministers of Apollo gradually collected such objects in the groves and temple as were fitted to astonish the senses of the admiring multitude. The splendor of marble, the magic of painting, the invaluable statues of gold and silver, represented (to use the language of antiquity) not the resemblance of any earthly habitation, but rather expressed the image of Olympus, adorned and enlightened by the actual presence of the gods.

The protection and superintendance of this precious depository of riches and superstition belonged to the *Amphictyons*, as already noticed. But the inhabitants of Delphi, who, if we may use the expression, were the original proprietors of the oracle, always continued to direct the religious ceremonies, and to conduct the important business of prophecy. It was their province alone to determine at what time, and on what occasion, the Pythia should mount the sacred tripod, to receive the prophetic steams by which she communicated with Apollo. When overflowing with the heavenly inspiration, she uttered the confused words, or rather fantic sounds, irregularly suggested by the impulse of the god; the Delphians collected these sounds, reduced them into order, animated them with sense, and adorned them with harmony. The Pythia, appointed and dismissed at pleasure, was a mere instrument in the hands of those artful ministers, whose character became so venerable and sacred, that they were finally regarded, not merely as attendants and worshippers, but as the peculiar family of the god. Their number was considerable, and never exactly ascertained, since all the principal inhabitants of Delphi, claiming an immediate relation to Apollo, were intitled to officiate in the rites of his sanctuary; and even the inferior ranks belonging to that sacred city were continually employed in dances, festivals, processions, and in displaying all the gay pageantry of an airy and elegant superstition.

Delphi was conveniently situated for the conflux of votaries, lying in the centre of Greece, and, as was then imagined, of the universe. It was customary for those who consulted the oracle to make rich presents to the god; his servants and priests feasted on the numerous victims which were sacrificed to him; and the rich magnificence of his temple had become proverbial even in the age of Homer. In after-times, Cræsus, the wealthiest of monarchs, was particularly munificent in his donations. This sacred repository of opulence was therefore often the object of plunder. Neoptolemus was slain, while sacrificing, on suspicion of a design of that kind. Xerxes divided his army at *Panopeus*, and proceeded with the main body through *Boeotia* into *Attica*, while a party, keeping *Parnassus* on the right, advanced along *Schiste* to Delphi; but was taken with a panic when near *Ilium*, and fled. This monarch, it is related, was as well apprised of the contents of the

Delphi.

Delphi, temple and the sumptuous offerings of Halyattes and Delphinia. Cræsus as of the effects which he had left behind in his own palace. The divine hoard was seized by the Phocæans under Philomelus, and dissipated in a long war with the Amphictyons. The Gauls experienced a reception like that of the Persians, and manifested similar dismay and superstition. Sylla, wanting money to pay his army, sent to borrow from the holy treasury, and when his messenger would have frightened him, by reporting a prodigy, that the sound of a harp had been heard from within the sanctuary, replied, it was a sign that the god was happy to oblige him.

The trade of Apollo, after it had flourished for a long period, was affected by the mal-practices of some concerned in the partnership, who were convicted of bribery and corruption, and ruined the character of their principal. The temple in the time of Strabo was reduced to extreme poverty; but the offerings which remained were very numerous. Apollo was silent, except some efforts at intervals to regain his lost credit. Nero attempted to drive him, as it were by violence, from the cavern; killing men at the mouth and polluting it with blood; but he lingered on, and would not entirely forsake it. Answers were reported as given by him afterwards, but not without suspicion of forgery. An oracle of Apollo at another place informed the consulters, that he should no more recover utterance at Delphi, but enjoined the continuance of the accustomed offerings.

The city of Delphi was free under the Romans. In the time of Pausanias, who has particularly described it, there still remained an invaluable treasure of the offerings within the court of the temple. The number, variety, and beauties of these were prodigious. The store appeared inexhaustible; and the robbery of Nero, who removed five hundred brazen images, was rather regretted than perceived. The holy treasuries, though empty, served as memorials of the piety and glory of the cities which erected them. The Athenian portico preserved the beaks of ships and the brazen shields: trophies won in the Peloponnesian war. And a multitude of curiosities remained untouched.

Constantine the Great, however, proved a more fatal enemy to Apollo and Delphi than either Sylla or Nero. He removed the sacred tripods to adorn the Hippodrome of his new city; where these, with the Apollo, the statues of the Heliconian muses, and the celebrated Pan dedicated by the Greek cities after the war with the Medes, were extant when Sozomen wrote his history. Afterwards Julian sent Oribasius to restore the temple; but he was admonished by an oracle to represent to the emperor the deplorable condition of the place. 'Tell him the well-built court is fallen to the ground. Phœbus has not a cottage, nor the prophetic laurel, nor the speaking fountain (Cassotis); and even the beautiful water is extinct.' See DELPHOS.

DELPHINIA, in antiquity, feasts which the inhabitants of Egina celebrated in the honour of Apollo, surnamed *Delphinus*, so called, as it is pretended, because he assumed the form of a dolphin to conduct Cassalius and his colony from the isle of Crete to the *Sinus Crissæus Delphinium*, one of the courts of judicature of the Athenians; so called from the proximity of the place, where they held their assemblies, to the temple of Apollo Delphinus

DELPHINIUM, DOLPHIN-FLOWER, or LARK-SPUR: A genus of the trigynia order, belonging to the polyandria class of plants; and in the natural method ranking under the 26th order, *Multifloræ*. There is no calyx; the petals are five; the nectarium bifid, and horned behind; the siliquæ three or one. There are seven species; four are cultivated in gardens. Two of these are annual, and two perennial. They are herbaceous plants of upright growth, rising from 18 inches to four feet in height, garnished with finely divided leaves, and terminated by long spikes of pentapetalous flowers of blue, red, white, or violet colours.—One species, the *consolida*, is found wild in several parts of Britain, and grows in corn-fields. According to Mr Withering, the expressed juice of the petals, with a little alum, makes a good blue ink. The seeds are acrid and poisonous. When cultivated, the blossoms often become double. Sheep and goats eat this plant: horses are not fond of it; cows and swine refuse it.—The first mentioned species makes a very fine appearance in gardens, and is easily propagated by seeds; being so hardy, that it thrives in any soil or situation.

DELPHINUS, or DOLPHIN; a genus of fishes belonging to the order of Cete. There are three species.

1. The delphinus, or dolphin. Historians and philosophers seem to have contended who should invent most fables concerning this fish. It was consecrated to the gods, was celebrated in the earliest time for its fondness of the human race, was honoured with the title of the *sacred fish*, and distinguished by those of *boy-loving* and *philanthropic*. It gave rise to a long train of inventions, proofs of the credulity and ignorance of the times. Aristotle steers the clearest of all the ancients from these fables, and gives in general a faithful history of this animal; but the elder Pliny, Ælian, and others, seem to preserve no bounds in their belief of the tales related of this fish's attachment to mankind. Scarce an accident could happen at sea, but the dolphin offered himself to convey to shore the unfortunate. Arion the musician, when flung into the ocean by the pirates, is received and saved by this benevolent fish.

*Inde (fide majus) tergo Delphinea recurvo,
Se memorant onere supposuisse novo.
Ille sedens citkaramque tenens, pretiumque vehendi
Cantat, et aquorcas carmine mulcet aquas.*

Ovid. *Fasti*, lib. ii. 113.

But (past belief) a dolphin's arched back
Preserved Arion from his destined wrack;
Secure he sits, and with harmonious strains
Requites his bearer for his friendly pains.

We are at a loss to account for the origin of those fables, since it does not appear that the dolphin shows a greater attachment to mankind than the rest of the cetaceous tribe. We know that at present the appearance of this fish, and the porpoise, are far from being esteemed favourable omens by the seamen; for their boundings, springs, and frolics, in the water, are held to be sure signs of an approaching gale.

It is from their leaps out of that element, that they assume a temporary form that is not natural to them; but which the old painters and sculptors have almost always given them. A dolphin is scarce ever exhibited by the ancients in a straight shape, but almost always

Delphi-
nium,
Dephinus.

ways.

Delphinus. ways incurvated : such are those on the coin of Alexander the Great, which is preserved by Belon, as well as on several other pieces of antiquity. The poets describe them much in the same manner, and it is not improbable but that the one had borrowed from the other :

Tumidumque pando transfilit dorso mare
Tyrrhenus omni piscis exsultat freto,
Agitatque gyros. SENEC. Trag. Agam. 450.
 Upon the swelling waves the dolphins show
 Their bending backs; then swiftly darting, go,
 And in a thousand wreaths their bodies throw.

* Plate
 CLV.

The natural shape of the dolphin * is almost straight, the back being very slightly incurvated, and the body slender: the nose is long, narrow, and pointed, not much unlike the beak of some birds, for which reason the French call it *l'oye de mer*. It has in all 40 teeth; 21 in the upper jaw and 19 in the lower; a little above an inch long, conic at their upper end, sharp-pointed, bending a little in. They are placed at small distances from each other; so that when the mouth is shut the teeth of both jaws lock into one another: the spout hole is placed in the middle of the head; the tail semilunar; the skin is smooth, the colour of the back and sides dusky, the belly whitish: it swims with great swiftness; and its prey is fish. It was formerly reckoned a great delicacy: Dr Caius says, that one which was taken in his time was thought a present worthy the Duke of Norfolk, who distributed part of it among his friends. It was roasted and dressed with porpoise sauce, made of crumbs of fine wheat bread, mixed with vinegar and sugar. This species of dolphin must not be confounded with that to which seamen give the name; the latter being quite another kind of fish, the *coryphæna hippuris* of Linnæus, and the *dorado* of the Portuguese.

2. The phocæna, or porpoise. This species is found in vast multitudes in all parts of the British seas; but in greatest numbers at the time when fish of passage appear, such as mackerel, herrings, and salmon, which they pursue up the bays with the same eagerness as a dog does a hare. In some places they almost darken the sea as they rise above water to take breath: but porpoises not only seek for prey near the surface, but often descend to the bottom in search of sand-eels and sea-worms, which they root out of the sand with their noses in the same manner as hogs do in the fields for their food. Their bodies are very thick towards the head, but grow slender towards the tail, forming the figure of a cone. The nose projects a little, is much shorter than that of the dolphin, and is furnished with very strong muscles, which enables it the readier to turn up the sand. In each jaw are 48 teeth, small, sharp-pointed, and a little moveable: like those of the dolphin, they are so placed as that the teeth of one jaw locks into those of the other when closed. The eyes are small; the spout hole is on the top of the head; the tail semilunar. the colour of the porpoise is generally black, and the belly whitish; but they sometimes vary. In the river St Laurence there is a white kind; and Dr Borlase, in his voyage to the Scilly isles, observed a small species of cetaceous fish, which he calls *thornbacks*, from their broad and sharp fin on the back. Some of these were brown, some quite white, others spotted: but whether they were only a variety

of this fish, or whether they were small grampuses, Delphinus. which are also spotted, we cannot determine. The porpoise is remarkable for the vast quantity of the fat or lard that furrounds the body, which yields a great quantity of excellent oil: from this lard, or from their rooting like swine, they are called in many places *sea-hogs*; the Germans call them *meerschwein*; the Swedes *marssuin*; and the English *porpoise*, from the Italian *porco pesce*.—This was once a royal dish, even so late as the reign of Henry VIII. and from its magnitude must have held a very respectable station at the table; for in a household book of that prince, extracts of which are published in the third volume of the Archæologia, it is ordered, that if a porpoise should be too big for a horse-load, allowance should be made to the purveyor. This fish continued in vogue even in the reign of Elizabeth: for Dr Caius, on mentioning a dolphin (that was taken at Shoreham, and brought to Thomas Duke of Norfolk, who divided and sent it as a present to his friends) says, that it eat best with porpoise sauce, which was made of vinegar, crumbs of fine bread, and sugar.

3. The orca, or grampus, is found from the length of 15 feet to that of 25. It is remarkably thick in proportion to its length, one of 18 feet being in the thickest place 10 feet diameter. With reason then did Pliny call this, “an immense heap of flesh armed with dreadful teeth. It is extremely voracious; and will not even spare the porpoise, a congenerous fish. It is said to be a great enemy to the whale, and that it will fasten on it like a dog on a ball, till the animal roars with pain. The nose is flat, and turns up at the end. There are 30 teeth in each jaw: those before are blunt, round, and slender; the farthest sharp and thick; between each is a space adapted to receive the teeth of the opposite jaw when the mouth is closed. The spout-hole is in the top of the neck. The colour of the back is black, but on each shoulder is a large white spot; the sides marbled with black and white; the belly of a snowy whiteness. These fishes sometimes appear on our coasts; but are found in much greater numbers off the North Cape in Norway, whence they are called the *North-Capers*. These and all other whales are observed to swim against the wind; and to be much disturbed, and tumble about with unusual violence, at the approach of a storm.

4. The beluga, a species called by the Germans *wit-fisch*, and by the Russians *beluga*; both signifying “white fish:” but to this the last add *moriskaia*, or “of the sea,” by way of distinguishing it from a species of sturgeon so named: the head is short; nose blunt: spiracle small, of the form of a crescent: eyes very minute: mouth small: in each side of each jaw are nine teeth, short, and rather blunt; those of the upper jaw are bent and hollowed, fitted to receive the teeth of the lower jaw when the mouth is closed: pectoral fins nearly of an oval form: beneath the skin may be felt the bones of five fingers, which terminate at the edge of the fin in five very sensible projections. This brings it into the next of rank in the order of being, with the *Manati*. The tail is divided into two lobes, which lie horizontally, but do not fork, except a little at their base. The body is oblong, and rather slender, tapering from the back (which is a little elevated) to the tail. It is quite destitute of the dorsal fin. Its length is from 12 to 18 feet. It makes great use of

Delphinus, Delphos. its tail in swimming; for it bends that part under it, as a lobster does its tail, and works it with such force as to dart along with the rapidity of an arrow. It is common in all the Arctic seas; and forms an article of commerce, being taken on account of its blubber. They are numerous in the Gulph of St Laurence, and go with the tide as high as Quebec. There are fisheries for them and the common porpessie in that river. A considerable quantity of oil is extracted; and of their skins is made a sort of Morocco leather, thin, yet strong enough to resist a musket-ball. They are frequent in the Dwina and the Oby; and go in small families from five to ten, and advance pretty far up the rivers in pursuit of fish. They are usually caught in nets, but are sometimes harpooned. They bring only one young at a time, which is dusky; but grow white as they advance in age, the change first commencing on the belly. They are apt to follow boats, as if they were tamed; and appear extremely beautiful, by reason of their resplendent whiteness.

DELPHINUS, in astronomy, a constellation of the northern hemisphere.

DELPHOS, a town, or rather village, of Turkey in Asia, in the province of Libadia; occupying part of the site of the ancient Delphi. See DELPHI.

† *Candler's Travels in Greece.* A late traveller † informs us, that some vestiges of temples are visible; and above them, in the mountain-side are sepulchres, niches with horizontal cavities for the body, some covered with slabs. Farther on is a niche cut in the rock with a seat, intended, it seems, for the accommodation of travellers wearied with the rugged track and the long ascent. The monastery is on the site of the Gymnasium. Strong terrace walls and other traces of a large edifice remain. The village is at a distance. Castalia is on the right hand as you ascend to it, the water coming from on high and crossing the road; a steep precipice, above which the mountain still rises immensely, continuing on in that direction. The village consists of a few poor cottages of Albanians covering the site of the temple and oracle. Beneath it to the south is a church of St Elias, with areas, terrace walls, arches, and vestiges of the buildings once within the court. The concavity of the rock in this part gave to the site the resemblance of a theatre. Turning to the left hand, as it were toward the extremity of one of the wings, you come again to sepulchres hewn in the rock, and to a semicircular recess or niche with a seat as on the other side. Higher up than the village is the hollow of the Stadium, in which were some seats and scattered fragments.

Higher up, within the village, is a piece of ancient wall, concealed from view by a shed, which it supports. The stone is brown, rough, and ordinary, probably that of Parnassus. On the south side are many inscriptions, with wide gaps between the letters, which are negligently and faintly cut; all nearly of the same tenor, and very difficult to copy. They register the purchase of slaves who had entrusted the price of their freedom to the god; containing the contract between Apollo and their owners, witnessed by his priests and by some of the archons. This remnant seems to be part of the wall before Cassotis; as above it is still a fountain, which supplies the village with excellent water, it is likely from the ancient source.

The water of Castalia in the neighbourhood, from

which the Pythia, and the poets who versified her answers, were believed to derive a large share of their inspiration, descends through a cleft of Parnassus; the rock on each side high and steep, ending in two summits; of which one was called *Hyampeia*, and had beneath it the sacred portion of Autonous, a local hero as distinguished as Phylacus. From this precipice the Delphians threw down the famous *Æsop*. By the stream, within the cleft, are seen small broken stairs leading to a cavity in which is water, and once perhaps up to the top. Grooves have been cut, and the marks of tools are visible on the rock; but the current, instead of supplying a fountain, now passes over its native bed, and hastens down a course deep-worn to join the Pleistus. Close by, at the foot of the eastern precipice, is a basin with steps on the margin, once, it is likely, the bath used by the Pythia. Above, in the side of the mountain, is a petty church dedicated to St John, within which are excavations resembling niches, partly concealed from view by a tree.

DELTA, is a part of Lower Egypt, which takes up a considerable space of ground between the branches of the Nile and the Mediterranean Sea: the ancients called it the *Isle of Delta*, because it is in the shape of a triangle, like the Greek letter of that name. It is about 130 miles along the coast from Damietta to Alexandria, and 70 on the sides from the place where the Nile begins to divide itself. It is the most plentiful country in all Egypt, and it rains more there than in other parts, but the fertility is chiefly owing to the inundation of the river Nile. The principal towns on the coast are Damietta, Rosetta, and Alexandria; but within land, Menoufia, and Maala or Elmala.

DELTOIDES, in anatomy. See ANATOMY, *Table of the Muscles*.

DELUGE, an inundation or overflowing of the earth, either wholly or in part, by water.

We have several deluges recorded in history; as that of Ogyges, which overflowed almost all Attica; and that of Deucalion, which drowned all Thessaly in Greece: but the most memorable was that 'called the *Universal Deluge* or *Noah's Flood*,' which overflowed and destroyed the whole earth; and from which only Noah, and those with him in the ark, escaped.

This flood makes one of the most considerable epochs in chronology. Its history is given by Moses, Gen. ch. vi. and vii. Its time is fixed, by the best chronologers, to the year from the creation 1656, answering to the year before Christ 2293. From this flood, the state of the world is divided into *diluvian* and *antediluvian*. See ANTEDILUVIANS.

Among the many testimonies of the truth of this part of the Mosaic history, we may account the general voice of mankind at all times, and in all parts of the world. The objections of the free-thinkers have indeed principally turned upon three points, viz. 1. The want of any direct history of that event by the profane writers of antiquity; 2. the apparent impossibility of accounting for the quantity of water necessary to overflow the whole earth to such a depth as it is said to have been: and, 3. There appearing no necessity for an universal deluge, as the same end might have been accomplished by a partial one.

1. The former of these objections has given rise to several very elaborate treatises, though all that has yet been

Delta, Deluge.

1
Era of the deluge,

2
Objections to the fact.

Deluge. been done in this way has scarcely been able to silence the objectors. Mr Bryant, in his System of Mythology, has with great learning and considerable success endeavoured to show, that the deluge was one of the principal, if not the only foundation of the Gentile worship; that the first of all their deities was Noah; that all nations of the world look up to him as their founder; and that he, his sons, and the first patriarchs, are alluded to in most if not all of the religious ceremonies not only of the ancient but of the modern heathens. In short, according to this author, the deluge, so far from being forgot, or obscurely mentioned by the heathen world, is in reality conspicuous throughout every one of their acts of religious worship.

3
Bryant's
account of
the ancient
heroes.

The Egyptian Osiris, according to him, was the same with Ham the son of Noah, though the name was sometimes bestowed on Noah himself. That this is the case, is evident, he thinks, from its being said that he was exposed in an ark, and afterwards restored to day; that he planted the vine, taught mankind agriculture, and inculcated upon them the maxims of religion and justice. Something of the same kind is related of Perseus. He is represented by some ancient historians as a great astronomer, and well versed in other sciences. After being conceived in a shower of gold, he was exposed in an ark upon the waters, and is said to have had a renewal of life.—The history of Myrina the amazon affords a kind of abridgement and mixture of the histories of Osiris and Perseus. Similar to these is the history of Hercules himself. But our author observes, that under the titles of *Osiris*, *Perseus*, *Myrina*, &c. the ancients spoke of the exploits of a whole nation, who were no other than the Cushites or Cushites, the descendants of Cush the son of Ham and father of Nimrod. These people spread themselves into the most remote corners of the globe; and hence the heroes whom they represented are always set forth as conquering the whole world.—According to Diodorus Siculus, the Egyptian Osiris was the same with the Dionysus of the Greeks. He is said to have been twice born, and to have had two fathers and two mothers; to have been wonderfully preserved in an ark; to have travelled all over the earth; taught the use of the vine, to build, plant, &c. The Indians claim him as a native of their country, though some allow that he came from the west. Of Cronus and Astarte, it is said that they went over the whole earth, disposing of the countries as they pleased, and doing good wherever they came. The same is related of Ouranus, Themis, Apollo, &c. though all their exploits are said to have been the effects of conquest, and their benevolence enforced by the sword. In a similar manner he explains the histories of other heroes of antiquity: and having thus, in the characters and history of the most celebrated personages, found traces of the history of Noah and his family, our author proceeds to inquire into the memorials of the deluge itself to be met with in the history or religious rites of the different nations of antiquity. “We may reasonably suppose (says he), that the particulars of the extraordinary event would be gratefully commemorated by the patriarch himself, and transmitted to every branch of his family; that they were made the subject of domestic converse, where

with in
heathen
authors.

the history was often renewed, and ever attended with a reverential awe and horror, especially in those who had been witnesses to the calamity, and had experienced the hand of providence in their favour. In process of time, when there was a falling off from the truth, we might farther expect, that a person of so high a character as Noah, so particularly distinguished by the Deity, could not fail of being revered by his posterity; and, when idolatry prevailed, that he would be one of the first among the sons of men to whom divine honours would be paid. Lastly, we might conclude, that these memorials would be interwoven in the mythology of the Gentile world; and that there would be continual allusions to these ancient occurrences in the rites and mysteries as they were practised by the nations of the earth. In conformity to these suppositions, I shall endeavour to show that these things did happen; that the history of the deluge was religiously preserved in the first ages; that every circumstance of it is to be met with among the historians and mythologists of different countries; and traces of it are to be found particularly in the sacred rites of Egypt and of Greece.

“It will appear from many circumstances in the more ancient writers, that the great patriarch was highly revered by his posterity. They looked up to him as a person highly favoured by heaven; and honoured him with many titles, each of which had a reference to some particular part of his history. They styled him *Prometheus*, *Deucalion*, *Atlas*, *Theuth*, *Zuth*, *Xuthus*, *Inachus*, *Osiris*. When there began to be a tendency towards idolatry, and the adoration of the sun was introduced by the posterity of Ham, the title of *Helius*, among others, was conferred upon him. They called him also *Mov* and *Mov*, which is the moon. When colonies went abroad, many took to themselves the title of *Minyade* and *Minyæ* from him; just as others were denominated *Achæmenide*, *Aurita*, *Heliada*, from the sun. People of the former name are to be found in Arabia and in other parts of the world. The natives at Orchomenos were styled *Minyæ*, as were some of the inhabitants of Thessaly. Noah was the original Zeus and Dios. He was the planter of the vine, and inventor of fermented liquors: whence he was denominated *Zeuth*, which signifies ferment, rendered *Zeus* by the Greeks. He was also called *Dionusos*, interpreted by the Latins *Bacchus*, but very improperly. Bacchus was Chus the grandson of Noah; as Ammon may in general be esteemed Ham, so much revered by the Egyptians.

“Among the people of the east, the true name of the patriarch was preserved, they called him *Noas*, *Naus*, and sometimes contracted *Nous*; and many places of sanctity, as well as rivers, were denominated from him. Anaxagoras of Clazomenæ had obtained some knowledge of him in Egypt. By him the patriarch was denominated *Noas* or *Nous*; and both he and his disciples were sensible that this was a foreign appellation; notwithstanding which he has acted as if it had been a term of the Greek language. Eusebins informs us, that the disciples of Anaxagoras say, ‘that *Nous* is by interpretation, the deity *Dis* or *Dios*; and they likewise esteem *Nous* the same as *Prometheus*, because he was the renewer of mankind, and was said to have fashioned them again,’ after they had

distinguish-
ed.

Deluge. had been in a manner extinct. After this, however, he gives a solution of the story upon the supposition that Nous is the same with the Greek word νοῦς the mind; that 'the mind was *Prometheia*; and Prometheus was said to renew mankind, from new forming their minds, and leading them, by cultivation, from ignorance.'

"Suidas has preserved, from some ancient author, a curious memorial of this wonderful personage, whom he affects to distinguish from Deucalion, and styles *Nannacus*. According to him, this Nannacus was a person of great antiquity, and prior to the time of Deucalion. He is said to have been a king, who, foreseeing the approaching deluge, collected every body together, and led them to a temple where he offered up his prayers for them, accompanied with many tears. There is likewise a proverbial expression about Nannacus applied to people of great antiquity.

"Stephanus gives great light to this history, and supplies many deficiencies. 'The tradition is (says he), that there was one formerly named *Annacus*, the extent of whose life was above 300 years. The people who were of his neighbourhood and acquaintance had inquired of an oracle how long he was to live: and there was an answer given, that when Annacus died, all mankind would be destroyed. The Phrygians, upon this account made great lamentations, from whence arose the proverb το ἐπι Αἰννακῆ κλαύσειν, the lamentation for *Annacus*, made use of for people or circumstances highly calamitous. When the flood of Deucalion came, all mankind were destroyed, according as the oracle had foretold. Afterwards, when the surface of the earth began to be again dry, Zeus ordered Prometheus and Minerva to make images of clay in the form of men; and, when they were finished, he called the winds, and made them breathe into each, and render them vital.'

From these histories Mr Bryant concludes as follows: "However the story may have been varied, the principal outlines plainly point out the person who is alluded to in these histories. It is, I think, manifest, that Annacus, and Nannacus, and even Inachus, relate to Noacus or Noah. And not only these, but the histories of Deucalion and Prometheus have a like reference to the patriarch; in the 600th year, and not the 300th, of whose life the waters prevailed upon the earth. He was the father of mankind, who were renewed in him. Hence he is represented by another author, under the character of Prometheus, as a great artist, by whom men were formed anew, and were instructed in all that was good.

"Noah was the original Cronus and Zeus; though the latter is a title conferred sometimes upon his son Ham. There is a very particular expression recorded by Clemens of Alexandria, and attributed to Pythagoras, who is said to have called the sea the *tear of Cronus*; and there was a farther tradition concerning this person, that he drank, or swallowed, up all his children. The tears of Isis are represented as very mysterious. They are said to have flowed whenever the Nile began to rise, and to flood the country. The overflowing of that river was the great source of affluence to the people, and they looked upon it as their

chief blessing; yet it was ever attended with mystical tears and lamentations. This was particularly observed at Coptos, where the principal deity was Isis. An ancient writer imagines that the tears and lamentations of the people were to implore an inundation; and the tears of Isis were supposed to make the river swell. But all this was certainly said and done in memorial of a former flood, of which they made the overflowing of the Nile a type.

"As the patriarch was by some represented as a king called *Naachus* and *Naachus*; so by others he was styled *Inachus*, and supposed to have reigned at Argos. Hence Inachus was made a king of Greece; and Phoroneus and Apis brought in succession after him. But Inachus was not a name of Grecian original: it is mentioned by Eusebius, in his account of the first ages, that there reigned in Egypt Telegonus, a prince of foreign extraction, who was the son of Ones the shepherd, and the seventh in descent from Inachus. And in the same author we read, that a colony went forth from that country into Syria, where they founded the ancient city of Antioch: and that they were conducted by Casus and Belus, who were sons of Inachus. By Inachus is certainly meant Noah: and the history relates to some of the more early descendants of the patriarch. His name has been rendered very unlike itself, by having been lengthened with terminations, and likewise fashioned according to the idiom of different languages. But the circumstances of the history are so precise and particular, that we cannot miss of the truth.

"He seems in the east to have been called *Noas*, *Noasis*, *Nusus*, and *Nus*; and by the Greeks his name was compounded *Dionusus*. The Amonians, wherever they came, founded cities to his honour: hence places called *Nusa* will often occur: and indeed a great many of them are mentioned by ancient authors. These, though widely distant, being situated in countries far removed, yet retained the same original histories; and were generally famous for the plantation of the vine. Misled by this similarity of traditions, people in after times imagined that Dionusus must necessarily have been where his history occurred: and as it was the turn of the Greeks to place every thing to the account of conquest, they made him a great conqueror, who went over the face of the whole earth, and taught mankind the plantation of the vine. We are informed, that Dionusus went with an army over the face of the whole earth, and taught mankind, as he passed along, the method of planting the vine, and how to press out the juice, and receive it in proper vessels. Though the patriarch is represented under various titles, and even these not always uniformly appropriated; yet there will continually occur such peculiar circumstances of his history as will plainly point out the person referred to. The person preserved is always mentioned as preserved in an ark. He is described as being in a state of darkness, which is represented allegorically as a state of death. He then obtains a new life, which is called a second birth; and is said to have his youth renewed. He is, on this account, looked upon as the first-born of mankind; and both his antediluvian and postdiluvian states are commemorated, and sometimes the intermediate state is also spoken of. Diodorus calls him *Deucalion*; but describes the deluge as

Deluge.

Inachus, Deucalion, and Prometheus, the same with Noah.

Deluge.

in a manner universal. 'In the deluge which happened in the time of Deucalion, almost all flesh died.' Apollodorus having mentioned Deucalion *ἢ λαρρακι*, *consigned to the ark*, takes notice, upon his quitting it, of his offering up an immediate sacrifice to the God who delivered him. As he was the father of all mankind, the ancients have made him a person of very extensive rule; and supposed him to have been a king. Sometimes he is described as a monarch of the whole earth; at other times he is reduced to a petty king of Thessaly. He is mentioned by Helladius in this latter capacity; who speaks of the deluge of his time, and of his building altars to the gods. Apollonius Rhodius supposes him to have been a native of Greece, according to the common notion: but notwithstanding his prejudices, he gives so particular a character of him, that the true history cannot be mistaken. He makes him indeed the son of Prometheus, the son of Japetus; but in these ancient mythological accounts all genealogy must be entirely disregarded. Though this character be not precisely true, yet we may learn that the person represented was the first of men, through whom religious rites were renewed, cities built, and civil polity established in the world; none of which circumstances are applicable to any king of Greece. We are assured by Philo, that Deucalion was Noah; and the Chaldeans likewise mentioned him by the name of Xisuthrus, as we are informed by Cedrenus.

7
Deucalion
proved not
to have be-
longed to
Thessaly.

"That Deucalion was unduly adjudged by the people of Thessaly to their country solely, may be proved from his name occurring in different parts of the world, and always accompanied with some history of the deluge. The natives of Syria laid the same claim to him. He was supposed to have founded the temple at Hierapolis, where was a chasm through which the waters after the deluge were said to have retreated. He was likewise reported to have built the temple of Jupiter at Athens; where there was a cavity of the same nature, and a like tradition, that the waters of the flood passed off through this aperture. However groundless the notions may be of the waters having retreated through these passages, yet they show what impressions of this event were retained by the Amonians, who introduced some history of it wherever they came. As different nations succeeded one another in these parts, and time produced a mixture of generations, they varied the history, and modelled it according to their notions and traditions, yet the ground-work was always true, and the event for a long time universally commemorated. Josephus, who seems to have been a person of extensive knowledge; and versed in the histories of nations, says, that this great occurrence was to be met with in the writings of all persons who treated of the first ages. He mentions Berofus of Chaldea, Heronymus of Egypt, who wrote concerning the antiquities of Phenicia; also Alnafeas, Abydenus, Melon, and Nicolaus Damascenus, as writers by whom it was recorded; and adds, that it was taken notice of by many others.

8
Accounts of
the flood
among the
eastern na-
tions.

"Among the eastern nations, the traces of this event are more vivid and determinate than those of Greece, and more conformable to the accounts of Moses. Eusebius has preserved a most valuable extract to this purpose from Abydenus; which was taken from

VOL. V.

the archives of the Medes and Babylonians. This writer speaks of Noah, whom he names Scifithrus, as a king; and says, that the flood began upon the 15th day of the month Desius: that during the prevalence of the waters, Scifithrus sent out birds, that he might judge if the flood had returned: but that the birds not finding any resting place, returned to him again. This was repeated three times; when the birds were found to return with their feet stained with soil; by which he knew that the flood was abated. Upon this he quitted the ark, and was never more seen of men, being taken away by the gods from the earth. Abydenus concludes with a particular, in which the eastern writers are unanimous; that the place of descent from the ark was in Armenia, and speaks of its remains being preserved for a long time. Plutarch mentions the Noachic dove, and its being sent out of the ark. But the most particular history of the deluge, and the nearest of any to the account given by Moses, is to be found in Lucian. He was a native of Samosata, a city of Comagene, upon the Euphrates, a part of the world where memorials of the deluge were particularly preserved, and where a reference to that history was continually kept up in the rites and worship of the country. His knowledge therefore was obtained from the Asiatic nations among whom he was born, and not from his kinsmen the Helladians, who were far inferior in the knowledge of ancient times. He describes Noah under the name of Deucalion; and says, 'that the present race of mankind are different from those who first existed; for those of the antediluvian world were all destroyed. The present world is peopled from the sons of Deucalion; having increased to so great a number from one person. In respect to the former brood, they were men of violence, and lawless in their dealings. They regarded not oaths, nor observed the rights of hospitality, nor showed mercy to those who sued for it. On this account they were doomed to destruction: and for this purpose there was a mighty eruption of waters from the earth, attended with heavy showers from above; so that the rivers swelled, and the sea overflowed, till the whole earth was covered with a flood, and all flesh drowned. Deucalion alone was preserved to repeople the world. This mercy was shown to him on account of his piety and justice. His preservation was effected in this manner: He put all his family, both his sons and their wives, into a vast ark which he had provided, and he went into it himself. At the same time animals of every species, boars, horses, lions, serpents, whatever lived upon the face of the earth, followed him by pairs: all which he received into the ark, and experienced no evil from them; for there prevailed a wonderful harmony throughout, by the immediate influence of the Deity. Thus were they wafted with him as long as the flood endured.' After this he proceeds to mention, that, upon the disappearing of the waters, Deucalion went forth from the ark, and raised an altar to God; but he transposes the scene to Hierapolis in Syria, where the natives pretended, as has been already mentioned, to have very particular memorials of the deluge.

"Most of the authors who have transmitted to us these accounts, at the same time inform us, that the remains of the ark were to be seen in their days on one

Deluge.

9
Remains of
the ark said
to have
been long
of visible.

Deluge. of the mountains of Armenia. Abydenus particularly says, in confirmation of this opinion, that the people of the country used to get small pieces of the wood, which they carried about by way of amulet. And Berofus mentions, that they scraped off the asphaltus with which it was covered, and used it as a charm. Some of the fathers seem to insist on the certainty of the ark being still remaining in their time. Theophilus says expressly, that the remains were to be seen upon the mountains of Aram, or Armenia. And Chrysostom appeals to it as to a thing well known. 'Do not (says he) those mountains of Armenia bear witness to the truth? those mountains where the ark first rested? And are not the remains of it preserved there even unto this day?'

10
Boats or
ships car-
ried in pro-
cession by
the Amo-
nians and
Egyptians.

"There was a custom among the priests of Amon, in which was an oracular shrine held in great veneration. They were said to have been 80 in number, and to have carried the sacred vessel about just as they were directed by the impulse of the Deity. This custom was likewise in use among the Egyptians; and bishop Pocock has preserved three specimens of ancient sculpture, wherein this ceremony is displayed. They are of wonderful antiquity, and were found by him in Upper Egypt.

"Part of the ceremony in most of the ancient mysteries consisted in carrying about a ship or boat; which custom, upon due examination, will be found to relate to nothing else but Noah and the deluge. The ship of Isis is well known, and the festivity among the Egyptians whenever it was carried in public. The name of this, and of all the navicular shrines, was *Baris*; which is remarkable; for it was the very name of the mountain, according to Nicolaus Damascenus, on which the ark of Noah rested, the same as Ararat in Armenia. He mentions, that there is a large mountain in Armenia, which stands above the country of the Minyæ, called *Baris*; to this it was said that many people betook themselves in the time of the deluge, and were saved; and there is a tradition of one person in particular floating in an ark, and arriving at the summit of the mountain. We may be assured then, that the ship of Isis was a sacred emblem; in honour of which there was among the Egyptians an annual festival. It was in after times admitted among the Romans, and set down in their kalender for the month of March. The former, in their description of the primary deities, have continually some reference to a ship or float. Hence we frequently read of *θεοὶ ναυπηγοὶ* (sailing gods). They oftentimes, says Porphyry, describe the sun in the character of a man sailing upon a float. And Plutarch observes to the same purpose, that they did not represent the sun and the moon in chariots, but wafted about upon floating machines. In doing which they did not refer to the luminaries, but to a person represented under these titles. The sun, or Orus, is likewise described by Jamblichus as sitting upon the lotus, and sailing in a vessel.

11
Wonderful
ship of Se-
sostris ex-
plained.

"It is said of Sesostris, that he constructed a ship which was 280 cubits in length. It was of cedar, plated without with gold, and inlaid with silver; and it was, when finished, dedicated to Osiris at Thebes. It is not credible that there should have been a ship of this size, especially in an inland district, the most re-

mote of any in Egypt. It was certainly a temple and a shrine. The former was framed upon this large scale; and it was the latter on which the gold and silver were so lavishly expended. There is a remarkable circumstance relating to the Argonautic expedition: that the dragon slain by Jason was of the size of a trireme; by which must be meant, that it was of the shape of a ship in general, for there were no triremes at the time alluded to. And I have moreover shown, that all these dragons, as they have been represented by the poets, were in reality temples, *Dracontia*; where, among other rites, the worship of the serpent was instituted. There is therefore reason to think, that this temple, as well as that of Sesostris, was fashioned, in respect to its superficial contents, after the model of a ship; and as to the latter, it was probably intended, in its outlines, to be the exact representation of the ark, in commemoration of which it was certainly built. It was a temple sacred to Osiris at Theba; or, to say the truth, it was itself called *Theba*; and both the city, said to be one of the most ancient in Egypt, as well as the province, was undoubtedly denominated from it. Now *Theba* was the name of the ark. It is the very word made use of by the sacred writer; so that we may, I think, be assured of the prototype after which this temple was fashioned. It is said indeed to have been only 280 cubits in length; whereas the ark of Noah was 300. But this is a variation of only one-fifteenth in the whole: and as the ancient cubit was not in all countries the same, we may suppose that this disparity arose rather from the manner of measuring than from any real difference in the extent of the building. It was an idolatrous temple, said to have been built by Sesostris in honour of Osiris. I have been repeatedly obliged to take notice of the ignorance of the Greeks in respect to ancient titles, and have shown their misapplication of terms in many instances; especially in their supposing temples to have been erected by persons to whom they were in reality sacred. Sesostris was Osiris; the same as Dionusius, Menes, and Noah. He is called *Scifithrus* by Abydenus; *Xixouthros* by Berofus and Apollodorus; and is represented by them as a prince in whose time the deluge happened. He was called *Zuth*, *Xuth*, and *Zeus*; and had certainly divine honours paid him.

"Pausanias gives a remarkable account of a temple of Hercules at Eruthra in Ionia; which he mentions as of the highest antiquity, and very like those of Egypt. The deity was represented upon a float, and was supposed to have come thither in this manner from Phenicia. Aristides mentions, that at Smyrna, upon the feast called *Dionysia*, a ship used to be carried in procession. The same custom prevailed among the Athenians at the Panathenæa; when what was termed the sacred ship was borne with great reverence through the city to the temple of Demeter at Elenfis. At Phalerus, near Athens, there were honours paid to an unknown hero, who was represented in the stern of a ship. At Olympia, the most sacred place in Greece, was a representation of the like nature. It was a building like the fore-part of a ship, which stood facing the end of the Hippodromus, and towards the middle of it was an altar, upon which, at the renewal of each Olympiad, certain rites were performed.

"I think it is pretty plain that all these emblematical

Deluge.

tions ex-
plained.

Deluge. tical representations, of which I have given so many instances, related to the history of the deluge, and the conservation of one family in the ark. This history was pretty recent when these works were executed in Egypt, and when the rites were first established; and there is reason to think, that in early times most shrines of the Mizraim were formed under the resemblance of a ship, in the memory of this great event. Nay, farther, both ships and temples received their names from thence; being styled by the Greeks, who borrowed largely from Egypt, *Navis* and *Ναῦς*, and mariners *Ναυται*, *Nautæ*, in reference to the patriarch who was variously styled *Noas*, *Noûs*, and *Noah*.

“However the Greeks may, in their mysteries, have sometimes introduced a ship as a symbol, yet in their references to the deluge itself, and to the persons preserved, they always speak of an ark. And though they were apt to mention the same person under various titles, and by these means different people seem to be made principals in the same history; yet they were so far uniform in their account of this particular event, that they made each of them to be exposed in an ark. Thus it is said of Deucalion, Perseus, and Dionusus, that they were exposed upon the waters in a machine of this fabric. Adonis was hid in an ark by Venus, and was supposed to have been in a state of death for a year. Theocritus introduces a pastoral personage named *Comates*, who was exposed in an ark for the same term, and wonderfully preserved. Of Osiris being exposed in an ark we have a very remarkable account in Plutarch; who mentions, that it was on account of *Typhon*, and that it happened on the 17th of the month Athyr, when the sun was in Scorpio. This, in my judgment, was the precise time when Noah entered the ark, and when the flood came, which, in the Egyptian mythology, was called *Typhon*.

13
Explanati-
on of the
word Ty-
phon.

“Typhon is one of those whose character has been greatly confounded. This has arisen from two different personages being included under one name, who undoubtedly were distinguished in the language of Egypt. Typhon was a compound of *Tuph* or *Tupha-On*; and signified an high altar of the Deity. There were several such in Egypt, upon which they offered human sacrifices; and the cities which had these altars were styled *Typhonian*. But there was another Typhon, who was very different from the former, however by mistake blended with that character. By this was signified a mighty whirlwind and inundation: and it oftentimes denoted the ocean; and particularly the ocean in a ferment. For, as Plutarch observes, by Typhon was understood any thing violent and unruly. It was a derivative from *Tuph*, like the former name; which *Tuph* seems here to have been the same as the *Suph* of the Hebrews. By this they denoted a whirlwind; but among the Egyptians it was taken in a greater latitude, and signified any thing boisterous, particularly the sea. Plutarch speaks of it as denoting the sea; and says likewise, that the foam of the sea was called the foam of Typhon. It signified also a whirlwind, as we learn from Euripides, who expresses

it *Tuphos*; and the like is to be found in Hesychius, who calls it a violent wind.

“The history of Typhon was taken from hieroglyphical descriptions. In these the dove, *oïnas*, was represented as hovering over the *mundane* egg, which was exposed to the fury of Typhon: For an egg, containing in it the elements of life, was thought no improper emblem of the ark, in which were preserved the rudiments of the future world. Hence in the Dionusiaca, and in other mysteries one part of the nocturnal ceremony consisted in the consecration of an egg. By this, as we are informed by Propyry, was signified the world. This world was Noah and his family; even all mankind, inclosed and preserved in the ark.

“In respect to Typhon, it must be confessed that the history given of him is attended with some obscurity. The Grecians have comprehended several characters under one term, which the Egyptians undoubtedly distinguished. The term was used for a title as well as a name; and several of those personages which had a relation to the deluge were styled Typhonian or Diluvian. All these the Grecians have included under one and the same name Typhon. The real deity by whom the deluge was brought upon the earth had the appellation of Typhonian, by which was meant *Diluvii Deus* (A). It is well known that the ark was constructed by a divine commission; in which, when it was completed, God inclosed the patriarch and his family. Hence it is said, that Typhon made an ark of curious workmanship, that he might dispose of the body of Osiris. Into this Osiris entered; and was shut up by Typhon. All this relates to the Typhonian deity who inclosed Noah, together with his family, within the limits of an ark. The patriarch also, who was thus interested in the event, had the title of Typhonian. I have shown that the ark by the mythologists was spoken of as the mother of mankind. The stay in the ark was looked upon as a state of death and of regeneration. The passage to life was through the door of the ark, which was formed in its side. Through this the patriarch made his descent; and at this point was the commencement of time. This history is obscurely alluded to in the account of Typhon; of whom it is said, that without any regard to time or place, he forced a passage and burst into light obliquely through the side of his mother. This return to light was described as a revival from the grave; and Plutarch accordingly mentions the return of Osiris from *Hades*, after he had been for a long season inclosed in an ark and in a state of death. This renewal of life was by the Egyptians esteemed a second state of childhood. They accordingly, in their hieroglyphics, described him as a boy, whom they placed upon the lotos or water lily, and called him Orus. He was the supposed son of Isis; but it has been shown that Isis, Rhea, Atargatis, were all emblems of the ark, that *receptacle* which was styled the mother of mankind. Orus is represented as undergoing from the Titans all that Osiris suffered from Typhon; and the history at bottom is the same. Hence it is said

4 Z 2

of

(A) “Plutarch owns that the Egyptians in some instances esteemed Typhon to be no other than Helius the chief deity; and they were in the right, though he will not allow it.”

Deluge. of Isis, that she had the power of making people immortal; and that when she found her son Orus, in the midst of the waters, dead through the malice of the Titans, she not only gave him a renewal of life, but also conferred upon him immortality."

In this manner does our author decypher almost all the ancient fables of which no satisfactory solution was ever given before. He shows that the primitive gods of Egypt, who were in number eight, were no other than the eight persons saved in the ark; that almost all the heathen deities had one way or other a reference to Noah. He shows that he was characterised under the titles of Janus, Nereus, Proteus, Oannes, Dagon, &c. &c. and in short, that the deluge, so far from being unknown to the heathens, or forgot by them, was in a manner the basis of the whole of their worship. He traces the history of the raven and dove sent forth by Noah in the customs of various nations, not only in the east but the west also. Of the numberless testimonies of the truth of this part of sacred history to be met with among the western nations, however, we shall select one more, which is an ancient coin usually known by the name of the *Apamean medal*. "The learned Falconerius (says Mr Bryant) has a curious dissertation upon a coin of Philip the Elder, which was struck at Apamea (B), and contained on its reverse an epitome of this history. The reverse of most Asiatic coins relate to the religion and mythology of the places where they were struck. On the reverse of this coin is delineated a kind of square machine floating upon water. Through an opening in it are seen two persons, a man and a woman, as low as the breast; and upon the head of the woman is a veil. Over this ark is a triangular kind of pediment, on which there sits a dove; and below it another, which seems to flutter its wings, and hold in its mouth a small branch of a tree. Before the machine is a man following a woman, who by their attitude seem to have just quitted it, and to have got upon dry land. Upon the ark itself, underneath the persons there inclosed, is to be read in distinct characters, ΝΩΕ. The learned editor of this account says, that it had fallen to his lot to meet with three of these coins. They were of brass, and of the medallion size. One of them he mentions to have seen in the collection of the Duke of Tuscany; the second in that of the Cardinal Ottoboni; and the third was the property of Augustino Chigi, nephew to Pope Alexander VII."

15
Accounts
of the flood
to be met
with in
China and
Japan.

Not content with these testimonies, however, which are to be met with in the western regions, or at least in those not very far to the eastward, our author shows that "the same mythology (of the Egyptians), and the same hieroglyphics, were carried as far as China and Japan; where they are to found at this day. The Indians have a person whom they call Buto or Budo. This is the same as Boutus of Egypt, Battus of Cyrene, and Bœotus of Greece. The account given of him is similar to that of Typhon; for it is said that he did not come to life in the usual way, but made himself a passage through the side of his mother; which mother is represented as a virgin. This history,

though now current among the Indians, is of great antiquity, as we may learn from the account given of this personage by Clemens Alexandrinus. 'There is a cast of Indians (says he) who are disciples of Boutas. This person, on account of his extraordinary sanctity, they look up to as a god.' The name of Boutas, Battus, and Bœotus, though apparently conferred upon the patriarch, yet originally related to the machine in which he was preserved. Of this some traces may be found among the Greeks. One of the Amonian names for the ark were Aren and Arne; and Bœotus is said by Diodorus Siculus to have been the son of Neptune and Arne, which is a contraction of *arene* the ark. The chief city, Boutus in Egypt, where was the floating temple, signified properly the city of the float or ark. The Bœotians, who in the Dionusiaca so particularly commemorated the ark, were supposed to be descended from an imaginary personage, *Bœotus*; and from him likewise their country was thought to have received its name. But Bœotian was merely a variation from Boutus, and Eatus, the ark; which in ancient times was indifferently styled Theba, Argus, Aren, Butus, and Bœotus. The term Cibotus is a compound of the same purport, and signifies both the temple of the ark and also a place for shipping.

"All the mysteries of the Gentile world seem to have been memorials of the deluge, and of the event which immediately succeeded. They consisted for the most part of a melancholy process; and were celebrated by night in commemoration of the state of darkness in which the patriarch and his family had been involved. The first thing at those awful meetings was to offer an oath of secrecy to all who were to be initiated: after which they proceeded to the ceremonies. These began with a description of chaos: by which was signified some memorial of the deluge. Chaos was certainly the same as *βυθός*, the great abyss. Who says Epiphanius, is so ignorant as not to know, that Chaos and Buthos, the abyss, are of the same purport?"

Chaos.

"The names of the deities in Japan and China, and the form of them, as well as the mythology with which they are attended, point out the country from whence they originally came. In China the deity upon the lotos in the midst of waters has been long a favourite emblem, and was imported from the west. The insignie of the dragon was from the same quarter. The Cuthites worshipped Cham, the sun; whose name they variously compounded. In China most things which have any reference to splendor and magnificence, seem to be denominated from the same object. Cham is said, in the language of that country, to signify any thing *supreme*. Com is a fine building or palace, similar to Coma of the Amonians, Cum is a lord or master; Cham a sceptre. Lastly, by Cham is signified a priest, analogous to the Chamauim and Chamienim of Cutha and Babylonia. The country itself is by the Tartars called *Ham*. The cities Cham-ju, Champion, Compition, Cumdan, Chamul, and many others of the same form, are manifestly compounded of the sacred term Cham. Cambalu, the name of the ancient metropolis

(B) Our author had before shown that the ancient name of Apamea was *Cibotus*, one of the names of the ark.

Deluge. tropolis, is the city of Cham-bal; and Milton styles it very properly *Cambaul, seat of Cathaian Chan*. By this is meant the chief city of the Cuthean monarch; for Chan is a derivative of Chaen, a prince. It seems sometimes in China and Japan to have been expressed Quan and Quano.

“ Two temples are taken notice of by Hamilton, near Syrian in Pegu, which he represents as so like in structure, that they seem to be built on the same model. One of these was called Kiakiack, or the *God of Gods temple*. The other is called *the temple of Dagon*; and the doors and windows of it are perpetually shut, so that none can enter but the priests. They will not tell of what shape the idol is, but only say that it is not of a human form. The former deity, Kiakiack, is represented as asleep, of a human shape, and 60 feet long; and when he awakes, the world is to be destroyed. As soon as Kiakiack has dissolved the frame and being of this world, Dagon will gather up the fragments, and make a new one. I make no doubt but the true name of the temple was *Iach-Iach*, and dedicated to the same god as the Jaclusi in Japan. Mr Wise takes notice of the Grecian exclamation to Dionusus, when the terms *Iacche, O Iacche*, were repeated: and he supposes, with great probability, that the Peguan name had a reference to the same deity. It is certain, that the worship, of Dionusus prevailed very early among the nations in the east. The Indians used to maintain, that his rites first began among them. Professor Bayer has shown, that traces of his worship are still to be observed among the Tamuli of Tranquebar. ‘ They have a tradition (says he), that there was once a gigantic person named *Maidashuren*, who was born at Nisadabura near the mountain Meru. He had the horns of a bull, and drank wine and made war upon the gods. He was attended by eight *Pudam*, who were gigantic and mischievous dæmons, of the family of those Indian shepherds called *Kobaler*.’ In this account we have a manifest reference to the history of Dionusus, as well as that of the Dionusians, by whom his rites were introduced. And we may perceive, that it bears a great resemblance to the accounts transmitted by the Grecians. What are these *Kobaler*, who were descended from the shepherds, but the same as the *Cobali* of Greece, the uniform attendants upon Dionusus? a set of priests whose cruelty and chicanery rendered them infamous. ‘ The *Cobali* (says an ancient author) were a set of cruel dæmons, who followed in the retinue of Dionusus. It is a term made use of for knaves and cheats.’

“ As the deity, in the second temple of Syrian, to which strangers were not admitted, was not of a human form, and was called *Dagon*, we may easily conceive the hidden character under which he was described. We may conclude, that it was no other than that mixed figure of a man and a fish, under which he was of old worshipped both in Palestine and Syria. He is expressed under this symbolical representation in many parts of India; and, by the Bramins is called *Wishnou* or *Vishnou*. Dagon and Vishnou have a like reference. They equally represent the man of the sea, called by Berossus *Oannes*; whose history has been reversed by the Indians. They suppose that he will restore the world when it shall be destroyed by the chief God. But by Dagon is signified the very person thro’

whom the earth has been already restored when it was in a state of ruin; and by whom mankind was renewed. Dagon and Noah I have shown to be the same Vishnou is represented, like Dagon, under the mixed figure of a man and a fish, or rather of a man, a princely figure, proceeding from a fish. The name of this district, near which the temples above stand, we find to be called *Syrian*; just as was named the region where stood the temples of Atargatus and Dagon. Syrus, Syria, and Syrian are all of the same purport, and signify Cœlestis and Solaris, from *Schor*, the sun.”

Our author next proceeds to describe some of the Indian temples or pagodas; particularly those of falseite, Eliphanta, and another called *Elora* near Aorangeabad in the province of Balagate, which was visited by Thevenot. That traveller relates, that “ upon making diligent inquiry among the natives about the origin of these wonderful buildings, the constant tradition was, that all these pagodas, great and small, with all their works and ornaments, were made by giants; but in what age they could not tell.”

“ Many of these ancient structures (continues Mr Bryant) have been attributed to *Ramsander*, or Alexander the Great; but there is nothing among these stately edifices that in the least favours of Grecian workmanship; nor had that monarch, nor any of the princes after him, opportunity to perform works of this nature. We have not the least reason to think that they ever possessed the country: for they were called off from their attention this way by feuds and engagements nearer home. There is no tradition of this country having been ever conquered except by the fabulous armies of Hercules and Dionusus. What has led people to think that these works were the operation of Alexander, is the similitude of the name *Ramt Alexander*. To this person they have sometimes been attributed; but *Ramt Alexander* was a deity, the supposed son of Bal; and he is introduced among the personages who were concerned in the incarnations of Vishnou.

“ The temple of Elora, and all the pagodas of which I have made mention, must be of great antiquity, as the natives cannot reach their era. They were undoubtedly the work of the Indo-Cuthites, who came so early into these parts. And that these structures, were formed by them, will appear from many circumstances; but especially from works of the same magnificence which were performed by them in other places. For scarce any people could have effected such great works, but a branch of that family which erected the tower of Babylonia, the walls of Balbec, and the pyramids of Egypt.”

Having then described a number of East Indian idols of surprising magnitude, “ the Babylonians and Egyptians (says he), and all of the same great family, used to take a pleasure in forming gigantic figures, and exhibiting other representations equally stupendous. Such were the colossal statues at Thebes, and the sphinx in the plains of Coume. The statue erected by Nebuchadnezzar in the plains of Dura, was in height threescore Babylonish cubits. It was probably raised in honour of *Cham*, the sun; and perhaps it was also dedicated to the head of the Chaldaic family; who was deified, and revered under that title. Marcellinus takes notice of a statue of Apollo named *Comens*; which, in the time of the emperor Verus, was brought:

Deluge.

Deluge. brought from Seleucia to Rome. This related to the same deity as the preceding. We may also infer, that the temple at Kamju was erected to Cham the sun, whom the people worshipped under the name of *Samo-nifu*."

It is remarkable, that in Japan the priests and nobility have the title of *Cami*. The emperor Quebacondono, in a letter to the Portuguese viceroy 1585, tells him, that Japan is the kingdom of Chamis; whom, says he, we hold to be the same as *Scin*, the origin of all things. By *Scin* is probably meant *San*, the sun: who was the same as Cham, rendered here *Chamis*. The laws of the country are spoken of as the laws of Chamis; and we are told by the Kæmpfer, that all the gods were styled either *Sin* or *Cami*. The founder of the empire is said to have been *Tensio Dai Sin*, or "Tensio the god of light." Near his temple was a cavern religiously visited, upon account of his having been once hid when no sun nor stars appeared. He was esteemed the fountain of day, and his temple was called *the temple of Naiku*. Near this cavern was another temple, in which the canusi or priests showed an image of the deity sitting upon a cow. It was called *Dainits No Kay*, "the great representation of the sun." One of their principal gods is *Jakusi*, similar to the Iacchus of the West. Kæmpfer says, that he is the Apollo of the Japanese, and they describe him as the Egyptians did Orus. His temple stands in a town called *Minnoki*: and *Jakusi* is here represented upon a gilt tarate flower; which is said to be the *nymphaea patustris maxima*, or *faba Egyptiaca* of Prosper Alpinus. One half of a large scallop shell is like a canopy placed over him; and his head is surrounded with a crown of rays. They have also an idol named *Menippe*, much revered in different parts. Both these, continues our author, relate to the same person, viz. Noah. Kæmpfer, an author of great credit, saw the temple of Dabys, which he truly renders *Daibod*, at Jedo in Japan. By *Dai-Bod* was meant the god Budha, whose religion was styled the *Budso*, and which prevailed greatly upon the Indus and Ganges. Kæmpfer, from whom Mr Bryant takes this account, says, that the people of Siam represent him under the form of a Moor, in a sitting posture, and of a prodigious size. His skin is black, and his hair curled (probably woolly), and the images about him are of the same complexion. "This god was supposed (says Mr Bryant) to have neither father nor mother. By *Budha* we are certainly to understand the idolatrous symbol called by some nations *Buddo*; the same as *Argus* and *Theba* (names for the ark). In the mythology concerning it, we may see a reference both to the machine itself and to the person preserved in it. In consequence of which we find this person also styled *Bod*, *Budha*, and *Buddo*; and in the West *Butus*, *Battus* and *Bæotus*. He was said by the Indians not to have been born in the ordinary way, but to have come to light indirectly through the side of his mother. By Clemens of Alexandria he is called *Bouta*: and in the history of this person, however varied, we may perceive a relation to the arkite deity of the sea, called *Ioseidon* or Neptune; also to Arculus and Dionusus, styled *Bæotus* and *Thebanus*. Kæmpfer has a curious history of a deity of this sort called *Abutto*; whose temple stood in the province of Bungo, upon the sea-

shore, near the village of Toma. About a quarter of a German mile before you come to this village stands a famous temple of the god *Abutto*; which is said to be very eminent for miraculously curing many inveterate distempers, as also for procuring a wind and good passage. For this reason, sailors and passengers always tie some farthings to a piece of wood, and throw it into the sea, as an offering to this *Abutto*, to obtain a favourable wind. The same deity, but under a different name, was worshipped in China. The *Apis*, *Mneuis*, and *Anubis* of Egypt, have often been mentioned and explained as well as the *Minotaur* of Crete. The same hieroglyphics occur in Japan; and we are informed by Marco Polo, that the inhabitants worship idols of different shapes. Some have the head of an ox, some of a swine, and others the head of a dog. The most common representation in this country is that of *Godso Ten Oo*, or 'the ox-headed prince of heaven.'

"It has already been taken notice, that the ark was represented under the symbol of an egg, called the *mundane egg*; which was exposed to the rage of Typhon. It was also described under the figure of a lunette, and called *Salene*, the moon. The person by whom it was framed, and who through its means was providentially preserved, occurs, under the character of a steer, and the machine itself under the semblance of a cow or a heifer. We have moreover been told, that it was called *Cibotus*, which Clemens of Alexandria calls *Thebocha*. Epiphanius mentions it by the name of *Idaal Baoth*; and says that, according to an eastern tradition, a person named *Nun* was preserved in it. The horse of Neptune was another emblem, as was also the hippopotamus or river-horse. The people of Elis made use of the tortoise for the same purpose, and represented Venus as resting upon its back. Some traces of these hieroglyphics are to be found in Japan, which were certainly carried thither by the Indic Ethiopians.

"From an account of a temple of *Daiboth* (probably the same with *Daibod*) at Meaco in Japan, we may perceive, that the people there speak of the renewal of the world at the deluge as the real creation, which I have shown to be a common mistake in the histories of this event. And though the story is told with some variation, yet in all the circumstances of consequence it accords very happily with the mythology of Egypt, Syria, and Greece. It matters not how the emblems have by length of time been misinterpreted. We have the *mundane egg* upon the waters, and the concomitant symbol of the moon; and the egg at last opened by the assistance of the sacred steer, upon which the world issues forth to this day." The author proceeds afterwards to mention the great veneration paid in these parts to the ox and cow; and says, that nobody dares injure them. One deity of the Japanese was Canon, the reputed lord of the ocean. He was represented in an erect posture, crowned with a flower, and coming out of the mouth of a fish. He is represented in the same manner by the natives of India, and named *Vishnou* and *Macauter*; and he is to be found in other parts of the East. Father Bousshet mentions a tradition among the Indians concerning a flood in the days of *Vishnou* which covered the whole earth. It is moreover reported of him, that seeing the prevalence of

Deluge. of the waters, he made a float : and being turned into a fish, he steered it with his tail. This person, in the account of the Banians by Lord, is called *Menow*; which certainly should be expressed *Men-Now*. It is said, that in the Shaster of this people, a like history is given of the earth being overwhelmed by a deluge, in which mankind perished; but the world was afterwards renewed in two persons called *Menou* and *Ceteroupa*. Vishnou is described under many characters, which he is said at times to have assumed. One of these, according to the bramins of Tanjour, was that of Rama Sami. This undoubtedly is the same as Sama Rama of Babylonia, only reversed; and it relates to that great phenomenon the Iris; which was generally accompanied with the dove, and held in veneration by the Semarim.

“As the history of China is supposed to extend upwards to an amazing height, it may be worth while to consider the first eras in the Chinese annals, as they are represented in the writings of Japan: for the Japanese have preserved histories of China; and by such a collation, I believe no small light may be obtained towards the discovery of some important truths. Hitherto it has not been observed that such a collation could be made.

17
Japanese
history of
China.

“In the histories of this country, the first monarch of China is named *Fohi*; the same whom the Chinese call *Fohi*, and place at the head of their list. This prince had, according to some, the body, according to others the head, of a serpent. If we may believe the Japanese historians, he began his reign above 21,000 years before Christ. The second Chinese emperor was Sin-Noo, by the people of China called *Sin Num*; and many begin the chronology of the country with him. He is supposed to have lived about 3000 years before Christ; consequently there is an interval of near 18,000 years between the first emperor and the second; a circumstance not to be credited. The third, who immediately succeeded Sin-Noo, was Hoam-Ti. In this account we may, I think, perceive, that the Chinese have acted like the people of Greece and other regions. The histories which were imported they have prefixed to the annals of their nation; and adopted the first personages of antiquity, and made them monarchs in their own country. Whom can we suppose Fohi, with the head of a serpent, to have been, but the great founder of all kingdoms, the father of mankind? They have placed him at an immense distance, not knowing his true era. And I think we may be assured, that under the character of Sin Num and Sin-Noo we have the history of Noah; and Haam-Ti was no other than Ham. According to Kæmpfer, Sin-Noo was exactly the same character as Serapis of Egypt. ‘He was an husbandman, and taught mankind agriculture, and those arts which relate to the immediate support of life. He also discovered the virtues of many plants; and he was represented with the head of an ox, and sometimes only with two horns. His picture is held in high estimation by the Chinese.’ Well indeed might Kæmpfer think, that in Sin-Noo he saw the character of Serapis; for this personage was no other than Sar-Apis, the great father of mankind, the same as Men-Neuas of Egypt, the same also as Dionus and Osiris. By Du Halde he is called *Chin-Nong*, and made the next monarch after Fohi. The Chinese

accounts afford the same history as has been given above. Deluge.

“As the family of Noah consisted of eight persons inclusive, there have been writers who have placed some of them in succession, and supposed that there were three or four persons who reigned between Sin-Noo and Hoam. But Du Halde says, that in the true histories of the country, the three first monarchs were Fohi, Chin-Nong, and Hoam, whom he styles *Hoang-Ti*. To these, he says, the arts and sciences owe their invention and progress. Thus we find, that those who were heads of families have been raised to be princes; and their names have been prefixed to the lists of kings, and their history superadded to the annals of the country. It is further observable, in the accounts given of those supposed kings, that their term of life, for the first five or six generations, corresponds with that of the patriarchs after the flood, and decreases much in the same proportion.

18
History
of Japan.
“The history of Japan is divided into three eras; which consist of gods, demigods, and mortals. The person whom the natives look upon to be the real founder of their monarchy is named *Synmu*; in whose reign the Sintoo religion, the most ancient of the country, was introduced. It was called *Sin-sju* and *Chami-mitsa*; from Sin and Chami, the deities which were the objects of worship. At this time it is said that 600 foreign idols were brought into Japan. To the Sintoo religion was afterwards added the Budso, together with the worship of Amida. This deity they commonly represented with the head of a dog, and esteemed him the guardian of mankind. This religion was more complicated than the former, and abounded with hieroglyphical representations and mysterious rites. It is the same which I have termed the *Arkite Idolatry*, wherein the sacred steer and cow were venerated. The deity was represented upon the lotus and upon a tortoise, and orientimes as proceeding from a fish. In this also, under the character of Budha, we may trace innumerable memorials of the ark, and of the person preserved in it. The author above, having mentioned the eleventh emperor inclusive from Syn Mu, tells us, that in his time these rites began. ‘In his reign Budo, otherwise called Κοβογυς, came over from the Indies to Japan; and brought with him, upon a white horse, his religion and doctrines.’ We find here, that the object of worship is made the person who introduced it (a mistake almost universally prevalent); otherwise, in this short account, what a curious history is unfolded!

“The only people to whom we can have recourse for any written memorials concerning these things are the inhabitants of India Proper. They were, we find, the persons who introduced these hieroglyphics both in China and Japan. It will therefore be worth while to consider what they have transmitted concerning their religious opinions; as we may from hence obtain still greater light towards explaining this symbolical worship. Every manifestation of God’s goodness to the world was in the first ages expressed by an hieroglyphic; and the Deity was accordingly described under various forms, and in different attitudes. These at length were mistaken for real transfigurations; and Vishnou was supposed to have appeared in different shapes, which were styled *incarnations*.

Deluge. *tions.* In one of these he is represented under the figure before mentioned, of a princely person coming out of a fish. In another he appears with the head of a boar, treading upon an evil demon, which seems to be the same as the Typhon of the Egyptians. On his head he supports a lunette, in which are seen cities, towers, in short, all that the world contains. In Baldæus we have a delineation and history of this incarnation. Kircher varies a little in his representation, yet gives him a similar figure of the Deity, and styles him *Vishnou Barachater*. By this I should think was signified Vishnou, "the offspring of the fish." The bramins say, that there was a time when the serpent with a thousand heads withdrew itself, and would not support the world, it was so overburdened with sin. Upon this the earth sank in the great abyss of waters, and mankind and all that breathed perished. But Vishnou took upon himself the form above described, and diving to the bottom of the sea, lifted up the earth out of the waters, and placed it, together with the serpent of a thousand heads, upon the back of a tortoise.

19
Account of
the cosmogony and
deluge
given by
the Parsees.

"In the third volume of M. Perron's *Zendavesta*, there is an account given of the cosmogony of the Parsees; also of the subsequent great events that ensued. The supreme Deity, called by him *Ormisdæ*, is said to have accomplished the creation at six different intervals. He first formed the heavens; at the second the waters; at the third the earth. Next in order were produced the trees and vegetables: in the fifth place were formed birds and fishes, and the wild inhabitants of the woods; and in the sixth and last place, he created man. The man thus produced is said to have been an *ox-like* person, and is described as consisting of a purely divine and a mortal part. For some time after his creation he lived in great happiness; but at last the world was corrupted by a dæmon named *Ahriman*. This dæmon had the boldness to visit heaven; whence he came down to the earth in the form of a serpent, and introduced a set of wicked beings, called *karsesters*. By him the first ox-like personage, called *Aboudad*, was so infected that he died; after which Kaiomorts, probably the divine part, of which the ox was the representative, died also. Out of the left arm of the deceased proceeded a being called *Goschoraum*, who is said to have raised a cry louder than the shout of 1000 men. After some conversation between the supreme Deity and Goschoraum, it was determined to put Ahriman to flight, and to destroy all those wicked persons he had introduced; for there now seemed to be an universal opposition to the Supreme Deity Ormisdæ. At this season a second ox-like personage is introduced by the name of *Taschter*. He is spoken of both as a star and a sun. At the same time he is mentioned as a person upon earth under three forms. By *Taschter* is certainly signified *De Ashter*; the same person whom the Greeks and Syrians represented as a female, and called *Asarte*. She was described horned, and sometimes with the head of a bull; supposed to proceed from an egg; and they esteemed her the same as Juno and the moon. At last it was thought proper to bring an universal inundation over the face of the earth; that all impurity might be washed away: which being accomplished by *Taschter*, every living creature perished, and the earth

was for some time entirely covered. At last, the waters retreating within their proper bounds, the mountain of Albordi in Ferakh-kand first appeared; which the author compares to a tree, and supposes that all other mountains proceeded from it. After this there was a renewal of the world; and the earth was restored to its pristine state. The particular place where Ormisdæ planted the germina from whence all things were to spring, was Ferakh-kand; which seems to be the land of Arach: the country upon the Araxes in Armenia."

Thus we have given an ample specimen of this very ingenious author's method of reasoning, and discovering traces of the sacred history even in things which have been thought least to relate to it. That the Greeks and western nations had some knowledge of the flood, has never been denied, and from what has been already related, it appears that the same has pervaded the remotest regions of the east. The knowledge which these people have of the fall of man, and the evil consequences which ensued, cannot, according to our author, be the consequences of their intercourse with Christians; for their traditions afford neither any traces of Christianity nor its founder. Whatever truths may be found in their writings, therefore, must be derived from a more ancient source. "There are (says he) in every climate some shattered fragments of original history; some traces of a primitive and universal language: and these may be observed in the names of deities, terms of worship, and titles of honour, which prevail among nations widely separated, who for ages had no connection. The like may be found in the names of pagodas and temples; and of sundry other objects which will present themselves to the traveller. Even America would contribute to this purpose. The more rude the monuments, the more ancient they may possibly prove, and afford a greater light upon inquiry."

The accounts hitherto met with in this continent, indeed, are far from being equally authentic and satisfactory with those hitherto treated of. In Acasta's history of the Indies, however, we are informed, that the Mexicans make particular mention of a deluge in their country, by which *all men* were drowned. According to them, one *Viracocha* came out of the great lake Titicaca in their country. This person staid in Tiaguanaco, where at this day are to be seen the ruins of some ancient and very strange buildings. From thence he came to Cusco, where mankind began to multiply. They show also a small lake, where they say the sun hid himself; for which reason they sacrifice largely to him, both men and other animals.—Hennepin informs us, that some of the savages are of opinion, that a certain spirit, called *Otkon* by the Iroquois, and *Atahauta* by those at the mouth of the river St Laurence, is the Creator of the world; that *Messou* repaired it after the deluge. They say, that this Messou or Otkon, being a hunting one day, his dogs lost themselves in a great lake, which thereupon overflowing, covered the whole earth in a short time, and swallowed up the world. According to Herrera, the people of Cuba knew that the heavens and the earth had been created: and said they had much information concerning the flood; and that the world had been destroyed by water, by three persons, who

American
accounts of
the deluge.

Deluge. came three several ways. Gabriel de Cabrera was told by a man of more than 70 years of age, that an old man, knowing the deluge was to come, built a great ship, and went into it with his family and abundance of animals; that he sent out a crow, which did not at first return, staying to feed on the carcases of dead animals, but afterwards came back with a green branch. He is said to have added other particulars nearly consonant to the Mosaic account, as far as Noah's sons covering him when drunk, and the other scoffing at it. The Indians, he said, descended from the latter, and therefore had no clothes; but the Spaniards descending from the former, had both clothes and horses.--The same author likewise informs us, that it was reported by the inhabitants of Castilla del Oro in Terra Firma, that when the universal deluge happened, one man with his wife and children escaped in a canoe, and that from them the world was peopled. The Peruvians, according to our author, likewise affirmed, that they had received by tradition from their ancestors, that, many years before there were any incas or kings, when the country was very populous, there happened a great flood: the sea breaking out beyond its bounds, so that the land was covered with water, and all the people perished. To this it is added by the Guancas, inhabiting the vale of Xaasea, and the natives of Chiquito in the province of Callao, that some persons remained in the hollows and caves of the highest mountains, who again peopled the land. Others affirm, that all perished in a deluge, only six persons being saved in a float, from whom descended all the inhabitants of that country. In Nieuhoff's voyages to Brasil, we are informed, that the most barbarous of the Brasilians, inhabiting the inland countries, scarce knew any thing of religion or an Almighty Being: they have some knowledge remaining of a general deluge: it being their opinion that the whole race of mankind were extirpated by a general deluge, except one man and his sister, who, being with child before, they by degrees re-peopled the world. M. Thevet gives us the creed of the Brasilians in this matter more particularly. In the opinion of these savages, the deluge was universal. They say, that *Sommay*, a Caribbee of great dignity, had two children named *Tamendonare* and *Ariconte*. Being of contrary dispositions, one delighting in peace and the other in war and rapine, they mortally hated each other. One day Ariconte, the warrior, brought an arm of an enemy he had encountered to his brother, reproaching him at the same time with cowardice. The other retorted by telling, that if he had been possessed of the valour he boasted, he would have brought his enemy entire. Ariconte on this threw the arm against the door of his brother's house. At that instant the whole village was carried up into the sky, and Tamendonare striking the ground with violence, a vast stream of water issued out from it, and continued to flow in such quantity, that in a short time it seemed to rise above the clouds, and the earth was entirely covered. The two brothers, seeing this, ascended the highest mountains of the country, and with their wives got upon the trees that grew upon them. By this deluge all mankind, as well as all other animals, were drowned, except the two brothers abovementioned and their wives: who having descended when the flood abated, became heads of two different nations." &c.

VOL. V.

To these American testimonies we may add another from the remote and uncivilized island of Otahete. Dr Watson†, in his discourse to the clergy, informs us, that one of the navigators to the southern hemisphere having asked some of the inhabitants of that island concerning their origin, was answered, that their supreme God, a long time ago, being angry, dragged the earth through the sea, and their island being broken off, was preserved. In the East Indies also we are informed by Dr Watson‡, that Sir William Jones, by whom a society for the advancement of Asiatic literature has been instituted at Calcutta, has discovered, that in the oldest mythological books of that country, there is such an account of the deluge as corresponds sufficiently with that of Moses.

II. The fact being thus established by the universal consent of mankind, that there was a general deluge which overflowed the whole world; it remains next to inquire, by what means it may reasonably be supposed to have been accomplished. The hypotheses on this subject have been principally the following.

1. It has been asserted, that a quantity of water was created on purpose, and at a proper time annihilated, by divine power. This, however, besides its being absolutely without evidence, is directly contrary to the words of the sacred writer whom the asserters of this hypothesis mean to defend. He expressly derives the waters of the flood from two sources; first, the fountains of the great deep, which he tells us were all broken up; and secondly, the windows of heaven, which he says were opened: and speaking of the decrease of the waters, he says, the fountains of the deep and the windows of heaven were stopped, and the waters returned continually from off the earth. Here it is obvious, that Moses was so far from having any difficulty about the quantity of water, that he thought the sources from whence it came were not exhausted; since both of them required to be stopped by the same almighty hand who opened them, lest the flood should increase more than it actually did.

2. Dr Burnet, in his *Telluris Theoria Sacra*, endeavours to show, that all the waters in the ocean are not sufficient to cover the earth to the depth assigned by Moses. Supposing the sea drained quite dry, and all the clouds of the atmosphere dissolved into rain, we should still, according to him, want much the greatest part of the water of a deluge. To get clear of this difficulty. Dr Burnet and others have adopted Descartes's theory. That philosopher will have the antediluvian world to have been perfectly round and equal, without mountains or valleys. He accounts for its formation on mechanical principals, by supposing it at first in the condition of a thick turbid fluid replete with divers heterogeneous matters; which, subsiding by slow degrees, formed then selves into different concentric strata, or beds, by the laws of gravity. Dr Burnet improves on this theory, by supposing the primitive earth to have been no more than a shell or crust investing the surface of the water contained in the ocean, and in the central abyss which he and others suppose to exist in the bowels of the earth. * At the time of the flood, this outward crust, according to him, broke in a thousand places; and consequently sunk down among the water which thus spouted up in vast cataracts, and overflowed the whole surface. He supposes also, that before the flood there was a

Deluge.

perfect coincidence of the equator with the ecliptic, and consequently that the antediluvian world enjoyed a perpetual spring; but that the violence of the shock by which the outer crust was broken, shifted also the position of the earth, and produced the present obliquity of the ecliptic. This theory, it will be observed, is equally arbitrary with the former. But it is, besides, directly contrary to the words of Moses, who assures us, that all the high hills were covered; while Dr Burnet affirms that there were then no hills in being.

25
Centre of gravity of the earth supposed to be shifted.

3. Other authors, supposing a sufficient fund of water in the abyss or sea, are only concerned for an expedient to bring it forth: accordingly some have recourse to a shifting of the earth's centre of gravity, which, drawing after it the water out of its channel, overwhelmed the several parts of the earth successively.

26
Mr Whiston's theory

4. The inquisitive Mr Whiston, in his *New Theory of the Earth*, shows from several remarkable coincidences, that a comet descending in the plane of the ecliptic, towards its perihelion, passed just before the earth on the first day of the deluge; the consequences whereof would be, first, that this comet, when it came below the moon, would raise a vast and strong tide, both in the small seas, which according to his hypothesis were in the antediluvian earth (for he allows no great ocean there as in ours), and also in the abyss which was under the upper crust of the earth. And this tide would rise and increase all the time of the approach of the comet towards the earth; and would be at its greatest height when the comet was at its least distance from it. By the force of which tide, as also by the attraction of the comet, he judges, that the abyss must put on an elliptical figure, whose surface being considerably larger than the former spherical one, the outward crust of the earth, incumbent on the abyss, must accommodate itself to that figure, which it could not do while it held solid, and conjoined together. He concludes, therefore, that it must of necessity be extended, and at last broke by the violence of the said tides and attraction; out of which the included water issuing, was a great means of the deluge: this answering to what Moses speaks of the "fountains of the great deep being broke open."—Again, the same comet, he shows, in its descent towards the sun, passed so close by the body of the earth, as to involve it in its atmosphere and tail for a considerable time; and of consequence left a vast quantity of its vapours, both expanded and condensed, on its surface; a great part of which being rarefied by the solar heat, would be drawn up into the atmosphere, and afterwards return in violent rains: and this he takes to be what Moses intimates by "the windows of heaven being opened," and particularly by the "forty days rain." For as to the following rain, which with this made the whole time of raining 150 days, Mr Whiston attributes it to the earth coming a second time within the atmosphere of the comet as the comet was on its return from the sun. Lastly, to remove this vast orb of waters again, he supposes a mighty wind to have arisen, which dried up some, and forced the rest into the abyss through the clefts by which it came up; only a good quantity remained in the alveus of the great ocean, now first made, and in lesser seas, lakes, &c. This theory was at first only proposed

as an hypothesis; but, on further consideration, Mr Whiston thought he could actually prove that a comet did at that time pass very near the earth, and that it was the same which afterwards appeared in 1680. After this, he looked upon his theory no longer as an hypothesis, but published it in a particular tract, entitled, *The Cause of the Deluge demonstrated*. But the uncertainty of the comet's return in 1758, and the absolute failure to that which ought to have appeared in 1788 or 1789, must certainly render Mr Whiston's calculations for such a length of time extremely dubious; and the great similarity between the tails of the comets and streams of electric matter renders his supposition of their being aqueous vapours exceedingly improbable.

Deluge.

5. According to Mr de la Pryme, the antediluvian world had an external sea as well as land, with mountains, rivers, &c. and the deluge was effected by breaking the subterraneous caverns, and pillars thereof, with dreadful earthquakes, and causing the same to be for the most part, if not wholly, absorbed and swallowed up, and covered by the seas that we now have. Lastly, this earth of ours arose out of the bottom of the antediluvian sea; and in its room, just as many islands are swallowed down, and others thrust up in their stead. On this, as on all the other hypotheses, it may be remarked, that it is quite arbitrary, and without the least foundation from the words of Moses. The sacred historian speaks not one word of earthquakes, nay, from the nature of the thing, we know it is impossible that the flood could have been occasioned by an earthquake, and the ark preserved, without a miracle. It is certain, that if a ship sinks at sea, the commotion excited in the water by the descent of such a large body, will swallow up a small boat that happens to come too near. If the pillars of the earth itself then, were broken, what must the commotion have been when the continents of Europe, Asia, and Africa, descended into the abyss at once? not to mention America, which lying at so great a distance from Noah, he might be supposed out of danger from that quarter. By what miracle was the little ark preserved amidst the tumult of those impetuous waves which must have rushed in from all quarters? Besides, as the ark was built not at sea, but on dry ground; when the earth on which it rested sunk down, the ark must have sunk along with it; and the waters falling in as it were overhead, must have dashed in pieces the strongest vessel that can be imagined. Earthquakes, also, operate suddenly and violently; whereas, according to the Mosaic account, the flood came on gradually, and did not arrive at its height till six weeks, or perhaps five months, after it began.

27
Theory of Mr de la Pryme.

6. Mr Hutchinson and his followers present us with Hutchinson's a theory of the deluge, which they pretended to derive from the word of God itself. This theory hath been particularly enlarged upon and illustrated by Mr Catcot, who in 1763 published a volume on the subject. This gentleman asserts, that when the world was first created, at the time when it is said to have been "without form and void," the terrestrial matter was then entirely dissolved in the aqueous; so that the whole formed, as it were, a thick muddy water. The figure of this mass was spherical; and on the outside of this sphere lay the gross dark air. Within the sphere of earth and water was an immense cavity, called by Mo-
ses

28

Deluge. ses the *deep*; and this internal cavity was filled with air of a kind similar to that on the outside. On the creation of light, the internal air received elasticity sufficient to burst out through the external covering of earth and water. Upon this the water descended, filled up the void, and left the earth in a form similar to what it hath at present. Thus, according to him, the antediluvian world, as well as the present, consisted of a vast collection or nucleus of water, called the *great deep*, or the *abyss*; and over this the shell of earth perforated in many places; by which means the waters of the ocean communicated with the abyss. The breaking up of these fountains was occasioned by a miraculous pressure of the atmosphere, from the immediate action of the Deity himself. So violent was this pressure, that the air descended to where it had been originally; occupied the space of the abyss; and drove out the waters over the whole face of the dry land. But this account, so far from being infallibly certain, seems inconsistent with the most common observations. No pressure, however violent, will cause water rise above its level, unless that pressure is unequal. If, therefore, the atmosphere entered into the supposed abyss, by a vehement pressure on the surface of the ocean, that pressure must only have been on one place, or on a few places: and even though we suppose the atmosphere to have been the agent made use of, it is impossible that it could have remained for any time in the abyss without a continued miracle; as the pressure of the water would immediately have forced it up again through those holes which had afforded it a passage downwards.

The explication given from Hutchinson by Mr Catcot, of the "windows of heaven," is somewhat extraordinary. According to him, these windows are not in heaven, but in the bowels of the earth; and mean no more than the cracks and fissures by which the *airs*, as he calls them, found a passage through the shell or covering of earth, which they utterly dissolved and reduced to its original state of fluidity. It is, however, difficult to conceive how the opening of such windows as these could cause a violent rain for 40 days and nights.

It is not to be supposed, that we can pretend to ascertain any thing on the subject more than others have done. The following conjectures, however, may be offered on the manner in which the deluge might have happened without any violence to the established laws of nature.

1. If we consider the quantity of water requisite for the purpose of the deluge, it will not appear so very extraordinary as has been commonly represented. The height of the highest hills is thought not to be quite four miles. It will therefore be deemed a sufficient allowance, when we suppose the waters of the deluge to have been four miles deep on the surface of the ground. Now it is certain, that water, or any other matter, when spread out at large upon the ground, seems to occupy an immense space in comparison of what it does when contained in a cubical vessel, or when packed together in a cubical form. Suppose we wanted to overflow a room 16 feet every way, or containing 256 square feet, with water, to the height of one foot, it may be nearly done by a cubical vessel of six feet filled with water. A cube of eight feet will

cover it two feet deep, and a cube of ten feet will very nearly cover it four feet deep. It makes not the least difference whether we suppose feet or miles to be covered. A cube of ten miles of water would very nearly overflow 256 square miles of plain ground to the height of four miles. But if we take into our account the vast number of eminences with which the surface of the earth abounds, the abovementioned quantity of water would do a great deal more. If, therefore, we attempt to calculate the quantity of water sufficient to deluge the earth, we must make a very considerable allowance for the bulk of all the hills on its surface. To consider this matter, however, in its utmost latitude: The surface of the earth is supposed, by the latest computations, to contain 199,512,595 square miles. To overflow this surface to the height of four miles, is required a parallelopiped of water 16 miles deep, and containing 49,878,148 square miles of surface. Now, considering the immense thickness of the globe of the earth, it can by no means be improbable, that this whole quantity of water may be contained in its bowels, without the necessity of any remarkable abyss or huge collection of water, such as most of our theorists suppose to exist in the centre. It is certain, that as far as the earth has been dug, it hath been found not dry, but moist; nor have we the least reason to imagine, that it is not at least equally moist all the way down to the centre. How moist it really is cannot be known, nor the quantity of water requisite to impart to it the degree of moisture it has; but we are sure it must be immense. The earth is computed to be near 8000 miles in diameter. The ocean is of an unfathomable depth; but there is no reason for supposing it more than a few miles. To make all reasonable allowances, however, we shall suppose the whole solid matter in the globe to be only equal to a cube of 5000 miles; and even on this supposition we shall find, that all the waters of the deluge would not be half sufficient to moisten it. The abovementioned parallelopiped of water would indeed contain 798,050,368 cubic miles of that fluid; but the cube of earth containing no less than an hundred and twenty-five thousand millions of cubic miles, it is evident that the quantity assigned for the deluge would scarce be known to moisten it. It could have indeed no more effect this way, than a single pound of water could have upon 150 times its bulk of dry earth. We are persuaded therefore, that any person who will try by experiment how much water a given quantity of earth contains, and from that experiment will make calculations with regard to the whole quantity of water contained in the bowels of the earth, must be abundantly satisfied, that though *all* the water of the deluge had been thence derived, the diminution of the general store would, comparatively speaking, have been next to nothing.

2. It was not from the bowels of the earth only that the waters were discharged, but also from the air; for we are assured by Moses, that it rained 40 days and 40 nights. This source of the deluvian waters hath been considered as of small consequence by almost every one who hath treated on the subject. The general opinion concerning this matter we shall transcribe from the *Universal History*, Vol. I. where it is very fully expressed. "According to the observations made of the

Deluge.

quantity of water that falls in rain, the rains could not afford one ocean, nor half an ocean, and would be a very inconsiderable part of what was necessary for a deluge. If it rained 40 days and 40 nights throughout the whole earth at once, it might be sufficient to lay all the lower grounds under water, but it would signify very little as to the overflowing of the mountains; so that it has been said, that if the deluge had been made by rains only, there would have needed not 40 days, but 40 years, to have brought it to pass. And if we suppose the whole atmosphere condensed into water, it would not all have been sufficient for this effect; for it is certain that it could not have risen above 32 feet, the height to which water can be raised by the pressure of the atmosphere: for the weight of the whole air, when condensed into water, can be no more than equal to its weight in its natural state, and must become no less than 800 times denser; for that is the difference between the weight of the heaviest air and that of water."

On this subject we must observe, that there is a very general mistake with regard to the air, similar to the abovementioned one regarding the earth. Because the earth below our feet appears to our senses firm and compact, therefore the vast quantity of water, contained even in the most solid parts of it, and which will readily appear on proper experiment, is overlooked, and treated as a non-entity. In like manner, because the air does not always deluge with excessive rains, it is also imagined that it contains but very little water. Because the pressure of the air is able to raise only 32 feet of water on the surface of the earth, it is therefore supposed we may know to what depth the atmosphere could deluge the earth if it was to let fall the whole water contained in it. But daily observations show, that the pressure of the atmosphere hath not the least connection with the quantity of water it contains. Nay, if there is any connection, the air seems to be lightest when it contains most water. In the course of a long summer's drought, for instance, the mercury in the barometer will stand at 30 inches, or little more. If it does so at the beginning of the drought, it ought to ascend continually during the time the dry weather continues; because the air is all the while absorbing water in great quantity from the surface of the earth and sea. This, however, is known to be contrary to fact. At such times the mercury does not ascend, but remains stationary; and what is still more extraordinary, when the drought is about to have an end, the air, while it yet contains the whole quantity of water it absorbed, and hath not discharged one single drop, becomes suddenly lighter, and the mercury will perhaps sink an inch before any rain falls. The most surprising phenomenon, however, is yet to come. After the atmosphere has been discharging for a number of days successively a quantity of matter 800 times heavier than itself, instead of being *lightened* by the discharge, it becomes *heavier*, nay *specifically* heavier, than it was before. It is also certain, that very dry air, provided it is not at the same time very hot, is always heaviest; and the driest air which we are acquainted with, namely Dr Priestley's *dephlogisticated* air, is considerably heavier than the air we commonly breathe. For these reasons we think the quantity of water contained in the whole atmosphere ought to be considered

as *indefinite*, especially as we know that by whatever agent it is suspended, that agent must counteract the force of gravity, otherwise the water would immediately descend; and while the force of gravity in any substance is counteracted, that substance cannot appear to us to gravitate at all.

3. The above considerations render it *probable* at least, that there is in nature a quantity of water sufficient to deluge the world, provided it was applied to the purpose. We must next consider whether there is any natural agent powerful enough to effectuate this purpose. We shall take the phrases used by Moses in their most obvious sense. The *breaking up of the fountains of the deep* we may reasonably suppose to have been the opening of all the passages, whether small or great, through which the subterraneous waters possibly could discharge themselves on the surface of the earth. The *opening of the windows of heaven* we may also suppose to be the pouring out the water contained in the atmosphere thro' those invisible passages by which it enters in such a manner as totally to elude every one of our senses, as when water is absorbed by the air in evaporation. As both these are said to have been opened at the same time, it seems from thence probable, that one natural agent was employed to do both. Now it is certain, that the industry of modern inquirers hath discovered an agent unknown to the former ages, and whose influence is so great, that with regard to this world it may be said to have a kind of *omnipotence*. The agent we mean is electricity. It is certain, that by means of it, immense quantities of water can be raised to a great height in the air. This is proved by the phenomena of water-spouts. Mr Forster relates, that he happened to see one break very near him, and observed a flash of lightning proceed from it at the moment of its breaking. The conclusion from this is obvious. When the electric matter was discharged from the water, it could no longer be supported by the atmosphere, but immediately fell down. Though water-spouts do not often appear in this country, yet every one must have made an observation somewhat similar to Mr Forster's. In a violent storm of thunder and rain, after every flash of lightning or discharge of electricity from the clouds, the rain pours down with increased violence; thus shewing, that the cloud, having parted with so much of its electricity, cannot longer be supported in the form of vapour, but must descend in rain. It is not indeed yet discovered that electricity is the cause of the suspension of water in the atmosphere; but it is certain that evaporation is promoted by electrifying the fluid to be evaporated*. It may therefore be admitted as a *possibility*, that the electric fluid contained in the air is the agent by which it is enabled to suspend the water which rises in vapour. If therefore the air is deprived of the due proportion of this fluid, it is evident that rain must fall in prodigious quantities.

Again, we are assured from the most undeniable observations, that electricity is able to swell up water on the surface of the earth. This we can make it do even in our trifling experiments; and much more must the whole force of the fluid be supposed capable of doing it, if applied to the waters of the ocean, or any others. The agitation of the sea in earthquakes is a sufficient proof of this †. It is certain, that at these times there is a discharge of a vast quantity of electric matter from

Deluge.

the

Deluge. and what reason can there be to extend the flood beyond the occasion of it, which was the corruption of mankind?—The only probability then of asserting the universality of the flood, as to the globe of the earth, is from the destruction of all living creatures, together with man. Now though men might not have spread themselves over the whole surface of the earth, yet beasts and creeping things might, which were all destroyed with the flood; for it is said, ‘that all flesh died that moved upon the earth, both of fowl and of cattle, and of every creeping thing that creepeth upon the earth, and every man.’ To what end should there be not only a note of universality added, but such a particular enumeration of the several kinds of beasts, creeping things and fowls, if they were not all destroyed? To this I answer; I grant that, as far as the flood extended, all these were destroyed: but I see no reason to extend the destruction of these beyond that compass and space of the earth where men inhabited, because the punishment upon the beasts was occasioned by, and could not but be concomitant with, the destruction of man, but (the occasion of the deluge being the sin of man, who was punished in the beasts that were destroyed for his sake, as well as in himself) where the occasion was not, as where there were animals and no men, there seems no necessity of extending the flood thither.—But to what end, will it therefore be replied; did God command Noah, with so much care, to take all kinds of birds, beasts, and creeping things, into the ark with him, if all those living creatures were not destroyed by the flood? I answer, because all those things were destroyed wherever the flood was. Suppose then the whole continent of Asia was peopled before the flood, which is as much as in reason we may suppose: I say, all the living creatures in that continent were destroyed; or if we may suppose it to have extended over our whole continent of the ancient known world, what reason would there be, that in the opposite part of the globe, which we suppose to be unpeopled then, all the living creatures should there be destroyed, because men had sinned in this? and would there not have been on this supposition a sufficient reason to preserve living creatures in the ark for future propagation,” &c.

33
A partial deluge proved to be impossible.

Thus we have the strength of all the arguments that have been offered in support of a partial deluge, and which may all be summed up in the three following articles, 1. The impossibility, in a natural way, of accounting for the quantity of water necessary to overflow the whole world; 2. The small number of mankind supposed at that time to have existed on the earth; and, 3. The inutility of an universal deluge, when the divine purposes could have been equally well answered by a partial one. But to all this we may make one general answer, that a partial deluge is in the nature of things impossible. We cannot imagine that the waters could accumulate upon any country without going off to the sea, while the latter retained its usual level; neither can we suppose any part of the sea to remain above the level of the rest. On the supposition of bishop Stillingfleet therefore, that the deluge extended over the whole continent of Asia, we know that it must have covered the high mountains of Ararat, on which the ark rested; Caucasus, Taurus, &c. The height of Ararat is in-

determined, as no traveller of any credit pretends to have ascended to its top; but from the distance at which it is seen, we can scarce look upon it to be inferior to the most celebrated mountains of the old continent*. Sir John Chardin thinks that some part of Caucasus is higher; and supposing each of these to be only a mile and an half in height, the sea all round the globe must have been raised to the same height; and therefore all that could remain of dry ground as a shelter to animals of any kind, must have been the uninhabitable tops of some high mountains scattered at immense distances from one another. We may therefore with equal reason suppose, that these were in like manner covered, and that no living creature whatever could find shelter even for a moment: and it is certainly more agreeable to the character of the Deity to believe, that he would at once destroy animal life by suffocation in water, rather than allow numbers of them to collect themselves on the tops of mountains to perish with hunger and cold. It is besides very improbable, that any creature, whether bird or beast, could sustain a continued rain of 40 days and 40 nights, even without supposing them to have been absolutely immersed in water.

This consideration alone is sufficient to show, that if there was a deluge at all, it must have been universal with regard to the world as well as the human race; and the possibility of such a deluge by natural means has already been evinced. Under the article ANTEDELUVIANS it is shown, that, according to the most moderate computations, the world must have been vastly more full of people than at present. The least calculation there made indeed seems incredible; since, according to it, the world must have contained upwards of 68,719 times as many inhabitants as are at present to be met with in the empire of China, the most populous country in the world: but China bears a much larger proportion to the habitable part of the world than this. The violences exercised by mankind upon one another, have always been the means of thinning their numbers, and preventing the earth from being overstocked with inhabitants; and the strong expression in Scripture, that the “earth was filled with violence,” shows that it must have gone to an extraordinary height. But though this violence must have undoubtedly thinned the old world of its inhabitants, it must likewise have dispersed some of them into distant regions. There is therefore no reason for supposing, that before the flood the human race were not driven into the remotest regions of the habitable world, or that America was destitute of inhabitants then more than it is at present. At any rate, the schemes of Vossius and Coetlogon, who would confine the whole race of mankind to a small part of Asia, must appear evidently futile and erroneous in the highest degree.

Some objections have been made to the doctrine of an universal deluge from the state of the continent of America, and the number of animals peculiar to that and other countries, which could not be supposed to travel to such a distance either to or from the ark of Noah. On this subject Bishop Stillingfleet observes, that the supposition of animals being propagated much farther in the world than mankind before the flood, seems very probable, “because the production of animals is parallel in Genesis with that of fishes, and both

Deluge.

34
Objections from some species of animals being peculiar to certain countries.

of

Deluge. of them different from man. For God saith, Let the waters bring forth every moving creature that hath life, viz. fish and fowl: And accordingly it is said, that the waters brought forth abundantly every living creature after their kind, and every fowl after his kind. Accordingly, in the production of beasts, we read, 'Let the earth bring forth the living creature after his kind, cattle, and every creeping thing, and beast of the earth, after his kind: and it was so.' But in the production of man it is said, 'Let us make man in our image, after our own likeness.' From hence I observe this difference between the formation of animals and of man, that in one God gave a prolific power to the earth and waters for the production of the several living creatures which came from them, so that the seminal principles of them were contained in the matter out of which they were produced; which was otherwise in man, who was made by a peculiar hand of the great Creator himself, who thence is said to have formed man out of the dust of the ground.

"If now this supposition be embraced, by it we presently clear ourselves of many difficulties concerning the propagation of animals in the world, and their conservation in the ark; as how the unknown kind of serpents in Brazil, the slow-bellied creature in the Indies, and all those strange species of animals seen in the West Indies, should either come into the ark of Noah, or be conveyed out of it into those countries which are divided by so vast an ocean on one side, and at least so large a tract of land on the other. Besides, some kind of animals cannot live out of the climate wherein they are; and there are many sorts of animals discovered in America and the adjoining islands, which have left no remainders of themselves in these parts of the world. And it seems very strange that these should propagate into those parts of the world from the place of the flood, and leave none at all of their number behind them in these parts whence they were propagated."

35
Replies by
Mr Cock-
burn.

To this Mr Cockburn, in his treatise on the deluge, replies, 1. That as it pleased God to create only one man and one woman at the beginning, and their posterity were sufficient to overspread the earth, it might well be supposed to be furnished with animals from an original pair of each. 2. On the supposition of many pairs of brute animals having been created originally, they must when the human race were few in number, have multiplied to such a degree as to render the world uninhabitable. In confirmation of this, he informs us from the accounts of the Indian missionaries, that in the kingdom of Champna in the Indies, the river called by the natives *Tinacoreu*, but by the Portuguese *Varella*, goes up 80 leagues into the country to a mountain called *Moncalor*, above which it is much broader, but not so deep by far; there being banks of sand in some places, and lands overflowed with water, where there are an infinite number of fowls that cover all the country; inasmuch, that by reason of them the whole kingdom of Chintaluhos had for 40 years been desolate, though it was eight days journey in length; which, at 30 miles a-day, made it 240 miles long. After passing this country, another was met with more wild, and full of great rocks; where there were a vast number of animals yet worse than the fowls, as elephants, rhinoceroses, lions, bears, buffaloes, and other beasts in such multitudes, that whatever men cultivated for the sup-

port of life was spoiled or destroyed by them, nor was it possible for the inhabitants to prevent it.

Deluge

The Isle of France may be said to be the kingdom of rats. They come down from the mountains like an army, creep up the steepest rocks, march into the flat country, assemble in the marshy grounds, and bring desolation every where, especially in the night. Men can scarce sleep for them, and are obliged to roll themselves in such things as may best secure them from their bitings. It was the same in the Isle of Bourbon, which was as much infested with them at first, till it became more fully peopled. "We have good reason therefore (says Mr Cockburn) to conclude, that there was but one pair of animals created at first, that they might not increase too fast for mankind; and though they would multiply much more, and increase faster than men could do, they had room to spread themselves for a long time without much annoyance to man; and as men increased in number and extended their habitations, they would be able to drive them further off, or defend themselves from their depredations." The same mode of reasoning is by our author made use of with regard to aquatic animals. The multitude of these indeed, however great, could be no detriment to man who lived on land; but if we consider how large and numerous a spawn fishes cast at once, and in how short a time they multiply to immense numbers, he thinks it reasonable to conclude, that only one pair was created at once; and that the command to the waters to bring forth abundantly both fish and fowl, related only to the variety of species, not to a number of each.

3. Though at the restoration of the world it was to be repopled by six persons instead of two, and though at the same time animal food was given to man, yet Noah was commanded only to take a single pair of each of the animals, clean beasts, which are but a few in number, only excepted. It is further observable, that notwithstanding this scanty supply of animals, they had increased so much by the time of Nimrod, that it then became necessary to hunt and destroy them; and Nimrod was celebrated for his courage and skill in that necessary employment. "So numerous (adds he) were the animals before the flood, though but two of a kind were created, that Dr Woodward, from the remains of that earth, as well the animal as vegetable productions of it still preserved, concludes, that 'at the time the deluge came, the earth was so loaded with herbage, and so thronged with animals, that such an expedient was even wanting to ease it of the burden, and to make room for a new succession of its productions.'"

4. Mr Cockburn is of opinion, that America must have been peopled before the flood, as the old continent could not be supposed able to hold the number of inhabitants.

38
Of the
peopling of
America,
and migra-
tion of ani-
mals to it.

5. With regard to the main difficulty, viz. how the animals peculiar to different countries could travel to such distances to and from the ark, Mr Cockburn replies, that America, which Bishop Stillingfleet chiefly insists upon, has nothing peculiar to it, but what may equally well be urged both with respect to Asia and Africa; each of them having animals peculiar to themselves. It is a so possible, that there might formerly be a more easy communication between the

Asiatic

Deluge. Asiatic and American continents than there is now. See the article AMERICA, n^o 101—113.

Our author likewise observes, that though the ark rested on mount Ararat, yet we are not told where it was built, which might be far enough from the place where it is commonly supposed; so that those animals which are peculiar to America might not have so far to travel to the ark as is commonly imagined. This argument, however, seems to be very inconclusive; for though we should suppose the ark to have been constructed in America itself, the animals of Mesopotamia would have had as far to travel from thence to America, as the American animals from their own country to Mesopotamia, according to the common opinion. But in whatever part of the earth Noah lived and the ark was built, it was at God's command that the several kinds of animals came thither in order to their preservation; and his command could bring them from the farthest parts of the earth during the 120 years that the world lay under condemnation. Though after all, none of the animals might have very far to travel to the ark; for if only one pair of each kind was created at first, and all of these in or near one place, since they were all brought before Adam, and received names from him, there is no absurdity in supposing that some of every kind might remain in the country where they were first produced, from whence Noah's habitation might not be very distant. Neither can any objection be brought from the extinction of some species of animals in certain countries of the world, since they might have been hunted and destroyed either by the human race or by other creatures. Thus it is said, that there are now few or no deer in Switzerland, though formerly there were a great many when it was full of woods. In Britain also there are no wolves now to be found, though the island was infested with them in former times.

39
Of the subsistence of carnivorous animals in the ark.

In considering the subject of the deluge, among other questions which occur, one is, by what means were the ravenous animals, which feed only upon flesh, supported in the ark? For this some authors have supposed, that Noah, besides those animals whom he took into the ark for preservation, took likewise a great number for slaughter. For this purpose bishop Wilkins has allowed no fewer than 1825 sheep, though he was of opinion, that there were no carnivorous animals before the flood; and this latter opinion is adopted by Mr Cockburn. The idea indeed of slaughtering a number of harmless animals to satisfy a few vile rapacious ones, and that too in a place designed for the common asylum of the animal creation, seems inconsistent with that scheme of mercy displayed in the whole transaction. It is by much the more probable supposition then, that though some animals had been accustomed to live on flesh in their natural state, they could nevertheless subsist upon vegetable food. This seems the more probable, as some animals naturally carnivorous, particularly dogs and cats, may be supported in their domestic state by vegetable food alone. If we extend this to the whole canine and feline genera, we shall take in the most of the beasts of prey; as lions, tygers, leopards, panthers, wolves, foxes, hyenas, &c. Bears are well known sometimes to feed on berries; snakes will eat bread and milk; and there is no reason to suppose that even the most car-

nivorous birds could not be kept alive by grain or other vegetable food. By thus excluding such a number of useless animals, a very considerable space will be allowed for the circulation of air in the ark, the want of which seems to be the most inexplicable difficulty, if we may judge from the present constitution of things. It seems indeed to be certain, that no equal number of animals could subsist for a twelvemonth in an equal space so closely shut up as they were. The ark, it is true, contained near two millions of cubic feet; but considering the number of its inhabitants, the great space necessary for the food with which they were to be supplied, and the continual pollution of the air by their dung and filth, as well as the effluvia from their bodies, there seems little probability that even such a vast bulk of air could suffice for any length of time. This difficulty will appear the greater, when we consider that any ventilation was impossible, as this could not have been done without opening both the door and window; and the former, we are certain, was not opened until the time that the command was given to come forth out of the ark. Neither is there the smallest probability, that the opening of a single window could renew the air in such a manner as to make it fit for breathing throughout the whole extent of the ark. In this particular therefore, we must have recourse to the immediate interposition of Divine power, and suppose that the air was miraculously preserved of a sufficient degree of purity, as the garments of the Israelites were preserved from turning old, and their feet from being affected by the journey through the desert in which they wandered so long.—Many other questions concerning the economy of the ark might be proposed; as, how they supplied themselves with water? in what manner they could use fire for the dressing of their victuals? &c. But as every answer to these must be founded wholly upon conjecture, and none can pretend that there was a natural impossibility of effecting any of these things, we forbear to insist farther upon them. The case, however, it is very different with respect to the air necessary for sustaining animal life: for here there is a plain impossibility in a natural way; nay, we may even doubt whether the general mass of atmosphere, after being deprived of its electric matter, or otherwise altered in such a manner as to let fall such a quantity of the water it contained, was fit for the support of animal life; so that a miracle would have been necessary at any rate. To this indeed it may be replied, that on such a supposition, men and other animals would have been destroyed, not by the flood, but by the vitiated air they breathed. But, as has been already hinted, it is improbable that any living creature could resist the violent rain which took place, and which would soon drive the birds from their shelter, as the waters beginning to overflow the ground would soon expel the human race from their houses; and it would not be till the end of the 40 days and 40 nights that the air could be at its worst state, long before which time all animal life would be extinct.

Deluge.
40
Want of a proper circulation of air the greatest difficulty.

We shall conclude this article with considering some of the alterations which are supposed to have taken place in the world in consequence of the deluge. One of these is the much greater quantity of water on the present

41
Changes which have taken place in consequence of the deluge.

Deluge. present than on the old world. Dr Keil has indeed endeavoured to prove, that the present extent of the surface of the waters is necessary to raise such a quantity of vapours as may supply the surface of the earth with rain and with springs. In answer to this, it is said, that it may justly be questioned whether all springs are derived from the vapours raised by the sun's heat? and, 2. Whether the primitive earth stood in need of such a quantity of rain to render it fertile as the present? Dr Woodward gives the following reason for supposing the antediluvian seas to have been nearly of the same extent with those at present, viz. that "the spoils of the sea, the shells and other marine bodies, are left in such prodigious numbers, and in heaps upon heaps in the earth, besides those which have long since perished, that they could not have been left in such quantities had not the seas occupied much the same space as they do now." This argument, however, is thought by Mr Cockburn to be also inconclusive: "For (says he) 1. Animal food, whether fish or flesh, was not used by mankind before the deluge: but, 2. Suppose it had, yet for the first 500 years the number of mankind was but small, and likely at a great distance from the sea; so that the increase of all kinds of fish during so long a time must have been prodigious. We need not be surpris'd, then, at the immense quantities of the exuviae of marine animals left on the earth by the deluge. But the reason he brings to prove that the several continents of the world were encompassed by seas as they are now, viz. that as there are different sorts of fishes in the different seas of the world, so the exuviae of the same kind are generally found upon contiguous lands, does not always hold, since there are some shells found in the continent which are strangers to the parts of the sea conterminous to these continents. That the seas in the present earth are vastly more extended, and consequently the dry land so much less in proportion, may likewise be inferred from the great multitude of islands that lie near the shores of the greater continents, if it be true what some allege, that they are parts broken off by the deluge from the main land, which before that reached to and beyond them. And though islands are thought to be rarely found in the great ocean, yet there have of late been found in the midst of the Indian ocean vast clusters of islands, &c.

To all this it may be replied, That the Mosaic account says nothing of the extent of the seas either before or after the flood; but simply tells us, that the waters were poured out upon the surface of the earth from the windows of heaven and the fountains of the deep, and that as the flood decreased the waters returned from off the face of the earth. If part of them returned, we have not the least reason to suppose that the whole did not do so likewise. That the fish, as well as land animals, were more numerous in the antediluvian world than now when such quantities are destroyed by mankind, is very probable, as we see they abound to this day in uninhabited places. This may account for the astonishing quantities of their exuviae to be met with in many different parts of the earth; but from the formation of islands nothing can be concluded concerning the antediluvian world. The late discoveries have shown that many islands have a volcanic origin; others are formed by the growth of

coral; some by an accumulation of sea-weeds and other matters floating upon the surface of the ocean, and contained upon sand banks or sunk rocks; while not a few of those near the great continents owe their origin to the quantities of mud brought down by the great rivers which empty themselves into the ocean. Authentic history scarce affords an instance of an island formed by the breaking off a piece from the continent, though it does many of islands being joined to continents by some one or other of the causes just mentioned.

The inferior fertility of the earth after the deluge is much insisted upon by the same author, for the following reasons: "1. The grant of animal food to Noah and his posterity; which he thinks is an indication of greater barrenness in the ground than formerly. 2. Our Saviour compares the days of Noah with those of Lot; and as the country about Sodom is said to have been exceedingly fertile like *the garden of the Lord*, he is of opinion that the antediluvian world must have been very fertile also. 3. As (according to Dr Woodward) the first earth brought forth all manner of plants of itself without any labour or culture of man, and even before there was a man to till the ground, we may reasonably suppose that the exterior stratum or surface of the earth consisted of such terrestrial matter as was fit for these productions; that is, of a rich light mould, affording plentifully matter for vegetation. Now, though God was pleased, upon man's transgression, to withdraw in part his benediction from the earth; yet the earth itself was untouched till the deluge, the same surface of rich mould was still upon it, and brought forth plentifully, especially when man's culture for corn was added. But the inundation of waters at the deluge greatly altered the constitution of the earth itself: it mixed and confounded this upper stratum of vegetative earth with other terrestrial matter not fit for vegetation, with sand, gravel, stones, and all kinds of mineral matter, which must needs render the earth in general much less fertile than before, and which made the plough necessary to dig up the proper vegetative mould and bring it to the surface, and also manure or compost to increase and enrich; neither of which before the flood it needed. 4. There is a moral reason why the earth after the flood should be less fertile than before. The luxuriant productions of the first earth, after man's nature became corrupted, and to deviate more and more from righteousness, served only to excite and foment his lusts, and to minister plentiful fuel to his vices and luxury. To cut off, therefore, such occasion of sin and wickedness, God, in great mercy to men, retrenched the earth in its former fertility, thereby obliging them to labour and diligence, and employing most of their time to procure their necessary subsistence, which the earth by diligent culture will still afford, but not that luxuriant abundance it did before the flood. If we take a survey of the different regions and countries of the world, we shall find this to be the truth of the case. Some places, both in Asia and America, are as it were a paradise in respect of the rest, to show us perhaps what was and would have been the state of the earth had not men sinned; but far the greatest part is nothing to be compared to these, and evidently shows that effect which the sins of men had upon the

Deluge. earth itself. In a word, if we take a survey of the whole, it cannot be thought that the first blessing was restored to the earth after the flood, or that it came out of the hands of its maker in the state it is at present, since so great a part of it bears still the marks of the curse laid upon it."

Notwithstanding all that is here alleged, the extraordinary fertility of the ancient earth must still appear very problematical, if we consider all circumstances. For,

1. Even at the creation, when the earth was at its utmost perfection, we cannot suppose that every part of it produced spontaneously like the garden of Eden. On the contrary, we are told that this garden was *planted* by the Lord God, and that Adam was put into it to *dress it* and to *keep it*. It appears, therefore, that even in the Paradisaical state the earth would not have produced food for man without culture; for as God *planted* the first garden, there can be no doubt that had man continued in his state of innocence and multiplied, he must have *planted* other gardens when it became necessary. After the fall, the fertility of the earth was expressly removed, and that not in a slight degree; but if we can judge from the present state of things, it must have become extremely wild and barren. Thus, when it is said, "Thorns also and thistles shall it bring forth to thee;" we may judge of the state of the soil from that which we see bringing forth thorns and thistles at this day. Every one knows that an abundant crop of these weeds indicates poor ground, which will require a great deal of cultivation to bring it into order. Nay, that we may be sure that the cultivation of the earth was at this time no easy matter, it is likewise said, "In sorrow shalt thou eat of it all the days of thy life." Hence it would appear, that the antediluvian earth, instead of being more fertile, was much more barren than at present. That the labour of cultivating the ground at that time was also so great as to be almost intolerable, is evident from the speech of Lamech on the birth of Noah: "This same (says he) shall comfort us concerning our work and toil of our hands, concerning the ground which the Lord hath cursed."

2. There is a very evident natural reason why the antediluvian world should have been more barren than the present, and why the deluge should have removed that barrenness. Under the article ANTEDILUVIANS, n^o 19, it is hinted, that the purity of the air at that time was a principal cause of the longevity of the human race. If this was really the case, which is very probable, we must suppose the atmosphere to have then contained a greater quantity of *dephlogisticated air* than it does at present; for late experiments have put it beyond doubt, that from this the support of animal life is immediately derived. But this kind of air, however favourable to animal life, is found to be very unfavourable to vegetation; and therefore, in proportion to its abundance in the antediluvian atmosphere, the animals would be healthy, and the vegetables weak, puny, and sickly. But the deluge, by overflowing the earth for a whole year, destroyed every animal and vegetable, and consequently induced a vast putrefaction all over the globe; the consequence of which was the production of an immense quantity of what is called *phlogisticated air*. This mixing with the pure atmo-

sphere, vitiated it to such a degree as to make it less friendly to animal life, but more so to vegetation. Hence the present world must naturally be more fertile than the former; and not only on this account, but by reason of its being manured by the stagnation of the waters upon its surface for a twelvemonth, and the immense quantity of animal matter left by them, the ground, instead of being lessened in its fertility as Dr Woodward supposes, must have been restored, as far as we can judge, to the very state it was in at its original formation.

3. That this was really the case appears probable from what the Deity said to Noah after offering up his sacrifice. "I will not (says he) curse the ground any more for man's sake." Now this was plainly intimating that the earth was restored to its primitive fertility, and that he would no more take it away; for when he did so to the primitive world it was in these words, "Cursed is the ground for thy sake." That the curse here alluded to was really the depriving the earth of its fertility, and not the overflowing the earth with water, is evident; because, after declaring that he would no more curse the ground for man's sake, he adds, "Neither will I again smite every living thing as I have done."

4. The moral reasons assigned why the present world should be less fertile than the former, seem to be inconclusive. However barren we may reckon the earth just now, it is certain that it produces, or might produce, much more than would suffice for all its inhabitants. The difficulties which mankind undergo are not at all owing to the barrenness of the earth; but to their own conduct, or their oppression of one another. Neither does it clearly appear that animal food is really in any degree cheaper than vegetable, but rather the contrary; so that whatever was the reason of this grant after the flood, we cannot fairly ascribe it to a foresight of the future barrenness of the earth.

Another question which naturally occurs on the subject of the deluge is, Whether there was any rain before it or not? The argument against the existence of rain before the flood is obviously derived from the rainbow being made a symbol of the divine favour immediately after. It is certain, indeed, that unless we suppose the nature of light or of water to have been different before this event from what it was afterwards, there is a natural impossibility of the refraction of the sun's light being prevented from showing the appearance of a rainbow whenever the sun and cloud were in a certain position with regard to one another. It appears improbable, to those who take this side of the question, that the Deity should institute any thing as an emblem of his displeasure being turned away, when the same emblem had been seen perhaps a very short time before the catastrophe happened. On the other hand it is replied, that there is no absurdity in supposing this to have been the case: for though the rainbow existed before the deluge, yet it never was appointed to be the symbol of this particular event, viz. the reconciliation of the Deity; and the impossibility of vegetables being supplied with a sufficient quantity of moisture without rain is likewise urged as a decisive argument. Still, however, it appears, that even vegetation may subsist, and that in its utmost perfection,

Deluge.

Demades ||
Demetrius. fection, without rain : for we are informed, that by means of a mist the ground was originally watered, and vegetables supplied with moisture, before there was any rain ; and if this was the case at one time, it might have been at any other, or at any number of times we can suppose. Indeed, as matters stand at present, this would undoubtedly be a very scanty supply ; and perhaps so it was in the antediluvian world : and thus the want of rain might have been one cause of that barrenness in the antediluvian world which we have already mentioned as probable, and which Mr Bryant mentions as the opinion of all the ancient mythologists.

For particular deluges, or overflowings of various parts of the earth by water, see the article **INUNDATION**.

DEMADES, a famous Athenian, who, from being a mariner, became a great orator, and appeased Philip by his eloquence, after the famous victory over the Athenians at Cheronea, in the 338th year B. C.

DEMAIN, or **DEMESNE**, in its common acceptation, is used for the lands round a manor-house, occupied by the lord.

DEMAIN, or *Demefne*, in law, is commonly understood to be the lord's chief manor-place, with the lands thereto belonging, which he and his ancestors have, time out of mind, kept in their own manual occupation.

DEMAND, in its popular sense, denotes a calling for or requiring one's due.

DEMAND, in law, has a more special signification, as contradistinguished from *plaint* : for all civil actions are pursued either by demands or complaints ; according to which the pursuer is called either *demandant* or *plaintiff* : viz. in real actions, *demandant* ; and in personal actions, *plaintiff*. See **PLAINTIFF**.

There are two kinds of demands : the one in *deed*, *de facto*, as in every precipe : the other in *law*, *de jure* ; such is entry in land, distress for rent, &c.

DEMEMBRATION, in Scots law. See **Law**, N^o clxxxvi. 17.

DEMEMBRE, in heraldry, is said of dismembered animals, or those with their limbs cut off.

DEMENSE. See **DEMAIN**.

DEMESNE LANDS. See **REVENUE**, n^o 5.

DEMETÆ (anc. geog.), a people of Britain, considered as a branch of the Silures, occupying that inner corner formed by the Bristol Channel and the Irish Sea.

DEMETRIA, a festival in honour of Ceres, called by the Greeks *Demeter*. It was then customary for the votaries of the goddess to lash themselves with whips made with the bark of trees. The Athenians had a solemnity of the same name in honour of Demetrius Poliorcetes.

DEMETRIOWITZ, a city of the duchy of Smolensko, in the Russian empire, situated upon the river Ugra, in E. Long. 37. 0. N. Lat. 53. 20.

DEMETRIUS, a son of Antigonus and Stratonice, surnamed *Poliorcetes*, "Destroyer of towns." At the age of 22, he was sent by his father against Ptolemy, who invaded Syria. He was defeated near Gaza ; but he soon repaired his loss by a victory over one of the generals of the enemy. He afterwards sailed with

a fleet of 250 ships to Athens, and restored the Athenians to liberty, by freeing them from the power of Cassander and Ptolemy, and expelling the garrison, which was stationed there under Demetrius Phalereus. After this successful expedition, he besieged and took Munychia, and defeated Cassander at Thermopylæ. His reception at Athens after these victories was attended with the greatest fervility, and the Athenians were not ashamed to raise altars to him as to a god, and consult his oracles. This uncommon success raised the jealousy of the successors of Alexander, and Seleucus, Cassander, and Lyfimachus united to destroy Antigonus and his son. Their hostile armies met at Ipsus, 299 years before the Augustan age. Antigonus was killed in the battle ; and Demetrius, after a severe loss, retired to Ephesus. His ill success raised him many enemies ; and the Athenians, who had lately adored him as a god, refused to admit him into their city. He soon after ravaged the territory of Lyfimachus, and reconciled himself to Seleucus, to whom he gave his daughter Stratonice in marriage. Athens now laboured under tyranny, and Demetrius relieved it and pardoned the inhabitants. The loss of his possessions in Asia recalled him from Greece, and he established himself on the throne of Macedonia by the murder of Alexander the son of Cassander. Here he was continually at war with the neighbouring states, and the superior power of his adversaries obliged him to leave Macedonia, after he had sat on the throne for seven years. He passed into Asia, and attacked some of the provinces of Lyfimachus with various success ; but famine and pestilence destroyed the greatest part of his army, and he retired to the court of Seleucus for support and assistance. He met with a kind reception : but hostilities were soon begun ; and after he had gained some advantages over his son-in-law, Demetrius, was totally forsaken by his troops in the field of battle, and became an easy prey to the enemy. Though he was kept in confinement by his son-in-law, yet he maintained himself like a prince, and passed his time in hunting and in every laborious exercise. His son Antigonus offered Seleucus all his possessions, and even his person, to procure his father's liberty ; but all proved unavailing, and Demetrius died in the 54th year of his age, after a confinement of three years, 286 years before Christ. His remains were given to Antigonus, and honoured with a splendid funeral pomp at Corinth, and thence conveyed to Demetrias. His posterity remained in possession of the Macedonian throne till the age of Perseus, who was conquered by the Romans. Demetrius has rendered himself famous for his fondness of dissipation when among the dissolute, and for his love of virtue and military glory in the field of battle. He has been commended as a great warrior ; and his ingenious inventions, his warlike engines, and stupendous machines in his war with the Rhodians, justify his claims to that character. He has been blamed for his voluptuous indulgences ; and his biographer observes that no Grecian prince had more wives and concubines than Poliorcetes. His obedience and reverence to his father has been justly admired ; and it has been observed, that Antigonus ordered the ambassadors of a foreign prince, particularly to remark the cordiali-

Demetrius. ty and friendship which subsisted between him and his son.

DEMETRIUS, surnamed *Conatus*, succeeded his father Antigonus on the throne of Macedonia. He reigned 12 years, and was succeeded by his son Philip.

DEMETRIUS, a son of Philip, king of Macedonia, delivered as an hostage to the Romans. His modesty delivered his father from a heavy accusation laid before the Roman senate. When he returned to Macedonia, he was falsely accused by his brother Perseus, who was jealous of his popularity, and his father too credulously consented to his death.

DEMETRIUS I. surnamed *Soter* or *Savior*, was son of Seleucus Philopator the son of Antiochus the Great, king of Syria. His father gave him as a hostage to the Romans. After the death of Seleucus, Antiochus Epiphanes, the deceased monarch's brother, usurped the kingdom of Syria, and succeeded by his son Antiochus Eupator. This usurpation displeased Demetrius, who was detained at Rome. He procured his liberty on pretence of going to hunt, and fled to Syria, where the troops received him as their lawful sovereign. He put to death Eupator and Lysias, and established himself on his throne by cruelty and oppression. Alexander Bala, the son of Antiochus Epiphanes, laid claims upon the crown of Syria, and defeated Demetrius in a battle, 250 years before Christ.

DEMETRIUS II. surnamed *Nicanor*, or *Conqueror*, was son of Soter, to whom he succeeded by the assistance of Ptolemy Philometer. He married Cleopatra, the daughter of Ptolemy, who was before the wife of the expelled monarch Alexander Bala. Demetrius gave himself up to luxury and voluptuousness, and suffered his kingdom to be governed by his favourites. At that time a pretended son of Bala, called *Diodorus Tryphon*, seized a part of Syria; and Demetrius, to oppose his antagonist, made an alliance with the Jews, and marched into the east, where he was taken by the Parthians. Phraates king of Parthia gave him his daughter Rhodogyné in marriage; and Cleopatra was so incensed at this new connection, that she gave herself up to Antiochus Sidetes her brother-in-law, and married him. Sidetes was killed in a battle against the Parthians, and Demetrius regained the possession of the kingdom. His pride and oppression rendered him odious; and his subjects asked a king of the house of Seleucus from Ptolemy Physcon king of Egypt: and Demetrius, unable to resist the power of his enemies, fled to Ptolemais, which was then in the hands of his wife Cleopatra. The gates were shut up against his approach by Cleopatra; and he was killed by order of the governor of Tyre, whither he had fled for protection, A. U. C. 627. He was succeeded by Alexander Zebina, whom Ptolemy had raised to the throne.

DEMETRIUS *Phalereus*, a celebrated orator and peripatetic philosopher, was the scholar of Theophrastus. He acquired so much authority at Athens, that he governed the city for ten years; and ruled with so much wisdom and virtue, that they set up 36 statues in honour of him. By the slanders of some malicious persons in his absence, he was, however, condemned to die; and his images were pulled down: which when Demetrius heard, he said, they could not pull down that virtue for which those images were set up. He escaped into

Egypt, and was protected by Ptolemy Lagus. This king, it is said, asked his advice concerning the succession of his children to the throne; viz. whether he ought to prefer those he had by Euridice to Ptolemy Philadelphus whom he had by Berenice? and Demetrius advised him to leave his crown to the former. This displeased Philadelphus so much, that, his father being dead, he banished Demetrius; who was afterwards killed by the bite of an asp. Demetrius composed more works in prose and verse than any other peripatetic of his time; and his writings consisted of poetry, history, politics, rhetoric, harangues, and embassies. None of them are extant except his rhetoric, which is usually printed among the *Rhetores Selecti*.

DEMETRIUS, a cynic philosopher, disciple of Apollonius Thyaneus, in the age of Caligula. The emperor wished to gain the philosopher to his interest by a large present; but Demetrius refused it with indignation, and said, If Caligula wishes to bribe me, let him send me his crown. Vespasian was displeased with his insolence, and banished him to an island. The cynic derided the punishment, and bitterly inveighed against the emperor. He died in a great old age; and Seneca observes, that "nature had brought him forth to show mankind that an exalted genius can live securely without being corrupted by the vice of the surrounding world."

DEMI (formed from *dimidium*), a word used in composition with other words to signify *half*.

DEMI-*Attici*, boroughs or larger villages of Attica. The Athenian tribes were distributed into Demi. Homer, in his catalogue, distinguishes the Athenians by the appellation *Demos*. And when Theseus prevailed on them to quit the country and settle at Athens, they still continued to frequent the Demi, and to perform their several religious ceremonies there (Pausanias, Livy).

DEMI-*Culverin*, a piece of ordnance usually $4\frac{1}{2}$ inches bore, 2700 pound weight, 10 feet long, and carrying point blank 175 paces.

DEMI-*Culverin of the least size*, is $4\frac{1}{4}$ inches bore, 10 feet long, and 2000 pound weight. It carries a ball of 4 inches diameter and of 9 pounds weight, and its level range is 174 paces.

DEMI-*Culverin of the largest sort*, is $4\frac{3}{4}$ inches bore, $10\frac{1}{2}$ feet long, and weighs 3000 pounds weight. It carries a ball $4\frac{1}{2}$ inches diameter, weighing 12 pounds 11 ounces, point blank 178 paces.

DEMI-*God*. See HERO.

DEMI-*Gorge*, in fortification, is that part of the polygon which remains after the flank is raised, and goes from the curtain to the angle of the polygon. It is half of the vacant space or entrance into a bastion.

DEMI-*Quaver*, a note in music, two of which are equal to a quaver.

DEMI-*Semi-Quaver*, in music, the shortest note, two of them being equal to a semi-quaver.

DEMISE, in law, is applied to an estate either in fee-simple, fee-tail, or for term of life or years; and so it is commonly taken in many writs. The king's death is in law termed the demise of the king.

DEMISE, and REDEMISE, denote a conveyance where there are mutual leases made from one to another of the same land, or something out of it.

DEMIURGE (from *δμιος*, which denotes a public servant,

Demetrius
||
Demiurge.

Democracy *servant*, and *εργον work*), in the mythology of the eastern philosophers, was one of the $\mu\omicron$ ns employed by the supreme Deity in the creation of the world. The character they give him is a compound of shining qualities and insupportable arrogance; and his excessive lust of empire effaces his talents and virtues. He is represented as claiming dominion over the new world he has formed, as his sovereign right; and excluding totally the supreme Deity from all concernment in it, he demands from mankind, for himself and his associates, divine honours.

DEMOCRACY, from *δημο* people, and *κρατειν* to command or govern; the same with a popular government, wherein the supreme power is lodged in the hands of the people: such were Rome and Athens of old; but as to the modern European republics, Basil only excepted, their government comes nearer to aristocracy than democracy. See LAW, no 15.

DEMOCRITUS, one of the greatest philosophers of antiquity, was born at Abdera, a town of Thrace, about the 80th Olympiad; that is, about 460 years before Christ. His father, says Valerius Maximus, was able to entertain the army of Xerxes; and Diogenes Laertius adds, upon the testimony of Herodotus, that the king, in requital, presented him with some Magi and Chaldeans. From these Magi and Chaldeans Democritus received the first part of his education; and from them, whilst yet a boy, he learned theology and astronomy. He next applied to Leucippus, and learned from him the system of atoms and a vacuum. His father dying, the three sons, for so many there were, divided the estate. Democritus made choice of that part which consisted in money, as being, though the least share, the most convenient for travelling; and it is said, that his portion amounted to above 100 talents, which is near 20,000l. Sterling. His extraordinary inclination for the sciences and for knowledge, induced him to travel into all parts of the world where he hoped to find learned men. He went to visit the priests of Egypt, from whom he learned geometry; he consulted the Chaldeans and the Persian philosophers; and it is said, that he penetrated even into India and Ethiopia, to confer with the Gymnosophists. In these travels he wasted his substance; after which, at his return, he was obliged to be maintained by his brother; and if he had not given proofs of the greatest understanding, and thereby procured to himself the highest honours, and the strongest interest of his country, he would have incurred the penalty of that law which denied the interment in the family-sepulchre to those who had spent their patrimony. After his return from travelling, he lived at Abdera, and governed there in a most absolute manner, by virtue of his consummate wisdom. The magistrates of that city made him a present of 500 talents, and erected statues to him even in his lifetime: but being naturally more inclined to contemplation than delighted with public honours and employments, he withdrew into solitude and retirement. Democritus incessantly laughed at human life, as a continued farce, which made the inhabitants of Abdera think he was mad; on which they sent for Hippocrates to cure him: but that celebrated physician having discoursed with the philosopher, told the Abderians, that he had a great veneration for Democritus; and that, in his opinion, those who esteemed themselves the most heal-

thy were the most distempered. Democritus died, according to Diogenes Laertius, in the 361st year before the Christian era, aged 109. It is said that he put out his eyes, in order that he might meditate more profoundly on philosophical subjects; but this has little probability. He was the author of many books, which are lost; and from these Epicurus borrowed his philosophy.

DEMONSTRABLE, a term used in the schools to signify that a thing may be clearly proved. Thus, it is demonstrable, that the three angles of a triangle are equal to two right ones.

DEMONSTRATION, in logic, a series of syllogisms, all whose premises are either definitions, self-evident truths, or propositions already established. See LOGIC.

DEMONSTRATIVE, in grammar, a term given to such pronouns as serve to indicate or point out a thing. Of this number are *hic, hac, hoc*, among the Latins; and *this, that, these those*, in English.

DEMONSTHENES, the famous Athenian orator, was born at Athens 381 B. C. He lost his father at seven years of age; and was placed under the conduct of guardians, who robbed him of his substance, and neglected his education. Demosthenes repaired this loss by his love of eloquence and his extraordinary abilities. He became the disciple of Isæus and Plato, and applied himself to study the orations of Isocrates. At the age of 17 he gave an early proof of his eloquence and abilities against his guardians, from whom he obtained the retribution of the greatest part of his estate. His rising talents were, however, impeded by various natural defects. But these were at last conquered by dint of resolution and unwearied attention. He declaimed by the sea-shore, that he might be used to the noise of a tumultuous assembly; and with the pebbles in his mouth, that he might correct a defect in his speech. He practised at home with a naked sword hanging over his shoulder, that he might check an ungraceful motion to which he was subject. He also confined himself in a subterraneous cave, to devote himself more closely to studious pursuits; and to eradicate all curiosity of appearing in public, he shaved one half of his head. In this solitary retirement, by the help of a glimmering lamp, he composed the greatest part of his orations, which have ever been the admiration of every age; though his contemporaries and rivals inveighed against them, and observed that they smelt of oil. His abilities as an orator raised him to consequence at Athens, and he was soon placed at the head of government. In this public capacity he roused his countrymen from their indolence, and animated them against the encroachment of Philip of Macedonia. In the battle of Cheronæa, Demosthenes betrayed his pusillanimity, and saved his life by flight. After the death of Philip, he declared himself warmly against his son and successor Alexander; and when the Macedonians demanded of the Athenians their orators, Demosthenes reminded his countrymen of the fable of the sheep which delivered their dogs to the wolves. By the prevalence of party, however, he was forced to retire from Athens; and in his banishment, which he passed at Trezen and Ægina, he lived with more effeminacy than true heroism. When Antipater made war against Greece after the death of Alexander, Demosthenes

Demosthenes.
Demosthenes.

Demosthenes.

henes was publicly recalled from his exile, and a galley was sent to fetch him from Ægina. His return was attended with much splendor, and all the citizens crowded at the Piræus to see him land. His triumph and popularity were short. Antipater and Craterus were near Athens, and demanded all the orators to be delivered up into their hands. Demosthenes fled to the temple of Neptune in Calauria; and when he saw that all hopes of safety were vanished, he took a dose of poison, which he always carried in a quill, and expired on the day that the Thesmophoria were celebrated, 322 years before Christ. The Athenians raised a brazen statue to his honour, with an inscription translated into this distich:

*Si tibi par menti robur, Vir magne, fuisset,
Græcia non Macedo succubisset hero.*

Demosthenes has been deservedly called *the prince of orators*. Indeed no orator had ever a finer field than Demosthenes in his Olynthiacs and Philippics, which are his capital orations; and undoubtedly to the greatness of the subject, and to that integrity and public spirit which breathe in them, they owe a large portion of their merit. The subject is, to excite the indignation of his countrymen against Philip of Macedon, the public enemy of the liberties of Greece; and to guard them against the treacherous measures by which that crafty tyrant endeavoured to lull them into a neglect of their danger. To attain this end, we see him use every proper means to animate a people distinguished by justice, humanity, and valour; but in many instances become corrupt and degenerate. He boldly accuses them of venality, indolence, and indifference to the public good: while, at the same time, he reminds them of their former glory, and of their present resources. His contemporary orators, who were bribed by Philip, and who persuaded the people to peace, he openly reproaches as traitors to their country. He not only prompts to vigorous measures, but teaches how they are to be carried into execution. His orations are strongly animated, and full of the impetuosity and ardour of public spirit. His composition is not distinguished by ornament and splendor. It is an energy of thought, peculiarly his own, which forms his character, and raises him above his species. He seems not to attend to words, but to things. We forget the orator, and think of the subject. He has no parade and ostentation, no studied introductions: but is like a man full of his subject; who, after preparing his audience by a sentence or two for the reception of plain truths, enters directly on business.

The style of Demosthenes is strong and concise; though sometimes, it must be confessed, harsh and abrupt. His words are highly expressive, and his arrangement firm and manly. Negligent of lesser graces, he seems to have aimed at the sublime which lies in sentiment. His action and pronunciation are said to have been uncommonly vehement and ardent; which, from the manner of his writings, we should readily believe. His character appears to have been of the austere rather than of the gentle kind. He is always grave, serious, passionate; never degrading himself, nor attempting any thing like pleasantries. If his admirable eloquence be in any respect faulty, it is that he sometimes borders on the hard and dry. He

may be thought to want smoothness and grace: which is attributed to his imitating too closely the manner of Thucydides, who was his great model for style, and whose history he is said to have transcribed eight times with his own hand. But these defects are more than atoned for by that masterly force of masculine eloquence, which, as it overpowered all who heard it, cannot in the present day be read without emotion.

CICERO calls him a perfect model, and such as he himself wished to be. These two great princes of eloquence have been often compared together; but the judgment hesitates to which to give the preference. The Archbishop of Cambray, however, seems to have stated their merits with great justice and perspicuity in his Reflections on Rhetoric and Poetry. The passage, translated, is as follows. "I do not hesitate to declare, that I think Demosthenes superior to Cicero. I am persuaded no one can admire Cicero more than I do. He adorns whatever he attempts. He does honour to language. He disposes of words in a manner peculiar to himself. His style has great variety of character. Whenever he pleases, he is even concise and vehement; for instance, against Cataline, against Verres, against Antony. But ornament is too visible in his writings. His art is wonderful, but it is perceived. When the orator is providing for the safety of the republic, he forgets not himself, nor permits others to forget him. Demosthenes seems to escape from himself, and to see nothing but his country. He seeks not elegance of expression; unfought for he possesses it. He is superior to admiration. He makes use of language, as a modest man does of dress, only to cover him. He thunders, he lightens. He is a torrent which carries every thing before it. We cannot criticize, because we are not ourselves. His subject enchains our attention, and makes us forget his language. We lose him from our sight: Philip alone occupies our minds. I am delighted with both these orators; but I confess that I am less affected by the infinite art and magnificent eloquence of Cicero, than by the rapid simplicity of Demosthenes."

DEMPSTER (Thomas), a very learned man, but of a singular character. He was born in Scotland, but we do not find in what year. He went over to France for the sake of embracing the catholic religion, and taught classical learning at Paris about the beginning of the 17th century. Tho' his business was to teach school; yet he was as ready to draw his sword, and as quarrelsome as if he had been a duellist by profession: and it is said, that there scarce passed a day but he had something or other of this kind upon his hands. This spirit and turn of temper drew him into many scrapes; and one in particular, which obliged him to quit the country. Grangier, principal of the college of Beauvais at Paris, being obliged to take a journey, appointed Dempster his substitute. Dempster caused whip a scholar, in full school, for challenging one of his fellows to fight a duel. The scholar, to revenge this affront, brought three gentlemen of his relations, who were of the king's life-guards, into the college. Dempster made the whole college take arms; hamstringed the three life-guard-men's horses before the college gate; and put himself into such a posture of defence, that the three sparks were forced to ask for quarter. He gave them their lives; but imprisoned them, and did not

Demosthenes
Dempster.

Dempster
||
Denbigh

not release them for some days. They sought another way to revenge themselves: they caused an information to be made of the life and moral behaviour of Dempster, and got some witnesses to be heard against him. Upon this he went over to England, where he found refuge; but did not make any long stay. He went abroad again, and read lectures upon polite learning in several universities; in that of Nismes particularly, where he disputed for a professor's chair, and obtained it. He went to Bologna, and was professor there for the remainder of his life; and was then also admitted a member of the Academy della Rotte. He died there in September 1625, leaving behind him several learned works; as Commentaries on *Rosinus de Antiquitatibus Romanorum*, and upon Claudian, &c.; four books of Epistles; several dramatic pieces, and other poems; some books of law; an Apparatus to the History of Scotland; a Martyrology of Scotland; and a List of the Scottish Writers.

DEMPSTER of Court, the name formerly given in Scotland to the common executioner or hangman.

DEMSTER, or DEEMSTER. See DEEMSTER.

DEMULCENTS, among physicians, medicines good against acrimonious humours. Such are the roots of marsh-mallows, of white lilies, of liquorice, and of viper-grass, the five emollient herbs, &c.

DEMURRAGE, in commerce, an allowance made to the master of a ship by the merchants, for staying in a port longer than the time first appointed for his departure.

DEMURRER, in law, a stop put to any action upon some point of difficulty which must be determined by the court, before any further proceedings can be had in the suit.

DEN, a syllable which, added to the names of places, shows them to be situated in valleys or near woods; as Tenterden.

DENARIUS, in Roman antiquity, the chief silver coin among the Romans, worth in Sterling money about sevenpence three farthings. As a weight, it was the seventh part of a Roman ounce.

DENARIUS is also used in law-books for an English penny.

DENBIGHSHIRE, a county of Wales, bounded on the south by Merioneth and Montgomery shires, on the north by Flintshire and the Irish Sea, on the west by Caernarvon and part of Merionethshire. It is about 40 miles long and 21 broad. The air is wholesome, but sharp; the county being pretty hilly, and the snow lying long on the tops of the mountains. The soil in general is barren; but the vale of Clwyd, so called from its being watered by that river, is a very fertile pleasant spot, of great extent, and well inhabited. The chief commodities are black cattle, sheep, and goats, rye, called here *amelcorn*, and lead-ore. The county sends two members to parliament, *viz.* knight for the shire, and a burghers for Denbigh the capital.

DENBIGH, the capital town of Denbighshire in N. Wales. It is seated on the side of a rocky hill, on a branch of the river Clwyd, and was formerly a place of great strength, with an impregnable castle, now demolished. It is pretty large, well built, and inhabited by tanners and glovers, and gives the title of Earl to the noble family of Fielding. W. Long. 3. 30. N. Lat. 53. 15.

DENDERMOND, a handsome and strong town of the Austrian Netherlands, in Flanders, with a strong citadel. It was taken by the allies in 1706, and by the French in 1745. It is surrounded by marshes and fine meadows, which the inhabitants can lay under water when they please. It is seated at the confluence of the rivers Dender and Schelde. E. Long. 4. 3. N. Lat. 51. 3.

DENDRACHATES, in natural history, the name used by the ancients for an extremely elegant and beautiful species of agate, the ground of which is whitish, variegated with veins of a brighter white. These veins are beautifully disposed in a number of various figures; but generally in many concentric irregular circles, drawn round one or more points. It is common also, in various parts of this stone, to find very beautiful delineations of trees, mosses, sea-plants, and the like, so elegantly expressed, that many have erroneously taken them for real plants included in the substance of the stone; whence the name *dendrachates*.

DENDRANATOMY, a term used by some for a description of the various parts of trees; as root, trunk, branch, bark, wood, pith, flower, fruit, &c. See PLANTS, VEGETATION, &c.

DENDROMETER (from *dendron* for a tree and *metron* *I measure*), an instrument lately invented by Messrs Duncombe and Whittel, for which they obtained a patent, so called from its use in measuring trees. This instrument consists of a semicircle A, divided into two quadrants, and graduated from the middle; upon the diameter B there hangs a plummet L for fixing the instrument in a vertical position; there is also a chord D parallel to the diameter, and a radius E, passing at right angles through the diameter and chord. From a point on the radius hangs an altimeter C, between the chord and diameter, to which is fixed a small semicircle G, and a screw to confine it in any position. The altimeter, which is contrived to form the same angle with the radius of the instrument as the tree forms with the horizon, is divided from its centre both ways into forty equal parts; and these parts are again subdivided into halves and quarters. Upon the small semicircle G, on which is accounted the quantity of the angle made by the altimeter and radius, are expressed degrees from 60 to 120, being 30 on each quadrant. The radius is numbered with the same scale of divisions as the altimeter. There is also a nonius to the small semicircle, which shows the quantity of an angle to every five minutes. On the back of the instrument the stock M of the sliding piece is confined to the axis N, which moves concentrically parallel to the elevation index F on the opposite side, to which it is fixed. This index is numbered by a scale of equal divisions with the altimeter and radius: at the end of the index is a nonius, by which the angles of elevation above, or of depression below, the horizon, measured upon the semicircle of the instrument, are determined to every five minutes. There is also a groove in the radius, that slides across the axis by means of a screw I, working between the chord and semicircle of the instrument; and this screw is turned by the key O. Upon the stock M is a sliding piece, P that always acts at right angles with the altimeter, by means of a groove in the latter. To the flank of the sliding piece is affixed a moveable limb Q, which forms the

Dender-
mond
||
Dendrome-
ter.

Plate
CLXV.

Dendrometer.

same angle with the altimeter as the bough forms with the body or trunk of the tree. This limb may be of any convenient length, divided into equal parts of the same scale with all the foregoing divisions. At the extremity of the fixed axis, on a centre, an index R, with telescopic sights, works horizontally upon the moveable limb of the sliding piece. Upon this horizontal index R may be fixed a small quadrant T, described with any convenient radius from the centre on which the index moves, and divided into 90 degrees, beginning at a right line drawn from the centre at right angles with the fiducial edge of the said index; and upon the extremity of the axis is a nonius, whereby to determine the quantity of an angle upon the quadrant every five minutes. There are also two small circular arches S, S, serving to keep the sights in a parallel position, each containing an equal number of degrees. Upon these arches is measured the angle, subtending a side equal to the difference of the altitudes of the observed objects above the plane of the horizon, and whose base is the nearest distance between the perpendiculars in which these objects are situated. The dendrometer is fitted to a theodolite, and may be used either with or without it as occasion requires.

The principal use of this instrument is for measuring the length and diameter of any tree, perpendicular or oblique, to an horizontal plane, or in any situation of the plane on which it rests, or of any figure, whether regular or irregular, and also the length and diameter of the boughs, by mere inspection; and the inventors of it have calculated tables, annexed to their account of the instrument itself, by the help of which the quantity of timber in a tree is obtained without calculation, or the use of a sliding rule. The instrument is rectified by setting it in a perpendicular position, by means of the plummet, and screwing it to the staff; then the altimeter is placed in the exact position of the tree, whether perpendicular, reclining, or inclining, and screwed fast. If the tree stands on level ground, the horizontal distance from the tree to the axis of the instrument is measured with a tape-line, and the radius is moved with the key till that distance be cut upon it by the inside of the diameter: but if the ground be slanting, the distance from the tree to the instrument is measured, and the elevation index is moved till the point of the tree from which the distance was measured is seen through the sights, and there screwed fast; and the radius is moved backwards or forwards with the key till this distance is cut upon the elevation index by the perpendicular line of the altimeter; and the horizontal line will be marked upon the radius by the inside of the diameter. In order to obtain the length of the tree, the elevation index is first moved downwards, till the bottom of the tree cut by the horizontal wires is observed through the lights, and the feet and inches marked by the index upon the altimeter below the point of sight or horizontal line are noted down; then the index is moved upwards till the part to which you would measure, cut by the horizontal wires, is seen, and the feet and inches marked on the altimeter above the point of sight are noted: these two quantities added together give the exact length of the tree, which is inserted in a field-book. For the girth of the tree, the circumference

in that part where the horizontal distance was taken, is measured with the tape-line; and a sixth part of this circumference is added to the distance on the radius, which was before cut by the inside of a diameter, because the tape-line, in taking, the distance, cannot be applied to the centre of the body of the tree; then the elevation index is lowered to that part of the tree, of which the diameter is to be taken and screwed fast. Set the moveable limb of the sliding piece quite straight, and the edge of the horizontal index upon the first division of it. Turn the whole instrument about to the left hand till you see through the sights the left side of the tree cut exactly by the perpendicular wires; then the instrument being fixed, move the sights only upon the sliding piece, till you see the right side of the tree cut also by the perpendicular wires; and you will find the true diameter marked by the horizontal index upon the sliding piece, which is to be entered in a distinct column of the field-book.

For the boughs: let the distance on the radius be now reduced to its former quantity, and the elevation index moved upwards till the bough is seen through the sights and screwed fast. Set the moveable part of the sliding piece in a position parallel to the bough, and the edge of the horizontal index on the first division of it. Turn the whole instrument about till you see through the sights the shoot of the bough close to the trunk cut by the perpendicular wires; then move the sights till you see the other end of the bough cut by the said wires, and note the feet and inches marked by the horizontal index on the moveable limb of the sliding piece, which will give the true length of the bough to be inserted in the field-book. And the girth of the bough may be obtained by directing the sights of that part of it whose girth is desired; then by moving the elevation index downwards till you see the under side of the bough cut by the horizontal wires, and there noting the feet and inches marked by the said index on the altimeter; after which, let the elevation index be moved upwards till the upper side of the bough cut by the horizontal wires is seen; the feet and inches marked upon the altimeter are to be noted as before. The former quantity subtracted from the latter will give the true diameter of the bough, which is entered in the field-book. The true solidity both of the body of the tree and of the boughs may be found from the diameter and lengths in tables calculated for this purpose.

The dendrometer, fitted to a theodolite, may be applied to measuring the heights and distances of objects, accessible or inaccessible, whether situated in planes parallel or oblique to the plane in which the instrument is placed. It may be also used for taking all angles, whether vertical, horizontal, or oblique, in any position of the planes in which they are formed; and thus for facilitating the practical operations of engineering, land surveying, levelling, mining, &c. and for performing the various cases of plane trigonometry without calculation; of which the inventors have subjoined to their account of this instrument many examples.

DENDROPHORIA, in antiquity, the carrying of boughs or branches of trees; a religious ceremony so called, because certain priests called from thence

dendrophori,

Dendrometer, Dendrophoria.

Deneb *dendrophori*, tree-bearers marched in procession, carrying the branches of trees in their hands in honour of some god, as Bacchus, Cybele, Sylvanus, &c. The college of the dendrophori is often mentioned in ancient marbles; and we frequently see in basso-relievos the bacchanals represented as men carrying little shrubs or branches of trees.

Denmark.

DENEb, an Arabic term signifying *tail*, used by astronomers to denote several fixed stars. Thus, *deneb elect*, signifies the bright star in the lion's tail. *Deneb adigege*, that in the swan's tail, &c.

DENHAM (Sir John), an eminent English poet, the only son of Sir John Denham, chief baron of the exchequer in Ireland, and one of the lords commissioners there, was born in Dublin in 1615; but his father, in 1617, being made a baron of the exchequer in England, he received his education in that country. In his youth he followed gaming more than any thing else; but, in 1641, published a tragedy called the *Sophy*, which was much admired by the best judges; and, in 1643, wrote his famous poem called *Cooper's Hill*; which Mr Dryden pronounces will ever be the standard of good writing for majesty of style. Denham was sent ambassador from Charles II. to the king of Poland; and at the Restoration was made surveyor-general of his majesty's buildings, and created knight of the Bath. On obtaining this post, he is said to have renounced his poetry for more important studies; though he afterwards wrote a fine copy of verses on the death of Cowley. He died at his office in Whitehall in 1668; and his works have been often since printed.

DENIER, a small French copper-coin, of which twelve make a sol.

There were two kinds of deniers, the one tournois, the other paris, whereof the latter was worth a fourth part more than the former.

DENIZEN, in English law, an alien made a subject by the king's letters-patent; otherwise called *donation*, because "his legitimation proceeds *ex donatione regis*, from the king's gift."

A denizen in Britain is in a kind of middle state between an alien and a natural born subject, and partakes of both of them. He may take lands by purchase or devise, which an alien may not; but cannot take by inheritance; for his parent, through whom he must claim, being an alien, had no inheritable blood, and therefore could convey none to the son; and, upon a like defect of blood, the issue of a denizen born before denization, cannot inherit to him; but his issue born after may. A denizen is not excused from paying the alien's duty, and some other mercantile burdens. And no denizen can be of the privy council; or either house of parliament, or have any office of trust civil or military, or be capable of any grant of lands, &c. from the crown.

DENMARK, one of the most ancient monarchies in Europe, comprehending the peninsula of Jutland, and the islands of Zealand, Tunen, &c. But Denmark, properly so called, is only that part of Scandinavia which formerly went by the name of *Cimbrica Chersonesus*, and now is called *Jutland*. Including Holstein, it is bounded by the sea called the *Gategate* on the north; by the Baltic on the east; by the river Elbe, which separates it from Bremen, on the south; and by

VOL. V.

the duchy of Saxe-Lawenburg towards the south-east, Denmark, extending from 54. 40. to 58. 20. N. Lat.

The origin of the name *Denmark* is very uncertain. The most probable conjecture concerning it is that of *Saxo-Grammaticus*, the most ancient and best Danish historian. He derives it from *Dan* the son of *Humble*, the first king, and *Mark* or *Mare*, forming a country in several dialects of the Teutonic; according to which etymology, the word *Denmark* signifies the land, or country, of *Dan*.—This *Dan* is thought to have lived about 1038 years before the Christian era. Almost all historians agree that he was the son of *Humble*, a native of Zealand. His possessions and influence were very considerable, not only in Zealand, but in the islands of Langland and Molua. It was his courage, however, and skill in the art of war, that induced the inhabitants of Denmark to choose him for their king. He was called to the assistance of the Jutlanders upon an irruption of the Saxons into their territories, and promised the sovereignty of the country if he drove out the enemy. On this he immediately raised an army, gained a complete victory over the Saxons, and obliged them to leave the country; and he was accordingly elected king.

In such early ages as these, we are not to look for any authentic history either of this or any other kingdom. The history of Denmark, for a great number of ages after the reign of *Dan*, is filled with fabulous exploits of heroes, encounters with giants, dragons, &c. One of their kings named *Frotho*, who reigned about 761 years before Christ, is said to have conquered all Britain, Sleswick, Russia, Pomerania, Holstein, &c. an assertion which cannot easily be credited, considering the difficulty which succeeding warriors, even the greatest in the world, found to subdue the inhabitants of those countries.—It is certain, however, that anciently the kingdom of Denmark made a much more conspicuous figure than it does at present. The Danes appear to have had a very considerable naval force almost from the foundation of their empire; and the conquests they undoubtedly made in Britain are certain proofs of their valour.

The natural enemies of the Danes were the Swedes, Norwegians, and Saxons; especially the first. With one or other of these nations almost perpetual war was carried on. The kingdom was also often rent by civil dissensions; which the neighbouring monarchs did not fail to take advantage of, in order to reduce the kingdom of Denmark under their subjection. As neither party, however, generally came off with advantage, the history of these wars affords nothing interesting or entertaining.—One of the greatest of the Danish monarchs was *Valdemar I.* who obtained the throne in 1157; having defeated and killed his competitor *Swen*, a great monarch. He maintained a long war with the Vandals, whose power he at last entirely broke, and reduced under his subjection the island of Rugen. He also proved victorious over the Norwegians, so that their king and queen came in person to submit to him. In 1165, he also laid the foundations of the city of Dantzic: which, though it hath since become a place of such consequence, consisted at first only of a few poor fishermen's huts; but the privileges and immunities conferred upon it by this monarch, soon proved the means of its becoming a flourishing city.

5 C

Denmark. city.—In 1169, he entirely subdued the Courlanders ; and, soon after, was invested with the duchy of Holstein, by the emperor Frederic Barbarossa. He is said to have been poisoned by a quack medicine, given with a design to recover him from a distemper with which he was seized in 1182.

5
Power of Denmark in 1195. In the year 1195, Canute, Valdemar's successor, caused a muster to be made of all the men fit to bear arms in his dominions ; and ordered each province to fit out its proportion of shipping, every way equipped, and ready for action. The whole force of Denmark, at that time, consisted of 670 ships of war, besides the squadrons supplied by vassals, tributary states, and allies. The number of land forces is not mentioned. In the reign of this prince, the Danish dominions were enlarged by the entire conquest of Stromar ; the districts of Lubec and Hamburg, formerly known by the name of *Nordalbingia*, but now included under the general name of *Holstein*. He died in 1203, and was succeeded by Valdemar II, who proved a very great and warlike prince. In 1121, he founded the city of Stralsund, opposite to the Isle of Rugen. The same year his queen died in child-bed ; and in memory of her he built the castle of *Droningholm*, that name im-

6
Expedition of Valdemar II. against the Livonians. porting the *Queen's-Island*. In 1218, he undertook an expedition against the Livonians, having received advice that they, assisted by the Lithuanians, Muscovites, and other barbarous nations, had driven from their habitations all those in their neighbourhood who had embraced Christianity, and taken an oath of allegiance to the crown of Denmark. Fitting out a powerful fleet, therefore, he immediately set sail for that country ; but his troops were no sooner landed, than they were seized with a panic at the sight of such a powerful army of savages as were assembled to oppose them. The king himself was slain at the unusual spectacle of a whole army clothed in skins, and resembling beasts more than human creatures. Encouraged, however, by the bishops who attended him, he ventured an engagement, and overthrew the barbarians with incredible slaughter. This victory was gained near the fortress of *Valdemar*, which received its name on that account.

7
Flourishing state of the kingdom. How potent and flourishing the kingdom of Denmark was at this time, appears from an estimate of the revenues of the tributary provinces, those countries conquered by Valdemar, and the standing forces of the whole kingdom. This account was copied by Pontanus from Witfeld a writer of those days, who had it from a register kept by Valdemar's steward. From the provinces were daily sent in 24 lasts of oats, 24 lasts of rye, and half that quantity of wheat ; 13 talents of cheese and butter, and nine of honey ; 24 oxen, 300 sheep, 200 hogs ; and 600 marks of coined money. This was the certain revenue : but to this was added near an equal sum from adventitious circumstances ; such as fines, forfeitures, taxes on law-suits and pleadings, with a variety of other contingencies ; the whole amounting to upwards of 100,000 marks a-day, or 23,730,000*l.* per annum ; a sum in those days almost incredible.—With this revenue were kept for constant service 1400 great and small ships for the king's use, each of which at a medium carried 121 soldiers, making the whole of the standing forces, besides garrisons, consist of 169,400 fighting men.

In 1223, a very great misfortune befel Valdemar,

notwithstanding all his power. Henry earl of Swerin, otherwise called *Henry Palatine*, a German prince, having been deprived of part of his dominions by Valdemar, surprised and carried off the king himself, and kept him close prisoner for three years. The conditions on which he at last obtained his liberty were very hard. He was obliged to pay a prodigious sum of money ; to relinquish Holstein, Swerin, Hamburg, and all his possessions on the other side of the Elbe ; and lastly, solemnly to swear that he would maintain this compulsive contract, and never take any measures to punish Henry or his associates. This treaty was signed on the 25th of March 1226.

Besides these territories which the Danish monarch had been obliged to cede by treaty, many tributary princes, took the opportunity of his captivity to recover their liberty ; and among the rest, the inhabitants of Lubec revolted, and entered into alliance with Albert duke of Saxony against Valdemar. The latter, however, was not of a disposition to submit tamely to such treatment. He obtained a dispensation from the Pope to break his engagements with Henry, and immediately entered Holstein at the head of a numerous army. Here he was met by several German princes, at the head of a very numerous army ; and a desperate engagement ensued. Valdemar at first had the advantage ; but being wounded in the eye, his troops were at last defeated with great slaughter. It doth not appear that ever the king of Denmark was able to revenge himself of his enemies, or to recover the dominions he had lost. So far from this, he was obliged, in 1228, to cede Lawenberg to the duke of Saxony, who had already seized on Ratzburg and Molna. Soon after this, his eldest son Valdemar was accidentally killed as he was hunting, and his two other sons married the daughters of his two greatest enemies. Abel, the third son, married the daughter of Adolphus duke of Holstein ; and Eric, the second, married the duke of Saxony's daughter. These misfortunes are supposed to have hastened his death, which happened in the month of April 1242.

On the death of Valdemar, the kingdom was divided between the two young princes ; and between them a war commenced the very next year. A peace was concluded the year following, and war renewed the year after ; but how long it continued, we are not informed. In 1250, Eric paid a visit to his brother Abel, intreating his mediation between him and the princes of Holstein, with whom he was then at war. Abel received him, in appearance, with great kindness, and promised that his utmost endeavours to procure a reconciliation should not be wanting ; but in the mean time, laid a plan for having him murdered at sea : this was effected, and Abel became master of the whole kingdom.

The new king did not long enjoy the sovereignty he had so wickedly obtained. He was tormented by his own conscience ; especially when he found among his brother's papers, one by which he was left heir to the whole kingdom on the decease of Eric, and many kind expressions with regard to himself. He was at last killed in a battle with his own subjects in 1252, on account of some taxes he intended to impose.

From this time to the year 1333, the kingdom of Denmark gradually declined. Usurpers established themselves

Denmark.

Kingdom divided among a number of petty tyrants.

Denmark. themselves in different provinces, while the kings of Sweden did not fail to avail themselves of the distracted state of the Danish affairs. In 1333, died Christopher II. who possessed only the cities of Scanderburg in Jutland and Neoburg in Fionia, with some few other inconsiderable places, of all the hereditary dominions of Denmark. Halland, Holbec, Calemburg, and Samsoe, were held by Canute Porfius; Schonon, Lyftre, and Bleking, by the king of Sweden, to whom they had been lately sold: John earl of Wagria had the jurisdictions of Zealand, Falstre, Laaland, and Femerin; Gerhard, of Jutland and Fionia; and Lawrence Jonea, of Lang-land and Arras.

After the death of Christopher, an interregnum of seven years ensued.—The first attempt for the sovereignty was made by Otho, second son to the late king, who laid a scheme for driving Gerhard out of Jutland; but not being able to accomplish it, he was taken prisoner, and closely confined by Gerhard.—The king of Sweden next wrote to Pope Benedict XIII. beseeching his Holiness to confirm to him the provinces of Schonon and others which he possessed; and to allow him to subdue the rest of the kingdom, which was now usurped and rendered miserable by a set of petty princes, who knew not how to govern. To influence him the more powerfully, he also promised to hold this kingdom of the Pope; and to pay him the usual tax collected by the church. This request, however, was refused. Valdemar of Sleswic, nephew to Gerhard, then aspired to the sovereignty. He had formerly been elected king; but had given over all thoughts of enjoying the sovereignty, on account of the superior influence of Christopher: but now resumed his ambitious views at the instigation of his uncle. Several of the nobility also cast their eyes on young Valdemar Christopher's son, now at the emperor's court. But while each of these princes were laying schemes to aggrandise themselves, the unhappy Danes were distressed by exorbitant taxes, famine, and pestilence: the two last in consequence of the former. The peasants neglected to cultivate the lands, which they held on a very precarious tenure; the consequence of this was poverty and an unwholesome diet; and this, co-operating with the peculiar disposition of the air, produced a plague, which destroyed more than half the inhabitants of the country. The poor dropped down dead on the streets with disease and hunger, and the gentry themselves were reduced to a state of wretchedness; yet, though the whole kingdom was evidently on the verge of ruin, ambitious projects employed the great, as if every thing had been in the most profound tranquillity.

In the midst of these grievous calamities, Gerhard, sovereign of Jutland, proposed to his nephew Valdemar an exchange of territories, which he believed would prove favourable to the designs of the latter on the crown. A treaty for this purpose was actually drawn up and signed; but the inhabitants, notwithstanding their distressed situation, so highly resented their being disposed of like cattle, from one master to another, that they refused to pay the usual taxes. Gerhard resolved to compel them; and therefore led 10,000 men, whom he had levied in Germany, into the heart of the province. Providence, however, now raised up an enemy to this tyrant. One Nicholas Norevi, a man greatly

esteemed for his courage, public spirit, and prudence, beheld with sorrow the condition to which Denmark was reduced. He had long meditated a variety of projects for its relief, and at last imagined things were in such a situation that the whole depended on his single arm. Young Valdemar, Christopher's son, had a number of adherents in the kingdom; his most dangerous enemy was Gerhard; and could he be removed, the Jutlanders would at least be free from an oppressor, and might choose Valdemar, or any other they thought proper, for their sovereign. Collecting a body of chosen horse, therefore, he marched in the night to Randerhusen, where Gerhard had fixed his head quarters; and having forced open the tyrant's quarters, immediately put him to death. He then fled with the utmost expedition; but was pursued and overtaken by a party of the enemy's horse, through which he forced his way and escaped. Gerhard's sons hearing of his death, retired into Holstein from whence they had come; leaving the army, composed chiefly of Holsteiners, to be cut in pieces by the enraged peasants, who fell upon them from every quarter.

Still, however, the Holsteiners kept possession of the citadels and fortified places, from whence Nicholas resolved to dislodge them. He accordingly raised a body of forces; attacked and took Landen, a castle situated on the river Scherne: After which he laid siege to Albeg; but the garrison making an obstinate defence, he turned the siege into a blockade, by which they were soon reduced to great extremity. The governor sent an express to the sons of Gerhard, acquainting them with the impossibility of his holding out more than a few days, without being relieved. This determined them to march to the relief of so important a place. They came up with Nicholas just as the governor was ready to surrender, but were defeated; though Nicholas was unfortunately killed in the engagement.

Jutland having thus regained its liberty, the rest of the kingdom followed its example. Zealand first openly declared itself. Here Henry, Gerhard's son, maintained several garrisons; and resolved to defend his possessions in spite of all the power of the inhabitants. For this purpose he drew together an army; but, in the mean time, a tumult arose among the peasants on account of a Danish nobleman slain by the Holsteiners. By this the people were at last so irritated, that falling upon the Holsteiners sword in hand, they killed 300 of them, drove the rest out of the island, and chose Valdemar, Christopher's son, for their sovereign.

The Danes now resumed their courage; the lands were cultivated, the famine and pestilence ceased, and the kingdom began to flourish as formerly. Matters continued in a prosperous way till 1387, when Margaret mounted the throne. She raised the kingdom to its highest pitch of glory, as partly by her address, and partly by hereditary right, she formed the union of Calmar, by which she was acknowledged sovereign of Sweden, Denmark, and Norway. She held her dignity with such firmness and courage, that she was justly styled the *Semiramis of the North*. Her successors being destitute of her great qualifications, the union of Calmar fell to nothing: but Norway still continued annexed to Denmark. About the year 1442, the

Denmark. crown of Denmark fell to Christian count of Oldenburg, from whom the present royal family of Denmark is descended; and, in 1536, the protestant religion was established in Denmark by that wise and politic prince Christian III.

Christian IV. of Denmark, in 1629, was chosen for the head of the Protestant league formed against the house of Austria: but, though brave in his own person, he was in danger of losing his dominions; when he was succeeded in that command by the famous Gustavus Adolphus, king of Sweden. The Dutch having obliged Christian, who died in 1648, to lower the duties of the Sound, his son Frederic III. consented to accept of an annuity of 150,000 florins for the whole. The Dutch, after this, persuaded him to declare war against Charles Gustavus king of Sweden, which had almost cost him his crown in 1657. Charles stormed the fortrefs of Fredericstadt; and in the succeeding winter, he marched his army over the ice to the island of Funen, where he surpris'd the Danish troops, took Odensee and Nyburg, and marched over the Great Belt to besiege Copenhagen itself. Cromwell, the English usurper, interposed: and Frederic defended his capital with great magnanimity till the peace of Roschild: by which Frederic ceded the provinces of Halland, Bleking, and Scania, the island of Bornholm, Bahus, and Drontheim, in Norway, to the Swedes. Frederic sought to elude those severe terms; but Charles took Cronenburg, and once more besieged Copenhagen by sea and land. The steady intrepid conduct of Frederic under these misfortunes endeared him to his subjects; and the citizens of Copenhagen made an admirable defence, till a Dutch fleet arrived in the Baltic, and beat the Swedish fleet. The fortune of war was now entirely changed in favour of Frederic, who showed on every occasion great abilities, both civil and military: and having forced Charles to raise the siege of Copenhagen, might have carried the war into Sweden, had not the English fleet, under Montague, appeared in the Baltic. This enabled Charles to besiege Copenhagen a third time: but France and England offering their mediation, a peace was concluded in that capital; by which the island of Bornholm returned to the Danes; but the island of Rugen, Bleking, Halland, and Schoncn, remained with the Swedes.

17
Several provinces ceded to Sweden.

18
Remarkable revolution, by which the king is rendered absolute.

The year 1660 affords us an example of a revolution almost unequalled in the annals of history, viz. that of a free people resigning their liberty into the hands of their sovereign, and of their own accord, and without the least compulsion, rendering him despotic. This was occasioned by the great character which Frederic had acquired by his prudent and valiant conduct when Copenhagen was besieged by the king of Sweden; and at that time he had also taken care to ingratiate himself with the commonalty, by obliging the nobility to allow them some immunities which they did not enjoy before; allowing them also, by a special edict, to possess lands, and enjoy all the privileges of nobility. After the conclusion of the treaty with Sweden, a diet was summoned at Copenhagen, to take into consideration the state of the kingdom, which was now very much exhausted, both by reason of the debts in which it was involved and by the calamities of war. This distressed state of affairs was, by the commons, at-

tributed to the nobility; who, on the other hand, took no care to conciliate the affections of the inferior classes, but rather increased the discontents by their arrogance. They had even the imprudence to remonstrate against the immunities abovementioned, which had been granted by the king during the siege. In consequence of this the deputies of the commons and clergy united against them; and being joined by the citizens of Copenhagen, formed a very considerable party. On bringing forward in the assembly the sums necessary for the national exigencies, a general excise was proposed by the nobles on every article of consumpt; and to which they themselves were willing to submit, though, by an express law, their order was to be exempted from all taxes. This offer was accompanied with a remonstrance to the king, in which they endeavoured not only to reclaim many obsolete privileges, but to add fresh immunities, and introduce many other regulations, all of them tending to diminish the royal prerogative, and check the rising influence of the commons and clergy. This proposal occasioned great disputes in the diet; and the two inferior orders insisted that they would not admit of any tax which should not be levied equally upon all ranks, without reserve or restriction. The nobles not only refused to comply with this proposal, but even to be subject to the tax for more than three years; pretending that all taxes whatever were infringements on their privileges. By way of compensation, however, they proposed new duties upon leather and stamped paper, and at last offered to pay a poll-tax for their peasants. This exchange seemed at first to be agreeable to the two inferior estates; but they suddenly altered their mind, and demanded that the fiefs and domains, which the nobles had hitherto possessed exclusively, and at a very moderate rent, should be let to the highest bidder.

Denmark.

Such a proposal appeared to the nobles to be to the last degree unreasonable. They said it was an infraction of their dearest privileges; as, by the 46th article of the coronation oath taken by Frederic, the possession of the royal fiefs was guaranteed to their order; but, in the heat of dispute, one of the chief senators having imprudently thrown out some reproachful expressions against the commons, a general ferment ensued, and the assembly was broken up in confusion. This gave occasion to the interposition of the king's friends; and an idea of rendering the crown hereditary, and enlarging the royal prerogative, began to be suggested as the proper method of humbling the nobility. This was first broached by the bishop of Zealand, at whose house a numerous meeting was held on the 6th of October 1660, where the scheme was fully laid open and approved; an act for rendering the crown hereditary drawn up; and the best method of publicly producing it taken into consideration. All this time the king seemed quite inactive, nor could he be prevailed upon to take any part in an affair which so nearly concerned him. But this indolence was abundantly compensated by the alertness and diligence of the queen; between whom and the heads of the party matters were soon concerted. On the morning of the 8th of October, therefore, the bishop of Zealand having obtained the consent and signature of the ecclesiastical deputies, delivered it to Naufen burgomaster of Copenhagen and speaker of the commons. The latter, in a most persuasive

Denmark. suasive speech, expatiated upon the wretched state of the kingdom, the oppressive power of the nobles, and the virtues of the king; concluding with an exhortation to the commons, to subscribe the act as the only means of saving their country.

The exhortations of the speaker had such an effect upon the assembly, that they subscribed it without a single dissent; the nobles being all the while in perfect security, and entirely ignorant of the transaction. Next day it was presented to the king by the bishop and Naufen; and as they were returning from the palace, they met the senator who had already given offence to the commons. With him they had a violent altercation, and were threatened with imprisonment for presuming to approach the king without acquainting the order of nobles. This threat was now altogether nugatory. The nobles having got some intelligence of what was going forward, had just assembled in order to consider of what was to be done, when the deputies of the two other estates entered, and informed them of their proceedings, and delivered to them the proposal for rendering the crown hereditary. By this declaration the nobles were thrown into the utmost consternation; but judging it improper to put a negative on the proposal at present, they endeavoured to gain time, and replied, that though they willingly gave their assent to the declaration, yet that, as it was a matter of great consequence, it deserved the most serious discussion. Naufen, however, replied, that the other estates had already taken their resolution; that they would lose no time in debate; and that if the nobles would not concur with them, they would immediately repair to the palace by themselves, where they had not the least doubt that the king would graciously accept their proffer.

In the mean time the nobles had privately dispatched a messenger to the king, intimating, that they were willing to render the crown hereditary in the male line of his issue, provided it was done with all the usual formalities. But this proposal did not prove agreeable to his majesty, unless they would confirm the right of succession to the female line also. He added, however, with great appearance of moderation, that he by no means wished to prescribe rules for their conduct; they were to follow the dictates of their own judgment; but as for his part, he would owe every thing to their free consent. While the nobles were waiting for this answer, the other deputies, perceiving that they wished to keep the matter in suspense, lost all patience, and repaired in solemn procession to the court; where, being admitted into the royal presence, the matter was opened by the bishop of Zealand. He addressed his majesty on the resolution taken by the clergy and commons, offering in their name to render the crown hereditary, and to invest him with absolute authority; adding, that they were ready to sacrifice their lives in the defence of an establishment so salutary to their country. His majesty thanked them for their favourable intentions; but mentioned the concurrence of the nobles as a necessary condition; though he had no doubt of this when they should have time to accompany the declaration with all the necessary formalities; he assured them of his protection, promised a redress of all grievances, and dismissed them with an exhortation to continue their sittings until they should have

brought their design to perfection, and he could receive their voluntary submission with all due solemnity.

On departure of the commons from the place where they had been conferring with the nobles, the latter had been so distracted and confused, that they broke up without coming to any resolution, designing, however, to decide the matter finally at their meeting on the afternoon of the following day. But while they were thus wavering and irresolute, the court and the popular party took the necessary measures to force them to a concurrence. This was effectually done by an order to shut the gates; for by this they were so much dispirited that they instantly dispatched deputies to the court, with a message that they were ready to concur with the commons, and subscribe to all the conditions of the royal pleasure.

Nothing now remained but to ratify the transaction with all proper solemnity. Accordingly, on the 16th of October, the estates annulled, in the most solemn manner, the capitulation or charter signed by the king on his accession to the throne; absolved him from all his engagements; and cancelled all the limitations imposed upon his sovereignty. The whole was concluded by the ceremony of doing homage, taking the new oath with great ceremony; after which a new form of government was promulgated under the title of *The Royal Law of Denmark*.

Frederic was succeeded, in 1670, by his son Christian V. who obliged the Duke of Holstein Gottorp to renounce all the advantages he had gained by the treaty of Roschild. He then recovered a number of places in Schonen; but his army was defeated in the bloody battle of Lunden by Charles XI. of Sweden. This defeat did not put an end to the war; which Christian obstinately continued, till he was defeated entirely at the battle of Landskroon; and he had almost exhausted his dominions in his military operations, till he was in a manner abandoned by all his allies, and forced to sign a treaty on the terms prescribed by France, in 1679. Christian, however, did not desist from his military attempts; and at last he became the ally and subsidiary of Louis XIV. who was then threatening Europe with chains. Christian, after a vast variety of treating and fighting with the Holsteiners, Hamburgers, and other northern powers, died in 1699. He was succeeded by Frederic IV. who, like his predecessors, maintained his pretensions upon Holstein; and probably must have become master of that duchy, had not the English and Dutch fleets raised the siege of Tonningen; while the young king of Sweden, Charles XII. who was no more than 16 years of age, landed within eight miles of Copenhagen, to assist his brother-in-law the Duke of Holstein. Charles probably would have made himself master of Copenhagen, had not his Danish majesty agreed to the peace of Travendahl, which was entirely in the Duke's favour. By another treaty concluded with the States-General, Frederic obliged himself to furnish a body of troops, who were to be paid by the confederates; and who afterwards did great service against the French.

Notwithstanding this peace, Frederic was perpetual-ly engaged in wars with the Swedes; and while Charles was an exile at Bender, he marched through Holstein in Swedish Pomerania; and in the year 1712, into Bremen, and took the city of Stade. His troops, however,

Denmark.

19
Perpetual wars with that kingdom.

Denmark. however, were totally defeated by the Swedes at Gadesbafch, who laid his favourite city of Altena in ashes. Frederic revenged himself, by seizing great part of the ducal Holstein, and forcing the Swedish general, count Steinbock, to surrender himself prisoner, with all his troops. In the year 1716, the successes of Frederic were so great, by taking Tonningen and Stralsund, by driving the Swedes out of Norway, and reducing Wismar and Pomerania, that his allies began to suspect he was aiming at the sovereignty of all Scandinavia. Upon the return of Charles of Sweden from his exile, he renewed the war against Denmark with a most embittered spirit; but on the death of that prince, who was killed at the siege of Fredrichal, Frederic durst not refuse the offer of his Britannic majesty's mediation between him and the crown of Sweden; in consequence of which a peace was concluded at Stockholm, which left him in possession of the duchy of Sleswic. Frederic died in the year 1730, after having, two years before, seen his capital reduced to ashes by an accidental fire. His son and successor, Christian Frederic, made no other use of his power and the advantages with which he mounted the throne, than to cultivate peace with all his neighbours, and to promote the happiness of his subjects, whom he eased of many oppressive taxes.

20
An advantageous treaty with Great Britain.

In 1734, after guaranteeing the Pragmatic Sanction, Christian sent 6000 men to the assistance of the emperor, during the dispute of the succession to the crown of Poland. Though he was pacific, yet he was jealous of his rights, especially over Hamburgh. He obliged the Hamburghers to call in the mediation of Prussia, to abolish their bank, to admit the coin of Denmark as current, and to pay him a million of silver marks. He had, two years after, viz. 1738, a dispute with his Britannic majesty about the little lordship of Steinhorst, which had been mortgaged to the latter by the Duke of Holstein Lawenburg, and which Christian said belonged to him. Some blood was spilt during the contest; in which Christian, it is thought, never was in earnest. It brought on, however, a treaty, in which he availed himself of his Britannic majesty's predilection for his German dominions; for he agreed to pay Christian a subsidy of 70,000 l. Sterling a-year, on condition of keeping in readiness 7000 troops for the proportion of Hanover: this was a gainful bargain for Denmark. And two years after, he seized some Dutch ships for trading without his leave to Iceland; but the difference was made up by the mediation of Sweden. Christian had so great a party in that kingdom, that it was generally thought he would revive the union of Calmar, by procuring his son to be declared successor to his then Swedish majesty. Some steps for that purpose were certainly taken: but whatever Christian's views might have been, the design was frustrated by the jealousy of other powers, who could not bear the thoughts of seeing all Scandinavia subject to one family. Christian died, in 1746, with the character of being the father of his people.

His son and successor, Frederic V. had, in 1743, married the princess Louisa daughter to his Britannic majesty. He improved upon his father's plan for the happiness of his people; but took no concern, ex-

cept that of a mediator, in the German war. For it was by his intervention that the treaty of Closter-seven was concluded between his royal highness the late duke of Cumberland and the French general Richelieu. Upon the death of his first queen, who was mother to his present Danish majesty, he married a daughter of the duke of Brunswic Wolfenbuttel; and died in 1766.

He was succeeded by his son Christian VII. his present Danish majesty, who married the princess Carolina Matilda of England. But this alliance proved extremely unfortunate, which is generally ascribed to the intrigues of the queen dowager, mother-in-law to the present king. She is represented as ambitious, artful, and designing; and as one who wished to have set aside the king himself in favour of her own son Frederic. On the arrival of the young queen, however, she received her with much apparent affection, telling her the faults of her husband, and at the same time promising to assist her on all occasions in reclaiming him from his vicious courses. Thus, under pretence of kindness and friendship, she sowed the seeds of dissention betwixt the royal pair before the unfortunate princess had the least suspicion of her danger; and while the unthinking queen revealed to the dowager all her secrets, the latter is said to have placed spies about the king to keep him constantly engaged in riot and debauchery, to which he was at any rate too much inclined. At last it was contrived to throw a mistress in his way, which he was advised to keep in his palace.—It was impossible that any woman could pass such a piece of conduct unnoticed; however, in this affair, the queen dowager behaved with her usual duplicity. In the absence of the king she pretended great resentment against him, and even advised the queen not to live with him; but as soon as he returned, when his consort reproached him, though in a gentle manner, with his conduct, she not only took his part, but insisted that it was presumptuous in a queen of Denmark to pretend to direct her husband's conduct. Notwithstanding this incendiary behaviour, the queen was in a short time reconciled to her husband, and lived on very good terms with him until she again excited the jealousy of the dowager by assuming to herself the direction of that part of the public affairs which the dowager had been accustomed to look upon as her own privilege. For some time it seemed to be difficult for her to form any effectual plan of revenge, as the king had displaced several of her friends who had for some time had a share in the administration. Two new favourites, Brandt and Struensee, had now appeared; and as these paid great court to the queen, the dowager took occasion to insinuate not only that the queen was harbouring improper designs with regard to the government, but that she had an intrigue with Struensee. The new ministers indeed behaved imprudently, in attempting to make a reformation in several of the departments of the state at once, instead of waiting patiently until an opportunity should offer, and in these precipitate schemes they were certainly supported by the queen. These instances of want of circumspection in the ministers, were represented by the dowager and her party to be a settled scheme to make an alteration in the government; and a design was even spoken

21
Intrigues of the dowager and misfortunes of the young queen.

Denmark. spoken of to supersede the king as being incapable of governing, to declare the queen regent during the minority of her son, and to make Struensee prime minister.

Thus a very formidable opposition was formed against Brandt and Struensee; and as the latter had made some innovations in the military department as well as the civil, some of the principal officers, who were the creatures of the dowager, represented him as designing to overthrow the whole system of government. When matters were brought to a proper bearing, it was at last resolved to surprise the king in the middle of the night, and force him instantly to sign an order which was to be ready prepared, for committing the obnoxious persons to separate prisons, accuse them of high treason in general, and particularly with a design to dethrone or poison the king. If this could not be properly authenticated, it was determined to suborn witnesses to confirm the report of a criminal correspondence between the queen and count Struensee. This design was executed on the night of the 16th of January 1772, when a masked ball was given at the court of Denmark. The queen, after having danced most part of the night with count Struensee, retired to her chamber about two in the morning. About four the same morning, prince Frederic got up, and went with the queen dowager to the king's bed-chamber, accompanied by general Eichstedt and count Rantzau. Having ordered the king's valet de chambre to awake him, they informed his majesty that the queen, with count Struensee, his brother, and Brandt one of the new ministers, were at that moment busy in drawing up an act of renunciation of the crown, which they would immediately compel him to sign: and therefore there was a necessity for him to give an order for the arrestment. The king is said to have hesitated for some time, and inclined to refuse this scandalous requisition; but at length, through importunity, and according to some accounts, being even threatened into compliance, he consented to what they required. Count Rantzau was dispatched, at that untimely hour, into the queen's apartments, and immediately executed the orders of the king. The unfortunate princess was conveyed in one of the king's coaches to the castle of Cronenburgh, together with the infant princess, attended by Lady Mostyn, and escorted by a party of dragoons. Struensee and Brandt were seized in their beds and imprisoned, as well as several other members of the new administration, to the number of 18. The queen dowager and her adherents seemed to assume the government entirely into their own hands, and a total change took place in the departments of administration. The prince royal, son of queen Matilda, then in the fifth year of his age, was put under the care of a lady of quality, who was appointed governess, under the superintendency of the queen dowager. Struensee and Brandt were put in irons, and very severely treated: they underwent long and frequent examinations; and Struensee at last confessed that he had a criminal intercourse with the queen. Both their heads were struck off on the 23th of April; but many of their partisans were set at liberty. The confession of Struensee is by many, and indeed with no small degree of probability, supposed to have been extorted by fear of the torture, and to have no foundation in truth; but as no means were used by the court of Britain to clear up the queen's character, the affair must undoubtedly

22

of Struensee
and
Brandt.

wear a suspicious aspect. At last, however, his Britannic majesty interfered so far as to send a small squadron of ships to convoy the unhappy princess to Germany. Here the city of Zell was appointed for her residence; and in this place she died of a malignant fever on the 10th of May 1775, aged 23 years and 10 months.

The inhuman treatment of this princess did not long prove advantageous to the queen dowager and her party: A new revolution took place in April 1784, when the queen dowager's friends were removed, a new council was formed under the auspices of the prince royal, and no instrument deemed authentic unless signed by the king, and countersigned by the prince. Since that time, the king, who from the beginning of his administration showed a great degree of incapacity, has been entirely laid aside from public business, and has no share in the government. The Danes are at present engaged on the side of Russia in her war with the Turks, the immediate opponent of Denmark being Sweden.

The kingdom of Denmark at present is divided into six grand districts or provinces; viz. 1. Denmark properly so called, comprehending the islands of Zealand, Funen, Langland, Laaland, Falstria, Molna, Samsoe, Arroe, Bornholm, Anholt, Leflaw, and that part of the continent called *North Jutland*. 2. The duchy of Sleswick, or South Jutland. 3. The duchy of Holstein. 4. The earldoms of Oldenburg and Delmenhorst. 5. The kingdom of Norway; and 6. Iceland, with the islands lying in the Northern Seas; for a particular description of which see these articles.

The language of Denmark is a dialect of the Teutonic, and bears a strong affinity to the Norwegian tongue; but is disagreeable to strangers, on account of the drawling tone with which it is pronounced. They have borrowed many words from the German; and, indeed, the high Dutch is used in common discourse by the court, the gentry, and the burghers. The better sort likewise understand French, and speak it fluently. The Lutheran doctrine is universally embraced through all Denmark, Sweden, and Norway; so that there is not another sect in these kingdoms. Denmark is divided into six dioceses, one in Zealand, one in Funen, and four in Jutland: but the bishops are, properly speaking, no other than superintendants, or *primi inter pares*. They have no cathedrals, ecclesiastical courts, or temporalities. Their business is to inspect the doctrine and morals of the inferior clergy. The revenue of the bishop of Copenhagen amounts to about 2000 rix dollars; and this is the richest benefice in the kingdom. The clergy are wholly dependant on the government. They never intermeddle, nor are employed or consulted in civil affairs. They, nevertheless, have acquired great influence, and created a sort of spiritual tyranny over the minds of the common people, by whom they are much revered. They are, generally speaking, men of exemplary lives, and some erudition. Their churches are kept more clean, and better adorned, than those of England: the people are great lovers of music, and their organists commonly entertain the congregation for half an hour before or after service. The state of literature is very low in Denmark. There is, indeed, an university at Copenhagen; but meanly endowed, and very ill supplied with masters. Taste and the belles lettres are utterly unknown in this country, which yet has produced some

men of great eminence in mathematics and medicine ; such as Tycho Brahe, Borrichius, and the Bartholines.

The constitution of Denmark was heretofore of the free Gothic original. The convention of the estates, even including the representatives of the boors or peasants, elected a king for his personal virtues, having still a regard to the son of their late monarch, whom, however, they made no scruple of setting aside, if they deemed him unworthy of the royal dignity. They enacted laws ; conferred the great offices of state ; debated all affairs relating to commerce, peace, war, and alliances ; and occasionally gave their consent to the imposition of necessary taxes. The king was no other than chief magistrate, generalissimo, and as it were prime minister to his people. His business was to see justice administered impartially ; command the army in time of war ; to encourage industry, religion, arts, and sciences ; and to watch over the interests of his subjects.

In 1660, however, the constitution was new modelled, as has been already related, and which was to the following purport. "The hereditary kings of Denmark and Norway should be in effect, and ought to be esteemed by their subjects, the only supreme head upon earth ; they shall be above all human laws, and shall acknowledge, in all ecclesiastical and civil affairs, no higher power but God alone. The king shall enjoy the right of making and interpreting the laws, of abrogating, adding to, and dispensing with them. He may also annul all the laws which either he or his predecessors shall have made, excepting this royal law, which must remain irrevocable, and be considered as the fundamental law of the state. He has the power of declaring war, making peace, imposing taxes, and levying contributions of all sorts," &c. &c.

Then follow the regulations for the order of succession, the regency in case of minority, the majority of the king, the maintenance of the royal family ; and, after having enumerated all the possible prerogatives of regal uncircumscribed authority, as if sufficient had not yet been laid down, it is added in the 26th article : "All that we have hitherto said of power and eminence, and sovereignty, and if there is any thing further which has not been expressly specified, shall all be comprised in the following words : "The king of Denmark and Norway shall be the hereditary monarch, and endued with the highest authority ; inasmuch, that all that can be said and written to the advantage of a Christian, hereditary and absolute king, shall be extended under the most favourable interpretation to the hereditary king or queen of Denmark and Norway," &c. &c.

The laws of Denmark are so concise, that the whole body is contained in one quarto volume, written in the language of the country. Every man may plead his own cause, without employing either counsel or attorney ; but there are a few advocates for the benefit of those who cannot or will not speak in their own defence. The proceedings are so summary, that a suit may be carried through all the courts, and finally decided, in 13 months. There are three courts in Denmark, and an appeal lies from the inferior to the superior tribunal. The lowest of these is, in cities and towns, denominated the *Byfogt's Court* ; and in the country, the *Herredsfogds*. Causes may be appealed from this to the *Landstog*, or general head court for

the province ; but the final appeal lies to the court of *High-right* in Copenhagen, where the king presides in person, assisted by the prime nobility. The judges of the two other courts are appointed by his majesty's letters patent, to sit and determine causes *durante bene placito*. These are punishable for any misdemeanours of which they may be guilty ; and when convicted of having passed an unjust sentence, they are condemned to make reparation to the injured party. Their salaries are very inconsiderable, and paid out of the king's treasury, from the fines of delinquents, besides a small gratuity from the plaintiff and defendant when sentence is passed. Such is the peculiar privilege enjoyed by the city of Copenhagen, that causes appealed from the *Byfogt's* court, instead of passing through the provincial court, are tried by the burgomaster and common-council ; from whence they proceed immediately to the highest court as the least resource. Affairs relating to the revenue are determined in the rent chamber of Denmark, which is analogous to a court of exchequer. To another tribunal, composed of some members from this rent-chamber, from the admiralty, and college of commerce, merchants appeal for redress, when their commodities are seized for non-payment of duties. All disputes relating to the sea are determined by the court of admiralty, constituted of commissioners appointed for these purposes. The chancellery may be more properly termed a *secretary's office*. It consists of clerks, who write and issue all the king's decrees and citations, transcribe papers, and, according to the directions they receive, make draughts of treaties and alliances with other nations. The government of Denmark is very commendable for the excellent policy it maintains. Justice is executed upon criminals with great severity ; and such regulations are established as effectually prevent those outrages that are daily committed in other countries. No man presumes to wag his tongue against the government, far less to hatch schemes of treason. All the subjects are, or seem to be, attached to their sovereign by the ties of affection. Robbery on the high-way, burglary, coining or clipping, are crimes seldom or never heard of in Denmark. The capital crimes usually committed are theft and manslaughter. Such offenders are beheaded very dexterously with one stroke of a sword. The executioner, though infamous, is commonly rich ; because, over and above the functions of his office, he is employed in other scandalous occupations, which no other person will undertake. He, by means of his understrapper, called the *pracher*, empties all the jakes, and removes from houses, stables, or streets, dead dogs, horses, &c. which no other Dane will vouchsafe to touch on any consideration whatsoever.

The Danish nobility and gentry are all included in the term *noblesse* ; and formerly there were no distinctions of title : but within these 60 or 70 years, some few favourites have been dignified with the titles of *count* and *baron*. These, and these only, enjoy the privilege of disposing of their estates by will ; though others may make particular dispositions, provided they have sufficient interest to procure the king's approbation and signature. The noblesse of Denmark formerly lived at their own seats with great magnificence ; and at the conventions of estates met the king with numerous and superb retinues ; but since he became absolute, they are so impoverished by exorbitant taxes, that they can

Denmark.

28

Slavish condition of the Danish subjects.

hardly

Denmark. hardly procure subsistence; and, for the most part, live obscurely in some corner of their ruined country palaces, unless they have interest enough to procure some employment at court. They no longer inherit the spirit and virtues of their ancestors; but are become servile, indolent ostentatious, extravagant, and oppressive.

Their general character is a strange composition of pride and meanness, insolence and poverty. If any gentleman can find a purchaser for his estate, the king, by the Danish law, has a right to one third of the purchase-money: but the lands are so burdened with impositions that there would be no danger of an alienation, even tho' this restriction was not in force. Nay, some gentlemen in the Island of Zealand have actually offered to make a surrender to the king of large tracts of very fertile land in the Island of Zealand, if his majesty would be pleased to accept of them in place of the impositions laid on them. The reason of this is, because, by the law of Denmark, if any estate is burdened beyond what it can bear, the owner must make up the deficiency out of his other estates if he has any. Hence the king generally refuses such offers; and some gentlemen have been transported with joy when they heard that his majesty had been "graciously pleased to accept their whole estates."

This oppression of the nobles by the king produces in them a like disposition to oppress the commons; and the consequence of all this is, that there is no part of the world where extravagance and dissipation reigns to such a degree. The courtiers maintain splendid equipages, wear fine clothes, drink a vast quantity of French wine, and indulge themselves with eating to excess. Such as derive money from their employments, instead of purchasing land in Denmark, remit their cash to the banks of Hamburgh and Amsterdam. The merchants and burghers tread in the steps of their superiors: they spend all their gains in luxury and pleasure, afraid of incurring the suspicion of affluence, and being stripped by taxation. The peasant, or boor, follows the same example. No sooner has he earned a rix-dollar than he makes haste to expend it in brandy, lest it should fall into the hands of his oppressive landlord. This lower class of people are as absolute slaves as the negroes in the West-Indies, and subsist upon much harder fare. The value of estates is not computed by the number of acres, but by the stock of boors, who, like the timber, are reckoned a parcel of the freehold; and nothing can be more wretched than the state of these boors. They feed upon stock-fish, salted meats, and other coarse diet: there is not the least piece of furniture of any value in their houses, except feather-beds, of which there is great plenty in Denmark; and which are used not only as beds to lie on but as blankets for covering. After the boor has toiled as a slave to raise the king's taxes, he must pay the overplus of his toil to his needy landlord. Should he improve his ground and repair his farm-house, his cruel master will immediately transplant him to a barren farm and a naked habitation, that he may let the improved ground to another tenant at a higher price. The peasants likewise sustain a great deal of damage and violence from the licentious soldiers that are quartered in their houses. They are moreover obliged to furnish horses and waggons for the royal family

VOL. V.

and all their attendants when the king makes a progress through the country, or removes his residence from one palace to another. On such occasions the neighbouring boors are summoned to assemble with their cattle and carriages, and not only to live at their own expence, but to bear every species of outrage from the meanest lacquies of those who attend his majesty. The warlike spirit of the Danes no longer subsists: the common people are mean-spirited, suspicious, and deceitful; nor have they that talent for mechanics so remarkable in some northern nations. While the peasants are employed in their labour without doors, the women are occupied at home in spinning yarn for linen, which is here made in great perfection.

In Denmark, all persons of any rank above the vulgar dress in the French taste, and affect finery; the winter-dress of the ladies is peculiar to the country, very neat, warm, and becoming. The common people are likewise remarkably neat, and pride themselves in different changes of linen. They are very little addicted to jollity and diversion: their whole amusements consist in running at the goose on Shrove Tuesday, and in winter in being drawn in sleds upon the ice. They also feast and make merry at weddings and funerals. With respect to marriage, the man and woman frequently cohabit together on contract long before the ceremony is performed. The nobility and gentry pique themselves on sumptuous burials and monuments for the dead: the corpse is very often kept in a vault, or in the chancel of a church, for several years, before an opportunity offers of celebrating the funeral.

The taverns in this country are poorly supplied; and he who diets in them must be contented to eat in a public room, unless he will condescend to pay an extravagant price for a private apartment. The metropolis is but indifferently furnished with game. The wild-ducks and plover are hardly eatable; but the hares are good, and the markets sometimes produce tolerable roebuck. Their sea-fish are not to be commended; but the rivers produce plenty of delicious carp, perch, and craw-fish. The gardens of the gentry are well provided with melons, grapes, peaches, and all sorts of greens and salads in perfection.

The army of Denmark is composed, 1. of the troops of Denmark and Holstein; and, 2. of Norway.

The forces of Denmark and Holstein are divided into regulars and national or militia. These forces (the foot and horse guards excepted who are all regulars) are not separated, as in our army, into distinct regiments, but are formed in the following manner: Before the late augmentation, every regiment of infantry, when complete, consisted of 26 officers and 1632 privates, divided into ten companies of fusileers and two of grenadiers. Of these 1632 privates, 480, who are chiefly foreigners enlisted in Germany, are regulars. The remaining 1152 are the national militia, or peasants who reside upon the estates of their landholders, each estate furnishing a certain number in proportion to its value. These national troops are occasionally exercised in small corps upon Sundays and holidays; and are embodied once every year for about 17 days in their respective districts. By a late addition of ten men to each company, a regiment of infantry is increased to 1778, including officers. The expence of each

Army of
Denmark.

Denmark. each regiment, which before amounted to L. 6000, has been raised by the late augmentation to L. 8000. The cavalry is upon the same footing; each regiment consisting of 17 officers, including serjeants and corporals, and 565 privates, divided into five squadrons. Of these about 260 are regular and the remainder national troops. The regiments of foot and horse guards are regulars; the former is composed of 21 officers and 465 men, in five companies; and the latter of 7 officers and 154 men, in two squadrons.

The forces of Norway are all national troops or militia, excepting the two regiments of Sundenfield and Nordenfield; and as the peasants of that kingdom are free, the forces are levied in a different manner from those of Denmark. Norway is divided into a certain number of districts, each whereof furnishes a soldier. All the peasants are, upon their birth, registered for the militia; and the first on the list supplies the vacancy for the district to which he belongs. After having served from 10 to 14 years they are admitted among the invalids; and when they have attained the seniority of that corps receive their dismissal. These troops are not continually under arms; but are only occasionally exercised like the national forces of Denmark. A fixed stipend is assigned to the officers, nearly equal to that of the officers in the regulars; but the common soldiers do not receive any pay except when they are in actual service, or performing their annual manœuvres. The Academy of Land Cadets, instituted by Frederic IV. supplies the army with officers. According to this foundation, 74 cadets are instructed in the military sciences at the expence of the king. The whole amount of the Danish troops is computed at 60,900.

From their insular situation the Danes have always excelled as a maritime people. In the earlier ages, when piracy was an honorable profession, they were a race of pirates, and issued from the Baltic to the conquests of England and Normandy. And though, since the improvement of navigation by the invention of the compass, other nations have risen to a greater degree of naval eminence, still, however, the Danes, as they inhabit a cluster of islands, and possess a large tract of sea-coast, are well versed in maritime affairs, and are certainly the most numerous, as well as the most experienced, sailors of the north.

The greatest part of the Danish navy is stationed in the harbour of Copenhagen, which lies within the fortifications: the depth of water being only 20 feet, the ships have not their lower tier of guns on board, but take them in when they get out of port. Beside large magazines, each vessel has a separate storehouse on the water's edge, opposite to which she is moored when in harbour, and may by this means be instantly equipped. The number of registered seamen is near 40,000, and are divided into two classes; the first comprises those inhabiting the coasts, who are allowed to engage in the service of merchant-ships trading to any part of the world. Each receives 8s. annually from the crown as long as he sends a certificate of his being alive; but is subject to a recal in case of war. The second comprehends the fixed sailors, who are constantly in the employ of the crown, and amount to about 4000, ranged under four divisions, or 40

companies: they are stationed at Copenhagen for the ordinary service of the navy, and work in the dock-yard. Each of them, when not at sea, receives 8s. Denmark. Dennis. *per* month, beside a sufficient quantity of flour and other provisions; every two years a complete suit of clothes; and every year breeches, stockings, shoes, and a cap. Some of them are lodged in barracks. When they sail, their pay is augmented to 20s. *per* month. The marine artillery consists of 800 men, in four divisions.

The whole navy consists of 38 ships of the line, including 9 of 50 guns and one of 44, and 20 frigates; but if we except those which are condemned, and those which are allotted only for parade, we cannot estimate that in 1779 the fleet consisted of more than 25 ships of the line and 15 frigates fit for service; a number, however, fully adequate to the situation of Denmark; and if we include the excellence of the sailors, it must be esteemed as complete a navy as any in the north. ³¹ Navy.

The revenue of his Danish majesty arises from taxes laid on his own subjects; from the duties paid by foreigners, from his own estate, crown-lands, and confiscations. The taxes are altogether arbitrary, and therefore fluctuating; but they are always grievous to the subject. They commonly consist of customs or toll, for export and import; of exercise upon the consumption of wine, salt, tobacco, and all kinds of provisions; of taxes upon marriages, paper, brewing, grinding, and the exercise of different professions; of impositions on land, poll-money, ground-rent for all houses in Copenhagen and elsewhere; of money raised for maintaining fortifications, and for a portion to the king's daughter when she happens to be married: but this seldom exceeds 100,000 rixdollars. One considerable article in the revenue is the toll paid by foreign ships that pass through the Sound, or *Ore-Sound* (the strait between Schonen and Zealand), into the Baltic. This was originally no other than a small contribution, which trading nations agreed to make for maintaining lights at certain places, to direct their course through the passage in dark and stormy weather. At the same time these trading nations agreed, that every ship should pass this way and pay its share of the expence, rather than use the Great Belt, which is the other passage, but unprovided with any such conveniency. In process of time the Danes converted this voluntary contribution into an exorbitant toll, and even exacted arbitrary sums, in proportion to the weakness of the nation whose ships they visited. These exactions sometimes involved them in quarrels with their neighbours, and the toll was regulated in repeated treaties. ³² Revenue.

DENNIS, or ST DENNIS, a famous town of the Isle of France, with a Benedictine abbey, wherein are the tombs of the kings of France, with a considerable treasure. E. Long. 2. 26. N. Lat. 48. 56.

DENNIS (John), the celebrated critic, was the son of a reputable tradesman in London, and born in the year 1657. He received the first branches of education at the great school in Harrow on the Hill, where he commenced acquaintance and intimacy with many young noblemen and gentlemen, who afterwards made considerable figures in public affairs, whereby he laid the foundation of a very strong and extensive interest, which might, but for his own fault, have been of infinite

Denmark. nite use to him in future life. From Harrow he went to Caius-college Cambridge; where, after his proper standing, he took the degree of bachelor of arts. When he quitted the university, he made the tour of Europe; in the course of which he conceived such a detestation for despotism, as confirmed him still more in those Whig principles which he had from his infancy imbibed.

On his return to England he became early acquainted with Dryden, Wycherly, Congreve, and Southerne; whose conversation inspiring him with a passion for poetry, and a contempt for every attainment that had not something of the *belles lettres*, diverted him from the acquisition of any profitable art, or the exercise of any profession. This, to a man who had not an independent income, was undoubtedly a misfortune: however, his zeal for the Protestant succession having recommended him to the patronage of the duke of Marlborough, that nobleman procured him a place in the customs worth L. 120 *per annum*; which he enjoyed for some years, till from profuseness and want of economy, he was reduced to the necessity of disposing of it to satisfy some very pressing demands. By the advice of Lord Halifax, however, he reserved to himself in the sale of it, an annuity for a term of years; which term he outlived, and was, in the decline of his life, reduced to extreme necessity.

Mr Theo. Cibber relates an anecdote of him, which we cannot avoid repeating, as it is not only highly characteristic, of the man whose affairs we are now considering, but also a striking and melancholy instance, among thousands, of the distressful predicaments into which men of genius and literary abilities are perhaps apter than any others to plunge themselves, by paying too slight an attention to the common concerns of life, and their own most important interests. "After that he was worn out (says that author) with age and poverty, he resided within the verge of the court, to prevent danger from his creditors. One Saturday night he happened to saunter to a public house, which in a short time he discovered to be without the verge. He was sitting in an open drinking-room, when a man of a suspicious appearance happened to come in. There was something about the man which denoted to Mr Dennis that he was a bailiff. This struck him with a panic; he was afraid his liberty was at an end; he sat in the utmost solicitude, but durst not offer to stir lest he should be seized upon. After an hour or two had passed in this painful anxiety, at last the clock struck twelve; when Mr Dennis, in an ecstasy, cried out, addressing himself to the suspected person, "Now, Sir, bailiff or no bailiff, I don't care a farthing for you, you have no power now." The man was astonished at his behaviour; and when it was explained to him, was so much affronted with the suspicion, that had not Mr Dennis found his protection in age, he would probably have smarted for his mistaken opinion. A strong picture of the effects of fear and apprehension, in a temper naturally seditious and jealous as Mr Dennis's; of which the following is a still more whimsical instance. In 1704 came out his favourite tragedy, *Liberty Asserted*; in which were so many strokes on the French nation, that he thought they were never to be forgiven. He had worked himself into a persuasion that

the king of France would insist on his being delivered up, before he would consent to a peace: and full of this idea of his own importance, when the congress was held at Utrecht, he is said to have waited on his patron the duke of Marlborough, to desire that no such article might be stipulated. The duke told him he really had no interest then with the ministry; but had made no such provision for his own security, though he could not help thinking he had done the French as much injury as Mr Dennis himself. Another story relating to this affair is, that being at a gentleman's house on the coast of Sussex, and walking one day on the sea-shore, he saw a ship sailing, as he fancied, towards him: he instantly set out for London, in the fancy that he was betrayed; and, congratulating himself on his escape, gave out that his friend had decoyed him down to his house, to surrender him up to the French.

Mr Dennis, partly through a natural peevishness and petulance of temper, and partly perhaps for the sake of procuring the means of subsistence, was continually engaged in a paper-war with his cotemporaries, whom he ever treated with the utmost severity: and, though many of his observations were judicious, yet he usually conveyed them in language so scurrilous and abusive, as destroyed their intended effect; and as his attacks were almost always on persons of superior abilities to himself, viz. Addison, Steele, and Pope, their replies usually turned the popular opinion so greatly against him, that, by irritating his testy temper the more, it rendered him a perpetual torment to himself; till at length, after a long life of vicissitudes, disappointments, and turmoils, rendered wretched by indiscretion, and hateful by malevolence, having outlived the reversion of his estate, and reduced to distress, from which his having been daily creating enemies had left him scarcely any hopes of relief, he was compelled to what must be the most irksome situation that can be conceived in human life, the receiving obligations from those whom he had been continually treating ill. In the very close of his days, a play was acted for his benefit at the little theatre in the Hay-market, procured through the united interests of Messrs Thomson, Mallet, and Pope; the last of whom, notwithstanding the gross manner in which Mr Dennis had on many occasions used him, and the long warfare that had subsisted between them, interested himself very warmly for him; and even wrote an occasional prologue to the play, which was spoken by Mr Cibber. Not long after this, viz. on the 6th of January 1733, he died, being then in the 77th year of his age.

Mr Dennis certainly was possessed of much erudition, and a considerable share of genius. In prose, he is far from a bad writer, where abuse or personal scurrility does not mingle itself with his language. In verse, he is extremely unequal; his numbers being at some times spirited and harmonious, and his subjects elevated and judicious; and at others flat, harsh, and puerile.—As a dramatic author, he certainly deserves not to be held in any consideration. It was justly said of him by a wit, that he was the most complete instructor for a dramatic poet, since he could teach him to distinguish good plays by his *precepts*, and bad ones by his *examples*.

Dennis.

Denomina-
tion
||
Dentatus.

DENOMINATION (from *denomino*, of *de* and *no-men*, "a name;" a name imposed on any thing, usually expressing some quality predominant therein.

DENOMINATOR, in arithmetic, a term used in speaking of fractions. See **ARITHMETIC**, n^o 21.

DENSITY of BODIES, is that property directly opposite to rarity, whereby they contain such a quantity of matter under such a bulk.

Accordingly, a body is said to have double or triple the density of another body, when, their bulk being equal, the quantity of matter is in the one double or triple the quantity of matter in the other.

DENSITY of the Air, is a property that has employed the later philosophers, since the discovery of the Torricellian experiment.

It is demonstrated, that in the same vessel, or even in vessels communicating with each other, at the same distance from the centre, the air has every where the same density. The density of air, *ceteris paribus*, increases in proportion to the compressing powers. Hence the inferior air is denser than the superior; the density, however, of the lower air is not proportional to the weight of the atmosphere on account of heat and cold, and other causes perhaps which make great alterations in density and rarity. However, from the elasticity of the air, its density must be always different at different heights from the earth's surface: for the lower parts being pressed by the weight of those above, will be made to accede nearer to each other, and the more so as the weight of the incumbent air is greater. Hence the density of the air is greatest at the earth's surface, and decreases upwards in geometrical proportion to the altitudes taken in arithmetical progression.

If the air be rendered denser, the weight of bodies in it is diminished; if rarer, increased, because bodies lose a greater part of their weight in denser than in rarer mediums. Hence, if the density of the air be sensibly altered, bodies equally heavy in a rarer air, if their specific gravities be considerably different, will lose their equilibrium in the denser, and the specifically heavier body will preponderate. See **PNEUMATICS**.

DENTALIUM, in natural history, a shell-fish belonging to the order of vermes testacea. The shell consists of one tubulous straight valve, open at both ends. There are eight species, distinguished by the angles, striæ, &c. of their shells.

DENTARIA, TOOTH-WORT, or Tooth-violet: A genus of the siliquosa order, belonging to the tetrady-namia class of plants; and in the natural method ranking under the 39th order, *Siliquosæ*. The siliqua parts with a spring, and the valvules roll spirally backwards; the stigma is emarginated; the calyx closing longitudinally. There are three species, all of them hardy perennials; producing annual stalks 12 or 18 inches high, adorned with many-lobed leaves, and spikes of quadrupetalous cruciform flowers of a red or purple colour. They delight in shady places; and are propagated either by seeds or parting the roots. The seeds may be sown in autumn or early in the spring, in a shady border of light earth; and when the plants are three inches high, they may be planted where they are to remain. The time for parting the roots is in October or November, or early in the spring.

DENTATUS (Curius), a renowned disinterested Roman general, whose virtues render him more me-

morable than even his great military reputation, flourished 272 years B. C. He was thrice consul; he conquered the Samnites, Sabines, and Lucanians; and gave each citizen 40 acres of land, allowing himself no more. The ambassadors of the Samnites making him a visit, found him boiling turnips in a pipking; upon which they offered him gold to come over to their interest; but he told them his design was not to grow rich, but to command those who were so. He defeated Pyrrhus near Tarentum, and received the honour of a triumph.

DENTELLA, in botany: A genus of the monogynia order, belonging to the pentandria class of plants. The calyx is a five-parted perianthium, with small subulated leaves; the stamina five short subulated filaments; the antheræ small; the pericarpium a globular, bilocular capsule; the seeds egg-shaped, and very numerous.

DENTILES, or DENTILS, in architecture, an ornament in corniches bearing some resemblance to teeth, particularly used in the Ionic and Corinthian orders. See **ARCHITECTURE**.

DENTIFRICE, in medicine, a remedy for the teeth. There are various kinds; generally made of earthy substances finely pounded, and mixed with alum, or some other saline substances; but these are pernicious, on account of their wearing away the enamel of the teeth; but more especially by the septic quality with which these earthy substances are endowed. On this account, a portion of Peruvian bark finely pounded is now commonly added, which answers the double purpose of cleaning the teeth, and preserving them afterwards from corruption.

DENTISCALPRA, in surgery, an instrument for scouring yellow, livid, or black teeth; to which being applied near the gums, it scrapes off the foul morbid crust.

DENTITION, the breeding or cutting the teeth in children. See (*Index* subjoined to) **MEDICINE**.

DENUNCIATION, a solemn publication or promulgation of any thing.

All vessels of enemies are lawful prizes, after denunciation or proclamation of war. The design of the denunciation of excommunicated persons is, that the sentence may be the more fully executed by the person's being more known.

DENUNCIATION at the Horn, in Scots law. See **LAW**, Part III. N^o clxvi. 14.

DENYS (the Little). See **DIONYSIUS**.

DEOBSTRUENTS, in pharmacy, such medicines as open obstructions. See **DETERGENT**.

DEODAND, in English customs, a thing given or forfeited as it were to God, for the pacification of his wrath in a case of misadventure, whereby a Christian soul comes to a violent end, without the fault of any reasonable creature.

As, if a horse strike his keeper and kill him: if a man, in driving a cart, falls so as the cart-wheel runs over him, and presses him to death: if one by felling a tree, and gives warning to the standers-by to look to themselves, yet a man is killed by the fall thereof: in the first place, the horse; in the second, the cart-wheel, cart and Horses; and in the third, the tree, is *Deo dandus*, "to be given to God," that is, to the king, to be distributed to the poor by his almoner, for expiation of

Dentella
||
Deodand.

this

Dephleg- this dreadful event; though effected by irrational, nay, senfeless and dead creatures.

Dephlogi-
sticated
Air.

Omnia quæ movent ad mortem sunt Deodanda.
What moves to death, or kills him dead,
Is *Deodand*, and forfeited.

This law seems to be an imitation of that in Exodus, chap. xxi. "If an ox gore a man, or a woman, with his horns, so as they die; the ox shall be stoned to death, and his flesh not be eat; so shall his owner be innocent."

Fleta says, the Deodand is to be sold, and the price distributed to the poor, for the soul of the king, his ancestors, and all faithful people departed this life.

DEPHLEGMATION, is an operation by which the superabundant water of a body is taken from it; and it is principally effected by evaporation or distillation. Dephlegmation is also called *concentration*, particularly when acids are the subject. See CONCENTRATION.

DEPHLOGISTICATED, in chemistry, any thing deprived of the phlogiston supposed to be contained in it.

DEPHLOGISTICATED *Air*, an invisible elastic fluid, of somewhat greater specific gravity than that of the common atmosphere, and capable of supporting animal life and flame for a much longer time than the air we commonly breathe.

This fluid was first discovered by Dr Priestley, and a very short time after by Mr Scheele, who appears to have been entirely unacquainted with what the Doctor had done. The methods of making it artificially are enumerated under the article AEROLOGY; here we shall make some observations on the way in which nature seems to accomplish the same end. Under that article, as well as that of FIXED *Air*, and others connected with them, it has been observed, that this kind of air becomes convertible into fixed air by the addition of a certain proportion of phlogiston or charcoal; and that these two ingredients may be again separated by certain means; the dephlogisticated air assuming its proper state, and the charcoal its own native form. A great number of experiments also are there related concerning the effects of vegetables in purifying tainted air, and their emission of the dephlogisticated kind; which has been thought to indicate, that vegetation is probably one of the methods by which nature supplies the great quantity of this fluid necessary for the purposes of animal life. This was suggested by an experiment of Dr Priestley, who had discovered that pump-water, on being exposed to the light of the sun, soon began to emit pure air; and that, after some days, a quantity of green matter accumulated on the sides of the vessel. This was naturally supposed to be of the vegetable kind, till Sir Benjamin Thomson found it to consist of a number of very minute animals. Upon this discovery he disputed the commonly received opinion, that vegetation is employed by nature as a purifier of the atmospherical air. He likewise opposed the conclusion drawn from Dr Ingenhoufz's experiments, who had observed that fresh leaves of plants immersed in water, and exposed to the light, emitted a vast quantity of dephlogisticated air. Sir Benjamin justly observed, that a leaf certainly ceased to vegetate after being separated from the plant on which it grew; and therefore the emission of this kind of air could by no means be ascribed to

vegetation: as a more decisive proof of which, he likewise urged, that leaves, after being entirely dead and withered, would notwithstanding emit dephlogisticated air for a very considerable time. Thus matters seemed to be rendered doubtful: but by an attentive observation of all circumstances relating to these experiments, we shall find that considerable light will be thrown upon the subject.

In the first place, we are to consider that the light of the sun, or at least a very strong light of some kind, is necessary in all these productions of dephlogisticated air; for if the apparatus is set in a very dark place, little will be formed, and that of a bad quality. So ignorant are we of the nature of this mysterious fluid, that scarce any inquiry has been made into its mode of operation in producing dephlogisticated air. By some the element of light has been supposed to be phlogiston itself, or some modification of it: but since the discovery of the identity of phlogiston and charcoal, it is probable that this opinion will not be held by many. One experiment, however, commonly brought in favour of this supposition, deserves particular attention. This is the property which light has of giving a black colour to the calces of silver; a phenomenon so remarkable, that it has been imagined an indubitable proof of the identity of light and phlogiston. In like manner, the pure and dephlogisticated spirit of nitre is found to be converted into the phlogisticated and smoking kind by exposure to the solar rays. The extensive diffusion of the substance called *phlogiston*, however, is now so well known, that we may reasonably conclude, that in these experiments it was contained in the ingredients themselves, and not in the light. Thus when silver is precipitated by chalk, and the mass turns black on exposure to the sun's rays, we are very sure that the chalk contains phlogiston; and that there is an attraction between the metallic calx and this principle: but we are by no means ascertained of the nature of light, as not being in any manner of way the subject of our investigation except by observing its effects. As in all other cases, therefore, where light is concerned, we can only say that such a thing is the effect of the operation of light, and not the substance of the element made visible, or converted into some other thing; we have no reason, in this case, to say, that the blackening of the metallic calx is any other than an effect of the light's operation, and not the detention of any part of its substance. This operation may be easily conceived to be the promoting of the union of the phlogiston and calx, which we know that light has a great tendency to do at any rate when we augment its action in such a manner as to make it become *fire*. The tendency of light, therefore, to promote an union betwixt phlogiston and other substances, will explain this and many other experiments in a very easy manner. In the case of chalk and calx of silver, the action of the light enables the calx to attract the phlogiston of the chalk, and thus become black. If the calx is not precipitated by chalk, but by an alkali, it must be in contact either with air, water, or some other fluid. All these undoubtedly contain phlogiston. With regard to air, it has not been denied that it is a general receptacle of all the decayed and volatile parts of vegetables and animals; that it contains vast quantities of inflammable air, which are constantly emitted from

Dephlogi-
sticated
Air.

Dephlogi-
ficated
Air.

from various parts of the earth; and, according to the Phlogistians, that fluid called *phlogisticated air*, which constitutes the other part of the fluid we breathe, likewise contains a quantity of the same matter. We are not to be surpris'd therefore that, in the case of the calx of silver, some of these substances should be oblig'd to part with a little of their phlogiston, sufficient to blacken the metallic earth. In order to prove that *light* and phlogiston are the same, the experiment ought to succeed in a perfect vacuum, of which there is no probability; though indeed it has never been tried that we know of. In like manner, when spirit of nitre is rendered high coloured and smoking by exposure to the sun in a glass, the phlogiston may come either from the glass itself, which is now found to contain phlogiston, or from the quantity of air which is necessary to be left in the glass, in order to make the experiment succeed.

Thus we may reasonably suppose the blackening of the calx of silver, and the rendering clear spirit of nitre high-coloured, to proceed only from the separation of phlogiston by means of light, and its consequent attraction by the calx or acid; and in other cases, where any similar effect is observed by the exposure of bodies to that element, we are to suppose that it is occasioned by the detachment of phlogiston from one substance and its attachment to another. In the case of the emission of dephlogisticated air by means of light, therefore, we may, by reasoning analogically, conclude, that it is occasioned by the absorption of phlogiston by the substance which is said to emit the air.

Before this matter, however, can be determined exactly, we ought to be well acquainted with the composition of dephlogisticated air itself; and indeed, without this, it seems almost in vain to speak upon the subject. But, notwithstanding the labours and ingenuity of modern aerologists, this point has not been in any degree settled. On examination, it is found to consist of an invisible fluid which does not appear to gravitate, and which in all probability is no other than elementary fire; and of another substance equally invisible, but capable of attaching itself to certain bodies, particularly iron, and adding to its weight very considerably. On attempting to procure this substance by itself, we find the attachment so strong, that no force of fire can separate them. In attempting a decomposition by means of the electric spark, all that has been yet done, even with the greatest power of electricity excited by Van Marum's new machine, is to make it lose some part of its bulk, the remainder appearing by the eudiometer to have undergone no change. Dr Priestley, in his sixth volume of *Experiments on Air*, acquiesces in the opinion suggested to him by Mr Watt, that the air in question is nothing else but one of the component parts of water united with the element of heat. Allowing this to be just, and indeed there is no experiment hitherto published by which it can be contradicted, the natural method of the production of dephlogisticated air from water may be easily explained. This only requires us to suppose, that the substances immersed in the water, are by the action of the sun's light made to attract part of the phlogiston of the water; in consequence of which the dephlogisticated part of that element, instantly being

volatilized by the light and heat of the sun (for heat is necessary for the production as well as light), assumes the properties of dephlogisticated air. But why, it may be asked, does water of itself emit dephlogisticated air without any substance whatever immersed in it? or, after certain substances have been immersed in it, by which this emission is promoted, why does the production of air stop with regard to any particular substance, and any determined quantity of water? Thus, it may be said, if any quantity of water, suppose a pint, yields one inch of cubic air by the immersion of a certain substance into it, why does not this substance attract from it all the phlogiston it is capable of absorbing? Instead of this, the water appears, by the colour it acquires, to be more phlogisticated than before; and the substance immersed, by being put into fresh water, will immediately occasion the emission of new quantities of air, and this for several times running. But to this it may be replied, that though the substance immersed attracts the phlogiston of the water, the latter will part with it only to a certain degree; and it is well known, that when two substances are united to the point of saturation by chemical attraction, the abstraction of a part of one of them will increase the attraction betwixt the remainder to a great degree. Though the substance immersed in the fluid, therefore, has originally a greater attraction for the phlogiston of the water than the dephlogisticated part of the element itself; yet as the one gradually augments, and the other diminishes, a balance soon takes place. With regard to the green colour generally assumed by the water after such experiments, it most probably proceeds from an accumulation of some terrestrial particles partly supplied by the immersed substance, or perhaps from a disposition to generate the green matter observed by Dr Priestley. That the substance immersed in the water does really part with some particles, is evident, because the water smells of it, as when raw silk is made use of; nor can we suppose that any vegetable or animal substance, such as are found to be alone fit for these experiments, can endure a long maceration in water without parting with a considerable quantity of their component parts. Indeed, under the article CHARCOAL, it is shown that this body, though now allowed to be pure phlogiston, or the next thing to it, has the power of separating other phlogistic matter, probably such as is more impure, from different substances. Hence its property of whitening tartar, purifying malt spirits, &c. It is not unreasonable, therefore, to suppose, that a dead leaf, though a very phlogistic substance, may have the power of attracting more phlogiston from the water, and thus allowing part of that element to be changed into dephlogisticated air; while, in lieu of the phlogiston attracted from the water, it diffuses a certain portion of its own substance through the fluid, and thus gives it the colour in question. With regard to the other difficulty, viz. that water, when exposed to the solar rays, will emit dephlogisticated air without any thing immersed in it, it may be accounted for from the ease with which the dephlogisticated part of the water is volatilized; so that the attraction of the other is not able to detain it. This we find exemplified in several chemical experiments, as when a volatile alkali is joined with any of the more fixed acids; for in these cases the alkali,

Dephlogi-
ficated
Air.

Dephlogi-
ficated
Air.

notwithstanding the mutual attraction betwixt it and the acid, will be made to fly off by a strong heat.

On the supposition that dephlogisticated air is composed of elementary fire and one of the constituent parts of water, there is very little difficulty in accounting for the origin of the immense quantity necessary to supply the animal creation with it. Under the article DAMPS, it has been shown that a vast quantity of fixed air is continually elaborated in the bowels of the earth. This is composed entirely of dephlogisticated air, compounded with a certain portion of phlogiston. Part of this fixed air must be undoubtedly evaporating constantly from the surface, and would as certainly infect the lower parts of the atmosphere, were there not some natural causes for its decomposition. One of these undoubtedly is the absorption of the phlogistic part by vegetables, which under the article AGRICULTURE is shown to be their proper food. But when the phlogiston is absorbed, a great quantity of dephlogisticated air is prepared, which supplies the deficiency occasioned by the respiration of animals. It must likewise be observed, that after the dephlogisticated air has been spoiled either by respiration or the support of flame, it is not for that reason entirely destroyed, but only converted into fixed air, and consequently may again be purified as before.

It may be likewise reasonably supposed, that in cases where vegetation does not take place, and in spring before the plants begin to exert their vegetative powers, and in autumn, or the beginning of winter, when they decay, the vegetable soil itself may perform this office: and indeed the circumstance of fresh vegetable mold affording an agreeable smell when turned up, as is mentioned under the article AGRICULTURE, seems to be a considerable confirmation of this.

The property which water has of absorbing fixed air, and also phlogiston, may likewise induce us to suppose that it acts as a purifier not only of the common atmosphere, but of that which issues from the earth; and hence some waters, particularly that of the ocean, are found to contain air of a purer kind than that of the atmosphere.

As light, however, is an indispensable requisite in all these cases, a difficulty still remains concerning the production of dephlogisticated air in winter, when the light and heat are so much diminished. In this season, indeed, it is probable that a quantity will be produced greatly inferior to that which the summer affords: but here we may very reasonably have recourse to the immense magazine of the atmosphere itself; which, from the mere circumstance of quantity, must be much more than sufficient to answer the expences of one season; especially when we consider, that in summer a superabundant quantity is certainly produced. Add to this, that in extreme cold, fixed air seems not only to be less noxious than at other times, but even necessary for the preservation of health*. We must likewise consider, that during the winter season there will be a constant flux of the cold air of the northern and southern regions towards the equator; and this, however imperceptible to the inhabitants, will keep up a constant circulation of atmospherical fluid, so that there cannot be any stagnation even in the calmest weather and most severe and long continued frosts.

Soon after Dr Priestley began his experiments on

air, he found that the red colour of the blood depends on the air; that by coming in contact with it, the black venous blood became in a very short time of a beautiful florid colour; and that even the under side of a clot of blood, by exposure to the air, will lose its disagreeable dark colour, and assume the same with that of blood newly drawn. These effects are entirely to be attributed to the dephlogisticated part: and his theory of respiration being a phlogistic process, seems to be fully confirmed by the discovery of the composition of fixed air. For, as fixed air is known to be composed of phlogiston and dephlogisticated air, we cannot suppose this phlogiston to be derived from any other source than the lungs. The doctor in this theory likewise obviates an objection that might naturally occur, that the air has not immediate access to the blood in the lungs, because of the thin membranes of the vessels which intervene. But, from his experiments, it appears that this is no obstacle. The serum of blood he finds to be capable of transmitting dephlogisticated air, or at least of propagating this effect through a very considerable thickness of its own substance, as well as through bladders moistened with it; a property which does not belong to any other animal fluid.

As dephlogisticated air is now known to be the immediate support of animal life, it has naturally been supposed that it might answer valuable purposes in medicine; but the difficulty of procuring it in sufficient quantity has hitherto prevented these hopes from being realized, excepting only in cases of drowning, where it is said to produce very great effects. With regard to any method of preparing it, no farther discovery has been made than what is suggested under the article AEROLOGY.

DEPILATORY MEDICINES, those applied in order to take off the hair; such are lime and orpiment known to be, but which ought to be used with great caution.

DEPONENT, in Latin grammar, a term applied to verbs which have active significations, but passive terminations or conjugations, and want one of their participles passive.

DEPONENT, in the law of Scotland, a person who makes a deposition. See DEPOSITION.

DEPOPULATION, the act of diminishing the number of people in any country, whether by war or bad politics.

DEPORTATION, a sort of banishment used by the Romans, whereby some island or other place was allotted to a criminal for the place of his abode, with a prohibition not to stir out of the same on pain of death.

DEPOSIT, among civilians, something that is committed to the custody of a person, to be kept without any reward, and to be returned again on demand.

DEPOSITARY, in law, a person intrusted as keeper or guardian of a deposit.

DEPOSITION, in law, the testimony given in court by a witness upon oath.

DEPOSITION is also used for the sequestering or depriving a person of his dignity and office.

This deposition only differs from abdication, in that the latter is supposed voluntary, and the act of the dignitary, or officer himself; and the former of compulsion, being the act of a superior power, whose authority

Air.

Deprecation
Depth. rity extends thereto. Some say the deposition, and some the abdication, of king James II.

Deposition does not differ from deprivation: we say indifferently, a deposed, or deprived bishop, official, &c.

Deposition differs from suspension, in that it absolutely and for ever strips or divests a priest, &c. of all dignity, office, &c. whereas suspension only prohibits, or restrains, the exercise thereof.

Deposition only differs from degradation, in that the latter is more formal, and attended with more circumstances, than the former; but in effect and substance they are the same; those additional circumstances being only matter of show, first set on foot out of zeal and indignation, and kept up by custom, but not warranted by the laws or canons. See DEGRADATION.

DEPRECATION, in rhetoric, a figure whereby the orator invokes the aid and assistance of some one; or prays for some great evil or punishment to befall him who speaks falsely, either himself or his adversary.

DEPRECATORY, or DEPRECATIVE, in theology, a term applied to the manner of performing some ceremonies in the form of prayer.

The form of absolution is deprecative in the Greek church, being conceived in these terms, *May God absolve you*: whereas it is in the declarative form in the Latin church, and some of the reformed churches, *I absolve you*.

DEPRESSION of the POLE. When a person sails or travels towards the equator, he is said to depress the pole; because as many degrees as he approaches nearer the equator, so many degrees will the pole be nearer the horizon. This phenomenon arises from the spherical figure of the earth.

DEPRESSOR, or DEPRIMENS, in anatomy, a name applied to several muscles, because they depress the parts they are fastened to.

DEPRIVATION, in the common law, the act of bereaving, divesting, or taking away a spiritual promotion or dignity: as when a bishop, vicar, prebend, or the like, is deposed or deprived of his preferment, for some matter, or fault, in fact, or in law. See DEPOSITION.

Deprivation is of two kinds; *a beneficio, et ab officio*.

DEPRIVATION *a beneficio* is, when for some great crime a minister is wholly and for ever deprived of his living or preferment: which differs from suspension, in that the latter is only temporary.

DEPRIVATION *ab officio*, is when a minister is for ever deprived of his order: which is the same, in reality, with what we otherwise call *deposition* and *degradation*; and is usually for some heinous crime deserving death, and is performed by the bishop in a solemn manner. See DEGRADATION.

DEPTFORD, a town three miles east of London, on the southern banks of the Thames; chiefly considerable for its fine docks for building ships, and the king's yard. E. Long. 0. 4. N. Lat. 51. 30.

DEPTH, the measure of any thing from the surface downwards.

Measuring of DEPTHS by the Barometer, depends on the same principles on which heights are measured by

the same instrument. The mensuration of depths being chiefly applied to mines, is still more precarious than the mensuration of heights, on account of the various kinds of vapours with which these subterranean regions are filled. But for a particular account of these difficulties, with the best methods of obviating them, see the articles BAROMETER and MINES.

DEPTH of a Squadron, or Battalion, is the number of men in a file; which in a squadron is three, and in a battalion generally six. See SQUADRON, FILE, &c.

We say, the battalion was drawn up six deep; the enemies horse were drawn up five deep.

DEPURATION is the freeing of any fluid from its heterogeneous matter or feculence. It is of three kinds. 1. Decantation; which is performed by letting the liquid to be depurated stand for some time in a pretty deep vessel, till the gross sediment has fallen to the bottom; after which the clear fluid is poured off. 2. Despumation; which is performed by means of the whites of eggs, or other viscid matter, and is also called CLARIFICATION. 3. Filtration. See CHEMISTRY, n^o 69.

DEPURATORY FEVER, a name given by Sydenham to a fever which prevailed much in the years 1661, 1662, 1663, and 1664. He called it depuratory, because he supposed that nature regulated all the symptoms in such a manner, as to fit the febrile matter, prepared by proper concoction, for expulsion in a certain time, either by a copious sweat or a freer perspiration.

DEPUTATION, a mission of select persons out of a company or body, to a prince or assembly, to treat of matters in their name.

DEPUTY, a person sent upon some business by some community.

DEPUTY is also one that exercises an office in another's right; and the forfeiture or misdemeanour of such deputy shall cause the person whom he represents to lose his office.

DEPUTATUS, among the ancients, a name applied to persons employed in making of armour; and likewise to brisk active people, whose business was to take care of the wounded in engagements, and carry them off the field.

DER, a syllable frequently prefixed to the names of places in England. It is said to signify that such were formerly places where wild beasts herded together, so called from the Saxon *deop, fera*, unless the situation was near some river.

DERBEND, a strong town of Asia, in Persia, said to have been founded by Alexander the Great. The walls are built with stones as hard as marble; and near it are the remains of a wall which reached from the Caspian to the Black Sea. It is seated near the Caspian Sea, at the foot of Mount Caucasus. E. Long. 50. 0. N. Lat. 42. 8.

DERBY, the capital of a county of the same name in England. It is thought to have received its name from being formerly a park or shelter for deer; and what makes this supposition more probable is, that the arms of the town consist of a buck couchant in a park. It is very ancient, having been a royal borough in the time of Edward the Confessor. At present it is a neat town, very populous, and sends two members to parliament. In digging for foundations of houses, hu-

Derbyshire man bones of a monstrous size have sometimes been found. The trade consists in wool, corn, malt, and ale, of which considerable quantities are sent to London. Here also is that curious machine for throwing silk, the model of which Sir Thomas Lombe, at the hazard of his life, brought from Italy. Before that time, the English merchants used to purchase thrown silks of the Italians for ready money. But by the help of this wonderful machine, one hand-mill will twist as much silk as 50 people could do without it. It works 73,726 yards of silk every time the water-wheel goes round, which is thrice in a minute. The house in which it is contained is five or six stories high, and half a quarter of a mile in length. When Sir Thomas's patent expired in 1732, the parliament were so sensible of the value and importance of the machine, that they granted him a further recompence of 14,000 l. for the hazard and expence he had incurred in introducing and erecting it, upon condition he should allow an exact model of it to be taken. This model is deposited in the Tower of London, in order to prevent so curious and important an art from being lost. The town of Derby is watered by a river and a brook; the latter of which has nine bridges over it, the former only one. Derby gives title of Earl to the noble family of Stanley, being the second earldom in England. W. Long. 1. 45. N. Lat. 52. 57.

DERBY-SHIRE, a county of England, bounded on the east by Nottinghamshire, and a part of Leicestershire, which last bounds it also on the south. On the west it is bounded by Staffordshire, and part of Cheshire; and on the north by Yorkshire. It is near 40 miles in length from south to north; about 30 in breadth on the north side, but on the south no more than six.—The air is pleasant and healthful, especially on the east side; but on the west, about the peak, it is sharper and more subject to wind and rain. The soil is very different in different parts of the country. In the east and south parts it is very fruitful in all kinds of grain; but in the west, beyond the Derwent, it is barren and mountainous, producing nothing but a little oats. There is, however, plenty of grass in the valleys, which affords pasture to a great number of sheep. This part of the country is called the *Peak*, from a Saxon word signifying an eminence. Its mountains are very bleak, high, and barren; but extremely profitable to the inhabitants. They yield great quantities of the best lead, antimony, iron, scythe-stones, grind-stones, marble, alabaster, a coarse sort of crystal, azure, spar, and pit-coal. In these mountains are two remarkable caverns, named *Pool's Hole*, and *Elden-Hole*; for a description of which, see these articles.

DEREHAM, a town of Norfolk in England, situated in E. Long. 1. 0. N. Lat. 52. 40. It is pretty large, and the market is noted for wollen yarn.

DERELICTS, (from *de*, and *relinquo*, "I leave"), in the civil law, are such goods as are wilfully thrown away, or relinquished by the owner.

DERELICT is also applied to such lands as the sea receding from leaves dry, and fit for cultivation. If they are left by a gradual recess of the sea, they are adjudged to belong to the owner of the adjoining lands; but when an island is formed in the sea, or a

VOL. V.

large quantity of new land appears, such derelict lands belong to the king.

DERHAM (Doctor William), a very celebrated English philosopher and divine, born in 1657. In 1682, he was presented to the vicarage of Wargrave in Berkshire; and, in 1689, to the valuable rectory of Upminster in Essex; which latter lying at a convenient distance from London, afforded him an opportunity of conversing and corresponding with the greatest virtuofos of the nation. Applying himself there with great eagerness to natural and experimental philosophy, he soon became a distinguished member of the Royal society, whose Philosophical Transactions contain a great variety of curious and valuable pieces, the fruits of his laudable industry. In his younger years he published his *Artificial Clockmaker*, which has been often printed: and in 1711, 1712, and 1714, he preached those sermons at Boyle's lecture which he afterward digested under the well-known titles of *Physico-Theology* and *Astro-Theology*, and enriched with valuable notes and copper-plates. The last thing he published of his own composition was *Christo-Theology*, a demonstration of the divine authority of the Christian religion, being the substance of a sermon preached at Bath in 1729. This great good man, after spending his life in the most agreeable as well as improving study of nature, died at Upminster in 1735; and, beside many other works, left a valuable collection of curiosities, particularly specimens of birds and insects of the island.—It may be necessary just to observe, that Dr Derham was very well skilled in medical as well as in physical knowledge; and was constantly a physician to the bodies as well as to the souls of his parishioners.

DERIVATION, in medicine, is when a humour which cannot conveniently be evacuated at the part affected, is attracted from thence, and discharged elsewhere; thus, a blister is applied to the neck to draw away the humour from the eyes.

DERIVATION, in grammar, the affinity one word has with another, by having been originally formed from it. See **DERIVATIVE**.

DERIVATIVE, in grammar, a word which takes its origin from another word, called its *primitive*.—Such is the word derivative itself, which takes its origin from the primitive *rivus*, a rivulet or channel, out of which lesser streams are drawn; and thus *manhood*, *deity*, *lawyer*, &c. are derived from *man*, *deus*, *law*, &c.

DERMESTES, in zoology, a genus of insects belonging to the order of coleoptera. The antennæ are clavated, with three of the joints thicker than the rest; the breast is convex; and the head is inflected below the breast. The species are pretty numerous.

1. The *lardarius* is of an oblong form and of a dim black colour, easily distinguishable by a light brown stripe that occupies transversely almost the anterior half of the elytra. That colour depends on small grey hairs situated on that part. The stripe is irregular at its edges, and intersected through the middle by a small transversal streak of black spots, three in number on each of the elytra, the middlemost of which is somewhat lower than the rest, which gives the black streak a serpentine form. Its larva that is oblong, somewhat

5 E

Larv,

Derham,
Dermestes.

Dermestes hairy, and divided into segments alternately dark and light coloured, gnaws and destroys preparations of animals preserved in collections, and even feeds upon the insects; it is also to be found in old bacon. 2. The domesticus varies greatly in size and colour, some being found of a dark brown, others of a much lighter hue. The form of it is oblong, almost cylindrical. The elytra are striated, the thorax is thick and rather gibbous. This little animal, when touched, draws in its head under its thorax and its feet beneath its abdomen, remaining so motionless that one would think it dead. This is the same insect which makes in wooden furniture those little round holes that reduce it to powder. 3. The violaceus is a beautiful little insect: its elytra are of a deep violet blue. The thorax is covered with greenish hairs, the legs are black. The whole animal being of a glittering brilliancy renders it a pleasing object. The larva, as well as the perfect insect, inhabits the bodies of dead animals. 4. The fumatus is of a light brown, except the eyes, which are black. It is however sometimes more or less deep. The thorax is margined, and the insect has the whole carriage of a scarabæus; but its antennæ have the character of those of the dermestæ. This little creature is found in dung. It also frequently finds its way into houses. 5. The ferrugineus is the largest genus; its colour is a rusty iron, having many oblong, velvety, black spots upon the elytra, which gives the insect a gloomy, yet elegant appearance. The antennæ differ from the preceding species; the three last articulations being considerably longer, thicker, and not perfoliated.

There are 25 other species, distinguished by their colour.—Many varieties of this genus, as well as the larvæ, are to be met with in dried skins, bark of trees, wood, seeds, flowers, the carcasses of dead animals, &c.—The lardarius, so destructive to birds, insects, and other subjects of natural history preserved in cabinets, is to be killed by arsenic.

DERNIER RESSORT. See **RESSORT**

DEROGATION, an act contrary to a preceding one, and which annuls, destroys, and revokes it, either in whole or in part.

DEROGATORY, a clause importing derogation. A derogatory clause in a testament, is a certain sentence, cipher, or secret character, which the testator inserts in his will, and of which he reserves the knowledge to himself alone, adding a condition, that no will he may make hereafter is to be reckoned valid, if this derogatory clause is not inserted expressly and word for word. It is a precaution invented by lawyers against latter-wills extorted by violence, or obtained by suggestion.

DERP, a town of Livonia, and capital of a palatinate of the same name, with a bishop's see, and an university. It is subject to the Russians, and lies near the river Ambeck. E. Long. 31. 55. N. Lat. 30. 40.

DETRONA, **DETRON** or **DETRON** (anc. geog.), a colony of the Cispadana; called *Julia Augusta*, on inscriptions and coins; midway between Genoa and Placentia, and situated to the east of the Tanarus in Liguria. Now Tortona, a city of Milan. E. Long. 9. 12. N. Lat. 45.

DETROSA, (anc. geog.); the capital of the Ileræones, in Tarraconensis, or the Hither Spain: a mu-

nicipum and colony; surnamed *Julia Ilergavonia* (Coin.) **Dertofani**, the people. Now Tortosa, in Catalonia, on the Ebro. E. Long. 15. N. Lat. 40. 45.

DERVENTIO, (anc. geog.); a river of the Brigantes in Britain. Now the Darwent, in the east of Yorkshire, falling into the Ouse. Also a town of the Brigantes on the same river. Now called *Auldby*, seven miles from York, to the north-east (Camden).

DERVIS, or **DERVICH**, a name given to a sort of monks among the Turks, who lead a very austere life, and profess extreme poverty; though they are allowed to marry. The word is originally Persian, *دردیش* signifying a "beggar," or person who has nothing: and because the religious, and particularly the followers of Mevelava, profess not to possess any thing, they call both the religious in general, and the Mevelavites in particular, *Dervises* or *Derviches*.

The dervises, called also *Mevelavites*, are a Mahometan order of religious; the chief or founder whereof was one Mevelava. They are now very numerous. Their chief monastery is that near Cogna in Natolia, where the general makes his residence, and where all the assemblies of the order are held; the other houses being all dependent on this, by a privilege granted to this monastery under Ottoman I.

The dervises affect a great deal of modesty, patience, humility, and charity. They always go bare-legged and open-breasted, and frequently burn themselves with hot irons, to inure themselves to patience. They always fast on Wednesdays, eating nothing on those days till after sun-set. Tuesdays and Fridays they hold meetings, at which the superior of the house presides. One of them plays all the while on a flute, and the rest dance, turning their bodies round and round with the greatest swiftness imaginable. Long custom to this exercise from their youth has brought them to such a habitude, that it does not discompose them at all. This practice they observe with great strictness, in memory of Mevelava their patriarch's turning miraculously round, as they pretend, for the space of four days, without any food or refreshment; his companion Hamfa playing all the while on the flute: after which he fell into an ecstasy, and therein received wonderful revelations for the establishment of his order. They believe the flute an instrument consecrated by Jacob and the shepherds of the Old Testament, because they sang the praises of God upon them. They profess poverty, chastity, and obedience, and really observe them while they remain dervises; but if they choose to go out and marry, they are always allowed.

The generality of dervises are mountebanks: some apply themselves to legerdemain, postures, &c. to amuse the people; others give in to sorcery and magic: but all of them, contrary to Mahomet's precept, are said to drink wine, brandy, and other strong liquors, to give them the degree of gaiety their order requires.

Beside their great saint Mevelava, there are particular saints honoured in some particular monasteries: as Kiderele, greatly revered in the monasteries of Egypt, and held by some to be St George; and by others, with more probability, the prophet Elias.

The dervises are great travellers; and, under pretence of preaching, and propagating their faith, are continually passing from one place to another: on which account they have been frequently used as spies.

Derventio,
Dervis.

There

Desaguliers
||
Descant.

There are also dervises in Persia, called in that country *Abdals*, q. d. *servants of God*. They lead a very penurious, austere life, and preach the Alcoran in the streets, coffee-houses, and wherever they can meet with auditors. The Persian dervises retail little but fables to the people, and are in the utmost contempt among the men of sense and letters.

There are in Egypt two or three kinds: those that are in convents, are in a manner of the religious order, and live retired; though there are of these some who travel, and return again to their convents. Some take this character, and yet live with their families, and exercise their trades: of this kind are the dancing dervises at Damascus, who go once or twice a week to a little uninhabited convent, and perform their extraordinary exercises; these also seem to be a good people: but there is a third sort of them who travel about the country, and beg, or rather oblige people to give, for whenever they found their horn something must be given them. The people of these orders, in Egypt, wear an octagonal badge, of a greenish white alabaster, at their girdles, and a high stiff cap without any thing round it.

DESAGULIERS (John Theophilus), who introduced the practice of reading public lectures in experimental philosophy in London, and who made several improvements in mechanics; was the son of the reverend John Desaguliers, a French protestant refugee, and was born at Rochelle in 1683. His father brought him to England an infant; and at a proper age placed him at Christ-church college, Oxford; where he succeeded Dr Keil in reading lectures on experimental philosophy at Hart Hall. The magnificent duke of Chandos made Dr Desaguliers, his chaplain, and presented him to the living of Edgware, near his seat at Cannons: and he was afterwards chaplain to Frederic prince of Wales. He read lectures with great success to the time of his death in 1749. He communicated many curious papers printed in the Philosophical Transactions; published a valuable *Course of Experimental Philosophy*, in 2 vols 4to; and gave an edition of *Gregory's Elements of Catoptrics and Dioptrics*, with an appendix on reflecting telescopes, 8vo. He was a member of the Royal Society, and of several foreign academies.

DESART, a large extent of country entirely barren, and producing nothing. In this sense some are sandy desarts; as those of Lop, Xamo, Arabia, and several others in Asia; in Africa, those of Libya and Zara: others are stony, as the desart of Pharan in Arabia Petrea.

The *DESART*, absolutely so called, is that part of Arabia south of the Holy Land, where the children of Israel wandered forty years.

DESCANT, in music, the art of composing in several parts. See COMPOSITION.

Descant is three-fold, viz. plain, figurative, and double.

Plain DESCANT is the ground-work and foundation of all musical compositions, consisting altogether in the orderly placing of many concords, answering to simple counterpoint. See COUNTERPOINT.

Figurative or Florid DESCANT, is that part of an air of music wherein some discords are concerned, as well, though not so much, as concords. This may be term-

ed the ornamental and rhetorical part of music, in regard that there are introduced all the varieties of points, syncopes, diversities of measures, and whatever is capable of adorning the composition.

DESCANT Double, is when the parts are so contrived, that the treble, or any high part, may be made the bass; and, on the contrary, the bass the treble.

DESCARTES. See CARTES.

DESCENDANT. The issue of a common parent, *in infinitum*, are called his descendants. See the article DECENT.

DESCENSION, in astronomy, is either right or oblique.

Right DESCENSION, is an arch of the equinoctial, intercepted between the next equinoctial point and the intersection of the meridian, passing through the centre of the object, at its setting, in a right sphere.

Oblique DESCENSION, an arch of the equinoctial, intercepted between the next equinoctial point and the horizon, passing through the centre of the object, at its setting in an oblique sphere.

DESCENT, in general, is the tendency of a body from a higher to a lower place; thus all bodies, unless otherwise determined by a force superior to their gravity, descend towards the centre of the earth. See GRAVITY and MECHANICS.

DESCENT, or *Hereditary Succession*, in law, is the title whereby a man, on the death of his ancestor, acquires his estate by right of representation, as his heir at law. An heir, therefore, is he upon whom the law casts the estate immediately on the death of the ancestor; and an estate so descending to the heir is in law called the *inheritance*.

Descent is either *lineal* or *collateral*. The former is that conveyed down in a right line from the grandfather to the father, and from the father to the son, and from the son to the grandson. The latter is that springing out of the side of the line or blood; as from a man to his brother, nephew, or the like.

The doctrine of descents, or law of inheritances in fee-simple, is a point of the highest importance: (See the article FEE). All the rules relating to purchases, whereby the legal course of descents is broken and altered, perpetually refer to this settled law of inheritance as a *datum* or first principle universally known, and upon which their subsequent limitations are to work. Thus a gift in tail, or to a man and the heirs of his body, is a limitation that cannot be perfectly understood without a previous knowledge of the law of descents in fee-simple. One may well perceive, that this is an estate confined in its descent to such heirs only of the donee as have sprung or shall spring from his body: but who those heirs are, whether all his children both male and female, or the male only, and (among the males) whether the eldest, youngest, or other son alone, or all the sons together, shall be his heir; this is a point that we must resort back to the standing law of descents in fee-simple to be informed of.

And as this depends not a little on the nature of kindred, and the several degrees of consanguinity, it will be necessary to refer the reader to the article CONSANGUINITY, where the true notion of this kindred or alliance in blood is particularly stated.

We shall here exhibit a series of rules or canons of inheritance, with illustrations, according to which, by

Descant
||
Descent.

Descent. the law of England, estates are transmitted from the ancestor to the heir.

1. "Inheritances shall lineally descend to the issue of the person last actually seized *in infinitum*, but shall never lineally ascend."

To understand both this and the subsequent rules, it must be observed, that by law no inheritance can vest, nor can any person be the actual complete heir of another, till the ancestor is previously dead. *Nemo est hæres viventis*. Before that time, the person who is next in the line of succession is called an *heir apparent* or *heir presumptive*. Heirs apparent are such whose right of inheritance is indefeasible, provided they outlive the ancestor; as the eldest son or his issue, who must, by the course of the common law, be heirs to the father whenever he happens to die. Heirs presumptive are such, who, if the ancestor should die immediately, would in the present circumstances of things be his heirs; but whose right of inheritance may be defeated by the contingency of some nearer heir being born: as a brother or nephew, whose presumptive succession may be destroyed by the birth of a child: or a daughter, whose present hopes may be hereafter cut off by the birth of a son. Nay, even if the estate hath descended, by the death of the owner, to such a brother, or nephew, or daughter; in the former cases, the estate shall be divested and taken away by the birth of a posthumous child; and in the latter, it shall also be totally divested by the birth of a posthumous son.

We must also remember, that no person can be properly such an ancestor as that an inheritance in lands or tenements can be derived from him, unless he hath had actual seisin of such lands, either by his own entry, or by the possession of his own or his ancestor's lessee for years, or by receiving rent from a lessee of the freehold: or unless he hath what is equivalent to corporal seisin in hereditaments that are incorporeal; such as the receipt of rent, a presentation to the church in case of an advowson, and the like. But he shall not be accounted an ancestor who hath had only a bare right or title to enter or be otherwise seized. And therefore all the cases which will be mentioned in the present article, are upon the supposition that the deceased (whose inheritance is now claimed) was the last person actually seized thereof. For the law requires this notoriety of possession, as evidence that the ancestor had that property in himself, which is now to be transmitted to his heir. Which notoriety hath succeeded in the place of the ancient feudal investiture, whereby, while feuds were precarious, the vassal on the descent of lands was formerly admitted in the lord's court (as is still the practice in Scotland); and therefore received his seisin, in the nature of a renewal of his ancestor's grant, in the presence of the feudal peers: till at length, when the right of succession became indefeasible, an entry on any part of the lands within the county (which if disputed was afterwards to be tried by those peers), or other notorious possession, was admitted as equivalent to the formal grant of seisin, and made the tenant capable of transmitting his estate by descent. The seisin therefore of any person, thus understood, makes him the root or stock from which all future inheritance by right of blood must be derived; which is very briefly expressed in this maxim, *seisina facit stipitem*.

Blackst.
Comment.

When therefore a person dies so seized, the inheritance first goes to his issue: as if there be Geoffrey, John, and Matthew, grandfather, father and son; and John purchases land, and dies: his son Matthew shall succeed him as heir, and not the grandfather Geoffrey; to whom the land shall never ascend, but shall rather escheat to the lord.

2. "The male issue shall be admitted before the female."—Thus sons shall be admitted before daughters; or, as our male lawgivers have somewhat uncomplaisantly expressed it, the worthiest of blood shall be preferred. As if John Stiles hath two sons, Matthew and Gilbert, and two daughters, Margaret and Charlotte, and dies; first Matthew, and (in case of his death without issue) then Gilbert, shall be admitted to the succession in preference to both the daughters.

3. "Where there are two or more males in equal degree, the eldest only shall inherit; but the females all together."—As if a man hath two sons, Matthew and Gilbert, and two daughters, Margaret and Charlotte, and dies; Matthew his eldest son alone shall succeed to his estate, in exclusion of Gilbert the second son and both the daughters; but if both the sons die without issue before the father, the daughters Margaret and Charlotte shall both inherit the estate as coparceners.

4. "The lineal descendants, *in infinitum*, of any person deceased, shall represent their ancestor; that is, shall stand in the same place as the person himself would have done had he been living."—Thus the child, grandchild, or great-grandchild (either male or female), of the eldest son, succeeds before the younger son, and so *in infinitum*. And these representatives shall take neither more nor less, but just so much as their principles would have done. As if there be two sisters, Margaret and Charlotte; and Margaret dies, leaving six daughters; and then John Stiles the father of the two sisters dies without other issue: these six daughters shall take among them exactly the same as their mother Margaret would have done had she been living; that is, a moiety of the lands of John Stiles in coparcenary: so that upon partition made, if the land be divided into twelve parts, thereof Charlotte the surviving sister shall have six, and her six nieces, the daughters of Margaret one a-piece.

5. "On failure of lineal descendants, or issue, of the person last seized, the inheritance shall descend to the blood of the first purchaser; subject to the three preceding rules."—Thus, if Geoffrey Stiles purchases land, and it descends to John Stiles his son and John dies seized thereof without issue; whoever succeeds to this inheritance must be of the blood of Geoffrey the first purchaser of this family. The first purchaser, *perquisitor*, is he who first acquired the estate to his family, whether the same was transferred to him by sale or by gift, or by any other method, except only that of descent.

6. "The collateral heir of the person last seized must be his next collateral kinsman of the whole blood."

First, he must be his next collateral kinsman either personally or *jure representationis*; which proximity is reckoned according to the canonical degrees of consanguinity: See CONSANGUINITY. Therefore, the brother being in the first degree, he and his descendants shall exclude the uncle and his issue, who is only

Descent.

Descent.

in the second.—Thus if John Stiles dies without issue, his estate shall descend to Francis his brother, who is lineally descended from Geoffrey Stiles his next immediate ancestor or father. On failure of brethren or sisters and their issue, it shall descend to the uncle of John Stiles, the lineal descendant of his grandfather George: and so on *in infinitum*.

But, secondly, the heir need not be the nearest kinsman absolutely, but only *sub modo*; that is, he must be the nearest kinsman of the *whole* blood: for if there be a much nearer kinsman of the *half* blood, a distant kinsman of the whole blood shall be admitted, and the other entirely excluded.—A kinsman of the whole blood is he that is derived, not only from the same ancestor, but from the same couple of ancestors. For as every man's own blood is compounded of the bloods of his respective ancestors, he only is properly of the whole or entire blood with another who hath (so far as the distance of degrees will permit) all the same ingredients in the composition of his blood that the other hath. Thus, the blood of John Stiles being composed of those of Geoffrey Stiles his father, and Lucy Baker his mother, therefore his brother Francis, being descended from both the same parents, hath entirely the same blood with John Stiles; or he is his brother of the whole blood. But if, after the death of Geoffrey, Lucy Baker the mother marries a second husband, Lewis Gay, and hath issue by him: the blood of this issue, being compounded of the blood of Lucy Baker (it is true) on the one part, but that of Lewis Gay (instead of Geoffrey Stiles) on the other part, it hath therefore only half the same ingredients with that of John Stiles; so that he is only his brother of the half blood, and for that reason they shall never inherit to each other. So also, if the father has two sons, A and B, by different venters or wives; now these two brethren are not brethren of the whole blood, and therefore shall never inherit to each other, but the estate shall rather escheat to the lord. Nay, even if the father dies, and his lands descend to his eldest son A, who enters thereon, and dies seised without issue; still B shall not be heir to this estate, because he is only of the half blood to A, the person last seised: but had A died without entry, then B might have inherited: not as heir to A his half-brother, but as heir to their common father, who was the person last actually seised.

The rule then, together with its illustration, amounts to this, That in order to keep the estate of John Stiles as nearly as possible in the line of his purchasing ancestor, it must descend to the issue of the nearest couple of ancestors that have left descendants behind them; because the descendants of one ancestor only are not so likely to be in the line of that purchasing ancestor as those who are descended from two.

But here a difficulty arises. In the second, third, fourth, and every superior degree, every man has many couples of ancestors, increasing according to the distances in a geometrical progression upwards, the descendants of all which respective couples are (representatively) related to him in the same degree. Thus, in the second degree, the issue of George and Cecilia Stiles and of Andrew and Esther Baker, the two grandfathers and grandmothers of John Stiles, are each in the same degree of propinquity; in the third degree, the respective issues of Walter and Christian Stiles, of

Luke and Francis Kempe, of Herbert and Hannah Baker, and of James and Emma Thorpe, are (upon the extinction of the two inferior degrees) all equally intitled to call themselves the next kindred of the whole blood to John Stiles. To which therefore of these ancestors must we first resort in order to find out descendants to be preferably called to the inheritance? In answer to this, and to avoid the confusion and uncertainty that might arise between the several stocks wherein the purchasing ancestor may be sought for,—

7. The seventh and last rule or canon is, “That in collateral inheritances the male stocks shall be preferred to the female (that is, kindred derived from the blood of the male ancestors shall be admitted before those from the blood of the female);—unless where the lands have in fact descended from a female.”—Thus the relations on the father's side are admitted *in infinitum*, before those on the mother's side are admitted at all; and the relations of the father's father, before those of the father's mother; and so on.

For the original and progress of the above canons, the reasons upon which they are founded, and their agreement with the laws of other nations, the curious reader may consult *Blackstone's Commentaries*, Vol. II. p. 208—237.

We shall conclude with exemplifying the rules themselves by a short sketch of the manner in which we must search for the heir of a person, as John Stiles, who dies seised of land which he acquired, and which therefore he held as a feud of indefinite antiquity. See the *Table of DESCENTS* on Plate CLVI.

In the first place succeeds the eldest son, Matthew Stiles, or his issue, (n^o 1.) :—if his line be extinct, then Gilbert Stiles and the other sons respectively, in order of birth, or their issue, (n^o 2.) :—in default of these, all the daughters together, Margaret and Charlotte Stiles, or their issue, (n^o 3.)—On failure of the descendants of John Stiles himself, the issue of Geoffrey and Lucy Stiles, his parents, is called in: *viz.* first, Francis Stiles, the eldest brother of the whole blood, or his issue, (n^o 4.) :—then Oliver Stiles and the other whole brothers respectively, in order of birth, or their issue, (n^o 5.) :—then the sisters of the whole blood altogether, Bridget and Alice Stiles, or their issue, (n^o 6.)—In defect of these, the issue of George and Cecilia Stiles, his father's parents; respect being still had to their age and sex, (n^o 7.) :—then the issue of Walter and Christian Stiles, the parents of his paternal grandfather, n^o 8. :—then the issue of Richard and Anne Stiles, the parents of his paternal grandfather's father, (n^o 9.) :—and so on in the paternal grandfather's paternal line, or blood of Walter Stiles, *in infinitum*. In defect of these, the issue of William and Jane Smith, the parents of his paternal grandfather's mother, (n^o 10.) :—and so on in the paternal grandfather's maternal line, or blood of Christian Smith, *in infinitum*; till both the immediate bloods of George Stiles, the paternal grandfather, are spent.—Then we must resort to the issue of Luke and Francis Kempe, the parents of John Stiles's paternal grandmother, (n^o 11.) :—then to the issue of Thomas and Sarah Kempe, the parents of his paternal grandmother's father, (n^o 12.) :—and so on in the paternal grandmother's paternal line, or blood of Luke Kempe, *in infinitum*. In default of which

Descent.

Descent
||
Deserter.

which, we must call in the issue of Charles and Mary Holland, the parents of his paternal grandmother's mother, n^o 13.) : and so on in the paternal grandmother's maternal line, or blood of Frances Holland, *in infinitum* ; till both the immediate bloods of Cecilia Kempe, the paternal grandmother, are also spent.— Whereby the paternal blood of John Stiles entirely failing, recourse must then, and not before, be had to his maternal relations ; or the blood of the Bakers, (n^o 14, 15, 16.), Willis's (n^o 17), Thorpe's (n^o 18, 19.), and White's (n^o 20) ; in the same regular successive order as in the paternal line.

The student should bear in mind, that during this whole process, John Stiles is the person supposed to have been last actually seized of the estate. For if ever it comes to vest in any other person, as heir to John Stiles, a new order of succession must be observed upon the death of such heir ; since he, by his own seisin, now becomes himself an ancestor, or *stipes*, and must be put in the place of John Stiles. The figures, therefore, denote the order in which the several classes would succeed to John Stiles, and not to each other : and before we search for an heir in any of the higher figures, (as n^o 8.) we must be first assured that all the lower classes (from n^o 1 to 7.) were extinct at John Stiles's decease.

DESCENT, or *Succession*, in the law of Scotland. See Law, Part III. N^o clxxx. clxxxi.

DESCENT of the crown. See SUCCESSION.

DESCENT of Dignities. A dignity differs from common inheritances, and goes not according to the rules of the common law : for it descends to the half-blood ; and there is no coparcenership in it, but the eldest takes the whole. The dignity of peerage is personal, annexed to the blood ; and so inseparable, that it cannot be transferred to any person, or surrendered even to the crown : it can move neither forward nor backward, but only downward to posterity ; and nothing but corruption of blood, as if the ancestor be attainted of treason or felony, can hinder the descent to the right heir.

DESCENT, in genealogy, the order of succession of descendants in a line or family ; or their distance from a common progenitor : Thus we say, one descent, two descents, &c.

DESCENT, in heraldry, is used to express the coming down of any thing from above ; as, a lion *en descent* is a lion with his head towards the base points, and his heels towards one of the corners of the chief, as if he were leaping down from some high place.

DESCHAMPS (Francis), a French poet, born in Champagne, was the author of a tragedy intitled Cato of Utica, and a history of the French theatre. He died at Paris in 1747.

DESCRIPTION, in literary composition, is such a strong and beautiful representation of a thing, as gives the reader a distinct view and satisfactory notion of it. See NARRATION and Description.

DESEADA, or DESIDERARA, one of the Caribbee islands, subject to France, lying eastward of Guadaloupe.

DESERT, or DESART. See DESART.

DESERTER, in a military sense, a soldier who, by running away from his regiment or company, abandons the service.

A deserter is, by the articles of war, punishable by

death ; which, after conviction, is executed upon him at the head of the regiment he formerly belonged to, with his crime written on his breast.

DESERTION, in law. See LAW, N^o clx. 24.

DESHABILLE, a French term, naturalized of late. It properly signifies a night-gown, and other necessaries made use of in dressing or undressing. Mr — is not to be spoken with, he is yet in his *deshabille*, i. e. undressed or in his night-gown. The word is compounded of the privative *de* and *s'habiller*, " to dress one's self."

DESHACHE', in heraldry, is where a beast has its limbs separated from its body, so that they still remain on the escutcheon, with only a small separation from their natural places.

DESIDERATUM, is used to signify the desirable perfections in any art or science : thus, it is a desideratum with the blacksmith, to render iron fusible by a gentle heat, and yet preserve it hard enough for ordinary uses ; with the glassman and looking-glass maker, to render glass malleable ; with the clock-maker, to bring pendulums to be useful where there are irregular motions, &c.

DESIGN, in a general sense, the plan, order, representation, or construction of a building, book, painting, &c. See ARCHITECTURE, PAINTING, POETRY, ORATORY, and HISTORY.

DESIGN, in the manufactories, expresses the figures wherewith the workman enriches his stuff or silk, and which he copies after some painter or eminent draughtsman, as in diaper, damask, and other flowered silk and tapestry, and the like.

In undertaking of such kinds of figured stuffs, it is necessary, says Mons. Savary, that, before the first stroke of the shuttle, the whole design be represented on the threads of the warp, we do not mean in colours, but with an infinite number of little packthreads, which, being disposed so as to raise the threads of the warp, let the workmen see, from time to time, what kind of silk is to be put in the eye of the shuttle for woof. This method of preparing the work is called *reading the design*, and *reading the figure*, which is performed in the following manner : A paper is provided, considerably broader than the stuff, and of a length proportionate to what is intended to be represented thereon. This they divide lengthwise, by as many black lines as there are intended threads in the warp ; and cross these lines, by others drawn breadthwise, which, with the former, make little equal squares ; on the paper thus squared, the draughtsman designs his figures, and heightens them with colours as he sees fit. When the design is finished, a workman reads it, while another lays it on the simblot.

To read the design, is to tell the person who manages the loom, the number of squares or threads comprised in the space he is reading, intimating at the same time, whether it is ground or figure. To put what is read on the simblot, is to fasten little strings to the several packthreads, which are to raise the threads named ; and this they continue to do till the whole design is read.

Every piece being composed of several repetitions of the same design, when the whole design is drawn, the drawer, to re-begin the design afresh, has nothing to do but to raise the little strings, with slip-knots, to the

Desertion
||
Design.

Design. top of the simblot, which he had let down to the bottom: this he is to repeat as often as is necessary till the whole be manufactured.

The ribbon-weavers have likewise a design, but far more simple than that now described. It is drawn on paper with lines and squares, representing the threads of the warp and woof. But instead of lines, whereof the figures of the former consist, these are constituted of points only or dots, placed in certain of the little squares formed by the intersection of the lines. These points mark the threads of the warp that are to be raised, and the spaces left blank denote the threads that are to keep their situation: the rest is managed as in the former.

DESIGN is also used, in painting, for the first idea of a large work, drawn roughly, and in little, with an intention to be executed and finished in large.

In this sense, it is the simple contour or outlines of the figures intended to be represented, or the lines that terminate and circumscribe them: such design is sometimes drawn in crayons or ink, without any shadows at all; sometimes it is hatched, that is, the shadows are expressed by sensible outlines, usually drawn across each other with the pen, crayon, or graver. Sometimes, again, the shadows are done with the crayon rubbed so as that there do not appear any lines: at other times, the grains or stroke of the crayon appear, as not being rubbed: sometimes the design is washed, that is, the shadows are done with a pencil in Indian ink, or some other liquor; and sometimes the design is coloured, that is, colours are laid on much like those intended for the grand work.

DESIGN, in music, is justly defined by Rousseau to be the invention and the conduct of the subject, the disposition of every part, and the general order of the whole.

It is not sufficient to form beautiful airs, and a legitimate harmony; all these must be connected by a principal subject, to which all the parts of the work relate, and by which they become one. Thus unity ought to prevail in the air, in the movement, in the character, in the harmony, and in the modulation. All these must indispensably relate to one common idea which unites them. The greatest difficulty is, to reconcile the observation of those precepts with an elegant variety, which, if not introduced, renders the whole piece irksome and monotonous. Without question, the musician, as well as the poet and the painter, may risk every thing in favour of this delightful variety; if, under the pretext of contrasting, they do not endeavour to cheat us with false appearances, and instead of pieces justly and happily planned, present us with a musical minced meat, composed of little abortive fragments, and of characters so incompatible, that the whole assembled forms a heterogeneous monster.

*Non ut placidis coeant immitia, non ut
Serpentes avibus gimentur, tigribus agni.*

Translated thus:

But not that nature should revers'd appear;
Mix mild with fierce, and gentle with severe;
Profane her laws to contradiction's height;
Tygers with lambs, with serpent's birds unite.

It is therefore in a distribution formed with intelligence and taste, in a just proportion between all the parts, that the perfection of design consists; and it is

above all, in this point, that the immortal Pergoleso has shown his judgment and taste, and has left so far behind him all his competitors. His *Stabat Mater*, his *Orfeo*, his *Serva Patrona*, are, in three different species of composition, three masterpieces of design equally perfect.

This idea of the general design of a work is likewise particularly applicable to every piece of which it consists; thus the composer plans an air, a duett, a chorus, &c. For this purpose, after having invented his subject, he distributes it, according to the rules of a legitimate modulation, into all the parts where it ought to be perceived, in such a proportion, that its impression may not be lost on the minds of the audience; yet that it may never be reiterated in their ears, without the graces of novelty. The composer errs in designing who suffers his subject to be forgot; he is still more culpable who pursues it till it becomes trite and tiresome.

DESIGNATION, the act of marking or indicating, and making a thing known. The designation of such an estate is made by the tenants, burmenis, and boundings. Among the Romans, there were designations of the consuls and other magistrates, some time before their election.

DESIGNATOR, a Roman officer, who assigned and marked each person his place and rank in public ceremonies, shows, processions, &c. The word is formed from the verb *designare*, to design.

The designator was a kind of marshal, or master of the ceremonies, who regulated the seats, march, order, &c. There were designators at funeral solemnities, and at the games, theatres, and shows, who not only assigned every one his place, but also led him to it; as appears from the prologue to the *Poenulus* of Plautus. Much of the same nature were the *agonotheta* of the Greeks.

DESIGNING, the art of delineating or drawing the appearance of natural objects, by lines, on a plane. To design, according to the rules of mathematics, makes the object of perspective. See PERSPECTIVE.

DESORTES (Francis), a French painter of the 18th century, was born at Champagne in 1661. He acquired great reputation, not only in France, but in England and Poland: he particularly excelled in still life. He was received into the academy of painting, made pictures for the tapestry of the Gobelins, and died at Paris in 1743.

DESPOT, a term sometimes used for an absolute prince: (see the next article). The word, in its first origin, signified the same with the Latin *herus*, and the English *master*: but in time it underwent the same fate on medals, as among the Latins, Cæsar did with regard to Augustus; ΒΑΣΙΛΕΥΣ answering to Augustus, and ΔΕΣΠΟΤΗΣ, *despotes*, to Cæsar. See CÆSAR. Thus, Nicephorus having ordered his son Stauracius to be crowned, the son, out of respect, would only take the name ΔΕΣΠΟΤΗΣ, leaving to his father that of ΒΑΣΙΛΕΥΣ. For it is to be noted, that it was just about the time that the emperors began to cease to use Latin inscriptions. This delicacy, however, did not last long; for the following emperors preferred the quality of ΔΕΣΠΟΤΗΣ to that of ΒΑΣΙΛΕΥΣ, particularly Constantine, Michael Ducas, Nicephorus Botoniates, Romanus Diogenes, the Comneni, and some others. In imitation

Designa
tion
Despot.

Despot imitation of the princes, the princesses likewise assumed the title of ΔΕΣΠΟΙΝΑ.

Defultor. It was the emperor Alexius, surnamed the Angel, that created the dignity of despot, and made it the first after that of emperor, above that of Augustus or Sebastocrator and Cæsar. See AUGUST.

The despots were usually the emperors sons or sons-in-law, and their colleagues or copartners in the empire, as well as their presumptive heirs. The despots that were sons of the emperors had more privileges and authority than those that were only sons-in-law. Codin. p. 38. describes the habit and ornaments of the despot. See the notes of father Goar on that author. Under the successors of Constantine the Great, the title *despot of Sparta* was given to the emperor's son or brother, who had the city of Sparta or Lacedæmon by way of appanage.

DESPOT is at present a title of quality given to Wallachia, Servia, and some of the neighbouring countries.

DESPOTICAL, in general, denotes any thing that is uncontrolled and absolute; but is particularly used for an arbitrary government, where the power of the prince is unlimited, and his will a law to his subjects: such are those of Turkey, Persia, and most of the eastern governments; and even those of Europe, if we except the republics, the British, and of late the French governments.

DESPOUILLE, in heraldry, the whole case, skin, or slough of a beast, with the head, feet, tail, and all appurtenances, so that being filled and stuffed it looks like the entire creature.

DESPREAUX. See BOILEAU.

DESSAW, a city in Upper Saxony, in Germany, situated on the river Elbe, 60 miles north-west of Dresden, and subject to the prince of Anhalt Dessaw. E. Long. 12. 40. N. Lat. 51. 50.

DESSERT, or **DESERT**, a service of fruits and sweetmeats, usually served up last to table.

DESSICATIVE, or **DESICATIVE**, in pharmacy, an epithet applied to such topical medicines as dry up the humours flowing to a wound or ulcer.

DESTINIES, in mythology. See PARCÆ.

DESTINY, among philosophers and divines. See FATE.

DESTRUCTION, in general, an alteration of any thing from its natural state to one contrary to nature; whereby it is deemed the same with CORRUPTION.

A chemical destruction, or corruption, is nothing but a resolution of the whole naturally mixt body into its parts.

DESUDATION, in medicine, a profuse and inordinate sweat, succeeded by an eruption of pustules, called *sudamina*, or *heat-pimples*.

DESULTOR, in antiquity, a vaulter or leaper, who, leading one horse by the bridle, and riding another, jumped from the back of one to the other, as the custom was after they had run several courses or heats. — This practice required great dexterity, being performed before the use of either saddles or stirrups. The custom was practised in the army when necessity required it; but chiefly amongst the Numidians, who always carried with them two horses at least for that purpose, changing them as they tired. The Greeks and Romans borrowed the practice from them; but only used it at races, games, &c. The Sarmatæ were

great masters of this exercise, and the Hussars have still some small remains of it.

DETACHMENT, in military affairs, a certain number of soldiers drawn out from several regiments or companies equally, to be employed as the general thinks proper, whether on an attack, at a siege, or in parties to scour the country.

DETENTION (from *detineo* "I detain"), the possession or holding of lands, or the like, from some other claimant. The word is chiefly used in an ill sense, for an unjust with-holding, &c.

DETENTS, in a clock, are those stops which, by being lifted up or let fall down, lock and unlock the clock in striking.

DETENT-Wheel, or **Hoop-wheel**, in a clock, that wheel which has a hoop almost round it, wherein there is a vacancy, at which the clock locks.

DETERGENTS, in pharmacy, such medicines as are not only softening and adhesive, but also, by a peculiar activity, conjoined with a suitable configuration of parts, are apt to abrade and carry along with them such particles as they lay hold on in their passage.

DETERIORATION, the impairing or rendering any thing worse: it is just the reverse of melioration.

DETERMINATION, in mechanics, signifies much the same with the tendency or direction of a body in motion. See MECHANICS.

DETERMINATION, among school-divines, is an act of divine power, limiting the agency of second causes, in every instance, to what the Deity predestinated concerning them. See PREDESTINATION.

DETERSIVES, the same with **DETERGENTS**.

DETINUE, in law, a writ or action that lies against one who has got goods or other things delivered to him to keep, and afterwards refuses to deliver them. — In this action, the thing detained is generally to be recovered, and not damages; but if one cannot recover the thing itself, he shall recover damages for the thing and also for the detainer. Detinue lies for any thing certain and valuable, wherein one may have a property or right; as for a horse, cow, sheep, hens, dogs, jewels, plate, cloth, bags of money, sacks of corn, &c. It must be laid so certain, that the thing detained may be known and recovered: and therefore, for money out of a bag, or corn out of a sack, &c. it lies not; for the money or corn cannot in this case be known from other money or corn; so that the party must have an action on the case, &c. Yet detinue may be brought for a piece of gold of the price of 22s. though not for 22s. in money.

DETONATION, in chemistry, signifies an explosion with noise made by the sudden inflammation of some combustible body: Such are the explosions of *gun-powder*, *fulminating gold*, and *fulminating powder*. As nitre is the cause of most explosions, the word *detonation* has been appropriated to the inflammation of the acid of this salt with bodies containing phlogiston; and it is frequently given to those inflammations of nitrous acid which are not accompanied with explosion. Thus nitre is said to detonate with sulphur, with coals, with metals; although in the ordinary method of making these operations, that is, in open crucibles, and with small quantities of detonating substances, the nitre does not truly explode. See NITRE.

DETRANCHE, in heraldry, a line bend-wise, pro-

Detach-
ment

Detranche

Dettingen proceeding always from the dexter-side, but not from the very angle diagonally athwart the shield.

Deucalion. **DEITTINGEN**, a village of Germany, in the circle of the Upper Rhine, and in the territory of Hanau. Here the Austrians and the British, in June 1743, were attacked by the French, who met with a repulse; but as the allies were inferior in number, they could not make the advantage of it they might otherwise have done. E. Long. 8. 45. N. Lat. 50. 8.

DEVA, or **DEUNA** (anc. geog.), a town of the Cornavii in Britain. Now *Chester*, on the Dec. W. Long. 3. Lat. 53. 15.

DEUCALDONIUS OCEANUS, or (which comes nearer the original pronunciation) *Duacaledonius*, so called from *Duab Gael*, the northern Highlanders: the sea on the north-west of Scotland.

DEUCALION, king of Thessaly. The flood said to have happened in his time (1500 B. C.), is supposed to have been only an inundation of that country, occasioned by heavy rains, and an earthquake that stopped the course of the river Peneus where it usually discharged itself into the sea. On these circumstances the fable of Deucalion's flood is founded.—According to the fable, he was the son of Prometheus. He governed his people with equity; but the rest of mankind being extremely wicked, were destroyed by a flood, while Deucalion and Pyrrha his queen saved themselves by ascending mount Parnassus. When the waters were decreased, they went and consulted the oracle of Themis, on the means by which the earth was to be repopled; when they were ordered to veil their heads and faces, to unloose their girdles, and throw behind their backs the bones of their great mother. At this advice Pyrrha was seized with horror: but Deucalion explained the mystery, by observing, that their great mother must mean the earth, and her bones the stones; when taking them up, those Deucalion threw over his head became men, and those thrown by Pyrrha, women.

Some have supposed that Deucalion, whom the Greeks have represented under a variety of characters, and concerning whom their poets have given many fabulous accounts, was the same with the patriarch Noah; and that Deucalion's flood in Thessaly, as well as that of Ogyges in Attica, and of Prometheus in Egypt, were the same with that of Noah recorded in scripture. Diodorus Siculus expressly says, that in the deluge which happened in the time of Deucalion almost all flesh died. Apollodorus having mentioned Deucalion *εὐκαλιόν*, "consigned to an ark," takes notice, upon his quitting it, of his offering up an immediate sacrifice, *Διὶ φεζίω*, "to the God who delivered him." As he was the father of all mankind, the ancients have given him great dignity and universal monarchy; though sometimes he is reduced to a petty king of Thessaly. Apollonius Rhodius makes him a native of Greece, and the son of Prometheus. We may learn, however, from their confused history, that the person represented was the first of men, through whom religious rites were renewed, cities built, and civil polity established in the world: none of which circumstances are applicable to any king of Greece. Philo assures us, that the Grecians call the person Deucalion, but the Chaldeans style him Noe, in whose time there happened the great eruption of waters.

VOL. V.

But as Lucian has given us the most particular history of the deluge, and that which comes nearest to the account given by Moses; and as he was a native of Samosata, a city of Commagene upon the Euphrates, a part of the world where memorials of the deluge were particularly preserved, and where an obvious reference to that history may be observed in the rites and worship of the country, we shall give the following extract of what he says on the subject. Having described Noah under the name of Deucalion, he says, that the present race of mankind are different from those who first existed; for those of the antediluvian world were all destroyed. The present world is peopled from the sons of Deucalion: having increased to so great a number from one person. In respect to the former brood, they were men of violence, and lawless in their dealings. They regarded not oaths, nor observed the rites of hospitality, nor showed mercy to those who sued for it. On this account they were doomed to destruction; and for this purpose there was a mighty eruption of waters from the earth, attended with heavy showers from above; so that the rivers swelled, and the sea overflowed, till the whole earth was covered with a flood, and all flesh drowned. Deucalion alone was preserved to repeople the world. This mercy was shown to him on account of his justice and piety. His preservation was effected in this manner: he put all his family, both his sons and their wives, into a vast ark which he had provided, and he went into it himself. At the same time animals of every species, boars, horses, lions, serpents, whatever lived upon the face of the earth, followed him by pairs; all which he received into the ark, and experienced no evil from them; for there prevailed a wonderful harmony throughout by the immediate influence of the Deity. Thus were they wafted with him as long as the flood endured. After this he proceeds to mention, that upon the disappearing of the waters Deucalion went forth from the ark and raised an altar to God.

Dr Bryant produces a variety of monuments that bear an obvious reference to the deluge in the Gentile history, besides this account of Deucalion and his flood. Analysis of Ancient Mythology, vol. ii. p. 193—250.

DEVENSHRING. See **DEVONSHEERING.**

DEVENTER, a large, strong, trading, and populous town of the United Provinces in Overijssel, with an university. It is surrounded with strong walls, flanked with several towers, and with ditches full of water. It is seated on the river Issel, 55 miles east of Amsterdam, and 42 west of Benthem. E. Long. 5. 8. N. Lat. 52. 18.

DEVEREUX (Robert), earl of Essex, the son of Walter Devereux, viscount Hereford, was born at Netherwood in Herefordshire, in the year 1567. He succeeded to the title of earl of Essex at ten years of age; and about two years after, was sent, by his guardian lord Burleigh, to Trinity-college in Cambridge. He took the degree of master of arts in 1582, and soon after retired to his seat at Lamphe in South-Wales. He did not however continue long in this retreat; for we find him, in his seventeenth year, at the court of queen Elizabeth, who immediately honoured him with singular marks of her favour. Authors seem very unnecessarily perplexed to account for this young earl's

5 F

gracious

Deucalion
||
Devereux.
De Dea Syria, vol. ii.
p. 282.

Devereux. gracious reception at the court of Elizabeth. The reasons are obvious; he was her relation, the son of one of her most faithful servants, the son-in-law of her favourite Leicester, and a very handsome and accomplished youth. Towards the end of (the following year) 1585, he attended the earl of Leicester to Holland; and gave signal proofs of his personal courage during the campaign of 1586, particularly at the battle of Zutphen, where the gallant Sidney was mortally wounded. On this occasion the earl of Leicester conferred on him the honour of knight banneret.

In the year 1587, Leicester being appointed lord steward of the household, Essex succeeded him in the honourable post of master of the horse; and the year following, when the queen assembled an army at Tilbury to oppose the Spanish invasion, Essex was made general of the horse. From this time he was considered as the happy favourite of the queen. And, if there was any mark yet wanting to fix the people's opinion in that respect, it was shown by the queen's conferring on him the honour of the garter.

We need not wonder, that so quick an elevation, and to so great a height, should affect so young a man as the earl of Essex; who showed from henceforwards a very high spirit, and often behaved petulantly enough to the queen herself, who yet did not love to be controlled by her subjects. His eagerness about this time to dispute her favour with Sir Charles Blunt, afterwards lord Montjoy and earl of Devonshire, cost him some blood; for Sir Charles, thinking himself affronted by the earl, challenged him, and after a short dispute, wounded him in the knee. The queen, so far from being displeased with it, is said to have sworn a good round oath, that it was fit somebody should take him down, otherwise there would be no ruling him. However, she reconciled the rivals; who, to their honour, continued good friends as long as they lived.

The gallant Essex, however, was not so entirely captivated with his situation, as to become insensible to the allurements of military glory. In 1589, Sir John Norris and Sir Francis Drake having failed on an expedition against Spain, our young favourite, without the permission or knowledge of his royal mistress, followed the fleet; which he joined as they were sailing towards Lisbon, and acted with great resolution in the repulse of the Spanish garrison of that city. The queen wrote him a very severe letter on the occasion; but she was, after his return, soon appeased. Yet it was not long before he again incurred her displeasure, by marrying the widow of Sir Philip Sidney. In 1591, he was sent to France with the command of 4000 men to the assistance of Henry IV. In 1596, he was joined with the lord high admiral Howard in the command of the famous expedition against Cadiz, the success of which is universally known. In 1597, he was appointed master of the ordnance; and the same year commanded another expedition against Spain, called the *Island voyage*, the particulars of which are also well known.

Soon after his return, he was created earl marshal of England; and on the death of the great lord Burleigh, in 1598, elected chancellor of the university of Cambridge. This is reckoned one of the last instances of this great man's felicity, who was now advanced too high to sit at ease; and those who longed for his ho-

nours and employments, very closely applied themselves to bring about his fall. The first great shock he received, in regard to the queen's favour, arose from a warm dispute between her majesty and himself, about the choice of some fit and able persons to superintend the affairs of Ireland. The affair is related by Camden; who tells us, that nobody was present but the lord admiral, Sir Robert Cecil secretary, and Windbank clerk of the seal. The queen looked upon Sir William Knolls, uncle to Essex, as the most proper person for that charge: Essex contended, that Sir George Carew was a much fitter man for it. When the queen could not be persuaded to approve his choice, he so far forgot himself and his duty, as to turn his back upon her in a contemptuous manner: which insolence her majesty not being able to bear, gave him a box on the ear, and bid him go and be hanged. Essex, like a blockhead, put his hand to his sword, and swore revenge. Where was his gallantry on this occasion? Could a stroke from an angry woman tinge the honour of a gallant soldier? This violent storm, however, soon subsided: and they were again reconciled, at least apparently.

The total reduction of Ireland being brought upon the tapis soon after, the earl was pitched upon as the only man from whom it could be expected. This was an artful contrivance of his enemies, who hoped by this means to ruin him; nor were their expectations disappointed. He declined this fatal preferment as long as he could: but, perceiving that he should have no quiet at home, he accepted it; and his commission for lord lieutenant passed the great seal on the 12th of March 1598. His enemies now began to insinuate, that he had sought this command, for the sake of greater things which he then was meditating; but there is a letter of his to the queen, preserved in the Harleian collections, which shows, that he was so far from entering upon it with alacrity, that he looked upon it rather as a banishment, and a place assigned him for a retreat from his sovereign's displeasure, than a potent government bestowed upon him by her favour.

To the Queen. From a mind delighting in sorrow;
 " from spirits wasted with passion; from a heart torn in
 " pieces with care, grief, and travail; from a man that
 " hateth himself, and all things else that keep him alive;
 " what service can your Majesty expect, since any ser-
 " vice past deserves no more than banishment and pro-
 " scription to the cursedest of all islands? It is your
 " rebels pride and succession must give me leave to ran-
 " som myself out of this hateful prison, out of my
 " loathed body; which, if it happen so, your majesty
 " shall have no cause to mislike the fashion of my death,
 " since the course of my life could never please you.

" Happy he could finish forth his fate,
 " In some unhaunted desert most obscure
 " From all society, from love and hate
 " Of worldly folk; then should he sleep secure.
 " Then wake again, and yield God ever praise,
 " Content with hips, and hawes, and brambleberry;
 " In contemplation passing out his days,
 " And change of holy thoughts to make him merry.
 " Who, when he dies his tomb may be a bush
 " Where harmless robin dwells with gentle thrush.

" Your Majesty's exiled servant,

" ROBERT ESSEX."

The

Devereux. The earl met with nothing in Ireland but ill success and crosses: in the midst of which, an army was suddenly raised in England, under the command of the earl of Nottingham; nobody well knowing why, but in reality from the suggestions of the earl's enemies to the queen, that he rather meditated an invasion on his native country, than the reduction of the Irish rebels. This and other considerations made him resolve to quit his post, and come over to England: which he accordingly did without leave. He burst into her majesty's bed-chamber as she was rising, and she received him with a mixture of tenderness and severity: but she, soon after, thought fit to deprive him of all his employments, except that of master of the horse. He was committed to the custody of the lord-keeper, with whom he continued six months. No sooner had he regained his liberty, than he was guilty of many extravagancies; to which he was instigated by knaves and fools, but perhaps more powerfully by his own passions. He first determined to obtain an audience of the queen by force. He refused to attend the council when summoned. When the queen sent the lord-keeper, the lord chief-justice, and two others, to know his grievances, he confined them; and then marched with his friends into the city, in expectation that the people would rise in his favour; but in that he was disappointed. He was at last besieged, and taken in his house in Essex-street; committed to the tower; tried by his peers, condemned, and executed. Thus did this brave man, this favourite of his queen, this idol of the people, fall a sacrifice to his want of that dissimulation, that cunning, that court-policy, by which his enemies were enabled to effect his ruin. He was a polite scholar, and a generous friend to literature.

To these who have not taken the trouble to consult and compare the several authors who have related the story of this unfortunate earl, it must appear wonderful, if, as hath been suggested, he was really beloved by queen Elizabeth, that she could consent to his execution. Now that she had conceived a tender passion for him, is proved beyond a doubt by Mr Walpole in his very entertaining and instructive *Catalogue of Noble Authors*.—"I am aware (says that author) that it is become a mode to treat the queen's passion for him as a romance. Voltaire laughs at it; and observes, that when her struggle about him must have been the greatest (the time of his death), she was sixty-eight.—Had he been sixty-eight, it is probable she would not have been in love with him."—"Whenever Essex acted a fit of sickness, not a day passed without the queen's sending often to see him; and once went so far as to sit long by him, and order his *broths and things*. It is recorded by a diligent observer of that court, that in one of his sick moods, he took the liberty of going up to the queen in his night-gown. In the height of these fretful fooleries, there was a mask at Black Fryars on the marriage of lord Herbert and Mrs Ruffel. Eight lady-maskers chose eight more to dance the measures. Mrs Fitton, who led them, went to the queen, and wooed her to dance. Her majesty asked what she was? *Affection*, she said. *Affection!* said the queen; *Affection is false*. Were not these the murmurs of a heart ill at ease? Yet her majesty rose, and danced. She was then sixty-eight. Sure it was as natural for her to be in love."

Mr Walpole farther observes, that her court and contemporaries had an uniform opinion of her passion for Essex, and quotes several instances from a letter written by Sir Francis Bacon to the earl; in which, among other things, he advises him to consult her taste in his very apparel and gestures, and to give way to any other inclination she may have. Sir Francis advised the queen herself, knowing her inclination, to keep the earl about her for *society*. What Henry IV. of France thought of the queen's affection for Essex, is evident from what he said to her ambassador.—"*Que sa majesté ne laisseroit jamais son cousin d'Essex esloigner de son cotillon.*"—After his confinement, on hearing he was ill, she sent him word, with tears in her eyes, that if she might with her honour, she would visit him.

"If (says Mr Walpole) these instances are problematic, are the following so? In one of the curious letters of Rowland White, he says, *the queen hath of late used the fair Mrs Bridges with words and blows of anger*. In a subsequent letter, he says, *the earl is again fallen in love with his fairest B. It cannot choose but come to the queen's ear, and then he is undone.*"—Essex himself says, that her fond parting with him when he set out for Ireland, pierced his very soul.

Probably the reader has now very little doubt as to queen Elizabeth's affection for the unfortunate Essex; but, in proportion to our belief of the existence of this affection, her motives for consenting to his execution become more inexplicable. Queen Elizabeth had a very high opinion of her beauty and personal attractions, and probably expected more entire adoration than the earl's passion for variety would suffer him to pay. Towards the latter end of her life, she was certainly an object of disgust. He had too much honest simplicity in his nature, to feign a passion which he did not feel. She foolishly gave credit to the stories of his ambitious projects incompatible with her safety; and was informed that he had once inadvertently said, that *she grew old and cankered, and that her mind was become as crooked as her carcase*. If this be true, where is the woman that would not sacrifice such a lover to her repentment?

It is said, however, that, concerning his execution, her majesty was irresolute to the last, and sent orders to countermand it; but, considering his obstinacy in refusing to ask her pardon, afterwards directed that he should die. It is reported, that the queen, in the height of her passion for the earl of Essex, had given him a ring, ordering him to keep it, and that whatever crime he should commit, she would pardon him when he should return that pledge. The earl, upon his condemnation, applied to admiral Howard's lady, his relation, desiring her, by a person whom she could trust, to return it into the queen's own hands; but her husband, who was one of the earl's greatest enemies, and to whom she had imprudently told the circumstance, would not suffer her to acquit herself of the commission; so that the queen consented to the earl's death, being full of indignation against so proud and haughty a spirit, who chose rather to die than implore her mercy. Some time after, the admiral's lady fell sick, and being near her death, she sent word to the queen that she had something of great consequence to communicate before she died. The queen came to her bedside, and having ordered all her attendants to withdraw, the lady re-

Device
|
Devise.

turned, but too late, the ring, desiring to be excused that she did not return it sooner : on which, it is said, the queen immediately retired, overwhelmed with grief.

The earl of Essex died in the thirty-fourth year of his age ; leaving by his lady one son and two daughters.

DEVICE, among painters. See DEVISE.

DEVIL (*Diabolus*), an evil angel, one of those celestial spirits cast down from heaven for pretending to equal himself with God. The Ethiopians paint the devil white, to be even with the Europeans who paint him black.

There is no mention of the word *devil* in the Old Testament, but only of the word *Satan* and *Belial*; nor do we meet with it in any heathen authors, in the sense it is taken among Christians, that is, as a creature revolted from God. Their theology went no farther than to evil genii or dæmons.

Some of the American idolaters have a notion of two collateral independent beings, one of whom is good, and the other evil ; which last they imagine has the direction and superintendance of this earth, for which reason they chiefly worship him ; whence those that give us an account of the religion of these savages give out, with some impropriety, that they worship the devil. The Chaldeans, in like manner, believed both a good principle and an evil one ; which last they imagined was an enemy to mankind.

Isaiah, speaking, according to some commentators, of the fall of the devil, calls him *Lucifer*, from his former elevation and state of glory : but others explain this passage of Isaiah in reference to the king of Babylon, who had been precipitated from this throne and glory. The Arabians call Lucifer, *Eblis* ; which some think is only a diminutive or corruption of the word *Diabolus*.

DEVIL on the Neck, a tormenting engine made of iron, straitening and wincing the neck of a man, with his legs together, in a horrible manner ; so that the more he stirreth in it, the straiter it presseth him ; formerly in use among the persecuting papists.

DEVINCTION (*Devinctio*), in antiquity, was used to signify a love-charm or incantation to gain the affection a person beloved.

It was done by tying knots ; and is thus described by Virgil in his eighth Eclogue :

Necte tribus nodis ternos, Amarylli, colores :
Necte, Amarylli modo ; et Veneris, dic, vincula necto.

DEVISE, or DEVICE, in heraldry, painting, and sculpture, any emblem used to represent a certain family, person, action, or quality ; with a suitable motto, applied in a figurative sense. See MOTTO.

The essence of a device consists in a metaphorical similitude between the things representing and represented : thus, a young nobleman, of great courage and ambition, is said to have borne for his devise, in a late carousal at the court of France, a rocket mounted in the air, with this motto in Italian, "*poco duri purche m'inalzi* ;" expressing, that he preferred a short life, provided he might thereby attain to glory and eminence.

The Italians have reduced the making of devises into an art, some of the principal laws of which are these.

1. That there be nothing extravagant or monstrous in the figures. 2. That figures be never joined which have no relation or affinity with one another ; excepting some whimsical unions established in ancient fables, which custom has authorised. 3. That the human body be never used. 4. The fewer figures the better. 5. The motto should be every way suitable.

DEVISE, in law, the act whereby a person bequeaths his lands or tenements to another by his last will or testament.

DEUNX, in Roman antiquity, 11 ounces, or $\frac{1}{12}$ of the LIBRA.

DEVOLVED, something acquired by right of devolution. Such a right is devolved to the crown : such an estate devolved on M— by the death of N—.

The word is also used for a right, acquired by a superior, of conferring a benefice, when the inferior and ordinary collator has neglected to confer, or has conferred it on an unqualified person.

If a patron neglects to present to a benefice in six months, the presentation lapses or devolves upon the bishop, from thence to the primate, and from thence to the king.

DEVOLUTION, in law, a right acquired by succession from one to another.

DEVONSHEERING, a term used by the farmers to express the burning of land by way of manure : the method is to cut off the turf about four inches thick, and burn it in heaps, and then spread the ashes upon the land. The name is probably derived from its having been earliest practised in Devonshire.

DEVONSHIRE, a county of England, bounded on the south by the English channel, on the north by the Bristol channel, on the east by Somersetshire, and on the west by Cornwall. It is about 69 miles long and 66 broad. The soil is various ; in the western parts of the country it is coarse and moorish, bad for sheep, but proper for black cattle. In the northern parts, the dry soil and downs are well adapted to sheep, with numerous flocks of which they are well covered. Tolerable crops of corn are also produced there when the land is well manured. The soil of the rest of the country is rich and fertile both in corn and pasture, yielding also in some places plenty of marle for manuring it. In other places they pare off and burn the surface, making use of the ashes as a manure. Dr Campbell styles it a rich and pleasant country ; as in different parts it abounds with all sorts of grain, produces abundance of fruit, has mines of lead, iron, and silver, in which it formerly exceeded Cornwall, though now it is greatly inferior. On the coast also they have herring and pilchard fisheries. Devonshire sends two members to parliament, and gives title of Duke to the noble family of Cavendish.

DEVOTION, DEVOTIO, a sincere ardent worship of the Deity.

Devotion, as defined by Jurieu, is a softening and yielding of the heart, with an internal consolation, which the souls of believers feel in the practice or exercise of piety. By devotion is also understood certain religious practices, which a person makes it a rule to discharge regularly ; and with reason, if the exactitude be founded on solid piety, otherwise it is vanity or superstition,

Devise
||
Devotion.

Devotion. perfidious. That devotion is vain and trifling, which would accommodate itself both to God and to the world. *Trevoux.*

The character of devotion has frequently suffered from the forbidding air which has been thrown over it, by the narrowness of bigotry on one hand, or the gloom of superstition on the other. When freer and more cheerful minds have not had occasion to see it accompanied with those feelings of delight and benevolence which naturally attend it, they are apt to be prejudiced against piety at large, by mistaking this ungracious appearance for its genuine form. Nor has the rant of vulgar enthusiasts contributed a little to beget or strengthen the same aversion, in persons of a cool and speculative temper; who have happened to meet with such images and phrases among religionists of a certain strain, as ill suit the rational, pure, and spiritual nature of true devotion. It may likewise be remarked on the other side, that people of taste and sensibility have not seldom been disgusted with the insipid style too often employed on such subjects, by those who possess neither, or who purposely avoid every thing of that kind, from an aim at simplicity misunderstood, or perhaps from a fear of being thought too warm, in an age of fashionable indifference and false refinement.

Wherever the vital and unadulterated spirit of Christian devotion prevails, its immediate object will be to please Him whom we were made to please, by adoring his perfections; by admiring his works and ways; by entertaining with reverence and complacence the various intimations of his pleasure, especially those contained in holy writ; by acknowledging our absolute dependence, and infinite obligations; by confessing and lamenting the disorders of our nature, and the transgressions of our lives; by imploring his grace and mercy through Jesus Christ; by interceding for our brethren of mankind; by praying for the propagation and embellishment of truth, righteousness, and peace on earth; in fine, by longing for a more entire conformity to the will of God, and breathing after the everlasting enjoyment of his friendship. The effects of such a spirit habitually cherished, and feelingly expressed before him, with conceptions more or less enlarged and elevated, in language more less emphatical and accurate, sententious or diffuse, must surely be important and happy. Among these effects may be reckoned, a profound humility in the sight of God, a high veneration for his presence and attributes, an ardent zeal for his worship and honour, an affectionate faith in the Saviour of the world, a constant imitation of his divine example, a diffusive charity for men of all denominations, a generous and unwearied self-denial for the sake of virtue and society, a total resignation to Providence, an increasing esteem for the gospel, with clearer and firmer hopes of that immortal life which it has brought to light.

DEVOTION, among the Romans, was a kind of sacrifice or ceremony, whereby they consecrated themselves to the service of some person. The ancients had a notion, that the life of one might be ransomed by the death of another; whence those devotions became frequent for the lives of the emperors. Devotion to any particular person was unknown among the Romans till the time of Augustus. The very day after

the title of Augustus had been conferred upon Octavianus, Pacuvius, a tribune of the people, publicly declared, that he would devote himself to Augustus, and obey him at the expence of his life (as was the practice among barbarous nations), if he was commanded. His example was immediately followed by all the rest; till at length it became an established custom never to go to salute the emperor, without declaring that they were devoted to him.—Before this, the practice of the Romans was that of devoting themselves to their country. See DECIVS.

DEUTEROCANONICAL, in the school theology, an appellation given to certain books of holy scripture, which were added to the canon after the rest; either by reason they were not wrote till after the compilation of the canon, or by reason of some dispute as to their canonicity. The word is Greek, being compounded of *δευτερος second*, and *κανονικος canonical*.

The Jews, it is certain, acknowledged several books in their canon, which were put there later than the rest. They say, that under Esdras, a great assembly of their doctors, which they call by way of eminence the *great synagogue*, made the collection of the sacred books which we now have in the Hebrew Old Testament. And they agree that they put books therein which had not been so before the Babylonish captivity; such are those of Daniel, Ezekiel, Haggai, &c. and those of Esdras and Nehemiah.

And the Romish church has since added others to the canon, that were not, nor could not be, in the canon of the Jews; by reason some of them were not composed till after. Such is the book of Ecclesiasticus; with several of the apocriphal books, as the Maccabees, Wisdom, &c. Others were added still later, by reason their canonicity had not been yet examined; and till such examen and judgment they might be set aside at pleasure.—But since that church has pronounced as to the canonicity of these books, there is no more room now for her members to doubt of them, than there was for the Jews to doubt of those of the canon of Esdras. And the deuterocanonical books are with them as canonical as the proto-canonical; the only difference between them consisting in this, that the canonicity of the one was not generally known, examined, and settled, so soon as that of the others.

The deuterocanonical books in the modern canon, are the book of Esther, either the whole, or at least the seven last chapters thereof; the epistle to the Hebrews; that of James; and that of Jude; the second of St Peter; the second and third of St John; and the Revelation. The deuterocanonical parts of books, are, in Daniel, the Hymn of the three children; the prayer of Azariah; the histories of Susannah, of Bel and the Dragon; the last chapter of St Mark; the bloody sweat, and the appearance of the angel, related in St Luke, chap. xxii; and the history of the adulterous woman in St John, chap. viii.

DEUTERONOMY, one of the sacred books of the Old Testament; being the last of those written by Moses: (See PENTATEUCH). The word is Greek, compounded of *δευτερος second* and *νομος law*.

Deuteronomy was written the 40th year after the delivery from Egypt, in the country of the Moabites beyond Jordan; Moses being then in the 120th year of

Deuterocanonical,
Deuteronomy.

Deutero-
potmi
||
Dew.

of his age. It contains, in Hebrew, 11 paraches, though only 10 in the edition of the rabbins at Venice; XX chapters, and 955 verses. In the Greek, Latin, and other versions, it contains XXXIV chapters. The last is not of Moses. Some say it was added by Joshua immediately after Moses's death; which is the most probable opinion. Others will have it added by Esdras.

DEUTEROPOTMI, in Grecian antiquity, a designation given to such of the Athenians as had been thought dead, and, after the celebration of the funeral rites, unexpectedly recovered. It was unlawful for the deuteropotmi to enter into the temple of the Eumenides, or to be admitted to the holy rites, till after they were purified, by being let through the lap of a woman's gown, that they might seem to be new born.

DEUTEROSIS, the Greek name by which the Jews called their Mischnah, or second law. See MISCHNAH.

DEW, a dense, moist vapour, found on the earth in spring and summer mornings, in form of a misting rain, being collected there chiefly while the sun is below the horizon.

It hath been disputed whether the dew is formed from the vapours *ascending* from the earth during the night-time, or from the *descent* of such as have been already raised through the day. The most remarkable experiments adduced in favour of the first hypothesis are those of Mr Dufay of the Royal Academy of Sciences at Paris. He supposed, that if the dew *ascended*, it must wet a body placed low down sooner than one placed in a higher situation: and, if a number of bodies were placed in this manner, the lowermost would be wetted first; and the rest in like manner, gradually up to the top.

To determine this, he placed two ladders against one another, meeting at their tops, spreading wide asunder at the bottom, and so tall as to reach 32 feet high. To the several steps of these he fastened large squares of glass like the panes of windows, placing them in such a manner that they should not overshadow one another. On the trial it appeared exactly as Mr Dufay had apprehended. The lower surface of the lowest piece of glass was first wetted then the upper, then the lower surface of the pane next above it; and so on, till all the pieces were wetted to the top. Hence it appeared plain to him, that the dew consisted of the vapours ascending from the earth during the night-time; which, being condensed by the coldness of the atmosphere, are prevented from being dissipated as in the day-time by the sun's heat. He afterwards tried a similar experiment with pieces of cloth instead of panes of glass, and the result was quite conformable to his expectations. He weighed all the pieces of cloth next morning, in order to know what quantity of water each had imbibed, and found those that had been placed lowermost considerably heavier than such as had been placed at the top; tho' he owns that this experiment did not succeed so perfectly as the former.

M. Muschenbroek, who embraced the contrary opinion, thought he had invalidated all Mr Dufay's proofs, by repeating his experiments, with the same success on a plane covered with sheet-lead. But to this Mr Dufay replied, that there was no occasion for suppo-

sing the vapour to rise through the lead, nor from that very spot; but that as it arose from the adjoining open ground, the continual fluctuation of the air could not but spread it abroad and carry it thither in its ascent.

But though this experiment of M. Muschenbroek's is not sufficient to overthrow those of Mr Dufay, it must still remain dubious whether the dew rises or falls. One thing which seems to favour the hypothesis of its descent is, that in cloudy weather there is little or no dew to be observed. From this M. de Luc brings an argument in favour of the hypothesis just now mentioned. He accounts for it in the following manner. *Phil. Trans.* vol. lxiii. part 2. When there were no clouds in the air, the heat of the inferior air and that which rises from the earth dissipates itself into the superior regions; and then the vapours which are dispersed throughout the air, condense, and fall down in dew: But, when the clouds continue, they separate the inferior from the superior part of the atmosphere, and thus prevent the dissipation of the heat, by which means the vapours remain suspended. When the sky grows cloudy, some hours after sun-set, although the heat has been sensibly diminished, it is again increased; because, continuing to rise out of the earth, it is accumulated in the inferior air. But neither can this be reckoned a positive proof of the descent of the dew; since we may as well suppose the heat of the atmosphere to be great enough to dissipate it in its ascent, as to keep it suspended after its ascent through the day.

On the other hand, its being found in greater quantities on bodies placed low down than on such as are high up, is no proof of the ascent of the dew; because the same thing is observed of rain. A body placed low down receives more rain than one placed in an elevated situation; and yet the rain certainly descends from the atmosphere. The reason why the dew appears first on the lower parts of bodies may be, that, in the evening, the lower part of the atmosphere is first cooled, and consequently most disposed to part with its vapour. It is also certain, that part of the water contained in the air may be condensed at any time on the sides of a glass, by means of cold, so as to run down its sides in small drops like dew. It seems, therefore, that this subject is not sufficiently determined by such experiments as have yet been made; nor indeed does it appear easy to make such experiments as shall be perfectly decisive on the matter.

Several substances, exposed to the same dew, receive and charge themselves with it in a very different manner; some more, others less, and some even not at all. The drops seem to make a sort of choice of what bodies they shall affix themselves to: glass and crystals are those to which they adhere in the most ready manner, and in the largest quantity; but metals of all kinds never receive them at all, nor do the drops ever adhere to them. The reason of this is probably because metals promote evaporation more than glass does. Thus, if a piece of metal and a piece of glass are both made equally moist, the former will be found to dry in much less time than the latter. Hence it would seem, that there is between metals and water some kind of repulsion: and this may be sufficient to keep off the very small quantity that falls in dew; for whatever tends to make water evaporate after it is actually in contact with

Dew.

Dew.

with any substance, also tends to keep the water from ever coming into contact with it. On this subject several curious particulars are mentioned by Dr Percival, relative to the attraction and repulsion between dew and glass or metalline vessels. The experiments were made by M. du Fay, who, in order to determine with certainty whether the difference between vitrified substances and metals was the same in all cases, set a china saucer in the middle of a silver plate, and on one side, adjoining to it, was placed a china plate, with a silver dish very much resembling the saucer in the middle. In this experiment the china saucer was covered with dew, but the plate, though extending four inches round it, was not moistened in the least. The china plate also had become quite moist, while the silver vessel in the middle had not received the smallest drop. M. du Fay next endeavoured to ascertain whether a china saucer set upon a plate of metal, as already described, did not receive more dew than it would have done if exposed alone. To accomplish this design, he took two watch crystals of equal dimensions, and placed the one upon a plate of silver, the other upon a plate of china, each with its concave uppermost. That which was upon the silver plate he surrounded with a ferrel of the same metal, well polished, that no watery particles might attach themselves to the convex surface of the glass. In this situation he exposed the crystals for several days successively, and always found five or six times more dew in that which was on the china plate than on the other placed on the silver. The repulsion between the dew and silver is further confirmed by the following experiment of M. du Fay, with regard to the crystal on the silver plate. He informs us, that the small quantity of dew on the inside near the centre, was in minute drops; and that round the border there was a space of five or six lines perfectly dry; towards which the drops regularly decreased in magnitude, as if the silver ferrel had driven away the dew from that part of the glass which was contiguous to it. These experiments were repeated thirty times with invariable success. M. du Fay's experiments have received a remarkable confirmation from some lately made by Dr Watson, now bishop of Landaff, with a view to determine the quantity of vapour that ascends from a given surface of earth. "By means of a little beeswax (says he), I fastened a half crown very near, but not quite contiguous, to the side of the glass; and, setting the glass with its mouth downward on the grass, it presently became covered with vapour, except that part of it which was next the half-crown. Not only the half-crown itself was free from vapour, but it had hindered any from settling on the glass which was near it; for there was a little ring of glass surrounding the half-crown, to the distance of a quarter of an inch, which was quite dry, as well as that part of the glass which was immediately under the half-crown; it seemed as if the silver had repelled the water to that distance. A large red wafer had the same effect as the half-crown; it was neither wetted itself, nor was the ring of glass contiguous to it wetted. A circle of white paper produced the same effect, so did several other substances, which it would be too tedious to enumerate."

SUBSTANCES of a very different kind from the usual dew are said to have sometimes fallen from the atmosphere. In the Phil. Trans. we are told, that in

the year 1695 there fell in Ireland, in the provinces of Leinster and Munster, for a considerable part of the winter and spring, a fatty substance resembling butter, instead of the common dew. It was of a clammy texture, and dark yellow colour; and was, from its great resemblance, generally called *dew-butter* by the country people. It always fell in the night, and chiefly in the moorish low grounds; and was found hanging on the tops of the grass, and on the thatch of the houses of the poor people. It was seldom observed to fall twice in the same place; and usually, wherever it fell, it lay a fortnight upon the ground before it changed colour; but after that it gradually dried up, and became black. The cattle fed in the fields where it lay as well as in others, and received no harm by it. It fell in pieces of the bigness of one's finger-end; but they were dispersed scatteringly about, and it had an offensive smell like a church-yard. There were in the same places very stinking fogs during the winter, and some people supposed this no other than a sediment from the fog. It would not keep very long, but never bred worms.

May-DEW whitens linen and wax; the dew of autumn is converted into a white frost. Out of dew putrified by the sun, arise divers insects, which change apace from one species into another: what remains is converted into a fine white salt, with angles like those of salt-petre, after a number of evaporations, calcinations, and fixations.

There is a spirit drawn from May-dew, which has wonderful virtues attributed to it. The method of collecting and preparing it, is prescribed by Hanneman, physician at Kiel. It is to be gathered in clean linen cloths; exposed to the sun in close vials; then distilled, and the spirit thrown upon the caput mortuum; this is to be repeated till the earth unite with the spirit, and become liquid; which happens about the seventh or eighth cohobation or distillation. By such means you gain a very red, odoriferous spirit. Stollerfoht, a physician of Lubec, thinks May-dew may be gathered in glass-plates, especially in still weather, and before sun-rise. And Etmuller is of the same sentiment. It might likewise be collected with a glass funnel, exposed to the air, having a crooked neck to bring the dew into a vial in a chamber. See Phil. Trans. n^o 3. Hoffman, and others. It is apparently from the preparation of this dew, that the brothers of the Rosy-Cross took their denomination. See ROSICRUCIANS.

DEW-Born, in country affairs, a distemper in cattle, being a swelling in the body, as much as the skin can hold, so that some beasts are in danger of bursting. This distemper proceeds from the greediness of a beast to feed, when put into a rank pasture; but commonly when the grass is full of water. In this case the beast should be stirred up and down, and made to purge well: but the proper cure is bleeding in the tail; then take a grated nutmeg, with an egg, and breaking the top of the shell, put out so much of the white as you may have room to slip the nutmeg into the shell; mix them together, and then let shell and all be put down the beast's throat; that done, walk him up and down, and he will soon mend.

DEW-Worm. See LUMBRICUS.

DE WIT (John), the famous pensionary, was born in 1625, at Dóft, where he prosecuted his studies so diligently, that, at the age of 23, he published *Elementa*

May-Dew
||
De Wit.

De Wit. *menta Curvarum Linearium*, one of the deepest books in mathematics at that time. After taking his degrees, and travelling, he, in 1650, became pensionary of Dort, and distinguished himself very early in the management of public affairs. He opposed with all his power the war between the English and the Dutch; and when the event justified his predictions, he was unanimously chosen pensionary of Holland. In this capacity he laboured to procure a peace with Cromwell; in which peace a secret article was introduced by one side or other, for the exclusion of the house of Orange. In the war with England after the king's restoration, when it was thought expedient, on Opdam's defeat and death, that some of their own deputies should command the fleet, he was one of the three put in commission; and wrote an accurate relation of all that happened during the expedition he was engaged in, for which, at his return, he received the solemn thanks of the States-General. In 1667, he established the perpetual edict for abolishing the office of Stadtholder, to fix the liberty of the republic, as it was hoped, on a firm basis; which produced seditions and tumults, that restored the office, on pretence that the De Wits were enemies to the house of Orange, and plundered the state. The pensionary begged dismissal from his post: which was granted, with thanks for his faithful services. But the invasion of the French, and the internal divisions among the Hollanders themselves, spread every where terror and confusion; which the Orange party heightened to ruin the De Wits. Cornelius, the pensionary's brother, was imprisoned and condemned to exile; and a report being raised that he would be rescued, the mob armed, and surrounded the prison where the two brothers then were together, dragged them out, barbarously murdered them, hung the bodies on the gallows, and cut them to pieces, which many of them even broiled, and ate with savage fury. Such was the end of one of the greatest geniuses of his age: of whom Sir William Temple, who was well acquainted with him, writes with the greatest esteem and admiration. He observes, that when he was at the head of the government, he differed nothing in his manner of living from an ordinary citizen. His office, for the first ten years, brought him in little more than 300*l.* and in the latter part of his life, not above 700*l.* *per annum.* He refused a gift of 10,000*l.* from the States-General, because he thought it a bad precedent in the government. With great reason, therefore, Sir William Temple, speaking of his death, observes, "He was a person that deserved another fate, and a better return from his country; after 18 years spent in their ministry, without any care of his entertainments or ease, and little of his fortune. A man of unwearied industry, inflexible constancy, sound, clear, and deep understanding, and untainted integrity; so that whenever he was blinded, it was by the passion he had for that which he esteemed the good and interest of his state. This testimony is justly due to him from all that were well acquainted with him: and is the more willingly paid, since there can be as little interest to flatter, as honour to reproach, the dead."

Besides the works already mentioned, he wrote a book containing those maxims of government upon which he acted; which will be a never-fading monu-

ment to his immortal memory. A translation of it from the original Dutch, intitled, *The true interest and political maxims of the republic of Holland*, has been printed in London; to the last edition of which, in 1646, are prefixed historical memoirs of the illustrious brothers Cornelius and John de Wit, by John Campbell, Esq.

DEXTANS, in Roman antiquity, ten ounces, or $\frac{1}{2}$ of their libra. See LIBRA.

DEXTER, in heraldry, an appellation given to whatever belongs to the right side of a shield or coat of arms: thus we say, *bend-dexter*, *dexter point*, &c.

DEXTROCHERE, or DESTROCHERE, in heraldry, is applied to the right arm painted in a shield, sometimes naked; sometimes clothed, or adorned with a bracelet; and sometimes armed, or holding some moveable or member used in the arms.

DEY, the title of the sovereign of Algiers, under the protection of the grand seignor. A prince under this title was appointed by the sultan, at the request of the Turkish soldiers, in the year 1710. The term *dey*, in the Turkish language, signifies an *uncle* by the mother's side; and the reason of the denomination is this: that the Turkish military consider the grand seignor as their father; the republic as their mother, by which they are nourished and maintained; and the dey as the brother of the republic, and consequently the uncle of all who are under his dominion. Besides the age, experience, and valour, which are necessary qualifications of a person to be elected, he must also be a native Turk, and have made the voyage to Mecca. He has no guards nor considerable retinue. He presides at the divan, and is most distinguished by the respect and submission which are paid him.

DIABETES, in physic, an excessive discharge of urine, which comes away crude, and exceeds the quantity of liquids drank. See (the *Index* subjoined to) MEDICINE.

DIABOLUS. See DEVIL.

DIABOLUS *Marinus*. See RAIA.

DIABOLUS *Metallosum*, a title given by chemists to jupiter or tin; because, when incorporated with other metals, it renders them incapable of reduction, or at least very difficult to undergo that operation.

DIACAUSTIC CURVE, a species of the caustic curves formed by refraction.

DIACHYLON, in pharmacy, an emollient digestive plaster, composed of mucilages or viscid juices drawn from certain plants. See PHARMACY.

DIACODIUM, in pharmacy, a syrup prepared from poppy-heads. It is also called the *syrupus de meconio*. See PHARMACY.

DIACOUSTICS, called also DIAPHONICS, the consideration of the properties of refracted sound, as it passes through different mediums: (See ACOUSTICS.) The word is formed from the Greek *dia per*, "thro'," which intimates a passage; and *ακουω* "I hear," *q. d.* the consideration of the passage of the sounds we hear. See SOUND.

DIACRII, in antiquity, was the name of a party or faction at Athens.—That city, we read, was divided into two parties: the one favourers of an oligarchy, who would have only a few persons employed in the government: the other consisted of such as were for a democratical or popular government, wherein the whole

Dextans.

! Diacrii.

Diadelphia whole people should have a share. The first were called *diacrii*, and the latter *pediaci*; the latter inhabiting the lower, and the former the *αγορα*, or upper quarter or part of the city.—The laws of Solon imported, that Piliſtratus should be chief of the *diacrii*; though the scholiast on Aristophanes's comedy *The Wasps*, affirms, that Pandion distributed the quarter of the *diacrii* among his sons, and put Lycus at their head.

Diagnosis.

DIADELPHIA (*δις* "twice," and *αδελφος* "a brother"), class the 17th in the sexual system, comprehending those plants which bear hermaphrodite flowers with two sets of united stamina; but this circumstance must not be absolutely depended on. They are the *papilionacei* of Tournefort, the *irregulares tetrapetali* of Rivinus, and the *leguminosa* of Ray. See **BOTANY**, the *Scheme*, p. 430, and Plate CII. fig. 17.

DIADEM, in antiquity, a head-band or fillet, worn by kings as a badge of their royalty. It was made of silk, thread, or wool, and tied round the temples and forehead, the ends being tied behind, and let fall on the neck. It was usually white, and quite plain; tho' sometimes embroidered with gold, and set with pearls and precious stones. In latter times, it came to be twisted round crowns, laurels, &c. and even appears to have been worn on divers parts of the body. See **CROWN**.—The word comes from the Latin *diadema*; of the Greek *διαδημα* "a little band encompassing the head," of the verb *διαδηω*, *cingo*, "I gird."

DIADEM, in heraldry, is applied to certain circles or rims serving to inclose the crowns of sovereign princes, and to bear the globe and cross, or the flower-de-luces, for their crest. The crowns of sovereigns are bound, some with a greater, and some with a less number of diadems.—The bandage about the heads of the Moors on shields is also called *diadem*, in blazoning.

DIÆRESIS, in surgery, an operation serving to divide and separate the part when the continuity is a hindrance to the cure.

DIÆRESIS, in medicine, is the consuming of the vessels of an animal body, when from some corroding cause certain passages are made, which naturally ought not to have been; or certain natural passages are dilated beyond their ordinary dimensions, so that the humours which ought to have been contained in the vessels extravasate or run out.

DIÆRESIS, in grammar, the division of one syllable into two, which is usually noted by two points over a letter, as *aulai* instead of *aulæ*, *dissolūenda* for *dissolūenda*.

DIÆTETÆ, in Grecian antiquity, a kind of judges, of which there were two sorts, the *cleroti* and *diallaclerii*. The former were public arbitrators, chosen by lot to determine all causes exceeding ten drachms, within their own tribe, and from their sentence an appeal lay to the superior courts.

The *diallaclerii*, on the contrary, were private arbitrators from whose sentence there lay no appeal, and accordingly they always took an oath to administer justice without partiality.

DIAGLYPHICE, the art of cutting or engraving figures on metals, such as seals, intaglios, matrices of letters, &c. or coins for medals. See **ENGRAVING**.

DIAGNOSIS (from *διαγνωω* to discern or distinguish), the diagnostics or the signs of a disease. They

are of two kinds, *viz.* the adjunct and pathognomonic; **Diagnostic** the first are common to several diseases, and serve only to point out the difference between diseases of the same species; the latter are those which always attend the disease, and distinguish it from all others.

Diagnostic
Dialeſis.

DIAGNOSTIC, in medicine, a term given to those signs which indicate the present state of a disease, its nature and cause.

DIAGONAL, in geometry, a right line drawn across a quadrilateral figure, from one angle to another; by some called the *diameter*, and by others the *diametral*, of the figure. See **GEOMETRY**.

DIAGORAS, surnamed the *Atheist*, lived in the 91st Olympiad. He was not a native of Athens, but he philosophized there. He delighted in making verses, and had composed a poem which a certain poet stole from him. He sued the thief, who swore it was his own, and got glory by it. This tempted Diagoras to deny a Providence. The Athenians summoned him to give an account of his doctrine. He fled, and they set a price upon his head, promising a reward to any who should kill him; but he took shipping, and was cast away.

DIAGRAM, in geometry, a scheme for explaining and demonstrating the properties of any figure, whether triangle, square, circle, &c. See **GEOMETRY**.

DIAGRAM, among ancient musicians, the same with the scale of the moderns. See **SCALE**.

DIAH, **DIAT**, a name given by the Arabs to the punishment of retaliation. By the Mahometan law, a brother, or the next relation of a murdered person, ought to take part against the murderer, and demand his blood in reparation for that which he has shed. Before the time of Mahomet, the Arabs had a custom of putting a freeman of their prisoners to death in lieu of every slave they lost in battle, and a man for every woman that was killed. But Mahomet regulated the laws of reprisal; directing in the Alcoran, by the *diat*, that a freeman should be required for a freeman, and a slave for a slave. The Turks, probably in consequence of this law, formerly massacred almost all their prisoners of war, but they now content themselves with enslaving and selling them.

DIAHEXAPLA, or **DIAHEXAPTE**, among farriers, a compound medicine, so called from its containing six ingredients, *viz.* birthwort and gentian roots, juniper-berries, bay-berries, myrrh, and ivory-shavings. It is commended for colds, consumptions, purfines, and many other disorders in horses.

DIAL, an instrument serving to measure time; which is effected by the aid of the sun, is called a *sun dial*. The word is from the Latin *dies* "day," because indicating the hour of the day. The ancients also called it *sciatherium*, from its effect by the shadow. See the article **DIALING**.

DIALECT, an appellation given to the language of a province, in so far as it differs from that of the whole kingdom. The term, however, is more particularly used in speaking of the ancient Greek, whereof there were four dialects, the Attic, Ionic, Æolic, and Doric; each of which was a perfect language in its kind, that took place in certain countries, and had peculiar beauties.

In Great Britain, besides the grand diversity of Eng-

Dialectics,
Dialing.

lish and Scotch, almost every county has a dialect of its own, all differing considerably in pronunciation, accent, and tone, although one and the same language.

DIALECTICS, in the literary history of the ancients, that branch of logics which taught the rules and modes of reasoning. See **LOGIC**, Part III.

Zeno Eleates was the first who discovered the natural series of principles and conclusions observed in reasoning, and formed an art thereof in form of a dialogue; which, for this reason, was called *dialectica*.

The *dialectica* of the ancients is usually divided into several kinds: the first was the *eleatica*, that of Zeno Eleates, which was threefold; *viz. consecutionum, colloquationum, and contentionum*. The first consisting of rules for deducing or drawing conclusions. The second, the art of dialogue; which became of such universal use in philosophy, that all reasoning was called *interrogation*: then, syllogism being laid aside, the philosophers did all by dialogue; it lying on the respondent to conclude and argue from the several concessions made. The last part of Zeno's dialectics, *Epistula*, was contentious, or the art of disputing and contradicting; though some, particularly Laertius, ascribe this part to Protagoras a disciple of Zeno.

The second is the *dialectica megarica*, whose author is Euclid, not the mathematician, but another of Megara. He gave much into the method of Zeno and Protagoras; though there are two things appropriated to him: the first, that he impugned the demonstrations of others, not by assumptions, but conclusions; continually making illations, and proceeding from consequence to consequence: the second, that he set aside all arguments drawn from comparisons of similitude as invalid.

He was succeeded by Eubulides, from whom the sophistic way of reasoning is said to be derived. In his time the art is described as manifold: *mentiens, fallens, electra, obvelata, arcevalis, cornuta, and calva*. See **SOPHISM**.

The third is the dialectics of Plato, which he proposes as a kind of analysis to direct the human mind, by dividing, defining, and bringing things to the first truth: where being arrived, and stopped there a little, it applies itself to explain sensible things, but with a

view to return to the first truth, where alone it can rest. Such is the idea of Plato's analysis. Dialectics
Dialing.

The fourth is Aristotle's dialectics; containing the doctrine of simple words, delivered in his book of *Prædicaments*; the doctrine of propositions, in his book *De Interpretatione*; and that of the several kinds of syllogism, in his books of *Analytics*, *Topics*, and *Elenchuses*.

The fifth is the dialectics of the Stoics; which they call a part of philosophy, and divide into rhetoric and dialectic; to which some add the definitive, whereby things are justly defined; comprehending likewise the canons or criterions of truth.

The Stoics, before they come to treat of syllogisms, have two principal places; the one about the signification of words, the other about the things signified. On occasion of the first, they consider abundance of things belonging to the grammarian's province: what, and how many letters; what is a word, diction, speech, &c. On occasion of the latter, they consider things themselves, not as without the mind, but as in it, received in it by means of the senses. Accordingly, they first teach, that *nil sit in intellectu, quod non prius fuerit in sensu*; "whatever is in the mind came thither by the senses;" and that *aut incurssione sui*, as Plato, who meets the sight; *aut similitudine*, as Cæsar by his effigy; *aut proportione*, either by enlarging as a giant or by diminishing as a pygmy; *aut translatione*, as a Cyclops; *aut compositione*, as a Centaur; *aut contrario*, as death; *aut privatione*, as a blind man.

The sixth is Epicurus's dialectics; for though he seems to have despised dialectic, he cultivated it with vigour. He was only averse to that of the Stoics; who he thought attributed too much to it, as pronouncing him alone wise who was well versed in dialectics. For this reason, Epicurus, seeming to set aside the common dialectics, had recourse to another way; *viz.* to certain canons which he substituted in their stead, the collection whereof he called *canonica*; and as all questions in philosophy are either *de re* or *de voce*, he gave separate rules for each. See **EPICUREANS**.

DIALIA, in antiquity, sacrifices performed by the *flamen dialis*. See **FLAMEN**.

D I A L I N G,

THE art of drawing dials on the surface of any given body or plane. The Greeks and the Latins called this art *gnomonica* and *sciatherica*, by reason it distinguishes the hours by the shadow of the gnomon. Some call it *photo-sciatherica*, because the hours are sometimes shown by the light of the sun. Lastly, others call it *horologiography*.

Utility of
this art.

Dialing is a most necessary art: for notwithstanding we are provided with moving machines, such as clocks and watches, to show time; yet these are apt to be out of order, go wrong, and stop: consequently they stand frequently in need of regulation by some invariable instrument, as a dial; which being rightly constructed and duly placed, will always, by means of the sun, inform us of the true solar time; which time being corrected by the equation table published annually in the epheme-

rides, almanacs, and other books, will be the mean time to which clocks and watches are to be set.

The antiquity of dials is beyond doubt. Some attribute their invention to Anaximenes Milesius; and others to Thales. Vitruvius mentions one made by the ancient Chaldee historian Berosus, on a reclining plane, almost parallel to the equinoctial. Aristarchus Samius invented the hemispherical dial. And there were some spherical ones, with a needle for a gnomon. The discus of Aristarchus was an horizontal dial, with its limb raised up all around, to prevent the shadows stretching too far. History

But it was late ere the Romans became acquainted with dials. The first sun-dial at Rome was set up by Papirius Cursor, about the year of the city 460; before which time, says Pliny, there is no mention of any account

account of time but by the sun's rising and setting: it was set up at or near the temple of Quirinus, but went ill. About 30 years after, M. Valerius Messala being consul, brought out of Sicily another dial, which he set up on a pillar near the rostrum; but for want of its being made for that latitude, it could not go true. They made use of it 99 years; till Martius Philippus set up another more exact.

But there seem to have been dials among the Jews much earlier than any of these. Witness the dial of Ahaz; who began to reign 400 years before Alexander, and within twelve years of the building of Rome; mentioned by Isaiah, chap. xxxviii. verse 8.

The first professed writer on dialing is Clavius; who demonstrates all, both the theory and the operations, after the rigid manner of the ancient mathematicians; but so intricately, that few, we dare say, ever read them all. Dechales and Ozanam give much easier demonstrations in their *Courses*, and Wolfius in his *Elements*. M. Picard has given a new method of making large dials, by calculating the hour-lines; and M. de la Hire, in his *Dialing*, printed in 1683, a geometrical method of drawing hour-lines from certain points determined by observation. Eberhardus Welperus, in 1625, published his *Dialing*, wherein he lays down a method of drawing the primary dials on a very easy foundation. The same foundation is described at length by Sebastian Munster, in his *Rudimenta Mathematica*, published in 1551. Sturmius, in 1672, published a new edition of Welperus's *Dialing*, with the addition of a whole second part, about inclining and declining dials, &c. In 1708, the same work, with Sturmius's additions, was republished with the addition of a fourth part, containing Picard's and de la Hire's methods of drawing large dials. Paterfon, Michael, and Muller, have each wrote on dialing, in the German tongue; Coetius in his *Horologiographia Plana* printed in 1689; Gauppenius, in his *Gnomonica Mechanica*; Bion, in his *Use of Mathematical Instruments*; the late ingenious Mr Ferguson, in his *Select Lectures*; Mr Emerson, in his *Dialing*; and Mr W. Jones, in his *Instrumental Dialing*.

3
Definitions

A *Dial*, accurately defined, is a plane, upon which lines are described in such a manner, that the shadow of a wire, or of the upper edge of another plane, erected perpendicularly on the former, may show the true time of the day.

The edge of the plane by which the time of the day is found, is called the *stile of the dial*, which must be parallel to the earth's axis: and the line on which the said plane is erected is called the *substile*.

The angle included between the substile and stile, is called the *elevation or height of the stile*.

Those dials whose planes are parallel to the plane of the horizon, are called *horizontal dials*; and those dials whose planes are perpendicular to the plane of the horizon, are called *vertical or erect dials*.

Those erect dials, whose planes directly front the north or south, are called *direct north or south dials*; and all other erect dials are called *decliners*, because their planes are turned away from the north or south.

Those dials whose planes are neither parallel nor perpendicular to the plane of the horizon, are called *inclining or reclining dials*, according as their planes make

acute or obtuse angles with the horizon; and if their planes are also turned aside from facing the south or north, they are called *declining-inclining* or *declining-reclining dials*.

The intersection of the plane of the dial, with that of the meridian, passing through the stile, is called the *meridian of the dial*, or the *hour-line of XII*.

Those meridians, whose planes pass through the stile, and make angles of 15, 30, 45, 60, 75 and 90 degrees with the meridian of the place (which marks the hour-line of XII.) are called *hour-circles*; and their intersections with the plane of the dial are called *hour-lines*.

In all declining dials, the substile makes an angle with the hour-line of XII.; and this angle is called the *distance of the substile from the meridian*.

The declining plane's difference of longitude, is the angle formed at the intersection of the stile and plane of the dial, by two meridians; one of which passes thro' the hour-line of XII. and the other through the substile.

Thus much being premised concerning dials in general, we shall now proceed to explain the different methods of their construction.

If the whole earth *aPcp*, were transparent, and hollow, like a sphere of glass, and had its equator divided into 24 equal parts by so many meridian semicircles, *a, b, c, d, e, f, g, &c.* one of which is the geographical meridian of any given place, as London (which is supposed to be at the point *a*;) and if the hours of XII were marked at the equator, both upon that meridian and the opposite one, and all the rest of the hours in order on the rest of the meridians, those meridians would be the hour-circles of London: then, if the sphere had an opaque axis as *PEp*, terminating in the poles *P* and *p*, the shadow of the axis would fall upon every particular meridian and hour, when the sun came to the plane of the opposite meridian, and would consequently show the time at London, and at all other places on the meridian of London.

Plate CLVIII.
fig. 1.
4
The universal principle on which dialing depends.

If this sphere was cut through the middle by a solid plane *ABCD*, in the rational horizon of London, one half of the axis *EP* would be above the plane, and the other half below it; and if straight lines were drawn from the centre of the plane to those points where its circumference is cut by the hour-circles of the sphere, those lines would be the hour-lines of a horizontal dial for London: for the shadow of the axis would fall upon each particular hour-line of the dial, when it fell upon the like hour-circle of the sphere.

5
Horizontal dial.

If the plane which cuts the sphere be upright as *AFCC*, touching the given place (London) at *F*, and directly facing the meridian of London, it will then become the plane of an erect direct south-dial: and if right lines be drawn from its centre *E* to those points of its circumference where the hour-circles of the sphere cut it, these will be the hour-lines of a vertical or direct south-dial for London, to which the hours are to be set as in the figure (contrary to those on a horizontal dial), and the lower half *Ep* of the axis will cast a shadow on the hour of the day on this dial, at the same time that it would fall upon the like hour-circle of the sphere, if the dial-plane was not in the way.

Fig. 2.

6
Vertical dial.

If the plane (still facing the meridian) be made to incline,

Plate
CLVIII.7
Inclining,
reclining,
and declin-
ing, dials.

incline, or recline, any given number of degrees, the hour-circles of the sphere will still cut the edge of the plain in those points to which the hour-lines must be drawn straight from the centre; and the axis of the sphere will cast a shadow on these lines at the respective hours. The like will still hold, if the plane be made to decline by any given number of degrees from the meridian towards the east or west: provided the declination be less than 90 degrees, or the reclamation be less than the co-latitude of the place: and the axis of the sphere will be a gnomon, or stile, for the dial. But it cannot be a gnomon, when the declination is quite 90 degrees, nor when the reclamation is equal to the co-latitude; because, in these two cases, the axis has no elevation above the plane of the dial.

And thus it appears, that the plane of every dial represents the plane of some great circle upon the earth; and the gnomon of the earth's axis, whether it be a small wire as in the above figures, or the edge of a thin plate, as in the common horizontal dials.

The whole earth, as to its bulk, is but a point, if compared to its distance from the sun: and therefore, if a small sphere of glass be placed upon any part of the earth's surface, so that its axis be parallel to the axis of the earth, and the sphere have such lines upon it, and such planes within, as above described; it will show the hours of the day as truly as if it were placed at the earth's centre, and the shell of the earth were as transparent as glass.

But because it is impossible to have a hollow sphere of glass perfectly true, blown round a solid plane; or if it was, we could not get at the plane within the glass to set it in any given position; we make use of a wire-sphere to explain the principles of dialing, by joining 24 semicircles together at the poles, and putting a thin flat plate of brass within it.

Fig. 1, 2.

8
Dialing by
the com-
mon terre-
strial globe.

A common globe of 12 inches diameter, has generally 24 meridian semicircles drawn upon it. If such a globe be elevated to the latitude of any given place, and turned about until one of these meridians cut the horizon in the north point, where the hour of XII is supposed to be marked, the rest of the meridians will cut the horizon at the respective distances of all the other hours from XII. Then if these points of distance be marked on the horizon, and the globe be taken out of the horizon, and a flat board or plate be put into its place, even with the surface of the horizon; and if straight lines be drawn from the centre of the board, to these points of distance on the horizon which were cut by the 24 meridian semicircles; these lines will be the hour-lines of a horizontal dial for that latitude, the edge of whose gnomon must be in the very same situation that the axis of the globe was, before it was taken out of the horizon: that is, the gnomon must make an angle with the plane of the dial, equal to the latitude of the place for which the dial is made.

If the pole of the globe be elevated to the co-latitude of the given place, and any meridian be brought to the north point of the horizon, the rest of the meridians will cut the horizon in the respective distances of all the hours from XII, for a direct south dial, whose gnomon must be an angle with the plane of the dial, equal to the co-latitude of the place; and the hours must be set the contrary way on this dial to what they are on the horizontal.

But if your globe have more than 24 meridian semicircles upon it, you must take the following method for making *horizontal* and *south dials*.

Plate
CLVIII.

9

To con-
struct a ho-
rizontal di-
al.

Elevate the pole to the latitude of your place, and turn the globe until any particular meridian (suppose the first) comes to the north point of the horizon, and the opposite meridian will cut the horizon in the south. Then, set the hour-index to the uppermost XII on its circle; which done, turn the globe westward until 15 degrees of the equator pass under the brazen meridian, and then the hour-index will be at I (for the sun moves 15 degrees every hour), and the first meridian will cut the horizon in the number of degrees from the north point that I is distant from XII. Turn on until other 15 degrees of the equator pass under the brazen meridian, and the hour-index will then be at II, and the first meridian will cut the horizon in the number of degrees that II is distant from XII: and so, by making 15 degrees of the equator pass under the brazen meridian for every hour, the first meridian of the globe will cut the horizon in the distances of all the hours from XII to VI, which is just 90 degrees; and then you need go no farther, for the distances of XI, X, IX, VIII, VII, and VI, in the forenoon, are the same from XII, as the distances of I, II, III, IV, V, and VI, in the afternoon: and these hour-lines continued through the centre, will give the opposite hour-lines on the other half of the dial.

Thus, to make a horizontal dial for the latitude of London, which is $51\frac{1}{2}$ degrees north, elevate the north pole of the globe $51\frac{1}{2}$ degrees above the north point of the horizon; and then turn the globe, until the first meridian (which is that of London on the English terrestrial globe) cuts the north point of the horizon, and set the hour-index to XII at noon.

Then turning the globe westward until the index points successively to I, II, III, IV, V, and VI, in the afternoon, or until 15, 30, 45, 60, 75, and 90 degrees of the equator pass under the brazen meridian, you will find that the first meridian of the globe cuts the horizon in the following number of degrees from the north towards the east, viz. $11\frac{1}{4}$, $24\frac{1}{4}$, $38\frac{1}{4}$, $55\frac{1}{4}$, $71\frac{1}{4}$, and 90; which are the respective distances of the above hours from XII upon the plane of the horizon.

To transfer these, and the rest of the hours, to a horizontal plane, draw the parallel right lines *ac* and *db*, upon that plane, as far from each other as is equal to the intended thickness of the gnomon or stile of the dial, and the space included between them will be the meridian or twelve o'clock line on the dial. Cross this meridian at right angles with the six o'clock line *gh*, and setting one foot of your compasses in the intersection *a*, as a centre, describe the quadrant *ge* with any convenient radius or opening of the compasses: then, setting one foot in the intersection *b*, as a centre, with the same radius describe the quadrant *fb*, and divide each quadrant into 90 equal parts or degrees, as in the figure.

Because the hour-lines are less distant from each other about noon, than in any other part of the dial, it is best to have the centres of these quadrants at a little distance from the centre of the dial plane, on the side opposite to XII, in order to enlarge the hour-distances thereabouts, under the same angles on the plane. Thus, the

The Line of Chords
 The Line of Latitudes
 The Line of Hours

Plate
CLVIII.

the centre of the plane is at *C*, but the centres of the quadrants are at *a* and *b*.

Lay a ruler over the point *b* (and keeping it there for the centre of all the afternoon hours in the quadrant *fb*) draw the hour-line of I through $11\frac{1}{3}$ degrees in the quadrant; the hour-line of II, through $24\frac{1}{4}$ degrees; of III, through $38\frac{1}{2}$ degrees; IV, through $53\frac{1}{2}$; and V, through $71\frac{1}{3}$: and because the sun rises about four in the morning, on the longest days at London, continue the hour-lines of IV and V in the afternoon through the centre *b* to the opposite side of the dial.— This done, lay the ruler to the centre *a* of the quadrant *eg*; and through the like divisions or degrees of that quadrant, viz. $11\frac{1}{3}$, $24\frac{1}{4}$, $38\frac{1}{2}$, $53\frac{1}{2}$, and $71\frac{1}{3}$, draw the forenoon hour-lines of XI, X, IX, VIII, and VII; and because the sun sets not before eight in the evening on the longest days, continue the hour-lines of VII and VIII in the forenoon, through the centre *a*, to VII and VIII in the afternoon; and all the hour-lines will be finished on this dial; to which the hours may be set, as in the figure.

Fig. 3.

Lastly, through $51\frac{1}{2}$ degrees of either quadrant, and from its centre, draw the right line *ag* for the hypotenuse or axis of the gnomon *agi*; and from *g*, let fall the perpendicular *gi*, upon the meridian line *ai*, and there will be a triangle made, whose sides are *ag*, *gi*, and *ai*. If a plate similar to this triangle be made as thick as the distance between the lines *ac* and *bd*, and set upright between them, touching at *a* and *b*, its hypotenuse *ag* will be parallel to the axis of the world, when the dial is truly set; and will cast a shadow on the hour of the day.

N. B. The trouble of dividing the two quadrants may be saved if you have a scale with a line of chords upon it (as represented on the plate); for if you extend the compasses from 0 to 60 degrees of the line of chords, and with that extent, as a radius, describe the two quadrants upon their respective centres, the above distances may be taken with the compasses upon the lines, and set off upon the quadrants.

Fig. 4.

IO
An erect
south dial.

To make an erect direct south dial. Elevate the pole to the co-latitude of your place, and proceed in all respects as above taught for the horizontal dial, from VI in the morning to VI in the afternoon; only the hours must be reversed, as in the figure; and the hypotenuse *ag* of the gnomon *agf*, must make an angle with the dial-plane equal to the co-latitude of the place. As the sun can shine no longer on this dial than from six in the morning until six in the evening, there is no occasion for having any more than 12 hours upon it.

II
Erect de-
clining
dial.

To make an erect dial, declining from the south towards the east or west. Elevate the pole to the latitude of your place, and screw the quadrant of altitude to the zenith. Then, if your dial declines towards the east (which we shall suppose it to do at present), count in the horizon the degrees of declination, from the east point towards the north, and bring the lower end of the quadrant to that degree of declination at which the reckoning ends. This done, bring any particular meridian of your globe (as suppose the first meridian) directly under the graduated edge of the upper part of the brazen meridian, and set the hour to XII at noon. Then, keeping the quadrant of altitude at the degree of declination in the horizon, turn the globe eastward

on its axis, and observe the degrees cut by the first meridian in the quadrant of altitude (counted from the zenith) as the hour-index comes to XI, X, IX, &c. in the forenoon, or as 15, 30, 45, &c. degrees of the equator pass under the brazen meridian at these hours respectively; and the degrees then cut in the quadrant by the first meridian, are the respective distances of the forenoon hours from XII on the plane of the dial.— Then, for the afternoon hours, turn the quadrant of altitude round the zenith until it comes to the degree in the horizon opposite to that where it was placed before; namely, as far from the west point of the horizon towards the south as it was set at first from the east point towards the north; and turn the globe westward on its axis, until the first meridian comes to the brazen meridian again, and the hour-index to XII: then, continue to turn the globe westward, and as the index point to the afternoon hours I, II, III, &c. or as 15, 30, 45, &c. degrees of the equator pass under the brazen meridian, the first meridian will cut the quadrant of altitude in the respective number of degrees from the zenith that each of these hours is from XII on the dial.— And note, that when the first meridian goes off the quadrant at the horizon in the forenoon, the hour-index shows the time when the sun will come upon this dial; and when it goes off the quadrant in the afternoon, the index will point to the time when the sun goes off the dial.

Plate
CLVIII.

Having thus found all the hour-distances from XII lay them down upon your dial-plane, either by dividing a semicircle into two quadrants of 90 degrees each (beginning at the hour-line of XII), or by the line of chords, as above directed.

In all declining dials, the line on which the stile or gnomon stands (commonly called the *substile-line*) makes an angle with the twelve o'clock line, and falls among the forenoon hour-lines, if the dial declines towards the east; and among the afternoon hour-lines, when the dial declines towards the west; that is, to the left hand from the twelve o'clock line in the former case, and to the right hand from it in the latter.

To find the distance of the substile from the twelve o'clock line: if your dial declines from the south toward the east, count the degrees of that declination in the horizon from the east point toward the north, and bring the lower end of the quadrant of altitude to that degree of declination where the reckoning ends: then, turn the globe until the first meridian cuts the horizon in the like number of degrees, counted from the south point toward the east; and the quadrant, and first meridian will then cross one another at right angles; and the number of degrees of the quadrant, which are intercepted between the first meridian and the zenith, is equal to the distance of the substile line from the twelve o'clock line; and the number of degrees of the first meridian, which are intercepted between the quadrant and the north pole, is equal to the elevation of the stile above the plane of the dial.

If the dial declines westward from the south, count that declination from the east point of the horizon towards the south, and bring the quadrant of altitude to the degree in the horizon at which the reckoning ends; both for finding the forenoon hours, and distance of the substile from the meridian: and for the afternoon hours, bring the quadrant to the opposite degree in the horizon,

zon,

Plate
CLVIII.

zon, namely, as far from the west towards the north, and then proceed in all respects as above.

Thus we have finished our declining dial; and in so doing, we made four dials, viz.

1. A north dial, declining eastward by the same number of degrees. 2. A north dial, declining the same number west. 3. A south dial, declining east. And, 4. A south dial declining west. Only, placing the proper number of hours, and the stile or gnomon respectively, upon each plane. For (as abovementioned) in the south-west plane, the subtilar-line falls among the afternoon hours; and in the south-east, of the same declination, among the forenoon hours, at equal distances from XII. And so all the morning hours on the west decliner will be like the afternoon hours on the east decliner: the south east decliner will produce the north-west decliner; and the south-west decliner the north-east decliner, by only extending the hour-lines, stile and substile, quite through the centre: the axis of the stile (or edge that casts the shadow on the hour of the day) being in all dials whatever parallel to the axis of the world, and consequently pointing towards the north pole of the heaven in north latitudes, and toward the south pole in south latitudes.

12
An easy
method for
construct-
ing of dials.

But because every one who would like to make a dial, may perhaps not be provided with a globe to assist him, and may probably not understand the method of doing it by logarithmic calculation; we shall show how to perform it by the plain dialing lines, or scale of latitudes and hours (as represented on the Plate), and which may be had on scales commonly sold by the mathematical instrument makers.

This is the easiest of all mechanical methods, and by much the best, when the lines are truly divided: and not only the half hours and quarters may be laid down by all of them, but every fifth minute by most, and every single minute by those where the line of hours is a foot in length.

Fig. 5.

Having drawn your double meridian line ab, cd , on the plane intended for a horizontal dial, and crossed it at right angles by the six o'clock line fe (as in fig. 3.), take the latitude of your place with the compasses, in the scale of latitudes, and set that extent from c to e , and from a to f , on the six o'clock line: then taking the whole six hours between the points of the compasses in the scale of hours, with that extent set one foot in the point c , and let the other foot fall where it will upon the meridian line cd , as at d . Do the same from f to b , and draw the right lines ed and fb , each of which will be equal in length to the whole scale of hours. This done, setting one foot of the compasses in the beginning of the scale at XII, and extending the other to each hour on the scale, lay off these extents from d to e for the afternoon hours, and from b to f for those of the forenoon: this will divide the lines de and bf in the same manner as the hour-scale is divided at 1, 2, 3, 4, and 6; on which the quarters may also be laid down, if required. Then, laying a ruler on the point c , draw the first five hours in the afternoon, from that point, through the dots at the numeral figures 1, 2, 3, 4, 5, on the line de ; and continue the lines of IIII and V through the centre c to the other side of the dial, for the like hours of the morning: which done, lay the ruler on the point a , and draw the last five hours in the forenoon through the

dots 5, 4, 3, 2, 1, on the line fb ; continuing the hour-lines of VII and VIII through the centre a to the other side of the dial, for the like hours of the evening; and set the hours to their respective lines, as in the figure. Lastly, make the gnomon the same way as taught above for the horizontal dial, and the whole will be finished.

To make an erect south-dial, take the co-latitude of your place from the scale of latitudes, and then proceed in all respects for the hour-line as in the horizontal dial; only reversing the hours, as in fig. 4. and making the angle of the stile's height equal to the co-latitude.

But, lest the young dialist should have neither globe nor wooden scale, we shall now show him how he may make a dial without any of these helps. Only, if he has not a line of chords, he must divide a quadrant into 90 equal parts or degrees for taking the proper angle of the stile's elevation; which is easily done.

With any opening of the compasses, as ZL , de- scribe the two semicircles LFk and LQk , upon the centres Z and z , where the six o'clock line crosses the double meridian line, and divide each semicircle into 12 equal parts, beginning at L (though, strictly speaking, only the quadrants from L to the six o'clock line need be divided); then connect the divisions which are equidistant from L , by the parallel lines KM, IN, HO, GP , and FQ . Draw VZ for the hypotenuse of the stile, making the angle VZE equal to the latitude of your place; and continue the line VZ to R . Draw the line Rr parallel to the six o'clock line, and set off the distance aK from Z to Y , the distance bI from Z to X , cH from Z to W , dG from Z to T , and eF from Z to S . Then draw the lines Ss, Tt, Ww, Xx , and Yy , each parallel to Rr . Set off the distance yT from a to 11, and from f to 1; the distance xX from b to 10, and from g to 2; wW from c to 9, and from h to 3; tT from d to 8, and from i to 4; sS from e to 7, and from n to 5. Then laying a ruler to the centre Z , draw the forenoon hour-lines through the points 11, 10, 9, 8, 7; and laying it to the centre z , draw the afternoon lines through the points 1, 2, 3, 4, 5, continuing the forenoon lines of VII and VIII through the centre Z , to the opposite side of the dial, for the like afternoon hours, and the afternoon lines IIII and V through the centre z , to the opposite side, for the like morning hours. Set the hours to these lines as in the figure, and then erect the stile or gnomon, and the horizontal dial will be finished.

To construct a south dial, draw the line VZ , making an angle with the meridian ZL equal to the co-latitude of your place; and proceed in all respects as in the above horizontal dial for the same latitude, reversing the hours as in fig. 4. and making the elevation of the gnomon equal to the co-latitude.

Perhaps it may not be unacceptable to explain the method of constructing the dialing lines, and some others; which is as follows:

With any opening of the compasses, as EA , according to the intended length of the scale, describe the circle $ADCB$, and cross it at right angles by the diameters CEA and DEB . Divided the quadrant AB first into 9 equal parts, and then each part into 10; so shall the quadrant be divided into 90 equal parts or degrees.

Plate
CLVIII.13

dial.14
Dialing
lines, how
construct-
ed.
Fig. 7.

Plate
CLVIII.

degrees. Draw the right line AFB for the chord of this quadrant; and setting one foot of the compasses in the point A , extend the other to the several divisions of the quadrant, and transfer these divisions to the line AFB by the arcs, 10, 10, 20, 20, &c. and this will be a line of chords, divided into 90 unequal parts; which, if transferred from the line back again to the quadrant, will divide it equally. It is plain by the figure, that the distance from A to 60 in the line of chords, is just equal to AE , the radius of the circle from which that line is made; for if the arc 60, 60 be continued, of which A is the centre, it goes exactly through the centre E of the arc AB .

And therefore, in laying down any number of degrees on a circle, by the line of chords, you must first open the compasses so, as to take in just 60 degrees upon that line, as from A to 60: and then, with that extent, as a radius, describe a circle, which will be exactly of the same size with that from which the line was divided: which done, set one foot of the compasses in the beginning of the chord line, as at A , and extend the other to the number of degrees you want upon the line; which extent, applied to the circle, will include the like number of degrees upon it.

Divide the quadrant CD into 90 equal parts, and from each point of division draw right lines, as i, k, l , &c. to the line CE ; all perpendicular to that line, and parallel to DE , which will divide EC into a line of sines; and although these are seldom put among the dialing lines on a scale, yet they assist in drawing the line of latitudes. For if a ruler be laid upon the point D , and over each division in the line of sines, it will divide the quadrant CB into 90 unequal parts, as Ba, Bb , &c. shown by the right lines $10a, 20b, 30c$, &c. drawn along the edge of the ruler. If the right line BC be drawn, subtending this quadrant, and the nearest distances Ba, Bb, Bc , &c. be taken in the compasses from B , and set upon this line in the same manner as directed for the line of chords, it will make a line of latitudes BC , equal in length to the line of chords AB , and of an equal number of divisions, but very unequal as to their lengths.

Draw the right line DGA , subtending the quadrant DA ; and parallel to it, draw the right line rs , touching the quadrant DA at the numeral figure 3. Divide this quadrant into six equal parts, as 1, 2, 3, &c. and through these points of division draw right lines from the centre E to the line rs , which will divide it at the points where the six hours are to be placed, as in the figure. If every sixth part of the quadrant be subdivided into four equal parts, right lines drawn from the centre through these points of division, and continued to the line rs , will divide each hour upon it into quarters.

F 8.

15
A dial on a
sard.

In fig. 8. we have the representation of a portable dial, which may be easily drawn on a card, and carried in a pocket book. The lines ad, ab , and bc of the gnomon, must be cut quite through the card; and as the end ab of the gnomon is raised occasionally above the plane of the dial, it turns upon the uncut line cd as on a hinge. The dotted line AB must be slit quite through the card, and the thread C must be put thro' the slit, and have a knot tied behind, to keep it from being easily drawn out. On the other end of this

thread is a small plummet D , and on the middle of it a small bead for showing the hour of the day.

To rectify this dial, set the thread in the slit right against the day of the month, and stretch the thread from the day of the month over the angular point where the curve lines meet at XII; then shift the bead to that point on the thread, and the dial will be rectified.

To find the hour of the day, raise the gnomon (no matter how much or how little) and hold the edge of the dial next the gnomon towards the sun, so as the uppermost edge of the shadow of the gnomon may just cover the shadow-line; and the bead then playing freely on the face of the dial, by the weight of the plummet, will show the time of the day among the hour-lines, as it is forenoon or afternoon.

To find the time of sun-rising and setting, move the thread among the hour-lines, until it either covers some one of them, or lies parallel betwixt any two; and then it will cut the time of sun-rising among the forenoon hours; and of sun setting among the afternoon hours, for that day of the year to which the thread is set in the scale of months.

To find the sun's declination, stretch the thread from the day of the month over the angular point at XII, and it will cut the sun's declination, as it is north or south, for that day, in the proper scale.

To find on what days the sun enters the signs: when the bead, as above rectified, moves along any of the curve-lines which have the signs of the zodiac marked upon them, the sun enters those signs on the days pointed out by the thread in the scale of months.

The construction of this dial is very easy, especially if the reader compares it all along with fig. 1. of Plate CLIX. as he reads the following explanation of that figure.

Draw the occult line AB parallel to the top of the Plate card, and cross it at right angles with the six o'clock line ECD ; then upon C , as a centre, with the radius CA , describe the semicircle AEL , and divide it into 12 equal parts (beginning at A), as Ar, As , &c. and from these points of division draw the hour lines r, s, t, u, v, E, w , and x , all parallel to the six o'clock line EC . If each part of the semicircle be subdivided into four equal parts, they will give the half-hour lines and quarters, as in fig. 2. Draw the right-line $ASDo$, making the angle SAB equal to the latitude of your place. Upon the centre A describe the arch RST , and set off upon it the arcs SR and ST , each equal to $23\frac{1}{2}$ degrees, for the sun's greatest declination; and divide them into $23\frac{1}{2}$ equal parts, as in fig. 2. Thro' the intersection D of the lines ECD and ADo , draw the right line FDG at right angles to ADo . Lay a ruler to the points A and R , and draw the line ARF through $23\frac{1}{2}$ degrees of south declination in the arc SR ; and then laying the ruler to the points A and T , draw the line ATG through $23\frac{1}{2}$ degrees of north declination in the arc ST : so shall the lines ARF and ATG cut the line FDG in the proper lengths for the scale of months. Upon the centre D , with the radius DF , describe the semicircle FoG ; which divide into six equal parts, Fm, mn, no , &c. and from these points of division draw the right lines mh, ni, pk , and ql , each parallel to oD . Then setting one foot of the compasses in the point F , extend the other to A , and describe

Plate
CLIX.
fig. 1. com-
pared with
fig. 8. of
preceding
plate.

describe the arc AZH for the tropic of φ : with the same extent, setting one foot in C , describe the arc AEO for the tropic of \ominus . Next setting one foot in the point b , and extending the other to A , describe the arc ACI for the beginnings of the signs ♊ and ♈ ; and with the same extent, setting one foot in the point l , describe the arc AN for the beginnings of the signs ♎ and ♏ . Set one foot in the point i , and having extended the other to A , describe the arc AK for the beginnings of the signs ♌ and ♍ ; and with the same extent, set one foot in k , and describe the arc AM for the beginnings of the signs ♉ and ♊ . Then setting one foot in the point D , and extending the other to A , describe the curve AL for the beginnings of γ and α ; and the signs will be finished. This done, lay a ruler from the point A over the sun's declination in the arch RST ; and where the ruler cuts the line FDC , make marks: and place the days of the months right against these marks, in the manner shown by fig. 2. Lastly, draw the shadow-line PQ parallel to the occult line AB ; make the gnomon, and set the hours to their respective lines, as in fig. 2. and the dial will be finished.

16
Universal
dials.

Plate
CLIX.
fig. 2.

There are several kinds of dials called *universal*, because they serve for all latitudes. One, of Mr Pardie's construction, was formerly considered as the best. It consists of three principal parts; the first whereof is called the horizontal plane (A), because in practice it must be parallel to the horizon. In this plane is fixed an upright pin, which enters into the edge of the second part BD , called the meridional plane, which is made of two pieces, the lowest whereof (B) is called the *quadrant*, because it contains a quarter of a circle, divided into 90 degrees; and it is only into this part, near B , that the pin enters. The other piece is a semicircle (D) adjusted to the quadrant, and turning in it by a groove, for raising or depressing the diameter (EF) of the semicircle, which diameter is called the *axis of the instrument*. The Third piece is a circle (G), divided on both sides into 24 equal parts, which are the hours. This circle is put upon the meridional plane so, that the axis (EF) may be perpendicular to the circle, and the point C be the common centre of the circle, semicircle, and quadrant. The straight edge of the semicircle is chamfered on both sides to a sharp edge, which passes through the centre of the circle. On one side of the chamfered part, the first six months of the year are laid down, according to the sun's declination for their respective days, and on the other side the last six months. And against the days on which the sun enters the signs, there are straight lines drawn upon the semicircle, with the characters of the signs marked upon them. There is a black line drawn along the middle of the upright edge of the quadrant, over which hangs a thread (H), with its plummet (I), for levelling the instrument. *N. B.* From the 23d of September to the 20th of March, the upper surface of the circle must touch both the centre C of the semicircle, and the line of γ and α ; and from the 20th of March to the 23d of September, the lower surface of the circle must touch that centre and line.

To find the time of the day by this dial. Having set it on a level place in sun-shine, and adjusted it by the levelling screws k and l , until the plumb line hangs over the back line upon the edge of the quadrant, and

parallel to the said edge; move the semicircle in the quadrant, until the line of γ and α (where the circle touches) comes to the latitude of your place in the quadrant: then turn the whole meridional plane BD , with its circle G , upon the horizontal plane A , until the edge of the shadow of the circle falls precisely on the day of the month in the semicircle; and then the meridional plane will be due north and south, the axis EF will be parallel to the axis of the world, and will cast a shadow upon the true time of the day among the hours on the circle.

N. B. As, when the instrument is thus rectified, the quadrant and semicircle are in the plane of the meridian, so the circle is then in the plane of the equinoctial. Therefore, as the sun is above the equinoctial in summer (in northern latitudes), and below it in winter; the axis of the semicircle will cast a shadow on the hour of the day, on the upper surface of the circle, from the 20th of March till the 23d of September; and from the 23d of September to the 20th of March the hour of the day will be determined by the shadow of the semicircle upon the lower surface of the circle. In the former case, the shadow of the circle falls upon the day of the month, on the lower part of the diameter of the semicircle; and in the latter case, on the upper part.

The method of laying down the months and signs upon the semicircle is as follows. Draw the right line ACB equal to the diameter of the semicircle ADB , and cross it in the middle at right angles with the line ECD , equal in length to ADB ; then EC will be the radius of the circle FCC , which is the same as that of the semicircle. Upon E , as a centre, describe the circle FCC , on which set off the arcs Ch and Gi , each equal to $23\frac{1}{4}$ degrees, and divide them accordingly into that number for the sun's declination. Then laying the edge of a ruler over the centre E , and also over the sun's declination for every fifth day of each month (as in the card-dial), mark the points on the diameter AB of the semicircle from a to g , which are cut by the ruler; and *there* place the days of the months accordingly, answering to the sun's declination. This done, setting one foot of the compasses in C , and extending the other to a or g , describe the semicircle $abcdefg$; which divide into six equal parts, and through the points of division draw right lines parallel to CD , for the beginning of the fines (of which one half are on one side of the semicircle and the other half on the other), and set the characters of the fines to their proper lines, as in the figure.

A universal dial of a very ingenious construction, has lately been invented by Mr G. Wright of London. The hour-circle or arch E , and latitude arch C , are the portions of two meridian circles; one fixed, and the other moveable. The hour or dial plate SEN at top is fixed to the arch C , and has an index that moves with the hour-circle E ; therefore the construction of this dial is perfectly similar to the construction of the meridians and hour-circle upon a common globe. The peculiar problems to be performed by this instrument are, 1. *To find the latitude of any place.* 2. *The latitude of the place being known, to find the time by the sun and stars.* 3. *To find the sun or star's azimuth and altitude.*

Previous to use, this instrument should be in a well-adjusted

adjusted state: to perform which, you try the levels of the horizontal plates *Aa*, by first turning the screws *BBBB* till the bubbles of air on the glass tubes of the spirit-levels (levels are at right angles to each other) which are central or in the middle, and remain so when you turn the upper plate *A* half round its centre; but if they should not keep so, there are small screws at the end of each level, which admit of being turned one way or the other as may be requisite till they are so. The plates *Aa* being thus made horizontal, set the latitude arch or meridian *C* steadily between the two-grooved sides that hold it (one of which is seen at *D*), by the screw behind. On this side *D* is divided the nonius or vernier, corresponding with the divisions on the latitude arch *C*, and which may be subdivided into 5 minutes of a degree, and even less if required. The latitude arch *C* is to be so placed in *D*, that the pole *M* may be in a vertical position; which is done by making 90° on the arch at bottom coincide with the \circ of the nonius. The arch is then fixed by the tightening screw at the back of *D*. Hang a silken plumb-line on the hook at *G*: which line is to coincide with a mark at the bottom of the latitude arch at *H*, all the while you move the upper plate *A* round its centre. If it does not so, there are four screws to regulate this adjustment, two of which pass through the base *I* into the plate *A*: the other two screws fasten the nonius piece *D* together; which when unscrewed a thread or two, the nonius piece may be easily moved to the right or left of 90° as may be found requisite.

Prob. 1. *To find the latitude of the place.* Fasten the latitude and hour circles together, by placing the pin *K* into the holes; slide the nonius piece *E* on the hour-circle to the sun's declination for the given day; the sun's declination you may know in the ephemeris by White, or other almanacs for every day in the year. The nonius piece *E* must be set on that portion of the hour-circle marked *ND* to *SD*, according as the sun has north or south declination. About 20 minutes or a quarter of an hour before noon, observe the sun's shadow or spot that passes through the hole at the axis *O*, and gently move the latitude arch *C* down in its groove at *D* till you observe the spot exactly fall on the cross line on the centre of the nonius piece *L*; and by the falling of this spot, so long as you observe the sun to increase in altitude, you depress the arch *C*: but at the instant of its stationary appearance the spot will appear to go no lower; then fix the arch by the screw at the back of *D*, and the degrees thereby cut by the nonius on the arch will be the latitude of the place required: if great exactness is wanted, allowance should be made for the refraction of the atmosphere, taken from some nautical or astronomical treatise.

Prob. 2. *The latitude of the place being given to find the time by the sun and stars.* From an ephemeris as before, you find the sun's declination for the day north or south, and set the nonius piece *E* on the arch accordingly. Set the latitude arch *C*, by the nonius at *D*, to the latitude of the place; and place the magnifying glass at *M*, by which you will very correctly set the index carrying a nonius to the upper XII at *S*. Take out the pin *K*, slacken the horizontal screw *N*, and gently move, either to the right or left as you see necessary, the hour-circle *E*, at the same time with the other hand moving the horizontal plate *A* round its axis

to the right and left, till the latitude arch *C* falls into the meridian; which you will know by the sun's spot falling exactly in the centre of the nonius piece, or where the lines intersect each other. The time may be now read off exactly to a minute by the nonius on the dial-plate at top, and which will be the time required. The horizontal line drawn on the nonius piece *L*, not seen in the figure, being the parallel of declination or path that the sun-dial makes, it therefore can fall on the centre of that line at no other time but when the latitude arch *C* is in the meridian or due north and south. Hence the hour-circle, on moving round with the pole, must give the true time on the dial-plate at top. There is a hole to the right, and cross hairs to the left, of the centre axis hole *O*, where the sun's rays pass through; whence the sun's shadow or spot will also appear on the right and left of the centre on the nonius piece *L*, the holes of which are occasionally used as sights to observe through. If the sun's rays are too weak for a shadow, a dark glass to screen the eye is occasionally placed over the hole. The most proper time to find a true meridian is three or four hours before or after noon; and take the difference of the sun's declination from noon at the time you observe. If it be the morning, the difference is that and the preceding day; if afternoon, that and the following day: and the meridian being once found exact, the hour-circle *E* is to be brought into this meridian, a fixed place made for the dial, and an object to observe by it also fixed for it at a great distance. The sights *LO* must at all times be directed against this fixed object, to place the dial truly in the meridian, proper for observing the planets, moon, or bright stars by night.

Prob. 3. *To find the sun's azimuth and altitude.* The latitude arch *C* being in the meridian, bring the pole *M* into the zenith, by setting the latitude-arch to 90° . Fasten the hour-circle *E* in the meridian, by putting in the pin *K*; fix the horizontal plates by the screw *N*; and set the index of the dial plate to XII, which is the south point: Now take out the pin *K*, and gently move the hour-circle *E*; leaving the latitude arch fixed, till the sun's rays or spot passing through the centre-hole in the axis *O* fall on the centre line of the hour-circle *E*, made for that purpose. The *azimuth* in time may then be read off on the dial-plate at top by the magnifying glass. This time may be converted into degrees, by allowing at the rate of 15 for every hour. By sliding the nonius piece *E*, so that the spot shall fall on the cross line thereon, the altitude may be taken at the same time if it does not exceed 45 degrees. Or the altitude may be taken more universally, by fixing the nonius piece *E* to the \circ on the divisions, and sliding down the latitude arch in such a manner in the groove at *D*, till the spot falls exactly on the centre of the nonius *E*. The degrees and minutes then shown by the nonius at *D*, taken from 90° , will be the altitude required. By looking through the sight holes *L*, *O*, the altitude of the moon, planets, and stars, may be easily taken. Upon this principle it is somewhat adapted for levelling also: by lowering the nonius piece *E*, equal altitudes of the sun may be had; and by raising it higher, equal depressions.

More completely to answer the purposes of a good theodolite, of levelling, and the performance of

Plate
CLX.

blems in practical astronomy, trigonometry, &c. Mr W. Jones of Holborn divides the horizontal plate *D* into 368° , and an opposite nonius on the upper plate *A*, subdividing the degrees into 5 or more minutes. A telescope and spirit-level applies on the latitude arch at *HG* by two screws, making the latitude arch a vertical arch; and the whole is adapted to triangular staffs with parallel plates, similar to those used with the best theodolites.

18
An equi-
noctial dial
more uni-
versal.
Fig. 2.

A dial more universal for the performance of problems than the above, though in some particulars not so convenient and accurate, is made by Mr Jones and other instrument-makers in London. It consists of the common equatorial circles reduced to a portable size, and instead of a telescope carries a plain sight. Its principal parts consist of the sight-piece *OP*, moveable over the declination's semicircle *D*. It has a nonius *Q* to the semicircle. A dark glass to screen the eye applies occasionally over either of the holes at *O*: these holes on the inner side of the piece are intersected by cross lines, as seen in the figure below; and to the sight *P* two pieces are screwed, the lower having a small hole for the sun's rays or shadow, and the upper two cross hairs or wires.

The declination circle or arch *D* is divided into two, 90° each; and is fixed perpendicularly on a circle with a chamfered edge, containing a nonius division that subdivides into single minutes the under equatorial circle *MN*, which in all cases represents the equator, and is divided into twice 12 hours, and each hour into five minutes. At right angles below this equatorial circle is fixed the semicircle of altitude *AB*, divided into two quadrants of 90° each. This arch serves principally to measure angles of altitude and depression; and it moves centrally on an upright pillar fixed in the horizontal circle *EF*. This circle *EF* is divided into four quadrants of 90° each, and against it there is fixed a small nonius plate at *N*. The horizontal circle may be turned round its centre or axis; and two spirit levels, *LL* are fixed on it at right angles to one another.

We have not room to detail the great variety of astronomical and trigonometrical problems that may be solved by this general instrument, as described in Jones's *Instrumental Dialing*. One example connected with our present purpose may here suffice, viz. *To find the time when the latitude is given*. Supposing the instrument to be well adjusted by the directions hereafter given. The meridian of the place should be first obtained to place the instrument in, which is settled by a distant mark, or particular cavities to receive the screws at *IGH*, made in the base it stands on. The meridian is best found by equal altitudes of the sun. In order to take these, you set the middle mark of the nonius on the declination arch *D* at *o*, and fix it by the screw behind; then set the horary or hour circle to XII. The circle *EF* being next made horizontal, you direct the sights to the sun, by moving the horizontal circle *EF* and altitude semicircle *AB*: the degrees and minutes marked by the nonius on the latter will be the altitude required. To take equal altitudes, you observe the sun's altitude in the morning two or three hours before noon by the semicircle *AB*: leave the instrument in the same situation perfectly unaltered till the afternoon, when by moving the horizontal circle *EF*, only find the direction of the sight or the sun's spot to be just

the same, which will be an equal altitude with the morning. The place of the horizontal circle *EF* against the nonius at each time of observation is to be carefully noted; and the middle degree or part between each will be the place where the semicircle *AB*, and sight *OP*, will stand or coincide with, when directed to the south or north, according to the sun's situation north or south at noon at the place of observation. Set the index or sight-piece *OP* very accurately to this middle point, by directing the sight to some distant object; or against it, let one be placed up: this object will be the meridian mark, and will always serve at any future time. To find the time, the meridian being thus previously known by equal altitudes of the sun (or star), and determined by the meridian mark made at a distance, or by the cavities in the base to set the screw in: Place the equatorial accordingly, and level the horizontal circle *EF* by the spirit-levels thereon. Set the semicircle *AB* to the latitude of the place, and the index of the sights *OP* to the declination of the sun, found by the ephemeris, as before directed. Turn the semicircle *D* till the sight-holes are accurately directed to the sun, when the nonius on the hour circle *MN* will show the time. It may easily be known when the sun's rays are direct through, by the spot falling on the lower intersectors of the marks across the hole at *O*. See the figure *S* adjoining.

The adjustments of this equatorial dial are to be made from the following trials. *1st*, to adjust the levels *LL* on *EF*: Place the *o* of any of the divisions on *EF* to the middle mark or stroke on the nonius at *N*; bring the air-bubbles in the levels in the centres of each case, by turning the several screws at *IGH*: this being exactly done, turn the circle *EF* two 90° or half round: if the bubble of air then remains in the centre, they are right, and properly adjusted for use; but if they are not, you make them so by turning the necessary screws placed for that purpose at the ends of the level-cases by means of a turn-screw, until you bring them to that fixed position, that they will return when the plate *EF* is turned half round. *2dly*, To adjust the line of sight *OP*: Set the nonius to *o* on the declination arch *D*, the nonius on the hour-circle to VI, and the nonius on the semicircle *AB* to 90° . Direct to some part of the horizon where there may be a variety of fixed objects. Level the horizontal circle *EF* by the levels *LL*, and observe any object that may appear on the centre of the cross wires. Reverse the semicircle *AB*, viz. so that the opposite 90° of it be applied to the nonius, observing particularly that the other nonii preserve their situation. If then the remote object formerly viewed still continues in the centre of the cross wires, the line of sight *OP* is truly adjusted; but if not, unscrew the two screws of the frame carrying the cross wires, and move the frame till the intersection appears against another or new object, which is half way between the first and that which the wires were against on the reversion. Return the semicircle *AB* to its former position: when, if the intersection of the wires be found to be against the half-way object, or that to which they were last directed, the line of sight is adjusted; if not, the operation of observing the interval of the two objects, and applying half way, must be repeated.

It is necessary to observe, that one of the wires should

Plate
CLX.

Plate
CLX.

should be in the plane of the declination circle, and the other wire at right angles; the frame containing the wires is made to shift for that purpose.

The hole at *P* which forms the sun's spot is also to be adjusted by directing the sight to the sun, that the centre of the shadow of the cross hairs may fall exactly on the upper hole: the lower frame with the hole is then to be moved till the spot falls exactly on the lower sight-hole.

Lastly, it is generally necessary to find the correction always to be applied to the observations by the semicircle of altitude *AB*. Set the nonius to 0 on the declination arch *D*, and the nonius to XII on the equator or hour-circle: Turn the sight to any fixed and distinct object, by moving the arch *AB* and circle *EF* only: Note the degree and minute of the angle of altitude or depression: Reverse the declination semicircle by placing the nonius on the hour-circle to the opposite XII: Direct the sight to the same object again as before. If the altitude or depression now given be the same as was observed in the former position, no correction is wanted; but if not the same, half the difference of the two angles is the correction to be added to all observations or rectifications made with that quadrant by which the least angle was taken, or to be subtracted from all observations made with the other quadrant. These several adjustments are absolutely necessary previous to the use of the instrument; and when once well done, will keep so, with care, a considerable time.

19
Universal
ring-dial.
Fig. 3, 4, 5.

The *Universal Astronomical Equinoctial Ring-Dial*, is an instrument of an old construction, that also serves to find the hour of the day in any latitude of the earth (see fig. 3.). It consists of two flat rings or circles, usually from 4 to 12 inches diameter, and of a moderate thickness; the outward ring *AE* representing the meridian of the place it is used at, contains two divisions of 90° each opposite to one another, serving to let the sliding piece *H*, and ring *G* (by which the dial is usually suspended), be placed on one side from the equator to the north pole, and on the other side to the south, according to the latitude of the place. The inner ring *B* represents the equator, and turns diametrically within the outer by means of two pivots inserted in each end of the ring at the hours XII.

Across the two circles is screwed to the meridian a thin pierced plate or bridge, with a cursor *C*, that slides along the middle of the bridge: this cursor has a small hole for the sun to shine through. The middle of this bridge is conceived as the axis of the world, and its extremities as the poles: on the one side are delineated the 12 signs of the zodiac, and sometimes opposite the degrees of the sun's declination; and on the other side the days of the month throughout the year. On the other side of the outer ring *A* are the divisions of 90°, or a quadrant of altitude: It serves, by the placing of a common pin *P* in the hole *h* (see fig. 4.), to take the sun's altitude or height, and from which the latitude of the place may easily be found.

20
Its use.

Use of the dial. Place the line *a* in the middle of the sliding piece *H* over the degree of latitude of the place. Suppose, for example, 51½ for London; put the line which crosses the hole of the cursor *C* to the day of the month or the degree of the sign. Open

the instrument till the two rings be at right angles to each other, and suspend it by the ring *G*; that the axis of the dial represented by the middle of the bridge be parallel to the axis of the earth, viz. the north pole to the north, and *vice versa*. Then turn the flat side of the bridge towards the sun, so that his rays passing through the small hole in the cursor may fall exactly in a line drawn through the middle of the concave surface of the inner ring or hour-circle, the bright spot by which shows the hour of the day in the said concave surface of the dial. *Note*, The hour XII cannot be shown by this dial, because the outer ring being then in the plane of the meridian, excludes the sun's rays from the inner; nor can this dial show the hour when the sun is in the equinoctial, because his rays then falling parallel to the plane of the inner circle or equinoctial, are excluded by it.

To take the altitude of the sun by this dial, and with the declination thereby to find the *latitude of the place*: Place a common pin *p* in the hole *h* projecting in the side of the meridian where the quadrant of altitude is: then bring the centre mark of the sliding-piece *H* to the 0 or middle of the two divisions of latitude on the other side, and turn the pin towards the sun till it cuts a shadow over the degree of the quadrant of altitude; then what degree the shadow cuts is the altitude. Thus, in fig. 4. the shadow *hg* appears to cut 35°, the altitude of the sun.

The sun's *declination* is found by moving the cursor in the sliding piece till the mark across the hole stands just against the day of the month; then, by turning to the other side of the bridge, the mark will stand against the sun's declination.

In order to find the *latitude* of the place, observe that the latitude and declination be the same, viz. both north or south; subtract the declination from the meridian or greatest daily altitude of the sun, and the remainder is the complement of the latitude; which subtracted from 90°, leaves the latitude. Example:

	Deg. mia.
The meridian altitude may be	57 48
The sun's declination for the day	19 18
	38 30
Complement of latitude	90 0

The latitude 51 30

But if the latitude and declination be contrary, add them together, and the sum is the complement of the latitude. This dial is sometimes mounted on a stand, with a compass, two spirit-levels, and adjusting screws, &c. &c. (see fig. 5.), by which it is rendered more useful and convenient for finding the sun's azimuth, altitudes, variation of the needle, declinations of planes, &c. &c.

An *Universal Dial on a plain cross*, is described by Mr Ferguson. It is moveable on a joint *C*, for elevating it to any given latitude on the quadrant *C* 0 90, as it stands upon the horizontal board *A*. The arms of the cross stand at right angles to the middle part; and the top of it, from *a* to *n*, is of equal length with either of the arms *ne* or *mk*. See fig. 6.

This dial is rectified by setting the middle line *tu* to the

Plate
CLX.

21
Universal
cross-dial
Fig. 6, 7, 8.

the latitude of the place on the quadrant, the board *A* level, and the point *N* northward by the needle; thus, the plane of the cross will be parallel to the plane of the equator. Then, from III o'clock in the morning till VI, the upper edge *kl* of the arm *io* will cast a shadow on the time of the day on the side of the arm *cn*; from VI till IX, the lower edge *i* of the arm *io* will cast a shadow on the hours on the side *oq*. From IX in the morning to XII at noon, the edge *ab* of the top part *an* will cast a shadow on the hours on the arm *nef*; from XII to III in the afternoon, the edge *cd* of the top part will cast a shadow on the hours on the arm *klm*; from III to VI in the evening, the edge *gh* will cast a shadow on the hours on the part *pqr*; and from VI to IX, the shadow of the edge *ef* will show the time on the top part *an*. The breadth of each part *ab*, *ef*, &c. must be so great, as never to let the shadow fall quite without the part or arm on which the hours are marked, when the sun is at his greatest declination from the equator.

To determine the breadth of the sides of the arms which contain the hours, so as to be in just proportion to their length; make an angle *ABC* (fig. 7.) of $23\frac{1}{2}$ degrees, which is equal to the sun's greatest declination; and suppose the length of each arm, from the side of the long middle part, and also the length of the top part above the arms, to be equal to *Bd*. Then, as the edges of the shadow, from each of the arms, will be parallel to *Be*, making an angle of $23\frac{1}{2}$ degrees with the side *Bd* of the arm, when the sun's declination is $23\frac{1}{2}^{\circ}$; it is plain, that if the length of the arm be *Bd*, the least breadth that it can have, to keep the edge *Be* of the shadow *Begd* from going off the side of the arm *de* before it comes to the end of it *ed*, must be equal to *ed* or *dB*. But in order to keep the shadow within the quarter divisions of the hours, when it comes near the end of the arm, the breadth of it should be still greater, so as to be almost doubled, on account of the distance between the tips of the arms.

The hours may be placed on the arms, by laying down the cross *abcd* (fig. 8.) on a sheet of paper; and with a black-lead pencil held close to it, drawing its shape and size on the paper. Then take the length *ae* in the compasses, and with one foot in the corner *a*, describe with the other the quadrant *ef*. Divide this arc into six equal parts, and through the points of division draw light lines *ag*, *ah*, &c. continuing three of them to the arm *ce*, which are all that can fall upon it; and they will meet the arm in these points through which the lines that divide the hours from each other, as in fig. 6. are to be drawn right across it. Divide each arm, for the three hours contained in it, in the same manner; and set the hours to their proper places, on the sides of the arms, as they are marked in fig. 33. Each of the hour spaces should be divided into four equal parts, for the half hours and quarters, in the quadrant *ef*; and right lines should be drawn through these division-marks in the quadrant, to the arms of the cross, in order to determine the places thereon where the subdivisions of the hours must be marked.

This is a very simple kind of universal dial; it is easily made, and has a pretty uncommon appearance in a garden.

Fig. 9. is called a *Universal Mechanical Dial*, as by its equinoctial circle an easy method is had of describing a dial on any kind of plane. For example: Suppose a dial is required on an horizontal pane. If the plane be immoveable, as *ABCD*, find a meridian line as *CF*; or if moveable, assume the meridian at pleasure: then by means of the triangle *EKF*, whose base is applied on the meridian line, raise the equinoctial dial *H* till the index *GI* becomes parallel to the axis of the earth, (which is so, if the angle *KEF* be equal to the elevation of the pole), and the 12 o'clock line on the dial hang over the meridian line of the plane or the base of the triangle. If then, in the night-time or a darkened place, a lighted candle be successively applied to the axis *GI*, so as the shadow of the index or stile *GI* fall upon one hour-line after another, the same shadow will mark out the several-hour lines on the plane *ABCD*. Noting the points therefore on the shadow, draw lines through them to *G*; then an index being fixed on *G*, according to the angle *IGF*, its shadow will point out the several hours by the light of the sun. If a dial were required on a vertical plane, having raised the equinoctial circle as directed, push forward the index *GI* till the tip thereof *I* touch the plane. If the plane be inclined to the horizon, the elevation of the pole should be found on the same; and the angle of the triangle *KEF* should be made equal thereto.

Mr Ferguson describes a method of making *three dials on three different planes, so that they may all show the time of the day by one gnomon*. On the flat board *ABC* describe an horizontal dial, with its gnomon *FGH*, the edge of the shadow of which shows the time of the day. To this horizontal board join the upright board *EDC*, touching the edge *GH* of the gnomon; then making the top of the gnomon at *G* the centre of the vertical south dial, describe it on the board *EDC*. Besides, on a circular plate *IK* describe an equinoctial dial, and, by a slit *cd* in the XII o'clock line from the edge to the centre, put it on the gnomon *EG* as far as the slit will admit. The same gnomon will show the same hour on each of these dials.

An Universal Dial, showing the hours of the day by a terrestrial globe, and by the shadows of several gnomons, at the same time; together with all the places of the earth which are then enlightened by the sun; and those to which the sun is then rising, or on the meridian, or setting. This dial is made of a thick square piece of wood, or hollow metal. The sides are cut into semicircular hollows, in which the hours are placed; the stile of each hollow coming out from the bottom thereof, as far as the ends of the hollows project. The corners are cut out into angles, in the insides of which the hours are also marked; and the edge of the end of each side of the angle serves as a stile for casting a shadow on the hours marked on the other side.

In the middle of the uppermost side, or plane, there is an equinoctial dial; in the centre whereof an upright wire is fixed, for casting a shadow on the hours of that dial, and supporting a small terrestrial globe on its top.

The whole dial stands on a pillar, in the middle of a round horizontal board, in which there is a compass and magnetic needle, for placing the meridian stile to-

Plate
CLIX.

Plate
CLIX.

ward the south. The pillar has a joint with a quadrant upon it, divided into 90 degrees (supposed to be hid from sight under the dial in the figure) for setting it to the latitude of any given place.

The equator of the globe is divided into 24 equal parts, and the hours are laid down upon it at these parts. The time of the day may be known by these hours, when the sun shines upon the globe.

To rectify and use this dial, set it on a level table or sole of a window, where the sun shines, placing the meridian stile due south, by means of the needle; which will be, when the needle points as far from the north fleur-de-lis toward the west, as it declines westward, at your place. Then bend the pillar in the joint, till the black line on the pillar comes to the latitude of your place in the quadrant.

The machine being thus rectified, the plane of its dial part will be parallel to the equator, the wire or axis that supports the globe will be parallel to the earth's axis, and the north pole of the globe will point toward the north pole of the heavens.

The same hour will then be shown in several of the hollows, by the ends of the shadows of their respective stiles: the axis of the globe will cast a shadow on the same hour of the day, in the equinoctial dial, in the centre of which it is placed, from the 20th of March to the 23d of September; and, if the meridian of your place on the globe be set even with the meridian stile, all the parts of the globe that the sun shines upon, will answer to those places of the real earth which are then enlightened by the sun. The places where the shade is just coming upon the globe, answer to all those places of the earth to which the sun is then setting: as the places where it is going off, and the light coming on, answer to all the places of the earth where the sun is then rising. And lastly, if the hour of VI be marked on the equator in the meridian of your place (as it is marked on the meridian of London in the figure) the division of the light and shade on the globe will show the time of the day.

The northern stile of the dial (opposite to the southern or meridian one) is hid from the sight in the figure, by the axis of the globe. The hours in the hollow to which that stile belongs, are also supposed to be hid by the oblique view of the figure: but they are the same as the hours in the front-hollow. Those also in the right and left hand semicircular hollows are mostly hid from sight; and so also are all those on the sides next the eye of the four acute angles.

The construction of this dial is as follows:

Fig. 9. On a thick square piece of wood, or metal, draw the lines ac and bd , as far from each other as you intend for the thickness of the stile $abcd$; and in the same manner, draw the like thickness of the other three stiles, $efghiklm$, and $nopq$, all standing outright as from the centre.

With any convenient opening of the compasses, as aA , (so as to leave proper strength of stuff when KI is equal to aA), set one foot in a , as a centre, and with the other foot describe the quadrantal arc Ac . Then, without altering the compasses, set one foot in b as a centre, and with the other foot describe the quadrant dB . All the other quadrants in the figure must be described in the same manner, and with the same open-

ing of the compasses, on their centres e, f, i, t , and no ; and each quadrant divided into six equal parts, for as many hours, as in the figure; each of which parts must be subdivided into 4, for the half-hours and quarters.

At equal distances from each corner, draw the right lines Ip and Kp , Lq , and Mq , Nr and Or , Ps and Qs ; to form the four angular hollows IpK , LqM , NrO , and PsQ , making the distances between the tips of these hollows, as IK , LM , NO , and PQ , each equal to the radius of the quadrants; and leaving sufficient room within the angular points pqr and s , for the equinoctial in the middle.

To divide the insides of these angles properly for the hour-spaces thereon, take the following method.

Set one foot of the compasses in the point I as a centre, and open the other to K ; and with that opening describe the arc Kt : then, without altering the compasses, set one foot in K , and with the other foot describe the arc It . Divide each of these arcs, from I and K to their intersection at t , into four equal parts; and from their centres I and K through the points of division, draw the right lines $I3$, $I4$, $I5$, $I6$, $I7$; and $K2$, $K1$, $K12$, $K11$; and they will meet the sides Kp and Ip of the angle IpK where the hours thereon must be placed. And these hour-spaces in the arcs must be subdivided into four equal parts, for the half hours and quarters.—Do the like for the other three angles, and draw the dotted lines, and set the hours in the insides where those lines meet them, as in the figure: and the like hour-lines will be parallel to each other in all the quadrants and in all the angles.

Mark points for all these hours on the upper side: and cut out all the angular hollows, and the quadrantal ones quite through the places where their four gnomons must stand; and lay down the hours on their insides, (as in fig. 10.), and set in their gnomons, which must be as broad as the dial is thick; and this breadth and thickness must be large enough to keep the shadows of the gnomons from ever falling quite out at the sides of the hollows, even when the sun's declination is at the greatest.

Lastly, draw the equinoctial dial in the middle, all the hours of which are equidistant from each other; and the dial will be finished.

As the sun goes round, the broad end of the shadow of the stile $abcd$ will show the hours in the quadrant Ac , from sun-rise till VI in the morning; the shadow from the end M will show the hours on the side Lq from V to IX in the morning; the shadow of the stile $efgh$ in the quadrant Dg (in the long days) will show the hours from sun-rise till VI in the morning; and the shadow of the end N will show the morning-hours, on the side Or , from III to VII.

Just as the shadow of the northern stile $abcd$ goes off the quadrant Ac , the shadow of the southern stile $iklm$ begins to fall within the quadrant Ft , at VI in the morning; and shows the time, in that quadrant, from VI till XII at noon; and from noon till VI in the evening in the quadrant mE . And the shadow of the end O shows the time from XI in the forenoon till III in the afternoon, on the side rN ; as the shadow of the end P shows the time from

Plate
CLIX.

from IX in the morning till I o'clock in the afternoon, on the side Qs .

At noon, when the shadow of the eastern stile $efgh$ goes off the quadrant bC (in which it showed the time from VI in the morning till noon, as it did in the quadrant gD from sun-rise till VI in the morning), the shadow of the western stile $nopq$ begins to enter the quadrant Hp ; and shows the hours thereon from XII at noon till VI in the evening: and after that till sun-set, in the quadrant qG : and the end Q casts a shadow on the side Ps from V in the evening till IX at night, if the sun be not set before that time.

The shadow of the end I shows the time on the side Kp from III till VII in the afternoon; and the shadow of the stile $abcd$ shows the time from VI in the evening till the sun sets.

The shadow of the upright central wire, that supports the globe at top, shows the time of the day, in the middle or equinoctial dial, all the summer half-year, when the sun is on the north side of the equator.

Having shown how to make sun-dials by the assistance of a good globe, or of a dialing scale, we shall now proceed to the method of constructing dials arithmetically; which will be more agreeable to those who have learned the elements of trigonometry, because globes and scales can never be so accurate as the logarithms in finding the angular distances of the hours. Yet as a globe may be found exact enough for some other requisites in dialing, we shall take it in occasionally.

The construction of sun-dials all on planes whatever may be included in one general rule: intelligible, if that of a horizontal-dial for any given latitude be well understood. For there is no plane, however obliquely situated with respect to any given place, but what is parallel to the horizon of some other place; and therefore if we can find that other place by a problem on the terrestrial globe, or by a trigonometrical calculation, and construct a horizontal dial for it; that dial applied to the plane where it is to serve will be a true dial for that place.—Thus, an erect direct south dial in $51\frac{1}{2}$ degrees north latitude, would be a horizontal-dial on the same meridian, 90 degrees southward of $51\frac{1}{2}$ degrees north latitude: which falls in with $38\frac{3}{4}$ degrees of south latitude. But if the upright plane declines from facing the south at the given place, it would still be a horizontal plane 90 degrees from that place, but for a different longitude, which would alter the reckoning of the hours accordingly.

CASE I. I. LET us suppose that an upright plane at London declines 36 degrees westward from facing the south, and that it is required to find a place on the globe to whose horizon the said plane is parallel; and also the difference of longitude between London and that place.

Rectify the globe to the latitude of London, and bring London to the zenith under the brass meridian; then that point of the globe which lies in the horizon at the given degree of declination (counted westward from the south point of the horizon) is the place at which the abovementioned plane would be horizontal.—Now, to find the latitude and longitude of that place, keep your eye upon the place, and turn the globe eastward until it comes under the graduated edge of the

brass meridian; then the degree of the brass meridian that stands directly over the place is its latitude; and the number of degrees in the equator, which are intercepted between the meridian of London and the brass meridian, is the place's difference of longitude.

Thus, as the latitude of London is $51\frac{1}{2}$ degrees north, and the declination of the place is 36 degrees west; elevate the north pole $51\frac{1}{2}$ degrees above the horizon, and turn the globe until London comes to the zenith, or under the graduated edge of the meridian; then count 36 degrees on the horizon westward from the south point, and make a mark on that place of the globe over which the reckoning ends, and bringing the mark under the graduated edge of the brass meridian, it will be found to be under $30\frac{1}{4}$ degrees in south latitude: keeping it there, count in the equator the number of degrees between the meridian of London and the brazen meridian (which now becomes the meridian of the required place), and you will find it to be $42\frac{3}{4}$. Therefore an upright plane at London, declining 36 degrees westward from the south, would be a horizontal plane at that place, whose latitude is $30\frac{1}{4}$ degrees south of the equator, and longitude $42\frac{3}{4}$ degrees west of the meridian of London.

Which difference of longitude being converted into time, is 2 hours 51 minutes.

The vertical-dial declining westward 36 degrees at London, is therefore to be drawn in all respects as a horizontal-dial for south latitude $30\frac{1}{4}$ degrees; save only that the reckoning of the hours is to anticipate the reckoning of the horizontal-dial by 2 hours 51 minutes: for so much sooner will the sun come to the meridian of London, than to the meridian of any place whose longitude is $42\frac{3}{4}$ degrees west from London.

2. But to be more exact than the globe will show us, we shall use a little trigonometry.

Let $NE\ SW$ be the horizon of London, whose zenith is Z , and P the north pole of the sphere; and let Zb be the position of a vertical plane at Z , declining westward from S (the south) by an angle of 36 degrees; on which plane an erect-dial for London at Z is to be described. Make the semidiameter ZD perpendicular to Zb ; and it will cut the horizon in D , 36 degrees west of the south S . Then a plane, in the tangent HD , touching the sphere in D , will be parallel to the plane Zb ; and the axis of the sphere will be equally inclined to both these planes.

Let WQE be the equinoctial, whose elevation above the horizon of Z (London) is $38\frac{3}{4}$ degrees; and PRD be the meridian of the place D , cutting the equinoctial in R . Then it is evident, that the arc RD is the latitude of the place D (where the plane Zb would be horizontal) and the arc RQ is the difference of longitude of the planes Zb and DH .

In the spherical triangle WDR , the arc WD is given, for it is the complement of the plane's declination from S to south; which complement is 54° (*viz.* $90^\circ - 36^\circ$): the angle at R , in which the meridian of the place D cuts the equator, is a right angle; and the angle RWD measures the elevation of the equinoctial above the horizon of Z , namely $38\frac{3}{4}$ degrees. Say therefore, As radius is to the co-sine of the plane's declination from the south, so is the co-sine of the latitude of Z to the sine of RD the latitude of D : which is of a different denomination

Plate
CLIX.

Fig. 4.

Plate
CLIX.

denomination from the latitude of *Z*, because *Z* and *D* are on different sides of the equator.

As radius - - - - - 10.00000
To co-sine 36° 0' = *RQ* 9.90796
So co-sine 51° 30' = *QZ* 9.79415

To sine 30° 14' = *DR* (9.70211) = the lat. of *D*, whose horizon is parallel to the vertical plane *Zb* at *Z*.

N. B. When radius is made the first term, it may be omitted; and then by subtracting it mentally from the sum of the other two, the operation will be shortened. Thus, in the present case,

To the logarithmic sine of *WR* = * 54° 0' 9.90796
Add the logarithmic sine of *RD* = † 38° 30' 9.79415

Their sum—radius - - - - - 9.70211
gives the same solution as above. And we shall keep to this method in the following part of this article.

To find the difference of longitude of the places *D* and *Z*, say, As radius is to the co-sine of 38½ degrees, the height of the equinoctial at *Z*, so is the co-tangent of 36 degrees, the plane's declination, to the co-tangent of the difference of longitudes. Thus,

To the logarithmic sine of ‡ 51° 30' 9.89354
Add the logarithmic tang. of § 54° 0' 10.13874

Their sum—radius - - - - - 10.03228
is the nearest tangent of 47° 8' = *WR*; which is the co-tangent of 42° 52' = *RQ*, the difference of longitude sought. Which difference, being reduced to time, is 2 hours 51½ minutes.

3. And thus having found the exact latitude and longitude of the place *D*, to whose horizon the vertical plane at *Z* is parallel, we shall proceed to the construction of a horizontal dial for the place *D*, whose latitude is 30° 14' south; but anticipating the time at *D* by 2 hours 51 minutes (neglecting the ½ min. in practice), because *D* is so far westward in longitude from the meridian of London; and this will be a true vertical dial at London, declining westward 36 degrees.

Fig. 5.

Assume any right line *CSL* for the substile of the dial, and make the angle *KCP* equal to the latitude of the place (*viz.* 30° 14'), to whose horizon the plane of the dial is parallel; then *CRP* will be the axis of the stile, or edge that casts the shadow on the hours of the day, in the dial. This done, draw the contingent line *EQ*, cutting the substilar line at right angles in *K*; and from *K* make *KR* perpendicular to the axis *CRP*. Then *KG* (= *KR*) being made radius, that is, equal to the chord of 60° or tangent of 45° on a good sector, take 42° 52' (the difference of longitude of the places *Z* and *D*) from the tangents, and having set it from *K* to *M*, draw *CM* for the hour-line of XII. Take *KN*, equal to the tangent of an angle less by 15 degrees than *KM*; that is, the tangent of 27° 52': and through the point *N* draw *CN* for the hour-line of I. The tangent of 12° 52' (which is 15° less than 27° 42'), set off the same way, will give a point between *K* and *N*, through which the hour-line of II is to be drawn. The tangent of 20° 8' (the difference between 45° and 52° 52') placed on the other side of *CL*, will determine the point through which

the hour-line of III is to be drawn: to which 2° 8', if the tangent of 15° be added, it will make 17° 8'; and this set off from *K* towards *Q* on the line *EQ*, will give the point for the hour-line of IV: and so of the rest.—The forenoon hour-lines are drawn the same way, by the continual addition of the tangents 15°, 30°, 45°, &c. to 42° 52' (= the tangent of *KM*) for the hours of XI, X, IX, &c. as far as necessary; that is, until there be five hours on each side of the substile. The sixth hour, accounted from that hour or part of the hour on which the substile falls, will be always in a line perpendicular to the substile, and drawn through the centre *C*.

Plate
CLIX,

4. In all erect dials, *CM*, the hour-line of XII, is perpendicular to the horizon of the place for which the dial is to serve; for that line is the intersection of a vertical plane with the plane of the meridian of the place, both which are perpendicular to the plane of the horizon: and any line *HO*, or *ho*, perpendicular to *CM*, will be a horizontal line on the plane of the dial, along which line the hours may be numbered; and *CM* being set perpendicular to the horizon, the dial will have its true position

5. If the plane of the dial had declined by an equal angle toward the east, its description would have differed only in this, that the hour-line of XII would have fallen on the other side of the substile *CL*, and the line *HO* would have a subcontrary position to what it has in this figure.

6. And these two dials, with the upper points of their stiles turned toward the north pole, will serve for other two planes parallel to them; the one declining from the north toward the east, and the other from the north toward the west, by the same quantity of angle. The like holds true of all dials in general, whatever be their declination and obliquity of their planes to the horizon.

CASE II. 7. If the plane of the dial not only declines, but also reclines, or inclines. Suppose its declination from fronting the south *S* be equal to the arc *SD* on the horizon; and its reclination be equal to the arc *Dd* of the vertical circle *DZ*: then it is plain, that if the quadrant of altitude *ZdD* on the globe cuts the point *D* in the horizon, and the declination is counted upon the quadrant from *D* to *d*; the intersection of the hour-circle *PRd*, with the equinoctial *WQE*, will determine *Rd*, the latitude of the place *d*, whose horizon is parallel to the given plane *Zb* at *Z*; and *RQ* will be the difference in longitude of the places at *d* and *Z*.

Fig 6.

Trigonometrically thus: Let a great circle pass thro' the three points, *W*, *d*, *E*; and in the triangle *Wdd*, right angled at *D*, the sides *WD* and *Dd* are given; and thence the angle *DWd* is found, and so is the hypotenuse *Wd*. Again, the difference, or the sum, of *DWd* and *DWR*, the elevation of the equinoctial above the horizon of *Z*, gives the angle *dWR*; and the hypotenuse of the triangle *WRd* was just now found; whence the sides *Rd* and *WR* are found, the former being the latitude of the place *d*, and the latter the complement of *RQ*, the difference of longitude sought.

Thus,

* The co-sine of 36.0, or of *RQ*.
‡ The co-sine of 38.30, or of *WRD*.

† The co-sine of 51.30, or of *QZ*.
§ The co-tangent of 36.0, or of *DW*.

Plate CLIX.

Thus, if the latitude of the place Z be $52^{\circ} 10'$ north; the declination $S D$ of the plane Zb (which would be horizontal at d) be 36° , and the reclination be 15° , or equal to the arc Dd ; the south latitude of the place d , that is, the arc Rd , will be $15^{\circ} 9'$; and RQ , the difference of the longitude, $36^{\circ} 2'$. From these data, therefore, let the dial (fig. 7.) be described, as in the former example.

8. There are several other things requisite in the practice of dialing; the chief of which shall be given in the form of arithmetical rules, simple and easy to those who have learned the elements of trigonometry. For in practical arts of this kind, arithmetic should be used as far as it can go; and scales never trusted to, except in the final construction, where they are absolutely necessary in laying down the calculated hour-distances on the plane of the dial.

Rule I. To find the angles which the hour-lines on any dial make with the substile. To the logarithmic sine of the given latitude, or of the stile's elevation above the plane of the dial, add the logarithmic tangent of the hour (*) distance from the meridian, or from the (†) substile; and the sum minus radius will be the logarithmic tangent of the angle sought.

Fig. 5.

For KC is to KM in the ratio compounded of the ratio of KC to $KG (=KR)$ and of KG to KM ; which making CK the radius 10,000,000, or 10,0000, or 10, or 1, are the ratio of 10,000,000, or of 10,0000, or of 10, or of 1, to $KG \times KM$.

Thus, in a horizontal dial, for latitude $51^{\circ} 30'$, to find the angular distance of XI in the forenoon, or I in the afternoon, from XII.

To the logarithmic sine of $51^{\circ} 30'$ 9.89354†
Add the logarithmic tang. of $51^{\circ} 0'$ 9.42805

The sum—radius is 9.32159 = the logarithmic tangent of $11^{\circ} 50'$, or of the angle which the hour-line of XI or I makes with the hour of XII.

And by computing in this manner, with the sine of the latitude, and the tangents of 30, 45, 60, and 75° , for the hours of II, III, IIII, and V in the afternoon; or of X, IX, VIII, and VII in the forenoon; you will find their angular distances from XII to be $24^{\circ} 18'$, $38^{\circ} 3'$, $53^{\circ} 35'$, and $71^{\circ} 6'$; which are all that there is occasion to compute for.—And these distances may be set off from XII by a line of chords; or rather, by taking 1000 from a scale of equal parts, and setting that extent as a radius from C to XII; and then, taking 209 of the same parts (which are the natural tangent of $11^{\circ} 50'$), and setting them from XII to XI and I, on the line bc , which is perpendicular to CG XII; and so for the rest of the hour-lines, which in the table of natural tangents, against the above distances, are 451, 782, 1355, and 2920, of such equal parts from XII, as the radius CG XII contains 1000,

And; lastly, set off 1257 (the natural tangent of $51^{\circ} 30'$) for the angle of the stile's height, which is equal to the latitude of the place.

Plate CLIX.

Rule II. The latitude of the place, the sun's declination, and his hour distance from the meridian, being given, to find (1.) his altitude, (2.) his azimuth. (1.) Let d be the sun's place; dR his declination; and, in the triangle PZd , Pd the sum, or the difference, of dR , and the quadrant PR , being given by the supposition, as also the complement of the latitude PZ , and the angle dPZ , which measures the horary distance of d from the meridian; we shall (by Case 4. of Keill's oblique spheric Trigonometry) find the base Zd , which is the sun's distance from the zenith, or the complement of his altitude.

Fig. 6.

And (2.) as sine Zd : sine Pd :: sine dPZ : dZP , or of its supplement DZS , the azimuthal distance from the south.

Or the practical rule may be as follows.

Write A for the sign of the sun's altitude, L and l for the sine and co-sine of the latitude, D and d for the sine and co-sine of the sun's declination, and H for the sine of the horary distance from VI.

Then the relation of H to A will have three varieties.

1. When the declination is toward the elevated pole, and the hour of the day is between XII and VI; it is

$$A = LD + Hld, \text{ and } H = \frac{A - LD}{ld}$$

2. When the hour is after VI, it is $A = LD - Hld$, and $H = \frac{LD + A}{ld}$

3. When the declination is toward the depressed pole, we have $A = Hld - LD$, and $H = \frac{A + LD}{ld}$

Which theorems will be found useful, and expeditious enough for solving those problems in geography and dialing which depend on the relation of the sun's altitude to the hour of the day.

Example I. Suppose the latitude of the place to be $51\frac{1}{2}$ degrees north: the time five hours distant from XII, that is, an hour after VI in the morning, or before VI in the evening; and the sun's declination 20° north. Required the sun's altitude.

Then to log. $L = \log. \sin. 51^{\circ} 30'$ 1.89354**
add log. $D = \log. \sin. 20^{\circ} 0'$ 1.53405

Their sum 1.42759 gives

$LD = \logarithm$ of 0.267664, in the natural sines.

And, to log. $H = \log. \sin. \dagger\dagger 15^{\circ} 0'$ 1.41300

add $\left\{ \begin{array}{l} \log. l = \log. \sin. \ddagger\dagger 38^{\circ} 0' \\ \log. d = \log. \sin. \S\S 70^{\circ} 0' \end{array} \right.$ 1.79414

1.97300

Their sum 1.18014 gives

$Hld = \logarithm$ of 0.151408, in the natural sines.

And

(*) That is, of 15, 30, 45, 60, 75° , for the hours of I, II, III, IIII, V, in the afternoon; and XI, X, IX, VIII, VII, in the afternoon.

(†) In all horizontal dials, and erect north or south dials, the substile and meridian are the same; but in all declining dials, the substile line makes an angle with the meridian.

(‡) In which case, the radius CK is supposed to be divided into 10,000 equal parts.

** Here we consider the radius as unity, and not 10,0000; by which, instead of the index 9, we have—1 as above; which is of no farther use than making the work a little easier.

†† The distance of one hour VI.

‡‡ The co-latitude of the place.

§§ The co-declination of the sun.

Plate CLIX.

And these two numbers (0.267664 and 0.151408) make 0.419072 = A ; which, in the table, is the nearest natural sine of $24^{\circ} 47'$, the sun's altitude sought.

The same hour-distance being assumed on the other side of VI, then $LD - Hld$ is 0.1:6256, the sine of $6^{\circ} 40\frac{1}{2}'$; which is the sun's altitude at V in the morning, or VII in the evening, when his north declination is 20° .

But when the declination is 20° south (or towards the depressed pole) the difference $Hld - LD$ becomes negative; and thereby shows, that an hour before VI in the morning, or past VI in the evening, the sun's centre is $6^{\circ} 40\frac{1}{2}'$ below the horizon.

Examp. 2. From the same data, to find the sun's azimuth. If H , L , and D , are given, then (by par. 2. of Rule II.) from H , having found the altitude and its complement Zd : and the arc Pd (the distance from the pole) being given; say, As the co-sine of the altitude is to the sine of the distance from the pole, so is the sine of the hour-distance from the meridian to the sine of the azimuth distance from the meridian.

Let the latitude be $51^{\circ} 30'$ north, the declination $15^{\circ} 9'$ south, and the time II h. 24 m. in the afternoon, when the sun begins to illuminate a vertical wall, and it is required to find the position of the wall.

Then, by the foregoing theorems, the complement of the altitude will be $81^{\circ} 32\frac{1}{2}'$, and Pd the distance from the pole being $109^{\circ} 5'$, and the horary distance from the meridian, or the angle dPZ , 36° .

To log. sin. $74^{\circ} 51'$ - 1.98464
Add log. sin. $36^{\circ} 0'$ - 1.76922

And from the sum - 1.75386
Take the log. sin. $81^{\circ} 32\frac{1}{2}'$ - 1.99525

Remains 1.75861 = log. sin.

35° , the azimuth distance sought.

When the altitude is given, find from thence the hour, and proceed as above.

This praxis is of singular use on many occasions; in finding the declination of vertical planes more exactly than in the common way, especially if the transits of the sun's centre are observed by applying a ruler with sights, either plain or telescopic, to the wall or plane whose declination is required. In drawing a meridian line, and finding the magnetic variation. In finding the bearings of places in terrestrial surveys; the transits of the sun over any place, or his horizontal distance from it, being observed, together with the altitude and hour. And thence determining small differences of longitude. In observing the variations at sea, &c.

24 improved declinator.

The declination, inclination, and reclinacion, of planes, are frequently taken with a sufficient degree of accuracy by an instrument called a declinator or declinator.

Plate CLXI. fig. 6.

The construction of this instrument, as somewhat improved by Mr Jones, is as follows: On a mahogany board $ABIK$, is inserted a semicircular arch $AGEB$ of ivory or box-wood, divided into two quadrants of 90° each, beginning from the middle G . On the centre C turns a vertical quadrant DFE , divided into 90° , beginning from the base E ; on which is a moveable index CF , with a small hole at F for the sun's rays to pass thro', and form a spot on a

VOL. V.

mark at C . The lower extremity of the quadrant at E is pointed, to mark the linear direction of the quadrant when applied to any other plane; as this quadrant takes off occasionally, and a plumb-line P hangs at the centre on C , for taking the inclinations and reclinations of planes. At H , on the plane of the board, is inserted a compass of points and degrees, with a magnetical needle turning on a pivot over it. The addition of the moveable quadrant and index considerably extend the utility of the declinator, by rendering it convenient for taking equal altitudes of the sun, the sun's altitude, and bearing, at the same time, &c.

Plate CLXI.

To apply this instrument in taking the declination of a wall or plane: Place the side ACB in an horizontal direction to the plane proposed, and observe what degree or point of the compass the N part of the needle stands over from the north or the south, and it will be the declination of the plane from the north or south accordingly. In this case, allowance must be made for the variation of the needle (if any) at the place; and which, if not previously known, will render this operation very inaccurate. At London it is now $22^{\circ} 30'$ to the west.

25 To take by it the declination, &c. and to find a meridian line.

Another way more exact may be used, when the sun shines out half an hour before noon. The side ACB being placed against the plane, the quadrant must be so moved on the semicircle ACB , and the index CF on DE , till the sun's rays passing through the hole at F fall exactly on the mark at G , and continued so till the sun requires the index to be raised no higher: you will then have the meridian or greatest altitude of the sun; and the angle contained between G and E will be the declination required. The position of CE is the meridian or 12 o'clock line. But the most exact way for taking the declination of a plane, or finding a meridian line, by this instrument, is, in the forenoon, about two or three hours before 12 o'clock, to observe two or three heights or altitudes EF of the sun; and at the same time the respective angular polar distances GE from G : write them down; and in the afternoon watch for the same, or one of the same altitudes, and mark the angular distances or distance on the quadrant AG : Now, the division or degree exactly between the two noted angular distances will be the true meridian, and the distance at which it may fall from the C , of the divisions at G will be the declination of the plane. The reason for observing two or three altitudes and angles in the morning is, that in case there should be clouds in the afternoon, you may have the chance of one corresponding altitude.

The quadrant occasionally takes off at C , in order to place it on the surface of a pedestal or plane intended for an horizontal dial; and thereby from equal altitudes of the sun, as above, draw a meridian or 12 o'clock line to set the dial by.

The base $ABIK$ serves to take the inclination and reclinacion of planes. In this case, the quadrant is taken off, and the plummet P is fitted on a pin at the centre C : then the side IGK being applied to the plane proposed, as QL (fig. 7.) of the plumb-line cuts the semicircle in the point G , the plane is horizontal; or if it cut the quadrant in any point at S , then will GCS be the angle of inclination. Lastly, if applying

5 I

the

Plate
CLXI.

the side ACB (fig. 7.) to the plane, the plummet cuts G , the plane is vertical; or if it cuts either of the quadrants, it is accordingly the angle of inclination. Hence, if the quantity of the angle of inclination be compared with the elevation of the pole and equator, it is easily known whether the plane be inclined or reclined.

Of the double Horizontal Dial, and the Babylonian and Italian Dials.

To the *gnomonic* projection, there is sometimes added a *stereographic* projection of the hour-circles, and the parallels of the sun's declination, on the same horizontal plane; the upright side of the gnomon being sloped into an edge, standing perpendicularly over the centre of the projection: so that the dial, being in its due position, the shadow of *that* perpendicular edge is a vertical circle passing through the sun, in the stereographic projection.

The months being duly marked on this dial, the sun's declination, and the length of the day at any time, are had by inspection (as also his altitude, by means of a scale of tangents). But its chief property is, that it may be placed true, whenever the sun shines, without the help of any other instrument.

Fig. 6.

Let d be the sun's place in the stereographic projection, $x\ dyz$ the parallel of the sun's declination, Zd a vertical circle through the sun's centre, Pd the hour-circle; and it is evident, that the diameter NS of this projection being placed duly north and south, these three circles will pass through the point d . And therefore, to give the dial its due position, we have only to turn its gnomon toward the sun, on a horizontal plane, until the hour on the common gnomonic projection coincides with that marked by the hour-circle Pd , which passes through the intersection of the shadow Zd with the circle of the sun's present declination.

The Babylonian and Italian dials reckon the hours, not from the meridian as with us, but from the sun's rising and setting. Thus, in Italy, an hour before sun-set is reckoned the 23d hour; two hours before sun-set the 22d hour; and so of the rest. And the shadow that marks them on the hour-lines, is *that* of the point of a stile. This occasions a perpetual variation between their dials and clocks, which they must correct from time to time, before it arises to any sensible quantity, by setting their clocks so much faster or slower. And in Italy, they begin their day, and regulate their clocks, not from sun-set, but from about mid-twilight, when the *Ave-Maria* is said; which corrects the difference that would otherwise be between the clock and the dial.

The improvements which have been made in all sorts of instruments and machines for measuring time, have rendered such dials of little account. Yet, as the theory of them is ingenious, and they are really, in some respects, the best contrived of any for vulgar use, a general idea of their description may not be unacceptable.

Fig. 8.

Let fig. 8. represent an erect direct south wall, on which a Babylonian dial is to be drawn, showing the hours from sun-rising; the latitude of the place, whose horizon is parallel to the wall, being equal to the angle KCR . Make, as for a common dial, $KG=KR$ (which

is perpendicular to CR) the radius of the equinoctial EQ , and draw RS perpendicular to CK for the stile of the dial; the shadow of whose point R is to mark the hours, when SR is set upright on the plane of the dial.

Then it is evident, that, in the contingent line EQ , the spaces K_1, K_2, K_3 . &c. being taken equal to the tangents of the hour-distances from the meridian, to the radius KG , one, two, three, &c. hours after sun rising, on the equinoctial day; the shadow of the point R will be found, at these times, respectively in the points 1, 2, 3, &c.

Draw, for the like hours after sun-rising, when the sun is in the tropic of Capricorn $\wp V$, the like common lines CD, CE, CF , &c. and at these hours the shadow of the point R will be found in those lines respectively. Find the sun's altitudes above the plane of the dial at these hours; and with their co-tangents Sd, Se, Sf , &c. to radius SR , describe arcs intersecting the hour-lines in the points d, e, f , &c. so shall the right lines $1d, 2e, 3f$, &c. be the lines of I, II, III, &c. hours after sun-rising.

The construction is the same in every other case; due regard being had to the difference of longitude of the place at which the dial would be horizontal, and the place for which it is to serve: and likewise, taking care to draw no lines but what are necessary; which may be done partly by the rules already given for determining the time that the sun shines on any plane; and partly from this, that on the tropical days, the hyperbola described by the shadow of the point R limits the extent of all the hour-lines.

Of the right placing of Dials, and having a true Meridian Line for the regulating of Clocks and Watches.

THE plane on which the dial is to rest being duly prepared, and every thing necessary for fixing it, you may find the hour tolerably exact by a large equinoctial ring-dial, and set your watch to it. And then the dial may be fixed by the watch at your leisure.

If you would be more exact, take the sun's altitude by a good quadrant, noting the precise time of observation by a clock or watch. Then compute the time for the altitude observed; and set the watch to agree with that time, according to the sun. A Hadley's quadrant is very convenient for this purpose: for by it you may take the angle between the sun and his image reflected from a basin of water; the half of which angle, subtracting the refraction, is the altitude required. This is best done in summer; and the nearer the sun is to the prime vertical (the east or west azimuth) when the observation is made, so much the better.

Or, in summer, take two equal altitudes of the sun in the same day; one any time between 7 and 10 in the morning, the other between 2 and 5 in the afternoon; noting the moments of these two observations by a clock or watch: and if the watch shows the observations to be at equal distances from noon, it agrees exactly with the sun: if not, the watch must be corrected by half the difference of the forenoon and afternoon intervals; and then the dial may be set true by the watch.

Thus, for example, suppose you had taken the sun's altitude when it was 20 minutes past VIII in the morning

Plate
CLXI.

Plate
CLXI.

ing by the watch ; and found, by observing in the afternoon, that the sun had the same altitude 10 minutes before III ; then it is plane ; that the watch was 5 minutes too fast for the sun : for 5 minutes after XII is the middle time between VIII h. 20m. in the morning, and III h. 50m. in the afternoon ; and therefore to make the watch agree with the sun, it must be set back five minutes.

26
A Meridian
line.

A good *meridian line*, for regulating clocks or watches, may be had by the following method.

Make a round hole, almost a quarter of an inch diameter, in a thin plate of metal ; and fix the plate in the top of a fourth window, in such a manner, that it may recline from the zenith at an angle equal to the co-latitude of your place, as nearly as you can guess : for then the plate will face the sun directly at noon on the equinoctial days. Let the sun shine freely thro' the hole into the room ; and hang a plumb-line to the ceiling of the room, at least five or six feet from the window, in such a place as that the sun's rays, transmitted through the hole, may fall upon the line when it is noon by the clock ; and having marked the said place on the ceiling, take away the line.

Having adjusted a sliding bar to a dove-tail groove, in a piece of wood about 18 inches long, and fixed a hook into the middle of the bar, nail the wood to the abovementioned place on the ceiling, parallel to the side of the room in which the window is ; the groove and bar being towards the floor : Then hang the plumb-line upon the hook in the bar, the weight or plummet reaching almost to the floor ; and the whole will be prepared for the farther and proper adjustment.

This done, find the true solar time by either of the two last methods, and thereby regulate your clock. Then, at the moment of next noon by the clock when the sun shines, move the sliding-bar in the groove, until the shadow of the plumb-line bisects the image of the sun (made by his rays transmitted thro' the hole) on the floor, wall, or on a white screen placed on the north-side of the line ; the plummet or weight at the end of the line hanging freely in a pail of water placed below it on the floor.—But because this may not be quite correct for the first time, on account that the plummet will not settle immediately, even in water ; it may be farther corrected on the following days, by the above method, with the sun and clock ; and so brought to a very great exactness.

N. B. The rays transmitted through the hole will cast but a faint image of the sun, even on a white screen, unless the room be so darkened that no sunshine may be allowed to enter but what comes thro' the same hole in the plate. And always, for some time before the observation is made, the plummet ought to be immersed in a jar of water, where it may hang freely ; by which means the line will soon become steady, which otherwise would be apt to continue swinging.

Description of two New Instruments for facilitating the practice of Dialing.

I. *The DIALING Sector*, contrived by the late Mr Benjamin Martin, is an instrument by which dials are drawn in a more easy, expeditious, and accurate manner. It is represented on the plate as now made by Mr

Jones of Holborn. The principal lines on it are the *line of latitudes* and the *line of hours*. They are found on most of the common plane scales and sectors ; but in a manner that greatly confines and diminishes their use ; for, first, they are of a *fixed length* ; and, secondly, *too small* for any degree of accuracy. But in this new *sector*, the *line of latitudes* is laid down, as it is called *sector-wise*, viz. one line of latitudes upon each leg of the sector, beginning in the centre of the joint, and diverging to the end (as upon other sectors), where the extremes of the two lines at 90° and 90° are nearly one inch apart, and their length $11\frac{1}{2}$ inches : which length admits of great exactness ; for at the 70th degree of latitude, the divisions are to quarters of a degree or 15 minutes. This accuracy of the divisions admits of a peculiar advantage, namely, that it may be equally communicated to any length from 1 to 23 inches, by taking the *parallel distances* (see fig. 5.), viz. from 10 to 10, 20 to 20, 30 to 30 ; and so on as is done in like cases on the lines of sines, tangents, &c. Hence its universal use for drawing dials of any prepared size. The line of hours for this end is adapted and placed contiguous to it on the sector, and of a size large enough for the very minutes to be distinct on the part where they are smallest, which is on each side of the hour of III.

From the construction of the line of hours before shown, the divisions on each side of the hour III are the same to each end, so that the hour-line properly is only a *double line of three hours*. Hence a line of 3 hours answers all the purposes of a line of 6, by taking the double extent of 3, which is the reason why upon the sector the line of hours extends only to $4\frac{1}{2}$.

To make use of the *line of latitude* and *line of hours* on the sector : As single scales only, they will be found more accurate than those placed on the common scales and sectors, in which the hours are usually subdivided, but into 5 minutes, and the line of latitudes into whole degrees. But it is shown above how much more accurately these lines are divided on the *dialing sector*. As an example of the great exactness with which horizontal and other dials may be drawn by it, on account of this new *sectoral* disposition of these scales, and how all the advantages of their great length are preserved in any lesser length of the VI o'clock line *ce* and *af* : Apply either of the distances of *ce* or *af* to the line of latitude at the given latitude of London, suppose $51^\circ 32'$ on one line to $51^\circ 32'$ on the other, in the manner shown in fig. 5. and then taking all the hours, quarters, &c. from the hour-scale by similar parallel extents, you apply them upon the lines *ed* and *fb* as before described. Fig. 2.

As the hour lines on the sector extend to but $4\frac{1}{2}$, the *double distance* of the hour 3, when used either *singly* or *sectorally*, must be taken, to be first applied from $51^\circ 32'$ on the latitudes, to its contact on the XII o'clock line, before the several hours are laid off. The method of drawing a vertical north or south dial is perfectly the same as for the above horizontal one ; only reversing the hours as in fig. 1. and making the angle of the stile's height equal to the complement of the latitude $38^\circ 28'$.

The method of drawing a *vertical declining dial* by the sector, is almost evident from what has been already said in dialing. But more fully to comprehend

Plate
CLXI.
fig. 4.

the matter, it must be considered there will be a variation of particulars as follow: 1. Of the *substilar* or *line* over which the stile is to be placed; 2. The height of the stile above the plane; 3. The difference between the meridian of the place and that of the plane, or their difference of longitude. From the given *latitude of the place*, and *declination of the plane*, you calculate the three requisites just mentioned, as in the following example. Let it be required to make an *erect south dial*, declining from the meridian *westward* $28^{\circ} 43'$. in the latitude of London $51^{\circ} 32'$. The first thing to be found is the distance of the substilar line GB (fig. 3.) from the meridian of the plane $G XII$. The analogy from this is: *As radius is to the sine of the declination, so is the co-tangent of the latitude to the tangent of the distance sought*, viz. As radius: $28^{\circ} 43'$: : tang. $38^{\circ} 28'$: tangent $20^{\circ} 55'$. This and the following analogy may be as accurately worked on the Gunter's line of sines, tangents, &c. properly placed on the sector, as by the common way from logarithms. Next, To find the plane's difference of longitude. *As the sine of the latitude is to radius, so is the tangent of the declination to the tangent of the difference of longitude*, viz. As $s 51^{\circ} 32'$: radius: : tang. $28^{\circ} 43'$: tang. $35^{\circ} 0'$. Lastly to find the height of the stile: *As radius is to the co-sine of the latitude, so is the co-sine of the declination to the sine of the stile's height*, viz. Radius: $s 38^{\circ} 28'$: : $s 61^{\circ} 17'$: $s 33^{\circ} 5'$.

Fig. 3.

The three requisites thus obtained, the dial is drawn in the following manner: Upon the meridian line $G XII$, with any radius GC describe the arch of a circle, upon which set off $20^{\circ} 55'$ from G to B , and draw GB , which will be the substilar line, over which the stile of the dial must be placed.

At right angles to this line GB , draw AQ indefinitely through the point G : then from the scale of latitudes take the height of the stile $33^{\circ} 5'$, and set it each way from G to A and Q . Lastly, take the double length of 3 on the hour-line in your compasses, and setting one foot in A or Q , with the other foot mark the line GB in D , and join $ADQD$, and then the triangle ADQ is completed upon the substilar line GB .

To lay off the hours, the plane's difference of longitude being 35° , equal to 2h. 20 min. in time, allowing 15° to an hour, so that there will be 2h. 20' between the point D and the meridian $G XII$, in the line AD . Therefore, take the first 20' of the hour-scale in your compasses, and set off from D to 2; then take 1 h. 20', and set off from D to 1; 2h. 20', and set off from D to 12; 3h. 20', from D to 11; 4h. 20' from D to 10; and 5h. 20' from D to 9, which will be 40 from A .

Then, on the other side of the substilar line GB , you take 40' from the beginning of the scale, and set off from D to 3; then take 1 h. 40', and set off from D to 4; also 2h. 40', and set off from D to 5; and so on to 8, which will be 20' from Q . Then from G the centre, through the several points 2, 1, 12, 11, 10, 9, on one side, and 3, 4, 5, 6, 7, 8, on the other, you draw the hour-lines, as in the figure they appear. The hour of VIII need only be drawn for the morning; for the sun goes off from this *west decliner* 20' before VIII in

the evening.—The quarters, &c. are all set off in the same manner from the hour scale as the above hours were.

The next thing is fixing the stile or gnomon, which is always placed in the substilar line GB , and which is already drawn. The stile above the plane has been found to be $33^{\circ} 5'$: therefore with any radius GB describe an obscure arch, upon which set off $33^{\circ} 5'$ from B to S , and draw GS , and the angle SGB will be the true height of the gnomon above the substilar line GB .

II. The *DIALING Trigon* is another new instrument of great utility in the practice of dialing; and was also contrived by the late Mr Martin. It is composed of two graduated scales and a plane one. On the scale AB is graduated the line of latitudes; and on the scale AC , the line of hours: these properly conjoined with the plane scale BD , as shown in the figure, truly represent the gnomonical triangle, and is properly called a *dialing trigon*. The hour-scale AC is here of its full length; so that the hours, halves, quarters, &c. and every single minute (if required) may be immediately set off by a steel point; and from what has before been observed in regard to the sector, it must appear that this method by the trigon is the most expeditious way of drawing dials that any mechanism of this sort can afford. As an example of the application of this trigon in the construction of an horizontal dial for the latitude of London $51^{\circ} 32'$, you must proceed as follows: Apply the trigon to the 6 o'clock line af (fig. 1.) on the morning side, so that the line of latitudes may coincide with the 6 o'clock line, and the beginning of the divisions coincide with the centre a ; and at $51^{\circ} 32'$ of the line of latitudes place the 6 o'clock edge of the line of hours, and the other end or beginning of the scale close against the plane scale cd , as by the figure at d ; and fastening these bars down by the several pins placed in them to the paper and board, then the hours, quarters, &c. are all marked off with a steel point instantly, and the hour-lines drawn through them as before, and as shown in the figure. When this is done for the side af or morning hours, you move the scale of latitudes and hours to the other side ce , or afternoon side, and place the hour-scale to $51^{\circ} 32'$ as before, and push down the hours, quarters, &c. and draw the lines through them for the afternoon hours, which is clearly represented in the figure.

In like manner is an *erect north or south dial* drawn (see fig 2.), the operation being just the same, only reversing the hours as in the figure, and marking the angles of the stile's height equal to the complement of the latitude.

This trigon may be likewise used for drawing *vertical declining dials* (fig. 3.), as it is with the same facility applied to the lines AQ , GB , and the hours and quarters marked off as before directed.

Mr Jones graduates on the scale BD of the trigon a line of chords, which is found useful for laying off the necessary angles of the stile's height. The scales of this trigon, when not in use, lie very close together, and pack up into a portable case for the pocket.

Dialing
|
Dialogue.

DIALING Lines or Scales, are graduated lines, placed on rules, or the edges of quadrants, and other instruments, to expedite the construction of dials. See Plate CLVIII.

DIALING-Sector. See DIALING, p. 803, and Plate CLXI.

DIALING-Sphere, is an instrument made of brass, with several semicircles sliding over one another, on a moving horizon, to demonstrate the nature of the doctrine of spherical triangles, and to give a true idea of the drawing of dials on all manner of planes.

DIALING-Trigon. See DIALING, p. 804, and Plate CLXI.

DIALING, in a mine, called also *Plumming*, is the using of a compass (which they call *dial*) and a long line, to know which way the load or vein of ore inclines, or where to shift an air-shaft, or bring an adit to a desired place.

DIALIS, in antiquity, a Latin term signifying something that belongs to Jupiter.—The word is formed from Διος, the genitive of Ζεϋς, Jupiter.

Flamen DIALIS. See FLAMEN.

DIALITHA, in the writings of the ancients, a word used to express the elegant ornaments of the Greeks and Romans, composed of gold and gems. They also called these *lithocolla*, “cemented stones or gems;” the gold being in this case as a cement to hold the stones together. They wore bracelets and other ornamental things about their habits thus made; and their cups and table-furniture for magnificent treats, were of this kind. The green stones were found to succeed best of all in these things; and the emerald and greenish topaz, or, as we call it, chrysolite, were most in esteem for this purpose. This use of the stones explains what Pliny very often says of them in his description: *Nihil jucundius aurum decet*, “Nothing becomes gold better:” this he says of the green topaz or chrysolite; and this and many other like passages have greatly perplexed the critics, who did not hit upon this explication.

DIALLING, or DIALING. See DIALING.

DIALOGISM, in rhetoric, is used for the soliloquy of persons deliberating with themselves. See SOLILOQUY.

DIALOGUE, in matters of literature, a conversation between two or more persons either by writing or by word of mouth.

Composition and Stile of written DIALOGUE. As the end of speech is conversation, no kind of writing can be more natural than dialogue, which represents this. And accordingly we find it was introduced very early, for there are several instances of it in the Mosaic history. The ancient Greek writers also fell very much into it, especially the philosophers, as the most convenient and agreeable method of communicating their sentiments and instructions to mankind. And indeed it seems to be attended with very considerable advantages, if well and judiciously managed. For it is capable to make the driest subjects entertaining and pleasant, by its variety, and the different characters of the speakers. Besides, things may be canvassed more minutely, and many lesser matters, which serve to clear up a subject, may be introduced with a better grace, by questions and answers, objections and replies, than can be conveniently done in a continued discourse.

There is likewise a further advantage in this way of writing, that the author is at liberty to choose his speakers: and therefore, as Cicero has well observed, when we imagine that we hear persons of an established reputation for wisdom and knowledge talking together, it necessarily adds a weight and authority to the discourse, and more closely engages the attention. The subject-matter of it is very intensive: for whatever is a proper argument of discourse, public or private, serious or jocose; whatever is fit for wise and ingenious men to talk upon, either for improvement or diversion; is suitable for a dialogue.

From this general account of the nature of dialogue, it is easy to perceive what kind of style best suits it. Its affinity with EPISTLES, shows there ought to be no great difference between them in this respect. Indeed, some have been of opinion, that it ought rather to sink below that of an epistle, because dialogues should in all respects represent the freedom of conversation; whereas epistles ought sometimes to be composed with care and accuracy, especially when written to superiors. But there seems to be little weight in this argument, since the design of an epistle is to say the same things, and in the same manner, as the writer judges would be most fit and proper for him to speak, if present. And the very same thing is designed in a dialogue, with respect to the several persons concerned in it. Upon the whole, therefore, the like plain, easy, and simple stile, suited to the nature of the subject, and the particular characters of the persons concerned, seems to agree to both.

But as greater skill is required in writing dialogues than letters, we shall give a more particular account of the principal things necessary to be regarded in their composition, and illustrate them chiefly from Cicero's excellent Dialogues concerning an Orator. A dialogue, then, consists of two parts, an *introduction*, and *the body of the discourse*.

1. The *introduction* acquaints us with the place, time, persons, and occasion, of the conversation. Thus Cicero places the scene of his dialogues at Crassus's country seat; a very proper recess, both for such a debate and the parties engaged in it. And as they were persons of the first rank, and employed in the greatest affairs of state, and the discourse held them for two days; he represents it to have happened at the time of a festival, when there was no business done at Rome, which gave them an opportunity to be absent.

And because the greatest regard is to be had in the choice of the persons, who ought to be such as are well acquainted with the subject upon which they discourse; in these dialogues of Cicero, the two principal disputants are Crassus and Antony, the greatest orators of that age, and therefore the most proper persons to dispute upon the qualifications necessary for their art. One would think it scarce necessary to observe, that the conference should be held by persons who lived at the same time, and so were capable to converse together. But yet some good writers have run into the impropriety of feigning dialogues between persons who lived at distant times. Plato took this method, in which he has been followed by Macrobius. But others, who have been willing to bring persons to discourse together, who lived in different ages, without such inconsistency, have wrote dialogues of the dead. Lucian has

Dialogue. has made himself most remarkable in this way. As to the number of persons in a dialogue, they may be more or less: so many as can conveniently carry on a conversation without disorder or confusion may be admitted. Some of Cicero's dialogues have only two, others three or more, and those concerning an orator seven. And it is convenient they should all, in some respects, be persons of different characters and abilities; which contributes both to the variety and beauty of the discourse, like the different attitude of figures in a picture. Thus, in Cicero's dialogues last mentioned, Crassus excelled in art, Antony principally for the force of his genius, Catullus for the purity of his stile. Scævola for his skill in the law, Cæsar for wit and humour; and though Sulpitius and Cotta, who were young men, were both excellent orators, yet they differed in their manner. But there should be always one chief person who is to have the main part of the conversation; like the hero in an epic poem or a tragedy, who excels the rest in action; or the principle figure in a picture, which is most conspicuous. In Plato's dialogues, this is Socrates; and Crassus, in those of Cicero above mentioned.

It is usual, likewise, in the introduction, to acquaint us with the occasion of the discourse. Indeed this is not always mentioned; as in Cicero's dialogue of the parts of oratory, where the son begins immediately with desiring his father to instruct him in the art. But it is generally taken notice of, and most commonly represented, as accidental. The reason of which may be, that such discourses appear most natural; and may likewise afford some kind of apology for the writer in managing his different characters, since the greatest men may be supposed not always to speak with the utmost exactness in an accidental conversation. Thus Cicero, in his dialogues concerning an orator, makes Crassus occasionally fall upon the subject of oratory, to divert the company from the melancholy thoughts of what they had been discoursing of before, with relation to the public disorders, and the dangers which threatened their country. But the introduction ought not to be too long and tedious. Mr Addison complains of this fault in some authors of this kind. "For though (as he says) some of the finest treatises of the most polite Latin and Greek writers are in dialogue, as many very valuable pieces of French, Italian, and English, appear in the same dress; yet in some of them there is so much time taken up in ceremony, that, before they enter on their subject, the dialogue is half over."

2. We come now to the *body* of the discourse, in which some things relating to the persons, and others to the subject, are proper to be remarked.

And as to the *persons*, the principal thing to be attended to is to keep up a justness of character through the whole. And the distinct characters ought to be so perfectly observed, that from the very words themselves it may be always known who is the speaker. This makes dialogue more difficult than single description, by reason of the number and variety of characters which are to be drawn at the same time, and each of them managed with the greatest propriety. The principal speaker should appear to be a person of great sense and wisdom, and best acquainted with the subject. No question ought to be asked him, or objection

Dialogue. started to what he says, but what he should fairly answer. And what is said by the rest should principally tend to promote his discourse, and carry it through in the most artful and agreeable manner. Where the argument is attended with difficulties, one another person or more may be introduced, of equal reputation, or near it, but of different sentiments, to oppose him and maintain the contrary side of the question. This gives opportunity for a thorough examination of the point on both sides, and answering all objections. But if the combatants are not pretty equally matched, and masters of the subject, they will treat it but superficially. And through the whole debate there ought not to be the least wrangling, peevishness, or obstinacy: nothing but the appearance of good-humour and good breeding, the gentleman and the friend, with a readiness to submit to conviction and the force of truth, as the evidence shall appear on one side or the other. In Cicero, these two characters are Crassus and Antony. And from them Mr Addison seems to have taken his Philander and Cynthio, in his *Dialogues upon the usefulness of ancient medals*, which are formed pretty much on Cicero's plan. Where younger persons are present, or such who are not equally acquainted with the subject, they should be rather upon the inquiry than dispute: And the questions they ask should be neither too long nor too frequent; that they may not too much interrupt the debate, or appear over talkative before wiser and more experienced persons. Sulpitius and Cotta sustain this character in Cicero, and Eugenius in Mr Addison. And it is very convenient there should be one person of a witty and jocular humour, to enliven the discourse at proper seasons, and make it the more entertaining, especially when the dialogue is drawn out to any considerable length. Cæsar has this part in Cicero. And in Mr Addison, Cynthio is a person of this turn, and opposes Philander in a merry way. Mr Addison's subject admitted of this: but the seriousness and gravity of Cicero's argument required a different speaker for the jocular part. Many persons ought not to speak immediately one after another. Horace's rule for plays is:

To crowd the stage is odious and absurd.

Let no fourth actor strive to speak a word.

Though Scaliger and others think a fourth person may sometimes be permitted to speak in the same scene without confusion. However, if this is not commonly to be allowed upon the stage, where the actors are present, and may be distinguished by their voice and habit; much less in a dialogue, where you have only their names to distinguish them.

With regard to the *subject*, all the arguments should appear probable at least, and nothing be advanced which may seem weak or trivial. There ought also to be an union in dialogue, that the discourse may not ramble, but keep up to the main design. Indeed, short and pleasant progressions are sometimes allowable for the ease and entertainment of the reader. But every thing should be so managed, that he may still be able to carry on the thread of the discourse in his mind, and keep the main argument in view, till the whole is finished. The writers of dialogue have not confined their discourses to any certain space of time; but either concluded them with the day, or broke off when their speakers have been tired, and reassumed them again the next day. Thus Cicero allows two days for

his

Dialogue
||
Diamasti-
gosis.

his three dialogues concerning an orator; But Mr Addison extends his to three days, allowing a day for each. Nor has the same method always been observed in composing dialogues. For sometimes the writer, by way of narrative, relates a discourse which passed between other persons. Such are the dialogues of Cicero and Mr Addison last mentioned, and many others both of the ancients and moderns. But, at other times, the speakers are introduced in person, as talking to each other. This, as Cicero observes, prevents the frequent repetition of those words, *he said*, and *he replied*; and by placing the hearer, as it were, in the conversation, gives him a more lively representation of the discourse, which makes it the more affecting. And therefore Cicero, who wrote his *dialogue of old age* in this manner, in which Cato, who was then in years, largely recounts the satisfactions of life which may be enjoyed in old age, tells his friend Atticus, he was himself so affected with that discourse, that when he reviewed it sometimes, he fancied they were not his own words, but Cato's. There are some other dialogues of Cicero written in the same way; as that *Of friendship*, and *Of the parts of Oratory*. And both Plato and Lucian generally chose this method.

DIALOGUE, in dramatic composition. See POETRY, chap. ii. 22, 23.

DIALTHÆA, in pharmacy, an unguent much used as a resolvent; so called from ALTHÆA, or marsh-mallows, which is the principal ingredient in it.

DIALUM, in botany: A genus of the monogynia order, belonging to the diandria class of plants. The corolla is pentapetalous: no calyx; the stamina at the upper side of the receptacle.

DIALYSIS, in grammar, a mark or character, consisting of two points, ··, placed over two vowels of a word in order to separate them, because otherwise they would make them a diphthong, as *Mosaic*, &c.

DIAMASTIGOSIS, a festival at Sparta in honour of Diana Orthia, which received that name ἀπο τοῦ μαστιγίου, from *whipping*, because boys were whipped be-

fore the altar of the goddess. These boys, called Bomoniceæ, were originally free born Spartans, but in the more delicate ages they were of mean birth, and generally of a slavish origin. This operation was performed by an officer in a severe and unfeeling manner; and that no compassion should be raised, the priest stood near the altar with a small light statue of the goddess, which suddenly became heavy and insupportable if the lash of the whip was more lenient or less rigorous. The parents of the children attended the solemnity, and exhorted them not to commit any thing either by fear or groans, that might be unworthy of Laconian education. These flagellations were so severe, that the blood gushed in profuse torrents, and many expired under the lash of the whip, without uttering a groan, or betraying any marks of fear. Such a death was reckoned very honourable; and the corpse was buried with much solemnity with a garland of flowers on its head. The origin of this festival is unknown. Some suppose that Lycurgus first instituted it to inure the youth of Lacedemon to bear labour and fatigue, and render them insensible to pain and wounds. Others maintain, that it is a mitigation of an oracle, which ordered that human blood should be shed on Diana's altar: and according to their opinion, Orestes first introduced that barbarous custom, after he had brought the statue of Diana Taurica into Greece. There is another tradition which mentions that Pausanias, as he was offering prayers and sacrifices to the gods, before he engaged with Mardonius, was suddenly attacked by a number of Lydians who disturbed the sacrifice, and were at last repelled with staves and stones, the only weapons with which the Lacedemonians were provided at that moment. In commemoration of this, therefore, that whipping of boys was instituted at Sparta, and after that the Lydian procession.

DIAMETER, in geometry, a right line passing thro' the centre of a circle, and terminated at each side by the circumference thereof. See GEOMETRY.

Diamasti-
gosis,
Diameter.
